In the social support category (Table 3), we only found that social comparison (in the form of benchmarking) was already implemented in the system for a limited number of measurements. However, the user had to filter each time to be able to benchmark the measure of interest (eg, near miss) at one level (eg, in the pharmacy) against another (eg, in the province). The assessors of the system suggested that rather than filtering all the time, it would be better if the benchmarking feature of the system could be enhanced by locking in the error reports—having them appear automatically. Moreover, we recommend guidelines on how to integrate other socially oriented persuasive strategies such as social learning, social facilitation, normative influence, competition, and social recognition. Holden and Karsh [7] found that social influence at the individual, group, organizational, and industry levels has the potential to influence medication error reporting.

Social Learning

This social strategy allows users to observe and imitate the behaviors and achievements of other (anonymous) users of the system [98]. The social learning strategy derives from the social learning theory proposed by Bandura [99]. The social learning theory states that people have the ability to imitate new behavior by coding or storing the ideas about the behavior in their memory, which eventually guide the actual performance of the behavior [100]. In the context of persuasive technology, social learning is simply implemented using the information of the target user about a target behavior performed by other users, for example, through a notification. In the context of MIRLS, a potential approach to implementing social learning is by enabling users to receive notifications (eg, via email) when fellow users in their group submit incident reports. These notifications would contain essential key points from the submitted reports. A typical notification message to this effect is “John [a pseudonym], here’s a new report we think you’ll be interested in.” We believe that messages such as this, which enable one user to learn from others’ reports, may motivate the target user to submit their reports given the benefit they derive from them. Given that users may be overwhelmed, they should be given the opportunity to determine the types of messages they wish to receive, the number within a given period such as a week or month, and even opt out completely by turning the feature off. More importantly, owing to privacy concerns, particularly within a facility setting, instead of basing the social learning strategy on key points from reported near misses or incidents, it can be based on the quantity of reports submitted within a specified period (refer to the *Normative Influence* section). According to 1 of the assessors, “I don’t think this [first Social Learning implementation] is appropriate if you can see who it is but if it is just numbers it would be useful. [N]otification within a facility could hamper the feeling of safe reporting because anonymity is compromised.” A second implementation of social learning is the provision of a news feed that highlights important reports submitted by other anonymous users that the user may find useful. A third implementation is the support of chat rooms or discussion rooms

where users can discuss near misses, incidents and lessons learned; share experiences and knowledge; and learn from one another in an anonymous fashion. The chat room and discussion forum feature may be extended and beneficial to nonpharmacists, as evident in 1 of the assessors’ comments, “Our users may find this useful. If they have the time, which currently they don’t have much of during the pandemic.”

Social Comparison

Social comparison allows users to compare their performance with that of others. It is derived from the social comparison theory proposed by Festinger [101], which centers on the belief that individuals have an inner drive to gain accurate self-evaluations through social comparison. It holds that by comparing one’s abilities and performances with those of similar others or peers, the individual is able to reduce uncertainty, learn, and improve self. This strategy has been used successfully in persuasive systems [102]. In the assessment of the Think Research or Pharmapod system, we found that social comparison was implemented at the pharmacy and provincial level in the form of benchmarking reports, tables, and dashboards. For example, 1 of the assessors responded thus, “within our own organization we may compare pharmacies with other pharmacies or between provinces of our pharmacies using reports provided.” Thus, the implementation of social comparison in the system can be improved. For example, users’ error reporting over a particular period, for example, week, month, or year, can be compared anonymously with the average at the pharmacy or provincial level using a bullet chart infographic.

Competition

Similar to social comparison, competition allows users to compare themselves with others, for example, in terms of number of reports, frequency, quality, or usefulness of reports to others. Competition leverages the natural drive of humans to outperform one another [98]. Research on persuasive technology shows that competition, regardless of gender, age, and culture, has the potential to motivate users to perform the target behavior [103]. In the fitness app domain, for example, Oyibo and Vassileva [98] found a significant relationship among social comparison, social learning, and competition, indicating that the more people compare themselves, the more they learn about the performance or achievements of others and the more competitive they become in their behaviors. In the context of MIRLS, users can be allowed to view where they are compared with other anonymous users in small sets (eg, on a leaderboard). The criterion for placement on the leaderboard can include the total number of reports, frequency, quality, or usefulness of the report to others (eg, over a weekly, monthly, or yearly period). The small sets of anonymous users can be drawn from the pool of users at the provincial or national level, which can change from time to time because of the need to foster anonymity. Moreover, the competition feature can be group based, involving anonymous pharmacies, organizations, or provinces. As 1 of the assessors remarked, “Perhaps [my organization] may wish to see how many incidents they are experiencing compared to another organization of the same industry channel and size.”

Cooperation

Unlike competition, where users compete to outperform one another, in cooperation, users work together in a collaborative fashion to achieve their individual and collective goals. In the assessment of the Think Research or Pharmapod IM system, we found that providing users the choice of being paired with another (anonymous) user, with the goal of motivating one another to achieve individual or collective goals may not be a good idea. This is based on the premise that the implementation of cooperation in MIRLS may compromise the principle of anonymity of users, upon which MI reporting is founded. Hence, we recommend that cooperation be implemented and used with caution if MIRLS were to support it in a given pharmacy. As commented by 1 of the assessors, “Why would anyone wish to be compared to [cooperate with] another user? Where’s the privacy aspect of such a feature?”

Normative Influence

Unlike informational influence, which is conformity to a certain behavior based on the acceptance of evidence about reality provided by others, normative influence is conformity based on an individual’s desire to fulfill others’ expectations to gain acceptance, fit in, or feel a sense of belonging [104]. In the context of reporting medication errors, the urge for individual users to report near misses and incidents might arise from perceived social pressure rather than actual pressure, considering that the submitted reports are anonymous or deidentified. Thus, a possible way of realizing the normative influence strategy in MIRLS is allowing the user to know about the number of other anonymous users in the facility, province, or nation that are reporting medication errors at a given time. For example, in COVID-19 contact tracing apps, Oyibo and Morita [105] found that socially oriented messages, such as “112 other people reported their COVID-19 diagnosis today,” have the potential to motivate app users to report their diagnosis by entering their one-time key into the app. Hence, we recommend that the system informs users at suitable intervals (eg, when they are logged on) about the quantity of other anonymous users within the pharmacy, province, or country who are reporting medication errors within a specific period. A message similar to the message by Oyibo and Morita [105], “10 other people submitted their incident reports today,” may be used to normatively influence users to submit their own incident reports as well if they have any pending or have not yet submitted.

Social Facilitation

Social facilitation refers to the improvement in a person’s performance as a result of the real, imagined, or implied presence of others. As stated in the study by Mohadis et al [84], “System users are more likely to perform a targeted [behavior] if they discern, via the system, that others are performing the [behavior] along with them.” In MIRLS, one way to realize social facilitation is to inform the user when they log on to the system (eg, to make a report) through news feed that they are not alone in their efforts to report an error, as other users elsewhere (eg, in the facility, province, or nation) at the current time are also attempting to making a report or logged on to the system. Motivational messages such as “You are not alone; X others are on the system at the moment submitting a report”

could be used to make the user feel the presence of other anonymous users whenever the former is logged into the system. A message such as this may encourage users, who have begun the process of submitting a report, to complete it. This type of message is similar to that which customers get when they are booking a hotel or shopping for a flight ticket on the web (eg, “5 other people are currently shopping for this flight ticket”). Although this type of message is commonly used in the e-commerce domain to create the impression that the user may miss procuring a given flight ticket if they do not act quickly (ie, buy it now), in the domain of medication error reporting, this is not the case. Rather, this type of message is used to let the user know that they are not alone—that there are similar others elsewhere who are trying to do the same task as them (submit a MI report).

Social Recognition

In social psychology, social recognition is the act of recognizing people such as employees for great work, contribution, and achievement by acknowledging them publicly. One possible way of implementing this strategy in an MIRLS is recognizing users for being one of the “most valuable players” of the month, quarter, or year. This can be at the facility, provincial, or national level. The criteria for recognition include the number, frequency, quality, or usefulness of the target user’s reports to the community. Although research shows that employees welcome social recognition in the workplace [84], it must be implemented with caution given the anonymity requirement aimed to protect users from punitive measures. We found that users may not welcome the second feature (“allowing other users to rate a user’s report anonymously based on how useful or helpful it is to them”) as they perceived it as a form of competition. For example, 1 of the assessors commented, “Rating makes this feel like a competition or to call out that can produce negative attitudes. Not helpful. Those entering data into a system may not be the same person who is involved in the incident.” Moreover, the user was also concerned about the part of the report being rated as well as privacy and anonymity, “What part of the report is being rated in this scenario?” It is worth noting that we conceived the social recognition rating feature similar to Google Play Store app rating system, in which users can rate an app on a 5-star scale. Although we did not explicitly detail the section of the report being anonymously rated by other users in the study, we intended it to encompass essential elements derived from the report analysis, such as the description of the near miss or incident, the lessons learned by the reporters, and possible recommendations and tips to prevent future recurrence. These key points may have been extracted from a set of similar aggregated reports submitted by different anonymous users at different times and included in the MI analysis report shared with users via the MIRLS by standard bodies such as Assurance and Improvement in Medication Safety (AIMS) [106]. AIMS is a standardized medication safety program that supports CQIs and sets a mandatory consistent standard for medication safety for all pharmacies in Ontario. Its goal is to minimize the risk of harm to patients caused by MIs in the province. Part of its mandate is to aggregate and analyze anonymous MI reports and produce and disseminate the results to stakeholders. This enables practitioners to learn from MIs and have a better understanding

of why they occur and how they can be prevented in the future [106]. Although in this study, we did not find the second social recognition feature to be useful to the assessors, there may be a need for a more comprehensive study in future research among a larger audience of community pharmacists to uncover its potential to motivate users to report medication errors more frequently.

System Credibility Support Assessment and Guidelines

Regarding the credibility support category (Table 4), the assessors reported that the system fully or partially supported a number of credibility-related persuasive strategies such as trustworthiness, credibility, expertise, and real-world feel. We discuss all these strategies together with the other 3 strategies in the credibility support category.

Authority

One of the principles of persuasion proposed by Cialdini [73], the authority principle, states that people are more likely to believe and obey those who are in positions of authority. Selassie et al [76] found that frontline staff working with children with autism (supported by a data entry management system) can be persuaded by the authority strategy. Moreover, in the study by Mohadis and Ali [84] on user perception of a physical activity app for older workers, 1 of the participants remarked, “Yeah, incorporating an expert [authority figure’s] view is very important so that we become more confident with whatever recommendations that the system offers.” In the context of community pharmacy, authority figures and bodies may include researchers, pharmacy managers, and professional bodies such as the Institute for Safe Medication Practices Canada [1]. Thus, we recommend the presentation of authority-based information and messages to users, for example, on the value of reporting medication errors and the benefits it can have for the profession, staff, and patient safety [47].

Third-Party Endorsement

Third-party endorsement is the act of publicly approving or supporting a product, system, or service by a reputable socially influential individual or organization other than the staff or company that owns it. Usually, the third party may have seen, interacted, and used the product, system, or service in question and is satisfied with the results, utility, or experience. In the business world, research has shown that the third-party endorsements have the potential to effectively earn companies the trust and loyalty of customers [21,69]. Moreover, research shows that the expertise and trustworthiness of a third-party organization endorsement have the potential to positively affect the perceived value of a firm, which in turn can positively affect customer loyalty [107]. Hence, to encourage pharmacists to use MIRLS, the designers should demonstrate that the system is approved or endorsed by authoritative bodies such as professional organizations (eg, World Health Organization and Institute for Safe Medication Practices), regulatory bodies, and government. To implement this persuasive strategy in MIRLS, one approach is to incorporate the corporate logos of the endorsing authoritative bodies within the user interface, such as on the system’s home page or in the footer, especially if it is a web-based application.

Expertise, Surface Credibility, and Trustworthiness

Research has shown that all 3 strategies are related. For example, Fogg and Tseng [108] postulated that credibility, a perceived quality of a system, comprises 2 key components: trustworthiness and expertise. In other words, a system is perceived to be credible if its perceived trustworthiness and perceived expertise are high. Trustworthiness is a key element in the credibility perception of systems such as websites. It is defined by terms such as well intentioned, truthful, and unbiased [109]. As stated in the study by Fogg et al [109], “the trustworthiness dimension of credibility captures the perceived goodness or morality of the source.” Similarly, expertise is a key element in the credibility perception of systems such as websites. It is defined by terms such as knowledgeable, experienced, competent, and professional [109]. As stated in the study by Fogg et al [109], “[t]he expertise dimension of credibility captures the perceived knowledge and skill of the source.” In a large-scale website credibility study conducted by Fogg et al [109], the authors found that perceived expertise and perceived trustworthiness have a significant impact on the perceived credibility of websites. In the context of MIRLS, to realize expertise, the visual and functional design of the system should reflect professionalism, expertise, and up-to-dateness to motivate users to use it. Moreover, to implement trustworthiness, the system should foster user anonymity, data deidentification, and data aggregation and live up to promises such as it not being used as a punitive tool to hold users accountable [65]. Finally, perceived credibility can be intentionally built into the system through its visual design, for example, by ensuring users enter accurate information using taxonomy-based option buttons, checklists, and drop-downs and reducing advertisements for a web-based system [47]. In our study, all 3 assessors agreed that perceived expertise is important or useful as well as implemented to a great extent in the system they were currently using. For example, 1 of the assessors commented, “The MIRLS is very easy to use and intuitive, and requires minimal training to get started.” However, “there is always room for improvement,” remarked another assessor. Failure to foster expertise in the system design may discourage frequent use and completion of tasks, as evident in the assessor’s comment, “Performance in speed is always a challenge and [the] latency [experienced in some] areas drive users to drop off or stop using.” Regarding trustworthiness, 2 assessors considered it important or useful. However, only 1 assessor considered it to be implemented in the current system. This is partly because of anonymity not being completely fostered in the system. This is evident in 1 of the assessors’ comments, “anonymity is fostered outside an organization (eg. when data sent to AIMS) and there is also a choice to report anonymously so the corporate level of an organization does not have visibility. [W]ithin a location the reports are not anonymous.” Finally, regarding surface credibility, 2 assessors considered it important or useful and implemented it in their current system. For example, all 3 assessors responded that there were no advertisements in the system and that was very important.

Verifiability

This refers to “the quality or state of being capable of being verified, confirmed, or substantiated” [110]. In the context of

MIRLS, persuasive messages (eg, on the value of error reporting to patient safety) aimed at motivating users should not only be credible but also verifiable. As stated in the study by Jones [111], carefully choosing persuasive messages and supporting materials that are verifiable, specific, and unbiased can be helpful in appealing to logic and increasing users' trust. Verifiability was implemented in WargaFit (a fitness app prototype aimed to encourage simple exercise such as body stretching in an office environment) by the provision of healthy tips accompanied with external links [84]. Similarly, verifiability in MIRLS can be realized through the provision of the source of information or inclusion of the URL in the persuasive message such as "Reporting reduces the number of future errors, diminishing personal suffering and decreasing financial costs" [112]. In our study, 2 assessors considered verifiability useful and not currently implemented in their system. For example, regarding harm levels, 1 of the assessors commented, "There are info points that explain [that] harm level comes from WHO but there is no link to the WHO to verify it."

Real-World Feel

Similar to expertise and trustworthiness, real-world feel is found to positively influence the perceived credibility of websites [109]. Real-world feel is the interaction with and experience of a virtual or electronic product, system, or service as though it is real. This is made possible by the product-, system-, or service-supporting features that mimic and foster real-world interaction and experience. In the case of e-commerce websites, for example, the real-world feel can be fostered by providing contact phone number, contact email address, and a quick response to customer service questions; listing the physical address of the organization behind the website; and showing photos of the members of the organization [109]. In the context of MIRLS, in addition to the aforementioned features, the system should be designed as close as possible to the nonelectronic (paper) version. This has the potential to reduce the cognitive effort required by a new user to make the transition. In the assessment of the Think Research or Pharmapod IM system, assessors stated that it supports real-world feel by mimicking the paper version and allows clients to customize their own forms and notifications or escalations. One way the system designers achieved real-world feel is to allow pharmacies and organizations to customize their MI report forms.

Persuasive System Implementation and Ethical Design Considerations

Our analysis reveals that there is a need to consider and address the ethical implications that may arise from integrating persuasive strategies into the existing MIRLS. These considerations include administrative (eg, anonymity) and choice of persuasive strategies (eg, monetary reward). For example, to ensure that the principle of anonymity is fostered in the implementation of social strategies, user identifications should be limited to pseudonyms, which the users can change from time to time. It is worth noting that a persuasive strategy that may be effective (or welcomed) in one community pharmacy may not be in another. Hence, there may be a need to get the potential users involved in deciding the set of persuasive strategies that will be implemented or effective in a given

pharmacy. Thus, the system should offer tailoring capabilities that support the chosen guidelines. Intervention researchers and designers may have to (1) investigate, before implementation, which of the recommended persuasive strategies a given group of pharmacy professionals may be or may not be receptive to and (2) implement only the set of strategies that are likely to be effective, as proven by empirical evidence. For these reasons, MIRLS should be designed in a way that enables pharmacies to turn on and off persuasive strategies that they consider useful and nonuseful, respectively. It is worth noting that some of the persuasive strategies in the PSD taxonomy may have to be combined to realize a holistic and functional persuasive feature that is useful. In other words, some of the persuasive strategies are complementary. For example, praise and feedback strategies must be combined to implement or realize a composite feature that provides immediate feedback of praise to the user upon submitting an incident report. In addition, reminders and verbal persuasion may be combined to realize a composite feature that verbally persuades the user through a reminder. For example, a verbal persuasion message ("Alice, remember to report your near misses and incidents to improve patient safety. Yes, you can.") can be sent to the user as a reminder by the pharmacy manager from time to time. Finally, authority, credibility, and verifiability may have to be combined to realize a persuasive message that is not only authoritative and credible but also verifiable.

Contributions

In this study, we have made a number of contributions to knowledge in the domain of community pharmacy and developers of health digital systems. This study is the first to provide guidelines on how to integrate persuasive strategies into MIRLS to increase their utility and motivate users to report MIs and near misses to improve patient safety and promote shared learning. Specifically, we provided MIRLS-specific persuasive design guidelines based on the PSD taxonomy proposed by Oinas-Kukkonen and Harjumaa [30]. Most of the PSD guidelines in the extant literature are concentrated in the domains of healthy eating [113] and physical activity [81,84,114]. Designers of MIRLS can leverage the current set of PSD guidelines in improving future iterations not only in community pharmacy but also in other settings where incident or error reporting is essential and part of the organizational practice. The second contribution is that this study lays the foundation for future empirical research aimed at investigating the effectiveness of persuasive strategies incorporated into MIRLS. Future research efforts should focus on ≥ 1 of the design guidelines in each of the 4 categories of the PSD taxonomy; implement them; and conduct a field study to examine the perception, acceptance, and adoption of the implemented strategies by the target community pharmacists.

Research Directions

In future work, we look forward to investigating the potential effectiveness of some of the proposed persuasive design guidelines presented in Tables 2-4 and Textbox 4 in field studies. First, we will create prototypes of the persuasive strategies and perform an empirical study to explore which set of strategies might be more effective. In addition, we will analyze the

potential influence of demographic variables, such as age, gender, and work experience, on the effectiveness of these strategies. Second, we will select the most persuasive strategies that the target community of pharmacy professionals are most responsive to and implement them in an actual MIRLS (eg, Think Research or Pharmapod). Third, we will conduct a field study (randomized controlled trial) to investigate the effect of the persuasive design on the rate of MI reporting among community pharmacy professionals using different provinces across Canada as case studies. More importantly, owing to the lack of studies on the relationship between system usability and medication error reporting, as our second scoping review shows, we recommend that future work be conducted in this area.

Limitations

Similar to most conceptual papers, our study has limitations owing to its preliminary nature, which stems from the nonmaturity of research on the persuasive design of MIRLS. The first limitation is that the results of the scoping reviews might have been limited one way or the other by the choice of search strings and the subjective assessment, understanding, and interpretations of the extracted data by the researchers that conducted the reviews. Hence, we recommend a more comprehensive review, particularly with regard to the second RQ, in which a formal review led to no included article, other than the article retrieved from Google Scholar search. The second limitation of our study is the convenience sample. In other words, the 3 assessors who assessed the Think Research or Pharmapod system using the PSD taxonomy were not sufficient to be representative of the entire population of community pharmacy professionals using MIRLS across Canada. For example, a persuasive feature that may be important and useful to a group of community pharmacists in one facility may not be useful to another group in another facility. Hence, the findings reported in the last 2 columns of [Tables 2-4](#) and [Textbox 4](#) may not generalize to a larger population sample involving a heterogeneous group of community pharmacists with different roles, working environments, years of working experience, professional qualifications, gender, personality, and economic status, which may influence their responses. In future

work, we hope to build on this preliminary study by conducting a formal research (eg, based on storyboards) involving a larger population sample to validate the generalizability of the findings of this study, particularly the effectiveness, acceptability, and adoption of the recommended persuasive strategies presented in [Tables 2-4](#) and [Textbox 4](#).

Conclusions

Although most medical practitioners agree that reporting medication errors improves the quality of care and safety for patients [21], in reality, the rate of reporting remains below expectations [115] owing to lack of motivation and other barriers [22-25]. In this study, we argued that although most current MIRLS have implemented recommended guidelines bordering on favorable administrative measures and utility, they lack motivational affordances that can facilitate or motivate frequent reporting. Hence, using the Think Research or Pharmapod system as a case study, we identified opportunities for incorporating persuasive strategies into MIRLS to make them more effective in motivating behavior change. The proposed persuasive design guidelines can be used by designers and developers in making MIRLS more effective in motivating users to report incidents and near misses more often to reduce risks of recurrence, improve patient safety, and foster shared learning among community pharmacy professionals and stakeholders. However, before the implementation of the recommended persuasive design guidelines in [Tables 2-4](#) and [Textbox 4](#), there is a need for thorough consideration and evaluation of the various ramifications, including administrative, regulatory, and ethical implications. The presented persuasive design guidelines open up new opportunities for persuasive design research in MI reporting. We acknowledge that some of the proposed persuasive strategies may not be suitable or effective in real-life settings. Hence, there is a need for further validation-based research and caution regarding their implementation. In future work, we aim to validate the suitability and effectiveness of the proposed persuasive strategies in motivating behavior change using storyboards, prototypes, and perception and evaluation studies involving community pharmacists across Canada.

Acknowledgments

This project was funded by the Social Sciences and Humanities Research Council Partnership Engage Grant (#1008-2020-0119).

Authors' Contributions

KO and PAG coordinated and supervised the assessment of the Think Research or Pharmapod platform and led the substantive writing of the paper. KO, SE, and TN conducted the scoping reviews including database search, retrieval of articles, screening and selection of included articles, and extraction and tabulation of data. CB facilitated access to the platform, contact with the assessors, and reviewed and edited the paper. DO provided technical assistance in the platform access and assessment and reviewed and edited the paper. KO used the data from the scoping reviews and assessment of the Think Research or Pharmapod platform to write the paper. PAG and JRB contributed to the editing of the paper.

Conflicts of Interest

CB is the vice president of Quality Improvement and Innovations at Think Research or Pharmapod, which is the partner organization for the Partnership Engage Grant that funded this research. All other authors declare no other conflicts of interest.

Abstract

Background: Ventricular tachycardia (VT) diagnosis is challenging due to the similarity between VT and some forms of supraventricular tachycardia, complexity of clinical manifestations, heterogeneity of underlying diseases, and potential for life-threatening hemodynamic instability. Clinical decision support systems (CDSSs) have emerged as promising tools to augment the diagnostic capabilities of cardiologists. However, a requirements analysis is acknowledged to be vital for the success of a CDSS, especially for complex clinical tasks such as VT diagnosis.

Objective: The aims of this study were to analyze the requirements for a VT diagnosis CDSS within the frameworks of knowledge and practice and to determine the clinical decision support (CDS) needs.

Methods: Our multidisciplinary team first conducted semistructured interviews with seven cardiologists related to the clinical challenges of VT and expected decision support. A questionnaire was designed by the multidisciplinary team based on the results of interviews. The questionnaire was divided into four sections: demographic information, knowledge assessment, practice assessment, and CDS needs. The practice section consisted of two simulated cases for a total score of 10 marks. Online questionnaires were disseminated to registered cardiologists across China from December 2022 to February 2023. The scores for the practice section were summarized as continuous variables, using the mean, median, and range. The knowledge and CDS needs sections were assessed using a 4-point Likert scale without a neutral option. Kruskal-Wallis tests were performed to investigate the relationship between scores and practice years or specialty.

Results: Of the 687 cardiologists who completed the questionnaire, 567 responses were eligible for further analysis. The results of the knowledge assessment showed that 383 cardiologists (68%) lacked knowledge in diagnostic evaluation. The overall average score of the practice assessment was 6.11 (SD 0.55); the etiological diagnosis section had the highest overall scores (mean 6.74, SD 1.75), whereas the diagnostic evaluation section had the lowest scores (mean 5.78, SD 1.19). A majority of cardiologists (344/567, 60.7%) reported the need for a CDSS. There was a significant difference in practice competency scores between general cardiologists and arrhythmia specialists ($P=.02$).

Conclusions: There was a notable deficiency in the knowledge and practice of VT among Chinese cardiologists. Specific knowledge and practice support requirements were identified, which provide a foundation for further development and optimization of a CDSS. Moreover, it is important to consider clinicians' specialization levels and years of practice for effective and personalized support.

clinical decision support system; requirements analysis; ventricular tachycardia; knowledge; clinical practice; questionnaires

Introduction

Sudden cardiac death (SCD) remains a significant public health issue, accounting for 50% of all cardiovascular deaths. The estimated annual incidences of SCD are 60 [1], 40.7 [2,3], and 36.8 [4] per 100,000 people in the United States, China, and Europe, respectively. Ventricular tachycardia (VT) is a major cause or precursor of SCD [5], which can be the initial or sole manifestation of diverse heart diseases [6,7]. VT diagnosis is challenging due to its similarity with some forms of supraventricular tachycardia, the complexity of clinical manifestations, heterogeneity of underlying diseases, and potential for life-threatening hemodynamic instability [6,8]. Diagnostic accuracy and timing are critical for patients with VT, as the stage of diagnosis determines the selection of treatment [9]. However, studies have revealed a substantial prevalence of misdiagnoses of VT [10-13], focusing on differential diagnosis between VT and supraventricular tachycardia. Although diagnostic error has been a challenge along the development of medicine, measuring diagnostic error can be difficult due to detection and reporting biases, with scarce reports indicating error rates of approximately 10%-15% [14]. We could not find additional estimates for the actual diagnostic error of VT; however, it is commonly acknowledged to represent a substantial challenge considering the complexity of the condition [9,15].

Diagnosis represents a complex cognitive process comprising a variety of different problem-solving tasks that are related to the clinical reasoning process, such as taking a medical history, forming a differential diagnosis, ordering examinations, and interpreting clinical findings [16]. The diagnostic process requires not only the retention of knowledge but also the judicious application of that knowledge at opportune moments, namely in clinical practice. A proper diagnosis of VT demands a great volume of knowledge. First, the clinician must be able to identify VT among the spectrum of wide QRS tachycardias by inspecting a list of electrocardiogram (ECG) features and comparing the findings to various diagnostic criteria or algorithms [17,18]. Once VT is identified by ECG interpretation, the next step is to diagnose the underlying diseases from a vast disease spectrum. This is a particularly challenging task, as any disease involving the myocardium can cause VT, such as coronary artery disease (CAD), all types of cardiomyopathies, myocarditis, inherited arrhythmia syndromes, autoimmune or inflammatory diseases, and others [7,9]. Moreover, translating the enormous body of knowledge into proper practice can be difficult [19], which is exacerbated by the fact that VT can cause stress to clinicians due to the probability of hemodynamic instability.

In response to this challenge, the clinical decision support system (CDSS) has emerged as a promising tool to augment the diagnostic capabilities of clinicians. Clinical decision support (CDS) is a process for enhancing health-related decisions with

pertinent, organized clinical knowledge and patient information, thus advancing health care delivery [20]. Use of a CDSS can provide clinicians with situation-specific knowledge that aids in making critical clinical decisions such as risk assessment, diagnosis, prognosis, and selection of therapy [21]. A clinical diagnostic decision support system (DDSS) is a computer-based algorithm that assists a clinician with one or more component steps of the diagnostic process [22]. A DDSS is expected to receive relevant patient information and return outputs to assist with the problems the clinician has encountered in the diagnostic process, such as suggesting a likely diagnosis. Some well-known DDSSs such as ISABEL [23] and Dxplain [24] provide a diagnosis list, which can offer a solution to the challenges associated with VT diagnosis. Most CDSSs exhibit efficacy in a laboratory or experimental environment; however, relatively few such systems are being used at present and the rate of use in routine clinical practice is low [20,25-27]. Studies have identified the main barriers to the widespread adoption of CDSSs, including vague requirements, poor integration with the clinical workflow, low user acceptance or trust, and lack of transparency. Among these barriers, comprehensive user requirements engineering should be performed at the very beginning of development, which should be continued iteratively throughout the CDSS design-development-implementation life cycle [25,26,28,29]. To address this gap, several recent studies have aimed at elucidating the clinical requirements for an effective and usable CDSS in the context of specific fields or scenarios [30-34] with a variety of methods, including focus groups [30,35], a workshop [34], expert discussion with a literature review [36,37], semistructured interviews [31,34,35,38], writing user stories [39], and system evaluation [40]. Overall, most studies have adopted a user-centered approach with qualitative analysis.

To our best knowledge, although an artificial intelligence model was reported for predicting the in-hospital mortality of VT [8], no CDSS has been developed for VT diagnosis. A recent systemic review of cardiovascular CDSSs found that the complexity of the clinical management of cardiovascular disease itself was a barrier during implementation [27], which emphasizes the need for an authentic clinical requirements analysis. Accordingly, the objective of this study was to analyze the requirements for a VT diagnosis CDSS within the frameworks of knowledge, practice, and CDS needs.

Methods

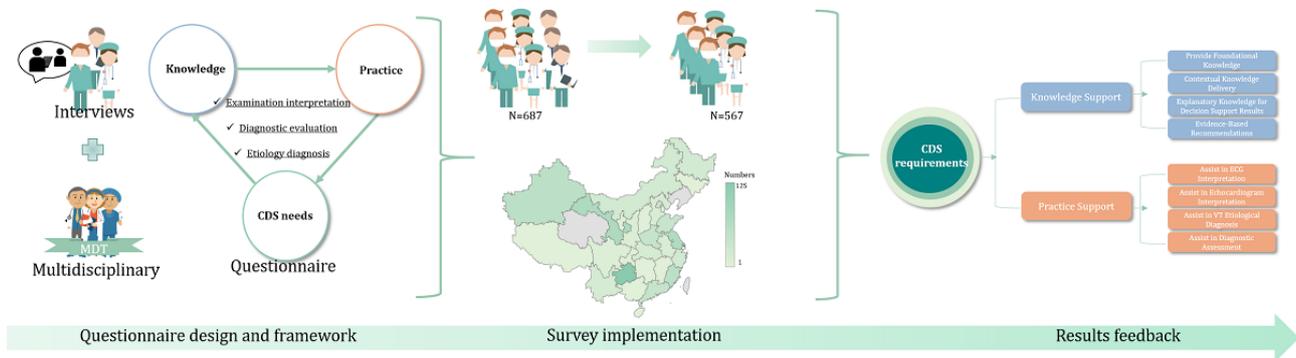

Study Design and Recruitment Process

Figure 1 shows the overall flow of our study, which consisted of semistructured interviews in the early stages and questionnaires in the later stages. To effectively implement and conduct the questionnaire assessment, we conducted open and explorative interviews about the challenges associated with the management of VT and the expected functions of a CDSS for VT. The interviews were conducted at Fuwai Hospital, the

national cardiovascular disease center of China. This hospital actively recruits cardiologists for their fellowships from all regions of China, resulting in a representative sample of interviewees. We sent interview invitations to all 56 cardiologists in the arrhythmia center, including cardiologists

from the fellowship program or established staff of Fuwai Hospital. Seven cardiologists responded and completed the interview, followed by a brief questionnaire to provide information on demographics and clinical experience (see [Multimedia Appendix 1](#)).

Figure 1. Schematic of the overall study workflow and assessment approach. CDS: clinical decision support; ECG: electrocardiogram; MDT: multidisciplinary team; VT: ventricular tachycardia.

A multidisciplinary team was formed to define the purpose of our study and the design of the questionnaire based on the interview results. The multidisciplinary team comprised three arrhythmia specialists, three experts in medical informatics and CDS, and one clinical statistician. The questionnaire was examined by an additional 20 arrhythmia specialists to ensure its clarity and feasibility. We conducted a nationwide cross-sectional survey with an online questionnaire in mainland China from December 31, 2022, to February 15, 2023. We recruited registered cardiologists using a convenience sampling approach from network groups associated with the Asian Heart Rhythm Association (AHRA) on WeChat, the dominant social media app in China. The AHRA is an academic organization focusing on arrhythmias, whose members are all registered cardiologists. Duplicate submissions were prevented through IP address constraints, and only completed responses were included for analysis.

Ethical Considerations

Participants provided online informed consent, which detailed the survey’s background, aim, methods, and confidentiality

Table 1. Design of the questionnaire.

Section	Content	Related questions
Knowledge	Examination interpretation, etiological diagnosis, diagnostic evaluation, conceptual knowledge	14
Practice	Examination interpretation, etiological diagnosis, diagnostic evaluation	7-13
Clinical decision support needs	Interpretable diagnosis, executable processes, knowledge support	15-18

Knowledge Assessment

Knowledge serves as the theoretical foundation for clinicians to make clinical diagnoses and is thus an essential competency for clinicians. The diagnosis of VT is difficult as it will largely depend on the clinician’s familiarity with the vast knowledge of the field. The European Society of Cardiology (ESC)

measures. To protect participants’ privacy, a signature was not required. Instead, participants clicked the “go on” button at the bottom of the informed consent page if they agreed to participate. According to data privacy protocols, no personal information, including the participants’ names or affiliations, was collected. Since patients were not the subject of this study, ethical approval was exempted by the ethics committee of the Institute of Medical Information, Chinese Academy of Medical Sciences/Peking Union Medical College [41]. Each participant received ~US \$3 as compensation.

Questionnaire Design

Overview

The questionnaire was divided into four sections (Table 1): demographic information (questions 1-6), knowledge assessment (question 14), practice assessment (questions 7-13), and CDS needs (questions 15-18). A comprehensive version of the questionnaire is provided in [Multimedia Appendix 2](#).

guideline suggests a protocol for VT diagnosis [15]. The multidisciplinary team abstracted the knowledge points from the ESC guideline for collecting information on the participants’ self-reported knowledge shortcomings.

Practice Assessment

Areas of Focus

To attain a more accurate gauge of the clinical practice competency, we used simulated cases rather than straightforward questions [42], which can help differentiate practice competency from knowledge. To mitigate the risk of low response rates and careless submissions associated with lengthy surveys [43], we designed two stepwise cases containing seven questions. According to the intention, the questions about clinical practice were divided into three parts: examination interpretation, etiological diagnosis, and diagnostic evaluation. Multiple-choice options were available for all the questions. We standardized the total score for each section to 10 points according to the weighting.

Examination Interpretation

Accurate interpretation of an examination is the basis for a correct etiological diagnosis. ECG is the first-line examination modality for arrhythmias, as nearly all arrhythmia episodes are detected by ECG. Therefore, for this section, we focused on the identification of VT and sites of origin of VT on ECG [15].

Etiological Diagnosis

A correct etiological diagnosis of VT is necessary for appropriate treatment. The main strategy is to identify or exclude structural heart diseases, including CAD, myocarditis, and cardiomyopathies [44]. In this section, we assessed the correctness of a diagnosis of arrhythmogenic right ventricular cardiomyopathy (ARVC) and acute myocarditis as the two cases.

Diagnostic Evaluation

Diagnostic evaluation is a process of collecting clinical information to confirm or exclude a suspected diagnosis. A diagnostic evaluation protocol for VT is recommended in the ESC guideline [15] with the goal of reducing the rate of diagnostic errors. Based on the cases with an etiological diagnosis, we assessed the competency of the participants to arrange further diagnostic evaluations.

CDS Needs

According to the ESC guideline [15] and universal CDSS functionality [25], the multidisciplinary team summarized the results of the interviews to produce a list of functions required for CDS, which could be divided into executable processes, interpretable diagnosis, and knowledge support. We employed this list to poll the functionalities required by the cardiologists for a VT CDSS.

Quality Control of Responses

To ensure the validity and reliability of our survey responses, we used two strategies to filter out potentially low-quality submissions. First, participants who completed the questionnaire in under 2 minutes were excluded. This threshold was determined through a pretest evaluation coupled with multidisciplinary team discussions. Second, responses were considered to be invalid if participants selected all the available options for questions 7, 8, 9, 11, 12, or 13. This exclusion criterion was established based on the consensus opinion of the multidisciplinary team, who deemed such selections to be unreasonable.

Statistical Analysis

We only included valid questionnaire responses in the statistical analysis. All data in the demographic section were categorical. Comparisons were performed using mean, median, range, and percentage. The scores in the practice section are expressed as continuous variables, using the mean, median, and range. The knowledge and CDS sections were phrased as single-choice questions asking clinicians about their subjective views on given statements using a 4-point Likert scale without a neutral option. The internal consistency of the questionnaire was assessed using the Cronbach α value.

In addition, we grouped participants separately by practice years and specialty for further subgroup analyses. The Kruskal-Wallis test was performed to investigate the relationship between practice scores and practice years or specialty. All analyses were conducted in R version 4.0.3 [45]. We analyzed most of the data descriptively using graphics produced by the R package ggplot2.

Results

Sociodemographic Characteristics of Participants

A total of 687 questionnaires were completed. After applying our quality control measures, 567 responses were considered valid, yielding a validity rate of 82.53%. Among the invalid questionnaires, 104 responses were excluded due to a completion time of less than 2 minutes and 16 were excluded for selecting all options in questions 7, 8, 9, 11, 12, or 13. Descriptive statistics regarding the sociodemographic characteristics of participants are presented in Table 2. Of the enrolled participants, 54.50% were men; 93.47% were general cardiologists and the others were cardiac arrhythmia specialists. More than half of the participants were from tertiary A hospitals. Only a small percentage of cardiologists had ever used a CDSS, and the majority reported needing a CDSS to assist them in the management of VT (Table 2).

Table 2. Demographic characteristics of the survey participants (N=567).

Characteristics	Participants, n (%)

^aCDSS: clinical decision support system.

Semistructured Interviews

Textbox 1 summarizes the results of the semistructured interviews, in which we focused on the challenges of VT management and CDSS needs. The responses of the seven cardiologists were focused, with each noting that etiological

diagnosis and interpretation of ECG results were their main challenges. The most important demand was the provision of quick and concise recommendations on diagnosis and treatment. The interviewees also expected the CDSS to provide clinical pathways.

Textbox 1. Results of the interviews.

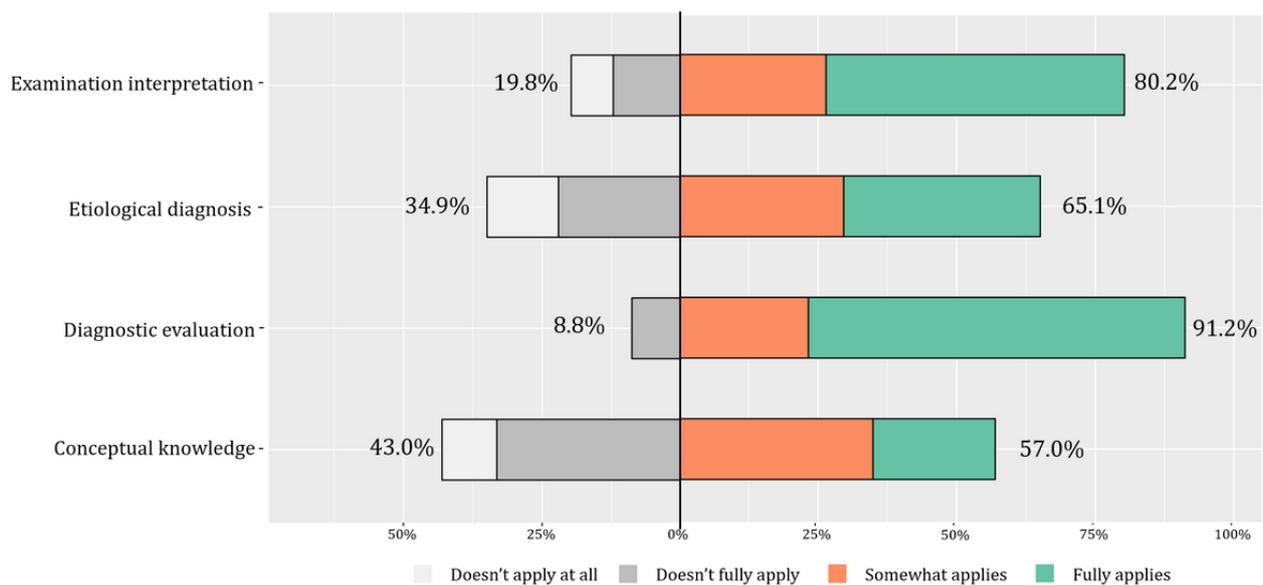

- Challenges in the management of ventricular tachycardia (VT)
 1. Etiological diagnosis
 2. Wide QRS tachycardia diagnosis on electrocardiogram (ECG)
 3. Determination of the location of VT origin on ECG
 4. Mechanisms of VT
 5. Drug treatment options
 6. Options for the treatment of polymorphic VT
- Clinical decision support system needs
 1. Rapid and concise recommendations for diagnosis and treatment
 2. Diagnostic and therapeutic pathways for different etiologies
 3. Aids in the identification of wide QRS
 4. Adjunctive etiological diagnosis
 5. Diagnostic supplements for related diseases

Knowledge

Figure 2 shows that there was an overall lack of knowledge with respect to diagnostic evaluation, with 383 of the 567 (68.0%) cardiologists indicating full need of assistant knowledge in diagnostic evaluation. This was followed by examination

interpretation, where 305 of the 567 (53.8%) cardiologists were in full need of knowledge regarding the interpretation of ECG, cardiac ultrasound, and other cardiac examinations. The need for conceptual knowledge was relatively lower, even though it still reached nearly 60%.

Figure 2. Knowledge assessment.

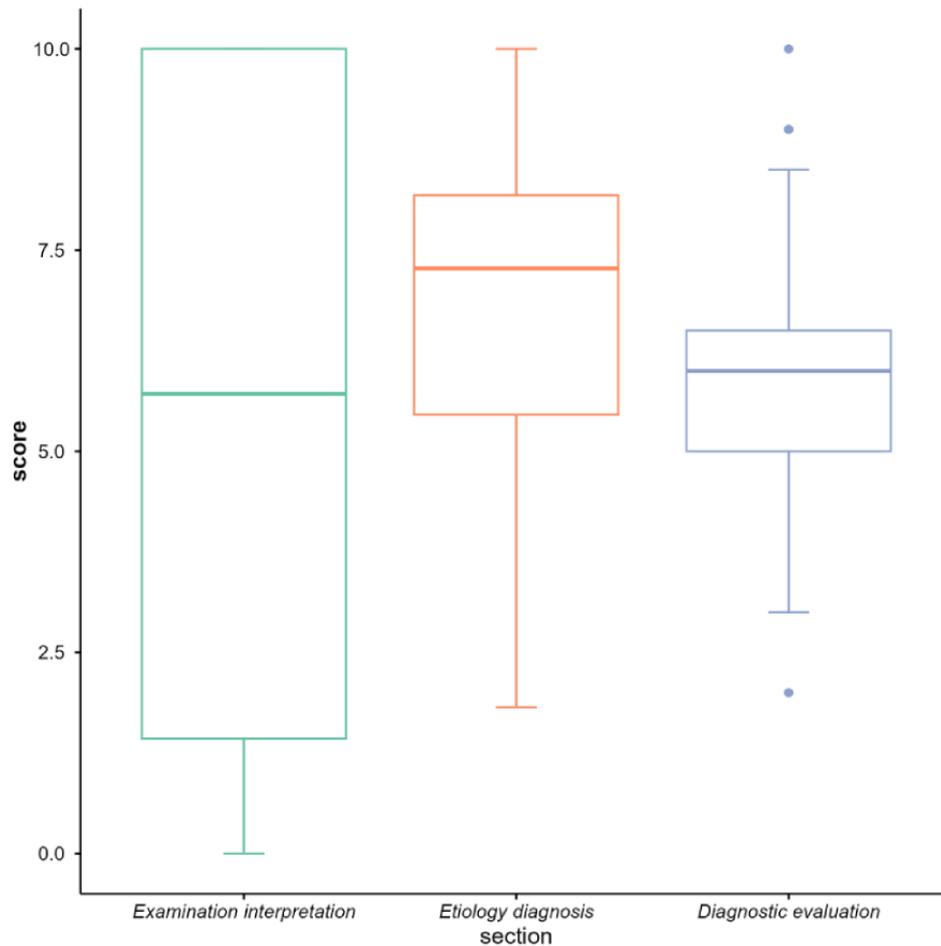

Practice

The overall average score of the practice questions was 6.11 (SD 0.55), the internal consistency of which was confirmed by a Cronbach α of 0.913. The mean scores of the examination interpretation, etiological diagnosis, and diagnostic evaluation were 6.22 (SD 3.94), 6.74 (SD 1.75), and 5.78 (SD 1.19),

respectively. As shown in Figure 3, the etiological diagnosis section was associated with the highest overall score and the distribution of scores was also more concentrated than for the other sections, especially when compared with the distribution of the examination interpretation scores that were more dispersed and polarized.

Figure 3. Practice assessment.

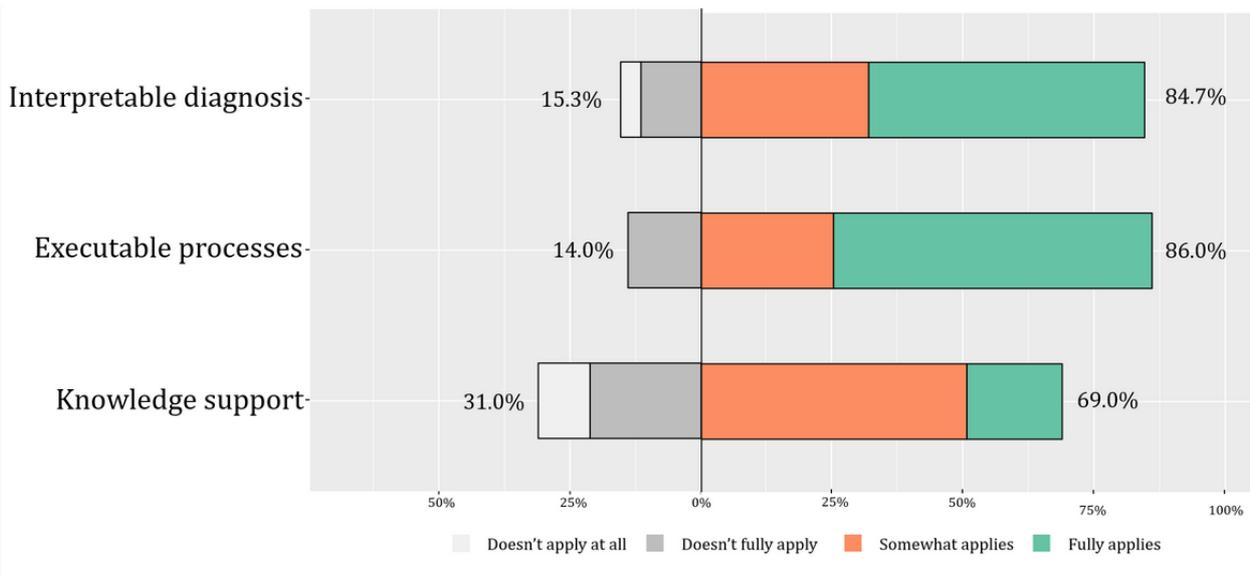

CDS Needs

The majority of the surveyed cardiologists reported a positive attitude toward CDS needs (Figure 4). There was relatively higher demand expressed for functions related to executable

processes and interpretable diagnosis. In particular, the executable processes function was considered to be an essential requirement of a CDSS by 344 of the 567 cardiologists (60.7%). Knowledge support function received the least support but was still close to 70%.

Figure 4. Clinical decision support needs assessment.

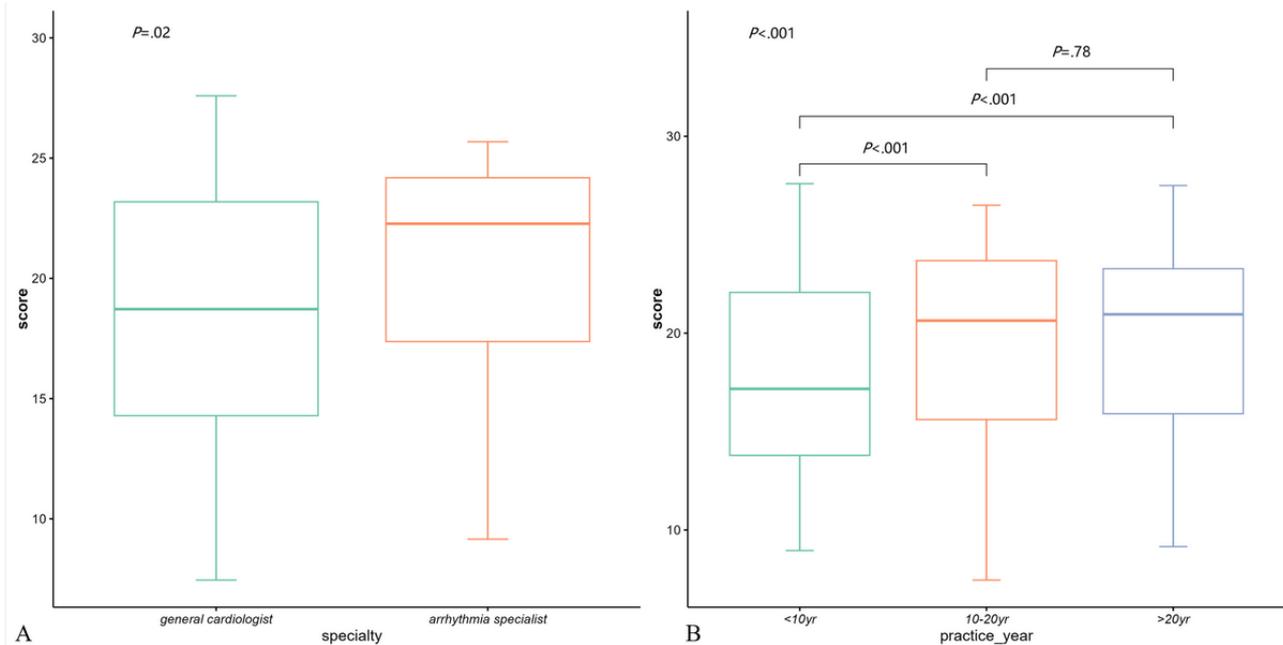

Subgroup Analysis

We divided all the cardiologists into subgroups based on specialty (Figure 5A) and practice years (Figure 5B). The Kruskal-Wallis test showed a significant difference in practice competency scores between general cardiologists and arrhythmia

specialists ($P=.02$). Subgroup analysis according to years of practice revealed a significant effect of experience on scores. The <10 years group had significantly lower scores compared to those of the 10-20 years and >20 years groups. However, there was no significant difference between those with 10-20 years and >20 years of experience.

Figure 5. Subgroup analyses according to (A) specialty and (B) years of practice.

Discussion

Principal Results

Based on a combination of semistructured interviews and questionnaires, this study conducted a large-scale nationwide survey for cardiologists to understand their knowledge and practice competence about VT diagnosis and their requirements for a related CDSS. The results indicated that knowledge and practice support in examination interpretation, etiological diagnosis, and diagnostic evaluation are considered to be essential for a VT diagnosis CDSS. In addition, the vast majority of the cardiologists gave a positive response with respect to the need for a CDSS.

CDSS Requirements

Previous research on CDSS requirements has primarily relied on methods such as interviews [31,34,35,38,39] and group discussions [30,34,35] to elicit users' subjective needs. Based on recommendations from clinical experts and medical informatics professionals within our research team, it was acknowledged that certain objective requirements might not be articulated by users during interviews. Consequently, a questionnaire was designed to assess and uncover the requirements that might not have been spontaneously expressed during interviews. Previous studies have used questionnaires to investigate the knowledge, attitudes, and practices of health care professionals in various specific tasks [46-53], providing a basis for our questionnaire approach. To objectively reflect cardiologists' knowledge and practice deficiencies, we opted to not directly inquire about specific knowledge points but

instead used two case scenarios to simulate authentic VT diagnostic situations, which is proven to be an appropriate method to assess practice competence [54]. The survey results endorsed the advantages of this mixed methods approach. The difficulties in VT diagnosis mentioned by the cardiologists during interviews primarily focused on distinguishing wide QRS tachycardias on ECG and identifying the etiology of VT, with no mention of diagnostic evaluation. However, results from the practice section of the questionnaire indicated poorer competence in diagnostic evaluation compared to etiological diagnosis, suggesting that the interviewees were not consciously aware of their weaknesses in diagnostic evaluation during interviews. Currently, there is no unified systematic method for conducting a CDS requirements analysis. While our method of integrating interviews and questionnaires provides a comprehensive approach, there is still room for improvement. Use of a simulation game has been suggested as a better means for clinical competence assessment [42]. Future research could consider incorporating cognitive analysis [55] and real-world system usability evaluation [56] to further optimize CDSS requirements analysis.

The objective results from case simulations also affirmed the cardiologists' need for decision support (Figure 4). Regarding knowledge requirements, the results from the CDS needs section of the questionnaire indicated that participants had relatively fewer demands for knowledge support compared to direct decision support. Moreover, the cardiologists revealed a preference for automatically prompted relevant knowledge during the diagnostic and therapeutic processes, which can provide more targeted knowledge support (Figure 2). The

challenge lies in ensuring that the CDSS accurately identifies the current diagnostic and therapeutic tasks; determines user knowledge gaps; and automatically retrieves, integrates, and presents knowledge support rapidly and accurately [57]. The results of the practice competence highlighted the need for improvement in the interpretation of diagnostic tests, etiological diagnosis, and diagnostic evaluation, suggesting the need for decision support in these three aspects, which were also highlighted as key clinical reasoning [58]. Notably, the accuracy of etiological diagnosis was relatively high, aligning with the lower knowledge demand for an etiological diagnosis (Figure 3). In terms of CDSS needs, the cardiologists favored direct decision support over knowledge support, including explanatory diagnoses and executable evaluation processes, which has also been recognized in recent studies [57,59,60].

Synthesizing the findings of this study, we propose the following recommendations of specific functions of a CDSS for VT diagnosis under a framework of knowledge and practice. With respect to knowledge support, the CDSS needs to (1) provide foundational knowledge by offering fundamental knowledge for each relevant disease that is available for clinicians to retrieve and browse; (2) contextualize knowledge delivery by providing closely related knowledge at decision points, including, but not limited to, the interpretation of diagnostic tests such as ECGs and echocardiograms, wide QRS complex differentiation, etiological diagnosis of VT, and the issuance of diagnostic test orders; (3) explain the knowledge underlying CDSS results; and (4) provide evidence-based recommendations at decision points with available evidence support. With respect to practice support, the CDSS should (1) assist in ECG interpretation, including distinguishing wide QRS complex tachycardias, identifying useful features for etiological diagnosis during sinus rhythm and VT, and recommending diagnostic test orders; (2) assist in echocardiogram interpretation, including the recognition of common etiologies of VT such as old myocardial infarction, ARVC, myocarditis, and the classification of phenotypes of cardiomyopathies; (3) provide suspected etiological diagnoses based on existing information for patients with VT, including acute coronary syndrome, ischemic cardiomyopathy, ARVC, and acute myocarditis, with specific emphasis on alerting clinicians who may not have considered the possibility of acute coronary syndrome; and (4) supplement diagnostic assessments with additional information, including critical medical history, physical examination, laboratory tests, and other examinations. Particularly, using a comprehensive differential diagnosis list is advocated to mitigate premature closure [14], as substantiated by a recent study [61].

Dxplain [24], one of the few DDSSs available for general practice, provides a diagnosis list according to input patient manifestations, which aligns with our proposed structure for VT etiological diagnosis. However, Dxplain lacks knowledge support, examination interpretation, and diagnostic assessment functions, which are highlighted as requirements for a VT CDSS as mentioned above. Another well-known commercial diagnostic support tool, ISABEL, not only serves as a diagnosis reminder but also provides knowledge support (ie, evidence-based knowledge of each disease). However, it does not satisfy the other requirements identified in this study [23,62]. Dr. Mayson

[63] is a Chinese commercial CDSS for general practice, which can abstract data from electronic health records to form a diagnosis list as well as provide assistance in diagnostic assessment. Like ISABEL, Dr. Mayson provides a knowledge database for each disease, including clinical practice guidelines. However, the knowledge support is at the disease level rather than the decision level. In addition, this CDSS does not assist with examination interpretation.

Although our study mainly investigated the specific functionalities for VT diagnosis, the results indicated some general CDSS functionalities, including interpretability of decision-making as well as the overall feasibility of the CDSS workflow. Several reviews [64–66] summarized other universal features worthy of consideration, such as integration with the clinical workflow and electronic health record system, reduction of manual input of patient data, execution users' desired action, avoidance of unnecessary alerts, documentation of reasons for rejecting recommendations, as well as the "five rights" of CDS (providing the right information to the right people in the right formats through the right channels at the right time) [67].

We believe that an excellent CDSS should provide tailored assistance for different types of clinicians. Thus, a subgroup analysis was performed according to the clinician characteristics in the practice section (Figure 5). As anticipated, arrhythmia specialists outperformed general cardiologists, which aligns with the findings of previous research [68]. The American College of Cardiology defines different types of cardiovascular specialists that have requirements for different types of support in cardiovascular health care [69]. A CDSS should be tailored to clinicians' specialization levels to assist in diagnostic and therapeutic practices. For highly specialized clinicians facing a narrow spectrum of diseases, CDSS assistance may be limited, while support for foundational diagnostic and therapeutic aspects outside their specialty may be necessary. Conversely, less specialized clinicians facing a broader spectrum of diseases may need support in staying updated with the latest diagnostic and therapeutic advancements. For instance, for less experienced clinicians facing patients with VT, the CDSS should always indicate the possibility of CAD. For experienced clinicians, as they have already cultivated the mindset to exclude CAD, the CDSS might only provide this alert when they miss the diagnosis of CAD. Furthermore, it is expected that the CDSS could continually adapt to individual needs through observing clinician users' behaviors. The impact of years of practice on performance seems to be nonlinear. Clinicians practicing for 10–20 years or more demonstrated better performance than those practicing for less than 10 years. However, there was no significant difference between the 10–20 years and >20 years groups, suggesting that clinical skills may grow in the first 10 years of practice but plateau afterward, thereby challenging the CDSS design to provide targeted support for clinicians with different levels of experience in practice. Additionally, for clinicians entering a bottleneck period in competence growth, the CDSS could facilitate education during practice, thereby supporting lifelong learning. Several studies have been performed in this regard in the areas of pharmaceutical skills [70], imaging interpretation [71], geriatric care [72], and periprocedural antithrombotic use [73].

Most existing CDSSs have been generally designed for health care providers but might not fully consider the diversity of requirements as well as their expertise levels [74]. The genuine needs of health care providers have not been effectively communicated to system developers, resulting in the design of CDSSs that struggle to fulfill their intended role of assistance and workload reduction. Our study centers around the clinical scenario of VT diagnosis, comprehensively exploring support requirements in both knowledge and practice. This investigation can thus provide a foundation for the development of a relevant CDSS. Additionally, we aspire for this study to serve as a reference for clinical needs research, encouraging more health care providers and system developers to scrutinize clinical requirements and establish a groundwork for the development of highly effective CDSSs.

Limitations

Although this study used a combination of structured interviews and questionnaires for assessment, inevitably, some subjective

factors from the participants may have biased the results. The questionnaire content of this study was carefully designed based on the results of the interviews as well as the experience of the multidisciplinary team; however, the questionnaire content was unable to cover all aspects of knowledge and practice related to VT diagnosis. Although specific functions for a VT diagnosis CDSS were proposed, they have not been evaluated in a real-world setting. As our team is currently developing a VT CDSS with these functions, more rigorous studies will be conducted to support these findings in our future research.

Conclusions

This comprehensive analysis of VT CDSS requirements using a mixed methods approach identified specific knowledge and practice support requirements. The derived functions provide a foundation for further development and optimization of a CDSS. Moreover, it is important to tailor the CDSS to clinicians' specialization levels and years of practice for effective and personalized support.

Abstract

Background: Improving shared decision-making (SDM) for patients has become a health policy priority in many countries. Achieving high-quality SDM is particularly important for approximately 313 million surgical treatment decisions patients make globally every year. Large-scale monitoring of surgical patients' experience of SDM in real time is needed to identify the failings of SDM before surgery is performed. We developed a novel approach to automating real-time data collection using an electronic measurement system to address this. Examining usability will facilitate its optimization and wider implementation to inform interventions aimed at improving SDM.

Objective: This study examined the usability of an electronic real-time measurement system to monitor surgical patients' experience of SDM. We aimed to evaluate the metrics and indicators relevant to system effectiveness, system efficiency, and user satisfaction.

Methods: We performed a mixed methods usability evaluation using multiple participant cohorts. The measurement system was implemented in a large UK hospital to measure patients' experience of SDM electronically before surgery using 2 validated measures (CollaboRATE and SDM-Q-9). Quantitative data (collected between April 1 and December 31, 2021) provided measurement system metrics to assess system effectiveness and efficiency. We included adult patients booked for urgent and elective surgery across 7 specialties and excluded patients without the capacity to consent for medical procedures, those without access to an internet-enabled device, and those undergoing emergency or endoscopic procedures. Additional groups of service users (group 1: public members who had not engaged with the system; group 2: a subset of patients who completed the measurement system) completed user-testing sessions and semistructured interviews to assess system effectiveness and user satisfaction. We conducted quantitative data analysis using descriptive statistics and calculated the task completion rate and survey response rate

(system effectiveness) as well as the task completion time, task efficiency, and relative efficiency (system efficiency). Qualitative thematic analysis identified indicators of and barriers to good usability (user satisfaction).

Results: A total of 2254 completed surveys were returned to the measurement system. A total of 25 service users (group 1: n=9; group 2: n=16) participated in user-testing sessions and interviews. The task completion rate was high (169/171, 98.8%) and the survey response rate was good (2254/5794, 38.9%). The median task completion time was 3 (IQR 2-13) minutes, suggesting good system efficiency and effectiveness. The qualitative findings emphasized good user satisfaction. The identified themes suggested that the measurement system is acceptable, easy to use, and easy to access. Service users identified potential barriers and solutions to acceptability and ease of access.

Conclusions: A mixed methods evaluation of an electronic measurement system for automated, real-time monitoring of patients' experience of SDM showed that usability among patients was high. Future pilot work will optimize the system for wider implementation to ultimately inform intervention development to improve SDM.

Introduction

Background

Contemporary health care puts patient-centered care at the heart of its delivery [1-4]. Shared decision-making (SDM) is a form of communication that promotes a dialogue between those involved in making health care choices. Therefore, treatment decisions are based on a shared understanding between patients and health care professionals of the evidence base for treatment and prognosis, patient values, preferences and beliefs, and clinical reasoning to personalize service delivery [5]. SDM is desired by patients and has become a key priority for health care systems globally [6-9]. Ensuring high-quality SDM when discussing and deciding treatments with patients can have many benefits, such as reduced information asymmetry or health service use [10,11]. It has been shown to contribute to good patient outcomes and satisfaction [12-15].

Globally, approximately 310 million operations are performed annually [16]. Surgery is often the only available treatment for a wide variety of minor and major medical conditions, and people increasingly choose surgical treatment (5.3% increase from 2009 to 2014 in the United Kingdom) [17]. Improving surgical patients' experience of SDM before surgery is particularly important because the effects of surgery are immediate and nonreversible. Patients cannot decide to discontinue treatment if the benefits fall short of expectations or side effects become unacceptable. Furthermore, making good surgical decisions may avoid negative impacts on health service costs (eg, through canceled operations) and patient outcomes [18-20].

Strategies aimed at improving SDM in complex health care settings can range from communication skills workshops for health care professionals [21] to educational videos [22] and booklets for patients [23]. However, their effects are mixed [14,15]. Systematic reviews of evidence to improve SDM conclude that achieving long-term change is likely to necessitate interventions that support the implementation of strategies at the organization, clinician, and patient levels [24-26]. However,

there is uncertainty about how to realize change on a large scale across health care systems [27-33]. One recommended way to achieve this is through routine monitoring of patients' experience of SDM [34], but robust methods are lacking. Existing approaches to data collection are delayed, potentially affecting patients' accounts of their experience and impacting the ability to respond quickly and effectively before surgical treatments. Advances in technology mean that novel approaches to assessing patients' experiences of SDM can incorporate automated, electronic data capture close to the point of treatment consultations. This offers opportunities for providing information more accurately and in a timely manner, offering an effective way to develop interventions to improve SDM before surgery. Systems routinely collecting electronic patient-reported measure (ePRM) data in other contexts have been shown to improve care and outcomes for patients, including quality of life outcomes in pediatric dermatology [35] or symptom reporting in chronic kidney disease [36]. We developed a novel system to routinely monitor patients' experience of SDM automatically and in real time.

The evaluation of existing ePRM systems highlights the importance of user-friendly processes for their optimal performance [37-40]. Furthermore, the principles of good usability are important because they can be vital to the widespread uptake of ePRM systems by patients and their successful implementation in clinical practice [41-43]. Usability is an outcome defined as the extent to which the system can be used by specified users [44]. Several methods are available to evaluate measures of usability in health care [45-49]. A widely used framework contains standards set by the International Organization for Standardization (ISO) [50,51]. The guidelines recommend evaluating and optimizing the concepts of system effectiveness (the ability of participants to complete the survey), system efficiency (resources required to complete the questionnaire), and user satisfaction (subjective opinions of participants' experience with the measurement system) to achieve good usability.

Aim and Objectives

We aimed to examine the usability of a novel, automated, real-time measurement system to monitor surgical patients' experience of SDM. The specific objectives were to evaluate the measurement system's (1) effectiveness, (2) efficiency, and (3) user satisfaction among a large sample of surgical patients from a wide range of surgical specialties.

Methods

We used quantitative and qualitative methods to examine usability by evaluating the indicators and metrics related to system effectiveness, system efficiency, and user satisfaction. This study adhered to the ISO guideline 9241-11:2018 and followed recommendations for the usability testing of electronic patient-reported outcome measures [49,51].

Context and Setting

This study is part of a wider project to develop, pilot, and evaluate a decision-support intervention that uses real-time monitoring of patients' experiences to improve SDM (the ALPACA Study [52]). The project was initially set up as a quality improvement project at a large acute National Health Service (NHS) Trust in England, United Kingdom, which provides a range of acute and specialized clinical care services in South West England.

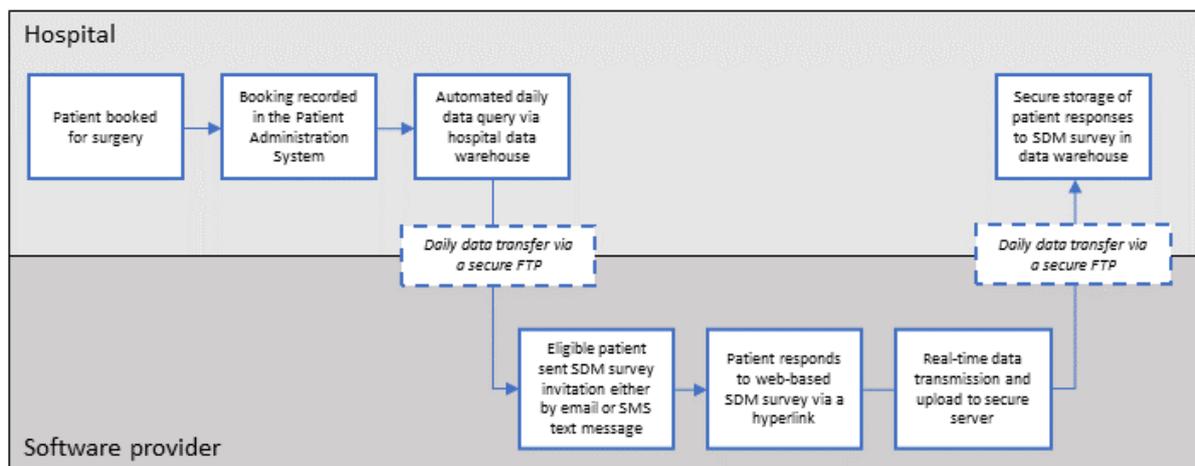

To facilitate automated, real-time data collection of patients' experience of SDM, a customizable off-the-shelf ePRM system (Cemplicity) was procured from a third-party software provider in March 2021. The software provider is an ISO 2001 certified, NHS-authorized ePRM provider, compliant with necessary accessibility and health data governance standards (eg, General Data Protection Regulations and Digital Technology Assessment Criteria). Before deployment and customization, the software provider tested the system development and design. Specifically, the prior rollout of the software across 6 countries and over 3000 health care institutions incorporated feedback from users across different health care settings and patients of diverse age groups, technology literacy, and health confidence. All measurement system interfaces are mobile optimized.

Customization for the purpose of this study was undertaken in collaboration with the software provider and included adapting the following: (1) the system's content and layout to include instruments to assess patients' experience of SDM and (2) data capture mechanisms to implement the system in the NHS Trust.

To assess patients' experience of SDM, 2 validated and widely used patient-reported measures were selected to measure SDM (CollaboRATE and SDM-Q-9). These were chosen by consensus within the study team, which was informed by a systematic review of SDM measurement instruments [53], national guidelines [25], and recommendations and use within the NHS clinical practice [34,54,55]. CollaboRATE is a 3-item instrument measured on a 10-point scale with answer options ranging from 0 ("no effort was made") to 9 ("every effort was made"). SDM-Q-9 consists of 9 items measured on a 6-point scale with answer options ranging from "completely disagree" to "completely agree." The measurement properties of both instruments have been demonstrated to be acceptable [56,57]. The measurement instruments were operationalized into a 12-question electronic survey format, branded to match the NHS Trust guidelines, and integrated into the patient-facing measurement system. Screenshots of the customized content are presented in [Multimedia Appendix 1](#).

To implement the measurement system, secure data exchange processes were established between the software provider and the NHS Trust's information technology system and subsequently widened to various patient cohorts within the surgical departments. Specifically, SQL data queries were developed to identify and extract details of patients booked for surgery from the electronic patient record system that routinely records the patients' demographic and clinical information. The queries were designed to run automatically, securely transferring data from the hospital to the software provider on a daily basis. The 2 SDM measures were administered to patients upon being booked for surgery, with invitations sent either by email or SMS text messaging if no email address was available. Patient responses were received and processed using the measurement system. A reciprocal data feed securely returned response data to the hospital data warehouse for secure storage. A flow diagram of the measurement system process is provided in [Figure 1](#).

Figure 1. Flow diagram of the process of automated real-time shared decision-making (SDM) monitoring through the measurement system. FTP: file transfer protocol.

Study Steering Group

A multidisciplinary study steering group was convened and consisted of a patient and public contributor, health care professionals, methodologists, social scientists, statisticians, and health services researchers. Regular meetings ensured the group's strategic oversight throughout and sought their input into the study design, research activities, and analyzing and interpreting results.

Patient and Public Involvement

We invited a patient and public contributor with lived experience of surgery to the study steering group, which was set up as part of the wider project. The input was sought from the patient and public contributor as appropriate throughout the study (eg, review of patient-facing materials, including survey invitation

and instructions, and interim findings from qualitative analyses). In addition, we organized a patient and public advisory meeting which 6 public contributors attended for 1 hour via a Zoom (Zoom Video Communications, Inc) meeting. The aim of the meeting was to obtain patient and public perspectives on the overall project plan and its key challenges. The topics discussed included recruitment, acceptability, and satisfaction with the measurement system, which informed the design aspects of this study.

Usability Concepts

The usability of the measurement system was examined by evaluating metrics and indicators relevant to 3 concepts, including system effectiveness, system efficiency, and user satisfaction. The definitions are summarized in [Textbox 1](#), and the details of their assessment are described subsequently.

Textbox 1. Definitions of usability concepts.

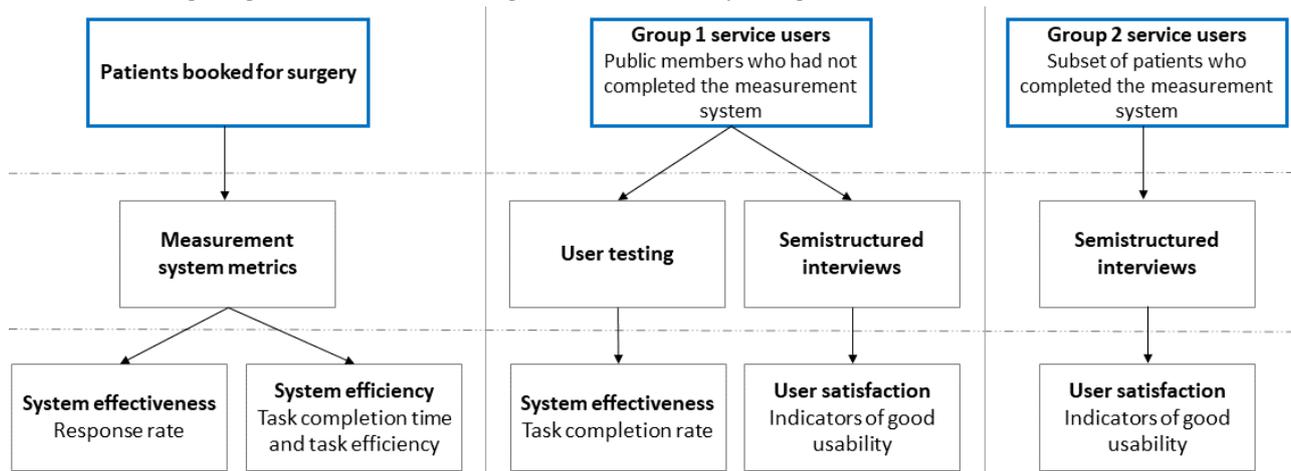

- System effectiveness: the ability of participants to perform tasks to achieve predetermined goals completely and accurately, without negative consequences (eg, poor layout of the system interface leading to participants missing or accidentally selecting system options) [36,49-51].
- System efficiency: the amount of participant resources required to achieve the prespecified goals [49,58].
- User satisfaction: the subjective opinions of the participants based on their experience of interacting with the system [49]. This includes any subjective reports about likes, dislikes, and recommendations for changes [51].

Participants and Procedures

We used multiple cohorts of participants and procedures for quantitative and qualitative data collection for this study. [Figure](#)

[2](#) illustrates the different cohorts of participants and provides an overview of the data collection procedures used to evaluate the usability concepts.

Figure 2. Overview of participant cohorts, data collection procedures, and usability concepts.

Participants and Recruitment

To obtain quantitative measurement system metrics to assess system effectiveness and efficiency (refer to the Quantitative Analysis section for further details), automated, real-time data collection was conducted between April 1 and December 31, 2021, and rolled out across 7 surgical departments: orthopedic, urology, gynecology, neurosurgery, gastrointestinal, vascular and breast. We included adult patients booked for elective surgery in these 7 specialties. Patients aged <18 years, those without the capacity to consent for medical procedures, those undergoing emergency and endoscopic procedures, and those without access to an appropriate internet-enabled device (ie, mobile phone, smartphone, PC, tablet, or similar device) were excluded.

We recruited 2 further groups of service users for user testing and interviews to obtain quantitative and qualitative data to assess system effectiveness and user satisfaction.

Group 1 participants were individuals who had not engaged with the measurement system before user-testing sessions to ensure naive user interactions [59] (refer to the User Testing section for detailed user-testing methods). Service users with experience of surgery were recruited through patient experience panels within 2 NHS Trusts (North Bristol NHS Trust and Bradford Teaching Hospitals NHS Foundation Trust). A panel coordinator identified and approached potential participants via email containing a recruitment advertisement. Sampling was purposive to achieve the maximum possible variation in recognized protected characteristics (eg, sex, disability, and race) and experience of surgery.

Group 2 participants were individuals who had engaged with the measurement system to explore user satisfaction after interacting with the system (refer to the *Semistructured Interviews* section for more details). These were a subset of eligible patients who completed the measurement system. A member of staff with authorized access to the patient administration system and patient response data stored in the data warehouse recruited participants via telephone. We used a purposive sampling strategy to achieve variation in characteristics, including age, ethnicity, sex, type of surgery

received, and experience of good or bad SDM (identified through survey responses).

Procedures

Measurement System Metrics

Relevant metrics automatically collected by the measurement system were used to examine usability quantitatively (eg, responses to questionnaire items and timestamps for starting and submitting the survey). Unique entries were recorded for each patient who received the invitation to complete the measurement system. Entries and corresponding data collected between April 1 and December 31, 2021, were available for analysis.

User Testing

Postdeployment user-testing sessions were conducted between June and December 2021 and were performed in a simulated environment.

Group 1 participants were invited to participate in a one-to-one 1-hour videoconference via Zoom with a researcher to complete the measurement system live. Sessions began by reminding participants about the aim and the process of user testing the measurement system. Service users were then sent an SMS text message or email invitation (depending on their preference) that included a test link to the survey. Specific user-testing links were set up to allow simulated completion of the measurement system (ie, responses were not used for live response data). Sessions assessed system effectiveness (including any issues related to system functionality or completion). A concurrent think-aloud technique was applied to vocalize reactions and thinking processes [60-62], supplemented with observational notes of any difficulties encountered [63,64].

User-testing sessions were conducted by 1 member of the study team who had experience in think-aloud methods (AGKM or CH). A topic guide was developed to guide conversations (Multimedia Appendix 2). Sessions were audio recorded and transcribed using unique identifiers to ensure anonymity. Field notes and any problems during the measurement system completion were recorded in a table using Excel (Microsoft Corp).

Semistructured Interviews

We conducted semistructured, in-depth interviews using retrospective probing to explore the service users' views about the indicators of usability of the measurement system [65].

Interviews were conducted with group 1 participants following user testing via the same web-based videoconferencing software. Group 2 participants were invited to take part in an approximately 30- to 45-minute phone or videoconferencing call (according to their preference) during which they reflected on completing the measurement system. The conversations followed a previously tested and refined topic guide that was based on standard usability concepts [51]. An example topic guide can be found in [Multimedia Appendix 2](#).

Interviews were performed by either of the 2 researchers (AGKM or CH), audio recorded, and anonymized during transcription.

Analysis

Quantitative Analyses

All quantitative analyses were performed by 3 researchers (TD, AGKM, and CH) using the statistical software package STATA (version 16.0; StataCorp LLC).

System Effectiveness

We assessed system effectiveness by calculating the user task completion rate based on usability testing sessions and the survey response rate based on measurement system metrics [66].

The user task completion rates were calculated as a percentage of tasks completed by the total number of tasks. A process map was created defining the number and type of tasks (or steps) required to complete the measurement system. Successful completion means that all tasks were completed without user errors. User errors were deviations or problems encountered that interfered with successful task completion. Noncritical errors were defined as those that were successfully addressed by the testers themselves following instructions from the observer. Critical errors were those that required the observer to intervene or take remedial actions.

The survey response rate was calculated as a percentage (number of completed surveys/number of patients invited \times 100). Surveys were considered complete when responses to all 3 items of the CollaboRATE measure and at least 7 out of 9 items of the SDM-Q-9 measure were returned.

System Efficiency

We assessed system efficiency by calculating the task completion time and task efficiency based on measurement system metrics [58,66].

The task completion time was defined as the time participants took from the first activity (starting the survey by following the hyperlink) to the last activity (submission of the survey). Task efficiency was defined as the time spent to complete each task (timestamps were recorded in the following format: hh:mm:ss). Analyses were based on those who completed the measurement system for whom typical first and last activity timestamps were

available (ie, atypical timestamps were those with no recorded activity time). Extreme outliers were excluded because the system allowed service users to leave and later return to the survey and continue submission (eg, the next day or the following week). These were defined as those with the task completion time >3 times the IQR [67].

Qualitative Analyses of User Satisfaction

User satisfaction was assessed by evaluating service users' self-reported experiences of using the system through user-testing sessions and semistructured interviews [66]. Discussions explored perceptions of usability aspects, including service users' interpretation of the system's ease of use and navigation, their satisfaction with instructions and visual display, and the likelihood of using the system again or recommending it to others.

Transcripts obtained from user-testing sessions and semistructured interviews were uploaded to the qualitative data management software NVivo (version 20.5.1; QRS International) and analyzed using thematic analysis [68]. This involved systematic coding of data to identify commonly mentioned concepts within the data and to develop themes and subthemes. The coding was inductive and iterative and followed predefined steps of data familiarization, generation of initial codes, and searching for themes. Coding was performed by 2 researchers independently who met regularly to review themes. Analysis and interpretation of qualitative data were further supported in 2 ways. First, a report of the interim findings was produced and discussed with the wider multidisciplinary steering group. Second, the presentation of interim findings to the patient and public advisory group sought further input.

Ethical Considerations

This study was part of a project spanning quality improvement and research. Therefore, it was subject to 2 governance processes requiring separate approvals. Monitoring patients' experience of SDM in routine clinical practice was initially approved through a quality improvement proposal at North Bristol NHS Trust (reference: Q80008). This was then incorporated into a larger program of work, where all processes were approved through the appropriate governance framework (Consent and SDM Program Board, reporting to the Clinical Effectiveness and Audit Committee). Ethics approval for conducting interviews with NHS patients was granted by the NHS Health Research Authority North West – Liverpool Central Research Ethics Committee (reference: 21/PR/0345). Participants provided electronic consent through a link to a secure data management platform (version 11.1.18, REDCap [Research Electronic Data Capture]; Vanderbilt University) [69] before any study activity commenced.

Results

Participants and Procedures

A total of 5794 surgical patients received invitations to complete the survey and for whom unique entries were recorded in the measurement system. Of these, 2254 returned the completed surveys (refer to [Table 1](#) for patient characteristics) and provided data for the analysis of measurement metrics.

Table 1. Characteristics of patients who completed the measurement system (N=2254).

Characteristics	Patients, n (%)
Sex	
Female	1243 (55.15)
Male	1011 (44.85)
Age group (y)	
<29	170 (7.54)
30 to 39	213 (9.45)
40 to 49	277 (12.29)
50 to 59	529 (23.47)
60 to 69	555 (24.62)
70 to 79	402 (17.83)
≥80	108 (4.79)
Ethnicity^a	
Other	104 (4.61)
White British	977 (43.35)
Specialty	
Breast	278 (12.33)
Colorectal	67 (2.97)
General	194 (8.61)
Gynecology	106 (4.7)
Neuro	288 (12.78)
Trauma, orthopedics and spinal	555 (24.62)
Upper gastrointestinal	41 (1.82)
Urology	584 (25.91)
Vascular	141 (6.26)

^aMissing data: n=1173.

A total of 25 service users (group 1: n=9; group 2: n=16) participated in user-testing sessions and semistructured interviews.

In group 1, a total of 9 service users completed 8 user-testing sessions. Most sessions were completed on a one-to-one basis (7/9, 78%). One session was completed with 2 participants, which included 1 service user with disability and their caregiver who provided additional support. All sessions were held via videoconference and lasted for an average duration of 43 (SD 15.1; range 29-78) minutes. Service users in this group were mostly female participants (6/9, 67%) and self-identified as Asian (1/9, 11%), other White background (1/9, 11%), and White British (7/9, 78%). Details about the surgical experience were known for 4 service users who represented orthopedic

(2/4, 50%), upper gastrointestinal (1/4, 25%), and ophthalmic (1/4, 25%) specialties.

In group 2, 16 service users completed semistructured interviews between June and November 2021. Most interviews were conducted via telephone (15/16, 94%), with 1 (6%) interview conducted via videoconference, lasting for an average duration of 36 (SD 9.9; range 21-50) minutes. Most service users in group 2 were female participants (10/16, 62%) and were 51 (SD 15.8) years on average. All participants were from a White British background (16/16, 100%). Efforts were made to recruit participants from a wide range of ethnic minority backgrounds; however, due to a large amount of missing data (Table 1), this was unsuccessful. The characteristics of group 2 participants are presented in Table 2.

Table 2. Characteristics of group 2 service users (n=16).

Characteristics	Service users, n (%)
Age (y), mean (SD; range)	51 (15.8; 23-80)
Sex, n (%)	
Female	10 (62)
Male	6 (38)
Ethnicity, n (%)	
White British	16 (100)
Surgery type, n (%)	
Breast	3 (19)
Colorectal	2 (13)
General	2 (13)
Gynecology	1 (6)
Trauma and orthopedics	2 (13)
Urology	5 (31)
Vascular	1 (6)

Usability Concepts

System Effectiveness

A process map to assess task completion contained 19 tasks (or steps) required to complete the measurement system. Tasks ranged from “Open text message/email” to “Click on ‘Submit’” and are detailed in [Multimedia Appendix 3](#).

A total of 171 tasks across 8 user-testing sessions were submitted by all 9 group 1 participants. One service user reported 2 noncritical errors across 2 tasks when completing the measurement system using a mobile phone. The first error occurred following task 1 “Open text message.” This forced an additional step to resolve a pop-up notification which prompted the service user to select an internet browser to open the survey link. The second error occurred following task 5 “Select response to question 1.” The displayed answer options for CollaboRATE item 1 were cut off at 8, not presenting answer option 9 (every effort was made). Further scrolling was required by the service user to be able to select the answer option 9. Both noncritical errors were managed and resolved without requiring observer input. Consequently, a total completion rate of 98.8% (169/171) was achieved. No critical errors or failures in completing the tasks were reported.

The survey response rate was 38.9% (2254 completed surveys/5794 patients invited × 100).

System Efficiency

Out of the 2254 responses available, 1106 (49.07%) were excluded from analysis. These 1106 responses included 719 (65.01%) responses with an atypical timestamp (ie, no activity time was recorded because the timestamp for the first and last activity was 00:00:00, which was identified as a technical issue and rectified by the software provider) and 387 (34.99%) responses identified as extreme outliers (ie, the task completion time was >12 min). Assessment of the completion time of 1148

(50.93%) of the 2254 responses showed that service users required an average median duration of 3 (IQR 2-4) minutes to complete the measurement system. Calculations of task efficiency showed that the average median time taken per task was 9 (IQR 6-13) seconds.

User Satisfaction

Analysis of qualitative data from user-testing sessions and semistructured interviews with a subset of patients revealed four main themes related to user satisfaction as follows: (1) acceptability, (2) ease of access to the system, (3) ease of use, and (4) satisfaction with the measurement system.

Acceptability

Indicators of Good Acceptability

Service users who were interviewed as part of the qualitative data collection frequently commented on the low burden of completing the measurement system, suggesting good acceptability among the participants. This was mainly because of the low number of questions contributing to the measurement system being considered quick and straightforward to use:

Short survey, key thing—not too much of your time.
[PT9, group 1]

I did it from my phone so yes it was very straightforward. [PT13, group 2]

I don't remember feeling any burden [...], it was quite easy. [PT19, group 2]

I don't think it seemed too long. It was enough. To be honest, if it had been a lot more, I probably wouldn't bother to do it. [PT21, group 2]

Furthermore, service users highlighted the common use of web-based surveys to obtain feedback in health care and other general settings. Therefore, they felt a certain level of familiarity with the measurement system, which contributed to the good acceptability:

I thought it was, I mean, pretty standard, you know, arial buttons, nought to ten on how much you disagree, agree, disagree to something so yes, familiar with many other surveys that I've seen before. [PT12, group 2]

Potential Barriers to Acceptability

Some barriers to completing the measurement system were highlighted. For example, participants mentioned that the service users may easily ignore or forget to complete the measurement system as follows:

It's easy not to [complete the measurement system], I've had them from places, not about health or anything important like that, but it's easy just [to] think, "Oh, I'll do that later," and then never go back to it. [PT7, group 1]

Another example included concerns about the number of SMS text messages and surveys received from other sources and the cumulative burden:

I mean the good thing about it is it's simple and easy and you just get the nudge, but on the other hand there are lots of other nudges coming through at you. [PT19, group 2]

This contributed to a small number of service users questioning the credibility of the invitation to complete the measurement system:

Something came through via email which to be honest I wasn't sure if it was a genuine thing or if it was something else. [PT10, group 2]

Solutions to Address Barriers

Service users were asked about the usability of solutions to address these issues and included support for reminder emails:

One follow-up is a good idea but not more than one possibly because then people start to feel a bit harassed, but I think a second one is a good idea because of the forgetting thing and they go oh yeah, I'll do it this time. [PT4, group 1]

Service users thought that the use of email would address this problem for some service users:

It is at the top of my email pile again, I'd better do it, so it jogs your memory, texts don't do that, it's a very momentary thing, text messaging. [PT13, group 2]

Furthermore, service users suggested to increase the personal relevance and awareness of the measurement system:

You've got to feel that you're going to benefit, and it's really relevant to you, for you to have the interest to do it. [PT7, group 1]

They [service users] really, really need to know it's coming because I don't know about you but we're very, very careful what we open and if this just appeared with no warning I wouldn't open it. [PT4, group 1]

Service users mentioned the need to highlight the brevity of the measurement system and the low number of questions:

There are people who will fill them in if they're told it's very short, which is why it's important that it says it's short. [PT9, group 1]

I think sometimes if you open one you can see that it's 100 questions you just think I probably won't do that. [PT14, group 2]

Ease of Access to the System

Indicators of Good Ease of Access to the System

All service users were able to access the measurement system without problems and commented on its ease of access through both methods, email and SMS text message:

I think most people nowadays are comfortable with computers and technology. [PT14, group 2]

Some service users expressed a preference for using either email or their phone to complete the measurement system. However, there was no conclusive evidence to suggest the superiority of either email or SMS text message:

I guess that for me making it [come to my phone] makes it more accessible 'cos you don't have to go in your emails. It automatically comes through and you can do it at any time and reply at any time, so you can do it when it's convenient to you and its literally just a text on your phone. [PT1, group 1]

Although I use a smart phone quite a lot, sometimes it's difficult to manipulate it, whilst a laptop I find much more easier to use. [PT8, group 1]

Furthermore, service users commented on the good comprehensibility and legibility of the content, contributing to good levels of ease of access to the system. For example, comments included that there was a sufficiently large font option for those who required or preferred larger screens:

I think the presentation of it on my phone, and I don't have a large phone, I just have a small phone, I could read all that quite easily. [PT7, group 1]

They were really easy to understand[...] The questions were very clear, I thought they were quite well[...] focused and well explained. [PT24, group 2]

Potential Barriers to Access to the System

Some service users expressed concerns regarding the system's ease of access for certain population groups. Most frequently, concerns were raised in connection with older adults and lack of access to technology. Furthermore, considerations included the ease of access to the measurement system for non-English-speaking service users and those with disabilities:

There's also a certain cohort would be using online. [...] I do think people will miss out but if it's just being pinged... whether it's on text or email [PT3, group 1]

People that English isn't their first language, that could be a bit of a consideration. [PT5, group 1]

Solutions to Address Barriers

The most frequently mentioned solutions were common alternatives to electronic data collection in connection with support measures for questionnaire completion:

I mean there's probably still a gap with the older generation who wouldn't be comfortable doing it, and would prefer doing it via communication of phone or in written format. [PT14, group 2]

Ease of Use

Most often, the simplicity of the system was highlighted in connection with the ease of completing the measurement system. Furthermore, the ease of use was often attributed to the brevity of the measurement system:

I actually thought it was quite simple and quite straightforward and easy. [PT3, group 1]

That has been perfectly straightforward, for someone who's not very IT literate, that was all fine. [PT7, group 1]

Yeah, that was very easy, it didn't take very long [...] I remember it did seem simple [PT23, group 2]

Moreover, most service users commented on the visual display, which was perceived as appealing and very clear. The clear layout of the survey contributed to high comprehensibility among participants:

It is very clear and also I quite like the bold type. [...] very clear again and very easy to read. [PT3, group 1]

It's pretty obvious straight off of that where the survey has come from including the logo and almost like the colours of the survey match with the NHS logo [...] I think that part of it makes it really easy. [PT21, group 2]

Yeah, that's laid out really spaced out and easy to read. [PT6, group 1]

Service users frequently mentioned the ease of navigation and thought it was "basic and straightforward" (PT20, group 2). Others mentioned further details regarding what they liked about the navigation:

There is no need to zoom in or zoom out or move around a page or click buttons to find the survey so I think all of that aspect is really easy. [...] It's easy to use and the agree or disagree buttons are really straight to the point. [PT21, group 2]

One service user also commented on the loading speed of the survey page:

I think it's easy to use because it doesn't take long to load which I think is important. [PT20, group 2]

No service user raised concerns that could be considered barriers to the ease of use of the measurement system.

Overall Satisfaction With the Measurement System

All service users provided positive feedback regarding the abovementioned themes of acceptability, ease of access to the system, and ease of use, which indicated high satisfaction with

the measurement system. General supportive comments were made throughout the user-testing sessions and semistructured interviews:

Yeah, absolutely brilliant. I'll give that 11 out of 10. [...] Somebody who designed this did a good job. [PT5, group 1]

All respondents agreed when asked whether they are likely to complete the measurement system again:

Yeah, I would definitely respond to it again. [PT6, group 1]

In addition, there were unprompted comments related to satisfaction with particular features. For example, service users pointed out that they particularly liked the "back buttons" to return to previous questions, the option to pause the measurement system and return at a different time, and the fact that there are contact details of the hospital in case this survey was received in error:

You've got the option, you can go back and change something, or if there was something you were worried about that you've done, it's clear that you can go back. [PT7, group 1]

Discussion

Principal Findings

This study examined the usability of a novel automated and real-time ePRM system to monitor patients' experience of SDM in routine clinical practice. We used a large sample from a diverse range of surgical specialties to evaluate system effectiveness, system efficiency, and user satisfaction.

Overall, the evaluation of the measurement system demonstrated good usability. Metrics relevant to the effectiveness and efficiency showed that the system can be used without problems and completed quickly. The results from qualitative testing sessions and interviews with 25 service users showed that the measurement system has good user satisfaction. It was perceived as acceptable, easy to access, and easy to use. Service users identified potential barriers to acceptability and ease of access to the system, which can inform strategies for the optimization of the measurement system.

Limitations

This study has certain methodological limitations. First, we purposively selected participants to include individuals from a wide socioeconomic background with varying computer literacy skills. While this study exceeded the recommended sample size for usability testing [70-72], service users in our sample were primarily White British (23/25, 92%), English-speaking adults with capacity to consent for medical treatments, and from specific geographic areas of the United Kingdom (West, South West, and North East England). This may limit the generalizability of the study findings. It is uncertain whether the inclusion of more participants from more diverse backgrounds would have elicited different perspectives on the measurement system. Second, only patients who had completed the measurement system were eligible to participate in semistructured interviews. Data protection regulations limited

our ability to recruit individuals who had not completed the survey. Therefore, we were unable to explore whether nonengagement with the system was due to reasons related to usability not mentioned by the study participants. Barriers to engagement may align with the themes identified during semistructured interviews, which are partly addressed by ongoing work (refer to the following section). Separately, there is ongoing work which includes conducting follow-up phone calls with patients to explore the reasons for nonengagement. Third, usability may also be evaluated using validated measurement instruments to capture quantitative measures of individuals' perception of usability from a larger, representative sample size [73,74]. This study did not include such measures in addition to the ePRM to avoid distorting usability outcomes. For example, the additional length of the survey may have affected system efficiency and impacted perceptions of ease of use. Instead, we included a range of methods to assess usability to triangulate the data sources [75].

Comparison With Prior Work

Existing research has investigated optimal strategies and methods for collecting ePRMs [40,76-79]. The usability evaluation of electronic platforms is common and has been fundamental in optimizing systems to collect ePRMs across a range of health care settings [80] and also within surgery [81,82]. Less is known about systems that monitor patients' experiences automatically and in real time. We are aware of only 1 recently published protocol describing a similar measurement system [83], but we were unable to identify studies with specific relevance to surgery or SDM. Our study addresses this gap and provides insights into the usability of an automated measurement system that monitors ePRMs for SDM in real time. The measurement system in our study was evaluated for service users undergoing surgical treatment; however, the findings may be applicable to other health care settings.

Evidence of good usability of an automated measurement system that captures surgical patients' experiences in real time supports the measurement systems' potential for scalability. The use of the system is recommended in similar health care settings where policy makers or official bodies wish to audit or monitor patients' experiences of SDM or aim to inform interventions to improve SDM before treatment. System effectiveness and efficiency are central components to service users' successful interaction with any system [51]. The usability concepts evaluated have been shown to be key in other systems rolled out in surgical departments [84] and are likely to play a role in the wider adoption of the measurement system [85]. This study showed that service users were able to successfully complete the measurement system and that they required little time and effort to do so. In addition, good user satisfaction is vital to a system's sustainability and is used as a measure of the success of digital information systems within health care organizations worldwide [86-88]. User satisfaction with ePRM systems and perceived acceptability, in particular, have been shown to be key to their uptake among stakeholders [89,90]. The qualitative evidence obtained from service users in this study demonstrated good acceptability, ease of access to the system, and ease of use, which suggests low concern regarding user satisfaction. Some steps to optimize the system to address identified usability

concerns and adapt SDM measurement to other care contexts [91] might be necessary before a wider rollout to other health care settings.

This study highlighted well-known barriers to ease of access to electronic measurement systems [92,93]. Specifically, literacy with electronic systems can be lower in older and frail adults and among individuals without capacity to consent [94-97]. While the measurement system response rate in this study (2254/5794, 38.9%) was notably higher compared to those reported in other studies evaluating measurement systems (eg, 18% in the study by Iversen et al [98], 20% in the study by Bliddal et al [99], or 30% in the study by Arner [82]), it may be indicative of such barriers experienced by surgical patients. The solutions to improve ease of access identified in this study include additional paper-based methods. Furthermore, barriers may be overcome through assisted data collection using a tablet computer at the point of care [100]. Additional resources may be required to ensure full and accurate data capture for adults without capacity to consent to medical treatments completing the measurement system [101]. Similarly, language barriers have been shown to affect service users' ease of access to the system and the quality of responses to ePRM systems [93,102]. Translating content can be key to addressing such language barriers, as demonstrated by widely used quality of life measures [103]. Further work is currently ongoing to address relevant issues to maximize inclusivity (ISRCTN [International Standard Randomised Controlled Trial Number] registry ID: 17951423). Specifically, this line of work seeks to explore the views of underserved groups (eg, limited income, older age, and ethnic minority groups) using qualitative methods to understand how the use of the system and future intervention development can be optimized to maximize inclusivity. This work will consider nondigital materials, translation of study materials, measurement system content, and measurement instruments using appropriate guidance [104] and will include non-English qualitative data collection. Detailed methods will be reported in a separate publication.

High-quality SDM can be a moderator and mediator of health and care quality [105], addressing the challenges of true patient-centered care (eg, reducing asymmetry in medical knowledge between patients and surgeons and addressing issues of individual preferences). To improve patients' experiences of SDM before surgery, additional intervention development work is needed to complement automated, real-time monitoring of SDM experiences. Evidence from other clinical settings suggests that interventions, including real-time feedback, in addition to routine monitoring of ePRMs, can lead to improvements in outcomes or clinical performance [81,106-108]. This study demonstrated the good usability of a measurement system that automatically collects, stores, and retrieves ePRM data and is ready to provide feedback on this information in digital format near to real time. This suggests that the system is ready to provide instantaneous feedback on surgical patients' experience of SDM to clinical teams, which has the potential to improve SDM. Future work will explore the optimal design and feasibility of feedback mechanisms and examine the acceptability of the system. Refinements to optimize the usability and inclusivity of the system are required before

evaluating the effectiveness of an intervention to improve SDM. Key to this work will be obtaining wider perspectives from other stakeholders involved in the intervention (eg, health care professionals and stakeholders from the lower-income, ethnic minority, and older age groups). In the long term, strategies to facilitate the implementation of the measurement system in routine clinical care will be investigated and evaluated using evidence-based approaches to intervention design [109].

Conclusions

We examined the usability of a measurement system for automated and real-time ePRM collection to monitor patients'

experience of SDM in a large sample using 2 brief, validated instruments. The findings suggest good usability and support scalability of the measurement systems to other secondary health care institutions and will inform its optimization. Complementary work is currently exploring the feasibility and acceptability of monitoring and feedback experience of SDM with patient and professional stakeholders. Future implementation and formal evaluation of the measurement system will be performed to establish whether routine monitoring and feedback of patients' experiences has the potential to improve SDM for surgical patients.

Acknowledgments

The ALPACA Study was funded by the National Institute for Health and Care Research (NIHR) Program Development Grant (NIHR205174). Furthermore, this study was supported by an NIHR Clinician Scientist award to AM (NIHR CS-2017-17-010) and by the NIHR Biomedical Research Centre at the University Hospitals Bristol and Weston National Health Service (NHS) Foundation Trust and the University of Bristol (BRC-1215-20011, NIHR203315). TD was funded by the NIHR Academy through an NIHR Methodology Internship Scheme. The quality improvement project was supported by the North Bristol NHS Trust and the "Next Big Thing Award," funded by the Southmead Hospital Charity. The views expressed in this publication are those of the authors and do not necessarily reflect those of the North Bristol NHS Trust, the UK NHS, or the NIHR. The authors would like to thank Omaid Ahmadyur for supporting the recruitment of the participants.

Authors' Contributions

AGKM and JB developed the idea for this study with input on the conceptualization from HLB, KA, and RM. CH and AGKM prepared the protocol, which was reviewed, discussed, and approved by all coauthors. CH, AGKM, KA, and RM established and formulated the methods for this review, with inputs from JB and VS. Recruitment and data collection were undertaken by CH, DH, SH, and AGKM. Data analysis was performed by CH and TD under the guidance of AGKM and RM. AGKM provided general oversight for this study. AGKM, SH, DH, and JB will take the lead on implementing the findings from this study with the help of CH, VS, and the ALPACA Study Team. The ALPACA Study Team members are: Andy Judge, Andrew Smith, Archana Lingampalli, Barnaby Reeves, Jessica Preshaw, Michael R Whitehouse, Paul Cresswell, Philip Braude, Shelley Potter, Timothy Beckett, and Timothy Whittlestone.

Abstract

Background: The rollout of the electronic health record (EHR) represents a central component of the digital transformation of the German health care system. Although the EHR promises more effective, safer, and faster treatment of patients from a systems perspective, the successful implementation of the EHR largely depends on the patient. In a recent survey, 3 out of 4 Germans stated that they intend to use the EHR, whereas other studies show that the intention to use a technology is not a reliable and sufficient predictor of actual use.

Objective: Controlling for patients' intention to use the EHR, we investigated whether disease-specific risk perceptions related to the time course of the disease and disease-related stigma explain the additional variance in patients' decisions to upload medical reports to the EHR.

Methods: In an online user study, 241 German participants were asked to interact with a randomly assigned medical report that varied systematically in terms of disease-related stigma (high vs low) and disease time course (acute vs chronic) and to decide whether to upload it to the EHR.

Results: Disease-related stigma (odds ratio 0.154, $P < .001$) offset the generally positive relationship between intention to use and the upload decision (odds ratio 2.628, $P < .001$), whereas the disease time course showed no effect.

Conclusions: Even if patients generally intend to use the EHR, risk perceptions such as those related to diseases associated with social stigma may deter people from uploading related medical reports to the EHR. To ensure the reliable use of this key technology in a digitalized health care system, transparent and easy-to-comprehend information about the safety standards of the EHR are warranted across the board, even for populations that are generally in favor of using the EHR.

Introduction

Background

The digital transformation of health care promises safety and efficiency gains by connecting all players in a health care system

[1-3]. One key technology to connect health professionals, insurance providers, and patients is the electronic health record (EHR), which will be implemented nationwide and mandatory for all patients in Germany starting on January 1, 2025. In the EHR, patients' medical data (eg, findings, diagnoses, therapies, vaccinations, discharge reports, emergency data, and medication

plans [4,5]) can be digitally documented, exchanged, and viewed [4,6]. Better coordination of health data can ultimately save costs in the health care system [7-9].

In Germany, the Patient Data Protection Act [10] mandates that it is ultimately the patient who controls the type of data that are stored and can be viewed in the EHR. Although a recent survey found that 3 out of 4 Germans state that they intend to use the EHR [11], its success ultimately depends on whether and under what circumstances it is actually *used* to store and share health data. As described below based on the available literature, intention to use is *not* a sufficient and reliable predictor of EHR use. Therefore, in this study, we sought to investigate to what extent intention to use predicts actual use and what additional factors may need to be taken into account to more reliably predict EHR use.

Related Work

The technology acceptance model (TAM) and its extensions such as the unified theory of acceptance and use of technology (UTAUT) assume a positive relationship between intention to use a technology (technology acceptance) and actual use [12-14]. In fact, empirical studies on social networks and online banking show that the greater the intention to use, the more likely the technology will actually be used. However, the same studies also show a statistical discrepancy between intention and behavior, as evidenced by the different variance (R^2) accounted for by the two constructs [15-17]. Questionnaire studies on this so-called “intention-behavior gap” suggest that intention is not a reliable predictor of behavior and consequently that other influencing factors must exist [18,19]. For instance, in the context of social media and electronic commerce, users often have massive privacy concerns to disclose their data and their intentions to use are generally low. Nonetheless, users tend to disclose their data if the benefits they expect from using the applications are sufficiently high [20]; this phenomenon is called the “privacy paradox” and has been confirmed repeatedly [15,20,21]. However, questionnaire studies on digital health technologies show no such paradox and more nuanced patterns. For health technologies, privacy concerns thus far either had no influence [22-24] or have been shown to have a systematic negative impact on intentions and actual technology use [25,26]. In summary, based on the available research, it is unclear to what extent intention to use predicts the actual use of digital health technologies such as the EHR. Theories of technology acceptance infer a direct, positive influence, whereas the results of various questionnaire studies suggest that other factors must play a role given the intention-behavior gap. Although the influence of a few technology-related factors (eg, controllability of data) on the intention to use an EHR have been investigated, a thorough investigation of disease-related factors has not yet been performed.

Methodologically, usage behavior has mostly been investigated using self-report questions about the frequency of use [15,16,27-29], which is associated with several limitations. First, frequency of use is only meaningful if the system is already established and widely used. In the case of new systems such as the EHR in Germany, frequency of use cannot be surveyed. Second, the actual context of use can be difficult to simulate in

questionnaire studies, making it difficult to distinguish between intention and behavior [30]. Since the models of technology acceptance described above (ie, TAM and UTAUT) have been evaluated using questionnaires, they may not provide reliable insights into usage behavior in the context of the EHR.

Therefore, to investigate usage behavior regarding the EHR in Germany, we selected a different approach for this study. In terms of uploading behavior, we first identified two possible use cases: (1) users who are living with different acute as well as chronic diseases (“patients with multimorbidity” use case), enabling a direct comparison between different medical findings in terms of risks and benefits of uploading to the EHR; and (2) users who are healthy or have little to no preexisting conditions before they develop a chronic or acute disease (“patients with first contact” use case). To investigate these use cases, we developed and used an interactive prototype of the EHR (ie, a click dummy) to investigate factors influencing the EHR users’ decision to upload medical reports. Compared to questionnaire studies, this approach has the advantage that the interaction with the click dummy is closer to a real interaction with the EHR, thereby increasing the ecological validity of behavioral measures [30]. To investigate the first use case, we used a mixed methods design where the experimental intervention was based on an interview study with potential EHR users [31]. The interview study showed that the time course of a disease (chronic vs acute) and disease-related stigma influence people’s decisions to upload a medical report to the EHR. The following experiment showed that respondents were more likely to upload a medical report of a chronic disease to the EHR than to upload a report of an acute condition. In contrast, respondents were less likely to upload a report of a disease with high stigma. When a disease with high stigma had a chronic time course, reports were still uploaded. We here report the results of the second use case in which participants interacted with one medical report only.

Methods

Ethical Considerations

This study was approved by the Ethics Committee of the Department of Psychology and Ergonomics (Institut für Psychologie und Arbeitswissenschaft) at Technische Universität (TU) Berlin (tracking number: AWB_KAL_1_230311). Participants volunteered to participate in the survey and informed consent was required. On the first page of the survey, participants were told about the investigator, the study purpose, what data were to be collected during the study, and where and for how long they would be stored. Participants were informed about the duration of the survey (approximately 8 minutes) as well as the compensation for participation. Participants were compensated with €1.60 (US \$1.75) for their time and thus according to minimum wage. The participants also had the possibility to download a PDF of the participant information on the first page.

Participants’ personal data and responses were kept entirely anonymous and password-protected in the department’s data vault. An anonymized data set from the study was made available to other researchers for further analysis with open access. The documentation and availability of the research data

collected during the study were managed using the TU repository “DepositOnce,” adhering to the regulations for ensuring good scientific practice at TU Berlin, the guidelines of the “DepositOnce” internal research data repository, and data protection regulations. Compliance with these repository guidelines ensures the indexing and findability of the research data by third parties.

Participants

The study was conducted from May 9 to June 10, 2023. Based on an a priori power analysis for a logistic regression with three predictors as well as a false-positive rate α of .05 and a power of $1-\beta=0.80$, we aimed for a sample size of 186 participants. Individuals 18 years and older residing in Germany were eligible to participate in the study. Another prerequisite was that participants had no previous personal experience (own illness) with the diseases mentioned in the medical reports, as affected people deal with disease-related stigma differently than people who are not affected by the disease [32]. Sampling was conducted through Prolific [33], a click worker platform characterized by high data quality [34]. A total of 275 individuals participated in the study. The mean participation time was 9 minutes, 28 seconds (SD 3 minutes, 47 seconds) and the median was 8 minutes, 36 seconds.

Design

We used a 2×2 between-subject study design with the independent variables stigma (high vs low) and time course of illness (chronic vs acute). Stigma was operationalized as the risk that the medical findings could negatively affect the private,

professional, or social life of the affected person. For this purpose, the medical reports related to personal lifestyle, as reflected in tests for sexually transmitted diseases [31,32]. The time course is a classification of diseases in terms of their duration. These can be either acute (diseases of short duration that come on quickly) or chronic (diseases that develop slowly or last for a longer time). The dependent variable was the decision to upload the medical report (ie, whether participants were willing to upload the medical findings to the EHR). Furthermore, the intention to use the EHR was included as a covariate.

Materials

The stimuli used in the study were realistic but specially created for the purpose of the study. The medical reports were provided by various hospitals and a medical association. To make the reports appear as realistic as possible, they were edited on the official document heads of these institutions (see [Multimedia Appendix 1](#)). In selecting the diseases, both the related stigma and time course were systematically varied. To reflect different disease-related stigma, which covered different risks for professional and social life [35-38], diseases were divided according to their low and high stigmatization potential. To reflect different time courses, diseases were divided according to an acute and chronic time course. Furthermore, diseases were selected to occur regardless of age so that they would be perceived as realistic diseases by an age-diverse sample. [Table 1](#) shows the diseases used as stimuli, categorized by level of stigma potential and time course.

Table 1. Diseases used in the stimuli, categorized by level of stigma potential and time course.

Stigma potential	Acute disease	Chronic disease
Low	Fractured wrist	Type 1 diabetes
High	STD ^a (gonorrhoea)	Depression

^aSTD: sexually transmitted disease.

The interface software FIGMA was used to create the click dummy, which was modeled after the mobile EHR app of a German health insurance company (BARMER)—the eCare app—to support a realistic interaction with an EHR. Specifically, the click dummy allowed participants to upload findings, grant or revoke permissions to view medical reports, and create medication plans. Only the “Upload report” function was used in this study.

We used LimeSurvey (version 3.28.3+220315) to create and conduct a 5-page online survey (see [Multimedia Appendix 2](#)). The EHR click dummy and the medical reports were incorporated into the survey using iFrame. LimeSurvey software was used to ensure that all questions had to be answered to complete the study and receive the compensation. As in the previous study investigating the first use case [31], in this study, we tested the effect of the independent variables by querying the perceived privacy risk and perceived benefit of uploading findings to the EHR as manipulation checks. Based on the results of this previous study [31], we assumed that high stigma would result in a high perceived privacy risk and a chronic time course would result in a high perceived benefit of uploading the medical

report. Perceived privacy risk, perceived benefit, and intention to use were measured using a 7-point Likert scale ranging from 1 (“strongly disagree”) to 7 (“strongly agree”). The decision to upload the finding to the EHR was measured using a dichotomous item (yes/no).

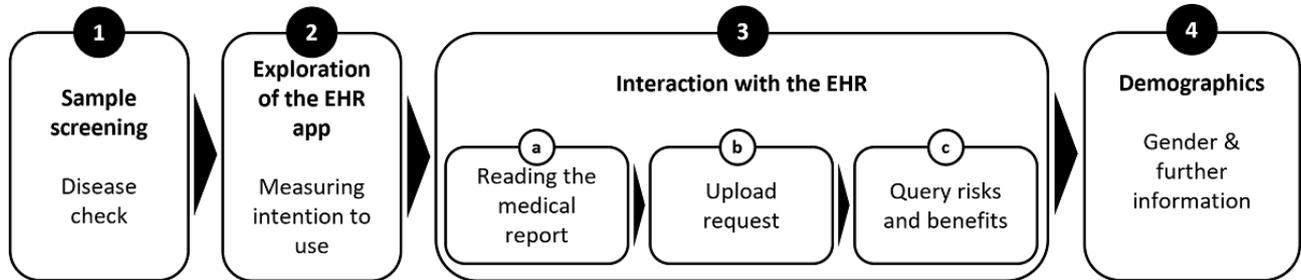

Procedure

The study procedure is shown schematically in [Figure 1](#). Before the start of the experiment, participants gave their informed consent. This was followed by screening questions related to disease experience (step 1). Participants who had experience with the diseases in the medical reports were excluded from the study. Subsequently, participants were given 1 minute to interact with the EHR click dummy and were then required to answer questions regarding their intention to use the EHR (step 2). Participants were then asked to interact with the medical report (step 3). In this process, each person was first randomly assigned to one of the four diseases shown in [Table 1](#) and asked to read an easy-to-understand description of the disease of approximately 2-3 sentences (see [Multimedia Appendix 3](#)) (step 3a). Participants then decided whether they wanted to upload

the report to their EHR (step 3b). Afterward, participants were asked to rate the perceived privacy risks and benefits of uploading the report (step 3c). The survey was completed with the collection of demographic characteristics (age, gender, education level, and experience with EHRs). In this step (step

4), the participants also had the opportunity to declare their responses invalid, while still receiving compensation, in case they did not pay sufficient attention to the instructions provided (eg, due to choosing random answers, inattentively reading questions, or rushing through the survey).

Figure 1. Overview of the study procedure. EHR: electronic health record.

Analysis

We cleaned and analyzed the data using RStudio (version 1.3.1093). Due to lack of variance inhomogeneity or a normal distribution, the analyses regarding perceived privacy risks and benefits were performed using the nonparametric Mann-Whitney *U* test. As mentioned above, we hypothesized that high stigma would result in a high perceived privacy risk and a chronic time course would result in a high perceived benefit of uploading the medical report. The influence of the independent variables (disease-specific stigma and time course) and the covariate “intention to use” on the upload decision were tested using multiple logistic regression with dummy coding. We hypothesized that usage behavior is negatively influenced by disease-specific stigma and positively influenced by time course and intention. To control for demographic and interindividual influences, we used multiple logistic regression with standardized coefficients for better comparability. In doing so, we followed the recommendations for testing control variables

[39] and tested the variables that have been shown to be causally related to privacy behavior along with the independent variables. The control variables were age, education level, and experience with the technical system, in this case the EHR [40,41].

Results

Sample Characteristics

A total of 275 observations were collected. Of those, 34 records were excluded, 29 because of participants’ previous medical histories, 3 because of incomplete questionnaires, and 2 because they were marked as invalid by participants. Figure 2 shows the flow of participants in the study based on the CONSORT (Consolidated Standards of Reporting Trials) statement [42].

Thus, a sample of 241 observations (146 male, 92 female, 1 diverse, 2 no information provided) was used for further analysis. Table 2 summarizes the demographic characteristics of the sample.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow chart. SP: stigma potential; TC: time course.

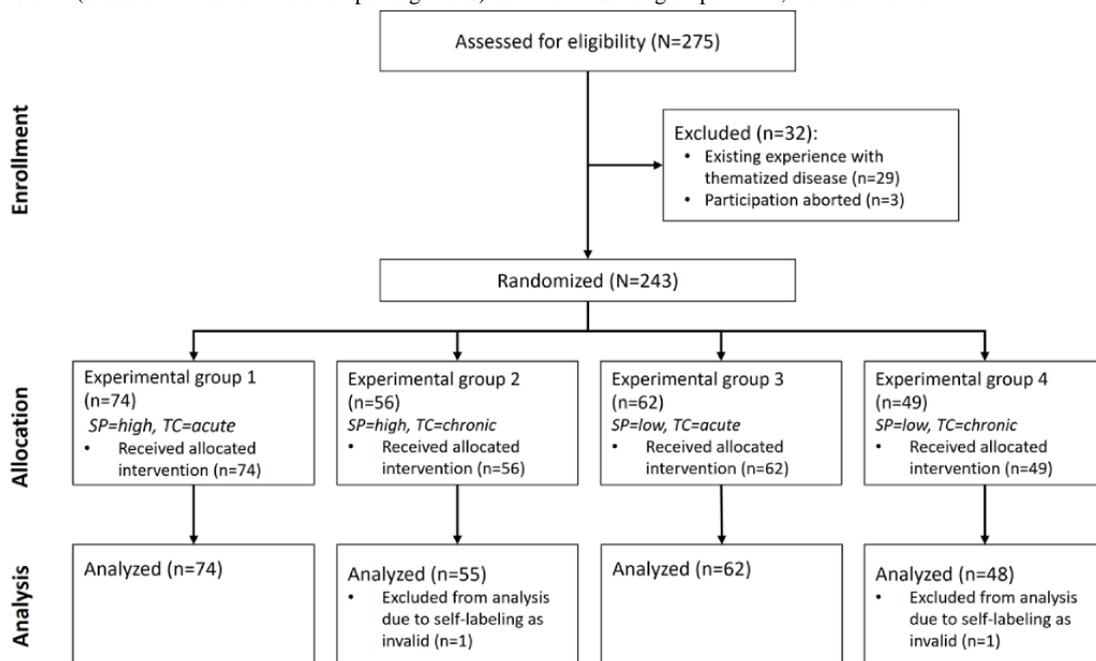

Table 2. Demographic data of the sample (N=241).

Demographic characteristic	Value
Age (years), mean (SD)	31.31 (9.76)
Gender, n (%)	
Female	92 (38.2)
Male	146 (60.6)
Other	3 (1.2)
Education, n (%)	
No degree	9 (3.7)
School leaving certificate	3 (1.2)
Secondary school certificate	18 (7.5)
General qualification for university entrance	66 (27.4)
Vocational training	33 (13.7)
University degree (bachelor's or master's degree)	112 (46.5)
Experience with the German EHR^a, n (%)	
EHR is unknown	61 (25.3)
EHR is known but not used	164 (68)
Occasional use	14 (5.8)
Regular use	2 (0.8)

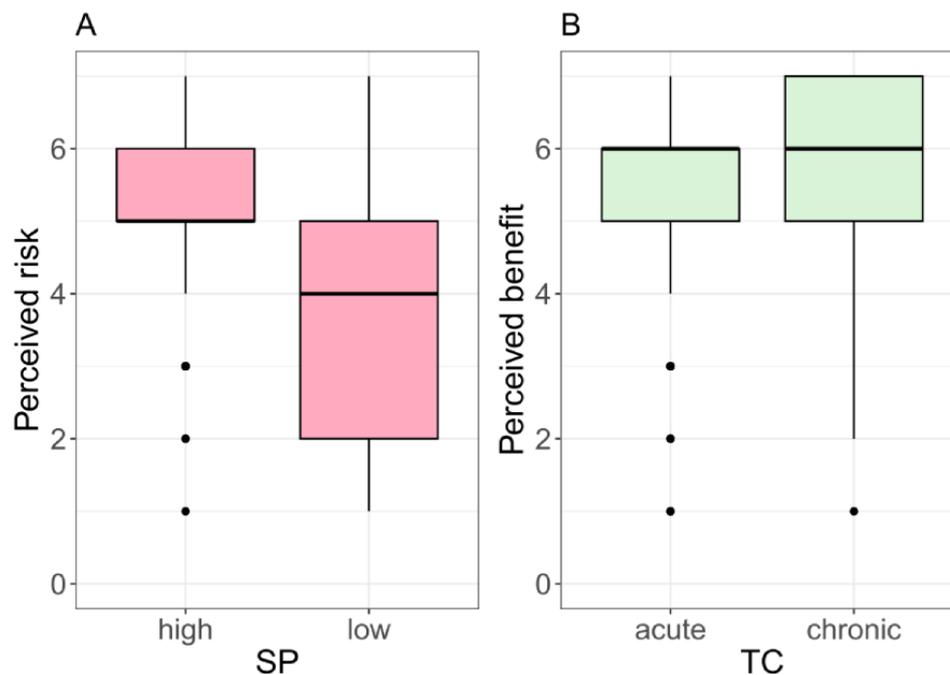

^aEHR: electronic health record.

Risk and Benefit Perception

We first checked whether stigma potential had an effect on privacy risk perception and whether time course had an effect on the benefit perception of uploading (see [Figure 3](#)). Mann-Whitney *U* tests showed a significant effect of stigma potential on privacy risk perception ($W=10,777$; $P<.001$), where high stigma was associated with high risk. The effect of the

disease time course on benefit perception was not significant ($W=6379$; $P=.14$), with a mean benefit perception of 5.34 (SD 1.39) for acute diseases and of 5.54 (SD 1.43) for chronic diseases. Consequently, in contrast to our study on the first use case with several medical reports [31], there was no relationship found between time course and perceived benefits when there is only one report to upload.

Figure 3. (A) Perceived risk in relation to stigma potential (SP) and (B) perceived benefit in relation to the disease time course (TC). The horizontal line in the box represents the median.

Controls

To investigate the potential association between the decision to upload the medical report and the independent variables disease-specific stigma and time course, we first performed a logistic regression (Hosmer-Lemeshow $R^2=0.319$, Nagelkerke $R^2=0.590$, Cox-Snell $R^2=0.537$; $\chi^2_{15}=86.973$; $P<.001$) to control for the covariate intention to use and the demographic variables age, sex, education level, and experience with the EHR. The covariate intention to use (odds ratio [OR] 2.497, 95% CI 1.831-3.456; $z=5.455$; $P<.001$) showed an association with the decision to upload, whereas none of the control variables had an effect. These variables were consequently removed from the model for further analyses.

Uploading Behavior

To examine the association between the decision to upload and the independent variables stigma potential and time course, we performed a logistic regression controlling for the covariate intention to use (Hosmer-Lemeshow $R^2=0.289$, Nagelkerke $R^2=0.551$, Cox-Snell $R^2=0.501$; $\chi^2_3=78.748$; $P<.001$). Intention to use was positively associated with uploading behavior; specifically, as intention to use increased, it was more than twice as likely that the report was uploaded to the EHR. In addition, there was a negative association between stigma and the decision to upload; specifically, when stigma was high, it was six times less likely that the report was uploaded than when stigma was low. Time course of the disease was not associated with the decision to upload a report. The summary of the results of the logistic regression are shown in Table 3.

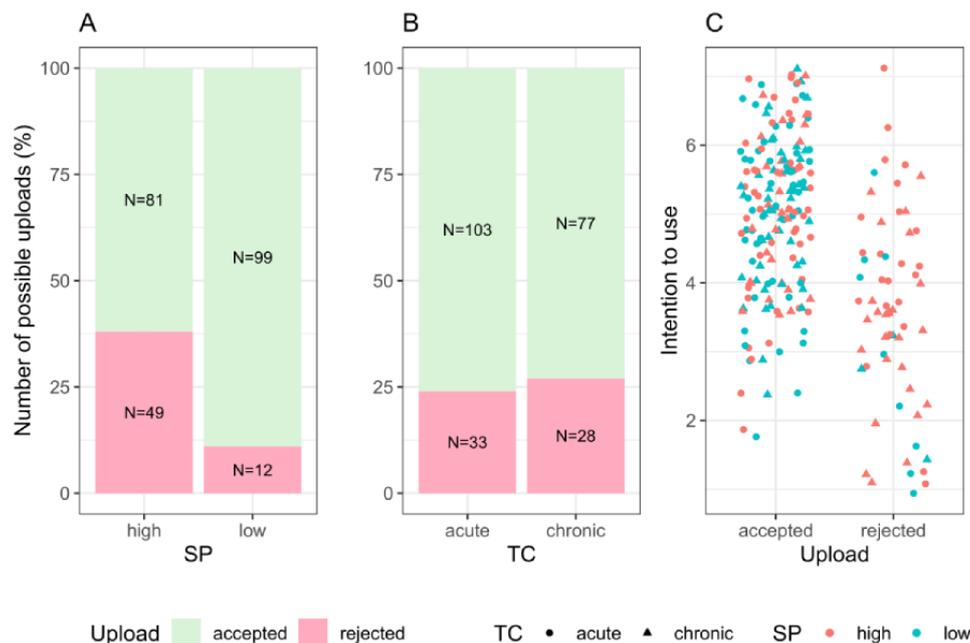

Table 3. Results of the logistic regression.

Variable	z value	P value	Odds ratio (95% CI)
Intention to use	6.210	<.001	2.682 (1.971-3.639)
Stigma potential	4.463	<.001	0.154 (0.064-0.336)
Time course	0.244	.81	1.093 (0.537-2.254)

The number of uploads is shown in Figure 4 in relation to the independent variables stigma potential (Figure 4A) and time course (Figure 4B). In addition, we show the relationship

between intention to use and the decision to upload a report as a function of the independent variables in Figure 4C.

Figure 4. Number of uploads to the electronic health record with respect to (A) stigma potential (SP) and (B) time course (TC), and (C) the influence of intention to use on the decision to upload as a function of SP and TC.

Discussion

Principal Findings

Our results show that the decision to upload an individual medical report is influenced by people's intention to use the EHR. However, the stigma potential of the diseases mentioned in the reports also influenced this decision. Specifically, uploading diseases with high stigma was associated with higher privacy risk than diseases with low stigma (see Figure 3A). Consequently, stigma potential had a negative influence on the decision to upload records (see Figure 4A), despite generally high intentions to use the EHR.

Thus, intention to use predicts the use of the EHR in part, whereas disease-specific factors such as related stigma can override the general intention. This is particularly evident in Figure 4C where the participants who uploaded reports both with high and low stigma had mostly high intentions to use the EHR (scores >4). However, such a clear distribution of intention to use (scores <4) did not emerge in the case of rejection of uploading. Rather, it is notable that the rejected findings are mainly those with high stigmatization potential (majority of red dots/triangles in Figure 4C). This shows that the effect strength of the stigmatization potential (OR 0.154) is significantly greater than that of the intention to use (OR 2.628). The fact that uploading is rejected due to disease-specific stigma despite high intention to use supports the assumptions of an intention-behavior gap in EHR use [18].

The time course of the diseases had no influence on the decision to upload an individual record. Findings with chronic and acute diseases were uploaded by the majority of participants and with approximately equal frequency (see Figure 3B).

For both use cases, case 1 (patients with multimorbidity) and case 2 (patients after first contact), the results suggest that

disease-specific stigma seems to exert an inhibiting influence on the decision to upload. In contrast, the time course only played a role in use case 1, where people interact with multiple reports at a time [31], but not when they interact with only one medical report (use case 2). This difference may be explained by the fact that patients' "health concerns" have a positive influence on their intention to share health data with others [22]. When faced with multiple medical reports, patients may be more aware and concerned about interactions between chronic diseases, because they more strongly affect the patient's health both now and in the future; consequently, the willingness to upload reports about chronic diseases increases. With a single report, interactions between diseases are less present, which means that the time course of a disease may play a reduced role in the decision to upload a record.

Implications

Both the intention to use and the stigma potential of diseases seem to influence whether patients upload an individual medical report to the EHR. Thus, in addition to increasing people's general intention to use the EHR via marketing and information, transparent and easy-to-comprehend information about the safety standards of the EHR (eg, for encrypting data) and the protection of medical records (eg, the control of access rights) are warranted, even for populations that are already in favor of using the EHR. Such combined interventions may help to reduce security concerns and enable realistic risk assessments of a data leak to ultimately ensure reliable use of the EHR as a key technology in any digitalized health care system.

Limitations and Future Directions

We deliberately excluded participants who already had a medical history with the diseases addressed in the stimuli to avoid bias in their responses. Individuals living with a stigmatized disease are more cautious to disclose the information, especially if the

disease is not immediately apparent [32,43]. The question arises to what extent the behavior of stigmatized individuals can be simulated under experimental conditions, provided that participants do not exhibit stigmatized characteristics. To further strengthen the validity and generalizability of our results, a follow-up study should examine the perspective of already affected individuals and compare the findings with the results of this study.

Another limitation is that the chronic and acute disease patterns used in the stimuli are not readily comparable. We decided to use the diseases listed in Table 1 as stimuli because they achieved the expected effects in the preliminary study [31]. We could only partially replicate these findings in the present study. For future studies, it would make sense to use diseases that can be more readily compared in terms of their stigma potential and time course (eg, gonorrhea and HIV or a wrist fracture and arthritis) to further strengthen the generalizability of the present findings.

Another limitation is that the distribution of our sample in terms of gender, age, and level of education does not correspond to that of the average German population. In particular, the level of education of our sample was above average. Although we were unable to detect any effects of the control variables age, gender, and level of education in the analysis, the results of this

study should be validated with a more representative sample in the future.

Conclusions

In our study, we investigated which disease-specific factors influence whether medical reports are uploaded to the EHR in a German setting. To answer this question, we varied the stigma potential and the time course of diseases in medical reports and controlled for the influence of participants' intention to use the EHR on uploading behavior. We demonstrated that intention to use had a positive effect on the decision to upload a report. In addition, we found that the stigma potential of the disease listed on the medical reports can inhibit uploading behavior. In particular, we found that the intention to use the EHR may be offset by the stigma potential of a specific record.

In summary, despite the fact that 3 out of 4 Germans state that they intend to use the EHR [11], actual use of this technology may depend on disease-specific factors. Consequently, to ensure successful implementation of the EHR, stakeholders in the health system should not only promote the EHR per se but further develop formats and evaluate them with the help of user testing that provide transparent and easy-to-comprehend information about the standards of data security and control in the EHR. Only in this way can users realistically assess the risks associated with individual EHR use and make an informed decision for (or against) EHR use.

Acknowledgments

We acknowledge support from the German Research Foundation and the Open Access Publication Fund of Technische Universität Berlin. We also thank the eV Studienwerk Villigst and the German Federal Ministry of Education and Research, who provided the doctoral scholarship (to NvK) without which this research would not have been possible. We would also like to thank the institutions that provided us with medical findings as well as all those who participated in the study.

Abstract

Background: Clinical decision support (CDS) tools that incorporate machine learning–derived content have the potential to transform clinical care by augmenting clinicians’ expertise. To realize this potential, such tools must be designed to fit the dynamic work systems of the clinicians who use them. We propose the use of academic detailing—personal visits to clinicians by an expert in a specific health IT tool—as a method for both ensuring the correct understanding of that tool and its evidence base and identifying factors influencing the tool’s implementation.

Objective: This study aimed to assess academic detailing as a method for simultaneously ensuring the correct understanding of an emergency department–based CDS tool to prevent future falls and identifying factors impacting clinicians’ use of the tool through an analysis of the resultant qualitative data.

Methods: Previously, our team designed a CDS tool to identify patients aged 65 years and older who are at the highest risk of future falls and prompt an interruptive alert to clinicians, suggesting the patient be referred to a mobility and falls clinic for an evidence-based preventative intervention. We conducted 10-minute academic detailing interviews (n=16) with resident emergency medicine physicians and advanced practice providers who had encountered our CDS tool in practice. We conducted an inductive, team-based content analysis to identify factors that influenced clinicians’ use of the CDS tool.

Results: The following categories of factors that impacted clinicians’ use of the CDS were identified: (1) aspects of the CDS tool’s design (2) clinicians’ understanding (or misunderstanding) of the CDS or referral process, (3) the busy nature of the emergency department environment, (4) clinicians’ perceptions of the patient and their associated fall risk, and (5) the opacity of the referral process. Additionally, clinician education was done to address any misconceptions about the CDS tool or referral process, for example, demonstrating how simple it is to place a referral via the CDS and clarifying which clinic the referral goes to.

Conclusions: Our study demonstrates the use of academic detailing for supporting the implementation of health information technologies, allowing us to identify factors that impacted clinicians’ use of the CDS while concurrently educating clinicians to ensure the correct understanding of the CDS tool and intervention. Thus, academic detailing can inform both real-time adjustments of a tool’s implementation, for example, refinement of the language used to introduce the tool, and larger scale redesign of the CDS tool to better fit the dynamic work environment of clinicians.

Introduction

Background

New technologies incorporating machine learning–derived content into clinical decision support (CDS) have the potential to bring transformative improvements to clinical care [1-3]. Identifying high-risk patients who merit referral for preventative care services has historically required cumbersome screening, but now can be rapidly completed by risk prediction algorithms that consider the patient’s entire electronic health record (EHR) [4-6]. By incorporating machine learning–derived content, clinicians’ decision-making can be augmented by insights that may otherwise go unnoticed. Yet the potential benefits of these CDS tools will only be realized when they are designed to fit the clinical contexts in which clinicians work [3,7]. Health information technologies (HITs), including CDS tools, that fail to fit clinicians’ decision-making processes and workflows are unlikely to be adopted and even risk increasing clinician burden and burnout [8-10].

However, even technologies that are designed using today’s best usability guidance [11] often fail to fit the clinical context upon initial implementation [12,13]. As health systems continue to evolve in response to emergent patient needs and expectations (eg, COVID-19 and its aftermath), regulatory requirements, and staffing challenges, CDS tools are being implemented in increasingly sensitive and complex environments. While implementation science frameworks consider a variety of contextual factors [14-16] and some methods exist for assessing and identifying them [17,18], there is a gap in methods for rapidly identifying contextual factors immediately postimplementation—when it may be easiest to respond to and redesign for emergent barriers to the technology’s use, safety, and effectiveness [19].

One method that has the potential to be adapted to rapidly identify contextual factors influencing the implementation of HIT is *academic detailing*. A repurposing of pharmaceutical sales representatives’ tactics, academic detailing is defined as a “personal visit by a trained person to health professionals in their own settings” [20]. The goal of these personal visits is to improve care quality and patient outcomes by promoting evidence-based practice through focused clinician education [21]. As an implementation method, academic detailing can be conceptualized as a combination of 3 Expert Recommendations for Implementing Change (ERIC; also known as Evidence-based Recommendations for Implementing Change) strategies: auditing and providing feedback, conducting educational outreach visits, and practice facilitation [14]. The method’s attention to the specific contexts in which clinicians make decisions—both by conducting visits in situ and by discussing

barriers to and strategies for making evidence-based decisions—may present a unique opportunity to not only promote the use of a newly implemented HIT but also identify contextual factors influencing its initial implementation.

Study Objective

We propose the use of academic detailing as a method for achieving two goals in the implementation of an emergency department (ED)–based CDS tool to prevent future falls: (1) ensuring the correct understanding of the tool and its evidence base and (2) identifying contextual factors influencing the tool’s initial implementation. As part of a long-term goal of assessing academic detailing for achieving these 2 aims, the objective of this study was to assess academic detailing through an analysis of the resultant qualitative data.

Methods

Study Context and Setting

This study was conducted at a large academic medical center located in the Midwestern United States. The associated ED, a level 1 trauma center, treats over 60,000 patients per year. The CDS tool being evaluated is intended to facilitate both screening for outpatient fall risk among older adults presenting to the ED and the referral to a fall prevention clinic for those patients at high risk. Our research team developed an outpatient fall risk prediction algorithm from EHR data and, in concert with our partner health system, designed and implemented a CDS tool to use the algorithm that went live in July 2020 [22,23]. In November 2020, the CDS was updated such that it enforced a “hard stop” in the clinician’s workflow and required them to interact with it.

Upon arrival to the ED, all patients aged 65 years and older with an in-system primary care provider are assessed for fall risk algorithmically based on their extant EHR data. For eligible patients who are at high risk for falls, during the discharge process, an interruptive CDS alert is shown to clinicians, which informs them of the patient’s risk factors and expedites the placement of a referral order to a mobility and falls clinic, an evidence-based preventive intervention. Patients who are referred are informed both by the nursing staff and in writing and are contacted to schedule an appointment by scheduling staff in the days following their ED visit. This intervention has been described in more detail elsewhere [23,24].

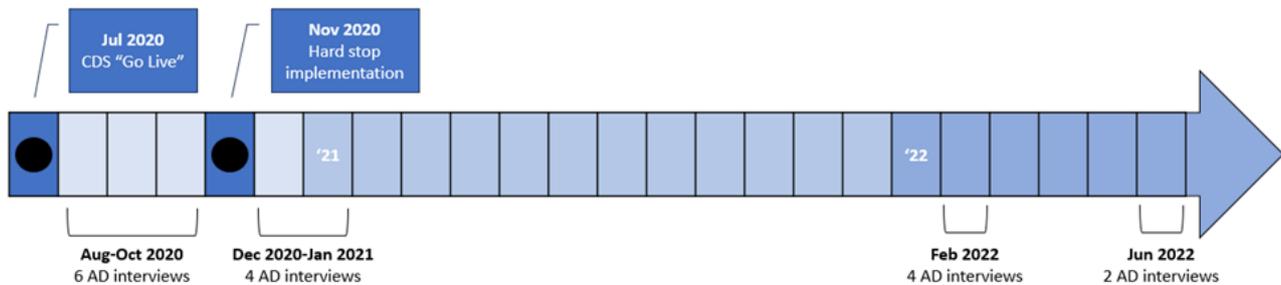

Study Design

To assess academic detailing as a method for simultaneously achieving the goals of ensuring the CDS was understood and identifying contextual factors influencing its implementation, we used a qualitative approach. We conducted 16 semistructured academic detailing interviews with emergency medicine resident

physicians (n=10) and advanced practice providers (n=6) who had previously encountered our CDS tool in practice, that is, within the last month. All interviews took place between August 2020 and June 2022, with 6 of the 16 interviews occurring prior to the implementation of the CDS hard stop (Figure 1). We purposively selected a range of participants based on how

frequently they responded to the CDS. The academic detailing interviews were led by an intervention expert (AM) who had a comprehensive understanding of the CDS tool and thus was able to identify and correct any misconceptions about the tool and its use—a critical aspect of effective academic detailing [21].

Figure 1. Timeline of clinical decision support implementation and academic detailing interviews. AD: academic detailing; CDS: clinical decision support.

Study Procedure

Interviews were roughly 10 minutes long and took place over the phone or in person while the clinician was on shift. The intervention expert used an interview guide developed using the critical incident technique, which asks the participants to mentally put themselves in the moment they first saw the tool in the EHR [25]. The interview guide (Multimedia Appendix 1) contained questions such as “How and when did you see the tool initially? What was your reaction? How did you make the decision to refer the patient or not?” Additionally, comments made by a participant that suggested an incomplete or inaccurate understanding of the tool were addressed by the intervention expert (eg, “the tool refers patients to the Mobility and Falls clinic, not the Faint and Falls clinic”). Phone interviews were transcribed in real time, while notes were taken during in-person interviews and then written out immediately after.

Ethical Considerations

This study was reviewed and determined to be exempt by the UW-Madison Health Sciences IRB (ID# 2020-1100). Participants were not compensated, and data were deidentified for analysis.

Data Analysis

We conducted an inductive, team-based content analysis [26,27]. Two researchers (AM and MAL) began by independently

reviewing and coding 4 interviews, line-by-line, to identify factors that influenced clinicians’ decision-making. The researchers then met to compare and refine codes until there was agreement. This process continued iteratively until all interviews were coded; the resultant codebook contained 31 codes and subcodes (eg, patient risk factors and clinician communication). Another researcher (HJB) generated categories of factors that influenced clinicians’ referral or nonreferral from the codes through a process of organizing similar and dissimilar codes, periodically incorporating feedback from the research team, until there was agreement.

Results

Overview

We identified five categories of factors that impacted clinicians’ use of the CDS: (1) aspects of the CDS tool’s design, for example, its features, usability, and how it fits in the clinician’s workflow; (2) clinicians’ understanding (or misunderstanding) of the CDS or referral process; (3) the busy nature of the ED environment; (4) clinicians’ perceptions of the patient and their associated fall risk; and (5) the opacity of the referral process. Table 1 organizes the identified factors by these categories, including a description of the type of clinician education that was done during the academic detailing interviews.

Table 1. Factors impacting clinicians’ CDS^a use identified through academic detailing and clinician education done during academic detailing interviews. Positive and negative factors are indicated by the +, +/-, and – symbols.

Categories of factors impacting clinicians’ CDS use through academic detailing	Factors impacting clinicians’ CDS use identified through academic detailing	Clinician education done during academic detailing interviews
Aspects of the CDS tool’s design	[+] CDS is simple. [+] CDS requires minimal input from the clinician. [+] CDS automatically identifies a high-risk patient and prompts care that the clinician would not otherwise have considered. [+/-] CDS enforces a hard stop in the clinician’s workflow. [+/-] CDS alert fires while the clinician is completing discharge in the EHR ^b .	<ul style="list-style-type: none"> Discussed why the CDS alert fires when it does and the potential benefits and challenges of it firing at a different point in the clinician’s workflow.
Clinicians’ understanding of the CDS or referral process	[-] Clinician confuses the geriatric mobility and falls clinic with the faint and falls clinic. [-] Clinician believes only patients being seen for a fall are appropriate referrals. [-] Clinician believes referring the patient will be cumbersome, ie, require written justification. [+] Clinician is familiar with the concept of the CDS from an organizational stakeholder’s communication.	<ul style="list-style-type: none"> Clarified which clinic the referral goes to. Clarified that referral is appropriate preventative care for patients regardless of their presenting problem. Demonstrated how simple and quick it is to place a referral via the CDS.
Busy nature of the ED ^c environment	[+/-] A busy ED environment.	
Clinicians’ perceptions of the patient and their associated fall risk	[+/-] Clinicians’ agreement with the CDS’s assessment of the patient’s fall risk. [-] Clinicians’ perception of the patient’s openness to, need for, or benefit from the intervention.	<ul style="list-style-type: none"> Demonstrated where in the CDS to find the reasons the patient is being flagged as high risk. Stressed the potential benefits of a successful referral for both the patient and health system.
Opacity of the referral process	[-] Clinicians lack clarity on where the referral goes once it is sent. [-] Clinicians are uncertain about who should communicate with the patient about the referral, ie, themselves or a nurse. [+/-] Clinicians (do not) have the information necessary for counseling patients on what to expect from the referral and why they are being referred.	<ul style="list-style-type: none"> Clarified which clinic the referral goes to. Clarified the importance of counseling patients on the referral and demonstrated where in the CDS to access information to support counseling patients on the referral. Demonstrated where in the CDS to find the reasons the patient was flagged as high risk.

^aCDS: clinical decision support.

^bEHR: electronic health record.

^cED: emergency department.

Aspects of the CDS Tool’s Design

The first category of factors that influenced clinicians’ use of the CDS was those that related to the design of the CDS tool. Many clinicians described the CDS as user friendly or easy to use, citing the limited number of clicks required and that the CDS did not require the clinician to enter any text. Further, clinicians found that the automatic nature of the CDS tool supported them in providing appropriate care that they otherwise would not have considered:

I appreciated how it fired on its own. I wasn’t even thinking about falls in the patient because he came in for [condition], not a fall. When it fired, I realized he was a great candidate, but it wasn’t something I thought about prior. [Participant 12]

Further, clinicians described how the CDS integration into their workflow impacted their use of the CDS. For one, the CDS enforced a “hard stop,” requiring the clinician to interact with it. While clinicians’ feelings on the hard stop varied from being

annoyed to finding it valuable, it was only described as impacting CDS use during high-volume times in the ED, which is discussed further in the next section. Clinicians generally appreciated where the CDS fit into their workflow—upon discharging the patient in the EHR—such that it “doesn’t seem like an additional step” (participant 15). Some clinicians noted the timing of the CDS as being too late in the care process to have a personal discussion with their patient about the referral, for example, they are discharging their patient in the EHR after they have already done their final visit to the patient’s room. Thus, when clinicians saw the CDS alert after their final visit with the patient, they described being less likely to refer the patient because of the additional time necessary to go back to the room to discuss the referral. However, most clinicians thought the CDS alert was well situated in their workflow:

It just pops up at discharge. It’s just a click, the referral order is already filled out. It’s very easy to use. It adds maybe 20 seconds to the discharge process. [Participant 14]

Clinicians' Understanding of the CDS and Referral Process

The second category of factors that influenced clinicians' use of the CDS was clinicians' understanding, or misunderstanding, of the CDS and the referral process. One such misunderstanding of the CDS was clinicians confusing a separate faint and falls cardiology Clinic with the actual target of the referral, the mobility and falls clinic, which specifically addresses geriatric falls. Consequently, 2 clinicians cited their nonreferral as due to the inappropriateness of the faint and falls clinic for their geriatric patient:

I think more of the syncope patients and possible cardiac or peripheral vertigo patients who don't need to be admitted or are younger and are less high risk and are anxious about having syncopal episodes for the first time.... We want to get [them to] an outpatient visit so they'll be more likely to follow up with the clinic and have [care] done. I don't think of it as much who just have a mechanical fall. [Participant 1]

Further, 6 clinicians described that they would not refer a patient who was being seen for another chief complaint, believing that only patients being seen for a fall are appropriate referrals.

Additionally, 3 clinicians expressed concerns about how cumbersome they believed the referral would be; however, their perception of the tool changed immediately once it was demonstrated that it only required 2 clicks. For example, participant 2 said:

The BPA would be less annoying if I knew I didn't need to justify it. If I had known that's all I had to do, I would have clicked [to accept the referral].

One clinician stated that they expected that the CDS would be cumbersome, that is, that they would have to write out the referral because they thought "[the CDS] would be like the other referrals" that they had come across in the EHR (participant 8).

On the other hand, 1 factor in this category that positively impacted clinicians' use of the CDS was that the CDS was familiar to some clinicians given previous communication from an organizational stakeholder (ie, clinical champion). For example, participant 12 said:

When the CDS fired, I knew [clinical champion] sent an email about this. From my interactions with this patient, I thought [they were] at high risk of fall and knew [they would] benefit from it. That's why I tried to place that consult.

Busy Nature of the ED Environment

The third category influencing CDS use was the busy nature of the ED environment. Five clinicians described the ED environment as a factor impacting their CDS use, whereas at least 1 clinician explicitly said, "the ED environment wouldn't affect whether or not I refer a patient" (participant 4). Clinicians varied in their description of the impact of the busy ED environment, ranging from "I would ignore the [CDS]" (participant 12) to "I just do the referral" (participant 14). Those clinicians who said that the ED environment increased their

likelihood of referring the patient cited the CDS's hard stop and a significant amount of text as associated factors that shaped their decision-making. While other clinicians described the amount of text in the CDS as a stressor, it was not otherwise described as influencing clinicians' use of the CDS.

Clinicians' Perceptions of the Patient and Their Associated Fall Risk

The fourth category of factors influencing the use of the CDS was clinicians' perceptions of the patient and their associated fall risk. Overall, most clinicians (10/16) agreed with the CDS's assessment of the patient's fall risk. One clinician said:

In general, my reaction has been "oh that kinda makes sense." It was always kind of a surprise in the sense that I hadn't really considered the risk of falls before, but it never seems outlandish that that was a potential concern. [Participant 3]

A few clinicians described instances of being annoyed by the firing of the CDS when it seemed irrelevant and thus did not use it. Conversely, another clinician was frustrated when the CDS did not fire when they expected to see it. Clinicians described occasionally not referring patients because they appeared to be "independent and functional" (participant 11) or "generally active and stable" (participant 10), or because their fall was "strictly mechanical" (participant 7).

Further, clinicians' perception of the patient's openness to or need for intervention impacted their CDS use. One clinician described factoring their assessment of the patient's openness to going to the mobility and falls clinic into their decision to refer the patient or not:

You can kind of get a vibe if someone is going to the doctor. If you tell them there's another doctor you can see; if they don't even want to talk to me, I doubt they're going to go to another doctor. If it's going to be useless, I don't want to waste everyone's time. I like to tell people and if they say I'm not going to that then I won't refer. I think I dictate if I'm going to [refer the patient] based on the conversation. [Participant 8]

Clinicians also described being more likely to refer patients who they perceived as having a greater need for the intervention. For example, a clinician said, "If the patient seems more anxious or [they] don't have as good of a support system or advocate, I would refer them" (participant 1). Alternatively, clinicians also described assessing how the referral would fit into the patient's care plan, for example, if the patient had an upcoming surgery, the clinician would opt not to refer the patient so as to not "throw an extra thing on top of them" (participant 6).

Opacity of the Referral Process

The final category of factors influencing clinicians' use of the CDS was the opacity of the referral process. One clinician described how they lacked clarity on where the referral goes once it is sent by saying, "it feels like I'm just sending the referral off to the void and I don't know who they're getting referred to" (participant 3). In contrast to a clinician confusing the mobility and falls clinic with the faint and falls clinic,

discussed previously, this clinician was specifically pointing to the lack of feedback they received about how the process of referring a patient to the mobility and falls clinic unfolds over time. Consequently, another factor clinicians said impacted their use of the CDS was the ambiguity around who should communicate with the patient about the referral: themselves or a nurse. Clinicians described this factor as being more prominent if they had already spoken to the patient and thus referring the patient would require them to initiate another conversation with the patient themselves or “hope the nurse will tell the patient” (participant 1).

Finally, a few clinicians said they lacked the necessary information to counsel the patient—either about what to expect from the referral and the mobility and falls clinic or about the reasons the patient had been flagged as high risk for falls. One clinician suggested that having guidance on how to counsel the patient might make referring patients an easier choice:

I haven't been really having detailed conversation about what this entails and what they should expect. In the moment I hadn't quite seen a link on how to counsel patients on this referral...I do want to refer patients...I just wish I knew what to tell patients.
[Participant 3]

Clinicians also described lacking sufficient information to explain to patients why they were flagged by the CDS as high risk for falls. In particular, clinicians said this information would likely influence their referring of patients being seen for chief complaints other than a fall by making it easier to explain the referral to the patient.

Clinician Education Done During Academic Detailing

During the academic detailing interviews, various misconceptions were addressed directly by the intervention expert through clinician education. First, 1 misconception described previously was the mistaken belief that a referral to the mobility and falls clinic would be inappropriate for people being seen for a chief complaint other than a fall. The intervention expert addressed this by clarifying that the CDS alert fires for any older adult being seen in the ED who is at high risk of falling in the future regardless of their presenting complaint, so barring any contraindications—for example, patient in hospice—it would be appropriate to refer the patient. The intervention expert also clarified, for clinicians who misunderstood, the correct target clinic of the referral (ie, the mobility and falls clinic). Generally, the intervention expert stressed the potential benefits of a successful referral for both the patient (eg, improved quality of life) and the health system (eg, reduced use).

Another misconception that was addressed via academic detailing was the perception that referring a patient would be too cumbersome. By demonstrating that accepting the CDS alert and placing a referral takes only 2 clicks, this misconception was promptly addressed. The intervention expert also demonstrated where in the CDS to access information to support counseling patients on the referral and where in the CDS to find the reasons the patient was flagged as high risk. Finally, for any clinicians who had issues with where the CDS

alert fired in their workflow, the intervention expert discussed the reasons for the alert firing when it does and the potential benefits and challenges of it firing at a different time. Oftentimes, after discussion, the clinician had a new appreciation for the complexity of designing the CDS alert.

Discussion

Principal Findings

This study demonstrates the use of academic detailing for supporting the early implementation of HIT, allowing us to identify and begin to address factors that impacted clinicians' use of the CDS while concurrently educating clinicians to ensure the correct understanding of the CDS tool and intervention. By bundling multiple ERIC strategies, academic detailing appears to be a promising method for providing timely feedback to improve HIT implementation.

Addressing Contextual Factors Within Detailing Sessions

A key component of the academic detailing method is its emphasis on clinician education [21] which, in the context of our study, involves correcting clinicians' misconceptions. For example, 1 misconception that we identified and addressed through clinician education was the mistaken belief that a referral to the mobility and falls clinic was only appropriate for people being seen for a fall. Given the nature of this CDS tool, that is, its ability to predict future risk, the impact of this misconception is that the opportunities to intervene in the routine care of high-risk patients being treated for other chief complaints would be missed. As participant 12 articulated, quoted in the “aspects of the tools design” results section, a particular value of the CDS tool is that it runs automatically, that is, does not require clinician initiation; thus, it can prompt the clinician to consider fall risk—and care to address that risk—that they may not have been considering previously. Embedding clinician education into academic detailing thus addressed a high-impact misconception with immediacy. However, it remains to be seen whether and how addressing these misconceptions translates to clinicians' use of the CDS tool. Our future work will explore the impact of these academic detailing sessions on implementation incomes, for example, clinicians' rates of referral and their acceptance of the tool.

Another important misconception to address within the academic detailing interviews was the perception that referring a patient would be too cumbersome. By demonstrating the simplicity of accepting the CDS alert and placing a referral, this misconception was promptly addressed which likely prevented its propagation. However, as described in the Results section, clinicians' perceptions of the CDS tool are situated within the context of the existing EHR and thus are beholden to a broader understanding of how similar tools work (ie, a mental model) [28]. As such, clinicians' responses to CDS alerts can be understood to be habitual, triggered by environmental cues [29]; therefore, solely addressing this misconception at the clinician level is unlikely to sustain CDS use over time. Altering clinicians' mental models of CDS tools and the EHR warrants systems-level redesign.

The content of the clinician education that is included in academic detailing is paramount to its success in increasing the use of an intervention [21]. Previous literature also notes the importance of the relationship between the clinician and the person doing the clinician education [21,30]. For this study, the intervention expert who conducted the academic detailing interviews had extensive experience working with the ED staff and had developed a rapport with them. To carry out academic detailing in another setting, there may be initial relationship- and trust building to do to achieve the detailed results our intervention expert was able to capture. Yet, given their role as a researcher (vs a fellow clinician), there were potentially missed opportunities for educating clinicians on topics that would have been better received from a colleague. For example, the deeply entrenched custom of referring to many older adults' community-based falls as being "mechanical," a catch-all term for falls that does not have an emergent, addressable cause, is

known to negatively affect care [31]. This could have potentially been addressed by a colleague; however, in this study, we did not address this clinician perception as it fell outside of the expertise of our intervention expert, that is, outside of the purview of the CDS tool and the referral it recommends.

Addressing Contextual Factors via Redesign

The factors impacting clinicians' use of the CDS point directly to opportunities to intervene in and improve the CDS implementation process (Textbox 1). As discussed previously, clinician education can be done immediately, within the academic detailing interview; however, the clinician education that had to be provided within the interview can inform the redesign of a better rollout (eg, addressing what are likely to be misconceptions up front). Future rounds of academic detailing should thus result in the need for less or different clinician education from the intervention expert.

Textbox 1. Potential approaches for intervening in the health information technology implementation process to improve clinical decision support acceptance and use.

Real time (within academic detailing interview)

- Demonstrating the current capabilities and function of the tool, for example, how easy it is to place a referral, where to access information about why the patient was flagged as high risk, and information to support counseling the patient on the referral.
- Discussing why the clinical decision support tool works the way it does and the potential benefits and challenges of redesigning it.
- Clarifying how the referral works, where it goes, and who is an appropriate candidate for the intervention.
- Addressing problematic or harmful misconceptions, for example, that there is no role the emergency department can play in providing preventive care after "mechanical falls."
- Discussing how successfully using the clinical decision support and placing a referral improves patient outcomes and health system outcomes, for example, by reducing future visits to the emergency department.

Short term (quick fixes)

- Attending regularly scheduled meetings with clinicians to remind them about the clinical decision support and clarify misconceptions about placing the referral.
- Associating the organizational stakeholder's name or image with the clinical decision support.
- Adding the mobility and falls clinic information to the clinical decision support, that is, the phone number and location.

Long term (adaptation and redesign)

- Developing feedback mechanisms for clinicians to hear about successfully referred patients.
- Clarifying roles around patient communication, that is, what is communicated by the clinician versus the nurse, and designing the clinical decision support to support those roles.
- Reviewing clinical decision support tools for potential interaction effects, for example, 2 clinical decision support tools fire on similar populations and are likely to be confused.
- Providing talking points on what the patient can expect after discharge with respect to scheduling and going to an appointment with the mobility and falls clinic.
- Providing talking points that explain why patients being seen for issues other than falls may be referred.
- Personalizing the timing of the clinical decision support alert for clinicians who tend to talk to patients before completing the discharge in the electronic health record, for example, moving the clinical decision support alert earlier in clinicians' workflow.

In the longer term, a variety of approaches could be used to address the factors we identified as impacting the clinicians' use of the CDS. For one, reviewing the CDS tools that are currently implemented in overlapping clinical contexts could identify potential interactions with the newly implemented CDS. To avoid interaction effects, the new CDS could be redesigned to differentiate it from others, for example, to alert a more

specific patient population or to have clear visual cues and messaging. Alternatively, a review of the CDS ecosystem may prompt the removal of underused or ineffective CDS tools. Recent research, while limited, suggests that health systems that optimize CDS alerts, that is, reduce unnecessary or less useful alerts, see improved CDS use [32]. Further, those effects

are not limited to the optimized CDS but spread to other CDS in the system [32].

Other redesigns that would address factors identified through academic detailing could address the workflow integration of the CDS. For example, for the clinicians who typically talk to a patient before completing the discharge in the EHR, moving the firing of the CDS alert earlier in the clinical workflow may be warranted. Beyond considering the timing of the CDS, to achieve workflow integration as defined by Salwei et al [33,34], the design of the CDS should consider the dimensions of flow, scope of patient journey, and level. An example of such a redesign could be—in the case where the fall risk CDS alert would happen earlier in the clinician’s workflow—allowing the clinician to “snooze” the alert until the point at which they have discussed the mobility and falls clinic referral with the patient. This design would increase the chance that the clinician would see the CDS prior to speaking with the patient for the last time, which could promote more meaningful patient counseling on fall risk; however, this design could also have unintended consequences, which should be explored prior to broad implementation.

In designing for CDS use, it is important to remember that increased use does not always equate to increased *appropriate* use (ie, referrals for patients that are a good fit for the mobility and falls clinic intervention). Thus, the findings from academic detailing should also be considered in light of, and be used to design to support, successful teaming between the CDS tool and the clinician. A potential design to promote teamwork between the CDS tool and the clinician could be to include on the CDS a list of exclusion criteria for the mobility and falls clinic that the CDS tool is unable or poorly able to assess (eg, late-stage dementia). The clinician, then, when considering referring the patient would be alerted to where their clinical judgment is especially necessary.

Work Systems Approach to Redesign

Given the breadth of potential redesign options and the challenge of prioritizing efforts to improve not only CDS use, but *appropriate* CDS use, it is pertinent to consider models that can hold and make sense of system complexity. One model that has proven to be valuable across a variety of health care domains and in supporting the design of technologies—the Systems Engineering Initiative for Patient Safety (SEIPS) model—conceptualizes the work of clinicians as happening in a *work system*, which invariably influences care processes and outcomes [35-37]. The SEIPS model, which synthesizes literature on job stress, job design, and health care quality [37,38], provides a theoretical foundation for understanding why the system is achieving certain outcomes and how the system may be redesigned to achieve alternative outcomes.

In a parallel analysis—presented elsewhere [39]—we found that the data we collected using the academic detailing method successfully mapped to the SEIPS model’s work system components, for example, the *people* who do the work, the *tasks* they complete, the *tools and technologies* they use, and the *physical and organizational environment* they work in. A key

aspect of the SEIPS model is the conceptualization of balance—that work system components that negatively influence processes and outcomes (barriers) may be balanced by positive components (facilitators) [37,40]. Thus, through redesign efforts, we can either seek to address the work system barrier or enhance the work system facilitator. Applying a work systems approach to system redesign to address the factors we identified through academic detailing has the potential to result in more sustainable HIT implementation.

Beyond redesigning the CDS itself, as discussed in the previous section, redesigning the work system to clarify the process of referring a patient to the mobility and falls clinic may be essential to promoting the appropriate use of the CDS. This would require creating clarity around who should communicate and about what with the patient (ie, the referring clinician and the nurse). Further, creating transparency around the positive outcomes of past referrals to the mobility and falls clinic (ie, success stories) may promote trust in the referring clinicians that this is an action worth taking.

Limitations

The following limitations of our study should be considered. First, the academic detailing method, as applied here, relies on the clinicians to report what they perceive as influencing their use of the CDS. However, it is possible that clinicians’ perceptions differ from what they actually do—a common challenge in understanding people’s work is the difference between “work as imagined” versus “work as done” [41]. Second, this study focuses on academic detailing around a specific CDS tool that produces an interruptive alert to which a clinician must respond that they agree or decline to refer the patient. It is possible that there are other considerations for CDS tools and HIT that operate differently from this study (eg, tools that require more in-depth information processing or that must be initiated by the clinician). Further, given this academic detailing method was applied in a live ED setting over nearly 2 years—including multiple waves of COVID-19—a variety of external factors may have contributed to clinicians’ use (and perception of their use) of the CDS. Finally, it is yet unclear how many rounds of academic detailing would be required to capture and address the majority of factors impacting the implementation of the HIT. Future research should explore the use of the academic detailing method over a broader range of the implementation process so that the effort and resources required to conduct the interviews are used most effectively.

Conclusions

With HIT developing at rapid speeds, it is essential we develop methods to support its integration into the complex environments in which they will be used. From our initial study, it appears that academic detailing is a promising method for both promoting the correct understanding of a CDS tool and identifying contextual factors influencing its implementation. Thus, academic detailing can inform real-time adjustments of a tool’s implementation (eg, refinement of the language used to introduce the tool), and larger scale redesign of the CDS tool to better fit the dynamic work environment of clinicians.

Acknowledgments

The authors would like to acknowledge the clinicians who participated in our academic detailing interviews and shared their insights with us. This work was supported by the Agency for Healthcare Research and Quality (grant R18HS027735; BWP, principal investigator). This work is solely the responsibility of the authors and does not represent the official views of the Agency for Healthcare Research and Quality.

Authors' Contributions

HJB performed data analysis and led the writing and revising of the manuscript. AM performed data collection and analysis and critically reviewed and revised the manuscript. MAL performed data analysis and critically reviewed and revised the manuscript. DJH, DAW, and MNS critically reviewed and revised the manuscript. BWP conceptualized and oversaw the study and critically reviewed and revised the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1

Interview guide for academic detailing interviews.

Abstract

Background: Monitoring childhood immunization programs is essential for health systems. Despite the introduction of an electronic immunization registry called e-Tracker in Rwanda, challenges such as lacking population denominators persist, leading to implausible reports of coverage rates of more than 100%.

Objective: This study aimed to assess the extent to which the immunization e-Tracker responds to stakeholders' needs and identify key areas for improvement.

Methods: In-depth interviews were conducted with all levels of e-Tracker users including immunization nurses, data managers, and supervisors from health facilities in 5 districts of Rwanda. We used an interview guide based on the constructs of the Human, Organization, and Technology-Fit (HOT-Fit) framework, and we analyzed and summarized our findings using the framework.

Results: Immunization nurses reported using the e-Tracker as a secondary data entry tool in addition to paper-based forms, which resulted in considerable dissatisfaction among nurses. While users acknowledged the potential of a digital tool compared to paper-based systems, they also reported the need for improvement of functionalities to support their work, such as digital client appointment lists, lists of defaulters, search and register functions, automated monthly reports, and linkages to birth notifications and the national identity system.

Conclusions: Reducing dual documentation for users can improve e-Tracker use and user satisfaction. Our findings can help identify additional digital health interventions to support and strengthen the health information system for the immunization program.

KEYWORDS

childhood immunization; electronic immunization registry; digital health interventions

Introduction

In 2021, a reported 18.2 million infants worldwide did not receive basic immunization, and an additional 6.8 million were only partially vaccinated, with associated higher deaths in low- and middle-income countries (LMICs) [1,2]. Health systems

worldwide are adopting digital tools to improve immunization service provision as well as monitoring [3]. Digital health interventions (DHIs) have the potential to improve the management and use of health information to enhance health worker performance and provision of care and ultimately improve health outcomes [4,5]. In LMICs, electronic

immunization registries (EIRs) were initiated to support improved vaccination coverage among children, primarily through better tracking of children by combining vaccine information from different sources into a single digital record [6,7].

DHIs (in the form of EIRs) are important for immunization programs. For clients, they can help to remind families through SMS text messaging when immunization is due or has been missed. For health workers, they can help ensure that children get the vaccinations they need, improve and simplify the reporting of immunization data, identify high-risk populations for targeted interventions, and allocate resources efficiently and effectively [5-7]. EIRs, enhanced by data-driven DHIs, can help the immunization program achieve its goals of effective immunization coverage and real-time data for decision-making. EIRs can serve their purpose for immunization programs even better if integrated and synergized with DHIs for other programs such as Civil Registration and Vital Statistics (CRVS) and the national identification system. For instance, registration of all newborn babies in EIRs can improve tracking of immunization status and monitoring coverage [7]. EIRs integrated with other programs can strengthen other health services for children by providing a database of newborn babies in the population. Examples include newborn metabolic screening and childhood nutrition programs for the identification and referral of malnourished children [7].

Despite the many opportunities, several challenges hinder the effectiveness of EIRs in LMICs, such as the increased burden of data collection for health workers, which is the result of maintaining paper and digital documentation and reporting systems [7]. The implementation of EIRs, similar to all DHIs, should be aligned with the needs, both in terms of addressing the concerns of the intended users and being relevant to the users [8]. However, there is limited evidence on how to implement digital tools most effectively and sustainably across the full range of health systems [9]. The World Health Organization has highlighted the need for implementation research to identify the crucial factors that affect the implementation of DHIs for health system strengthening [5]. Implementation research can provide a systematic understanding of users' perceptions and experiences and thus enhance the usability and acceptability of DHIs.

In Rwanda, children from 0 to 15 months of age are provided with vaccines against 11 infections according to the Expanded Program on Immunization (EPI), namely, tuberculosis, poliomyelitis, diphtheria, tetanus, measles, pertussis, hepatitis B, *Haemophilus influenzae* type B, rubella, *Streptococcus pneumoniae*, and rotavirus [10]. The latest report from the Global Alliance for Vaccines and Immunization from 2017 identified issues with the immunization health information system such as data quality, population denominators based on projections from census data, and implausible coverage rates of more than 100% [11], similar to other contexts in eastern and southern Africa [12]. Incidents of vaccine dropouts and incomplete immunization, particularly for Pentavalent 3, were also identified. Significant geographic variations in immunization rates were reported, with 1 district in the northern

part of the country reporting an overall coverage rate of as low as 88% [11,13].

The introduction of an EIR, known as e-Tracker, was launched in 2019 with the goal of improving overall data quality, data availability for monitoring of immunization defaulters or dropouts, and ultimately increasing immunization coverage [14]. The newly implemented e-Tracker has not yet been subject to research-based evaluations. The aim of this study was to assess the extent to which the immunization e-Tracker responds to stakeholders' needs and identify key areas for improvement in Rwanda's childhood immunization program.

Methods

Study Setting

This study was conducted among immunization nurses and data managers. Supervisors were included at the district hospital level. Health facilities were randomly selected from 5 districts in Rwanda—Gasabo, Rwamagana, Kamonyi, Gicumbi, and Rubavu, 1 from each of the 4 provinces and the City of Kigali of Rwanda. Gicumbi district, which is in the north of Rwanda, has 16 health centers; Kamonyi, in the south, has 13 centers; Rwamagana, in the east, has 15 health centers; Rubavu, in the west, has 13 centers; and Gasabo, in the central city of Kigali, has 16 health centers. In Kamonyi district and Gicumbi district, the routine immunization coverage rates for Pentavalent 3 and measles-rubella 1 in 2018 were 84% and 85%, respectively, while the coverage rate was higher than 89% in the remaining 3 districts. Gicumbi, Gasabo, and Kamonyi were among the districts with the largest percentage of underimmunized children, especially for the third dose of Pentavalent. The e-Tracker was introduced and operationalized in health centers in all districts of Rwanda in 2019.

The study participants were primary users of the immunization e-Tracker, either entering data or using the data: immunization nurses, data managers, and EPI supervisors.

Immunization-related services are organized at different levels of the health system. At the village level, community health workers engage with residents to raise awareness about childhood immunization. All primary health care services, including childhood immunization, are decentralized to the health center level. Immunization is provided at the health centers by immunization nurses or at health posts by the same nurses through community outreach in hard-to-reach areas. There are 499 health centers and 476 health posts in Rwanda [15]. More than 90% of children are immunized at the health center. All immunization sites (centers and posts) have weekly schedules of immunization days.

A health center typically has 2 immunization health workers, a nurse in charge of immunizations, and an assistant to deliver vaccines and keep records of all information pertaining to immunizations.

Figures 1 and 2 show the workflow of immunization at the health facility and the e-Tracker registration process and data visualization, respectively.

Figure 1. Workflow of immunization pertaining all the duties of a health worker (immunization nurse) on a vaccination day.

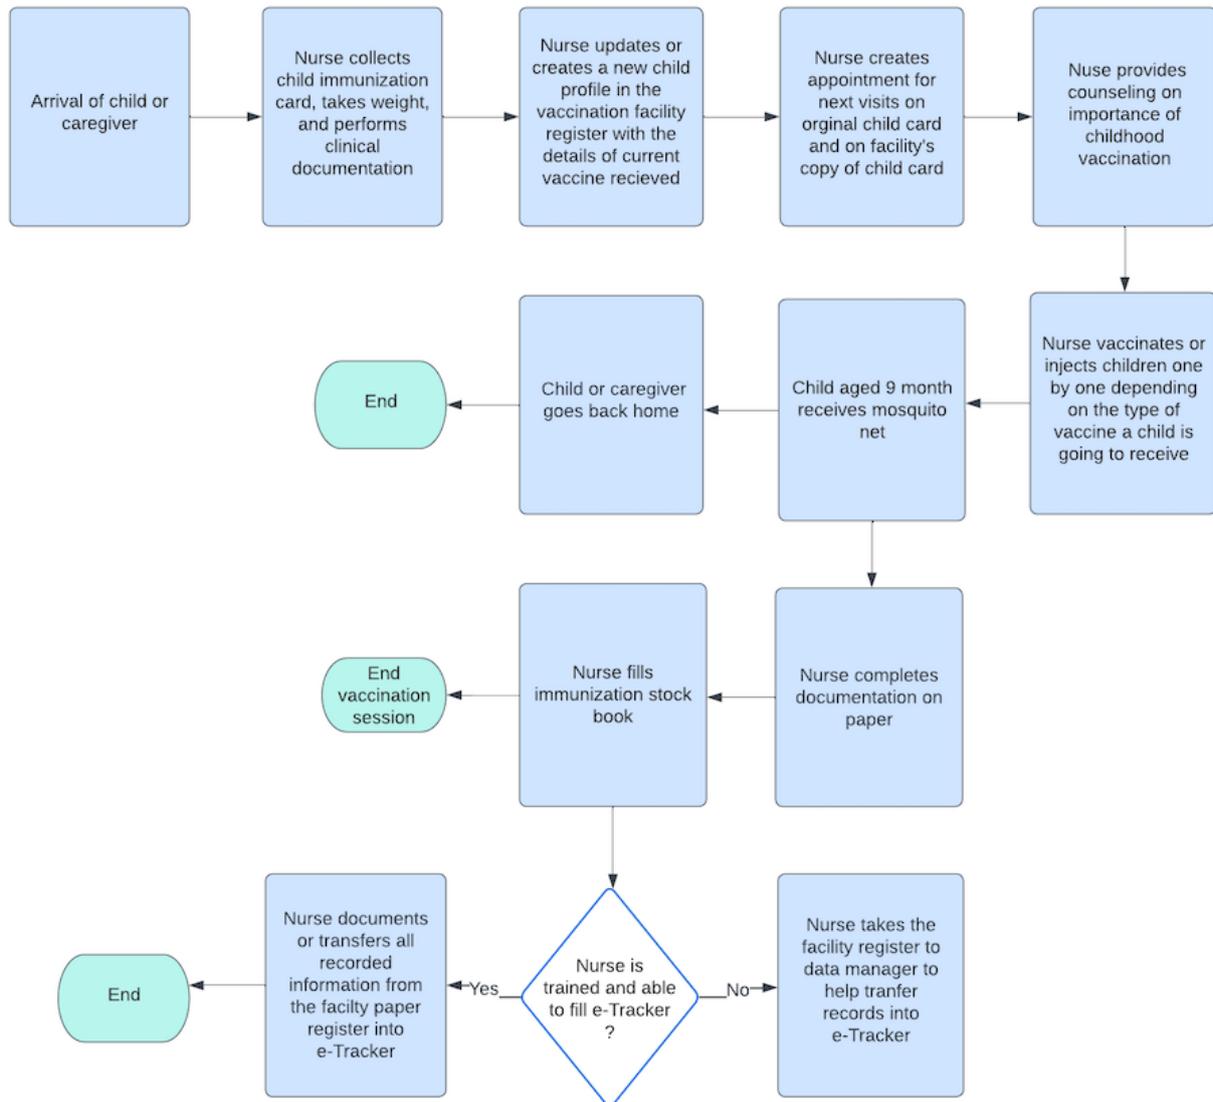

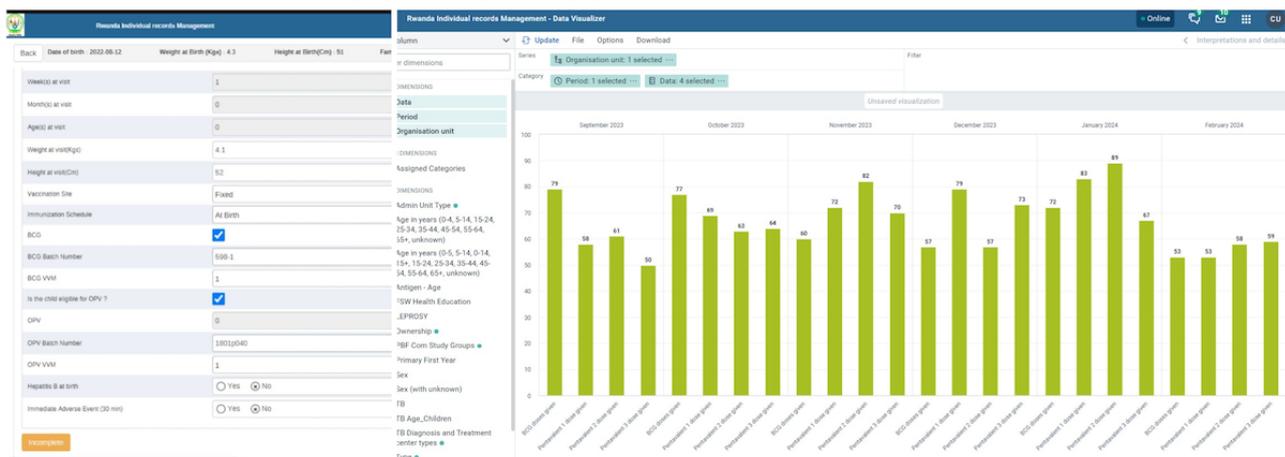

Figure 2. Immunization e-Tracker showing the client registration page and data visualization dashboard.

e-Tracker Implementation and Use

Implementation of the e-Tracker started in 2019 and was operational in all public health facilities. The e-Tracker runs on the District Health Information Software 2 (University of Oslo) platform, one of the most widely used digital health information

systems globally [16]. Three cadres of health workers were trained to use the e-Tracker—immunization nurses, data managers, and EPI supervisors. All individual information are first recorded on 2 sets of paper-based forms: the child’s immunization cards and the health center’s immunization paper registers. The immunization nurse or the data manager then

transfers the same information from the paper registers to the e-Tracker. At the end of the month, a set of predefined data is aggregated onto paper reporting forms by immunization nurses and handed over to the data manager, who then enters these data into the aggregate reporting system built in a separate instance of District Health Information Software 2, as a part of the health management information system (HMIS).

EPI supervisors, located at the district hospitals, use the e-Tracker to assess the progress of health facilities by comparing the number of children registered as successfully vaccinated on each indicator against the monthly target provided to the health

center (Table 1). The target is an estimate population based on the expected number of births in the area based on census data.

Users who have technical issues with e-Tracker can contact the central help desk. Phone calls or WhatsApp groups are typically used to resolve simple technical issues such as password reset, and for complicated issues, through visits to health centers. Immunization nurses from the health centers have a joint WhatsApp group with their respective EPI supervisors where they communicate issues regarding immunization and e-Tracker-related technical support in their district.

Table 1. Intended use and user roles in the immunization e-Tracker.

User	Intended use and user roles in the e-Tracker
Immunization nurse ^a	<ul style="list-style-type: none"> Data entry and registration of new children for immunization Update and follow up on subsequent immunizations until a child has completed his or her vaccination calendar
Data manager ^a	<ul style="list-style-type: none"> Data entry and registration of new children for immunization Update and follow up on subsequent immunizations until a child has completed his or her vaccination calendar Generate reports of comparisons of the health center's immunization coverage rate against the target
EPI ^b supervisor	<ul style="list-style-type: none"> Review reports from all health centers in the district catchment area and provide recommendations and feedback for improvement based on the data

^aData entry tasks could be shared by immunization nurses and data managers.

Study Design and Sampling

This study is an implementation research design that used descriptive qualitative methods [17,18] and formative evaluation to assess the extent to which the immunization e-Tracker responds to stakeholders' needs and identify key areas for improvement [19]. This was done through key informant interviews. The Human, Organization, and Technology-Fit (HOT-Fit) evaluation framework guided the data collection and analysis [20]. We chose the HOT-Fit framework because it has the potential to evaluate health information systems; encompasses comprehensive dimensions; and measures the fit between technological, human, and organizational aspects, all of which are critical for system adoption [20].

To select a sample of districts, we first assessed data reports retrieved from the e-Tracker and the national HMIS in the first 3 months of 2020 for all 30 districts in Rwanda. Four immunization indicators—Bacille Calmette-Guérin (BCG) and Pentavalent (penta) first, second, and third doses (penta1, penta2, and penta3)—were reviewed by a program manager together with a researcher (TU) to calculate completeness of data in the e-Tracker (e-Tracker-reported indicator and HMIS-reported indicator). We then selected 5 districts as follows: 1 district

among the best performers (Rwamagana district >80%), 1 from the worst performers (Rubavu district <15%), and 3 districts that were in the middle (Gasabo, Gicumbi, and Kamonyi districts: 50%-60%). We randomly included 6 health centers from each of the 5 districts. From this pool of health centers, key informants and participants were purposively sampled among primary users of the e-Tracker. To cover the variation of sites across the districts appropriately, we recruited 1 nurse and 1 data manager from 1 district before moving to the next to diversify the data collected.

Data Collection

This study was carried out in accordance with COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines (Multimedia Appendix 1) [21].

Based on the 3 constructs of the HOT-Fit framework, we created study-specific definitions for each of the constructs (Table 2) and formulated an interview guide with open-ended questions (Multimedia Appendix 2). Three pilot key informant interviews were conducted with immunization nurses and data managers in 1 district (Gasabo) to validate the tool prior to data collection. We further refined the questions in the guide based on the findings from these interviews (Multimedia Appendix 2).

Table 2. Specific domains of evaluation of the e-Tracker based on the constructs of the HOT-Fit^a framework.

^aHOT-Fit: Human, Organization, and Technology-Fit.

Separate interview guides were used for each category of participants. The interview questions were formulated based on each user's role both in the immunization program and the e-Tracker system. For instance, we asked questions related to user-specific employment and how e-Tracker is related to his or her job. Some e-Tracker technical questions were similar such as whether e-Tracker was easy to use, easy to learn, or about how e-Tracker responds (response time). One author (TU), a current PhD candidate, with experience in IT conducted 14 in-person, in-depth interviews with key informants (e-Tracker end users in primary health care centers and EPI supervisors in their affiliated district hospitals). Interviews were conducted with only the key informant and the interviewer present. The interviews were conducted in Kinyarwanda, took place over approximately 1 hour, and were audio recorded. No notes were taken. The audio was then transcribed in Kinyarwanda and translated into English by a bilingual professional. A group of 2 researchers (TU and ER) reviewed the translations for accuracy. The study team met on a weekly basis to evaluate the data collection process. After 4 interviews per key informant category, the data collector began hearing information repetition. The research team advised undertaking 1 more interview per participant category to ensure that no new findings were discovered. Data saturation was confirmed, and data collection was stopped. No repeat interviews were carried out.

Data Analysis

Translated interview transcripts were uploaded into NVivo 12 (Lumivero). Based on the HOT-Fit framework, a codebook was developed by the team through discussion. Using this agreed-upon codebook, 2 researchers (TU and ER) individually coded the data. A deductive coding style was applied to our data. Discrepancies in coding were discussed and resolved by the team.

The HOT-Fit Framework

After coding was completed by both researchers, the team compiled the relevant data extracts. We performed a framework analysis and worked together to place the extracted data within the HOT-Fit framework [20,22]. We analyzed interview transcripts to find all possible codes from all participants. We identified and summarized codes in accordance with constructs of the HOT-Fit framework and study-specific domains (Table 2). NVivo 12 analysis software was used to manage themes and codes.

Author Reflexivity

Prior to data collection, the interviewer and research team had minimal contact with participants (stakeholder engagement session). The participants were informed that the purpose of the study was to gather their views and experiences on e-Tracker use to assess how the immunization e-Tracker responds to stakeholders' needs and identifies areas for improvement. They

were also informed that this was part of a larger project studying the design and implementation of DHIs to improve childhood immunization in Rwanda. Authors entered this study with the belief that an e-Tracker had the potential to positively impact care providers' experiences; however, it took effort to prevent personal bias during data analysis. Due to COVID-19 restrictions, member checking was completed with 1 key informant from each category.

Ethical Considerations

This study was approved by the Rwanda National Ethics Committee (1011/RNEC/2020), the Norwegian (West) Regional Committee for Medical and Health Research Ethics (251925), and the Rwanda Ministry of Health's National Health Research Committee (reference NHRC/2021/PROT/002). All methods were performed in accordance with relevant guidelines and regulations by the World Medical Association Declaration of Helsinki—ethical principles for medical research involving human subjects [23].

The participants were informed about the study objectives, their voluntary participation, and their right to refuse participation

at any time. The written informed consent form was obtained from each participant after getting an explanation about the research purpose and confirming their participation in the study. The interviews took place in a safe room with the office door locked at the health facility. The recorded information was transcribed and anonymized. The audio recording device could only be accessed via a security code by the lead author (TU).

Results

Overview

In total, 14 e-Tracker users were interviewed (Table 3), including 5 immunization nurses, 5 data managers, and 4 EPI supervisors (1 EPI supervisor declined being interviewed due to clinical COVID-19 work). Most of the immunization nurses were female (4/5, 80%) and had more than 10 years of work experience (3/5, 60%). In contrast, data managers were mostly male (4/5, 80%), younger, and had work experience of 5 years or less (4/5, 80%). Half of the supervisors (2/4, 50%) were female. The supervisors had varying levels of work experience (Table 3). We present our findings based on the constructs of the HOT-Fit framework.

Table 3. Characteristics of study participants.

Characteristics	Immunization nurses (n=5)	Data managers (n=5)	Supervisors (n=4)
Sex, n (%)			
Male	1 (20)	4 (80)	2 (50)
Female	4 (80)	1 (20)	2 (50)

Technology

System Quality

Data managers and supervisors reported that the e-Tracker was not a complex system. Two (40%) of 5 nurses perceived the

e-Tracker as complex due to limited skills of computer literacy (Table 4: section A, construct 1).

Table 4. Summary of main findings in accordance with the HOT-Fit framework and quotes from key informant interviews.

Construct number and main findings	User's quotes
Section A: Technology	
System quality	
1. Ease of learning	"...that system [e-Tracker] is not difficult to use, except that it is not easy for everyone because there are some health centers for example that have immunization nurses who do not know how to use the computer." (EPI ^a supervisor 1)
2. Better data security than paper registers and forms	"e-Tracker is a secure system protected by personal credentials; it is not like paper registers where anyone can access." (Data manager 5)
3. Missing technical functionalities	"...as a person who is in the field and using it [e-Tracker] frequently, I realize that there are some functionalities that the e-Tracker is lacking. For example, it does not show me the next appointment for someone's vaccination or the list of who the nurses should be seeing today." (Data manager 5)
4. Not compatible for community outreach	"...internet connection that is not available, lack of outreach support—all these are challenges with using the e-Tracker." (Immunization nurse 1)
5. Connectivity issues and slow system response	"Things related to e-Tracker are slow, definitely slow. This is a challenge we usually face." (Immunization nurse 2)
Information quality	
6. Incomplete and unreliable data	"There are times when you register a child and when you go back to search him or her, you find that the actual information is not complete, or you find that the e-Tracker contains a duplicate of the child's records." (Immunization nurse 3)
7. Increased documentation workload	"I may fail to get time for instance, and they shift me to provide another health service, but, because there is much information that needs to be entered and I am responsible for that, I go quickly and take like one hour after work, or I come early in the morning to enter them." (Immunization nurse 4)
Service quality	
8. Delays in getting technical support	"It is difficult to get technical assistance because it is from central level and nowhere else...if the problem is simple like the system is off and then back on, those ones are quick and can be done on a phone call or WhatsApp, but bigger technical issues take time." (Data manager 2)
9. Alternative communication lines	"...talking about the other [communication] chain...I just call my superior at the hospital, and he conveys it to the central level technical team...and they gradually communicate with each other, and the information reaches us." (Data manager 4)
Section B: Human	
System use	
10. Does not meet the intended purpose	"What I expected from e-Tracker up to now, I can say that I have not yet seen its results. This may be due to other challenges, but the functionalities required by the nurses to use the e-Tracker well and properly are not yet available." (Supervisor 1)
11. Suboptimal use due to increased documentation workload	"This e-Tracker system is expected to be used by immunization nurses; it has apparently increased their work, which was not easy. That is simply to say, this is beyond their capacity." (Supervisor 1)
User satisfaction	
12. General dissatisfaction with the e-Tracker	"...Discriminating children's cards increases job, in e-Tracker it is simple; just search child and find him easily, but the use of e-Tracker did not stop papers, you complete all existing paper books and forms and then go complete e-Tracker." (Immunization nurse 2)
Section C: Organization	
Structure	
13. Lack of effective training processes	"...data manager who received training has gone, the one who replaced him does not actually know to use e-Tracker, he often called me asking, 'where can I click on?'...you realize that it is slowly by slowly." (Immunization nurse 2)
14. Lack of support for health workers in using technology	"...it happens that you register a child and when you go back to search for him [in the e-Tracker], you miss him simply because you do not know if it is a connection problem, or a low knowledge regarding how to search for him." (Immunization nurse 1)
Environment	
15. Performance-based financing	"We have many duties, and there are so many systems at health center...they come and say we give you PBF after seeing in the system how many children you have entered, and it is understandable that you will not receive any money if you didn't register any child." (Immunization nurse 3)

Construct number and main findings	User's quotes
Section D: Net benefits	
16. Perceived current benefits	"...the e-Tracker has a dashboard for data analysis. Like now, I sometimes say, let me see how many children we have registered this month; for the first, the second and the third dose of Penta, for instance." (Data manager 3)
17. Perceived future benefits for HWs ^b	"e-Tracker has made nothing easier for me. Instead, it has complicated things. Perhaps there is value in the e-Tracker if all these papers and books are removed. Then you may find that the e-Tracker will bring benefits." (Immunization nurse 3)

^aEPI: Expanded Program on Immunization.

^bHW: health worker.

Data security in the e-Tracker was generally perceived as satisfactory and better than data security using paper registers (Table 4: section A, construct 2). However, users reported several shortcomings. They cited the lack of several technical functionalities such as client lists, lists of defaulters, unspecific search and register functions, automated routine reports, and linkage to other systems such as birth notification and the national identity system (Table 4: section A, construct 3). Users expressed the need for a more flexible data entry tool that can operate offline, such as handheld tablets instead of desktop computers, to use during community outreach. They also cited poor connectivity and solely relying on health center–purchased internet as one of the most important reasons for the suboptimal use of the e-Tracker (Table 4: section A, construct 4). For system response time, 4 (80%) of 5 health workers and 4 (80%) of 5 data managers reported that the e-Tracker responds slowly. The remaining interviewees, particularly supervisors, located at hospitals with better internet connectivity, reported the opposite that the e-Tracker had a quick response time. Adequate support for network connectivity was lacking (Table 4: section A, construct 5). For example, immunization health workers at health centers were given modems, but they claimed that they were not given financial assistance for continued internet subscriptions.

Information Quality

Data in the e-Tracker were considered incomplete and unreliable and were not actively used by the immunization nurses (Table 4: section A, construct 6). Several underlying issues were identified as contributors to poor information quality. Users were required to document in the e-Tracker in addition to existing paper forms, which created double work. The double entry of data, combined with a mismatch between the data elements in the paper forms and the e-Tracker, results in users skipping some data fields in the e-Tracker. A common response with all users was the lack of time to complete documentations in the e-Tracker due to heavy workloads (Table 4: section A, construct 7). Two (40%) of the 5 interviewed immunization nurses were not trained in e-Tracker use, but even those who were trained and able to use the e-Tracker reported that the time allocated to them to fill the e-Tracker was insufficient. Three (60%) of 5 immunization nurses reported having to work overtime to enter data in the e-Tracker, 1 hour before or after work—a practice that users believed adversely affected data quality.

Service Quality

All interviewed nurses and data managers reported some form of delay in getting technical support (Table 4: section A, construct 8). Users' responses on this issue suggest that they might prefer reporting issues to their supervisor, who could then facilitate communication with the central support team.

Human

System Use

According to all interviewees, the e-Tracker did not meet overall user expectations. Further exploration revealed that users want a system that generates automated monthly reports and reduces documentation workload. The e-Tracker does not automatically generate any reports, and double documentation was identified as an important problem that impacted effective e-Tracker use (Table 4: section B, constructs 10, 11).

User Satisfaction

When asked whether they were satisfied with the e-Tracker, only 2 (40%) of 5 data managers said yes. The lack of technical functionalities and increased documentation workload were the leading causes of dissatisfaction for the data managers and health workers, respectively (Table 4 section B, construct 12).

Organization

Structure

Users described quarterly data quality assessment workshops to encourage e-Tracker use by health workers. Such assessments are usually done by data managers, nurses, and their supervisors by reviewing paper reports and e-Tracker reports and comparing them to HMIS reports for selected vaccination indicators, such as BCG. Health workers reported not receiving enough support in navigating digital systems in general (Table 4 section C, construct 13) and highlighted the need for regular training sessions on how to use the e-Tracker and a plan to deal with staff turnover. The planned training for users in 2021 did not happen due to the COVID-19 pandemic.

Environment

Performance-based financing was provided to the health workers based on the number of newborn babies registered as BCG vaccinated in comparison with their reported number of BCG vaccinations. The interviewees alluded to this as a reason for entering data for this specific indicator into the e-Tracker rather than the indicators for other vaccines. Performance-based financing in this context is based on the number of children

registered with BCG vaccination as a way of promoting the registration of newborn babies in the childhood immunization e-Tracker [24] (Table 4: section C, construct 15).

Net Benefits

Participants acknowledged the potential benefits of an e-Tracker provided technical and implementation issues are addressed. For example, all EPI supervisors reported that the tool could be helpful to monitor children's registration and vaccination status without visiting health centers physically. Two (40%) of 5 data

managers reported using the e-Tracker for monitoring and evaluation in terms of vaccination coverage for their respective health centers. In contrast, all health workers did not report any net benefits from the current use, although they see that the e-Tracker may contribute positively to their work in the future (Table 4: section D, construct 17).

Key Improvements

Textbox 1 provides a summary of the main recommendations for improvement of the e-Tracker based on our findings.

Textbox 1. Overall recommendations for key improvements highlighted by the users.

Immunization nurses

- Better client search and register function
- Produce lists of expected and missed clients to avoid searching in paper registers
- Facilitate tracking a defaulter or a dropout child and remind parents of the missed appointments
- Improve connectivity
- Offline e-Tracker version that will make it easier to collect data in case of network outage, handheld devices to help immunization outreach in difficult-to-reach areas
- Regular training on e-Tracker use

Data managers

- Generate automatic monthly reports
- Link e-Tracker to other systems such as Civil Registration and Vital Statistics and national identification systems

Expanded Program on Immunization supervisors

- Additional trainings on analysis of e-Tracker data
- Offline e-Tracker version and more devices to support nurses' work at primary health centers

Discussion

Principal Findings

This study explored stakeholders' experiences and perceptions of using the e-Tracker for the Rwandan childhood immunization program. Users of the e-Tracker described several issues that hamper effective data entry as well as data use. Data in e-Tracker were reported to be incomplete and unreliable as result of dual documentation on paper and digitally.

Rwanda is one of the few countries in Africa to implement an EIR at scale. Implementation of the e-Tracker is a top priority for the childhood immunization program. Along with technological resources such as computers and modems, a top-level team and 3 cadres of trained health professionals from each health center across the nation are assigned to support the implementation indicating significant organizational support for change. EIRs allow for real-time monitoring of immunization status and provide data for decision-making, and their evaluations play a key role in identifying strategies to improve their use [25]. Our findings demonstrate the need for technical improvements to fit clinical practice and increase benefits, addressing implementation-related issues such as workflow matching, as well as training and user support. User-informed development of technical functionalities has been shown to be linked to higher adoption of health information systems in a

systematic review of 55 studies [26]. Slow response times and delayed IT support adversely affected e-Tracker use in our study, factors also reported in other studies of digital information systems [27,28].

Creating an enabling environment for digital health systems by addressing issues such as training, and capacity strengthening in data entry and use, is equally important to ensure successful implementation [29]. Users cited a general dissatisfaction with the e-Tracker for several reasons including increased workload due to dual documentation and insufficient training. Several studies have reported similar dissatisfaction among users of digital health information systems in many cases as a result of the system's inability to match existing work patterns [26]. On the other hand, users are typically more satisfied when information systems offer good quality data; the higher the quality of the data the higher the satisfaction [27,30]. Users in this study perceived the information in the e-Tracker to be inaccurate and incomplete in comparison with the paper records and registers. None of the entered digital information was used by data managers or nurses for clinical practice.

Immunization nurses are the intended users of the e-Tracker, although the current workflow involves secondary data entry in the e-Tracker by the data manager in several health centers. While data managers and supervisors stated some benefits of the e-Tracker for their work, immunization nurses reported no

net benefits of the e-Tracker as it has been implemented in its current version. One of the reasons for this may be that the e-Tracker in its current form is not considered an essential part of the data ecosystem in the immunization health information system, particularly because the monthly reports are still paper based and not generated from the e-Tracker. In a setting such as Rwanda with scarce human resources for health, efficiency and costs are important considerations. Efficiency gains cannot be achieved unless health centers phase out paper immunization records and exclusively use the e-Tracker for data entry [31]. Similarly, a study conducted in Zambia and Tanzania showed that the use of the EIR decreased over time in settings where it was used in parallel with paper-based documentation compared to exclusive use [32]. In most other LMICs, paper-based documentation and reporting consume a significant proportion of health workers' time, which can be alleviated by well-implemented digital tools co-designed with the end user [31,33].

Organizations play a key role in supporting the adoption of digital systems directly and indirectly and sometimes inadvertently skewing priorities [20,30]. For instance, in our study, health workers are provided with performance-based financing based on BCG vaccine coverage rates, which might explain the relatively better completeness of these data in the e-Tracker.

Strengths

This study was conducted in sub-Saharan Africa, where there has been relatively limited research on EIRs and DHIs in general. Our findings are reasonably generalizable to the Rwandan context for two main reasons: (1) we sampled health centers at different stages of e-Tracker use, ranging from low to high, and (2) we included all users of the e-Tracker (immunization nurses, data managers, and supervisors).

Most studies that have applied the HOT-Fit framework have used quantitative methods to evaluate the effectiveness. We

chose qualitative methods to gain an in-depth understanding of user-reported barriers and opportunities for e-Tracker use [20]. Our research is aligned with the national health system priorities to improve data use in the immunization program [34]. Key stakeholders, including representatives from the Ministry of Health and the Rwanda Biomedical Center, were involved at every stage of the research. They were consulted and presented with the study plan and results.

Study Limitations

This study has some limitations. The study was conducted in 2021, after a relatively short period of e-Tracker use by the health centers. Since the first introduction of the tool, some improvements have been implemented and these were not captured in our study. For example, nationwide linkages between the CRVS and immunization registry have recently been established and health workers providing immunization can retrieve information about the child from the CRVS. The COVID-19 pandemic and the subsequent restrictions in the years following the implementation of the e-Tracker may have affected training, use, and perceptions. Health workers from the immunization program (immunization nurses, data managers, and EPI supervisors) contributed immensely to the COVID-19 response, which may have affected their attitudes and perceptions toward their general workload and e-Tracker use.

Conclusions

The study findings revealed a low satisfaction level among the users of the immunization e-Tracker in Rwanda due to technical as well as implementation-related factors. Technical functionalities and implementation strategies co-designed with the user can help improve user experience and eventually maximize the benefits of the e-Tracker. Implementation strategies to reduce or remove dual documentation on paper and digital systems and to generate automated digital monthly immunization reports can save valuable time for health workers.

Acknowledgments

The authors thank the Ministry of Health and Rwanda Biomedical Center for their continued collaboration and facilitation of the research. They are also grateful to the participating health centers and the cooperation of study participants. They also acknowledge Michael Mugisha for his invaluable contribution to the conception and design of this research effort.

Abstract

Background: Given the dearth of resources to support rural public health practice, the solutions in health analytics for rural equity across the northwest dashboard (SHAREdash) was created to support rural county public health departments in northwestern United States with accessible and relevant data to identify and address health disparities in their jurisdictions. To ensure the development of useful dashboards, assessment of usability should occur at multiple stages throughout the system development life cycle. SHAREdash was refined via user-centered design methods, and upon completion, it is critical to evaluate the usability of SHAREdash.

Objective: This study aims to evaluate the usability of SHAREdash based on the system development lifecycle stage 3 evaluation goals of efficiency, satisfaction, and validity.

Methods: Public health professionals from rural health departments from Washington, Idaho, Oregon, and Alaska were enrolled in the usability study from January to April 2022. The web-based evaluation consisted of 2 think-aloud tasks and a semistructured qualitative interview. Think-aloud tasks assessed efficiency and effectiveness, and the interview investigated satisfaction and overall usability. Verbatim transcripts from the tasks and interviews were analyzed using directed content analysis.

Results: Of the 9 participants, all were female and most worked at a local health department (7/9, 78%). A mean of 10.1 (SD 1.4) clicks for task 1 (could be completed in 7 clicks) and 11.4 (SD 2.0) clicks for task 2 (could be completed in 9 clicks) were recorded. For both tasks, most participants required no prompting—89% (n=8) participants for task 1 and 67% (n=6) participants for task 2, respectively. For effectiveness, all participants were able to complete each task accurately and comprehensively. Overall, the participants were highly satisfied with the dashboard with everyone remarking on the utility of using it to support their work, particularly to compare their jurisdiction to others. Finally, half of the participants stated that the ability to share the graphs from the dashboard would be “extremely useful” for their work. The only aspect of the dashboard cited as problematic is the amount of missing data that was present, which was a constraint of the data available about rural jurisdictions.

Conclusions: Think-aloud tasks showed that the SHAREdash allows users to complete tasks efficiently. Overall, participants reported being very satisfied with the dashboard and provided multiple ways they planned to use it to support their work. The main usability issue identified was the lack of available data indicating the importance of addressing the ongoing issues of missing and fragmented public health data, particularly for rural communities.

Introduction

Data visualization dashboards developed to address health and equity have become increasingly popular [1,2]. Leveraging the longstanding history of using dashboards to aggregate and analyze data in public health [3] and medicine [4], these new dashboards cover myriad health equity-focused topics and target broad audiences. Recently, Thorpe and Gourevitch [5] identified 15 examples of US-based health dashboards that illustrate this growing trend. Examples range from a COVID-19 dashboard that highlights inequities in cases and deaths by geography to a policy dashboard that aggregates local laws and policies that affect population health [5]. Similar to these dashboards, the solutions in health analytics for rural equity across the northwest (SHARE-NW) dashboard (SHAREdash) was created to address health equity for rural communities.

Delivery and allocation of health services through public health agencies is a key mechanism for achieving health equity in the United States as they provide health prevention and promotion services and care [6]. Nationally, people in rural and frontier jurisdictions have significant health disparities compared with urban populations but are frequently the least well served by their public health agencies—local health departments (LHDs) [7,8]. Exacerbating this is the poor public health data systems, as updating to include information on structural and social factors has not been a top priority in LHDs' activities or spending [8,9]. Research has highlighted the critical need to improve timely and reliable population health data to inform resource allocation and decision-making [10-14]. Consequently, decisions regarding the delivery of public health services and care primarily rely on conventional wisdom. This results in services that frequently do not reflect the needs of the populations they serve resulting in wasteful, harmful, and inequitable inefficiencies that exacerbate existing disparities [15-17]. To address these issues and support LHDs serving rural areas, the goal of SHAREdash is to provide accessible and relevant data that will enable public health professionals to identify, communicate, and address health disparities in their jurisdictions and with their communities. Developed with user-centered participatory design methods and guided by Munzer's Nested Model for Visualization Design and Validation [18], SHAREdash is the first rigorously designed health equity dashboard developed for rural communities that we are aware of [19].

While clear objectives and thoughtful design are critical to ensuring the development of useful dashboards, Thorpe and Gourevitch [5] highlight the importance of evaluating dashboards and the need for a more rigorous assessment of the effectiveness and usefulness of health equity dashboards. Evaluating the performance of a dashboard through end user usability testing is a critical and often missed component of dashboard creation. The International Organization for

Standardization defines usability as “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specific context of use” [20,21]. Poor usability has been shown to increase errors [22-24], increase the time to complete tasks [25], and reduce user uptake [26-28] and implementation efforts [29].

Proper assessment of technology usability should occur at multiple stages throughout the system development lifecycle (SDLC) and use the methods most appropriate for that respective stage. In a review of usability study methodologies of health information technology by Yen and Bakken [30], the authors outline the importance of conducting multiple usability evaluations that align with the 5 stages of the SDLC. Furthermore, the Yen and Bakken [30] review clarifies the differences in usability evaluation types and goals based on the SDLC stage of the technology (Multimedia Appendix 1). Results from SHAREdash's usability testing for SDLC stages 1 and 2 have been previously published [10,19]. Stage 2 findings were used to make critical changes and inform dashboard completion. Now that SHAREdash is finished and has entered SDLC stage 3, we evaluated its usability by examining all components combined (ie, the finished dashboard). Thus, the aim of this study was to evaluate the SDLC stage 3 evaluation goals of efficiency, satisfaction, and validity for SHAREdash.

Methods

The SHARE-NW Project and Dashboard

SHARE-NW is a partnership research project that was created with the goal of making data available and accessible to rural LHD practitioners, while building their capacity for data use and data-driven decision-making [10]. Partnering with LHDs in Alaska, Idaho, Oregon, and Washington, 7 priority topic areas (obesity, diabetes, tobacco use, mental and behavioral health, violence and injury prevention, oral health, and demographics) were identified during stage 1 of the SDLC for SHAREdash [19]. Data for the dashboard come from 36 unique data sources, including national data from the Centers for Disease Control and Prevention as well as local agencies and health departments (Multimedia Appendix 2). Data were deemed relevant to be included in the dashboard if it (1) addressed 1 of the 7 priority areas and (2) was provided at the county level so that it would be relevant to LHDs. To ensure the dashboard is usable and relevant for users, its features (eg, dynamic filters, pop-up tooltips, and visualizations) were created in collaboration with the staff from partner LHDs during SDLC stage 2. SHARE-NW has also developed a curated repository of web-based trainings and webinars, including new training modules developed in 2021 and launched in 2022 when gaps were found in the related training desired by practitioners. The new training modules developed use problem-based learning to teach audiences how to use and communicate data to promote health equity.

After conducting a needs assessment with rural LHD professionals during SDLC stage 1 [10], members of the SHARE-NW team identified a set of initial design requirements for SHAREdash. These requirements guided design and development decisions that ranged from key decisions, such as the selection of the best software to create the dashboard, to smaller decisions such as which size font to use for a graph label. Together with the findings from the SDLC stage 2 usability study, SHAREdash was completed and launched in August 2021.

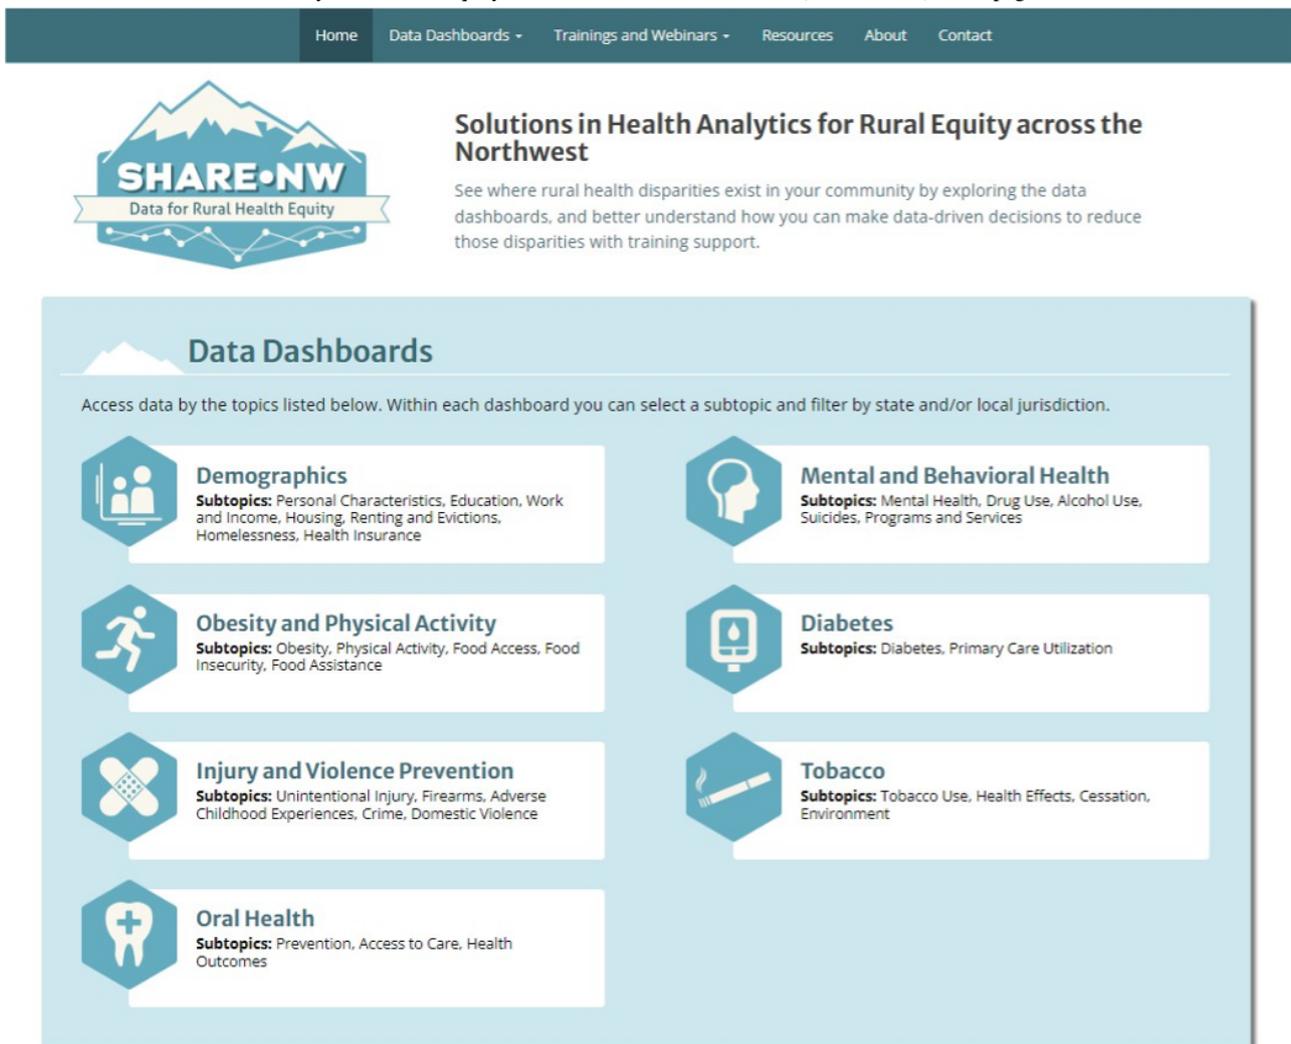

SHAREdash Website and Interface

SHAREdash is a Tableau-based dashboard with a header at the top of the main page for users to locate information about the project and team, access resources on relevant topics such as data, communication, and health equity, how to contact a member of the team, and find the dashboards organized by priority topic area. Users can also see relevant trainings and webinars (both via drop-down boxes) on SHAREdash’s main page. When users scroll down the main page, they can also find information on the website’s purpose and design and see the sources of data powering the website. The largest feature on the main page (Figure 1) links to the 7 dashboards on the priority topic areas mentioned previously [19]. Within each dashboard,

users can find state and county-level data organized by relevant subtopics. For example, the topic of “Tobacco” includes subtopics of “Tobacco use,” “Health effects,” “Cessation,” and “Environment.”

When users navigate to each of the main topics, they find a header that lists the main topic and each subtopic along the top, such that users can click through them. Within each subtopic, there are several drop-downs that allow users to filter the data. The primary drop-down prompts the user to “Select an Indicator.” Some examples of indicators for the topic of “Tobacco” and the subtopic of “Tobacco use” are as follows: “8th graders’ current tobacco use include Percent %,” “high school students who smoked tobacco in the past month: Percent %,” “Adults who currently smoke, Age-adjusted Percent %,” and “Current e-cigarette use: Percent %.” The remaining drop-downs allow users to filter the results by state, region, rurality (eg, rural or not rural), and jurisdiction types (eg, county). Users can export any of the dashboard views using the 3 options of export image, export to PDF, and share a link that is found along the top of the page. Along the bottom of each dashboard is the clickable link to view the data sources for this dashboard along with a statement explaining which data are listed as unavailable data within the dashboards.

Figure 1. The solutions in health analytics for rural equity across the northwest dashboard (SHAREdash) home page.

Study Setting and Participants

To evaluate this web-based dashboard, our study was conducted from January to April 2022. Participants were recruited from the states upon which SHAREdash was focused—Washington, Idaho, Alaska, and Oregon. All individuals who were rural public health professionals or trainees and had completed at least 1 prior SHARE-NW activity (2017-2022) and agreed to be contacted for future research activities (n=20). Prior SHARE-NW activities included the following: key informant interviews, interviews about the response to COVID-19, web-based surveys, dashboard mock-up testing sessions, dashboard usability testing activities, and group-based dashboard live training sessions. This ensured that all participants met the eligibility criteria of being at least 18 years old, working in public health for at least a year, and were in 1 of the 4 northwest states included in SHAREdash. Given public health differences by state, recruitment efforts ensured that at least 3 of the states were represented. Recruitment of this convenience sample had no additional inclusion or exclusion criteria.

Ethical Considerations

The University of Washington's institutional review board (IRB) approved the study protocol before participant recruitment (STUDY00013451). This study's IRB was approved as a modification to an original approval (MOD00011747; approved on December 13, 2021).

An initial recruitment email briefly summarizing the study purpose was sent to all prior participants in SHARE-NW activities. A follow-up recruitment email was sent 2 weeks after the initial email. The response rate for recruitment was 45% (n=9) with 1 person stating that they did not want to participate and the remaining 10 people not responding. Individuals who expressed interest were sent an email with information about the study, consent to participate, and instructions on scheduling their interview. Dashboard evaluation sessions consisted of 2 think-aloud tasks [31] and open-ended interview questions [32] regarding the participant's occupation and perceptions of the dashboard (Multimedia Appendices 3 and 4). Recruitment stopped when the following metrics were reached: (1) alignment with the published literature on the minimum number of participants needed to identify usability issues [33] and (2) when data saturation was reached. Given how stretched our public health partners were from the COVID-19 pandemic, the study team was cautious to not overburden them with study participation requests.

The think-aloud tasks served 2 purposes—the first was to refamiliarize the participant with SHAREdash and the second was to examine the usability components of effectiveness and efficiency. The first think-aloud task had the participant complete a simple task that consisted of switching between different subtopics, filtering for the participant's county, and changing the time frame being viewed. The second, more complex task included navigating to the right topic, filtering for a specific health outcome type, year, and rate, and identifying the original sources of the data being viewed. During testing, the moderator prompted participants to “think aloud” that is, verbalize their thoughts as they worked through the task. Following the tasks, the participants completed qualitative

interviews that asked participants for their perceptions regarding SHAREdash's efficiency, validity, and satisfaction. The semistructured interview guide included questions that asked about the design aesthetics and functionality of SHAREdash, how quickly they are able to perform tasks, and the benefits and issues with using SHAREdash. The evaluation sessions were completed and recorded via a videoconferencing platform since screen sharing was needed for the 2 think-aloud task evaluations. Transcripts were automatically generated by the videoconferencing platform and stored securely in a password-protected cloud-based repository. A member of the research team deidentified and corrected any errors in the verbatim transcripts prior to analysis.

Recruitment and Data Collection

Think-Aloud Task Analysis

Operational definitions of the outcomes align with the International Organization for Standardization definitions of efficiency, satisfaction, and validity [34]. Efficiency and validity were primarily evaluated through the think-aloud tasks. The number of clicks taken to complete the task indicated efficiency and data on the participants' success of task completion were operationalized as “yes” (eg, no assistance needed), “no” (eg, assistance needed), or “partial” (eg, where the moderator confirms participant choices as either correct or incorrect but offers no other assistance) which indicated validity. Task 1 could be completed in a minimum of 7 clicks and task 2 could be done in 9 clicks. Transcripts were automatically generated and edited by a member of the research team for accuracy. Descriptive statistics were used to analyze the data and was completed in Excel. Quotes from the think-aloud tasks were analyzed to evaluate common efficiency issues, examine overall satisfaction, and assess validity. A control arm was not used in this study based on prior work that identified the inability of participants to complete these tasks without SHAREdash [10,19].

Qualitative Analysis

Data analysis of qualitative interview transcripts started with a directed, deductive approach to content analysis that was guided by a codebook comprising the initial codes of efficiency, satisfaction, and validity [35]. From this initial schema, iterative coding categories emerged as themes were developed. Coding was performed in NVivo (Lumivero) to organize data and provide an audit trail. Our interdisciplinary team of researchers met for an initial 90-minute collaborative coding session to talk through coding procedures and develop consensus for initial categories. Subsequent coding was performed independently with researchers meeting for 60-minute coding meetings to discuss categories and resolve discrepancies. Procedures for ensuring credibility, transferability, dependability, and confirmability were incorporated throughout the research process to ensure data trustworthiness. These procedures included taking field notes, team debriefing, reflexive journaling, consideration of negative cases, and maintenance of an audit trail. Data saturation was reached with researchers initially identifying the potential for saturation after the sixth participant interview and later confirming it with the ninth and final participant.

Results

Overview

Interviews lasting an average of 21 (SD 5.4) minutes were conducted between January and April 2022. Of the 9 public health practitioners interviewed, 4 were from Idaho, 3 were from Oregon, and 2 were from Washington (Table 1).

Participants all identified as female, and the majority worked for health departments (n=8). Job positions included a director (n=2), managers (n=2), program specialists/coordinators (n=3), an epidemiologist (n=1), and a student/public health intern (n=1). Prior experience with Tableau was minimal with the majority (7/9, 78%) reporting less than 3 months experience to no experience.

Table 1. Demographics of dashboard evaluation participants (N=9).

Characteristic	Values, n (%)
State	
Idaho	4 (44)
Oregon	3 (33)
Washington	2 (22)
Organization type	
Local health department	7 (78)
State health department	1 (11)
Educational institution	1 (11)
Position	
Director	2 (22)
Coordinator	2 (22)
Manager	2 (22)
Other	3 (33)
Tableau experience	
0-3 months	7 (78)
>3 months	1 (11)
Not reported	1 (11)
Sex	
Female	9 (100)
Ethnicity	
Not reported	5 (56)

Think-Aloud Task Results

For efficiency, mean clicks were 10.1 (SD 1.4) for task 1 (with a minimum of 7 clicks) and 11.4 (SD 2.0) for task 2 (with a minimum of 9 clicks; Table 2). For task 1, extra clicks occurred when people tried to find the right place to filter for the correct dashboard page. One participant (participant 9) required partial assistance with one of the steps in the first task. They initially thought to navigate to the default subtopic of “Personal Characteristics” instead of the correct subtopic “Homelessness” in the “Demographics” dashboard. Although only 1 participant required assistance with this step, many participants took extra time with it. For task 2, extra clicks resulted from people looking

for the sources of the data, which were located at the footer of each dashboard. Most participants were able to find the “View Data Sources” button easily because of the dashboard’s instructions or because it was where they expected it based on their prior experience. However, 3 participants noted that they naturally scrolled to the bottom of the dashboard looking for it but confused the “Resources” button with the “View Data Sources” button. This issue not only resulted in extra clicks but also was the point where these participants required confirmation by the moderator to continue. Of the 3 participants, 2 who had this issue stated that they were confused because they expected the data sources to be in a clickable pop-up or an in-text citation, rather than loading onto a separate page.

Table 2. Efficiency task analysis results (N=9).

Task type	Task 1	Task 2
Efficiency		
Clicks, mean (SD)	10.1 (1.4)	11.4 (2.0)
Clicks, median (IQR)	10.5 (9.0-11.0)	11.0 (9.5-12.8)
Validity, n (%)		
Successful	8 (89)	6 (67)
Partial	1 (11)	3 (33)
Not successful	0 (0)	0 (0)

Validity scores for both tasks were high with all participants (n=9) able to complete each task accurately and comprehensively. Most participants received a “yes” indicating that they did not require any prompting—89% (n=8) participants for task 1 and 67% (n=6) participants for task 2. For participants who did not receive a score of “yes,” they only required the moderator to either confirm or deny their decisions prior to moving on, resulting in a score of “partial.” None of the participants received a “no,” indicating they could not finish the tasks.

Qualitative Results

The following 4 themes regarding efficiency were identified: “using the best terms and names to increase efficiency,” “drop-down filters reduce efficiency,” “minor navigation issues affect efficiency,” and “learnability will increase efficiency over time”. The primary issue that came up in the think-aloud tasks and the interviews was related to the dashboard labels and names that informed the theme of “using the best terms and names to increase efficiency.” Multiple participants brought up the term “jurisdiction” and pointed out that it is less intuitive than the word “county.” “I think ‘jurisdictions’ is obviously not wrong; it just would be a little bit more user-friendly to label it ‘county’” (participant 1). Similarly, as identified in the second task analysis, 2 participants found the “Resources” button confusing and suggested renaming it to something more specific to mitigate this confusion.

For the second theme of “drop-down filters reduce efficiency,” participants described how the functionality of the filters was difficult to navigate between some options due to the length of the drop-down boxes. For example, filtering to examine a single county requires users to search down a long drop-down list for the exact county they are looking for. Participants described this by saying, “Maybe it would be a nice feature to be able to type in a county versus the drop-down box or having to—well I guess you can ‘select all’ so you don’t have to go through and click them all to select, but just those little things might make it easier” [participant 4]. Another participant described how they expected the interface to be like other software they are used to using such that it allows users to enter free text into a search bar and then, “...when you start typing things it only picks the things that match it” (participant 8).

For the third theme of “minor navigation issues affect efficiency,” a few participants had difficulty locating the various subtopics within a dashboard, despite them being listed

underneath each dashboard topic. For example, 1 participant looked for the “homelessness” indicator under the wrong subtopic.

I was initially thinking, ‘Oh ‘Homelessness’ must be in one of these drop downs, because it was listed as a subtopic,’ but then I glanced across the screen, and—you know—I saw ‘Homelessness’ up in this corner [with the other subtopics]. [participant 2]

Similarly, 3 participants eventually correctly identified that “Demographics” was the dashboard where they would find homelessness data, but they initially looked for the “homelessness” indicator under the “Housing” subtopic instead of the “Homelessness” subtopic. A participant suggested ways that the design of SHAREdash could be updated to more clearly indicate the subtopics.

I would think that [the indicator] is definitely going to be in Oral Health. It took a bit when I first looked at [SHAREdash] to realize that there were tabs (e.g., different subtopics). I think the size of the font and the fact that they are the same color as the bar makes it, so they are not standing out. [participant 1]

These design suggestions were checked with some subsequent participants who agreed that changing the font size and color would help the subtopics stand out.

For the final theme of “learnability will increase efficiency over time,” participants spoke about how quickly they were able to figure things out in SHAREdash and reported that with repeated use they thought they would quickly improve over time. Half of the participants stated that first-use learnability was high such that SHAREdash was easy to use the first time they tried. “I would say that there’s not a lot of websites out there, where you can pick up on things that quickly. So, I immediately don’t have any areas for improvement” [participant 2]. Whereas the remaining half of the participants stated that they felt like they would get progressively better at using SHAREdash over time.

The following 3 themes related to overall satisfaction were identified: “high potential to support work,” “enables meaningful comparisons,” and “needs more up-to-date data.” For the theme of “high potential to support work,” participants spoke positively about how much they liked SHAREdash and the myriad ways they could use SHAREdash’s various features to support their work. One-third of the participants mentioned how unique and helpful it was to have the ability to export and share graphs.

I think it has a lot of features that aren't necessarily easily found [in other dashboards]...blowing it [SHAREdash] up to full screen, downloading it, sharing it—that's not necessarily common with dashboards, so I appreciate that...It could be really useful for like a grant application or demographic reporting for part of a program. [participant 5]

Two participants mentioned that they might direct others to the dashboard so they could interact with data, and this was described as something that would be “extremely useful” and “super helpful” in their work. Finally, several participants identified specific types of work that SHAREdash would meaningfully support such as completing community health assessments:

We would definitely want to look at this in relation to the approach that we took with our CHA [community health assessment]. Most recently, I was trying to mine all of the data sources that are already in existence to inform it and see where some gaps were, and then we did primary data seeking based off those gaps instead of trying to reproduce data that's already in existence. And so, this [SHAREdash] would be a really great one-stop-shop to look at a lot of different ones at one time. [participant 2]

I think it is already something that's on our radar when we talk about this CHA [community health assessment] that I mentioned. So, we're not here to duplicate efforts; let's use what's out there. And so, we'll probably refer to it [SHAREdash] for that. [participant 5]

For the theme of “enables meaningful comparisons,” all but 2 participants reported that they were highly satisfied with SHAREdash and cited the ability to compare their county or region with other neighboring or similar counties in different states as the reason why. Multiple participants stated they wanted to look at counties in nearby states given their close proximity and described how SHAREdash fills this gap since states do not typically share data with one another.

Being able to look at data kind of in the same place and say ‘Oh, what does your county look like?’ You know, which borders us in Oregon, but borders like three of the counties that I oversee. So, what's happening in their county? I can look that up and see if we're seeing similar trends, and the three counties that border that county. So having that originality, I think, is great and is probably a reason that I would go to the website to look at that at some point, or my team would. [participant 9]

It is nice that it includes multiple states, because we are border county in our state, and so a lot of times things that we see are only for Oregon. But we're right next to a couple of Washington counties and it would be great to, you know, compare in that manner as well...It's always really helpful when we can look at, you know, what is our information compared to our neighboring counties, what does our data look

like compared to counties of similar size. [participant 2]

I like that you can see a big picture, regionally. So not necessarily just like other counties in Idaho: being able to prepare to other regional and other states and perhaps similar geographic demographic areas that are comparable, but in different states kind of just to see what trends are like there comparatively. [participant 4]

The third theme of “needs more up-to-date data” described the biggest challenge that participants identified to their overall satisfaction with SHAREdash.

I think just what I commented on already is the age of the data that is present. So, it is very difficult to make a decision on data that's extremely outdated. And it's hard to make it relevant to your case. And I know that data can be hard to gather and hard to access, but for those of us who are looking at data to make decisions, that complicates that entire scenario. You want us to use data to make decisions, we need good data to make those decisions. Somebody has to put the data out. [participant 6]

Several participants acknowledged that none or out-of-date data are typical within public health, particularly for rural areas. “We're used to that, so I think for us that's not a missed expectation to click on it and be like ‘Oh, there's not any new data.’...That for us, that's normal” [participant 2]. However, this is a clear barrier to satisfaction and future use of SHAREdash.

There were 2 themes identified on validity called “reputable data sources increases validity” and “impact of missing data decreases validity.” Participants spoke about the second theme of “reputable data sources increases validity” by describing their confidence in the data quality and accuracy. A participant described this by stating that, “SHAREdash is a really amazing place to quickly get domestic violence rates across other states. And you can find the source easily. And it is a reputable source too” [participant 1].

Whereas, another participant emphasized more than just the high quality of the data sources, but also the fact that SHAREdash's team provided a second, external check on it:

So I think this is a great dashboard and it's so nice because part of my job is to pull [data] from all of these different data sources which I know SHARE has done, and it's been validated and checked and it's a combination of information from various places which is good to have. [participant 3]

For the “impact of missing data decreases validity” theme, task 1 had participants refined the population of interest to their specific county, which for some participants resulted in SHAREdash indicating that there were no data for their respective county available. Participants described how missing data in the dashboard impacted their ability to completely address the tasks in the think-aloud evaluation and how it would impact their work.

I think one of my biggest challenges, and it tends to be a challenge everywhere not just like solely for the dashboards, is that a lot of times when there were things I wanted to look at and there wasn't any data available because our population isn't that big. [participant 8]

Despite multiple participants acknowledging that problems with data availability for rural areas is a known issue and is not a fault of the dashboard, they still expressed frustration and dissatisfaction about this issue.

I was bummed when it didn't have the data that I was looking for. But like I said, it's probably just a result of that data not being available. [participant 4]

Discussion

Principal Findings

This SDLC stage 3 usability evaluation of SHAREdash, a dashboard designed for rural public health, indicates that overall SHAREdash is an efficient and valid tool that users reported being satisfied with. Task analyses and qualitative findings illustrate how SHAREdash's collaborative co-design process resulted in a tool that is easy to use and supports rural public health professionals' work. Thematic results also identified areas where SHAREdash can be improved to increase its usability such as changing some of the terms and names used and considering alternate ways for users to view and select information that are not just drop-down filters. However, this evaluation also uncovered usability issues related to the lack of public health data that go beyond design aspects and cannot be addressed through modifying SHAREdash's interface or navigation.

Issues related to obtaining quality public health data are well documented in the literature and include the critical problems of a lack of investment in public health data systems and infrastructure [36-39], issues with data quality [40-42] and data fragmentation [43,44], and the sparse data available about rural communities [8,45]. While every effort was made to include as much timely and comprehensive data as possible in SHAREdash, these larger data problems clearly impacted the usability of this tool. Thus, returning to the question posed by Thorpe and Gourevitch [5] regarding whether or not data dashboards for advancing health and equity are fulfilling their promise, findings from our study show that, to fully realize the potential of health equity-focused dashboards substantial investments in public health data need to be made. Unlike health care which benefited from the 2009 Health Information Technology for Economic and Clinical Health Act that supported the adoption of meaningful use of electronic health records [46,47], other systems, such as public health and social services, were not included in these incentives resulting in the numerous data issues seen today. The need for investments in public health data and systems was further clarified and reinforced by the COVID-19 pandemic which magnified many of these ongoing challenges [38,45,48]. To address this urgent problem, supportive policies that fund public health data collection and systems should leverage the successes of the Health Information Technology for Economic and Clinical

Health Act and learn from the opportunities to address and alleviate these issues.

Another key finding from this study is also related to data. All the participants emphasized the significance of the trustworthiness of the data in SHAREdash. These results align with prior literature that has articulated the dual importance of dashboards to use data from reputable sources and clearly display or link to original data sources [49]. In a 2020 study by Young and Kitchin [50] that examined user perspectives of 4 different city's dashboards to create design guidelines, the authors stipulate how critical the veracity (eg, accuracy, source, and age) of the included data is. Our findings reinforce this work and indicate the utility of their design guidelines for creating data dashboards of municipal data. Future dashboards of municipal data should use the guidelines provided by Young and Kitchin [50] in the early design and development stages and work with target users to refine them for their specific project needs.

Satisfaction with SHAREdash was high with most participants describing the usefulness of the dashboard in supporting their work. Almost all the participants reported that they would like to make local-level comparisons that cross their respective states and articulated how difficult this currently is. Participants reported how comparisons between counties across different states can be more meaningful than within if they are able to filter for key factors such as population size or number of services available and how helpful it is that SHAREdash facilitates this easily. Enabling such comparisons points to the importance of aggregating large amounts of data across states, particularly for rural health departments that have unique needs and face different challenges than their urban counterparts [51]. It also indicates the importance of continuing to elucidate the unique needs of rural public health. Future research should focus on rural public health so that tailored design guidelines and specialized tools can be developed to support their work in addressing health disparities.

Our SDLC stage 3 usability assessment indicated that SHAREdash is meeting the goal of providing accurate, accessible, and relevant data via a user-centered dashboard to address health equity for rural communities. Next steps for SHAREdash will focus on identifying the elements key to its integration into LHDs using an implementation science approach that is outlined in stage 4 of the SDLC [30]. Planning for this phase is underway and is working closely with future end users to proactively identify and understand barriers to integration as this was a clear lesson learned from a similar study implementing an ICU dashboard [52]. Furthermore, investing in efforts to understand what is needed to support the uptake of health equity-focused dashboards in public health practice is critical to ensuring their impact [5] and aligns with previously identified public health research priorities [53-55] that highlights the importance of using implementation science to translate and assess innovations into public health practice to ensure reach. It is hoped that through the user-centered development and thoughtful translation of informatics, tools such as SHAREdash will address the existing health disparities and improve rural health equity.

Limitations

While our methods were rigorous, this study has limitations. Despite reaching data saturation, the sample size is small, consisting of all female-identifying participants, and limited to the northwest United States. Of note, the public health workforce is 79% women [56], which made diversity by sex difficult to obtain. Future studies would benefit from a larger and broader sample. Additionally, the think-aloud task analysis did not have a control arm where participants completed the tasks without SHAREdash to provide a comparison. Finally, while aligned with the SLC stage 3 usability evaluation components, this study did not examine other aspects of usability that are outlined in the literature, and thus, might have missed certain usability aspects [57].

Conclusions

Evaluating the usability of health equity dashboards is crucial to creating effective and valuable tools. Our findings indicate that SHAREdash, a public health dashboard created to support promoting health equity among rural communities, is an efficient, valid tool that overall users are satisfied with. Results strongly suggest that the utility of dashboards such as SHAREdash would be improved with the availability of more public health data and supportive policies to achieve robust collection of public health data would be beneficial. Future research should continue to focus on building tools that meet the unique needs of professionals working in rural public health to better support and equip them to alleviate rural health disparities.

Acknowledgments

This work was funded by the Department of Health and Human Services, Office of the Assistant Secretary for Health (grant #1 CPIMP171144-01-00). We would like to thank the public health professionals who participated in this study; the SHARE-NW team members who are not authors of this paper for their contributions to this project; and the SHARE-NW Equity Advisory Committee members for their expertise and guidance.

Abstract

Background: Mental health conditions are a significant public health problem globally, responsible for >8 million deaths per year. In addition, they lead to lost productivity, exacerbate physical illness, and are associated with stigma and human rights violations. Uganda, like many low- and middle-income countries, faces a massive treatment gap for mental health conditions, and numerous sociocultural challenges exacerbate the burden of mental health conditions.

Objective: This study aims to describe the development and formative evaluation of a digital health intervention for improving access to mental health care in Uganda.

Methods: This qualitative study used user-centered design and design science research principles. Stakeholders, including patients, caregivers, mental health care providers, and implementation experts (N=65), participated in focus group discussions in which we explored participants' experience of mental illness and mental health care, experience with digital interventions, and opinions about a proposed digital mental health service. Data were analyzed using the Consolidated Framework for Implementation Research to derive requirements for the digital solution, which was iteratively cocreated with users and piloted.

Results: Several challenges were identified, including a severe shortage of mental health facilities, unmet mental health information needs, heavy burden of caregiving, financial challenges, stigma, and negative beliefs related to mental health. Participants' enthusiasm about digital solutions as a feasible, acceptable, and convenient method for accessing mental health services was also revealed, along with recommendations to make the service user-friendly, affordable, and available 24×7 and to ensure anonymity. A hospital call center service was developed to provide mental health information and advice in 2 languages through interactive voice response and live calls with health care professionals and peer support workers (recovering patients). In the 4 months after launch, 456 calls, from 236 unique numbers, were made to the system, of which 99 (21.7%) calls went to voicemails (out-of-office hours). Of the remaining 357 calls, 80 (22.4%) calls stopped at the interactive voice response, 231 (64.7%) calls were answered by call agents, and 22 (6.2%) calls were not answered. User feedback was positive, with callers appreciating the inclusion of peer support workers who share their recovery journeys. However, some participant recommendations

(eg, adding video call options) or individualized needs (eg, prescriptions) could not be accommodated due to resource limitations or technical feasibility.

Conclusions: This study demonstrates a systematic and theory-driven approach to developing contextually appropriate digital solutions for improving mental health care in Uganda and similar contexts. The positive reception of the implemented service underscores its potential impact. Future research should address the identified limitations and evaluate clinical outcomes of long-term adoption.

Introduction

Mental health conditions are an important public health issue globally, responsible for >8 million deaths per year [1-5]. Three million people die annually from the harmful use of alcohol, and 1 person dies every 40 seconds by suicide [1,2]. An estimated 970.1 million people (12.6% of the global population) experience some form of mental health problem [4]. Mental health conditions account for 5% of the global disability-adjusted life years and 12% to 20% of years lived with disability [4,6]. People with mental health conditions, on average, die 20 years prematurely [4,6] both due to mental as well as physical illnesses because mental health conditions are a risk factor for, or can complicate, physical illnesses, including physical injury and road traffic accidents, HIV or AIDS, cardiovascular diseases, and cancer [5,7]. People with mental health conditions also experience severe human rights violations, stigma, discrimination, abuse, and generally poor socioeconomic status [5,7-9].

Unfortunately, >75% of people with mental health problems do not have access to the care they need [1-3]. This is especially true for Uganda [10,11] and similar low- and middle-income countries (LMICs) where the treatment gap for mental disorders reaches 90% [12-14]. It is estimated that the ratio of mental health workers to population is 200 times smaller in LMICs compared with the high-income countries [3]. In LMICs, mental health is underprioritized in the face of other competing public health challenges such as HIV and AIDS, tuberculosis, malaria, and maternal and child health. Uganda, for example, spends 9.8% of its gross domestic product on health care, but <1% of this goes toward mental health care [10,11]. Consequently, Uganda experiences a shortage of mental health care facilities and professionals and poor and inconsistent access to medication and related mental health services [11]. In addition, most of the health workforce is limited to urban areas, yet >80% of the population lives in rural areas, thus geographically isolated from even the limited care available. Other important challenges facing mental health in Uganda include social norms [15], beliefs (such as witchcraft), lack of awareness of mental health disorders [8,11,16], pervasive stigma, and sociopolitical conflicts [13,17]; these not only result in an increase in the incidence of mental health problems but also lead to many people with mental health problems not seeking care and going undiagnosed.

To address some of the abovementioned challenges and improve access to mental health services in Uganda, we implemented the project *digitalizing mental health care and access in Uganda*. In this project, we followed a user-centered design (UCD) and a cocreation process to set up a hospital call center service to provide mental health information and advice to patients, caregivers, and the general public. This paper aimed to describe the development and formative evaluation of this mental health call center service.

Methods

Ethical Considerations

Ethical approval for the research study was obtained from the Makerere University School of Public Health research ethics committee (#SPH-2021-153) and the Uganda National Council of Science and Technology (#HS1868ES). All participants provided written informed consent before participating in the study activities.

Study Design

We conducted a qualitative case study using the principles of UCD [18-20] and design science research (DSR) [21,22]. UCD focuses on understanding and prioritizing the needs, preferences, and behavior of end users of a product throughout its development life cycle. UCD, therefore, calls for iterative and collaborative engagement of users to ensure high usability and utility of the product. DSR is a structured approach to creating and evaluating innovative solutions or artifacts, where the design process is treated as research that contributes to knowledge for improving the functional performance of artifacts. The steps involved in DSR mirror UCD and include the following: (1) identifying the problem and motivation (understanding user experiences and context of use); (2) defining the objective of the solution (specifying the requirements); (3) designing and development of (often novel) solutions using participatory or cocreation processes; and (4) demonstrating and evaluating the solutions to validate against requirements, assess usability, and long-term adoption. These steps help identify the facilitators and barriers of adoption so that they can be addressed early on in the project life cycle, allow user engagement and facilitate buy-in, ensure that the product fits the context of use and purpose, and has good usability [23,24] and clinical utility [25].

In the following sections, we describe each of the above 4 steps. Note that there was overlap and iterations over the steps as per the UCD best practice. To ease readability, we report the procedure and results from each step. Thereafter, we provide a general discussion and conclusion.

Step 1: Understanding User Experiences and Context to Identify the Problems

Participants and Recruitment

The participants included adults (≥ 18 years), patients recovering from mental disorders, caregivers of such patients, peer support workers (PSWs), mental health care providers, and persons involved in the implementation of call centers for telecoms or other health care centers. The health care providers, patients, caregivers, and PSWs were recruited from the Butabika National Mental Referral Hospital in Kampala, Uganda, which is also the site of implementation. Sampling was purposive to include different cadres and expertise of providers (informed by the third author, who is the head of Butabika Hospital) and to represent different mental health conditions, levels of education, and socioeconomic status of patients and caregivers to get diversity of experiences and views. The investigators (JKK, JN, and VK) physically approached the health care providers at Butabika Hospital, explained the project's purpose and the research activities involved (including participation in multiple group discussions and workshops), and obtained consent from those interested. These health care providers then reached out to patients under their care, caregivers, and PSWs; provided them with information about the study; and invited those interested for consent by the investigators, who explained the participants' rights and voluntary nature of participation. Participants in the last stakeholder category were recruited through the network of the first author who works in the digital health field in Uganda.

Data Collection

We conducted semistructured focus group discussions (FGDs) in which we explored participants' experience of mental illness and mental health care in Uganda (including unmet information and supportive care needs); experience with call center services from the commercial service sector or other digital health care services; and opinions about a proposed digital mental health service (ie, feasibility, appropriateness, expected benefits, or recommendations for successful implementation). The FGD guide is shown in [Textbox 1](#). There was flexibility in the order of the probes to allow free flow of ideas, with additional probes for clarification added by moderators as issues of interest arose. In addition, certain issues or probes were discussed in detail, paraphrased, or left out as appropriate depending on relevance

to the session participant or if such a topic had been sufficiently explored in the prior sessions.

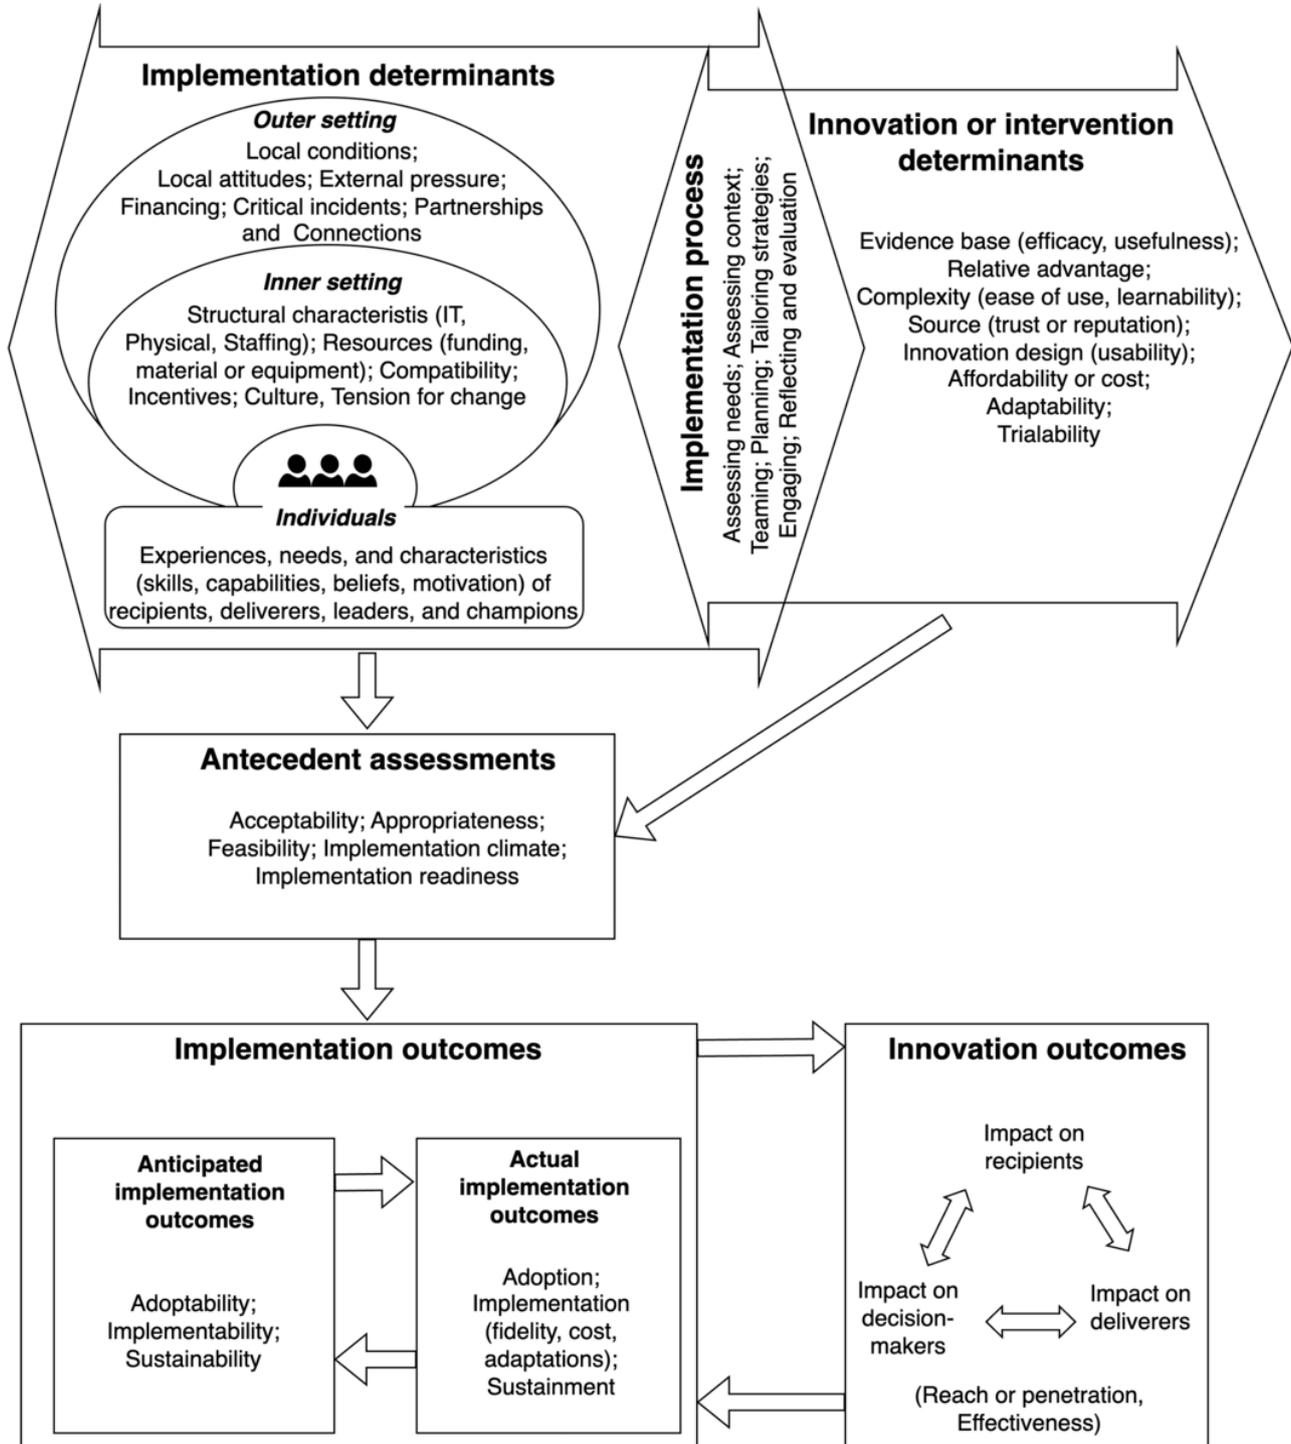

The sessions were conducted in English and Luganda (the lingua franca in Uganda) as appropriate for the participant category. In addition, we held male-only and female-only FGD sessions for patients to reduce the possibility that some participants would overshadow others during the discussion, but other sessions were mixed to ensure rich discussions since diverse viewpoints from different participants inspire others and spur discussion. The first and fourth authors (JKK and VK) were the moderators, while the second author (RN) was a notetaker. The sessions were audio recorded and later transcribed by the second author, who also translated the sessions in Luganda into English for analysis. The FGDs took place in November 2021.

We drew on the Consolidated Framework for Implementation Research (CFIR) [26] to inform data collection (and analysis; see the *Data Analysis* section). The CFIR is a *metatheoretical framework* developed by consolidating several implementation science theories into one comprehensive taxonomy of clearly defined, nonoverlapping constructs related to disseminating and implementing evidence-based interventions. These constructs fall into five domains: (1) the individuals affected or involved in the implementation, (2) the innovation (intervention), (3) the inner setting (organization) where the innovation is implemented, (4) the outer setting (wider societal context), and (5) the process of implementation. The CFIR is one of the most widely used theoretical frameworks to identify implementation barriers and facilitators (ie, a determinant framework) [27-31]. Following a literature review and feedback from researchers who have used the CFIR [29], a recent update, dubbed "CFIR 2.0," has been made, in addition to a CFIR outcomes addendum [32]. These updates have provided further clarification between constructs, including, for example, a distinction between "implementation determinants," which relate to the context, versus "innovation determinants," which relate to the characteristics of the innovation (eg, ease of use, relative advantage, cost, and efficacy of a technology). The implementation and innovation determinants inform the implementation process (needs assessment, user engagement, tailoring to user needs, incentives, marketing, etc) and moderate the anticipated and actual implementation outcomes through the antecedent assessments (tension or readiness for change, feasibility, acceptability, appropriateness, etc). The updates to the CFIR make it also useful for informing the design, implementation, and evaluation of innovations (ie, a process and evaluation framework) [30,31]. [Figure 1](#) shows an adaptation of the CFIR and its recent updates as used in this study [26,29,32].

Textbox 1. Focus group discussion guide.**Topic and questions or probes**

- Participants' understanding of mental health and mental problems
 - What is mental health, and what is mental health illness?
 - Do you know any forms of mental illness? What are the signs and symptoms?
 - What do you do with a person who has mental problems? What have you experienced? What is usually done, and what should be the correct thing to do?
 - Where can one get treatment? Probe about alternative healers, witchcraft, religious healers, etc
 - How are mental health or mental illnesses viewed in your community? Probe about stigma, myths, fear, and marginalization
- Mental health information, psychoeducation, and psychosocial support
 - What information about mental health problems or mental health care do you wish you knew early on in your mental illness journey?
 - What issues or topics do you think are the most important to address now? Are there any topics or issues that you still need information about? Give examples.
 - How or where do you get information about mental health and mental illnesses? Which ones are the best or preferred?
 - Tell us any challenges or limitations of these information sources.
 - Are there any services or persons that support you to cope with mental illness or care for your relatives with mental illness? Tell us more about these.
- Telemental health services
 - Tell us about your experience with interactive voice response (IVR) system or call centers: which industry or business? Any challenges and advantages? (moderator to explain IVR if participants do not know and can use the examples of telecoms or bank customer care lines to explain)
 - What are your thoughts on using such IVR systems for mental health information and care (telemental service)? Probes any experience of telemental health services, anticipated benefits, limitations, considerations on how to make it work, concerns about timing, phone ownership and access, privacy, etc. Probe for details and examples.
 - What are the likely barriers or facilitators for such a service?
 - Any thoughts about staffing and the role of peer support workers (PSWs)? Probe about acceptability to patients, benefit to PSWs, any anticipated challenges, and how to mitigate them.
 - Any other thoughts about using technology in mental health care?

Figure 1. The Consolidated Framework for Implementation Research (CFIR) used in this study [26,29,32].

Data Analysis

A directed (deductive) content analysis approach [33] was used. We began with a rapid qualitative analysis [34-36] of the FGDs in order to quickly identify the requirements and other insights needed to inform initial iterations of system development (see *Step 2: Specifying the Requirements of the System* section). Rapid qualitative analysis is aimed at getting actionable and targeted insights in a timely manner and is suitable for studies such as this one, where there is a need to refine and adapt an intervention or program, as opposed to developing new theories. A deductive approach is taken, using existing theories or

frameworks (in our case, the CFIR) to summarize the qualitative data into, for example, intervention characteristics or barriers and facilitators. In rapid qualitative research, data collection and analysis occur concurrently and iteratively, with findings from one phase informing the next iteration. The analysis is done not on the transcripts but on the summaries or notes taken during the FGDs or the audio recordings. In addition, multiple data collection methods are used to triangulate findings (eg, FGDs, field observations, debriefing, and reflections by the research team or other stakeholders and literature review). In our study, the rapid analysis was done by the first 4 authors (JKK, RN, JN, and VK) and involved note-taking during FGDs

and discussion and summarization of insights after each session. When necessary, recordings were listened to by researchers who, for example, was not present in the session before they contributed to the analysis or for validating the summaries. We summarized the findings into an initial list of mental health information topics to be covered by our system and design considerations (system requirements) based on the experiences and expectations of users, as well as contextual constraints.

Later, a traditional qualitative analysis was done [34-36]. The first and second authors (JKK and RN) independently read 1 of the 7 transcripts and extracted meaningful units or statements and coded them into themes related to the research objectives and the CFIR. They then met to discuss and refine the coding before independently coding the remaining transcripts. Three more meetings were held to compare and refine the coding, after which the findings were shared with all the authors for

discussion and interpretation. We focused on saliency [37] rather than frequency of issues and codes, such that even if an issue was mentioned once or by 1 participant category, we coded it as long as it related to the research question and CFIR constructs. As such, we did not count or rank the codes and themes. Basic Office software (Microsoft Corp) was used for coding and summarizing the qualitative data.

Results

Participants and FGD Sessions

We conducted 7 FGDs, each with 8-10 participants, for a total of 65 participants. The participants were fairly balanced by sex (female participants: 35/65, 54%; male participants: 30/65, 46%), and their ages ranged from 21 to 64 years, with a median of 40, IQR 12 years). Each session lasted approximately 1.5 hours. Table 1 shows the details of the FGD sessions.

Table 1. Details of focus group discussion (FGD) sessions (N=65).

FGD session	Stakeholder category	Participants, n (%)	Sex	Language	Notes
1	Patients	10 (15)	Female	Luganda	Sessions in Luganda (the most commonly spoken local language) and separated males and females to ensure participants speak freely and not overshadowed by opposite sex. Diagnoses represented included bipolar affective disorder, schizophrenia, and psychosis.
2	Patients	8 (12)	Male	Luganda	— ^a
3	Caregivers	9 (14)	Mixed	English	Separate sessions in English and in Luganda to get opinions from participants of different education status (English is learned in school in Uganda and is proxy for education and socioeconomic status). Diagnoses represented included bipolar affective disorder, schizophrenia, psychosis, epilepsy, and alcohol and substance use disorder.
4	Caregivers	10 (15)	Mixed	Luganda	—
5	Health care providers	10 (15)	Mixed	English	Staff of Butabika Hospital involved in care for patients and community outreaches, including psychiatrists, psychologists, psychiatric nurses, and psychiatric clinical officers.
6	PSWs ^b	10 (15)	Mixed	English	Volunteers with lived experience of mental illness. They work with Butabika Hospital to share their personal experience and support and educate other patients. They receive small stipends from the hospital, patients they help, or projects and grants to facilitate their work. Diagnoses represented included bipolar affective disorder, schizophrenia, and psychosis.
7	Implementers	8 (12)	Mixed	English	Customer care for telecoms, developers of IVR ^c systems, and implementers of hospital call centers in HIV or AIDS and cancer, private telemedicine company (general care), and mental health NGOs ^d .

^aNot applicable.

^bPSW: peer support worker.

^cIVR: interactive voice response.

^dNGO: nongovernmental organization.

Findings From the FGDs

Multimedia Appendix 1 shows the qualitative findings, including the CFIR domains, constructs, themes, and their explanation. Multimedia Appendix 2 contains illustrative quotes.

Overall, 39 themes emerged across 20 CFIR constructs in all the 5 domains and the antecedent assessments. The themes recurred across the participant groups, supporting their validity. The themes under the *individuals domain* highlighted several challenges that people with mental health conditions in Uganda

face, including the limited number of mental health care facilities, long distances to care, lack of mental health information, stigma against patients with mental health problems and their families, financial challenges, and unmet psychosocial needs. The themes also covered contextual issues that explain these challenges. These included issues about the nature of mental illness (chronic and with a high burden of caregiving); organizational issues (*inner setting*), such as understaffing of mental health facilities and frequent medication stockouts; and societal issues (*outer setting*), such as beliefs and cultural norms (eg, belief in witchcraft), which influence how people understand mental health problems and how they seek care. Themes under the domain *innovation determinants* covered participants' perception or expected benefit from the proposed mental health call center service, including affordability; familiarity with similar services and the technology (ubiquitous access to mobile phones); convenience; time and cost saving; and anonymity offered by telephone services, which protect users from the stigma. Finally, themes in the *implementation process* domain encompassed mostly participants' recommendations or strategies for successful implementation, such as linkage with other stakeholders involved in mental health care, marketing of the service (sensitization), training and supervision of staff for quality control, and the need to maintain the human touch rather than attempting to digitalize or automate mental health care delivery. These findings suggested the feasibility, acceptability, and appropriateness of the proposed solution (*antecedent assessments*).

There were also several insights or implicit findings not mentioned by the FGD participants but inferred from observations and the research team's understanding of the context. These are relevant for the implementation and can be mapped to CFIR constructs. For example, there has been an increase in the adoption of telemedicine in Uganda, especially following the COVID-19 pandemic, which has given credibility to such innovations and can explain the general enthusiasm shown by the participants (CFIR construct "evidence base" in *innovation determinants*). In fact, the participants in the implementers' category were themselves involved in implementing call centers for HIV or AIDS, private telemedicine clinics, and mental health NGOs and were aware of the growing scientific evidence globally that supports digital health. The COVID-19 pandemic is also an example of "critical incidents" that can disrupt (or encourage) implementation and delivery of innovations (*outer setting*) according to CFIR 2.0. Other issues included the external project grant (construct: "Financing"), Uganda government's positive digital transformation strategies and policies (construct: "External pressure"), and the position of Butabika Hospital as a national referral that is supposed to be exemplary (construct: "Performance measurement pressure").

Step 2: Specifying the Requirements of the System

Procedure and Team

Requirements were specified based on the understanding of the users' needs, challenges, and contextual constraints from the FGDs. The development team consisted of the first 3 authors (a physician and digital health expert, a research nurse, and a senior consultant psychiatrist, respectively), as well as a psychologist, a psychiatric nurse, and an IT professional specializing in telephone systems. The first 2 authors and the IT professional have previously worked together to set up a similar system at the Uganda Cancer Institute [38] from which they also drew insights. The team held 8 web-based meetings from December 2021 to March 2022 to iteratively discuss the system features, content (mental health information), and setup considerations. We started with the initial list from the rapid qualitative analysis (see the *Data Analysis* section), which we refined to remove conflicting requirements or those that are not feasible due to available resources (eg, video telemedicine). We also agreed on the priority features and mental health information topics.

Results

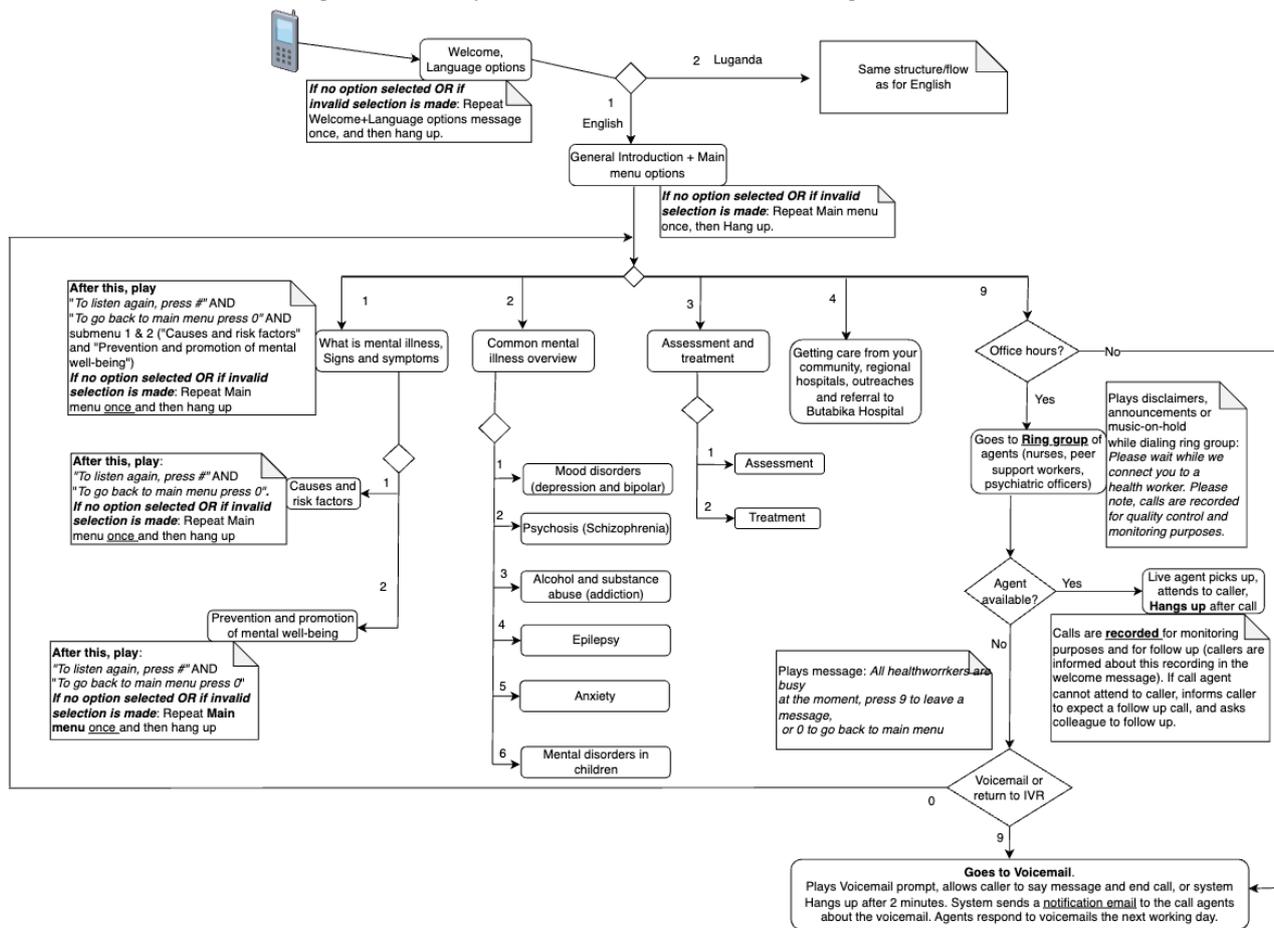

[Multimedia Appendix 3](#) lists the high-level requirements and how they were addressed in the system design and implementation. The key of these requirements is that the system or the intervention provides correct mental health information and psychosocial support in a culturally sensitive and nonstigmatizing manner and in multiple languages. In addition, the system should be easy to use (navigate), accessible 24×7, and affordable (free) to users; there should be no long queues; and it should fit within the workflow of the staff and not increase their workload. Finally, it should ensure privacy and confidentiality to users' information, and risks of harm to users should be minimized through quality control measures, training, and professionalism of staff.

Step 3: Design and Development of the System

Procedure and Team

We designed and developed a telephone system for providing mental health information and advice to callers as per the requirements ([Multimedia Appendix 3](#)). The system consists of 3 complimentary components or features: an interactive voice response (IVR), live calls, and voicemails. The IVR is the first component that users interact with, and since it is automated, it is available 24×7. It contains mental health information in audio format in English and Luganda. Callers get navigation instructions and choose from a menu of topics in a self-service manner by pressing the corresponding keys on their phones (eg, "Thank you for calling Butabika Hospital. Please choose your preferred language. For English, press 1, Bw'oba oyagala kuwuliriza mu Luganda, nyiga 2"). [Figure 2](#) shows the IVR flow and the topics covered.

Figure 2. Mental health information topics and how they are accessed in the interactive voice response (IVR).

From the IVR, callers can choose to speak directly (live call) with an agent, for example, to seek more clarification on information in the IVR or ask for information that is not covered by the IVR. If it is during office hours, the system connects the caller to the agent. We had a total of 8 agents comprising 2 PSWs, 1 psychologist, 2 psychiatric clinical officers, and 3 psychiatric nurses. The staff do not sit in a physical call center; rather, they are accessible via dedicated mobile phones. All their phones are dialed concurrently (“ring all” strategy), and whoever picks first responds to the caller. Outside working hours, callers are instructed by the system to leave a voicemail, and the call agents return the calls the next day; this is only possible from a softphone on a computer within the hospital since the caller’s number is hidden on the agents’ mobile phones for privacy reasons. All agents were encouraged to respond to the calls immediately, and a schedule was created for responding to voicemails. The psychologist provided supervision to the agents and handled any difficult cases, which the agents were encouraged to report or escalate whenever necessary.

Development of the system began by developing the IVR content (mental health messages and navigation instructions), which was done concurrently with the requirements specification process described in *Step 2: Specifying the Requirements of the System* section. The team iteratively wrote the script for mental health messages based on their clinical expertise, reviewed the Luganda translation, and discussed the IVR menu options and caller-system interaction based on the requirements and insights from prior work. We limited the IVR options to a manageable

number and organized the information in a logical order, that is, from general information (overview of mental illnesses) to specific information (eg, individual illness such as anxiety or depression). Attention was paid to ease of language (eg, description of concepts or illnesses in addition to naming them and reduction in use of medical jargon); tone (calm, empathic, and nonjudgmental); and cultural appropriateness (eg, acknowledging the role of faith and alternative medicine). The developed content was recorded in a professional audio recording studio and deployed in private branch exchange (PBX) software by the IT professional and the first author.

Results

The telephone system was implemented using Issabel (Issabel LLC), an open-source PBX software based on Asterisk (Sangoma Technologies Corp). It was deployed on a simple server (Intel Core i5 2.6 GHz, 8 GB RAM, 1-TB Hard disk) at Butabika Hospital and connected to a local mobile telecom provider via session initiation protocol with 12 trunks. The calls to the system are reverse billed and therefore are free to the callers.

In sum, we developed a total of 22 messages, 14 (64%) of which were on mental health or other practical information needs elicited from the participants, that is, overview of what mental illnesses are; the causes, signs, and symptoms; the common mental illnesses in Uganda; assessment and management of mental illness; and how to navigate the health care system. The remaining 8 (36%) messages contained navigation instructions

or feedback to user (welcome message, language selection, disclaimer, warning in case of emergency, the different menu options, invalid selection, message replay, returning to main menu, and voicemail instructions). The messages were then translated to Luganda for a total of 44 messages. [Figure 2](#) shows the topics addressed by the IVR messages (without some of the navigation messages).

Step 4: Demonstration and Evaluation

Procedure and Participants

Following deployment, we held a 1-day workshop with the PSWs, nurses, and psychiatric clinical officers (n=10) who had participated in the FGDs to test the system, get feedback about the IVR content, and identify and correct any system malfunctions or errors (eg, if there were language mix up or a wrong response for a particular IVR option chosen by the caller).

We held a second workshop to train the call agents on workflows, software system, and phone etiquettes and how to communicate with persons with mental health problems. We also discussed operational issues, for example, definition of office hours when live calls should be allowed, and schedules for returning voicemails and evaluation survey.

The system was advertised via the hospital website and social media channels, posters in the hospital, and personal contacts of the staff and participants. After go-live, we continued to supervise the call agents and held regular review meetings in which we listened to recorded calls and critiqued the conversations, offered support to the call agents (especially the PSW) in case of difficult calls, and collected feedback on usability and user perception of utility of the service.

Results

No major problems were found during the testing workshops, but participants reported that the workshops helped them better understand the service from practically trying it out. They showed enthusiasm for their roles as call agents and became ambassadors who advertised the service to patients and their social networks. Schedules were also drawn for returning calls and office hours defined, which were then programmed into the PBX, sending calls outside these hours to voicemail.

The system went live in August 2021. Detailed results from a survey of the callers and analysis of the use patterns will be reported in a separate study (under preparation), but here we summarize the observations from the first 4 months of operation.

From August to December 2022, a total of 456 calls, from 236 unique numbers (average of 4 calls per day), were made to the system, that is, reaching at least the IVR (automated) component. Of these, 99 (21.7%) calls were made during out-of-office hours for the call agents, so they went to voicemail and were called back within the following days. Of the remaining 357 calls made during office hours, 80 (22.4%) calls stopped at the IVR, while 231 (64.7%) proceeded to speak to a live agent (note that the percentages do not add up to 100% because some callers made multiple calls using the IVR or leaving a voicemail and later called and spoke to a live agent). Furthermore, the 22 (6.2%) calls were never answered by the

call agents. On average, live calls were answered within 11 (SD 7) seconds, and their average length was 3.5 (SD 2.8) minutes.

Callers came from all parts of the country (as far as 8 hours by road from Butabika Hospital), although the majority were from the central region (within a 1-hour distance from Butabika Hospital). They included caregivers seeking advice about relatives who were showing symptoms of mental illnesses or those already undergoing care; mental health patients who were relatively stable and were seeking advice about medication or return dates; and others such as clinicians from other health facilities, journalists, and government officials who wanted more information about the call center system or the mental health care services offered at Butabika Hospital. Calls about patients who had “escaped” from the hospital were also common, often made by concerned community members near the hospital who come across a person with mental illness wandering in the community. Generally, the service has been received positively. Callers were especially happy with the PSWs who shared their personal journeys with mental illnesses and recovery, and this encouraged them to overcome the stigma and negativity that they had about mental health care services. The PSWs also reported positive experiences, stating that working as call agents and helping others gave them a sense of purpose and brought order and calmness.

A key challenge was callers who required specific and individualized information that the call agents did not have at hand and could not be prerecorded in the IVR. Such information included requests for prescriptions, questions on stocks of certain medications, availability and cost of certain tests and procedures, or about the condition of a relative who was admitted in the hospital.

Reflexivity

The members of the research team who were involved in data collection and analysis (FGDs, workshops, and analysis meetings) are intimately familiar with the local context and understand participants’ realities (including participants’ access and use of mobile phones and the internet) since they come from the same region of the country and speak the local language (Luganda). This made it easier to communicate with the participants (even for sessions that were held in Luganda) and to understand and relate to the ideas or issues they raised. To reduce potential undue coercion, the clinicians involved in the care of the participants (patients and PSWs) did not participate in the FGDs sessions but participated in data analysis and interpretation. These clinicians were especially important in ensuring that the rest of the research team members were aware of assumptions and potential prejudices, for example, with regard to beliefs in witchcraft as a cause for mental illnesses or in faith healing, common among those with low education status. Clinicians working in mental health care in this context frequently encounter such beliefs and appreciate the importance of respecting them, which was also useful for informing how we crafted the mental health messages in the system. Moreover, 3 of the research team members were from a different high-income country and brought in different perspectives, which helped us question our interpretations and assumptions.

Discussion

Principal Findings

This paper describes the development and implementation of a digital health intervention aimed at improving mental health care in Uganda. Using principles of UCD [18-20] and DSR [21,22], we systematically engaged stakeholders, collected data on target users' experiences of mental health care, their opinions and recommendations about the proposed mental health telephone service, and contextual issues that could influence implementation. We used the CFIR, an established implementation science meta-framework [26-31], to collect and analyze these data and derive system requirements and then iteratively cocreated and tested the system.

We identified several challenges faced by patients with mental health problems and their caregivers in Uganda and peculiarities about the organization and the wider societal context, which supported the proposed innovation. These challenges included the severe shortage of mental health workers and services, lack of awareness, negative beliefs and norms, stigma, huge burden of caregiving, and financial challenges. At the same time, there is a general trend toward digitalization of health care to improve patient experience and efficiency of health care, and participants were enthusiastic about our proposed call center because they were familiar with the technology and considered it as a feasible, affordable, convenient, and efficient way to get mental health services without being stigmatized. The participants also gave several recommendations on how to successfully implement the intervention, for example, by making calls toll free, ensuring 24x7 availability, providing mental health information in multiple languages, using technologies or channels that are appropriate to the context (telephone calls and IVR), sufficient staffing to reducing call waiting times, sensitizing people about the service, and training and supervision of the call agents to ensure quality service. Early evaluation of the intervention shows that clients are very positive about the service, particularly with the use of PSWs (recovering patients) who share their lived experience with others.

Comparison With Prior Work

Prior research has demonstrated the value of mobile health (mHealth) in addressing some of the health care challenges in Uganda and similar contexts elsewhere. Systematic reviews on mHealth in general [39-45] or on specific clinical domains such as HIV or AIDS [45-47] and palliative care [48] have highlighted the improvement of health care coordination and communication between patients and health care providers, patient adherence to treatment and reduction of loss to follow-up, patient engagement and self-care, facilitation of community-based care, and improvement of access to care for rural or geographically isolated populations. Advantages such as ubiquity of mobile technology, affordability and acceptability by patients and health workers, interactivity and personalization, and saving of time and cost of traveling to health facilities have been cited. Examples of prior studies on mHealth in Uganda include use of IVR, SMS text messages, and phone calls to support the management of HIV or AIDS [49,50] and tuberculosis [51]; use of IVR to address barriers to fistula care

in Uganda [52]; SMS text messages for stroke rehabilitation [53]; and IVR for provision of cancer awareness and advice [38]. There is also a commercial digital health company that has operated different mHealth services in Uganda for approximately 10 years [54]. Unfortunately, the use of mHealth in mental health in Uganda and Africa in general is limited [8,55,56]. This is likely due to the general underfunding of mental health care services [10-14]. Available research on mHealth in mental health is mostly from developed countries [57-61], with many interventions using the internet and smartphone apps, which might not be accessible or affordable in Uganda or other LMICs. Interventions that use basic phone features such as SMS text messages, IVR, and voice calls are more appropriate in LMICs as they overcome infrastructural limitations. Such interventions are also relevant for low-income and migrant communities in developed countries since these populations face low digital health literacy and language barriers [62-65].

In the previous project led by the first author for the provision of cancer information [38], similar findings in terms of challenges faced by patients, requirements and recommendations for the system, and generally positive reception after implementation were reported. The cancer awareness system mainly used the IVR feature with prerecorded information, with the option to speak to a live agent added as an emergency due to the COVID-19 pandemic. The agents were health care workers (nurses and physicians) who, due to travel restrictions, had been free to handle phone calls. While callers appreciated this feature, it is otherwise not possible given the limited number of health workers. In this study, PSWs helped to address the shortage of health care professionals. A large multinational research study from Uganda and elsewhere has demonstrated the positive benefits of using PSWs, both for their own recovery and for the health care system [66-68]. Our study builds onto this prior work to innovatively and efficiently put this underused resource to use through digital health.

Strengths and Limitations of the Study

A strength of this study is the strong theoretical underpinning. Implementation studies have been faulted in the past for not being theory driven, which undermines the adoption of digital technologies [30]. The UCD and DSR approach used informed a systematic cocreation process of intervention development with user participation, while the CFIR allowed a comprehensive review of user, technological, and contextual issues to inform system requirements. Even so, we could not consider all the requirements or recommendations by the participants when designing the system because of resource limitations or contradictions. For example, some participants recommended adding video calling features to the system to enhance interaction and assessment of affect. Other participants had concerns about continuity of care, which indeed is difficult to achieve with the current call center system that lacks electronic medical records or mechanisms to ensure that callers are directed to agents with whom they have interacted with before. However, adding such features would make the system complex, expensive, and inaccessible to some such as those who mentioned inability to work with smartphones or had connectivity problems. Still, the insights from this

comprehensive assessment can inform future incremental iterations of the system during scale-up.

Conclusions

Participants were enthusiastic about the proposed call center because they were familiar with the technology and considered it as a feasible, affordable, convenient, and efficient way to get mental health services without being stigmatized. The system provided mental health information and linkage to health care providers and PSWs. The information in audio format made it accessible even to the people with low literacy, and the automated IVR allowed 24x7 access while reducing the pressure on the health care workforce. Translation to English and Luganda, the 2 most spoken languages in Uganda, increased reach, as did the reverse billing (no cost to the caller) and the use of basic telephone calls as the channel of access since many Ugandans still do not have affordable and reliable internet access.

Recommendations

In this study, people with mental illness, caregivers, and health care providers deemed a telephone-based mental health care service useful and necessary to increase access to mental health information and care and reduce stigma toward people with mental health problems. This positive view needs to be harnessed to scale up the digitalization of mental health care including providing therapy and establishing it in other mental health care settings in line with the current Ugandan digitalization policy and the Third National Development Plan. This method of mental health care may be replicable and scalable in other LMICs with mental health care system and personnel challenges similar to Uganda. Further research is needed to evaluate long-term adoption, patterns of use, and impact on clinical outcomes.

Acknowledgments

This project was funded by Digital Futures, a research collaboration between KTH Royal Institute of Technology, Stockholm University, and RISE Research Institutes of Sweden. Funders had no influence in the conduct of the research study.

Conflicts of Interest

Abstract

Background: A clinical decision support system (CDSS) based on the logic and philosophy of clinical pathways is critical for managing the quality of health care and for standardizing care processes. Using such a system at a point-of-care setting is becoming more frequent these days. However, in a low-resource setting (LRS), such systems are frequently overlooked.

Objective: The purpose of the study was to evaluate the user acceptance of a CDSS in LRSs.

Methods: The CDSS evaluation was carried out at the Jimma Health Center and the Jimma Higher Two Health Center, Jimma, Ethiopia. The evaluation was based on 22 parameters organized into 6 categories: ease of use, system quality, information quality, decision changes, process changes, and user acceptance. A Mann-Whitney U test was used to investigate whether the difference between the 2 health centers was significant (2-tailed, 95% CI; $\alpha=.05$). Pearson correlation and partial least squares structural equation modeling (PLS-SEM) was used to identify the relationship and factors influencing the overall acceptance of the CDSS in an LRS.

Results: On the basis of 116 antenatal care, pregnant patient care, and postnatal care cases, 73 CDSS evaluation responses were recorded. We found that the 2 health centers did not differ significantly on 16 evaluation parameters. We did, however, detect a statistically significant difference in 6 parameters ($P<.05$). PLS-SEM results showed that the coefficient of determination, R^2 , of perceived user acceptance was 0.703. More precisely, the perceived ease of use ($\beta=.015$, $P=.91$) and information quality ($\beta=.149$, $P=.25$) had no positive effect on CDSS acceptance but, rather, on the system quality and perceived benefits of the CDSS, with $P<.05$ and $\beta=.321$ and $\beta=.486$, respectively. Furthermore, the perceived ease of use was influenced by information quality and system quality, with an R^2 value of 0.479, indicating that the influence of information quality on the ease of use is significant but the influence of system quality on the ease of use is not, with $\beta=.678$ ($P<.05$) and $\beta=.021$ ($P=.89$), respectively. Moreover, the influence of decision changes ($\beta=.374$, $P<.05$) and process changes ($\beta=.749$, $P<.05$) both was significant on perceived benefits ($R^2=0.983$).

Conclusions: This study concludes that users are more likely to accept and use a CDSS at the point of care when it is easy to grasp the perceived benefits and system quality in terms of health care professionals' needs. We believe that the CDSS acceptance model developed in this study reveals specific factors and variables that constitute a step toward the effective adoption and deployment of a CDSS in LRSs.

Introduction

The use of health information systems has considerably transformed the health care sector in recent years [1]. Proper and coordinated implementation is beneficial to the enhancement of health care delivery [2,3]. An effective clinical decision support system (CDSS); low-cost, point-of-care diagnostics; effective remote clinics; home-based therapies; and improved communication with patients and across health care facilities are among the benefits [4,5]. Even though the implementation of a CDSS at the point of care has sought to improve treatment quality and resource efficiency, its use in low-resource settings (LRSs) has lagged behind due to a variety of restrictions.

In Ethiopia, the health care system is a 3-tiered system organized into primary, secondary, and tertiary levels of care [6]. Primary health care settings include primary hospitals, health centers, and health posts. Recently, an electronic community health information system and district health information software were implemented in Ethiopian public health centers. These tools are commonly used for routine data management tasks. Frontline workers, however, lacked easy access to decision support systems and other similar point-of-care technologies. Paper-based clinical guidelines (CGs), card sheets, and point-of-care charts were the only available resources, and only limited information is documented on the card sheets [7,8]. Delivering evidence-based services at the point of care by capturing the required clinical data, summarizing and processing them in a consistent manner, and constructing a patient flow sheet to monitor and record the progress of care from the

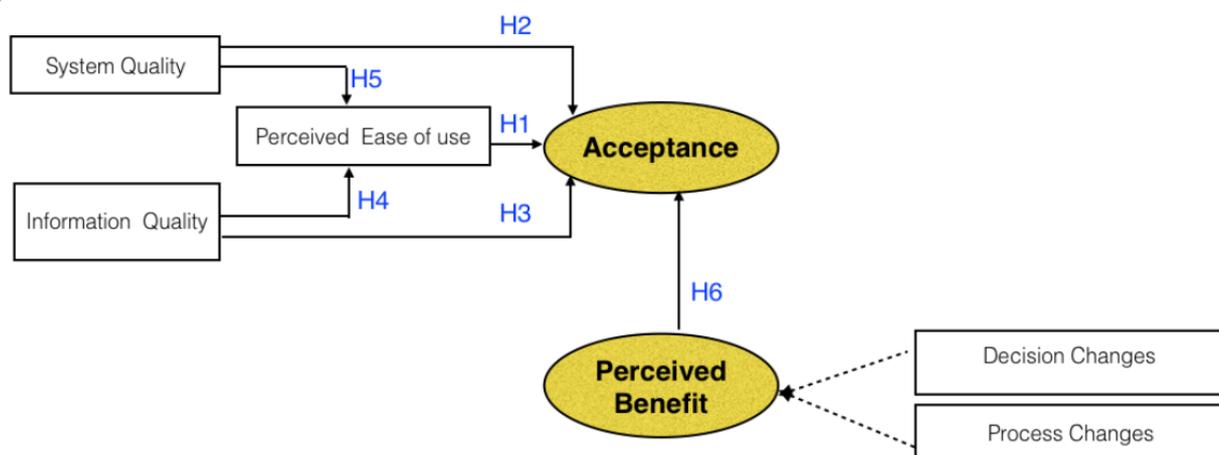

paper-based resources were challenging [7,8]. The Ethiopian national maturity health information assessment survey also revealed that there is a lack of health information infrastructure, a lack of decision support and knowledge management systems, and a lack of parameters and metrics for analyzing the impact of data [9].

Thus, introducing and integrating a CDSS with the existing health information system helps deliver appropriate, consistent, and integrated care. To introduce a CDSS in LRSs, we followed a 3-step approach:

- Step 1: A case study (maternal and childcare health services) needs analysis was conducted in LRSs to assess the available point-of-care evidence of the requirements for a CDSS, such as clinical pathways (CPs) or workflows [7,8].
- Step 2: We conducted a state-of-the-art review to investigate strategies and approaches for designing CDSS instruments for LRSs [10]. The aim was to review existing publications in the LRS context to explore recommended approaches and design considerations for building a CDSS.
- Step 3: A CDSS was developed based on the findings of the needs analysis and a review of the state of the art. The CDSS was designed to reduce delays and support frontline workers. The proposed CP algorithm, in particular, aims to find referrals and locally treatable cases by integrating knowledge-based approaches and historical evidence [11].

The aim of this study was to evaluate the user acceptance of a CDSS in LRSs. Overall, as depicted in Figure 1, this study proposed the following hypotheses to evaluate the user acceptance of the CDSS:

Figure 1. Computer-aided CDSS evaluation model hypotheses. Customized and adopted from Ji et al [20]. CDSS: Clinical decision support system; H: Hypothesis.

- Hypothesis (H)1: The perceived ease of use has a positive effect on the acceptance of a CDSS in LRSs.
- H2: System quality has a positive effect on the acceptance of a CDSS in LRSs.
- H3: Information quality has a positive effect on the acceptance of a CDSS in LRSs.
- H4: Information quality has a positive effect on the perceived ease of use of a CDSS in LRSs.

- H5: System quality has a positive effect on the perceived ease of use of a CDSS in LRSs.
- H6: Perceived benefits have a positive effect on the acceptance of CDSS in LRSs.

Methods

Ethical Considerations

Approval for the research was granted by the Institutional Review Board of the Institute of Health, Jimma University (reference number IHRPGI/467/19).

Study Settings and Participants

This study was conducted in low-resource primary health care centers, with a specific focus on the maternal and childcare health service units at the Jimma Health Center and the Jimma Higher Two Health Center. Both health centers are situated in Jimma Town, in the Oromia region, Southwestern Ethiopia. Each of them serves up to 40,000 people in its geographical area, accepts referrals from community health posts, and refers patients to the nearest hospital, such as the Shanan Gibe General Hospital and the Jimma University Specialized Hospital. The health centers serve and oversee both inpatient and outpatient cases. The number of personnel in the Jimma Higher Two Health Center is 34 and in the Jimma Health Center is 40, whereas in Ethiopia, the health center's maternal and child health service unit employs a much smaller number of health professionals, commonly 5-7 nurses and midwives. There were 5 nurses and midwives at the Jimma Health Center and 4 at the Jimma Higher Two Health Center during our investigation. The maternal and childcare health service unit is expected to serve 2000-2500 antenatal care (ANC), pregnant patient care, and postnatal care (PNC) cases annually.

Participants in the CDSS evaluation were health care professionals, such as midwives and nurses, who worked at the maternal and childcare health service unit at the Jimma Health Center and the Jimma Higher Two Health Center. The inclusion and exclusion criteria were as follows:

- Health care professionals were personnel at the maternal and childcare health service unit and were familiar with the existing clinical workflow, as well as volunteering to evaluate the CDSS.
- The ANC, pregnant patient care, and PNC cases that had been pre-recorded on the evaluation day were suitable for retrospective chart review to evaluate the CDSS.
- Both morning and afternoon evaluations were based on the pre-recorded cases from the respective morning and afternoon visits.

The CDSS evaluation was conducted in the health care professionals' spare time because the number of health care professionals at the maternal and childcare health service unit was limited, and they were so preoccupied and busy with their regular daily activities that it was not feasible to incorporate the evaluation into their routine. The health care professionals completed a questionnaire over the course of a half-day (as a summary of the half-day cases rather than as a case-by-case response), with the morning session taking place from 11:00

to 1:00 A.M. and the afternoon session taking place from 5.00 to 18:30 P.M.

The initial evaluation was conducted in August 2022 at the Jimma Health Center. The second round of evaluation took place at the Jimma Health Center and the Jimma Higher Two Health Center from December 20, 2022, until January 15, 2023.

Based on our previous experience [13], obtaining the expected sample size in an LRS was difficult due to a shortage of health care professionals in the maternal and childcare health service unit (usually 4-7).

To determine the optimal strategies, we consulted the existing literature in support of our evaluation study design. Based on the findings of Mburu and Oboko's study [14], we observed that 79 cases were sufficient to assess the use of mobile health (mHealth) interventions in Kenya. Additionally, Mburu and Oboko [14] also reported that 60 subjects were sufficient to detect the small and medium effects of an exogenous latent variable (independent variable) on an endogenous latent variable (dependent variable), according to the findings of Chin and Newsted [15] and Cohen [16], just as using 40 subjects was sufficient for Goodhue et al [17]. The minimum sample size needed to observe an effect with a given power (ie, the probability of observing a statistically significant result at level P if a true effect of a certain magnitude is present) is determined by the effect size. The effect size is associated with the path coefficient between a variable that is assumed to describe a cause and a variable that is assumed to be an effect: values <0.02 indicate no effect, values >0.15 indicate a medium effect, and values >0.35 indicate a large effect [17,18]. Moreover, using 70-80 samples was adequate to model functional brain relationship hypotheses in the study by Sideridis et al [19]. However, Sideridis et al [19] also explicitly noted that sample sizes of 50 participants were associated with a root mean square error of approximation of <0.05 , suggesting a satisfactory fit.

The study entailed a proof-of-principle CDSS evaluation using a convenience sample of 7 health professionals. Altogether, we reviewed 73 ANC, pregnant patient, and PNC cases.

Procedure and Measurement Instrument

A tutorial and a demonstration were provided to the health care professionals at the 2 health centers prior to using the CDSS. The health care professionals used and assessed the CDSS before completing a questionnaire. They used a retrospective chart review, specifically a half-day of pre-recorded patient card sheet data, to evaluate the CDSS. On the basis of pre-recorded cases, the goal was to evaluate how well the CDSS performed in identifying referrals and locally treatable cases that were actually made. The health care professionals then filled out questionnaires to provide their assessments and feedback on the CDSS. Each evaluation questionnaire was completed based on a half-day of ANC, pregnant patient, and PNC cases, as well as the health care professional's observation of the CDSS reaction to the presented cases. Next, the health care professionals answered a series of 5-point Likert scale items (1=strongly disagree, 2=disagree, 3=neutral, 4=agree, 5=strongly agree) about the CDSS [20]. The measurement instrument consisted of 22 parameters adopted from Ji et al's [12]

evaluation framework. The 22 measurement items were classified into 6 factors: system quality, information quality, service quality, perceived ease of use, user acceptability, and perceived benefits. Furthermore, we automated the questionnaire submission, which was accessed via a mobile phone or a laptop. Electronic questionnaire submission was preferred over paper-based alternatives. However, paper-based questionnaire submissions were used in some cases.

The CDSS at the Point of Care

We designed and developed a CDSS to meet the requirements of LRSs. An intelligent clinical wizard, minimum data and data readiness, adaptable features, and low-cost infrastructure are some of the notable requirements and prerequisites of LRSs based on our previous results [7]. Our CDSS incorporates both existing knowledge-based guidelines and data-driven evidence to provide the most relevant information for frontline workers at the time of care delivery [11]. The CDSS provides CPs (or workflows) for point-of-care services. The CP is a critical component of a CDSS for identifying referral and locally

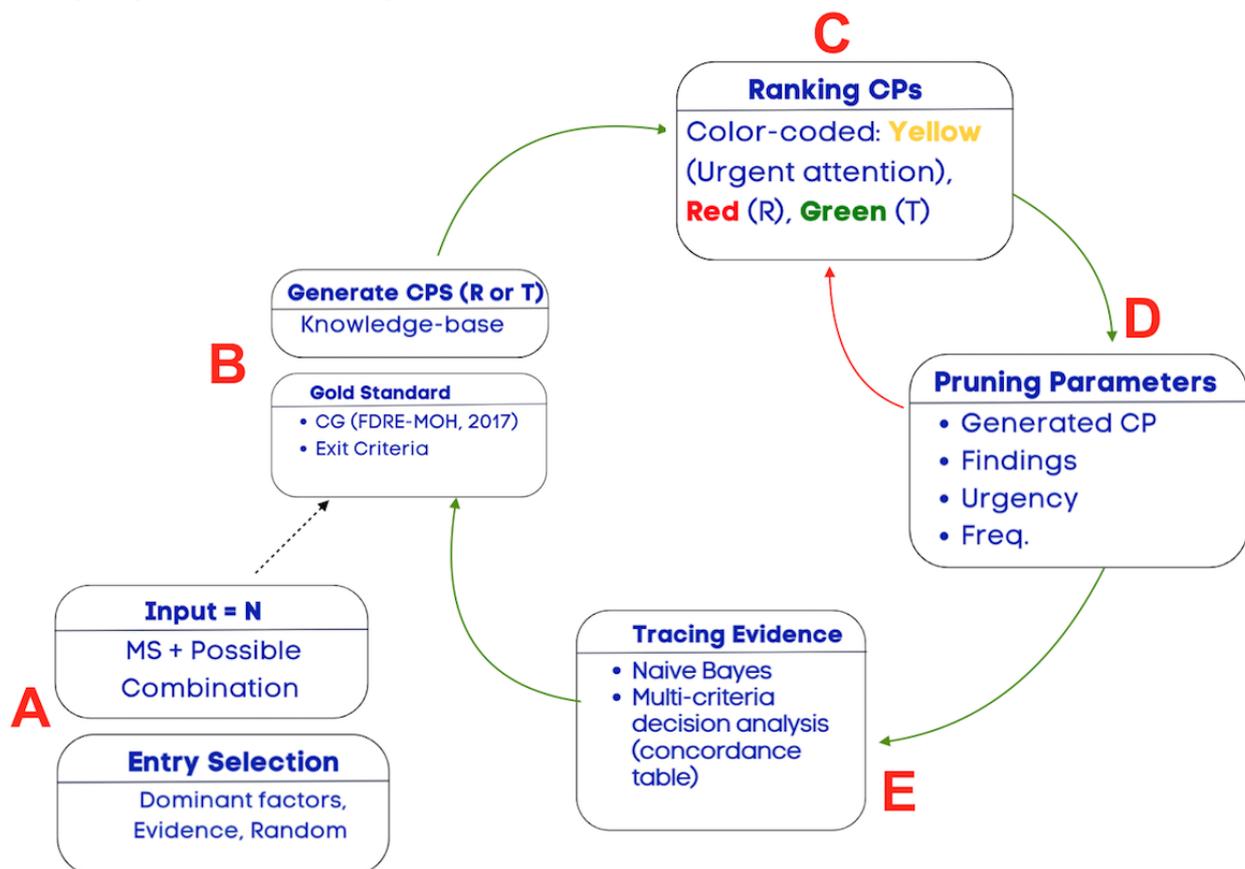

treatable cases, which is delivered in the form of a concordance table for multicriteria decision analysis and output [11].

The CDSS has the following major goals:

- Delivering automated CPs and computer-assisted pruning and selection.
- Going beyond existing paper-based evidence that is noninteractive and challenging to grasp, the computerized CDSS was designed to be interactive for ease of use and optimal usage.
- Combining existing CGs and historical evidence (data-driven evidence) to generate an adaptable clinical workflow.

To get the most out of services, the CDSS provides an automated, interactively adaptable CP (or workflow). To reduce arbitrariness in entry point selection, the CDSS provides a range of choices for initiating the CP, such as using evidence from historical records, dominant factors, or randomly initiating the signs and symptoms based on CGs. Figure 2A presents additional information about entry point processing.

Figure 2. CP-processing workflow. CG: Clinical guideline; CP: Clinical pathway; FDRE-MOH: Federal Democratic Republic of Ethiopia Ministry of Health; Freq.: Frequency; MS: Measured symptom.

The process is interactive, and our algorithm uses measured symptoms (MSs) and a combination of MSs to process the CPs:

- First, all CPs based on the first MS are generated, as shown in Figure 2B. CGs are used as the gold standard and criterion for validating the generated CP (also referred to as an exit criterion). If the generated CP is already found on the generated list, the frequency counter is incremented.

Otherwise, the generated CP is added (or appended) to the generated list of CPs. Federal Democratic Republic of Ethiopia Ministry of Health version 2017 (FDRE-MOH 2017) is used for CP processing.

- Second, a ranking of CPs is conducted to identify “referral” and “locally treatable” cases. The ranking is color-coded, as shown in Figure 2C, and the ranking criteria are based on CGs.

- Third, the dynamic CP list is pruned, as shown in [Figure 2D](#). CP pruning is based on pruning parameters. If the generated CP list is empty, fall-back and adjustment of the pruning criterion are supported. The pruning process was designed to be interactive, flexible, responsive, and engaging. The user intervention allows for fine-tuning based on domain knowledge and provides trust and understanding for the health care professional. Pruning can also be based on findings if the health care professional requires pruning of specific CP findings. The findings are based on the CGs.
- Fourth, the naive Bayes algorithm and historical records are used to provide data-driven evidence, as shown in [Figure 2E](#). The output is displayed in an easy-to-understand format, using a table to present the evidence. The ranked table provides evidence for assessing various factors, such as symptoms, findings, urgency, CP, CP frequency, accuracy, and prior and posterior probability, to facilitate evidence-based decision-making by the user. Since it provides evidence for analyzing various factors, we refer

to it as multicriteria decision analysis. In further detail, the multicriteria output used for decision analysis is displayed in the form of a table, also known as a concordance table. A concordance table is a data (evidence) table used as a cross-reference for integrating evidence from many sources for decision support. In this study, it was used primarily for tracing what evidence was available to support the presented case and identifying the evidence's source (historical records or knowledge-based evidence). A more detailed step-by-step description of the algorithms is found in [Figure 2A-E](#).

- Finally, the preceding steps are repeated for each additional MS.

In the end, the frontline worker must make the final decision based on the suggestions made by the algorithm. For this study and demonstration, the CDSS focused on 3 use cases, namely pregnant patient care, ANC, and PNC services. The sample user interface screenshot for each step is shown in [Figures 3-7](#).

Data Analysis

Statistical Package for Social Sciences (SPSS; IBM Corporation) version 26.0 [21], Microsoft Excel [22], Python (version 3.7) [23], and SmartPLS (version 26.0) [24] were used to conduct the analysis and modeling.

We followed the procedures and recommendations of Boone and Boone [25] for the CDSS evaluation based on Likert data analysis. Latent variables were computed by summing the following items:

- The perceived ease of use was a latent variable based on learnability, operability, user interface, data entry, advice to display, and legibility items.
- Response time and stability items were used to assess system quality.
- Information quality was based on security and CP performance items.
- Acceptance included usage, confirmation of expectations, overall quality satisfaction, overall satisfaction, and the intention to use items.
- Perceived benefits were created using decision change (change in order behavior, change in CP) and process change (effectiveness, overall usefulness, adherence to standards, medical quality, and user knowledge and skills) items.

To assess the scale of the CDSS evaluation data set, the validity of the measurement model was checked. Convergent validity was assessed using factor loading and average variance extracted (AVE), with a factor loading threshold of more than 0.70 and an AVE threshold of >0.50 [26,27]. In this study, items with factor loadings of less than 0.70 were candidates for deletion. The internal consistency and reliability of the CDSS evaluation

measurement model were assessed using Cronbach α [28] and composite reliability. A recommended value of >.70 for Cronbach α and composite reliability was accepted. We used the heterotrait-monotrait ratio of correlations (HTMT) [26,29] to check the discriminant validity of the measurement model and determined whether the value was less than 0.90 and acceptable. Moreover, perceived benefits are formative second-order construct based on decision changes and process changes. Collinearity was checked to ensure that it did not have a negative impact on the higher-order-construct measurement model, and critical levels of collinearity less than 0.50 were acceptable in this study, as recommended by Hair et al [26].

Following that, item-level and construct-level analyses were performed. On the one hand, an item-level analysis of the CDSS in LRSs between the 2 health centers was conducted. A nonparametric independent-samples statistical test, such as the Mann-Whitney *U* test [30], was used to see whether the 2 health centers were significantly different at the item level. We used the Mann-Whitney *U* test because we could not assume normality in either group and the independent data set observation assumptions were fulfilled, which are preconditions for the use of nonparametric data analysis [31]. Furthermore, there were no significant results from the Shapiro-Wilk test [32] on the normality of our evaluation data set. The significance level used for the inferential statistics was *P*=.05 and a 95% CI level.

On the other hand, we followed the recommendation of Boone and Boone [25] to use Pearson correlation for construct-level (latent variable) correlation analysis. As a result, Pearson correlation [25,33] was used to examine the factors influencing the acceptance of the CDSS in LRSs and the interrelationships between construct factors. In particular, the relationship between system quality and perceived ease of use, information quality

and perceived ease of use, user acceptance and perceived benefits, and user acceptance and information and system quality were explicitly explored.

Finally, structural equation modeling (SEM) is a multivariate statistical analysis technique that is used to analyze structural relationships. It is described in the literature as combined factor analysis and regression analysis for discovering relationships between measured variables and latent constructs [34]. There is a debate on how effective it is to discover causation beyond correlation. In papers dealing with applications of the technique, it is commonly used to express a causal hypothesis in a context where there is semantic information available that supports the validity of the hypothesis or at least does not contradict it [12,14,35]. Our study was a pilot study, not a full, cross-sectional analysis, and it intended to promote the use of partial least squares structural equation modeling (PLS-SEM) [26]. PLS-SEM was used to model the acceptance of the CDSS in LRSs, particularly to model the relationship between the CDSS evaluation measured items and construct variables, as well as between multiple construct variables. We noticed that penalized likelihood estimation algorithms based on regularized structural equation modeling (RegSEM) [36,37] and PLS-SEM [26] were the best candidates for our modeling. We preferred PLS-SEM for the following reasons:

- The SmartPLS [26,38] partial least squares (PLS) algorithm was used to analyze the model's path weight, and it performed well in Mburu and Oboko's [14] study.
- The variation-based structural equation models do not impose a sample size [39] or normality of distribution constraints [26,38].

Overall, to construct the PLS-SEM model for the CDSS in LRSs, first, composite factor analysis was used to examine the validity of the measurement model, including reliability and validity analysis. The relationships in path models with latent variables were then evaluated using PLS-SEM path analysis and coefficients. Finally, the statistical significance of PLS-SEM

results, such as path coefficients, outer weights, Cronbach α , and coefficient of determination (R^2) values, was determined using bootstrapping [26]. The bootstrapping settings were percentile bootstrap, 2-tailed test type, and significance level=.05.

Results

Characteristics

The 7 CDSS evaluators were all female (ie, $n=4$, 57%, from the Jimma Health Center and $n=3$, 43%, from the Jimma Higher Two Health Center), who worked as health care professionals (eg, midwives and nurses) in the health centers' maternal and childcare health service units. In total, 73 CDSS evaluation responses were recorded based on 116 ANC, pregnant patient care, and PNC cases ($n=4$, 5%, during the first evaluation period and $n=69$, 95%, during the second evaluation period). The response was 73 since the evaluation response was based on a summary of half-day cases rather than a case-by-case response. The average time for evaluating the CDSS and completing the questionnaire was 52.35 minutes, with the smallest and longest durations being 31 and 98 minutes, respectively. The Jimma Health Center accounted for 65.5% (76/116) cases, while the Jimma Higher Two Health Center accounted for 34.5% (40/116) cases. Furthermore, we observed that each health center handled 4-6 (3%-5%) cases per day on average. Overall, the first round of evaluation lasted 2 days and included 18 ANC, pregnant patient care, and PNC cases in the Jimma Health Center, which is above average. In round 2, there were 75 ANC cases, 7 pregnant patient care cases, and 16 PNC cases during our evaluation period. The second round of evaluation took place in both health centers, the Jimma Health Center and the Jimma Higher Two Health Center.

The computer-aided CDSS evaluation's mean (SD) score ranged from 4.29 (SD 0.485) to 4.52 (SD 0.503). [Table 1](#) provides more extensive details of each item score.

CDSS Evaluation Measurement Model

The factor loading of 20 (91%) of 22 items was greater than 0.70. The remaining items, legibility and medical quality, were eliminated since their factor loading value was less than 0.70. All the constructs had Cronbach α values greater than .70, except information quality, for which Cronbach α was .699,

which is close to .70. Table 2 provides more information about the measurement model's construct reliability and validity.

To establish discriminant validity, the HTMT on construct factors was used, and the results showed that all constructs passed the test. Table 3 displays the results of the discriminant validity assessment.

CDSS Evaluation Between the 2 Health Centers

The results of the nonparametric Mann-Whitney *U* test based on the 5-point Likert item evaluation data set collected from the Jimma Health Center and the Jimma Higher Two Health Center revealed that the 2 health centers did not differ significantly in the CDSS item-level evaluation factors, except

stability ($U=470.5$, $P=.022$), overall usefulness ($U=451.0$, $P=.012$), adherence to standards ($U=483$, $P=.024$), confirmation of expectations ($U=488.5$, $P=.04$), satisfaction with overall quality ($U=400.5$, $P=.001$), and overall satisfaction ($U=474.5$, $P=.023$). The findings of the CDSS evaluation using the Mann-Whitney *U* test are shown in [Table 4](#).

CDSS Evaluation Agreement Score Observation in the Jimma Health Center

Although the total number of observations in the first and second rounds of the CDSS evaluation were not equal, we found a positive mean agreement score increment in the majority of

evaluation parameters at the Jimma Health Center, which was calculated using “agree” and “strongly agree” responses. Adherence to the standards agreement score, however, declined from 1.00 to 0.974. The first and second round CDSS evaluation agreement score observations at the Jimma Health Center are shown in [Table 5](#).

Table 5. First and second round CDSS^a evaluation agreement score observations at the Jimma Health Center.

CDSS Evaluation: Construct Factor Interrelationships

We found a significant correlation ($r = 0.74$) between user acceptance and perceived benefits, with perceived benefits as construct factors based on process changes and decision changes.

The coefficient of correlation between perceived ease of use and information quality was $r = 0.63$. User acceptance was also correlated with information quality and system quality, with $r = 0.68$. [Figure 8](#) depicts a more detailed Pearson correlation test result.

Figure 8. Pearson correlation (N=73). Correlation values ranging from 0.50 to 0.70 are considered moderate, from 0.70 to 0.90 are considered strong, and from 0.9 to 1.0 are considered very strong [33].

Modeling the Acceptance of the CDSS in LRSs

The perceived user acceptance coefficient of determination (R^2) was 0.703, showing that user acceptance is influenced by system quality, information quality, perceived ease of use, and perceived benefits (Figure 9). More precisely, system quality ($\beta=.321$, $P<.05$) and perceived benefits ($\beta=.486$, $P<.05$) were shown to have a significant influence. However, the perceived ease of use had no positive effect on CDSS acceptance ($\beta=.015$, $P=.91$). Information quality also had no positive effect on CDSS acceptance in this study ($\beta=.149$, and $P=.25$).

Furthermore, we found that the perceived ease of use was influenced by system quality, and information quality, with an R^2 value of 0.479. The path coefficient of information quality on the perceived ease of use was $\beta=.021$ ($P=.89$), and hence, no significant effect was found. The path coefficient of system

quality on the perceived ease of use was $\beta=.678$ ($P<.05$), that is, a significant influence, whereas the perceived benefits impacted by decision and process changes had an R^2 value of 0.983. The path coefficients of decision changes and process changes were $\beta=.374$ and $\beta=.749$, respectively, and were significant ($P<.05$). Figure 9 depicts the path weights, P values, and coefficient of determination (R^2) for the CDSS evaluation PLS-SEM model developed using the CDSS Jimma Health Center and Jimma Higher Two Health Center evaluation data sets. The results, shown in Figure 9, can be interpreted as perceived ease of use \rightarrow perceived user acceptance ($\beta=.015$ and $P=.91$), for example. Overall, we found that the perceived ease of use had no positive effect on CDSS acceptance ($\beta=.015$, $P=.91$) but, rather, on the system quality ($\beta=.321$, $P<.05$) and perceived benefits ($\beta=.486$, $P<.05$) of the CDSS. Further information is presented in Table 6.

Figure 9. Computer-aided CDSS evaluation PLS-SEM model generated from the computer-aided CDSS Jimma Health Center and the Jimma Higher Two Health Center evaluation data sets, showing path weights (β), P values, and coefficient of determination (R^2). The yellow boxes represent indicators (or parameters). The construct variables are represented by the circle. The path indicates the path weight and P value. For example, a 0.321 (.002) value from system quality \rightarrow perceived user acceptance shows that $\beta=.321$ and $P=.002$. CDSS: clinical decision support system; PLS-SEM: partial least squares structural equation modeling.

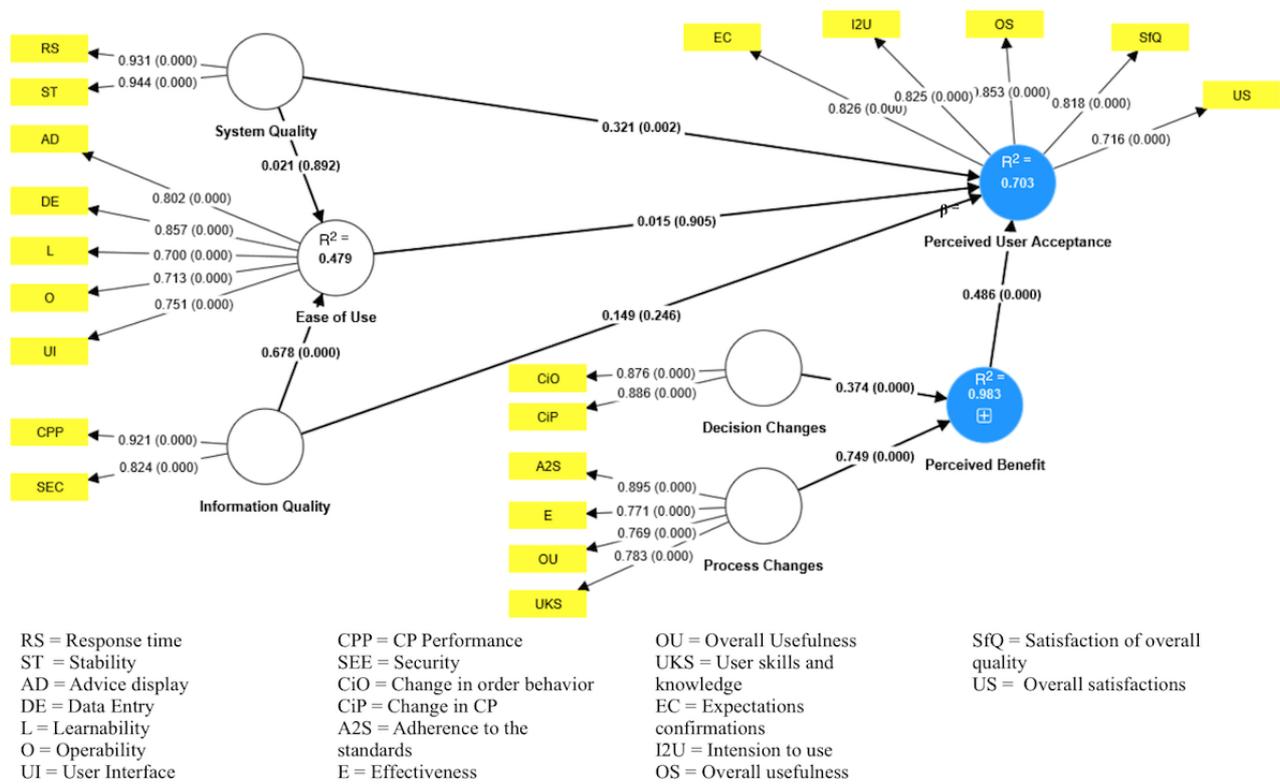

Table 6. Hypotheses conclusion based on PLS-SEM^a findings ($\beta=.015$, $P=.91$).

Discussion

Principal Findings

This study aimed to evaluate a CDSS for use at the point of care in primary care LRSs. The health care professionals in this study evaluated user acceptance of the CDSS.

The Cronbach α scale of 22 items appeared to be internally consistent, exceeding the minimum value of .70 required for acceptable reliability [26-28,32]. In this study, the 2 health centers did not differ significantly in terms of the CDSS's perceived ease of use, information quality, and perceived benefits (decision changes and process changes). However, we found a significant difference in system quality, such as stability, and perceived user acceptance, such as overall usefulness, adherence to standards, confirmation of expectations, satisfaction with overall quality, and overall satisfaction. This variation could be attributed to the first round of evaluation, which was based on the Jimma Health Center, or to the fact that more cases were observed in the Jimma Health Center than in the Jimma Higher Two Health Center, but more research and analysis are required. Furthermore, based on the first and second rounds of the CDSS evaluation, we observed a positive agreement score increment at the Jimma Health Center. However, this study was unable to observe a change in the Jimma High Two Health Center, since the first round of evaluation was limited to the Jimma Health Center.

This study highlighted a correlation between construct variables using Pearson correlation. The CDSS's system quality, information quality, and perceived benefits were vital for its acceptance in the LRS. The perceived benefits were based on decision and process changes. In accordance with our results, previous studies have demonstrated that the acceptance and use of mHealth apps in LRSs are influenced by users' perceptions that are aligned with health needs and expectations [14]. However, in this study, the perceived ease of use was moderately correlated with CDSS acceptance, whereas Ji et al [12] suggested that the perceived ease of use has a significant and direct impact on the acceptance of a CDSS. Figure 8 depicts further information about the Pearson correlation between the construct variables of the CDSS. Overall, we observed a low positive Pearson correlation between the perceived ease of use and acceptance, as well as between system quality and the perceived ease of use, when we considered the strength of correlation classification as in Mukaka [33]. System quality and acceptance, information quality and acceptance, and information quality and perceived ease of use all showed a moderately positive correlation. There was a high positive correlation between perceived benefits and acceptance, supporting Pande et al's [40] finding that perceived usefulness is significantly correlated to the intention to use.

This study also used PLS-SEM to evaluate several factors that impact the acceptance of a CDSS in LRSs. The result demonstrated that user acceptance is impacted by system quality, information quality, and perceived benefits, with an R^2 value of 0.703, as shown in Figure 9. The perceived benefits influenced by decision and process changes had an R^2 value of

0.983, whereas the R^2 score for the perceived ease of use as impacted by system and information quality was only 0.479. All retained R^2 values were greater than 0.10, as suggested by Falk and Miller [41]. The R^2 values of the perceived user acceptance and perceived benefits were substantial, as also indicated by the CDSS results of Cohen [18], who reported $R^2 > 0.26$, and Chin [42], who reported $R^2 > 0.67$. However, according to the criteria of Hair et al [43], R^2 of perceived benefits is greater than 0.75 and substantial, while R^2 of the perceived ease of use and user acceptance is greater than 0.50 and moderate. However, Mohamed et al [44] showed that the coefficient of determination must be larger than 0.19, the path coefficient between latent variables must be at least 0.1, and the significance level must be at least .05 in order to validate the model. Our CDSS evaluation model meets all these criteria, except the path coefficient from perceived ease of use to perceived user acceptance, which was 0.015. Hair et al [26], however, stated that path coefficients with standardized values greater than 0.20 are typically significant, while in this study, the path coefficient from perceived ease of use to user acceptance was 0.015, which is less than 0.10 and not significant. More information is depicted in Figure 9, which includes the details of the CDSS assessment PLS-SEM model developed from the CDSS Jimma Health Center and Jimma Higher Two Health Center evaluation data sets, including path weights, P values, and the coefficient of determination (R^2).

Overall, as shown in Table 6, the PLS-SEM results suggested that the perceived ease of use has no positive effect on CDSS acceptance ($\beta = .015$, $P = .91$) but, rather, on system quality ($\beta = .321$, $P = .002$) and perceived benefits ($\beta = .486$, $P < .001$) of the CDSS. We also observed that information quality had a positive influence on the perceived ease of use ($\beta = .678$, $P < .001$). However, system quality had no favorable impact on the perceived ease of use ($\beta = .021$, $P = .89$). The detailed conclusions and summary based on PLS-SEM are shown in Table 6.

Limitations

In this study, we evaluated our own proof-of-principle CDSS in LRSs. The small sample size and low number of cases in our study might limit the generalizability of our findings. As a result, difficulties that were not identified during this investigation may be identified during a longitudinal and case-by-case evaluation.

Conclusion

We designed and developed a CDSS based on LRS requirements, which we evaluated in 2 LRSs in Ethiopia: the Jimma Health Center and the Jimma Higher Two Health Center. Our overall result indicates that user acceptance is impacted by system quality, information quality, perceived ease of use, and perceived benefits, with an R^2 value of 0.703. Specifically, system quality and perceived benefits have a direct impact on user acceptance of the CDSS in LRSs. In this study, however, we found that the perceived ease of use and information quality had no positive effect on CDSS acceptability. Overall, the proposed acceptance model includes specific factors and

variables, which is an important step toward the successful adoption and implementation of a CDSS in LRSs.

Acknowledgments

We would like to thank the health care professionals at the Jimma Health Center's and the Jimma Higher Two Health Center's maternal and childcare health service units. Sisters Aynalem Wubet, Digi Abaraya, and Asiya, in particular, deserve special appreciation. Their voluntarism will not be forgotten. The evaluation was possible due to their efforts in administering the clinical decision support system evaluation from beginning to end. We would also like to thank Mr Balew Ayalew (a Jimma University lecturer) for facilitating and assisting with the supervision of the evaluation at the Jimma Higher Two Health Center. Finally, we thank the Network for Advancement of Sustainable Capacity in Education and Research in Ethiopia (NASCERE) program.

Authors' Contributions

GST, DAS, GKT, FV, JC, and BJ conceptualized the research goals and objectives, as well as the methodology. GST conducted data curation, formal analysis, investigation, visualization, and drafting of the manuscript. DAS, GKT, FV, JC, and BJ were involved in the supervision, validation, visualization, and review and editing of the manuscript, as well as the final proofreading. All authors have read and approved the final manuscript.

Abstract

Background: To enable personalized treatment and shared decision-making in chronic care, relevant health information is collected. However, health information is often fragmented across hospital information systems, digital health apps, and questionnaire portals. This also pertains to hemophilia care, in which scattered information hampers integrated care. We intend to co-design a nationwide digital personal health record (PHR) for patients to help manage their health information. For this, user perspectives are crucial.

Objective: This study aims to assess patients' and health care providers' perspectives regarding the use of a PHR in hemophilia care in the Netherlands, required functionalities, and expectations and concerns.

Methods: In this semistructured interview study, 19 pediatric and adult persons with hemophilia, parents, and women with other inherited bleeding disorders, as well as 18 health care providers working within and outside of hemophilia treatment centers, participated. Perspectives of patients and providers were explored separately. To explore requirements, participants were asked to prioritize functionalities.

Results: Participants expected a PHR would increase the transparency of health information, improve patients' understanding of their illness, and help the coordination of care between health care providers and institutions. Prioritized functionalities included the integration of relevant health information and patient-entered data. Formulated expectations and concerns focused on 4 themes: usability, safety, inclusiveness, and implementation. While patients expressed worries over medicalization (ie, more confrontational reminders of their illness), providers were concerned about an increased workload.

Conclusions: People with hemophilia, their parents, and health care providers welcomed the development of a PHR, as they expected it would result in better coordinated care. Formulated expectations and concerns will contribute to the successful development of a PHR for persons with hemophilia, and ultimately, for all persons with a chronic condition.

Introduction

Background

Persons with a chronic health condition, such as the bleeding disorder hemophilia, are encouraged to use eHealth tools to enable personalized treatment and shared decision-making. Hemophilia is an X-linked inherited coagulation factor deficiency of factor VIII (in hemophilia A) or factor IX (in hemophilia B), resulting in an increased bleeding tendency. The severity of hemophilia depends on the residual coagulation factor activity: severe (residual factor activity of <1%), moderate-severe (1%-5%), and mild (6%-40%). Especially in severe hemophilia muscle and joint bleeds are common, leading to painful and disabling joint damage and invalidity. Therefore, lifelong treatment and monitoring is necessary [1,2]. The hallmark of treatment for persons with severe hemophilia consists of replacement therapy with either repetitive prophylactic intravenous infusions of factor concentrate or subcutaneous injections of nonfactor replacement therapy. Preferably, prophylactic treatment is self-administered at home. In case of a bleed, intravenous coagulation factor concentrates are administered, either by people themselves or in the hospital, depending on the severity of a bleed and patients' expertise. Therefore, people are required to closely self-monitor bleeds and treatment efficacy and seek advice from a hemophilia treatment center if necessary.

Successful treatment demands an active role of the patient and well-developed self-management skills. Self-management is the ability to manage the clinical, psychosocial, and societal aspects of illness and its care, and its impact on life [3,4]. eHealth tools can help to facilitate this active role [5-9]. eHealth tools that are used by persons with hemophilia in the Netherlands include a digital treatment diary to log medication use and bleeding episodes [10], a questionnaire portal to complete patient-reported outcomes measures before follow-up visits [11], and patient portals offered by different health care institutions. However, since each tool has a separate log-in

procedure, usability is suboptimal. Similarly, individuals who are treated in various care institutions are required to use multiple patient portals. There is no data exchange between these portals, which results in scattered information. Especially for older individuals with comorbidities, as seen in hemophilia, this hampers integrated care [12,13]. The exchange of information between these eHealth tools, patient portals, and different health care institutions is suboptimal. This results in a loss of information and many requests for the same information, which may negatively impact patient safety [14].

Personal health records (PHRs) are being developed to resolve these problems and increase patient empowerment [15,16]. In contrast to a patient portal, a PHR's contents are managed and maintained by individuals, not health care institutions, as illustrated by the definitions presented in [Textbox 1](#). Individuals are able to access and manage their health information and share it with authorized family members or caretakers to help them in managing their care. In addition, people can add self-measurements, such as body weight or data from connected wearables, fill out patient-reported outcomes measures, and complete treatment logs. An example of a PHR is presented in [Figure 1](#). PHRs that are used by people with chronic conditions include PatientsKnowBest (CarePoint) [17] and all certified Dutch PHRs [18]. The Dutch government formulated strict health data exchange guidelines and regulations for PHRs [19]. Therefore, Dutch PHRs will ultimately include integrated medical data from all health care providers involved, regardless of their institution.

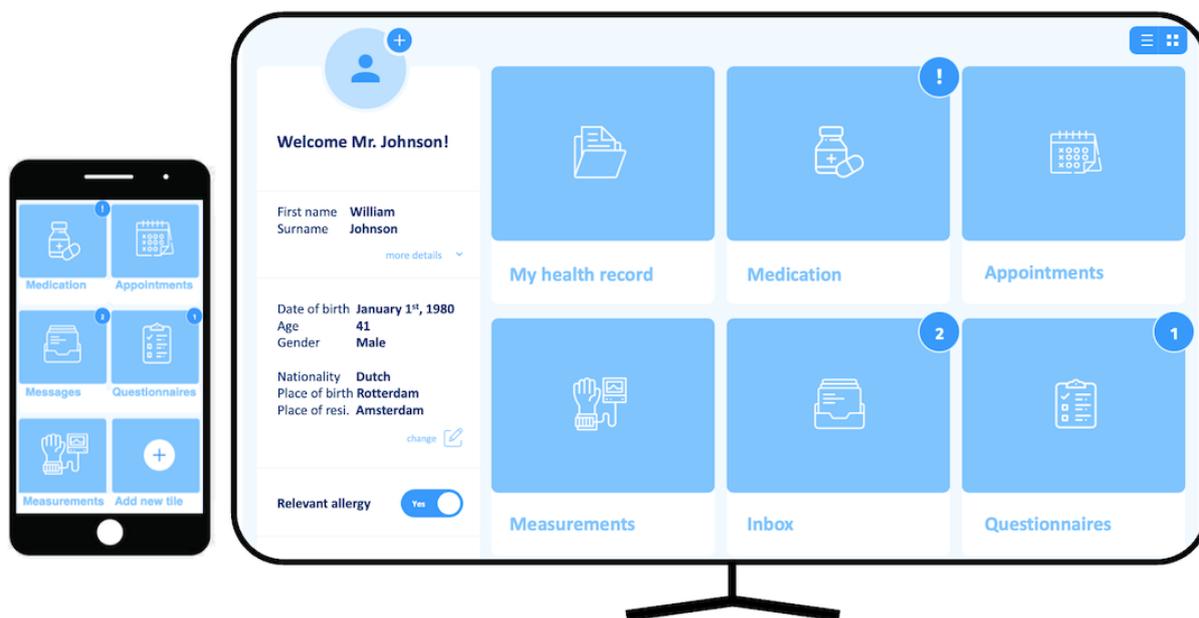

Because Dutch PHRs mainly focus on prevalent conditions as hypertension and diabetes, these are not well-equipped in providing for chronic conditions with a high level of self-management, such as hemophilia. Persons with hemophilia may especially benefit from using a PHR, because of the number of health care providers involved in their care, the chronic nature and burden of their condition, and the many self-management skills required from them.

Textbox 1. Definitions.**Contents**

- Patient portal: the patient-facing interface of an electronic health record that enables people to view sections of their medical record. This may include access to test results, medication lists, or therapeutic instructions. Health care providers or health care offices determine what health information is accessible for patients. Patient portals often have additional features, such as patient-professional messaging, requesting prescription refills, scheduling appointments, or communicating patient-reported outcomes. By definition, patient portals are “tethered,” which refers to a patient portal’s connection to an electronic health record.
- Personal health record (PHR): a PHR can have similar features as a patient portal. However, the main difference is that contents are managed and maintained by individuals not health care providers. People can access, manage, and share their health information and that of others for whom they are authorized, such as relatives. Health information from different health care institutions may reside in a single patient-managed PHR. Generally, PHRs are not tethered, with the exception of some, including those currently used in the Netherlands.

Note: The definitions are taken from Brands et al [9].

Figure 1. Example of a personal health record, adapted from MedMij.

**Objectives**

We intend to co-design a nationwide PHR that meets the needs of persons with hemophilia in the Netherlands, their parents, and health care providers. However, their perceptions on a PHR are not yet known. Therefore, our aim was to assess patients’ and health care providers’ perspectives regarding the use of a PHR, required functionalities, as well as expectations and concerns. These insights will help to determine whether a PHR is of value in hemophilia care, and will support its further development.

Methods

This is a multicenter, semistructured, qualitative interview study, performed in the Netherlands.

Participants

Study participants were Dutch adolescents and adult persons with hemophilia A and B, parents of young children and adolescents with hemophilia, women with other inherited

bleeding disorders, and health care providers working within and outside of hemophilia treatment centers. Adolescents aged 12 to 18 years were interviewed together with a parent. Children <12 years old were represented by the opinions of their parent. Health care providers included: medical specialists, (specialized) hemophilia nurses, allied professionals, and general practitioners (Table 1).

People with hemophilia and parents were recruited through open invitations disseminated by the Dutch Hemophilia Patient Society using their website, email newsletters, and Facebook page. In addition, they were recruited in 2 Dutch hemophilia treatment centers: the Amsterdam UMC and Erasmus MC. We used purposive sampling to include a diverse set of participants. Health care providers were recruited using the direct network of the researchers (MRB and SCG). Inclusion of participants was continued until thematic saturation was achieved, that is, until no new information was introduced in the last 2 interviews. Achieving saturation indicates that additional interviews would not further develop the qualitative theory derived from the data.

Table 1. Participant characteristics.

	Patients ^a (n=19)	Health care providers (n=18)
Sex, n (%)		
Male	14 (74)	2 (13)
Female	5 (26)	16 (87)

Data Collection

Interviews were conducted by MRB (a physician-researcher) and JJM (a physiotherapist-researcher) between September 1, 2020, and February 1, 2021. Interviews were conducted in person or using video conferencing, the latter due to the COVID-19 pandemic. Duration of interviews ranged from 44 to 96 minutes. All interviews were audiotaped and transcribed verbatim. The item topic list, which was used as an interview guide, was based on clinical expertise and experiences and on previous qualitative research conducted by the authors of this study on the quality of hemophilia care [20]. After discussing relevant personal details and current experiences with patient portals, the concept of a PHR was briefly explained using the image presented in Figure 1. Next, participants were asked about their perspective on the use of a PHR in hemophilia care, required functionalities, as well as expectations and concerns.

Regarding required functionalities, participants first openly discussed their ideas. Second, participants were presented a set of 25 cards, each depicting one functionality. Functionalities were split into 5 categories (Figure 2): medical information, tools for managing care, connecting with others, data entered by patients, and background information. The 25th card stated: “I do not want a PHR.” Cards were based on a qualitative study among 31 older adults with a chronic condition and their caretakers [21]. Cards functioned both as prompts and as an exploration of the most required functionalities. Participants were asked to choose the 5 cards which they considered essential. Third, participants chose the functionalities that they considered nice-to-have and those that they considered undesirable. Finally, participants were asked if they had gained new insights regarding the functionalities.

Figure 2. Functionality cards chosen by participants. *Most participants referred to 2 apps: the digital treatment diary app VastePrik and the patient-reported outcome measure portal KLIK. The 25th card, stating, “I do not want a PHR,” is not depicted; this card was chosen by 1 patient. HCP: health care provider; PHR: personal health record.

Data Analysis

In this qualitative study, a directed form of thematic content analysis was used, because elements of our coding scheme were predetermined by our research question. First, using the qualitative software program MAXQDA (VERBI Software), open coding was used to identify themes in interviews. MRB coded all and JM independently coded a third of the interviews. Next, axial coding was used to find connections, and a coding scheme was drafted by MRB and JJM. Thematic discussions

were conducted by MRB and JJM, under the supervision of senior researchers LH and SCG.

Ethical Considerations

The institutional review board of the Amsterdam University Medical Center approved this study (W20_383 # 20.428). All participants signed an informed consent form. Data were deidentified. All participating patients received a gift card worth €20 (US \$22) as compensation.

Results

Overview

Thematic saturation was reached at a total of 37 participants: 19 (51%) patients and 18 (49%) health care providers. Characteristics are presented in [Table 1](#). Of the 19 patients, 14 (74%) were male. Patients' median age was 39 (IQR 18-65) years. Furthermore, 11 (58%) had severe hemophilia and 12 (63%) used prophylaxis. In addition, 1 (5%) participant had a factor VII deficiency, and 1 (5%) had von Willebrand disease. Furthermore, 5 (26%) participants were parents of a child with hemophilia. The 18 interviewed health care providers covered all professions involved in the treatment of people with hemophilia. Among them, 7 (39%) worked in adult care, 7 (39%) in pediatric care, and 4 (22%) in both. In total, 16 (89%) were female and median work experience was 16 (IQR 8-23) years.

Perspectives

Overview

In assessing patients' and health care providers' perspectives toward a PHR in hemophilia care, three themes were identified: (1) transparency and ease, (2) understanding and control, and (3) coordination and safety. Statements expressed by patients were either patient-oriented or professional-oriented, that is, related to patients or professionals as the primary beneficiaries of PHRs. The same applied to professionals' statements. Therefore, in exploring themes, and in the matrix in [Table S1](#) in [Multimedia Appendix 1](#), we distinguished patients' and professionals' patient-oriented and professional-oriented views. Quotes are presented in [Table S2](#) in [Multimedia Appendix 1](#).

Transparency and Ease

Virtually all statements on transparency and ease were patient-oriented. Most patients and health care providers expressed a need for improved access by patients to their health information, by integrating health data into one platform. This is illustrated by quote 1 in [Table S3](#) in [Multimedia Appendix 1](#). Most patients and health care providers expected that improved accessibility would also increase transparency in care activities and treatment considerations (quotes 2 and 3). On a different note, some patients and providers questioned what patients would gain from entering more health data in digital tools, especially if they do not experience any symptoms.

Understanding and Control

Patients expressed a desire to gain better, more in-depth understanding of their own health status (quote 4). To achieve this level of understanding, patients said that they require more extensive and detailed health information than is available in the patient portals they were currently using, with additional explanations on what this information means. Such data availability would enable patients to verify if health care providers have understood their symptoms and considerations correctly, and to learn what information is documented (quote 5). In contrast, many patients worried that using a PHR would lead to constant reminders of their illness, and a disturbing confrontation with their illness (quote 6). Several health care

providers expressed a similar concern. Finally, many patients expressed a desire to inform health care providers more completely on the impact of illness on their lives, by communicating this through a PHR (quote 7/8).

Health care providers mainly expected that a PHR would improve patients' insight and self-management skills (quote 9/10). However, many questioned whether sufficient patients would use a PHR, since it requires considerable digital expertise, health literacy, and time investment (quote 11). They observed that many patients currently struggle with the interpretation of medical information in patient portals. Eventually, if more health information would become available in a PHR, this could become even more challenging. And would people who use little medication or have few health appointments find it useful? In contrast, nearly all health care providers would strongly welcome a complete overview of medication and other relevant health data (quote 12). Furthermore, more high-quality information entered by patients would help them to better understand the overall impact of illnesses. However, some health care providers perceived PHRs as a burden that increases their workload and responsibility: would they be expected to verify every data entry (quote 13)?

Coordination and Safety

Patients and health care providers elaborated broadly on the final theme: coordination of care and safety. Coordination of care refers to the process of organizing care activities among 2 or more persons involved in a patient's care, often, including the patient. Consequently, patient- and professional-oriented statements overlap. All participants anticipated a PHR would improve coordination of care (quote 14/20). Yet, patients stated that a semileading position in the coordination of their care is already expected from them. Three examples include transferring health information from one health care provider to the next, notifying health care providers in case of particularities, and most importantly, instructing those health care providers who are unfamiliar in treating bleeding disorders what to do in case of emergency situations (quote 16). Yet, most patients feel they have insufficient tools and skills to successfully fulfill this role. They expected that accessing and sharing their medical data would enable them to feel more in control (quote 15). Patients hypothesized it would also reduce preventable mistakes related to allergies, contraindications, and medical history. This view was shared by a minority of health care providers (quote 21).

All participants strongly emphasized the need to improve interprofessional collaborations between health care providers working in different organizations and with different backgrounds (quote 17/22). Still, multiple health care providers questioned whether patients should be able to partially control information flows between health care providers. They feared it is likely that patients will not fully understand all information, and do not always feel proficient to determine who should access their data (quote 18). If patients share all medical information with their care providers, it may overwhelm providers with irrelevant details. However, sharing too little could also result in harmful situations if important information is withheld (quote 19). Finally, some health care providers reasoned that a PHR

could result in a more rapid diagnosis of bleeding disorders, especially in female patients, because bleeding symptoms are generally presented to multiple health care providers.

Required Functionalities

Before presenting functionality cards, participants frequently discussed the following functionalities: an integrated summary of relevant health data and medication, requesting prescription refills, and a complete overview of care appointments and appointment planning.

An overview of prioritized functionality cards is presented in [Figure 2](#). Nearly all participants expected a PHR to contain a complete summary of relevant health information from multiple institutions, including test results, medication, or allergies. Second, integrated access to communication tools, including teleconsulting and chat was considered either essential or nice-to-have by 76% (28/37) of the participants. For functionalities related to appointment making and viewing, this was 78% (29/37). Yet, many health care providers remarked that patients may not have complete freedom in planning their appointments, to maintain some control as a health care provider. Third, 76% (28/37) of participants considered integrated access to commonly used health apps to be either essential or nice-to-have. Participants mainly referred to 2 health apps: a digital treatment diary and a questionnaire portal. They explained that by choosing the card “connected apps,” they implicitly also chose the cards “self-measurements” and “questionnaires.” Participants who did not chose the card “connected apps” were all current nonusers of these apps. Finally, some functionalities were considered less beneficial or unwanted: contacting fellow patients, background information, and scientific updates. One patient chose the card “I do not want a PHR,” because he did not consider himself to be ill and had low health care use. After discussing functionality cards, 3 additional nice-to-have functionalities were brought up: accessing a PHR from abroad, updates on novel treatment options, and explanations of medical terminology.

Expectations and Concerns

Overview

In analyzing patients’ and health care providers’ expectations and concerns, 4 themes were identified: (1) usability, (2) safety, (3) inclusiveness and interpretation, and (4) implementation. The theme matrix is shown in Table S3 in [Multimedia Appendix 1](#) and quotes are presented in Table S4 in [Multimedia Appendix 1](#).

Usability

All patients agreed that a PHR must be simple, easy to use, and easily accessible. Many patients stressed on having a low tolerance for crashes and bugs (quote 23). Some expressed usability concerns if PHRs were to have many functionalities. Finally, some said that health care providers working outside of hemophilia treatment centers must also be able to access PHRs, to facilitate shared care.

Health care providers agreed with the necessity of a simple layout (quote 24). They added that an integrated PHR should not only facilitate bleeding disorder care, but all care. Many

health care providers stressed that their private work notes must stay private, as is currently the case (quote 25). Finally, health care providers were deeply concerned with an increased workload if they would frequently have to access yet another application with additional health information in the limited time they have (quote 26). Quickly opening PHRs and overseeing all relevant information should meet high usability standards, to not hamper daily practice.

Safety

Safety was often mentioned in 2 distinct manners: safety in terms of privacy and in terms of reliable delivery of care. Related to its first meaning, nearly all patients and health care providers expected safety precautions to prevent data breaches (quote 27). As potential culprits, hackers, “big tech” companies, health care insurers, and “big pharma” companies were suggested (quote 30). The latter 2 terms were mostly mentioned by older patients. In addition, many patients insisted to personally authorize every person that may wish to access their PHR.

The second meaning of safety related to the reliable delivery of care. If a PHR were to become an important source of medical information for both patients and health care providers, many stressed it must always be up-to-date and can never go offline (quote 28). Several participants worried that PHRs could delay the delivery of care if patients must approve all information exchanges. Many health care providers worried that patients will not call their health care providers about emergency problems, but use a PHR’s chat function, resulting in a potentially harmful patient and doctor’s delay. Finally, several care providers warned that “bad input” results in “bad output” (quote 29/31). If nonvalidated, inaccurate tools are used to upload self-measurements, treatment plans will be based on incorrect information causing safety risks.

Inclusiveness and Interpretation

Many patients and health care providers said that using a PHR should remain optional and may never substitute face-to-face contacts (quote 32). They warned that many patients are likely to experience difficulties using PHRs, including people with low (health) literacy, low digital proficiency, or language barriers (quote 34). Concerns were raised about an increasingly widening “health gap,” by focusing on improving care for those patients who already have good access to care services and leaving behind those who do not. Still, even digital-minded, literate patients may struggle with interpreting and overseeing medical data (quote 33/35). Multiple health care providers referred to “data flooding”—patients who are overwhelmed by the large amount of data, making it impossible for them to determine what is relevant (quote 36). Some suggested this could be resolved by only including essential information in a PHR.

Implementation

Many health care providers and some patients mentioned that the complete integration of existing health apps and hospital information systems is essential for the success of PHRs but is challenging (quote 37/39/40). Will vocabulary and abbreviations be exchangeable and understandable for others? Next, many

participants stressed it takes “two to tango”—a patient as well as their health care providers need to work with a PHR for it to become useful in clinical care. Only if sufficient patients and health care providers use a PHR, it will become part of the routine delivery of care (quote 38).

Discussion

Principal Findings

In this study, we assessed patients’ and health care providers’ perspectives regarding the use of a PHR in hemophilia care in the Netherlands, required functionalities, as well as expectations and concerns. Overall, patients and health care providers welcomed the development of a PHR. Both groups recognized the dual effects of using PHRs, either regarding patients or health care providers as its primary beneficiaries. A PHR was generally thought to increase transparency through access to integrated health data, facilitate patients’ understanding of their illness, and improve coordination of care. Requested functionalities were mostly related to the integration of relevant medical information, medication, appointments, communication tools, and data entered by patients. Concerns were mostly related to usability, privacy, patients’ difficulties in managing information flows, variations in patients’ (digital) health literacy, interoperability, and insufficient uptake of PHRs. While patients more often expressed their worries over medicalization (ie, more confrontational reminders of their illness), providers were concerned about their responsibility for all data entered by patients and a potential increase in workload.

Comparison With Earlier Evidence

The perspectives, required functionalities, and expectations and concerns regarding a PHR or patient portal have not yet been studied among patients with congenital bleeding disorders. More research has been done in other populations.

Perspectives

Perspectives toward PHRs and patient portals were assessed by several studies. Perspectives reflect attitudes that define why people consider (or do not consider) using a PHR or patient portal and reveal their motivation and underlying goals. A Flemish questionnaire study assessed perspectives toward a patient portal among the general population [22]. Similar to our study, they found that increased transparency, understanding, and shared decision-making were anticipated. Unlike our study, PHRs’ warning functions for deteriorating health were often mentioned. This might be because patients with a congenital bleeding disorder are already well-educated in self-monitoring treatment effects. Three other studies mainly identified improved patient understanding as the most anticipated benefit of PHRs: a US mixed methods study among older adult patients [23], a US survey among the general population [24], and a German questionnaire study among persons with psoriasis and their health care providers [25]. The latter study also added interprofessional cooperation as an anticipated benefit [25]. Several reviews on patient portals and PHRs revealed a similar trend, in which transparency [26,27] and understanding and control [26-30], and to a lesser extent, coordination, were often stated as motivations for its use [26,30]. Thus, for the greater

part, attitudes overlap, although disease-specific differences do occur.

Study participants expected that a PHR will improve the coordination of care. Multiple health care providers questioned whether patients can (partially) control information flows between health care providers due to their limited comprehension of medical concepts. However, patients stated that they are already expected to adopt a semileading position in the coordination of their care. Therefore, with the appropriate support, a PHR could enable patients to better fulfill this semileading role. However, a PHR is not a panacea for all challenges in the delivery of care. A PHR will only improve physician’s delay if health care providers work together more closely. Similarly, by facilitating the exchange of health data, a PHR will not necessarily change the way that health care providers collaborate. Changes in the organization and delivery of care likely need to be made for PHRs to reach their full potential.

Finally, although the term “patient empowerment” was not expressed by patients nor health care providers, this concept occupies a central role in discussing PHRs’ benefits. Empowerment refers to being able to think critically and make autonomous, informed decisions [31-33]. Contrastingly, the concept “self-management” was often mentioned. It can generally be said that, once empowered, patients perform more self-management behavior [4]. In previous studies, the effects of using PHRs and patient portals on self-management ranged from inconclusive [34-38] to beneficial [39-44]. However, few to none of these PHRs truly enabled patients to collect, manage, and share their health information. Therefore, more research is needed to evaluate PHRs while they mature.

Required Functionalities

Most required functionalities identified in this study largely matched those identified in previous studies, although 3 were more prominently listed in other studies: requesting prescription refills [22], viewing clinician contact information [23], and proxy-access for a child or parent [24]. This may be because hemophilia treatment center contact information is already well-known among people with a severe congenital bleeding disorder due to long-term treatment relationships and centralized care. Furthermore, adequate alternatives for requesting prescription refills are already available. Finally, proxy-access was considered essential in a specific subgroup of parents and older adult patients in our study.

Expectations and Concerns

In previous studies, the frequently mentioned concerns were usability [16,23,24,26,28,29,34,42-48], privacy and safety [16,23,24,26,27,29,34,42-46,49], inclusiveness [23,27-29,42,43,46,48,50], comprehension of health data [26,29,49], and increased professional workload [16,25,29,48]. Taken together, PHRs are widely expected to be highly user-friendly, understandable, nonobligatory, secure, and inclusive for all patients. Interoperability issues have not previously been reported. However, it is expected that in the rapidly expanding landscape of digital health tools, this concern

will become more omnipresent due to the increasing fragmentation of information.

Strengths and Limitations

A strength of this study is that by identifying both patients' and health care providers' perspectives, we were able to assess similarities and differences. Moreover, by using multiple interviewing techniques, such as prompts, participants were stimulated to verbalize their thoughts. Yet, several limitations should be considered. First, by explaining the concept PHR and by using functionality cards, participants may have been influenced. We aimed to limit this risk through the standardization of explanations, and by only presenting cards after we had openly discussed functionalities. Second, by initially including participants through open advertisements and due to the COVID-19 pandemic that forced us to conduct part of the interviews using video conferencing, more digital-minded patients may have been included. Still, by actively including patients from outpatient clinics using purposeful sampling at a later phase, we aimed to minimize such selection. Third, although the gender distribution among the included health care providers represents the current workforce, it is likely that women have different perceptions on a PHR, based on earlier research on gender differences in electronic health record perceptions, although its exact implications remain uncertain [51,52]. Finally, an important limitation is that perspectives and expectations regarding a hypothetical tool are difficult to assess. It may be questioned whether participants truly know what it is that they want and need.

Implications

The greatest challenge in the implementation of PHRs may prove to be the fragmentation of the digital health landscape and its limited interconnectivity. PHRs may not reach their full potential until different hospital information systems and eHealth tools can be adequately connected. Several national and international initiatives have been established that aim to standardize health information technology [53-56]. Until these programs have yielded effects, we must proactively investigate how to promote inclusiveness of PHRs, and safeguard users' privacy. This can only be achieved by involving both patients and health care providers in the development of PHRs to acknowledge their different preferences and to motivate both. In doing so, we would advocate focusing on a PHR intended for a broader population of people with chronic conditions and not only for hemophilia, owing to considerable overlap in expectations and requirements. With hemophilia as a representative use case, these insights may aid the development of a PHR valuable for people with any chronic disease with a high level of self-management.

Conclusions

People with hemophilia, their parents, and health care providers welcomed the development of a PHR in hemophilia care and expressed positive attitudes regarding its use. The benefits of using a PHR on transparency, patients' understanding of their illness, and the improved coordination of care were widely anticipated. However, concerns regarding usability, privacy, inclusiveness, and interoperability need to be taken into account.

Acknowledgments

The authors thank all participants for the interviews. This project was supported by grant NWA.1160.18.038 (principal investigator: MHC) of the Netherlands Organization for Scientific Research (NWO) for the SYMPHONY consortium. The SYMPHONY consortium aims to orchestrate personalized treatment in patients with bleeding disorders. Beneficiaries of the SYMPHONY consortium are Bayer BV, CSL Behring BV, and Swedish Orphan Biovitrum (Belgium) BVBA/SPRL.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

MRB conducted 34 interviews and coded all interviews. JJM conducted 3 and coded 12 interviews. Thematic discussions were carried out by MRB, JJM, LH, and SCG. MRB and SCG drafted the first version of the manuscript. All authors provided feedback on the manuscript and approved the final manuscript. No generative artificial intelligence was used in writing this manuscript.

Conflicts of Interest

The institution of MHC has received investigator-initiated research and travel grants as well as speaker fees over the years from Netherlands Organization for Scientific Research (NWO) and Netherlands National research Agenda (NWA), the Netherlands Organization for Health Research and Development (ZonMw), the Dutch Innovatiefonds Zorgverzekeraars, Baxter, Baxalta, Shire, and Takeda, Pfizer, Bayer Schering Pharma, CSL Behring, Sobi Biogen, Novo Nordisk, Novartis, and Nordic Pharma, and for serving as a steering board member for Roche, Bayer, and Novartis, for which fees go to the Erasmus MC as an institution. The institution of KF received unrestricted research grants from CSL Behring and Novo Nordisk and her institution received consultancy fees from SOBI, Grifols, Takeda, Novo Nordisk, and Roche. SCG has received an unrestricted research grant from SOBI. The HemoNED Foundation received a grant or research support from Bayer, CSL Behring, Novo Nordisk, Octapharma, Pfizer, Roche, Sobi, and Takeda. Other authors have no relevant disclosures to report.

Abstract

Background: Among the numerous factors contributing to health care providers' engagement with mobile apps, including user characteristics (eg, dexterity, anatomy, and attitude) and mobile features (eg, screen and button size), usability and quality of apps have been introduced as the most influential factors.

Objective: This study aims to investigate the usability and quality of the Head Computed Tomography Scan Appropriateness Criteria (HAC) mobile app for physicians' computed tomography scan ordering.

Methods: Our study design was primarily based on methodological triangulation by using mixed methods research involving quantitative and qualitative think-aloud usability testing, quantitative analysis of the Mobile Apps Rating Scale (MARS) for quality assessment, and debriefing across 3 phases. In total, 16 medical interns participated in quality assessment and testing usability characteristics, including efficiency, effectiveness, learnability, errors, and satisfaction with the HAC app.

Results: The efficiency and effectiveness of the HAC app were deemed satisfactory, with ratings of 97.8% and 96.9%, respectively. MARS assessment scale indicated the overall favorable quality score of the HAC app (82 out of 100). Scoring 4 MARS subscales, Information (73.37 out of 100) and Engagement (73.48 out of 100) had the lowest scores, while Aesthetics had the highest score (87.86 out of 100). Analysis of the items in each MARS subscale revealed that in the Engagement subscale, the lowest score of the HAC app was "customization" (63.6 out of 100). In the Functionality subscale, the HAC app's lowest value was "performance" (67.4 out of 100). Qualitative think-aloud usability testing of the HAC app found notable usability issues grouped into 8 main categories: lack of finger-friendly touch targets, poor search capabilities, input problems, inefficient data presentation and information control, unclear control and confirmation, lack of predictive capabilities, poor assistance and support, and unclear navigation logic.

Conclusions: Evaluating the quality and usability of mobile apps using a mixed methods approach provides valuable information about their functionality and disadvantages. It is highly recommended to embrace a more holistic and mixed methods strategy when evaluating mobile apps, because results from a single method imperfectly reflect trustworthy and reliable information regarding the usability and quality of apps.

Introduction

Background

Mobile devices and mobile health (mHealth) apps have equipped the health care system with a strategy to improve health through enhanced self-management among patients and access to educational materials for health care professionals [1]. Considering their advantages regarding the fastest and most convenient ways to access health care services, they have been introduced as effective eHealth technology to address health priorities [2]. Recently, a global initiative has been launched to apply mobile technologies to provide health care services and manage various diseases [3]. A 2015 World Health Organization survey revealed that 15,000 mobile apps were available for health care use [4]. However, the continuity in the use of apps is highly challenging, and existing evidence presented poor user engagement and relatively high drop-out rates on apps among patients and health care providers (HCPs) [5]. Earlier research revealed that nearly half of mHealth app users avoid continuous use of them [6]. The drop-out rates in app-based interventions for chronic diseases were reported to be 43% (95% CI 29%-57%) in a meta-analysis by Meyerowitz-Katz et al [7].

Usability has been introduced as a surrogate marker for app quality and user engagement with them to address this challenge [8-10]. Given the significance, assessing the usability and quality of mobile apps occupies a crucial part of app development and users' overall assessment of app quality [6,8]. However, emerging research has debated that mobile apps suffer from usability and quality issues and are limited by their ability to address users' needs [9,11,12]. Physicians use many mobile apps to access a wide range of knowledge and information in educational materials, drug reference guides, x-ray results, laboratory test information, and clinical guidelines [13]. Medical apps were positively perceived, with physicians reporting increased dependency on the apps. The use of apps in the medical setting has steadily grown in recent years [14]. While a considerable number of physicians now use mobile devices and apps for clinical practices globally [7], there are also reports of drop-out rate and short-term engagement among physicians with these mobile apps [1]. Arguably, no clear understanding exists of the physicians' motivations and interests in adopting and long-term use of mobile apps [8]. A variety of factors, from organizational and social factors [15] to users' characteristics (eg, user dexterity and anatomy and positive attitude) [16-19] or mobile features (eg, screen and buttons size, poor resolution, and usability) [6,20-22], would influence the successful adoption of mobile apps among physicians.

Prior Work

Usability and quality issues have been reported as central to user engagement with mobile apps [6,21]. The research team previously developed a mobile app aimed at assisting physicians in prescribing head computed tomography (CT) scans based on appropriateness guidelines, the Head CT Scan Appropriateness

Criteria (HAC) mobile app [1]. However, during that study, neurology and neurosurgery residents expressed concerns about usability issues despite their interest in using the app. Therefore, before proceeding with full implementation, it is essential to identify and address usability problems of the app using mixed methods that involve participation from final users.

Goal

In this study, we seek to investigate the usability of HAC app using mixed methods research involving quantitative analysis of the Mobile Apps Rating Scale (MARS) for quality assessment, quantitative and qualitative think-aloud (TA) usability testing, and debriefing across 3 phases.

Methods

Study Setting

This study was conducted as part of a broader effort to develop a mobile app, known as the HAC app, based on clinical guidelines. The development occurred at an academic hospital with Kashan University of Medical Sciences (KAUMS) in Iran, which has 510 beds. This newly developed HAC app allows end users to search for appropriate CT scans based on diseases, signs, symptoms, and modalities, such as CT, CT angiography (CTA), and MRI. Appropriate CT scans refers to imaging studies that are deemed clinically justified and indicated based on established medical criteria, including patient symptoms, signs, and relevant clinical history, in accordance with evidence-based guidelines and best practices in diagnostic radiology.

The study involved 16 medical interns from an academic hospital at KAUMS. For this study, the focus was on assessing the end-user usability through a TA approach [23,24], evaluating the quality of the HAC app using the MARS [25], and conducting informal debriefing sessions to gather insights and opinions for the medical interns regarding the HAC app.

Profile of the HAC App: HAC App Content and Functionality

The HAC app was developed using applied 4-tier architecture, including presentation, data service, business logic, and data access layers. The app was designed using JavaScript in such a way that allows it to be installed and be compatible with the latest version of Android in 2021 (version 12) as well as earlier versions. The HAC app encompasses essential criteria arranged by Care Core guidelines for head CT scans. Care Core provides a list of disease titles, for example, head trauma, which is supplemented by the list of clinical criteria in terms of signs and symptoms of the given disease. Clicking the plus sign (+) provides the detailed clinical criteria. Under each main heading or in front of each condition, the appropriate imaging procedure in MRI, CT, and CTA is provided. A shortlist menu is designed to organize and quickly find frequently used diseases or clinical criteria. It enables users to add common diagnoses to the shortlist menu. Screenshots of the functionalities of the HAC app are presented in [Figures 1 and 2](#).

Figure 1. Head Computed Tomography Scan Appropriateness Criteria app search results for seizure.

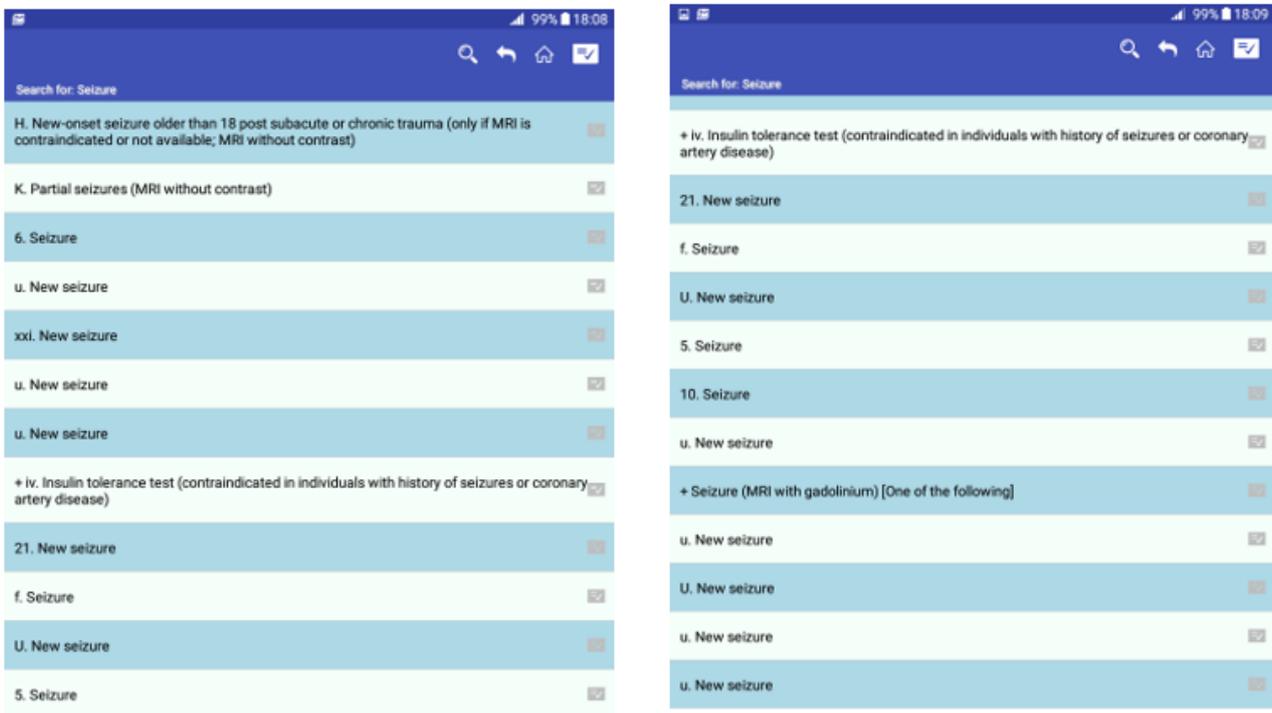

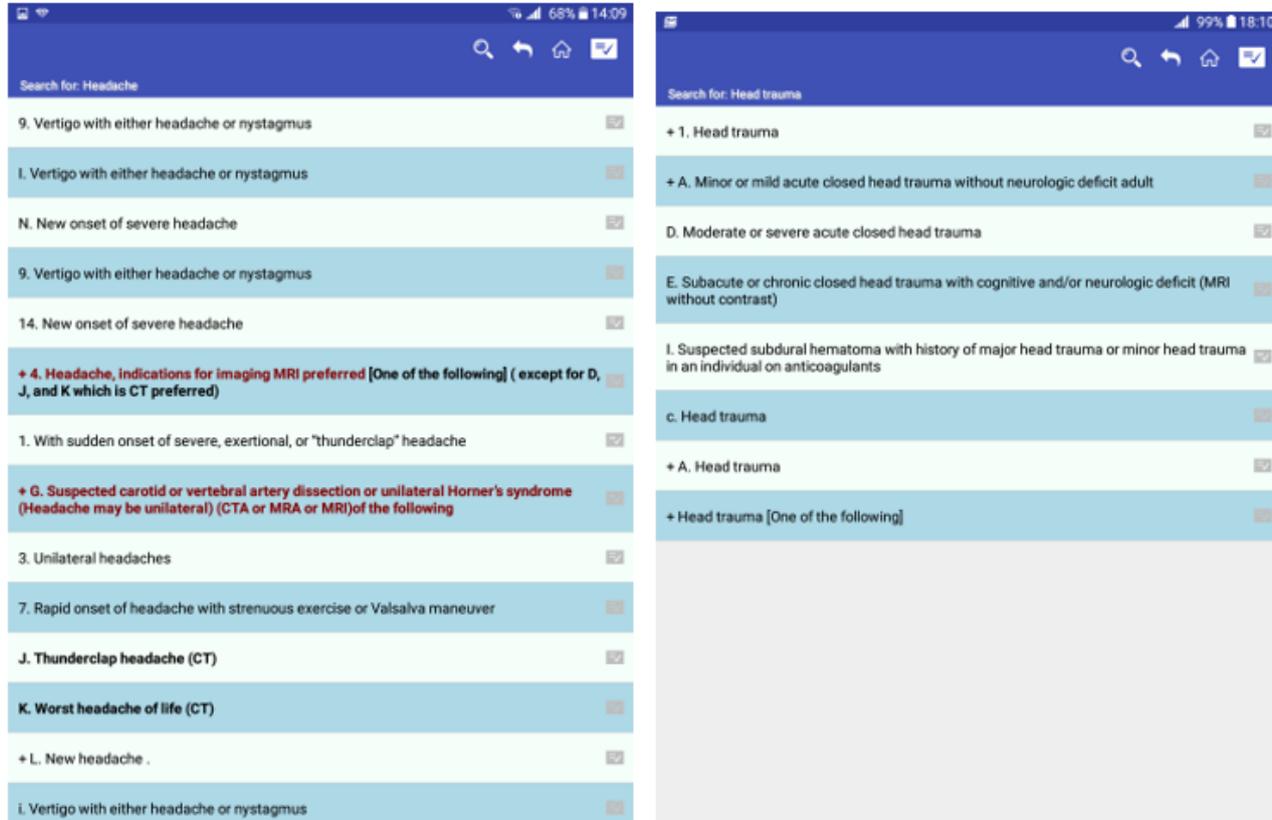

Figure 2. Head Computed Tomography Scan Appropriateness Criteria app search results for head trauma and headache.

Approaches to Conduct the Study

Three approaches have been used to conduct the research and achieve the study objectives.

The TA Usability Testing

In this phase, we tested the HAC app’s effectiveness, efficiency, error, and learnability. The study objectives have been determined to ensure the accurate fulfillment of the tasks, the correct selection of the icons and buttons, and end users’ use of the mobile app without errors in an efficient way. The TA

approach set out to determine the following measures to achieve the objectives:

- The effectiveness of participants' navigation of the app was measured by the accurateness and completeness of the HAC app on CT scan ordering based on diseases, signs, symptoms, and modalities, for example, CT, CTA, and MRI.
- The efficiency of the participants was specified by the number of touch targets on the app screen and the task completion time.
- The simplicity and learnability of the HAC app were measured by the number of tasks that were easily completed and the severity of errors made by the users.
- Errors indicated the number of user mistakes when using the HAC app.

MARS Quality Assessment

To evaluate the HAC app quality in terms of engagement, functionality, Aesthetics, information, and subjective quality, we applied the MARS tool [25], and the following dimensions were addressed:

- the overall quality score of the HAC app and its subscales, including Engagement, Functionality, Aesthetics, Information, and Subjective Quality
- a statistically significant difference between MARS subscales quality score
- a statistically significant difference between 2 sets of pairs of MARS subscales (eg, Engagement and Functionality or Functionality and Aesthetics)
- the correlation between MARS subscales for the HAC app
- the significant relationship between medical interns' characteristics (ie, age, gender, and interest in using mobile apps for learning and clinical practice) with MARS subscales

Debriefing

An informal debrief was conducted to review and digest interns' general ideas about using mobile apps and physicians' expectations for a suitable mobile app. It was also applied to collect underexplored facts for further revision of the HAC app.

Study Design and Data Analysis

Our study design was primarily based on methodological triangulation through the use of mixed methods research, and investigator triangulation to enhance the understanding and interpreting the results [26].

The mixed methods study involved quantitative (MARS quality assessment and TA quantitative usability testing) and qualitative methods (TA qualitative usability testing and debriefing) across 3 phases. By using the technique of investigator triangulation, a variety of researchers, such as medical practitioners, experts in health information technology, and professionals in health information management, were involved in the gathering and analyzing of the data. The details of each phase will be discussed in the subsequent sections.

Phase 1: TA Usability Testing Approach

Design

The study used a TA study design to explore the user's cognition, including feelings, thoughts, and whatever else comes to mind while interacting with a system to perform a task. This standard data collection method for assessing users' cognitive behavior during system interaction helps identify errors and necessary changes [23,24].

There are 2 fundamental usability testing methods: qualitative and quantitative [27]. Qualitative methods primarily aim to explore users' interaction experiences with a product and describe possible issues they encounter [28]. In contrast, the quantitative methods use various metrics, such as task times, completion rates, and errors, to measure and categorize the errors and problems users encounter during usability testing [29]. Both qualitative and quantitative methods were applied in this study to reach the research objectives. Usability evaluation was also conducted in the different stages of a product development life cycle. Formative evaluation was done in the early product development life cycle to shape the design direction. Summative assessment was performed toward the end of the product development (final product) to evaluate its performance against a set of metrics (eg, time on task and success rate) [28]. The participants implemented summative usability testing in this study to evaluate the performance of the HAC app.

Participant Recruitment

Previous evidence confirms that about 5 to 15 participants are sufficient to perform TA to enhance the expected level of problem discovery [30]. We recruited 16 medical interns who participated in 3 phases of the study. We applied social media to attract medical interns to join the study. We posted our research profile on the medical students' academic and social media channels, including the study title, research team, and overall study objectives. We invited those who finished their clinical internship in emergency medicine to participate in this study. Our multidisciplinary research team, including clinicians, significantly streamlined the recruitment process. The research team, consisting of members from diverse disciplines, encouraged their previous students to participate in the research. No rewards or compensations were paid to the participants.

Protocol

The TA usability testing was conducted in multiple sessions of the same activity. Developing a study protocol to ensure the consistency of each activity in each session helped the facilitator give all the necessary information to the participants, which seemed imperative [28]. The study protocol in this study consisted of session introduction, information capture methods (ie, observation and videotaping), task scenarios, user interactions with the product and any identified product problems and difficulties, and measurement criteria, which are discussed in the following sections.

Session Introduction

Interested volunteers were contacted to schedule face-to-face visits. TA sessions were held in the physicians' actual

workplace. It is widely believed that evaluations conducted in the field resemble the set-up that matches the user's real work context, providing "ecological validity" to the study and accurately reflecting the users' context [28].

Once the researcher arrived in the field, they gave the participants an overview of the session and the overall goals. They let them know about the presence of any facilitator or observers in the session and the rules for conducting the usability testing.

Ethical Considerations

Overview

This study was approved by the ethics review board at KAUMS (code #IR.KAUMS.MEDNT.REC.1399.075). The participants were informed the same and emphasized the voluntary nature of participation, assuring them of the confidentiality of information. The nonevaluative environment of the TA session was also explained by a trained moderator (researcher). Then, participants who attended the face-to-face meeting consented to participate in the study and TA session run.

Data Collection

The usability data collection protocol was generally implemented via 2 approaches: concurrent TA and retrospective TA protocols [31].

Because concurrent TA is more objective and less dependent on users' memory and prior experience of completed tasks compared with retrospective TA, concurrent TA was adopted as a standardized method to conduct usability testing of the HAC app [28,32].

Considering that most users are uncomfortable installing something on their devices (eg, mobiles or computers) [28] and the importance of using the same tool to capture usability-testing data, interaction with the HAC app was done via an Android mobile phone dedicated only to the research purposes. A portfolio of methods, including video screen-recording software, audio and screen recording, and notetaking, were applied to collect data. Four scenarios containing 4 to 6 tasks were given to the participant to interact with the HAC app. All the activities to accomplish the scenario, including the number of touch targets on the app screen, the task completion time, and the elapsed time, were captured using the free AZ Screen Recorder for Android (AZ Screen Recorder) [33].

Three evaluators facilitated the testing sessions and analyzed the results. The researchers adopted the verbal protocol to collect the data. Although the verbal protocol is the most traditional protocol with limited probing methods compared with active users' participation methods, such as communication - based and coaching protocols, it resembles an authentic context experience by not offering any external assistance to the users [34].

Thus, 1 researcher supervised the evaluation session, but neither user received instruction during the task performance stage. Attention was given to shortening the testing process and keeping a participant on the phone for >10 minutes [28]. Each TA session lasted for about 20 to 30 minutes.

Tasks Scenario

The scenarios (including their goals and actions) were designed to examine different parts and functions of the HAC app and covered the most common tasks that a clinician may use in a typical working application. Usability problems were detected by researchers from analyses of user behavior and expressions during interactions with the system.

Measurement

A coding framework was developed according to 5 usability characteristics and based on the International Organization for Standardization and Nielsen's definitions to recognize the specific user-computer interaction problems in detail to define the measurement criteria [35-37]. Nielsen put forward 5 usability attributes: learnability, efficiency, memorability, errors, and satisfaction [37].

Combining International Organization for Standardization and Nielsen usability attributes yields the following 6 criteria: efficiency, effectiveness, learnability, memorability, errors, and satisfaction. Because the participants only used the HAC app in this study, and there was no need to remember the options for the next session, we omitted memorability in our evaluation. The remaining 5 attributes were integrated into our coding framework [23].

We used the TA method to measure effectiveness, learnability, errors, and efficiency characteristics, and the MARS questionnaire was used to measure satisfaction.

Errors or usability problems were detected based on the analysis of the "critical issues" encountered by the participants during the interactions detected from the video reviews. Critical issues were defined as those that prevented task completion, "severe issues" were defined as those issues that caused significant slowdown or frustration, and "cosmetic issues" were the ones that remained and had minimal effect [38].

Learnability was evaluated by measuring the number of quickly completed tasks.

Data Analysis

Phase 1: TA Usability Testing

TA Quantitative Part

Data analysis and measurements of usability metrics were addressed based on a coding framework mentioned in the study design and protocol section. The usability characteristics and problems and their severity rating are described as follows:

Efficiency was measured by two metrics: (1) the number of touches targeted and (2) the task completion time. The mean time taken for the users to perform each task was based on the following equation:

$$\text{Efficiency} = \left[\frac{\text{total of full completion of a task (1) or noncompletion (0)}}{\text{(time spent on a task)}} \right] / \left[\frac{\text{total number of tasks} \times \text{number of users}}{\text{}} \right] \times 100 \text{ (1)}$$

Effectiveness was measured by the number of completed tasks (ie, task completion rate), indicating the task's success rate. The extent to which the user can fully and accurately achieve their

task goals. Effectiveness was measured using the following equation.

$$\text{Effectiveness} = [(\text{number of successfully completed tasks}) / (\text{total number of tasks performed})] \times 100 \text{ (2)}$$

The range of effectiveness was taken as “awful” (0%-50%), “bad” (50%-75%), “normal” (75%-90%), and “good” (90%-100%) [24].

Learnability was evaluated by measuring the number of quickly completed tasks.

Errors were identified as the number of user mistakes when performing the tasks.

Satisfaction was measured based on the user’s total score on the MARS questionnaire.

TA Qualitative Part

The video reactions of the participants were transcribed verbatim. Usability data, characterized by users’ comments, silences, repeated actions, and error messages, were collected through the recordings. Three members of the research team analyzed the obtained content. Transcripts and usability problems were also reviewed to identify the most common concerns. In any case of discrepancy in content analysis, a third-party reviewer was consulted.

These differences were categorized based on the tasks in the scenarios (ie, measurements, zoom and magnifying, and contrast and window level).

Data collected during the TA tasks (phase 1) were analyzed using fundamental inductive content analysis consisting of data reduction, data grouping, and the formation of concepts to answer research questions [39].

The inductive process is a bottom-up process that looks at all the issues as a whole by aggregating similar issues together until all the issues have been sorted into groups. Once all the groups (ie, subcategories) had been sorted, they were labeled to create more significant categories [40,41]. Thus, at the end of this process, we identified significant usability category issues and the specific problems associated with each one.

Phase 2: Evaluation of the Quality of the HAC App Using the MARS Questionnaire

Design

The participants (16 medical interns) were asked to complete the MARS questionnaire immediately after the TA session. MARS is the most popular scale and a highly reliable tool designed to assist researchers, professionals, and clinicians in classifying and assessing the quality of mHealth apps [25].

Data Collection

A validated and reliable Persian language version of MARS was used to collect the HAC app quality data [42].

MARS consists of 23 items in 5 objective quality subscales:

- Engagement encompasses 5 items and mainly focuses on entertainment and interest features of mobile apps.

- Functionality includes 4 items and addresses the ease of use and functional capabilities of mobile apps.
- Aesthetics consist of 3 items and discuss mobile app layout and visual appeal.
- The information includes 7 items and mainly considers quality, quantity, credibility, and visual enhancement of included information.
- The Subjective Quality subscale of MARS focuses on the overall rating of the app, its benefits, and its value.

Data Analysis

Each subscale item was rated a 5-point score from 1 (inadequate) to 5 (excellent). Usually, the mean score and SD were used to rate the quality of apps. Since the number of items in each subscale was different, we also used this formula [(mean of subscale/number of items in subscale)×(100)] to compute the score out of 100 and compare the subscales. To calculate the total HAC app score, the [(total mean of HAC app/total MARS items)×(100)].

Friedman test was applied to compare the users’ scores in 5 MARS subscales. The Wilcoxon test investigated the mean difference between 2 sets of pairs of MARS subscales. Spearman rank correlation coefficient was used to analyze the positive correlation between MARS subscales. Kruskal-Wallis and 1-way ANOVA tests were used to assess differences between medical interns’ characteristics and MARS’ subscales. All statistical analyses were performed using SPSS (version 16.0; IBM Inc) at a significance level of .05.

We applied inductive content analysis consisting of data reduction, data grouping, and the formation of concepts to analyze TA qualitative data and transform physicians’ ideas into categories in the debriefing phase.

Phase 3: Debrief Participants

A debrief session is an informal conversation to collect users’ experiences and [43] any features of the app that they particularly like or dislike, how easy or difficult it is to use, and what they think about the content and design of the app was discussed in the debriefing session. The medical interns’ general opinion regarding the effective mobile apps to assist HCPs in education or clinical practice was also investigated in this phase. During the analysis of the recorded videos and voices, it came to our attention that the debrief sessions which were carried out with the participation of clinicians’ research team, were the most active and engaging ones. To analyze and present the debriefed data, a narrative analysis method was used [44].

Results

Outline

The findings of each phase will be presented under the same headings in the methods section, including TA quantitative, TA qualitative, MARS quality assessment, and then a debriefing session.

Phase 1: TA Usability Testing

Overview

Table 1 illustrates the scenarios, goals, and actions needed to complete the tasks.

Table 1. Descriptions of the scenarios used in the usability testing.

Scenarios	Goals	Actions
1. A head trauma patient was admitted to the emergency department. Please check if the CT ^a scan indicated a patient with “minor or mild acute closed head trauma without neurologic deficit adult.”	According to the guidelines, search for appropriate imaging procedures for a given diagnosis.	<ol style="list-style-type: none"> 1. Selecting the search icon 2. Typing the disease title in the search box 3. Finding the head trauma from the query list 4. Clicking on the plus button 5. Check if the imaging procedure is recommended for the patient.
2. A patient was admitted to the emergency department with “new onset of seizures older than 18 following acute trauma.” Please select the appropriate imaging procedure for the case.	To use appropriate imaging procedures for seizures.	<ol style="list-style-type: none"> 1. Opening the search query 2. Typing the seizures into the search box 3. Navigating between items in the search list 4. Selecting the appropriate imaging procedure based on the patient’s symptoms
3. Headache and vertigo are common symptoms at the emergency department. Please add headache to the shortlist for forthcoming queries.	To apply a shortlist menu to collect appropriate imaging procedures for common diseases and symptoms.	<ol style="list-style-type: none"> 1. Adding headache to shortlist menu 2. Backing to the first page 3. Opening the shortlist 4. Deselecting the items you are not interested in anymore
4. A patient with proven subarachnoid hemorrhage (negative angiogram) was admitted to the hospital for follow-up. Please check for appropriate imaging procedures.	To use the CT ^a or CTA ^b button to access subarachnoid hemorrhage.	<ol style="list-style-type: none"> 1. Opening list of diseases under the title of CT 2. Finding subarachnoid hemorrhage 3. Moving one step backward 4. Selecting the CTA button 5. Navigating between items in the search list 6. Click on the plus sign to search for detailed information on subarachnoid hemorrhage and its subgroups.

^aCT: computed tomography.

^bCTA: computed tomography angiography.

TA Quantitative

Efficiency

On the basis of the equation 1, the HAC app’s relative overall efficiency was 97.8%. The average time spent for each scenario was 97.5 seconds, and the number of additional clicks was 0.93. The highest average of performing scenarios belonged to scenario 3 (109.25 seconds), and the lowest average was related to scenario 4 (83.875 seconds). Among the users, the highest total average time for 4 scenarios was related to user number 3 (161.8 seconds), and the lowest time was for user number 11 (58.0 seconds).

Effectiveness

The HAC app’s effectiveness in assisting users in performing the scenarios based on the equation 2 was good (97%). Of 16 users, 14 (88%) completed all 4 scenarios, 2 (13%) completed

3 scenarios, and 2 (13%) users had difficulty performing scenario 2, which was focused on searching for “new onset of seizures older than 18 following acute trauma.” The characteristics of this scenario that caused usability issues have been discussed under the heading TA qualitative, “inefficient data presentation and information control,” and “poor searching capabilities” (Figures 1 and 2).

Learnability

Out of 16 users, 11 (69%) managed to complete 4 scenarios, 4 (25%) users managed to complete 3 scenarios without encountering critical issues, and 2 (13%) users faced critical issues to complete 2 scenarios.

Errors

Out of 16 users, 10 (63%) users did not make any errors while doing the scenarios, and 6 (33%) users were able to do the scenarios with >1 errors (Table 2).

Table 2. Matrix of efficiency and effectiveness of the Head Computed Tomography Scan Appropriateness Criteria (HAC) mobile app^a.

User number	Efficiency, s					Effectiveness Total scenarios completed
	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Total average	
1	98	189	150	210	161.8	3
2	75	101	134	82	98.0	4
3	192	135	129	108	141.0	4
4	92	86	115	57	87.5	4
5	74	125	63	84	86.5	4
6	115	73	129	53	92.5	4
7	115	83	82	52	83.0	4
8	69	93	106	127	98.8	4
9	60	109	89	80	84.5	4
10	70	117	170	82	109.8	3
11	34	57	79	62	58.0	4
12	40	97	125	45	76.8	4
13	109	132	87	64	98.0	4
14	72	83	95	67	79.3	4
15	101	185	95	107	122.0	4
16	110	59	100	62	82.8	4

^aAverage efficiencies: scenario 1=89.125, scenario 2=107.75, scenario 3=109.25, scenario 4=83.87, total average=97.5.

TA Qualitative

The results of the inductive content analysis regarding usability issues were grouped into 8 main categories and discussed below.

Lack of Finger-Friendly Touch Targets

Most participants had difficulty tapping the target buttons, such as the shortlist button, or icons, such as the plus sign (+) on the screen, and it was an intensive task to perform successfully. The participants stated that the given features are inappropriate for finger-touch targets. It might be due to the wrong size of the buttons or the need for more padding between buttons and icons around the edge of the screen. Consequently, it led to selecting the wrong part of the screen and frequent mistapping of the shortlist menu. Most participants often used this statement: "I cannot get the button." Failure to press the targeted button and retouching the icons multiple times occurred frequently, resulting in a long time on the task and decreased efficiency. Moreover, it caused a failure of task completion by 2 users and reduced the effectiveness of the HAC app.

Poor Search Capabilities

Navigating the diseases and signs and symptoms was case-sensitive to the upper case. It made the searching diagnosis and signs and symptoms keywords awkward. The participant struggled to find diseases and signs and symptoms that had not been typed in upper case. Some participants forgot the "case-sensitive" feature every time they started the new scenario. Thus, participants backed out and jumped over the navigation process or tried to find the given case from a long list of search results. Both situations made it time-consuming and inefficient and caused participant frustration.

Input Problems

The main complaint by the participants was that the font size was inappropriately amplified with the limited mobile size. Participants mentioned that typing on the mobile phone screen was an intensive task. We found some difficulty in typing on the small screen; all the participant's attention was focused on what they had typed. The "case-sensitive" feature in searching data amplified the problem. The lack of finger-friendly touch targets also made the typing more cognitive load and distracted from their main concerns, interacting with the patients.

Inefficient Data Presentation and Information Control

Another usability issue that caused frustration among users was inefficient data presentation and information control. To apply the HAC app, users entered specific diseases, signs, or symptoms enclosed in the Care Core guideline in the "Index" box. However, the list of clinical criteria under the disease heading was grouped using the plus sign (+) to provide a proper data presentation. A long list of conditions in the form of a dropdown menu enclosing the common signs and symptoms made it confusing for the participant. Since the mobile screen was too small, providing a long list of search results makes it time-consuming and inefficient. The lack of proper information layering and data categorization made it difficult for the participant to scroll the list. The participant commented the following:

It requires much attention and is very inconvenient since we need to interact with patients, other colleagues, and clinical settings environment.

The critical issue was related to bringing cognitive load to the participants.

Unclear Control and Confirmation

Another failure dealt with providing feedback and confirmation. The participants expected the HAC app to inform them about what was happening, using appropriate feedback. For instance, when they were asked to add a given disease to the shortlist, they waited for a dialogue to let them know the conditions were added. The absence of the appropriate feedback resulted in the users being moved to the shortlist and checked on if the command was run. The exact process occurred when they were asked to remove the given disease from the shortlist. The users awaited a confirmation dialogue regarding spoken questions, such as a “yes” or a “no,” to remove the disease from the shortlist before executing the removing command. Without a physical response, users did not know the current system status and were not confident about the consequences of their prior actions. They felt confusion and frustration.

Lack of Predictive Capabilities

Some participants expected more predictive capabilities and automation to optimize manual tasks and increase efficiency across various functions. For example, a participant stated the following:

We prefer the HAC app to automatically move the most visited diseases or signs and symptoms to the shortlist menu.

They believed the sole manually supported feature for making a shortlist menu could be more efficient and less time-consuming.

Poor Assistance and Support

The participants thought some features on the HAC app, such as shortlists highlighted in red or items with the plus sign, were difficult to recall or interpret and caused cognitive load. The participants needed assistance or information to learn more about these features, such as tooltips, which display informative text, such as a description of its function when users hover over, focus on, or tap an icon. They were looking for a help tab and found it unclear because it was at the bottom of the “About us” tab. It caused the HAC app to be less self-descriptive and more dependent on external help, which needed to be clarified and made clearer.

Unclear Navigation Logic

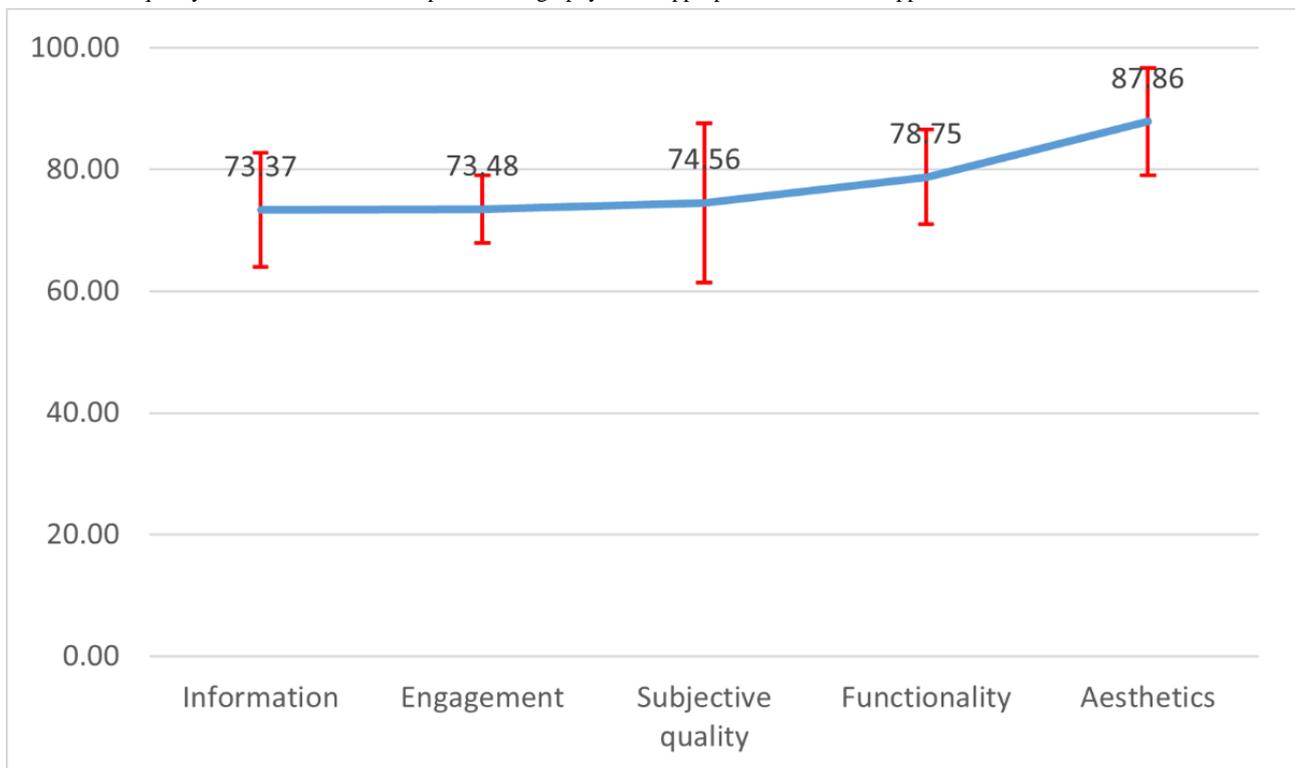

Some fundamental navigation control issues (eg, “back” function) were also reported during usability testing. For example, the participants tended to click the back button to return to the previous page, but it actually led them back to the home page. This drawback can lead to work duplication and frustration in task completion.

Phase 2: the Quality of the HAC App Using MARS

Analysis of Overall Quality Scores of the HAC App

Table 1 indicates that the overall quality score of the HAC app was favorable (82/100). Among the 4 MARS subscales, Information (73.37/100), and Engagement (73.48/100) had the lowest scores while Aesthetics had the highest score (87.86/100; Figure 3).

Figure 3. Overall quality scores of the Head Computed Tomography Scan Appropriateness Criteria app.

Analysis of Significant Differences and Correlation Between MARS Subscales

Using the Friedman test, the users' scores in 5 MARS subscales were compared, and the result revealed a significant difference ($P < .001$).

Wilcoxon test was applied to investigate the mean difference between 2 sets of pairs of MARS subscales. The results indicated a significant relationship between the Aesthetics subscale and Engagement ($P = .001$), Information ($P = .003$), Subjective Quality ($P = .004$), and Functionality ($P = .02$). A significant relationship was also found between the Functionality and Information subscales ($P = .01$; [Table 3](#)).

Table 3. The mean differences between 2 sets of pairs of MARS^a subscale scores.

MARS subscales	Engagement score	Information score	Subjective quality score	Functionality score	Aesthetics score
Information score	0.909	— ^b	—	—	—
Subjective quality score	0.53	0.900	—	—	—
Functionality score	0.057	0.013	0.32	—	—
Aesthetics score	0.001	0.003	0.004	0.02	—

^aMARS: Mobile Apps Rating Scale.

^bNot applicable.

Spearman rank correlation coefficient presented a positive correlation between information with functionality subscales, $r_{.588}$, $P = .02$. A positive correlation was also seen between information and satisfaction, $r_{.648}$, $P = .005$. [Table 4](#) indicates, in the subscale Information, the lowest score of the HAC app was “evidence base” (66.2/100), and the highest score was visual information (82/100). In the subscale Engagement, the lowest

score of the HAC app was for “customization” (63.6/100), and the highest score was interest (90/100). In the subscale Functionality, the lowest score of the HAC app was for “performance” (67.4/100), and the highest score was “ease of use” (91.2/100). In the subscale Aesthetics, the lowest score of the HAC app was “visual appeal” (83.6/100), and the highest score was “graphics” (91.2/100).

Table 4. Head Computed Tomography Scan Appropriateness Criteria app scoring based on Mobile App Rating Scale 4 subscales.

	Scores, mean (SD)	Score out of 100
Information		
Accuracy: the app contains what is described	3.6 (0.50)	72.4
Goals: specific, measurable, and achievable goals	3.6 (0.50)	72
Quality of information: the app correct, well-written, and relevant content to the goal	3.5 (0.63)	70
Quantity of information: the extent of coverage within the scope of the app	3.4 (0.72)	68
Visual information: visual (eg, charts, images, and videos) to describe concepts	4.1 (0.95)	82
Credibility: legitimate source of app	4.06 (0.25)	81.2
Evidence base: trialed and tested app	3.31 (1.07)	66.2
Engagement		
Entertainment	3.25 (0.44)	65
Interest: fun and entertaining of app	4.5 (0.63)	90
Customization: support all preferences for app features (eg, sound and content)	3.18 (0.54)	63.6
Interactivity: provide feedback, contain reminders, and notifications	3.8 (0.40)	76.3
Target group	3.62 (0.50)	72.4
Functionality		
Performance: accuracy and speed of the app functions and components (buttons and menus)	3.37 (0.80)	67.4
Ease of use: easy to learn how to use the app	4.56 (0.62)	91.2
Navigation: accurate, appropriate, uninterrupted moving between screens	3.8 (0.61)	76
Gestural design: consistency of (taps, swipes, and scrolls) across all components	3.9 (0.57)	78
Aesthetics		
Layout: arrangement and size of buttons, icons, menus, and content on the screen	4.43 (0.72)	88.6
Graphics: the quality and resolution of graphics used for buttons, icons, menus, and content	4.56 (0.51)	91.2
Visual appeal: look of app	4.18 (0.54)	83.6

Medical Interns' Characteristics and MARS Subscales

Of the 16 users participating in the study, none had used the HAC app before, and only 1 (6%) person had used similar applications. Among them, 8 (50%) users believed using mobile apps for learning and clinical practice is helpful and were interested in using them. [Figure 4](#) presents a significant

difference between medical interns' interest in using mobile apps for learning and clinical practice (low, medium, high) with the Engagement subscale using the Kruskal-Wallis test ($P=.03$).

[Figure 5](#) also indicates a significant difference between the medical interns' interest in using mobile apps with subjective quality subscales using a 1-way ANOVA test ($P=.04$).

Figure 4. Significant difference between engagement and interest in using the mobile app.

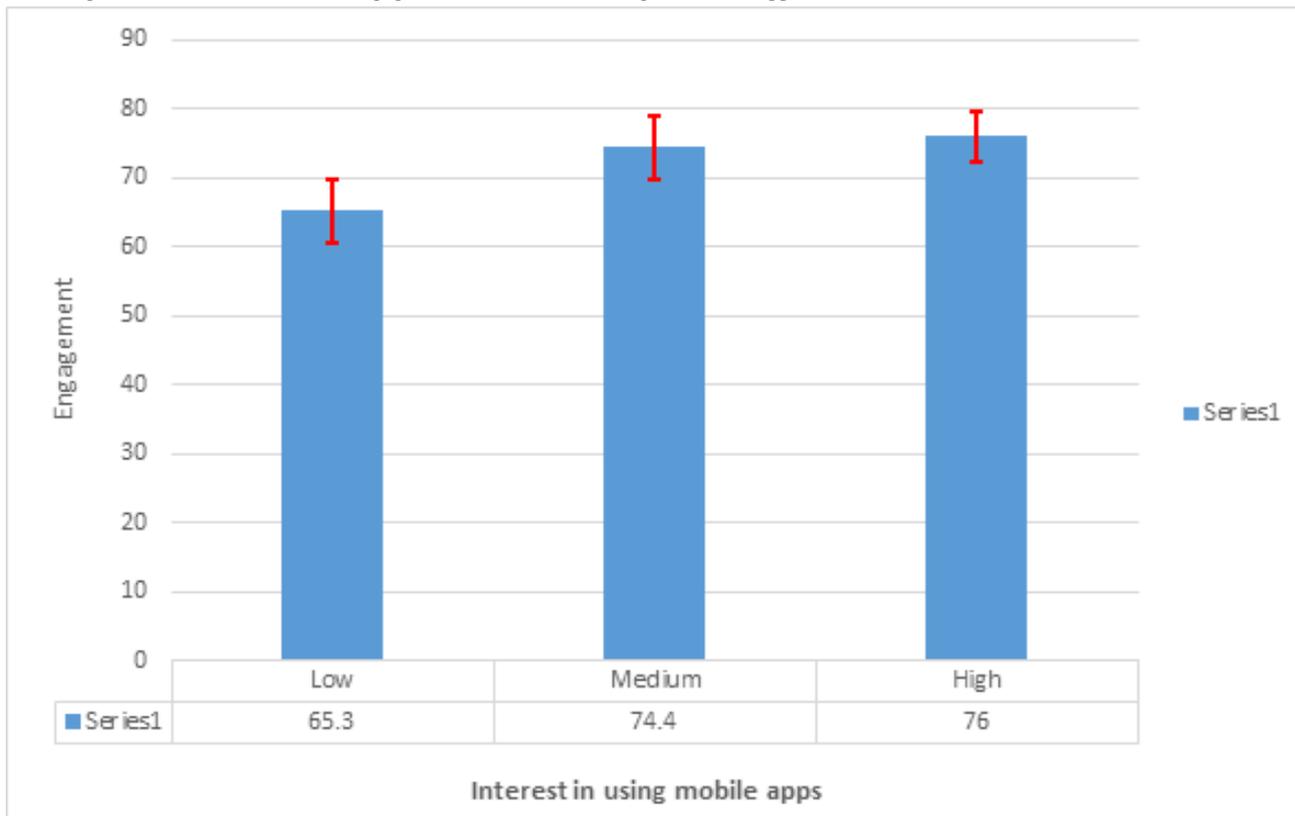

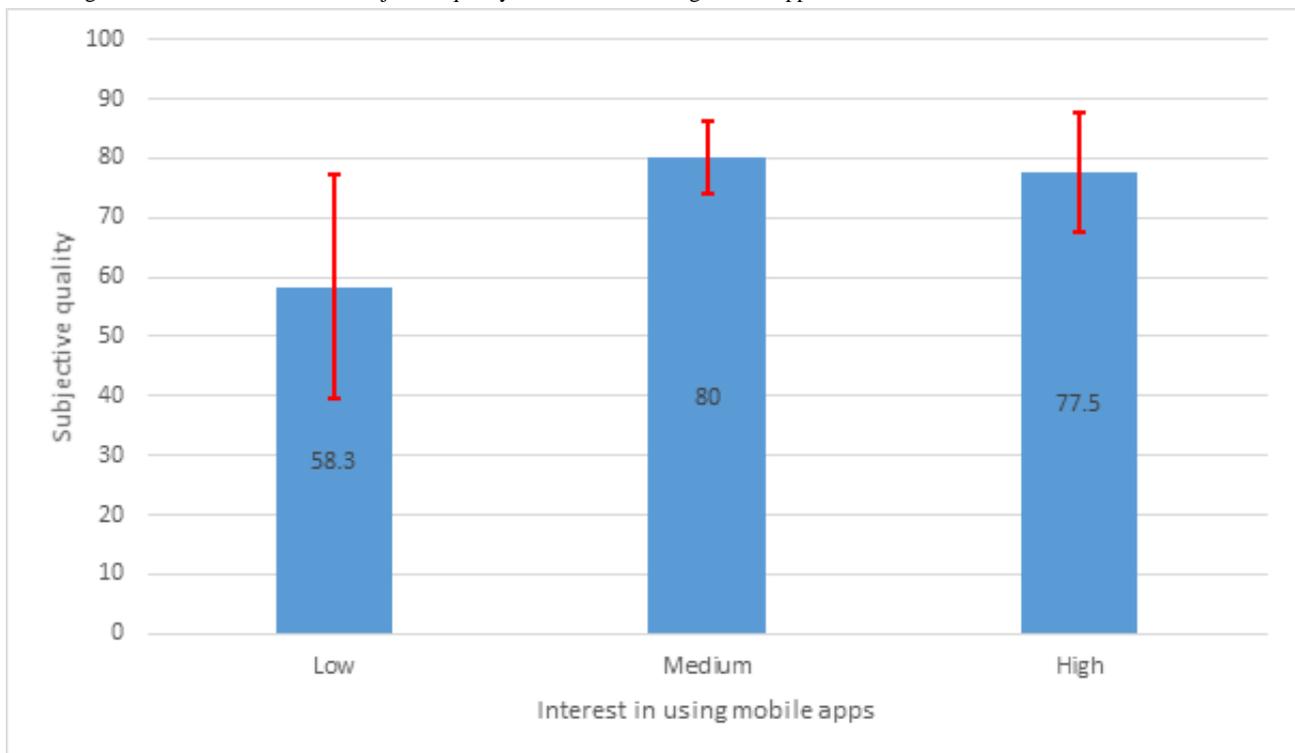

Figure 5. Significant difference between subjective quality and interest in using mobile app.

Phase 3: Debrief

We explored how useful they perceived the app to be, any features they particularly liked or disliked, how easy or difficult it was to use, and what they thought about the content and design of the app, which was discussed in the debriefing session.

Although all users appreciated the high simplicity and learnability of the HAC app, they debated that navigation between pages and search capabilities need serious consideration.

One of the participants wanted this tool to be equipped with voice recognition systems:

We use this tool while walking or moving in different parts of the hospital, and the possibility of typing or text entry increases the possibility of errors and, as a result, repeating the same action, which will reduce efficiency. [Participant 2]

Another participant believed this tool should provide access to the app at different times and conditions:

I am a doctor, and my hands are bloody; I do not want to touch my mobile too much, and I prefer this app to be able to search for the proper CT scan based on voice. [Participant 15]

Another participant expected that apps designed for students would pay more attention to the educational needs and learning styles of students:

I think this issue is so essential that medical education experts should also be used in the design of apps. Anyway, each of us has a style to learn. If this customization feature is not included in the design, surely some users will not be able to work with this system or at least feel comfortable and useful while working with it. [Participant 1]

Discussion

Principal Findings

Our findings demonstrated that the HAC app was practical and had acceptable usability in efficiency and effectiveness. It also displayed a positive quality score based on the MARS scale. In contrast, results of the TA usability test revealed that the HAC app has 8 notable usability issues. The results proved that despite the willingness of researchers and the simplicity of quantitative and questionnaire-based approaches to conducting usability testing [6,45], the observational, TA usability testing provided more unbiased, trustworthy, and insightful data in describing mobile app usability.

Nevertheless, through data analysis of the MARS subscales also brought to light the HAC app's usability issues, and its results support the qualitative TA results of this study. This agreement could be explained by the fact that MARS is a scale specifically designed to assess the quality of mobile apps [46]. Typically, the available usability scales and questionnaires are not highly reliable [6]; they are general scales designed primarily for evaluating the usability of computers or websites.

In addition, current usability and quality rating scales focus primarily on developers testing the usability of mobile apps, rather than end users who are patients or HCPs [46].

It is unlikely that usability issues will be thoroughly investigated in sole quantitative and questionnaire-based approaches [47] and need to be complemented by more objective and reliable approaches, such as TA methods.

In this study, HAC effectiveness assessment revealed that most users completed all 4 scenarios, although, 2 users faced problems completing scenario 2, which involved finding an appropriate imaging procedure for the “new onset of seizures” case. This failure may be due to the usability issues we categorized under “poor search capabilities” and “inefficient data presentation and

information control.” As shown in Figure 1, “poor searching capabilities” and “poor data presentation” caused a long list of seizure conditions, confusing the participant. Since the mobile screen was too small, providing a long list of search results brought more cognitive load to select the correct item, and 2 participants were left to perform this scenario later. However, they never got back to the scenario again. Our results support previous research findings. In the study, Chen et al [48] introduced proper navigation and searching capabilities as significant factors for users' rating of mHealth apps. Schwab and Langell [18] debated that ease of navigation is the foundation of an ideal mobile app since it smooths productivity and increases effectiveness. In the study to explore the usability of the physician-to-physician teleconsultation app in an orthopedic clinic, Choemprayong et al [49] presented mobile app usability issues in terms of data entry errors, presenting large-scale data and difficulty in selecting items from a list, which arise because of limited mobile screen size.

The HAC app also indicated acceptable efficiency and meantime completion for 4 scenarios. However, scenario 3 also showed the highest mean time completion. The problem might arise due to usability issues regarding the “lack of finger-friendly touch targets.” The limited screen size of mobile phones results in the inappropriate size of buttons or lack of enough padding between the shortlist button and icons around the edge of the screen. Our results agree with previous studies that tapping the mobile phone buttons correctly is a crucial factor; however, incorrect operations have been reported frequently in previous studies [49-51]. In addition to data presentation, the low resolution of smartphone screens can lead to data input errors [49]. Existing evidence revealed highly significant differences between user effectiveness and efficiency with button sizes. In the study, Conradi et al [22] reported substantial differences in error rate between button sizes (5×5 mm) compared with the other sizes (8×8 mm, 11×8 mm, and 14×14 mm). It has been debated that interaction with mobile devices due to limited screen size and resolution often requires additional considerations and a specially adapted interface. The literature also claimed that key size manipulation should be considered for users' operation posture and activities (eg, standing, sitting, and walking) in mobile phone interactions [22]. However, the wide variation in optimal button size for mobile phones from 2.6 to 41.8 mm represents human-computer interaction in handheld devices. It is still in its infancy and requires more context-awareness to provide assistance based on the knowledge of its environment. Another possible explanation for the highest-time completion for scenario 3 is the usability issue categorized as “unclear control and confirmation” in this study. The participants of this study verbalized a lack of providing feedback on the HAC app when they were asked to add a given disease or sign and symptom to the list. The absence of the confirmation dialogue for successfully adding the given items to the shortlist resulted in the users moving to the shortlist and checking if the command was run. The exact process occurred when they were asked to remove the given disease from the shortlist. This rechecking caused work duplication and led to less efficiency. Work duplication has a significant and negative influence on physicians' performance and has been introduced as physicians' barrier to using mobile apps. In a study, Payne et al [52] found

that physicians would use mobile apps to improve care workflow and productivity [38]. In another study, Ely et al [52] found that physicians believed if working with IT-related tools takes more than 2 minutes, they will not be efficient and practical for the point of care (39). Therefore, the effectiveness and efficacy of mobile apps serve as critical factors for physicians' intention to use mobile apps [52,53].

Regarding efficiency measures, our results also indicated significant variation in scenarios' time completion between the users. For example, user number 3 scored the highest total average time, nearly 3 times that of user number 11 (the lowest time), to perform the scenarios. Besides designing an optimal layout, significant variation in scenarios' time completion between the users may be due to the user characteristics. Xiong et al [20] debated that touch accuracy in mobile phones requires proper motor skills and "hand dexterity" in the operating fingers. Schwab and Langell [18] and Ozkan Gokalp-Yavuz [16] also highlighted the importance of user anatomy (eg, average index or thumb fingertip size) and user dexterity (ie, motor skills) in users' efficiency. Cho et al [51] reported usability problems related to the buttons of mobile apps developed using an eye-tracking system and retrospective TA usability evaluation.

The HAC app also showed a favorable quality score based on the MARS scale. However, the HAC app quality suffered from some drawbacks in Engagement and Information, which focus primarily on the effectiveness of apps in terms of interactivity, customizability, sending feedback, alerts, and reminders. Our results support previous results for assessing quality apps used by HCPs. In the study on drug reference apps in Taiwan, Chen et al [48] also reported poor engagement capabilities in terms of lack of entertainment, interactivity, and customization in the studied apps in Taiwan. In the study investigating influential factors in adopting a clinical photo documentation app for clinicians, Jacob discussed some drawbacks in engagement capabilities that need to be added for further revision of a given app [15]. Although few studies exist on using MARS to evaluate clinical apps adopted by HCPs, other relevant evidence supports our findings. In a qualitative study, Pokhrel et al [54] presented that HCPs prefer mobile apps that help them in their clinical practices, including "suggestive diagnosis and treatment after entering." Reports of studies that focused on using other IT toolkits also revealed that the IT tool would be effective among HCPs if it would support interactivity, answer physicians' questions, send feedback, and provide decision reasoning. Sandholzer et al [55] also introduced "prediction capabilities of mobile apps" as the most important preferences of medical students toward specific functionalities of future mobile apps. Despite the HAC app's drawbacks in engagement and information subscales, its quality in aesthetics has shown favorable MARS scoring. In a study of preferences and perceptions of users regarding graphical user interface and user experience, Sandesara et al [56] reported that minimalist design improves user experience and user control to fulfill a task in a specific order and time. The author argued that "simplicity is the ultimate sophistication" [56]. To the best of our knowledge, no study has evaluated and reported the items of each subscale of MARS and research is lacking on the evaluation of adopting and usability testing of a mobile app by HCPs [1]. Lack of

related literature to assess the items of each subscales of MARS led to poor in-depth understandings and meaningful perception of apps' quality features in previous evidence. Therefore, it was impossible to compare HAC app quality rating with previous research properly. However, the results of quality assessment using MARS supports TA qualitative findings of this study. HAC app quality scoring in the functionality subscale revealed the minimum score belonged to the performance items, which focuses on the accuracy and speed of the app functions and components such as buttons or menus. Navigation also scored the minimum rating in the given subscale. In the subscale Engagement, the item customization that supports providing all necessary settings for apps features and the item interactivity that allows user input, providing feedback, and containing reminders and notifications also acquired the minimum scoring.

Our findings in the debrief session indicated that physicians with clear awareness and understanding of their clinical context and work processes tend to use other data input methods, such as voice recognition, to interact with the HAC app. The results of physicians' workflow analysis and time and motion studies presented the medical profession as a multitasking job, not only managing patient care but also spending part of their activities on indirect tasks, from doing paper work and documentation to transitioning and traveling within the clinic area, or fetching or bringing something [57,58]. Thus, in designing mobile apps, performance accuracy and time on users' tasks in different positions while walking or standing should be addressed appropriately. It has been argued that interaction with mobile devices while walking influences people's visual acuity and suppresses this ability by nearly 20% compared with visual acuity while standing [22]. Conradi et al [22] debated that walking is prone to a very high number of error occurrences, which is remarkable in smaller buttons. Using mobile apps with text entry methods involves physicians experiencing various interaction issues in terms of difficulty in typing on the small screen, mistapping due to inappropriate size of the buttons or lack of spacing between buttons, poor data presentation, and so on. Any poor mobile interaction is attention-grabbing and makes physicians concentrate solely on interacting with the mobile app to increase their performance accuracy. It would distract them from their main concern, which is interacting with the patients.

Moreover, it results in a long time being on the task and decreases the efficiency and effectiveness of HCPs in clinical settings. Auditory and sonic interfaces occupy less visual attention and make users less engaged in the sole main task. Consequently, users can handle multiple tasks simultaneously [59]. Here, physicians should be equipped with an alternative input method, for example, speech recognition. Evidence revealed that speech recognition has the potential to be a more efficient and effective method to speed up the entry rates while declining the error rates. It was reported that speech recognition supports high entry rates (speaks at a mean entry rate of 13-45 words per minute while walking around) and a low error rate of <2% [60]. Given the requirement that medical interns suggested, they emphasized the importance of "context-awareness" design in mobile apps that focuses on capturing and exploring context-based information to describe

any entity (eg, persons, places, objects, and workflows) embedded in the environment to fully understand and characterize users' tasks [59].

Implications

The evaluation framework used in this study can serve as a guide for the design and improvement of future clinical mobile apps to ensure they meet usability and quality standards for use by HCPs. Identifying usability issues through user feedback and analysis can help developers improve the usability and user satisfaction of clinical mobile apps among HCPs. Moreover, the results of the study can serve as a reference for HCPs and developers in selecting and implementing clinical mobile apps with acceptable usability and quality. It emphasizes the importance of multidisciplinary research, incorporating medical education specialists' expertise, and considering user characteristics like motor skills and hand dexterity. The mixed methods approach used in the study, including MARS and TA analysis, can be adopted to gather valuable insights into user behavior and inform the design process of future apps for HCPs and developers. The study also suggests context-awareness design as a critical factor in developing meaningful IT-based solutions such as mobile apps.

Limitations

However, our investigation is subject to some limitations. It was conducted using a limited sample a specific target group (medical interns), and attending physicians and residents were not involved in the study. No contributions from IT experts and app developers were included in the evaluation of the HAC app. The study focused on the usability and quality of the HAC app in a specific medical context in Iran, which may limit the applicability of the findings to other health care settings or countries.

Conclusions

A mixed methods approach in evaluating the quality and usability of mobile apps yields valuable insights into the strengths and weaknesses of mobile apps. Adopting a holistic and multifaceted approach in evaluating mobile apps is highly recommended, as exclusively relying on a single methodology does not provide reliable and trustworthy information about the usability and quality of mobile apps. The results also presented that the unique characteristics of mobile devices, such as screen size, the users' anatomical characteristics, and motor skills, influence users' interaction and usability with mobile apps. Therefore, considering these characteristics and developing more tailored tools and methods for usability testing of mobile apps can bring potential benefits for developers, decision-makers, and HCPs.

Acknowledgments

The research team express their sincere gratitude to those who participated in the study.

The study was supported financially by the Deputy of Research and Technology of Kashan University of Medical Sciences (KAUMS) in Iran (grant 99190).

Authors' Contributions

ZM, AO, EN, and RK made substantial contributions to the conception and design of the study. FA, ZM, AO, HA, EN, ZN, and FH participated in data collection and performed the statistical analysis. ZM, EN, and FH contributed to manuscript drafting, revision, and approval. All authors read and approved the final manuscript.

Conflicts of Interest

Abstract

Background: Electronic patient-reported outcome measures (ePROMs) are standardized digital instruments integrated into clinical care to collect subjective data regarding patients' health-related quality of life, functional status, and symptoms. In documenting patient-reported progress, ePROMs can guide treatment decisions and encourage measurement-based care practices. Voxe is a pediatric and user-centered ePROM platform for patients with chronic health conditions.

Objective: We aimed to describe the user-centered design approach involving feedback from end users and usability testing of Voxe's platform features to support implementation in a pediatric health care setting.

Methods: Purposive sampling was used to recruit patients aged 8-17 years from 2 chronic illness populations in 2 pediatric hospitals in Canada. Patients' health care team members were also purposively recruited. One-on-one iterative testing sessions were conducted digitally by research team members with participants to obtain feedback on the appearance and functionalities of the Voxe platform prototype. Patients and health care providers (HCPs) completed Voxe-related task-based activities. International Organization for Standardization key performance indicators were tracked during HCP task-based activities. HCPs also completed the System Usability Scale. To test platform usability, the think-aloud technique was used by participants during the completion of structured tasks. After completing all task-based activities, patient participants selected 5 words from the Microsoft Desirability Toolkit to describe their overall impression and experience with the Voxe platform. Qualitative data about likes, dislikes, and ease of use were collected through semistructured interviews. Feedback testing sessions were conducted with patients and HCPs

until Voxe was acceptable to participating end users, with no further refinements identified. Quantitative and qualitative data analysis were completed using descriptive statistics and content analysis.

Results: A total of 49 patients and 38 HCPs were recruited. Patients were positive about Voxe's child-centered design characteristics and notification settings. HCPs rated Voxe as user-friendly and efficient, with the time to complete tasks decreasing over time. HCPs were satisfied with the Voxe platform functionalities and identified the value of Voxe's system notifications, summarized display of ePROM results, and its capacity to integrate with electronic medical records. Patients' and HCPs' high satisfaction rates with the Voxe prototype highlight the importance of being responsive to user suggestions from the inception of eHealth platform developments to ensure their efficient and effective design.

Conclusions: This paper describes the user-centered creation and usability testing of Voxe as an ePROM platform for implementation into clinical care for pediatric patients with chronic health conditions. As a patient-facing platform that can be integrated into electronic medical records, Voxe aligns with measurement-based care practices to foster quality patient-centered approaches to care. End users' positive feedback and evaluation of the platform's user-friendliness and efficiency suggest that Voxe represents a valuable and promising solution to systematically integrate patient-related outcome (PRO) data into complex and dynamic clinical health care settings.

Introduction

Patient-Reported Outcome Measures

Patient-reported outcome measures (PROMs) are gaining significant momentum in clinical practice and research to foster a patient-centered approach to health care delivery [1-4]. PROMs are questionnaires used to collect subjective information directly from the patient regarding their health-related quality of life (HRQoL), functional status, and symptoms [5,6]. By directing the foci of clinical encounters, PROMs can facilitate early detection and monitoring of patient symptoms, empower patients to actively participate in their care, enhance health care providers' (HCPs) understanding of patient needs, and influence joint discussions with patients about health outcome priorities [3,4]. In documenting patient-reported progress, PROMs can guide treatment decisions, positively influence patient outcomes [7], and encourage measurement-based care practices [8].

Despite the proposed value of PROMs, low PROM adoption rates have been attributed to factors related to the completion of paper-based PROMs, including limited time and resources among clinicians and low response rates from patients [4]. Digital electronic PROMs (ePROMS) have been designed to overcome cited barriers and to improve PROM data quality and completion time [1,9]. Many benefits have been documented such as greater patient preference and acceptability, higher data quality and response rates, and reduced health care costs [1]. Currently, platforms used for ePROM collection (eg, REDCap [Research Electronic Data Capture]) primarily target the clinical care of adults [9-11], with few designed specifically for the clinical management of children's physical, social, and emotional health [4,10,12-14]. The lack of child-friendly and age-appropriate ePROM platforms needs addressing as children as young as 5 have shown capacity to self-report on their HRQoL [15], and 8 years of age is the recommended age to administer self-reported measures to children [10]. In the context

of limited pediatric ePROM platforms, and with considerations around regulatory data privacy and management guidelines, secure servers for data storage and timely, responsive administrative and technical support [16,17], the development of new evidence-based platforms that enhance eHealth solutions for pediatric care should be prioritized.

User-Centered Design

User-centered design (UCD) is a popular design approach for developing eHealth innovations, including ePROM platforms [18]. When applying a UCD approach to optimize usability, compliance, and adoption of ePROM platforms, end users (ie, patients and HCPs) and key stakeholders (eg, decision- and policy-makers) are involved in the platform design processes [9,19,20]. Specifically, UCD outlines that (1) designers should understand end users and user-specific tasks, and (2) design processes are iterative to involve multiple cycles of design, testing, and redesign [21]. With attention to these parameters, using a UCD approach to eHealth platform development can create technologies that are meaningful, manageable, and sustainable for their user and organizational health care systems, potentially impacting the implementation success of eHealth solutions [22,23].

Voxe

Voxe is a pediatric, user-centered, and custom-built ePROM platform that is a progressive web application designed to integrate PROMs into the delivery of clinical care for pediatric patients with chronic health conditions [24]. Despite the profound and multidimensional impact of chronic disease on children's HRQoL, objective outcome metrics (eg, morbidity and mortality) alone are frequently used to determine the success of clinical interventions and care [25,26]. Given the paucity of child-oriented ePROM platforms in health care [27,28], Voxe represents a novel and child-friendly ePROM platform to facilitate the systematic integration of children's subjective evaluations regarding their physical, social, and emotional

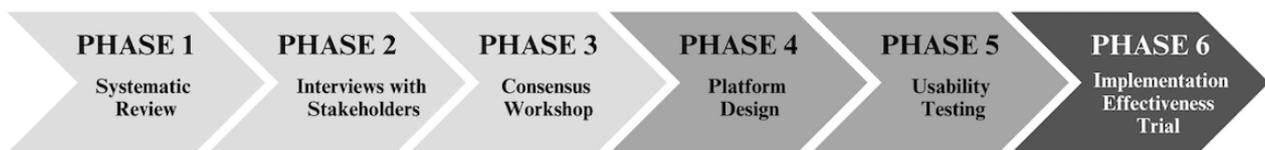

well-being in the delivery of care [24]. The advantages to having a custom-built progressive web application are (1) the ability to tailor the user experience specifically for pediatric patients, (2) to seamlessly integrate Voxe into the clinical workflow to reduce the barrier to ePROM completion, and (3) to ensure that Voxe is compatible with various electronic devices (eg, mobile phones, tablets, and computers). Additional distinguishing features include Voxe's capacity to incorporate any PROM, its capability to be created in different languages and its potential to integrate with any electronic medical record (EMR). Notably,

for the purpose of Phase 5, Voxe was integrated with the EMR Epic.

Objectives

Building on previously completed phases of Voxe's development (Figure 1) [25,29], this paper outlines Voxe's user-centered design approach (Phase 4) involving feedback from end users at 2 pediatric hospitals in Canada and subsequent usability testing (Phase 5) specific to Voxe's platform features. The discussion will highlight our user-centered approach as a strength in prioritizing end user needs prior to Voxe's implementation within a pediatric health care setting.

Figure 1. Overview of key phases involved in Voxe's development.

Methods

Study Participants and Inclusion Criteria

Purposive sampling was used to recruit patients followed by The Hospital for Sick Children (SickKids) Transplant and Regenerative Medicine Centre (TRMC) or Hematology and Oncology program at the Children's Hospital of Eastern Ontario (CHEO) across age, diagnosis, sex, gender, and ethnicity. Members of the patients' interdisciplinary health care teams at SickKids and CHEO were also purposively recruited across professional disciplines, years of practice, sex, gender, and ethnicity.

Patients were eligible if they met the following criteria: (1) heart, kidney, liver, or lung transplant recipients who were a minimum of 3 months posttransplant (SickKids) or followed by the Hematology and Oncology program (CHEO); (2) between 8 and 17 years of age; and (3) able to speak and read in English. Patients with significant cognitive impairments, as determined by a health care team member, were not eligible to participate. Eligible HCPs included any member of the interdisciplinary teams within the Hematology and Oncology program (CHEO; Phase 4) or the TRMC (SickKids; Phases 4 and 5).

Ethical Considerations

Ethical approval to conduct this study was obtained from the Institutional Research Ethics Board at SickKids (1000057043 for Phase 4 and 1000067700 for Phase 5). All participants provided informed consent prior to their involvement in this study, and interview transcripts were deidentified. All participants received a \$20 retail store gift card upon completion of study participation.

Phase 4: Generation of the Voxe ePROM Platform

Overview

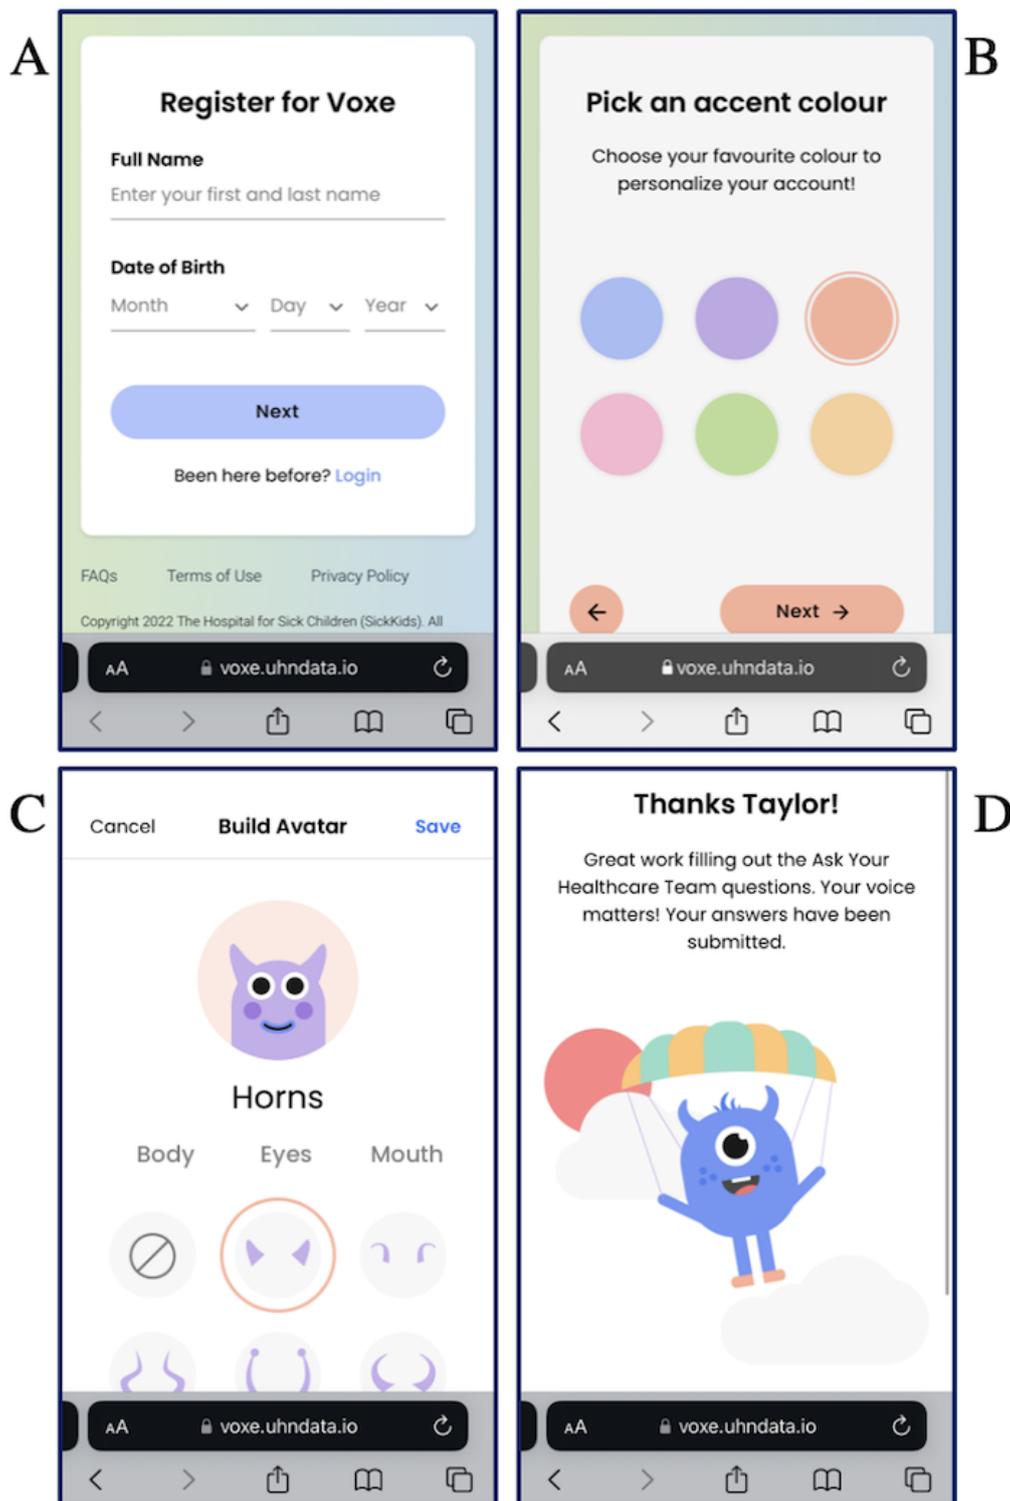

Previously completed phases of Voxe's development process (Phases 1-3) [30,31] informed the design of preliminary Voxe

wireframes. The PedsQL Generic Core Scales [32] were selected as the first ePROM to be designed within Voxe as it is considered the most widely used generic HRQoL pediatric PROM [33]. Voxe wireframes depicting the PedsQL Generic Core Scales adhere to the requirements noted in the e-Booklet for the Electronic Implementation of the PedsQL Generic Core Scales [34] and were reviewed personally by the lead original developer of the PedsQL.

Key stakeholders (eg, decision- and policy makers) were also consulted to identify Voxe users (ie, patients and HCPs) and the possible tasks end users would complete (ie, persona and task inventory development). Following the design of preliminary wireframes, a rapid and iterative testing methodology was used to evaluate and improve Voxe prior to its full development and launch [35]. Through a user-centered approach, one-on-one iterative testing sessions were conducted virtually with patients and HCPs by a member of the research team (SJP, SD) to elicit feedback on Voxe design features.

Patient features identified within Voxe for feedback included: (1) account personalization options, (2) text and email notifications, and (3) the display of Voxe ambassador GIFs. First, after registering for a Voxe account, patients have the option to personalize their account by selecting: (1) 1 of 6 accent colors which populate the header and buttons in the patient's portal and (2) 1 of 6 prebuilt avatars or a custom-built avatar. Figure 2 presents the Voxe Patient Registration (A) and Personalization (B, C) screens. Second, Voxe allows patients to opt for text or email reminder notifications to complete the ePROMs on their preferred device (ie, mobile phone, tablet, or computer). Notifications are delivered by Voxe at 7 and 3 days in advance of clinic appointments. Third, following registration on Voxe and completion of each ePROM, the Voxe ambassador is displayed as a GIF (ie, animated avatar) on the platform. Figure 2 illustrates a still image of one of the Voxe ambassador GIFs (D) on a screen.

Figure 2. Examples of the Voxe Patient Registration (A), Personalization (B, C), and Ambassador GIF (D) Screens.

HCP features-of-use identified within Voxe for feedback included (1) the integration of Voxe with the EMR, (2) system (Epic) notifications of patient Voxe completion, and (3) a presentation view in Voxe to visualize trends in ePROM results over time. Notably, Voxe's presentation screen was designed

for HCPs to show patients a high-level summary of their ePROM results through graphs specific to each domain or summary score, depending on the ePROM. Table 1 summarizes patient and HCP features in Voxe.

Table 1. Patient and HCP^a features in Voxe.

Patient features	HCP features
Account personalization: select accent color, select a prebuilt avatar, and custom-build an avatar	Voxe integration with the EMR ^b
Text or email reminder notifications to complete ePROMs ^c	System notifications of patient Voxe completion
Display of Voxe ambassador GIF (ie, animated avatar) following registration and ePROM completion	Presentation view in Voxe to visualize trends in ePROM results over time

^aHCP: health care provider.

^bEMR: electronic medical record.

^cePROM: electronic patient-reported outcome measure.

Data Collection

Both patient and HCP participants completed task-based activities pertaining to the Voxe platform. Examples of tasks patients completed include: “This is your first time using Voxe. What would you click on to begin creating your profile?”; “What would you do if you wanted to pick a different colour?”; “You are doing the survey and let's assume you wanted to go back to a previous question. What would you click?” HCPs completed tasks such as “Let's assume that you need to view the patient's PedsQL results from May 24, 2019. What would you click to access their past PROM results?”; “Let's now pretend you want to compare the patient's PedsQL results between January 2019-June 2019 only. Where would you click to do this?”; “Voxe has a patient-friendly presentation feature to show patients their results during clinic and invite better conversation. Click where you would go to show the patient their patient-friendly overview of their results.” During HCP task-based activities, International Organization for Standardization key performance indicators (KPIs) were tracked, as KPIs are deemed essential for evaluating the introduction of a novel technology, technique, or process [36,37]. Objective and subjective standards common in user experience design testing [38] were collected to measure (1) effectiveness—accuracy and completeness with which users achieve specific goals, displayed as a percentage of tasks successfully completed by users, and (2) efficiency—resources used in relation to results achieved, represented by the time it takes users to complete standard tasks successfully [39].

Following the completion of task-based activities, HCP participants completed the System Usability Scale (SUS), a 10-item Likert scale questionnaire to assess the KPI satisfaction [40,41]. The SUS is considered a reliable way to evaluate electronic platforms, in which a score of 68 is considered above average [40,41]. Following the completion of task-based activities, patient participants selected 5 words from a list of product reaction words outlined by the Microsoft Desirability Toolkit [42] (eg, creative, easy, and friendly) to describe their overall impression and experience with the Voxe platform.

Qualitative data were collected through semistructured interviews during which participants shared their likes and dislikes of the Voxe platform design and commented on the platform's ease of use and elements of functionality. Interviews were audio-recorded, transcribed verbatim, and deidentified.

Phase 5: Usability Testing of the Voxe ePROM Platform

Overview

To test the usability of the Voxe platform, the think-aloud technique was used in which participants verbalized their thoughts and feelings while interacting with Voxe to complete structured tasks [43,44]. The think-aloud technique is a well-known, formative usability testing approach to identify usability issues in the user interface designs of technologies such as ePROM platforms [45-47]. The think-aloud technique was integral to understanding the end user experience with Voxe and highlighting potential barriers to Voxe adoption that will inform its subsequent implementation [43,44].

Data Collection

Following the development of interfaces of the Voxe ePROM platform for patients and HCPs, one-on-one iterative testing sessions were conducted virtually by research team members (SJP, AD, MA, SD, and SO) with patient and HCP participants. The purpose of the testing sessions was to obtain patients' and HCPs' feedback on the appearance and functionalities of the Voxe platform prototype.

During the first 2 testing rounds, patient participants were asked to complete a core set of tasks on Voxe, which were presented to them in the form of scenarios that they may encounter while interacting with Voxe. Examples of tasks patients completed include: “This is your first time using Voxe. Please make an account, enter a phone number and log into your account.”; “How would you set your profile colour as yellow?”; “A few weeks have passed since your appointment at the hospital. During your appointment your nurse mentioned you can see a summary of your results to the PROMs you answered earlier on Voxe. How would you view your results from surveys you have completed?” The last 2 testing rounds were conducted to simulate “real-world” settings. An automated text message or email with an embedded hyperlink was sent to patients asking them to access Voxe remotely on a smartphone, tablet, or computer. Patients independently logged into Voxe using an anonymous username and password and navigated the platform to complete the ePROMs.

HCP participants accessed Voxe on a computer to complete a core set of tasks which simulate scenarios they may encounter while using Voxe in clinical practice. HCPs completed tasks such as “Click where you would go to view the patient's PedsQL

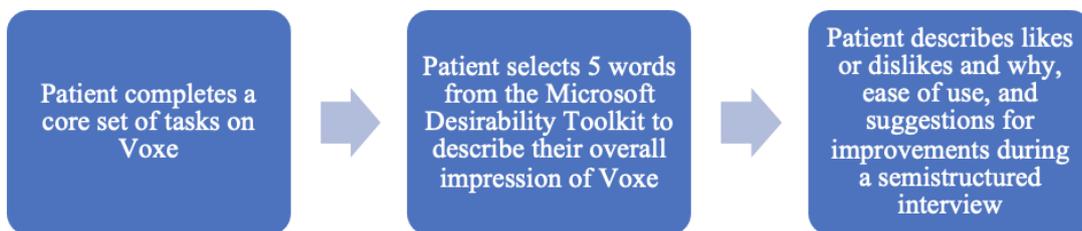

results”; “Let’s assume that you need to view the patient’s PedsQL results from an earlier date. What would you click to access patient’s past PROM results?”; “You are now meeting with the patient in clinic and would like to show them a quick summary of their PedsQL results. Click where you would go to share an overview of their results.” Using think-aloud methodology, patient and HCP participants voiced out loud what they were looking at, thinking, doing, and feeling as they navigated the platform [43,48].

After completing task-based activities, patient participants selected 5 words from the Microsoft Desirability Toolkit [42]

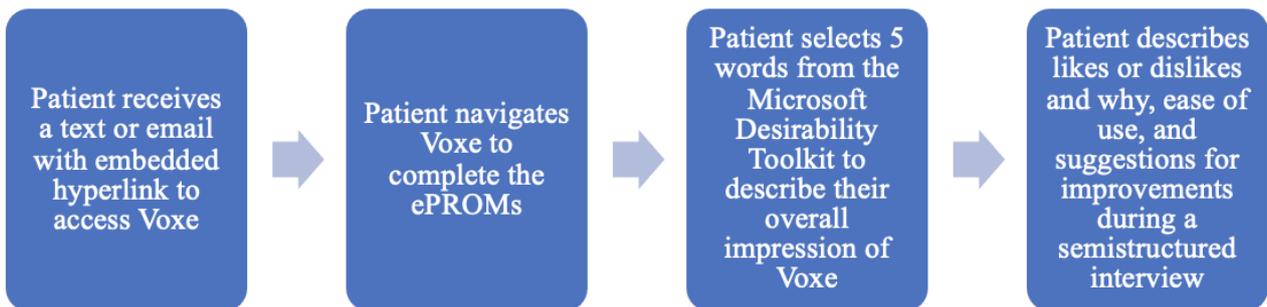

to describe their overall impression and experience with the Voxe platform. Qualitative data were collected through semistructured interviews to elicit information on what patient and HCP participants liked or disliked and why, the ease of use, elements of functionality in the context of typical practice workflow, and suggestions for improvements. Interviews were audio-recorded, transcribed verbatim, and deidentified. Rounds of iterative feedback testing were conducted with each participant population until Voxe was considered acceptable to participating end users with no further refinements identified [49-51]. Figure 3 presents an overview of usability testing procedures for patients and health care providers.

Figure 3. Overview of Phase 5 usability testing procedures for patients and health care providers. HCP: health care provider.

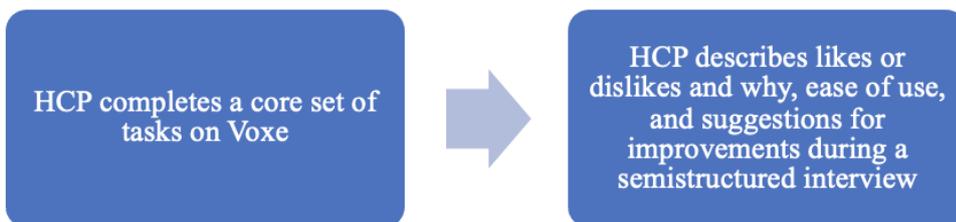

Phase 5—Patient Usability Testing Rounds 1 and 2

Phase 5—Patient Usability Testing Rounds 3 and 4

Phase 5—Health Care Provider Usability Testing

Data Analysis

Phase 4: Quantitative Data

Quantitative data from the platform creation testing sessions included (1) objective and subjective International Organization for Standardization KPIs, and (2) HCPs’ scores on the SUS questionnaire. Descriptive statistics were calculated and summarized as appropriate. The quantitative data were triangulated with qualitative data to provide a comprehensive understanding of end users’ experience with Voxe. Further

refinements were subsequently made to the Voxe platform design based on the triangulated data.

Phases 4 and 5: Qualitative Data

Research team members experienced in qualitative methods (SJP, AD, MA, SD, and SO) used content analysis to identify and organize meaningful patterns into codes across the data collected from qualitative interviews [52-54]. Codes were primarily developed deductively from key concepts in the interview guides [55], and categories were created to identify areas of similarity by collapsing codes with unifying features [56,57]. Categories were reviewed and refined until a consensus

was reached among team members. In the context of the current study, saturation as an end point criterion for completing data collection was determined when Voxe was considered acceptable to end users as measured by no further requests for refinements. NVivo 12 Lumivero was used for qualitative data management [58].

Results

Phases 4 and 5 Patient Participant Results

Patient Participants

A total of 49 patients from SickKids and CHEO participated in iterative testing rounds of Voxe in Phases 4 (platform creation) and 5 (usability testing) between September 2020 and August

2022. Among these, 19 patient participants were boys, 28 were girls, and 2 were nonbinary. Two participants were 8 or 9 years of age, 16 were between 10 and 13 years of age, and 31 were between 14 and 17 years of age. Participants identified as Asian (n=2); Black, Afro-Caribbean, or African American (n=4); Hispanic, Latino, or Spanish (n=1); South Asian (n=9); South Asian and White or Caucasian (n=4); White or Caucasian (n=28); and Other—White and Vietnamese (self-reported) (n=1). At SickKids, 12 and 13 participants participated in Phases 4 and 5, respectively. Of those, 8 participants were involved in both Phases 4 and 5. At CHEO, 12 participants participated in Phases 4 and 5. Eight participants were involved in both Phases 4 and 5. [Table 2](#) reports additional patient participant demographic information.

Patient Participant Experience

Increased Motivation Through Account Personalization Options

Several patients shared that the variety in options for customizing their personal Voxe account was an attractive feature of the Voxe platform to enhance their motivation to complete the ePROMs. Patients also appreciated that their personalization selections could be amended at any time. The personalization component was described as unique to Voxe, as one participant stated: “My favorite part was building the avatar... Because I think it’s what makes it different from other apps...it kind of just felt like you’re creating an avatar for a video game, which is pretty fun... [it] like makes doing something for the hospital actually fun” (Usability Testing SickKids #5).

ePROM Completion Facilitated Through Text and Email Notifications

Patients stated a collective preference for Voxe’s text notifications on the basis of checking text notifications more frequently than email notifications and being more familiar with texts. Patients also emphasized the convenience of notification alerts appearing on their mobile phone screens rather than being embedded in an email, as one patient stated that they might be “more inclined to miss it [the notification to complete their ePROMs in Voxe] if it was on... email...” (Design Testing CHEO #2). Despite an overarching preference for mobile phone notifications, select patients described the value of offering children a choice of email or text notifications, depending on personal preference. Overall, patients reported that the text and email notification feature of the Voxe platform helped facilitate their ability to complete the ePROMs.

Positive Reinforcement Fostered Through the Voxe Ambassador GIFs

Nearly all patients expressed that the ambassador’s presence in the platform reinforced a unique and child-centered sense of

delight, engagement, and accomplishment regarding completing ePROMs, as noted by one patient: “If you’re feeling down and you saw those animations... it’ll probably cheer you up” (Design Testing CHEO #1). Several participants also noted that completing ePROMs in Voxe represents a psychosocial intervention in and of itself to uplift their mood, as one patient shared: “You did what you had to do, and you did it perfectly... it makes you feel better” (Usability Testing CHEO #4).

Phases 4 and 5 Health Care Provider Participant Results

Health Care Provider Participants

A total of 38 HCPs from SickKids and CHEO participated in iterative testing rounds of Voxe (Phases 4 and 5) between April 2020 and January 2023. Of these, 6 HCPs were men and 32 were women. Eleven participants had worked in the SickKids TRMC or at CHEO between 6 months and 5 years, 9 participants had worked there between 6 years and 10 years, 4 participants had worked there between 11 and 15 years, 9 had worked there between 16 and 20 years, and 5 had worked there over 20 years. HCP participants identified as Asian (n=3); Asian and White or Caucasian (n=1); Black, Afro-Caribbean or African American (n=3); South Asian (n=1); White or Caucasian (n=29); and Other—Greek (self-reported) (n=1). [Table 3](#) reports additional HCP participant demographic information. At SickKids, 3 participants were involved in both Phases 4 and 5.

After completion of design testing, 94% (30/32) of HCPs described Voxe as being user-friendly, and 88% (28/32) felt that most people would learn to use Voxe quickly. Task success or effectiveness increased by 11.25% from Round 1 to Round 4. Task completion rate decreased by 7.34 seconds over the 4 rounds of testing. SUS or satisfaction increased from a B (75.94) to an A (83.75) between Round 1 and 4. [Table 4](#) comprises task success, task completion, and system usability score metrics.

Health Care Provider Participant Perspective

Integrating Voxe With the Electronic Medical Record Is Important

During design testing sessions, HCPs noted the importance of integrating Voxe with the EMR (eg, Epic) as opposed to a standalone ePROM platform to allow HCPs to access PRO data using the existing EMR portal. HCPs associated the value of Voxe's capacity for immediate data transfer between Voxe and the hospital EMR with reducing technological fatigue and optimizing clinical workloads, particularly specific to documentation procedures. For example, 1 HCP described: "I think it would really be very useful if you know that that link could happen between Voxe [and Epic] especially if we're meant to write a plan and to basically get integrated and pull into the note... I think it has to be as seamless as possible" (Design Testing SickKids #5).

System Notifications of Voxe Completion Are Helpful

HCPs discussed the importance of system notifications in EMRs to signify when a patient completes their ePROMs within Voxe. According to HCPs, EMR system notifications would serve as a helpful reminder for HCPs to regularly check patients' ePROM data in the EMR. Respective to notification placement within EMRs, HCPs preferred that the notification be viewed in a prominent area (eg, centered on the page) or in the form of an "In Basket" notification within Epic ("In Basket" is the communication hub in Epic). Several HCPs stated that an "In Basket" notification offered an added advantage of separating PRO data from other clinical data to ensure that ePROMs are reviewed by HCPs. This finding was captured by an HCP, who stated: "...the In Basket... it's a little bit separate from like, say [clinical] results... I feel like if it was mixed in... that could easily get... missed" (Usability Testing SickKids #6).

Using the Presentation View to See Trends Within Results Over Time Is Valuable

HCPs emphasized the value of this feature of Voxe. In particular, HCPs commented on the presentation screen's simplicity and ease of use to identify pertinent topics or issues that may require HCPs' heightened attention during clinical encounters. HCPs also described that the presentation screen's capacity to visualize ePROM results over different time points could represent a tool to facilitate conversations with patients and family members on issues related to HRQoL, including medication management and treatment adherence. For example, an HCP noted: "...if I can see consistently that their pain has affected their physical functioning... that's a tool that I can use to say, 'Well, look how you're rating this, and you still don't want to go on your medication?'... having a longer view is going to be even more powerful in our education and trying to help get buy-in with our plans" (Design Testing CHEO #8).

Discussion

Principal Findings

This paper provides an overview of a UCD approach and usability testing phases of a novel evidence-based pediatric ePROM platform prototype named Voxe. Patients particularly appreciated Voxe's child-friendly options for personalized profiles (eg, color and avatar selection) and the inclusion of Voxe ambassador GIFs (ie, animated avatars) in the platform. HCPs' SUS scores reflected high satisfaction rates with the Voxe platform prototype. Design testing sessions with HCPs also highlighted Voxe's ease of use and unique capacity for integration into the hospital EMR as valuable for streamlining clinical documentation and evaluation processes. Patients' and HCPs' high satisfaction with the Voxe prototype highlight the importance of being responsive to user suggestions from the

inception of eHealth platform developments to ensure their efficient and effective design [20,59].

Comparison With Prior Work

Patients' feedback on the Voxe prototype highlights the need to integrate developmentally responsive design considerations (eg, choice of color and avatars) in pediatric ePROM platforms to foster children's sense of engagement and motivation to complete ePROMs. While children and adolescents may be particularly amenable to using eHealth platforms due to their familiarity with technologies such as the internet and mobile phones, eHealth solutions should still respond to children's rapidly shifting development and associated ideas about the novelty or innovative nature of technology [60]. Insufficient consideration of the needs of the intended users in the development of eHealth platforms risks eHealth tools that are not able to fully accomplish their objectives [61], particularly if technologies do not align with end users' daily lives, habits, or rituals [22]. Patients' insights on Voxe's child-friendly characteristics contribute to a limited body of research regarding how to tailor ePROM platforms to the preferences of pediatric patients to optimize ePROM adoption and implementation [14,62,63].

The UCD approach that guided Voxe's development responds to existing calls for user-centered approaches to pediatric eHealth solution developments [64,65]. UCD is recognized as an optimal design approach for creating eHealth platforms [18,66,67] to help overcome eHealth implementation barriers, such as minimal clinical use of eHealth tools and low adoption rates in health care practices [68]. As eHealth technologies are often developed with a marginal level of engagement from end-users [68], Voxe's development phases offer practical steps for facilitating the inclusion of end users' perspectives in creating eHealth platform solutions specific to pediatric health care.

One challenge in pediatric health care practice is that most oral and written communications "with" children occur between adults [69-71]. Voxe's usability testing sessions highlighted Voxe's capacity for motivating pediatric patients to complete ePROMs and the potential to engage them in discussions concerning their care and treatment. For example, Voxe's development directly responded to what children considered most meaningful to them (eg, the incorporation of account personalization and Voxe ambassador GIFs), which may differ from adult-informed ideas about children's needs and preferences. Voxe also offers children time to reflect on pertinent issues they wish to emphasize in upcoming clinic appointments, and HCPs can review and consider patients' responses before clinical visits. Participants highlighted that Voxe's reminder notification system and presentation screen, which display the patient's summarized ePROM results, could be useful tools to facilitate child-provider communication regarding PRO data. The design and functionalities of the Voxe prototype responded to patient needs within the context of clinic visits, encouraging in-advance completion and purposively directing the foci of clinical encounters to patient priorities, offering the potential to improve satisfaction with health care [72-74].

The integration of ePROM data into EMRs presented another contextual variable driving ePROM platform development to address end user needs. Recent estimates suggest that most ePROM platforms are designed as stand-alone platforms, and only 60% (6/10) of ePROM systems offer compatibility for linking with EMRs [75]. In the context of limited pediatric ePROMs, Voxe is one of only a few pediatric-focused [4,76] or combined (ie, children and adults) [10] ePROM platforms to offer the capacity for front-end integration with EMRs. Similar to other cited benefits of ePROM platforms [6,72,74], Voxe can facilitate the integration of PRO data in patient EMRs in a manner that mirrors clinicians' existing workflows relative to documentation and assessment practices. During Voxe's usability evaluations, HCPs emphasized the value of Voxe's capacity for seamless integration into the EMR, which facilitated viewing and sharing mock PRO data in real time, and has the potential to offer time-saving benefits and remove potential burdens associated with logging into a stand-alone platform to review PRO data [74]. Overall, HCPs described how Voxe could help address key barriers pertaining to ePROM uptake in pediatric clinical practices, such as inconsistencies in compatibilities with EMRs, which has been cited among other associated challenges with PRO data management [6].

The Future Implementation of Voxe

The UCD approach and usability testing of Voxe outlined in this paper will inform the full operationalization and implementation of Voxe in pediatric health care settings. Future implementation initiatives will include (1) the delivery of HCP orientation sessions to familiarize HCPs with Voxe and (2) the evaluation (Phase 6) of the Voxe ePROM platform using a hybrid implementation-effectiveness design. Presently, the implementation of ePROMs in health care settings remains sparse and inconsistent [6], and transparent reporting on the use of implementation strategies to guide the future implementation of Voxe [77,78] will contribute to addressing this knowledge gap.

Strengths and Limitations

Voxe was designed and evaluated by an interdisciplinary research team with expertise in pediatric health research, including UCD and mixed methodology. This approach elicited participant perspectives through qualitative methods, garnering insights from a diverse sample of end user participants (ie, patients and HCPs) relative to age and clinician type. Participants completed simple tasks aligned with using Voxe which provided feedback about the changes needed prior to implementation. Evaluating the use of Voxe in more complex, "real-world" situations and to interpret patient ePROM results and trends longitudinally is a future aim of our program of research. We acknowledge that participants represented a small sample recruited from the SickKids TRMC and the Hematology and Oncology program at CHEO which limited eligible chronic health conditions and may have implications on the generalizability of our findings. Future studies should include participation from other pediatric hospitals and clinical programs. Of note, the sample recruited included English-speaking participants only. The absence of the perspectives of non-English speaking individuals to inform the

development of Voxe limits our transferability of findings within these populations.

Conclusions

This paper outlines Voxe's UCD approach and the usability testing of Voxe's platform features as an ePROM platform designed for implementation into clinical care delivery for pediatric patients with chronic health conditions. As a patient-facing platform that can be integrated into EMRs, Voxe

aligns with measurement-based care practices to foster quality patient-centered approaches to care. End users' positive feedback and evaluation of the platform's user-friendliness and efficiency suggest that Voxe represents a valuable and promising solution to systematically integrate PRO data in complex and dynamic clinical health care settings. Future collection of usage and outcome data will enable cost-benefit analyses to support the long-term integration of eHealth platforms in clinical services [79].

Acknowledgments

The development and usability evaluation of Voxe was funded by SickKids Transplant and Regenerative Medicine Centre—Pilot Grant Competition, Canadian Donation and Transplantation Research Program and Astellas Pharma Canada—Research Innovation Grant, Health Canada—Health Care Policy Contribution Program (agreement 1920-HQ-000105). The authors appreciate all children and health care providers who made time in their schedules to participate in this study. This research would not have been possible without their valuable insights.

Abstract

Background: Previous studies have evaluated the accuracy of the diagnostics of electronic symptom checkers (ESCs) and triage using clinical case vignettes. National Omaolo digital services (Omaolo) in Finland consist of an ESC for various symptoms. Omaolo is a medical device with a Conformité Européenne marking (risk class: IIa), based on Duodecim Clinical Decision Support, EBMEDS.

Objective: This study investigates how well triage performed by the ESC nurse triage within the chief symptom list available in Omaolo (anal region symptoms, cough, diarrhea, discharge from the eye or watery or reddish eye, headache, heartburn, knee symptom or injury, lower back pain or injury, oral health, painful or blocked ear, respiratory tract infection, sexually transmitted disease, shoulder pain or stiffness or injury, sore throat or throat symptom, and urinary tract infection). In addition, the accuracy, specificity, sensitivity, and safety of the Omaolo ESC were assessed.

Methods: This is a clinical validation study in a real-life setting performed at multiple primary health care (PHC) centers across Finland. The included units were of the walk-in model of primary care, where no previous phone call or contact was required. Upon arriving at the PHC center, users (patients) answered the ESC questions and received a triage recommendation; a nurse then assessed their triage. Findings on 877 patients were analyzed by matching the ESC recommendations with triage by the triage nurse.

Results: Safe assessments by the ESC accounted for 97.6% (856/877; 95% CI 95.6%-98.0%) of all assessments made. The mean of the exact match for all symptom assessments was 53.7% (471/877; 95% CI 49.2%-55.9%). The mean value of the exact match or overly conservative but suitable for all (ESC's assessment was 1 triage level higher than the nurse's triage) symptom assessments was 66.6% (584/877; 95% CI 63.4%-69.7%). When the nurse concluded that urgent treatment was needed, the ESC's exactly matched accuracy was 70.9% (244/344; 95% CI 65.8%-75.7%). Sensitivity for the Omaolo ESC was 62.6% and specificity of 69.2%. A total of 21 critical assessments were identified for further analysis: there was no indication of compromised patient safety.

Conclusions: The primary objectives of this study were to evaluate the safety and to explore the accuracy, specificity, and sensitivity of the Omaolo ESC. The results indicate that the ESC is safe in a real-life setting when appraised with assessments conducted by triage nurses. Furthermore, the Omaolo ESC exhibits the potential to guide patients to appropriate triage destinations effectively, helping them to receive timely and suitable care.

Introduction

Background

Seeking information online regarding medical symptoms is a common and well-known phenomenon among people and patients worldwide [1-4]. Usually, the general public searches online for symptoms associated with their medical condition before receiving a medical diagnosis. This includes websites of support groups, written blogs by patients, websites created by editors of popular media, governmental sites, and artificial intelligence (AI) interfaces. However, self-diagnostic web-based sources may be of varying quality in terms of reliability, with misleading information and possibly false advertising [5,6].

To address these problems, digital health care applications are spreading online, including self-diagnosis tools and electronic symptom checkers (ESCs) [7-10]. These are meant to provide solutions and information to the user seeking to learn more about symptoms or a condition they have or think they might have. In cases where access to human health care experts may be limited, telehealth services have tremendous promise for transforming the provision of health care services [11]. Conversely, studies find that healthier users use digital services more often than others and are also more likely to be younger, female, and more highly educated, and to have higher income levels [10,12,13].

Based on the user's input, ESCs use algorithms to make diagnostic suggestions, offer advice on what action to take, and help in identifying the relevant condition. This is medical triage, and it involves directing patients to the most suitable location within an appropriate time frame. In clinical practice, triage assessment and guidance are usually done by health care professionals either over the phone or face to face, for example, at a health care center [14]. Triage takes up a lot of professionals' time and its quality varies. Therefore, even the partial digitalization of triage in health care organizations could increase service uniformity, enhance efficiency, and free up working hours [15,16]. This inherently requires that health organizations and teams reorganize their workflows and work distributions to support clinical processes [17,18].

The Omaolo ESC questionnaires and algorithms in use are based on research evidence, probabilities, and expert opinions as to whether the condition described is mild and self-limiting. In terms of urgency, an assessment is made on how soon the condition would worsen without treatment or whether it requires the intervention of a health care professional. However, as with clinical decision-making in general, making an accurate diagnosis requires user-provided information, clinical examinations, various diagnostic tests, and potential consultations with other health care professionals [19,20].

Previous studies have evaluated the accuracy of the diagnostics of ESCs and triage using clinical case vignettes [21-27]. Variation exists between different ESCs, and the conditions

being assessed, including the triage capabilities [8,27-29]. In some studies, the diagnostic accuracy of clinicians has been shown to be superior in both primary and specialized health care when compared with ESC tools [22,23]. These studies have shown that users may be referred to as self-care even if they need professional help, and users for whom self-care would suffice are referred to unnecessary counseling. There are risks and the potential for error in ESC-based triage [8,21-29]. In particular, self-care guidance should be limited to cases where it is safe and appropriate. There is currently a limited amount of evidence available on the impact of ESCs on seeking treatment with real-life users [12,30]. However, respondents were satisfied with the ESC services they use [13,31,32].

A study comparing the accuracy of physicians' and computer diagnostics found that physicians listed the correct diagnosis first more often across all study vignettes compared with ESCs (79.1%-65.3% vs 40.5%-24.3%; $P < .001$) as well as in the top 3 diagnoses listed (84.3% vs 51.2%; $P < .001$) [24]. There is limited evidence of live clinical patient safety hazards associated with the use of ESCs, as safety has mainly been evaluated with the use of clinical vignettes [7,8,21,23,24,26]. When comparing AI and human doctors concerning triage and diagnosis, some AI systems were able to provide triage and diagnostic information on a level of clinical accuracy and safety comparable to human doctors [8,23,33]. However, ESCs on average make the user's triage more sensitive to the need for more urgent care than the user would need [22,34].

The seamless integration of ESCs into the broader health care triage process is crucial for achieving their intended goals, such as preventing emergency departments overcrowding and providing more accurate symptom assessment and triage for citizens. ESCs can offer citizens a preliminary triage level for their symptoms before contacting health care services [35]. In addition, ESCs and eHealth applications can serve an educational purpose by providing users with structured, research-based disease and treatment information that is easily accessible [36,37]. From a clinical perspective, the ability to accurately identify cases where self-care suffices is paramount in assessing an app's utility in preventing overcrowding and the "unnecessary use of healthcare services" [38].

Description of the Omaolo Electronic Symptom Checkers

Omaolo is a national web-based service for health care and social welfare. The purpose of Omaolo is to promote the health and well-being of citizens. Omaolo supports self-care and helps people to contact public health care professionals, if necessary. Omaolo is a medical device with a Conformité Européenne marking, manufactured by government-owned DigiFinland and Duodecim Publishing Company Ltd. Omaolo was granted a CE certificate in accordance with the requirements of European Union Regulation 2017/745 (Medical Device Regulation) in May 2022 [39]. The aim of the Omaolo ESC is to identify, based on an assessment of alarm symptoms and other pre-existing

conditions, situations that require immediate or urgent assessment and to conduct follow-up examinations and treatment without delay in situations where conservative treatment may lead to complications. The questionnaires and the algorithms the ESC uses are based on evidence and legal requirements [40].

The ESC operates as [41] the user initially receives reliable information about the symptom (articles from the Health Library Duodecim) and a short summary. If unable to decide on the course of action needed, the user can answer the ESC's questions. The ESC will then suggest the estimated needed treatment and its urgency. The results of the completed survey made by identified users are saved and prompted to be sent to a regional health care professional through Omaolo. The ESC algorithm initially seeks to identify alarming symptoms and then prompt the user to contact the nearest emergency department immediately. The idea is to identify situations where a professional assessment is necessary and to determine the urgency of the assessment. The user is encouraged to consider whether they may have symptoms that are not covered by the information or survey provided. As the questionnaires might not cover all possible situations that could be due to other illnesses, treatments, or other causes that the user may have, the following help text is displayed to the user at the end of the query: "If you have symptoms that have not been covered in the survey or other illnesses or medications that you think affect your need for treatment, contact your PHC provider or, in an emergency, the nearest emergency department." [41].

Textbox 1. Nurse's form questions.

- How did the user arrive at the reception (walk-in or via telephone contact)?
- Did you consult a doctor to assess the user's need for treatment (triage)?
- What was the most significant thing (observation, symptom, or discovery) that influenced your decision-making?
- Do you feel the need to change your assessment of the need for treatment (triage) after seeing the responses and recommendations of the electronic symptom checker? (yes or no)
- If yes, why did you change the assessment of the need for treatment (triage) after seeing the responses and recommendation of the electronic symptom checker?
- If you feel it is necessary to change your triage assessment, reselect where the user should be referred to according to the classification terms of the electronic symptom checker recommendation.

A total of 119 individual nurses took part in this study. A nurse's average age was 40 (SD 10.5) years (median 37, IQR 33-47 years), and their average amount of work experience in triage was 9.9 (SD 8.5) years (median 7, IQR 4-14 years).

In total, 3 in every 10 recruited patient users arrived through walk-in at the PHC centers, and the rest first contacted their center through telephone. Upon physically arriving at the PHC centers, the patients were asked if they were willing to participate in the study.

The patients answered the ESC when they arrived at the PHC center (on arrival at the center, they also filled out a consent form). Filling out the questions of the ESC was done in a separate quiet space without the research assistant interfering.

Description of the Omaolo service is described in detail in the study protocol [40].

Objectives

We hypothesize that the Omaolo ESC assessments are safe to use compared with the assessment of a triage nurse.

The aim is to study the clinical validity of the Omaolo ESC and to evaluate its exact triage accuracy, specificity, sensitivity, and safety. These parameters can be used to determine if Omaolo ESC can direct the right patient user to the right place at the right time. The main research question was: how well does triage by the ESC match the triage of a nurse [40] ([Multimedia Appendix 1](#))?

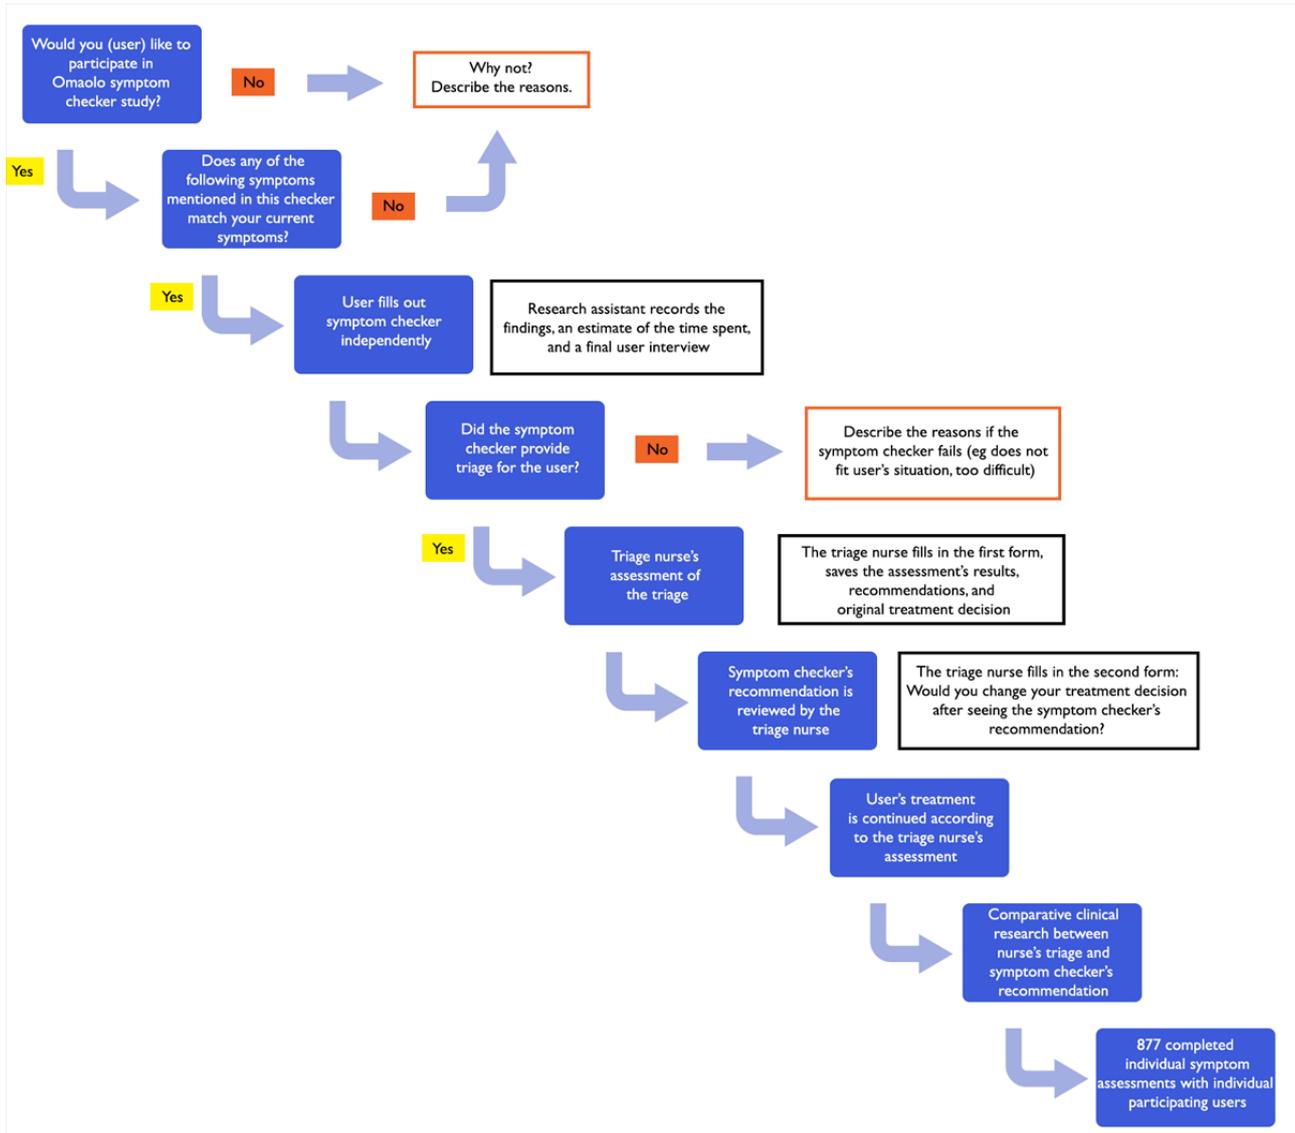

Methods

Study Design and Setting

The study setting was primary health care (PHC), and the data were collected at 18 PHC centers nationwide in Finland. The data were collected between June 1, 2018, and December 31, 2020. The study used the version of the Omaolo ESC that was in use in 2018. Each participating organization provided a study space where it is practically possible for the users (patients) to complete the ESC questionnaire and a nurse with at least 2 years' experience of triage nurse work in primary care to perform triage ([Textbox 1](#)).

Next, a triage nurse made a triage assessment of the same patient and filled out the study questionnaire related to the assessment of the patient's triage. The triage nurses did not get to know the result of the ESC until they had assessed the patient's condition themselves. After completing their questionnaire, the triage nurses finally got to see the results of the ESC triage concerning the same patient. Based on that result, the triage nurses filled out another questionnaire inquiring whether they felt it necessary to change their own assessment-based action recommendation after seeing the action recommendation of the ESC. The organization also ensured that the patient population of the study remained unscreened. No user-identifying age or gender data were collected for this study [40] ([Figure 1](#)).

Figure 1. Flowchart showing the collection of the symptom checker and nurse triage data.

Assessment of Electronic Symptom Checker Coverage and Triage Suggestion Levels

The results of the ESC triage and the assessments of nurses were analyzed from the completed study forms. Each assessment

was first analyzed individually, and the results concerning particular symptom assessments were combined.

The Ministry of Social Affairs and Health (MSAH) has provided a practical classification for levels of emergency and the Finnish Institute for Health and Welfare (THL) referral class classification with codes [42] (Figures 2-4).

Figure 2. An example showing how the triage comparison chart (confusion matrices) in Figure 3 was constructed with color-coded differences in triage levels (overly conservative, overly conservative but suitable, exactly matched, safe but under conservative, and potentially unsafe [resolved]). Matching rows (triage nurse) to their respective columns (symptom assessment) results in a safety assessment. P0-P4=classification of emergency care criteria. L2-4=referral urgency classes. The columns show how often, by ESC, the symptom assessment was overestimated, underestimated, or accurately matched compared with the assessment made by the triage nurse and the decision made on further referral. ESC: electronic symptom checkers; FN: false negative; FP: false positive; TN true negative; TP: true positive.

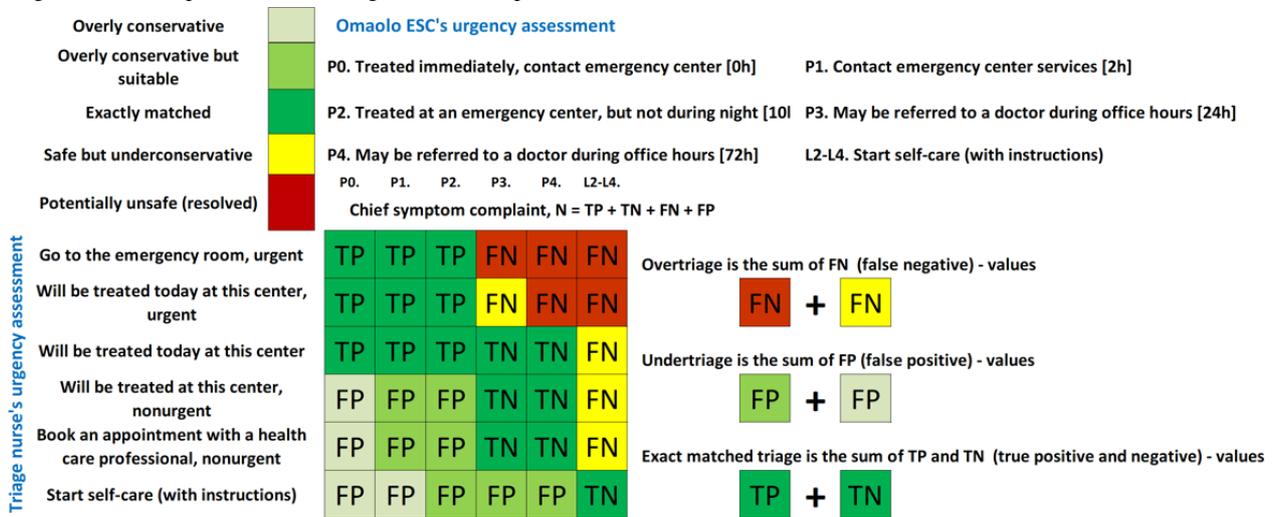

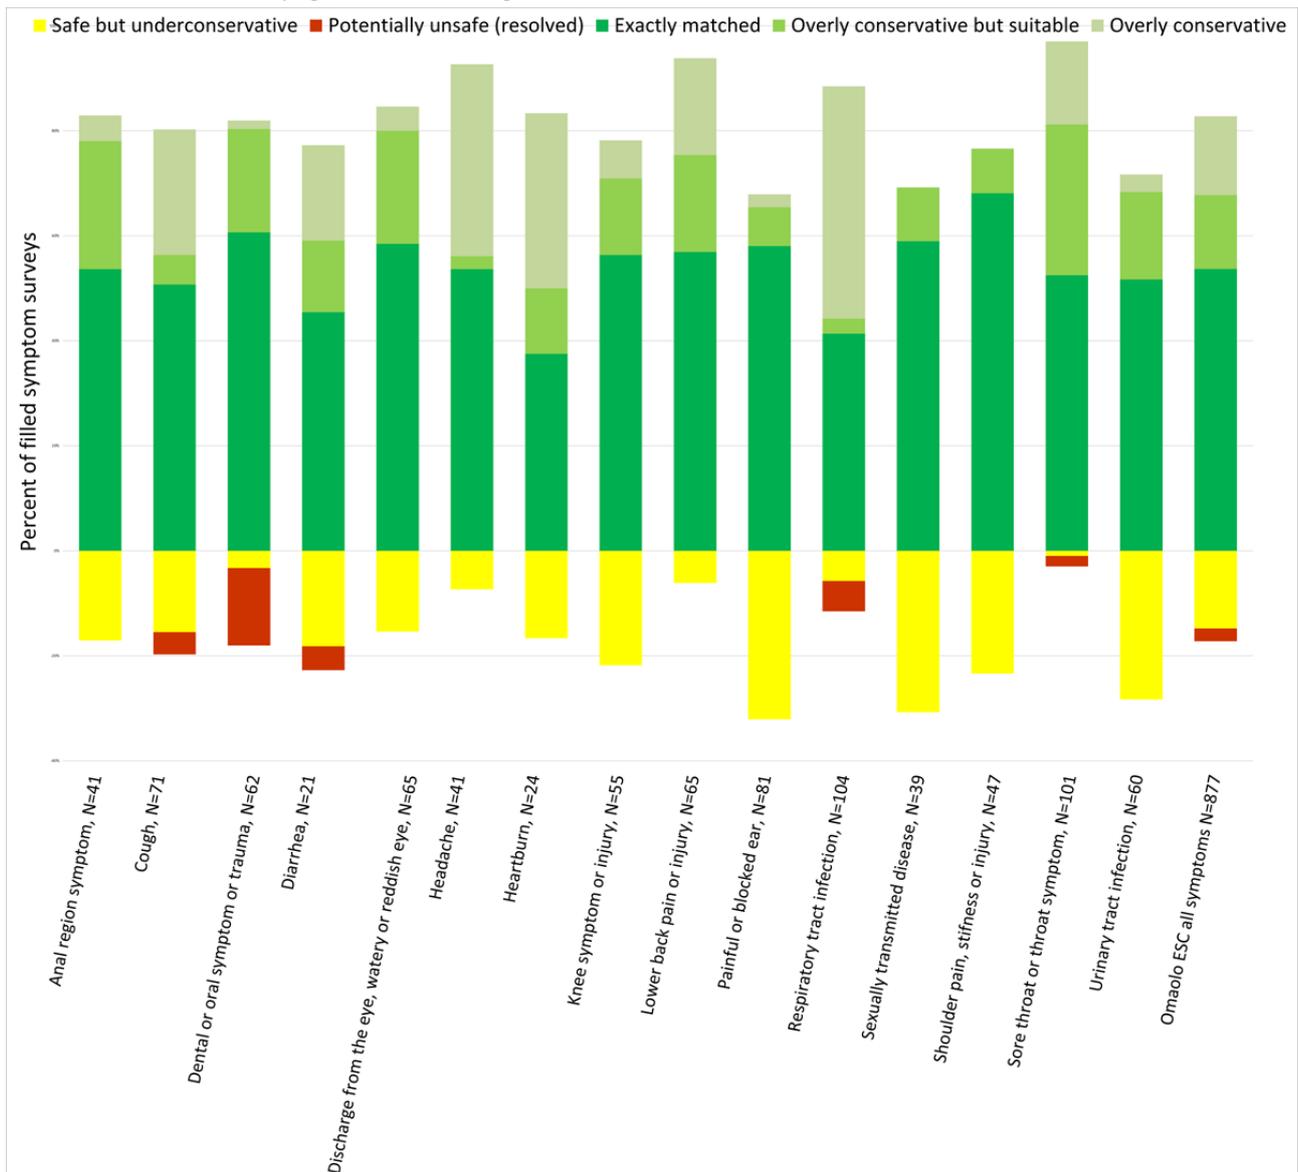

Figure 4. The individual bar heights (y-axis, %) reflect the proportional correspondence and accuracy levels of the electronic symptom checker triage with the nurse’s triage (overly conservative, overly conservative but suitable, exactly matched, safe but under conservative, and potentially unsafe [resolved]). Individual electronic symptom checkers are depicted on the x-axis.

These classification levels are as follows ranging from P0 to P4 and L2 to L4:

- P0: Treated immediately, contact emergency center (within 0 h)
- P1: Contact emergency center services (within 2 h)
- P2: Treated at an emergency center, but not during the night (within 10 h)
- P3: May be referred to a doctor during office hours (within 24 h)
- P4: May be referred to a doctor during office hours (within 72 h)
- L2-L4: Start self-care (with instructions)

Making use of the MSAH emergency levels, the Omaolo ESC and nurse triage were matched as, (1) exactly matched (ESC’s and triage nurse’s triage were the same), (2) overly conservative but suitable (ESC’s assessment was 1 triage level higher than the nurse’s triage), (3) safe but under conservative (ESC’s triage level was 1 triage level lower than the nurse’s triage), (4) overly

conservative (ESC’s triage level was 2 levels higher than the nurse’s triage), and (5) potentially unsafe (triage nurse assessed as urgent or an on-call duty but ESC assessed as nonurgent or self-care).

Assigning Accuracy Gold Standards to the Triage Nurse and the Electronic Symptom Checker

The nurse triage assessment is the gold standard, to which the recommendations of the ESC were compared. An assessment was also defined as potentially unsafe if a case was assessed by the nurse as urgent or an on-call duty but assessed by the ESC as nonurgent or self-care. These assessments were further investigated to ensure patient safety.

An external expert group was founded to analyze possible critical assessments and user safety. The group included one Omaolo developer nurse, 3 physicians with specialist degrees in general practice, 1 physician with a specialist degree in public health, 3 personnel working in the ESC development

department, and 1 coder responsible for the Omaolo ESC production.

Statistical Methods and Metrics for Assessing Triage Accuracy

Triage accuracy was calculated as the percentages of matches for each individual ESC and 95% CI. The calculations were based on the initial nurses' triage assessments. The hypothesis is that the Omaolo ESC is safe to use [40].

We set the safe symptom assessment based on a previous study, as at most one level of urgency less urgent than the assessment of a nurse, and the performance of the ESC as 97% safe accuracy across all completed assessments [23]. We also assumed that misdiagnosis by physicians occurs in approximately 5% of outpatients [43]. We estimated the required sample size by assuming the given range of safe advice at 97% and using a 95% CI, and we computed the CI estimate for the true proportion of safe ESC assessments [23].

Triage comparison charts (confusion matrices) are created in which true positive (TP) represents the outcome where the model

correctly predicts the positive class (condition is detected when present). True negative (TN) is the outcome where the model correctly predicts the negative class (condition is not detected when absent). False positive (FP) represents the outcome where the model incorrectly predicts the positive class (condition is detected when absent). False negative (FN) is the outcome where the model incorrectly predicts the negative class (condition is not detected when present). These values are crucial components in calculating the positive predictive values (PPVs), negative predictive values (NPVs), and Matthews correlation coefficient (MCC). The PPV, NPV, and MCC formulas are given as:

These values are typically extracted from a confusion matrix, as illustrated in Figure 3 and presented in Table 1 of the study.

Table 1. Results of matching the nurse triage (gold standard) with the Omaolo electronic symptom checker recommendation in 15 different symptoms^a.

Absolute magnitude of the Matthews correlation coefficient	Interpretation
±0.00-0.10	Negligible correlation
±0.10-0.39	Weak correlation
±0.40-0.69	Moderate correlation
±0.70-0.89	Strong correlation
±0.90-1.00	Very strong correlation

^aThe Omaolo electronic symptom checker recommendation is defined as safe if the critical condition was not assessed as urgent or on-call duty by the nurse but assessed by the electronic symptom checker as nonurgent or self-care. The CI range in the column reporting the number of completed assessments is assumed at safe advice of 97% and using a 95% CI. The table also shows positive predictive values and negative predictive values following the Matthews correlation coefficient.

The MCC ranges from 1 to +1, where ±1 indicates perfect agreement or disagreement, and 0 indicates no relationship.

Ethical Considerations

This study was reviewed by the Pirkanmaa hospital district's ethics committee (ETL-Code: R18126), and regional permission was additionally granted by each participating organization, all according to the regulations of the University of Tampere.

The most significant ethical issue related to the research setting is that the user's participation in the research does not affect their chances of receiving timely treatment. All users who fill out the symptom checker will be forwarded to an appointment with an experienced nurse. Denial of treatment for users who refused to participate in the study was strictly prohibited.

When users (patients) were recruited for this study, the research assistant informed the user about the study, distributed the study information sheet, and then asked if the user was willing to participate in the study. If, after being informed, the user was willing to participate in the study, they were asked to sign a consent form in which the user acknowledged that they had received sufficient information about the study and agreed to participate in it. The user was given an information sheet about the study with contact information in case the user wanted to

ask more about the study. The user was paid no amount of compensation.

The patient user's consent form was disconnected from the response form with a personal identification code, that is, the users were completely anonymized. No medical record data were collected or combined with research forms. The users could withdraw their consent to the study at any time. However, the completed forms cannot be destroyed after the data collection because the consent form containing the personal data does not have the identification code to identify the appropriate study forms to be destroyed.

Results

Overview

A total of 877 patient user assessment cases were successfully collected. No patient user identifying age or gender data were collected for this study.

Quantifying and Comparing the Levels of Urgency and Triage Accuracy

The ESC's and nurse's triage were exactly matched in 53.7% (471/877; 95% CI 49.2%-55.9%) of the cases in all symptom

assessments. Considering ESC's individual main symptom triage suggestions, the most exactly matched assessments were found for shoulder pain, stiffness, or injury (32/47, 68%), dental or oral symptom or trauma (37/61, 61%), and sexually transmitted disease (23/39, 59%).

The mean value for exactly matched or overly conservative but suitable for all symptom assessments was 66.6% (584/877; 95% CI 63.4%-69.7%). Safe assessments of ESCs accounted for 97.6% (856/877; 95% CI 95.6%-98.0%) of all assessments made (Table 1, Figures 2-4). Concerning acute cases in which the nurse evaluated that a user needed to be treated urgently the ESC's exactly matched accuracy was 70.9% (244/344; 95% CI 65.8%-75.7%), and in cases whether medical care should be sought or self-care is sufficient, matches were found in 65.9% of cases (351/533; 95% CI 61.7%-70.0%). Sensitivity for the Omaolo ESC was 62.6% and specificity was 69.2%. The proportions of evaluations occurred at a ratio of 100 suitable to 25 overtriage to 22 undertriage. The overly conservative triage (overtriage) suggestions made by the ESC occurred most often for respiratory tract infection in 44% (46/104), heartburn in 33% (8/24), and headache in 37% (15/41) of cases (Figure 4).

The question "Do you feel the need to change your assessment of the need for treatment (triage) after seeing the responses and recommendation from the ESC? (Yes/No)" was answered with the "Yes" option in 19 out of 877 assessments. In answering the follow-up question "If yes, why did you change the assessment of the need for treatment (triage) after seeing the responses and recommendation by the ESC?", the nurses frequently stated that the symptoms they were told by the user did not match with the ones the user had stated while filling the ESC (Table 2 and Multimedia Appendix 2). In the last section, in the case of an affirmative answer, the path of changing the triage ended with "If you feel it is necessary to change your triage assessment, reselect where the user should be referred to according to the classification terms of the ESC recommendation." In these 19 assessments, the nurses were found to have chosen a triage suggestion closer to that of the ESC assessment (Multimedia Appendix 2). In 80 cases across all completed 877 assessments, the triage nurse consulted a doctor in assessing the triage.

Table 2. Triage nurse form questions results, the y-axis represents the number of observations.

Symptom	Completed matched assessments, n	Percentage of safely matched advice symptom assessments, % (95% CI)	Exactly matched symptom assessments, % (95% CI)	Positive predictive value (precision), %	Negative predictive value, %	Matthews correlation coefficient
Anal region symptom	41	100 (91.4-100)	53.7 (37.4-69.3)	14.3	74.1	-0.133
Cough	71	95.8 (88.1-99.1)	50.7 (38.6-62.8)	52.2	48.1	0.004
Dental or oral symptoms or trauma	62	85 (74.2-93.1)	59.7 (46.5-72.0)	62.9	57.7	0.204
Diarrhea	21	95.2 (76.2-99.9)	45.5 (24.4-67.8)	0	66.7	-0.37
Discharge from the eye, watery or reddish eye	65	100 (90.0-99.6)	58.5 (45.6-70.6)	66.7	28.6	-0.036
Headache	41	100 (91.4-100)	53.7 (37.4-69.3)	50.0	66.7	0.138
Heartburn	24	100 (85.8-100)	37.5 (18.8-59.4)	26.7	55.6	-0.233
Knee symptom or injury	55	100 (93.5-100)	56.4 (42.3-69.7)	36.8	66.7	0.035
Lower back pain or injury	65	100 (94.5-100)	56.9 (44.0-69.2)	46.7	80.0	0.253
Painful or blocked ear	81	100 (95.6-100)	58.0 (46.5-68.9)	20.0	49.0	-0.115
Respiratory tract infection	104	94.2 (88.0-97.9)	41.3 (31.8-51.4)	40.2	45.4	-0.118
Sexually transmitted disease	39	100 (91.0-100)	59.0 (42.1-74.4)	50.0	61.3	0.093
Shoulder pain, stiffness, or injury	47	100 (92.5-100)	68.1 (52.9-80.9)	42.9	72.5	0.12
Sore throat or throat symptom	101	98 (93.0-99.8)	54.5 (42.3-62.5)	48.3	78.6	0.19
Urinary tract infection	60	100 (94.0-100)	51.7 (38.4-64.8)	57.1	46.9	0.04
In total	877	97.6 (96.4-98.5)	53.7 (50.3-57.1)	49.4	59.5	0.089

The Analysis of Critical Assessments

In total, 21 critical assessments were identified for further analysis. Details are given in Multimedia Appendix 3. Further analysis showed that there were no indications that patient safety

was endangered. In Figures 3 and 4, these patient user cases are marked as "Potentially unsafe" (resolved).

Discussion

Principal Findings

The findings suggest that while exact matches of the Omaolo ESC recommendations with the gold standard (nurse triage) occurred in just over half of the cases, nearly all cases were evaluated as safe, with urgency levels being at most 1 level less urgent compared with the nurses' triage. Concerning acute assessments, an exact match was found in nearly 3 out of 4 cases. This study assessed for the first time the safety of the Omaolo ESC within the Finnish PHC context.

Comparison to Previous Work

In a systematic review, the diagnostic accuracy and the triage-making abilities of ESC services such as Ada, Babylon, Buoy, K Health, Mediktör, Symptomate, and Your.MD were compared with those of general practitioners' assessment using clinical case vignettes. The average safe operating recommendations ranged from 90.1% (SD 7.4%) [23]. By contrast, the general practitioner's percentage of safe advice stood at 97.0% (SD 2.5%) [23]. Comparatively, the proportion of safe Omaolo ESC assessments across all investigated cases was 97.6% (856/877) using similar methods for safety assessment. These findings underscore the safety of Omaolo ESC compared with assessments by experienced nurses, particularly notable given the real-life setting of our study. By comparing Omaolo ESC's accuracy to internationally reported results, we can gauge its overall performance and capabilities [8,22-24,44].

A study examining Ada's use by 378 "walk-in" patients in urgent care compared its triage accuracy with that of a triage nurse using the Manchester Triage System, conducted under similar circumstances as the Omaolo ESC's triage accuracy study. Ada exhibited an undertriage rate of 8.9% (34/378) and an overtriage rate of 57.1% (216/378). Out of 378 participants, 344 (91%) were triaged identically or more conservatively, while 34 (8.9%) were undertriaged by the app. The assessment was deemed safe in 94.7% (358/378) of patients when compared with the Manchester Triage System assessment. In the Omaolo ESC study involving 877 users, 726 (83%) were triaged identically or more conservatively, with 151 (17%) being undertriaged. Notably, Omaolo ESC exhibited a 29% (255/877) overtriage rate, with evaluations occurring at a ratio of 100 suitable evaluations to 25 overtrriages to 22 undertrriages. Compared with Ada, in the Omaolo study, overtriage rates were lower.

A recent systematic review concluded that the median accuracy of studied apps in determining the necessity of emergency care was 80% (IQR 74.6%-86.8%) [20]. For Omaolo ESC's triage of acute cases where a nurse assessed urgent treatment as necessary, exact matches occurred in 244 out of 344 cases, representing 70.9% (95% CI 65.8%-75.7%) of cases, while matches indicating whether medical care should be sought or if self-care is sufficient occurred in 351 out of 533 cases, totaling 65.9% (95% CI 61.7%-70.0%) of cases. This is in line with the international figure of 73.3% (IQR 70.5%-82.3%) [8]. In addition, the median app sensitivity was 51.9% (IQR 40%-78.2%), and the median specificity was 93.3% (IQR

87.4%-96.4%) [8]. Omaolo ESC exhibited a sensitivity of 62.6% and a specificity of 69.2%.

ESC's capability to detect individuals in need of immediate treatment is vital for user safety. In addition to that, an ESC that holds promise for safely assisting in self-triage and that helps prevent overcrowding of emergency departments could bring added value to health care. Notably, concerning Omaolo, the least overtriage was observed in chief symptoms of sexually transmitted diseases (4/39, 10.3%), shoulder pain stiffness or injury (4/47, 8.5%), and painful or blocked ears (8/81, 9.9%). Conversely, more sensitive and risk-averse chief symptom assessments such as headaches (16/41, 39%), heartburn (11/24, 45.8%), and respiratory tract infections (49/104, 47.1%) exhibited higher rates of false positives, raising concerns about overcrowding and possible unnecessary health care service use. However, due to potentially serious conditions, these ESCs are set to be sensitive in order to rule out alarming symptoms.

A relatively high PPV was found in cough, dental or oral symptoms or trauma, discharge from the eye or watery or reddish eye, and urinary tract infection assessments. This indicates reduced false positives, beneficial when false positives have high costs or the condition is not severe. High PPV minimizes overtreatment and unnecessary costs. Conversely, a moderate PPV found from other assessments is acceptable if follow-up tests are inexpensive and harmless precautionary measures are taken. For the symptom assessments of anal region symptoms, diarrhea, heartburn, headache, and sexually transmitted diseases a low number of cases has to be taken into consideration when evaluating these values.

A relatively high NPV was found in assessments of anal region symptoms, dental or oral symptoms or trauma, diarrhea, headache, heartburn, knee symptoms or injury, lower back pain or injury, sexually transmitted diseases, shoulder pain and stiffness or injury, and sore throat or symptom. High NPV is crucial for serious or contagious conditions needing early intervention, minimizing false negatives. Moderate NPV observed in this study for cough, discharge from the eye, watery or reddish eye, painful or blocked ear, respiratory tract infection, and urinary tract infection is acceptable if the condition is not severe or resolves on its own.

The MCC shows weak positive relationships for dental or oral symptoms or trauma and lower back pain or injury and weak negative relationships for heartburn and diarrhea. Other assessments have negligible relationships, suggesting the symptom checker's predictions are slightly better than random guessing.

Strengths and Limitations of the Study

The real-life setting presents both strengths and potential weaknesses for this study. There are notable concerns regarding potential selection bias. First, users completing the ESC in PHC center waiting rooms may experience different symptoms compared with those using the ESC outside of such environments. Moreover, while the Omaolo ESC is designed for users over the age of 15 years, only individuals over the legal age of 18 years were recruited for this study, potentially limiting the generalizability of findings. Furthermore, users who

were unable to independently complete the ESC due to technological limitations (such as difficulty using a computer mouse or tablet devices) were excluded from the study, introducing another potential limitation.

In addition, the rarity of users with serious acute symptoms in this setting may skew the study results, as their symptoms may not be severe enough to interfere with ESC questionnaire completion. However, it is worth noting that the Omaolo ESC prompts users to urgently contact health care services if they are unable to complete the questionnaire due to the severity of their symptoms.

Furthermore, potential users with mild, self-treatable symptoms may have been excluded as such cases may remain unreported in this study context. Nonetheless, the study focused on completed ESC triage assessment accuracy, specificity, and sensitivity.

In some instances, the triage classification made by nurses may have been influenced by user-reported needs for sick leave certificates, potentially biasing the calculated ESC accuracy.

The data accumulation process was hindered by the COVID-19 pandemic, which slowed down research activities [45,46]. However, the exponential growth in individual Omaolo users during the pandemic, particularly with the use of the coronavirus ESC, was noted [47]. To address the scarcity of completed assessments for some ESCs and urgent cases, future research will supplement data with electronic patient cases, known as case vignettes. This approach will also allow for the assessment of ESC performance across rare symptoms and conditions in a primary care setting.

Finally, it is important to acknowledge that, for this study, the nurse's triage assessment was considered the gold standard. An alternative approach could have been to use outcomes during follow-up, such as revisits or hospitalizations after 30 days, to determine the success of the triage.

Implications and Future Research

In this study, heartburn and diarrhea were relatively infrequent as chief symptoms for safety and accuracy evaluations. However, it is crucial to monitor and supplement the safety assessments of these symptoms in future case vignette studies. Despite their limited representation in this study, the present results suggest that heartburn and diarrhea are likely safe to assess using the ESC. To address more common and less urgent situations, vignette studies will be instrumental. These vignettes, sourced from various contexts, will undergo thorough testing to ensure that individual vignettes' difficulty and correlation with overall assessment are carefully considered [48].

Moving forward, there should be an evolution toward more standardized methodologies and studies tailored to specific settings. Regulation and standardization of evaluations are vital for ensuring the transferability of findings across different contexts [49]. In addition, adopting a patient-centered approach is essential for evaluating ESCs effectively. A standardized

process with clear specifications for vignette-based clinical evaluation is necessary to guide developers and facilitate objective comparisons among ESCs. This approach will enhance the reliability and validity of ESC assessments and promote their widespread adoption in clinical practice [43,50].

The data suggests that the Omaolo ESC is reliable for preliminary symptom assessment and triage, demonstrating a high level of safety in aligning with triage recommendations from experienced nurses, especially in acute cases. Omaolo uses structured questions and fixed algorithms designed by professionals to provide medically qualified recommendations, though it does not use AI. The question of whether AI-based ESC systems would be a desirable advancement or introduce additional risk and uncertainty for patient safety is complex.

AI-based ESC systems have the potential to enhance efficiency and accuracy by continuously learning from vast datasets and adapting to evolving medical knowledge. They can rapidly process information and offer consistent assessments across different users and contexts, potentially covering a broader range of symptoms and conditions. However, there are risks associated with AI-based systems, including reliance on data quality and a potential lack of nuanced clinical judgment compared with human triage nurses.

While AI-based ESC systems can complement triage processes, human supervision, and oversight are essential to ensure patient safety. Human triage nurses provide contextual understanding, empathy, and critical thinking that AI systems may lack, intervening when AI-generated recommendations are uncertain or potentially harmful. Therefore, AI-based systems should be viewed as tools to augment rather than replace human triage nurses.

In conclusion, ESCs should augment traditional triage rather than substitute for it, potentially leading to benefits such as reduced phone calls and increased accessibility to health services. Omaolo ESC, with its acceptable specificity and accuracy, holds promise for preventing unnecessary use of primary health care services. In addition, well-structured ESC assessments systematically collect user medical history and symptom information, evidenced by triage nurses' decisions to adjust triage based on additional user-provided information.

Impacts of the Study on the Omaolo Electronic Symptom Checker Service

The results highlighting the safety of Omaolo have been crucial for the continuation of the ESC service in Finnish health care.

Conclusions

The primary objectives of this study were to evaluate the safety and provide essential insights into the accuracy, specificity, and sensitivity of the Omaolo ESC. The results indicate that the ESC is safe for use compared with assessments conducted by triage nurses. Furthermore, the Omaolo ESC exhibits the potential to guide patients to appropriate triage destinations aptly, ensuring they receive timely and suitable care.

Acknowledgments

This research was carried out in addition to the work of primary health care centers, municipalities, health care district-based health care organizations nationwide, Omaolo project employees, and Finnish Medical Society Duodecim employees.

Data Availability

The electronic datasets generated during and analyzed in this study are available from the corresponding author upon reasonable request. Paper forms used to create these datasets are stored in a locked cabinet. The consent form containing the user's name and signature is kept in a separate locked cabinet. All paper forms are stored in the Tampere University. The forms are disposed of with a shredder 10 years after the end of the study.

Conflicts of Interest

MK is the president of the Finnish Medical Society Duodecim. TK worked as a salaried part-time editor for Duodecim Medical publications until 2018. VL works in the MD PhD program of the Faculty of Medicine at the University of Helsinki.

Abstract

Background: Clinical trials are essential for medical research and medical progress. Nevertheless, trials often fail to reach their recruitment goals. Patient recruitment systems aim to support clinical trials by providing an automated search for eligible patients in the databases of health care institutions like university hospitals. To integrate patient recruitment systems into existing workflows, previous works have assessed user requirements for these tools. In this study, we tested patient recruitment systems KAS+ and recruIT as part of the MIRACUM (Medical Informatics in Research and Care in University Medicine) project.

Objective: Our goal was to investigate whether and to what extent the 2 different evaluated tools can meet the requirements resulting from the first requirements analysis, which was performed in 2018-2019. A user survey was conducted to determine whether the tools are usable in practice and helpful for the trial staff. Furthermore, we investigated whether the test phase revealed further requirements for recruitment tools that were not considered in the first place.

Methods: We performed semistructured interviews with 10 participants in 3 German university hospitals who used the patient recruitment tools KAS+ or recruIT for at least 1 month with currently recruiting trials. Thereafter, the interviews were transcribed and analyzed by Meyring method. The identified statements of the interviewees were categorized into 5 groups of requirements and sorted by their frequency.

Results: The evaluated recruIT and KAS+ tools fulfilled 7 and 11 requirements of the 12 previously identified requirements, respectively. The interviewed participants mentioned the need for different notification schedules, integration into their workflow, different patient characteristics, and pseudonymized screening lists. This resulted in a list of new requirements for the implementation or enhancement of patient recruitment systems.

Conclusions: Trial staff report a huge need of support for the identification of eligible trial participants. Moreover, the workflows in patient recruitment differ across trials. For better suitability of the recruitment systems in the workflow of different kinds of trials, we recommend the implementation of an adjustable notification schedule for screening lists, a detailed workflow analysis, broad patient filtering options, and the display of all information needed to identify the persons on the list. Despite criticisms, all participants confirmed to use the patient recruitment systems again.

Introduction

Background

Clinical trials are the gold standard of evidence-based medicine and are indispensable for medical progress. New diagnostics, therapies, and medications usually need to be evaluated in a randomized clinical trial. Despite the importance of clinical trials, it is often difficult for trial staff to identify a sufficient number of patients who meet the specific eligibility criteria of clinical trials and who are willing to participate. Therefore, many trials fail to include enough patients, thereby leading to statistical and financial as well as ethical problems in medical research [1-3]. One reason for this is the lack of time capacity of the trial staff [2].

Electronic systems can help to identify potential trial participants in hospitals or other health care institutions by generating a screening list of all patients who fulfill the eligibility criteria [4-6]. For example, in 2015, McCowan et al [7] published a report on stakeholders from various countries in Europe for the project EHR4CR (electronic health records systems for clinical research), which aimed to enhance the utilization of electronic health records for clinical research. Their findings indicated that a significant proportion of stakeholders perceived that a platform could facilitate the implementation of clinical trials [7].

Most of the described patient recruitment systems (PRSs) were implemented for a specific site or trial. The PRS approach is time-consuming and costly and therefore not scalable for other

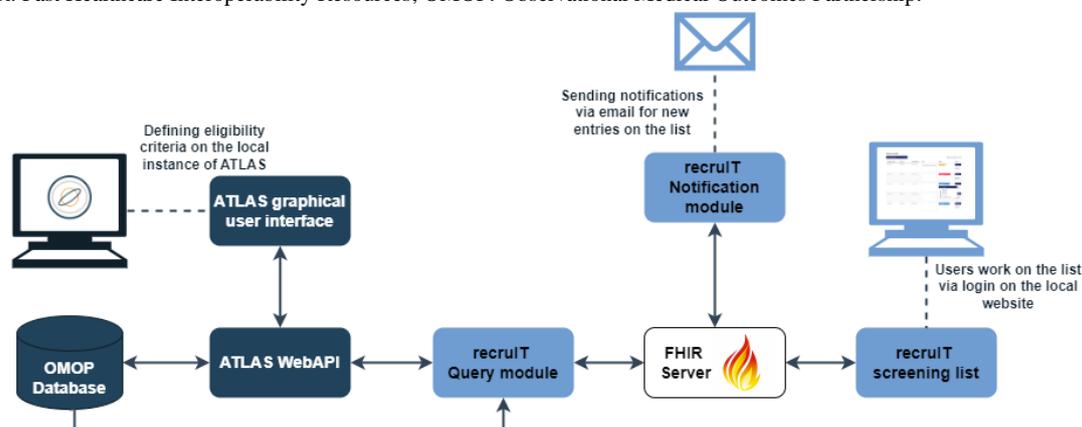

trials [8,9]. Few systems have been built with a generic approach, independent of specific use cases to support a wide range of experiments [5].

Medical Informatics in Research and Care in University Medicine

Data integration centers were established at university hospitals as part of the MIRACUM (Medical Informatics in Research and Care in University Medicine) project, a large-scale initiative in German medical informatics focusing on research and care in university medicine. One part of MIRACUM was the so-called Use Case 1 (alerting in care), which aimed to develop and evaluate a hospital-wide PRS in a multicentric study across all participating sites. The implemented systems, namely, recruIT and KAS+, were evaluated in this feedback analysis. Both systems are briefly presented in the following paragraphs.

As part of the MIRACUM project, a recruitment system has been in place at several sites to support a wide range of trials [10]. Based on previously identified system requirements [11], the software recruIT (MIRACUM project) was developed. The system is shown in Figure 1 and described in detail in [11]. This system relies on the Observational Medical Outcomes Partnership (OMOP) common data model, which is a software tool of the Observational Health Data Sciences and Informatics (OHDSI) [12]. The eligibility criteria of the trials can be formulated using the ATLAS (OHDSI) software. RecruIT generates a list of potentially eligible patients, which can be accessed through an internal website that shows all the basic information such as patient number, age, and gender of all entries [5].

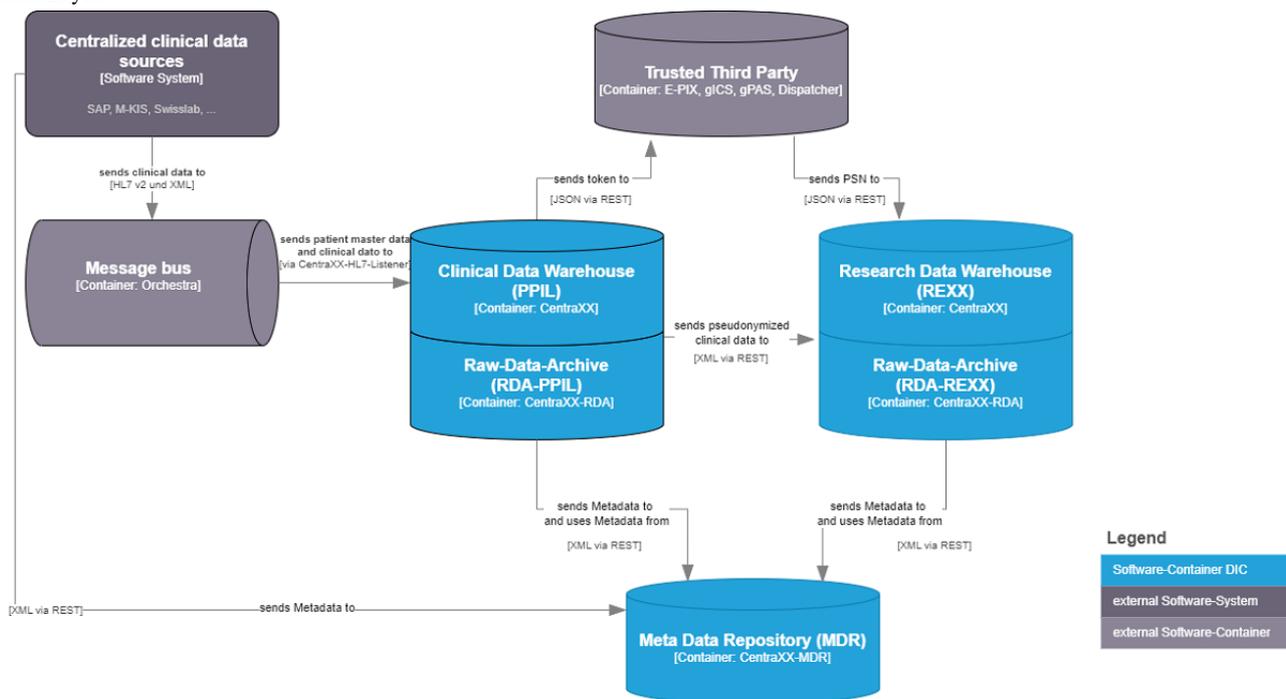

Figure 1. Architecture of the recruIT system. recruIT components are displayed in light blue, and Observational Health Data Sciences and Informatics (OHDSI) components are displayed in dark blue. The eligibility criteria are portrayed with the ATLAS graphical user interface. The query module triggers the search for new patients and writes all the results in the central Fast Healthcare Interoperability Resources (FHIR) store. The graphical user interface of recruIT (screening list) displays the results as a website. Users are informed about new results via email. API: application programming interface; FHIR: Fast Healthcare Interoperability Resources; OMOP: Observational Medical Outcomes Partnership.

Within the KAS+ infrastructure (Figure 2), all clinical systems transmit the patient data via HL7v2 and XML to the communication server orchestra. This distributes the data between the clinical systems and immediately transfers the data to the research platform. This consists of 2 CentraXX instances and 2 CentraXX raw-data-archives. The clinical data are read into Privacy Protection and Interface Layer, and if informed

consent has been given, the data are pseudonymized using the trusted third party tools and transferred to REXX. Within the research platform, the trials are administered and the inclusion and exclusion criteria are defined. If it is configured for a defined study, CentraXX immediately checks any new patient's data to determine whether a patient may be eligible for a trial and sends the proposal to the hospital information system (HIS).

Figure 2. Architecture of the KAS+ system. Data integration center components are shown in light blue, and external components are shown in gray. Eligibility criteria are managed in the CentraXX instance called Privacy Protection and Interface Layer. The CentraXX query module initiates the search for new patients, writes all the results to its internal database, and sends proposals to the hospital information system. PPIL: Privacy Protection and Interface Layer.

Requirements of PRS

In order for the system to be useful to the trial staff and clinicians, it needs to be fully integrated into their workflow [13]. Research has been conducted on the topic of implementing and evaluating PRS and on data elements needed for that purpose [11,14,15]. For example, Schreiweis and Bergh [14] performed unstructured interviews and identified PRS requirements of different health care actors. Although Schreiweis and Bergh [14] described the fundamental prerequisites, the specific desires of researchers for a PRS with integration in diverse workflows remain largely unidentified. Aside from the capacity to search for eligible individuals with the assistance of software, there is a paucity of information regarding the specific requirements researchers have for a PRS [14]. In a previous work [11], a number of people involved in patient recruitment were interviewed to assess how the recruitment process currently works, which data sources are useful, and which features they need from a PRS in general. With this information, a list of requirements was developed that a PRS should fulfill in order to meet the requirements of the trial staff.

Objective

The goal of our work is to investigate whether and to what extent the tools of the MIRACUM project can fulfill the requirements

resulting from the initial requirements analysis. Feedback should come from the real-world environment of patient recruitment. Therefore, a test phase is needed in which the trial staff will use the tool in their day-to-day work. A user survey will be conducted to determine whether the tools are usable in practice and helpful for the trial staff. The survey can also show whether additional requirements might arise from the test phase that were not considered in the initial requirements analysis. To avoid misunderstandings, we will refer to studies using the PRS as “trials” and to the investigation described here as our “study.”

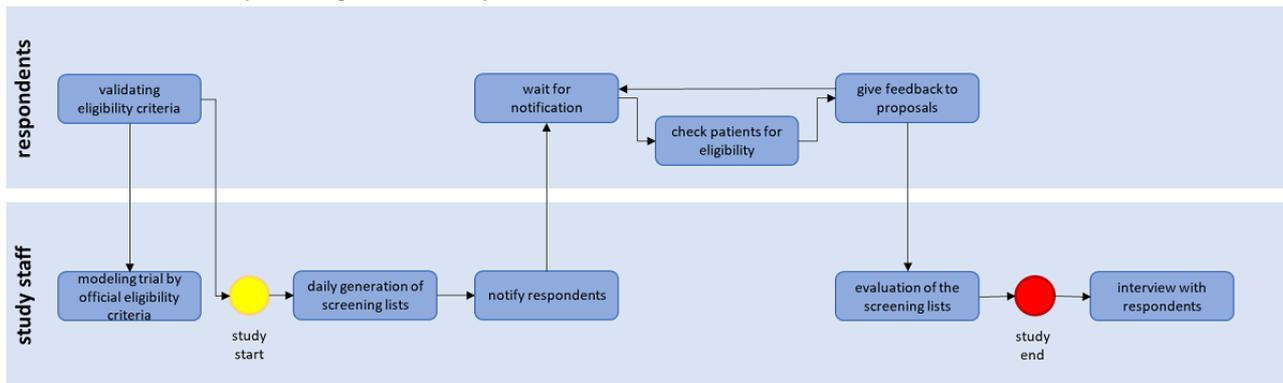

Methods

General Procedure

We conducted semistructured interviews with users of recruIT and KAS+ and derived requirements and feedback on the systems from these. Users (trial staff) had access to PRS instruments for at least 1 month. After this testing period, interviews were conducted according to the interview guide.

The test phase was part of an evaluation study to review the effectiveness of the software tools at 7 university hospitals. More detailed information regarding this study can be found in [16]. Figure 3 shows the tasks the study staff and the respondents had during the study.

Figure 3. Processes of the study involving users and study staff.

All respondents supervised at least 1 trial during the testing phase. For this study, 3 university hospitals from the evaluation study were included with all the respondents who gave interviews for analysis, either recorded and transcribed or stenographed. The other 4 university hospitals could not provide recorded or transcribed interviews, which is why they could not be included in this evaluation.

A few eligibility criteria were given in the study itself, such as the exclusion of trials with focus on psychological diagnosis. Other criteria were established by the sites to consider the local particularities: the exclusion of trials regarding children or cancer diagnosis, as the size of that site did not make such a tool necessary because the staff know the suitable patients. Another criterion for the trial selection was the expected recruitment of at least 4 patients over the course of 1 year to generate analyzable data.

The interview partners were selected at the respective study locations by the primary investigators. This approach was designed to leverage the domain knowledge and the local networks of the investigators to recruit test individuals for the

study in an optimal manner. Potential individuals were invited to participate in this study, and if they consented, a time was arranged for a face-to-face interview.

PRS

From KAS+, only part of the PRS was used during the study to meet the requirements of the ethics committee and generate the feedback necessary for the evaluation. We used the search engine in CentraXX, and the parameters used were defined together with the trial personnel. From the search results generated by CentraXX, we created the so-called screening lists with an SQL query. These results were copied to a template with feedback options. An example list is shown in Figure 4. Each morning, participants received an email with the screening list if any potentially eligible patients were identified or a notice that no suggestions had been generated. These lists were then used by the trial staff according to their usual recruitment workflows. The tabular format provides information on age, gender, and the last ward stored in the system for each patient ID. The adjacent checkboxes are used to record the recruitment status. They are also required to record the feedback on the proposals necessary for the study.

Figure 4. A mock screening list of the CentraXX system, which is provided to trial personnel in the form of a PDF file.

Study: Demostudy

26.08.2024

SAP-ID	Age	Gender	Last known ward	Patient encountered	Patient eligible	Patient informed	Consent received	Patient included	Notes
0123456789	29	female	TEST	<input type="checkbox"/> no <input type="checkbox"/> yes	→ <input type="checkbox"/> no <input type="checkbox"/> yes				
9876543210	65	male	DEMO	<input type="checkbox"/> no <input type="checkbox"/> yes	→ <input type="checkbox"/> no <input type="checkbox"/> yes				

Of the 3 sites included, 2 utilized the recruIT system to generate screening lists. The initial step in utilizing the system was to translate the eligibility criteria of all the participating trials to ATLAS cohorts. In the OMOP common data model, all information is represented by a medical terminology system.

Consequently, we also identified the corresponding codes and units of the aforementioned terminology systems for each eligibility criterion, prior to their portrayal in ATLAS. This procedure is also described in [17]. Figure 5 illustrates a cohort definition in ATLAS for 1 trial.

Figure 5. Sample trial as represented in the ATLAS software. All eligibility criteria are defined under inclusion criteria. In this example, the trial is looking for people who have been hospitalized since 2022, have type 2 diabetes, and are older than 50 years.

The screenshot displays the ATLAS software interface for defining a cohort. The top navigation bar includes tabs for Definition, Concept Sets, Generation, Samples, Reporting, Export, Versions, and Messages. The main content area is divided into three sections:

- Cohort Entry Events:** This section allows defining events that qualify for the cohort. It shows a criterion: "a visit occurrence of Any Visit" with an occurrence start date of "on or after 2022-01-01". There are buttons to "Add Initial Event...", "Add attribute...", and "Delete Criteria". Below this, there are options for "with continuous observation of at least 0 days before and 0 days after event index date" and "Limit initial events to: earliest event per person." A "Restrict initial events" button is also present.
- Inclusion Criteria:** This section lists the criteria for including patients in the cohort. It shows two criteria:
 - Demographics: Patients with age greater than 18 years
 - Type II Diabetes: Patients with a diagnosis of Type II diabetes after 2021-01-01
 There is a "Limit qualifying events to: earliest event per person." option.
- Cohort Exit:** This section defines when events will persist and when patients will be censored. It shows "Event Persistence" set to "end of continuous observation" and "Censoring Events" set to "Exit Cohort based on the following criteria:" with "No censoring events selected." and an "Add Censoring Event..." button.

Both sites used individual configurations in accordance with local ethics committee recommendations and data protection regulations. This leads to different information shown on the web-based screening list, which is shown in Figure 6. In both sites, a patient identification number was displayed as well as the date of the first suggestion of the patient and the recruitment status. The latter can be updated by the trial staff, and a text box is provided for each entry to store additional free text regarding the proposal. Additionally, the list shows when a patient is not

eligible anymore, for example, when he/she is discharged from the hospital or in case that the patient has been enrolled in another trial. For 1 site, some more information about the patients was shown on the list. This included gender, birth year, and information about the last visit and ward. The systems were updated on a daily basis, and notifications were configured either daily, weekly, or several times a week, in accordance with the user's wishes.

Figure 6. Exemplar representation of the screening list of the recruit system. The original screenshot was overwritten with English translation.

Fulfillment of Requirements

Identifying the requirements met by the tools is the first step. For this purpose, the results of Fitzer et al [11] were used, and each requirement was compared with the functional scope. These requirements were extracted and compiled into a table. Subsequently, it was indicated for both tools whether they completely fulfill, partially fulfill, or do not fulfill these requirements at all. For the KAS+ site, both the versions used in the study context and HIS integration were assessed.

Interviews

The authors used semistructured interviews. Most of the questions were open-ended. These questions asked interviewees to describe the process of identifying eligible patients with and without PRS. Additional questions were included, that is, if there were problems with usability and whether the system could be integrated into their workflow, with room for additional statements about their experiences. Moreover, we added 2 questions that required only a yes or no answer: whether the system could be integrated into their workflow and whether they would use it again. In addition, we asked for some demographic data, which include age and experience with patient recruiting. The full list of questions and their order is shown in [Multimedia Appendix 1](#). Although some of the questions required a “yes” or “no” answer, participants were given the opportunity to provide more detailed responses in full

text, and if they did, we included those responses as well in our analysis.

For organizational reasons, 1 site asked additional questions as described in the last part of the table in [Multimedia Appendix 1](#). Once all the interviews were transcribed, they were independently coded by 2 authors (RB and AS) according to Meyring method [18,19]. In this approach, the text to be analyzed was first examined for its key statements, and these were then summarized. These statements were then generalized into codes, and codes with the same meaning were summarized. The generalization was performed on the basis of a previously defined category system, which was then checked again against the source material [18,19]. After categorizing the codes, we structured and sorted them by using categories. Furthermore, any statements that contained a requirement for recruitment tools were marked. Afterward, the responses from the interviews were compared with the requirements already identified in [11] and checked to see if they were the same or if new ones had been mentioned.

Ethics Approval

This study received institutional review board approval from the ethics committees of Friedrich-Alexander University Erlangen-Nuremberg (approval 89_20B) as well as of Justus Liebig University Giessen (approval AZ 193/20) and Greifswald University Medicine (approval BB 084/20). Within this study,

no identifying personal data were centrally collected and analyzed. No compensation was offered.

Results

Study Participants

This study consists of a total of 11 participants, comprising 7 clinical trial investigators, 2 research assistants, and 2 physicians. In 1 instance, the interview was conducted with 2 individuals simultaneously. The ages of the interviewees ranged from 25 to 34 years (2 participants), 35 to 44 years (4 participants), and 45 to 54 years (4 participants). The average number of years of professional experience in patient recruitment was 10.4 years (range 1-21 years). Four participants worked in the field of neurology, 2 in cardiology, and 1 person each in the fields of dermatology, internal medicine, neurosurgery, and rheumatology. The participants used the screening list for 1-3 trials each.

Degree of Compliance With Requirements

In [11], the following 6 categories of requirements are described: notifications, overview of patients, overview of trials, search, patient data, and user management and interface. We omitted the category “overview of trials” in this study since it is implemented as part of another tool at all participating sites. The category “patient data” contains data elements that can be used for searching; all other categories are shown in Table 1. Both systems fulfill the main requirement of (1) generating a list of eligible patients and (2) notifying users. In addition, it is possible to tag participants, make notes, and track the recruitment status. Both investigated systems lacked integration with existing HISs. Comparison with clinical trial eligibility criteria is possible with diagnoses, demographics, laboratory results, and vital signs in both tools. The treatment data mentioned in [11] can only be partially queried by the tools.

Table 1. List of requirements defined by Fitzer et al [11] and implementation in the recruIT and KAS+ systems. Since a KAS+ test environment with different properties was used for this study, this is also indicated.

Requirements	recruIT (n=12)	KAS+ evaluation environment (n=12)	KAS+ (n=12)
Notifications			
Users are instantly notified if new suggestions are available	Yes ^a	Yes	Yes
Notifications are adjustable to individual preferences by the user	Yes	No ^b	No
Overview of patients			
Supports a list of all patient suggestions	Yes	Yes	Yes
Possibility to check suggestions by themselves	Yes	No	Yes
The list with suggestions is integrated into existing systems	No	No	Yes
Option to mark participants	Yes	Yes	Yes
Option to make notes	Yes	Yes	Yes
Option to track the recruitment status	Yes	No	Yes
Edit recruitment list by manually adding patients to list	No	No	Yes
Edit recruitment list by removing patients from list	Yes	No	
Integrating patient summaries into the patient recruitment system	Yes	No	Yes
Search			
Offers sophisticated search options	Partially ^c	Yes	Yes
User management and interface			
Contain a sophisticated rights concept to account for the various roles in the trial and at the clinical center	Partially	No	Yes
Requirements fulfilled	8	5	11

^aYes: implemented.

^bNo: not implemented.

^cPartially: partially implemented.

Interview Results

As the participants had no restrictions on how to integrate the tool into their workflow, the kind of integration varied. For 3 participating trials, the tool was a permanent part of the workflow; for others, it was used when the staff had spare time (n=2). Two interviewees made it the preferred source for patient

recruitment. When analyzing the transcribed interviews, we found 54 different codes. To put the codes into context with each other, we defined 5 groups: system integration, parameter, precision, system evaluation, and user interface.

System Integration

Statements about the update frequency differed between the requirement to enable real-time recruitment, daily, and weekly updates. The requirement to flexibly adjust the update and notification interval per trial was also mentioned by 3 participants. All other statements required a more flexible integration into the daily workflow of the trial staff. The lists should be processed flexibly, when there is time in the clinical daily work, and the list should be integrated into the local HIS. Generally, there should be no system discontinuities.

Parameter

Three respondents indicated that not all relevant criteria were available in the system, and 9 respondents mentioned specific data elements, namely, medications, pulmonary parameters, lung transplant list, laboratory results, cardiac echocardiography findings, general findings, admission letters, and alcohol abuse. In addition, 6 respondents expressed the necessity of filtering the list by ward, while 1 respondent proposed that this should encompass the entire patient journey. One respondent cited poor data quality and inadequate utilization of the International Statistical Classification of Diseases (ICD) and Related Health Problems for all criteria related to diagnosis (n=3).

User Interface

The majority of the statements in this group pertain to patient identification. Patient numbers should be fully displayed, and pseudonymous lists are considered impractical to use. In 1 interview, the full name of each patient was also requested, while in another one, this was mentioned as not relevant. The new features cited included more options for patient recruitment status (n=1), integration of better categorization and tagging options in the list (n=1), and the ability to sort suggestions by ward (n=1). In addition, 1 person commented that it would be nice to add a third category of soft exclusion criteria that would result in a warning on the generated list. This would be especially helpful in the case of discretionary decisions, for example, if patients are excluded due to a certain diagnosis, all patients on the list who had this diagnosis in the past should be flagged on the list so that the trial staff know that they need to check whether this diagnosis is still valid.

Precision

It was mentioned that the list contains too many suggestions that are not eligible for the trial (n=5) as well as too many eligible persons that are not on the list (n=2). The list contained no or few false positives (n=3) or false negatives (n=1). In addition, 1 respondent mentioned that subsequent adjustments to the filter criteria resulted in more accurate screening lists.

System Evaluation

The results regarding the feasibility of integrating the system into the workflow of trial staff were mixed. Overall, most of the interviewees (n=7) reported satisfaction with the system and expressed their desire to use it again in the future (n=8). However, some interviewees mentioned that they would only use the system for specific trials (n=2). Furthermore, 2 individuals highlighted that using the system resulted in labor savings during the recruitment process (n=2) and positively

impacted recruitment numbers (n=1). The system was capable of reaching different groups of people compared to traditional recruitment methods, which, as a result, broadens the pool of potential patients (n=2).

Evaluated Requirements

Requirements were derived from the statements of interviewees and are shown by frequency and category. We identified 4 requirements that were stated by 4 persons in the interviews. These were that whole patient numbers should be shown on the list to identify the patients properly. Further, they require a possibility to filter patients on the list after hospital wards. Two less concrete requirements were the better integration of the application in the clinical workflow and less false-positive suggestions on the list. All other requirements are shown in [Multimedia Appendix 2](#). [Multimedia Appendix 3](#) includes the code assignment for the requirements.

Five requirements were identified upon analyzing the interviews, which are highly similar to the ones in [11] ([Multimedia Appendix 4](#)). Three people mentioned the previously unimplemented requirements of integration into the local HIS and having flexible access to the lists. Although highlighting patients on the list is already possible, 1 interviewee proposed the ability to categorize and mark suggestions. This implies that the current implementation does not fully satisfy the users. One interviewee mentioned the need for more status options and an iterative patient search.

Discussion

Principal Findings

A comparison of the PRSs in question revealed that 8 (recruIT) and 11 (KAS+) of the 12 requirements identified in the previous analysis by Fitzer et al [11] can be fulfilled. Ten interviews were conducted with individuals involved in the recruitment of individuals for clinical trials at 3 distinct sites. Additionally, further requirements of the participants were identified. These requirements could be classified into different categories, and it was determined that integration into existing workflows is of particular importance for our interviewees. Many of the identified requirements are directly related to this.

Degree of Compliance With Requirements

Although certain requirements outlined in [11] were not implemented in the systems under evaluation, none of the interviewees mentioned any of them. Based on the results of this study, it is assumed that both manually adding or removing patients from the list and implementing a sophisticated role and rights concept do not have a high priority for the interviewees. However, it cannot be determined whether these requirements would be useful in the context of the PRS. Given that this study is confined to a limited number of trial centers, it is possible that these requirements will only become relevant when more people are involved and multiple trials are supported.

Interview Results

Certain interviewees mentioned new filtering options such as filtering for wards, despite the rarity or absence of these criteria in trial protocols. This indicates that for PRS implementation,

official eligibility criteria alone might not be sufficient; additional filtering criteria that are specific to recruitment workflows may also be relevant. Further investigation may prove valuable in identifying other criteria that could enhance patient filtering.

Many of the mentioned parameters lead to diagnostic examinations which, taken together, occur often [20,21]. Diagnostic examinations can vary widely, and the resulting data that need to be queried by a PRS can vary as well. This can create challenges in collecting data from the local HIS. Access to high quality data from different clinical systems and electronic health records, which is an important part of a PRS, remains an unresolved issue and is the subject of ongoing research and development [22-24]. This finding was also reported by McCowan et al [7], who conducted stakeholder interviews for the project EHR4CR in 2015. Over half of the interviewees expressed the opinion that problems could arise from the lack of functionality in their HISs and the absence of crucial data items in the primary care systems [7]. Problems with filtering can arise from data that are documented unstructured, incorrect, or too late. As described in a data completeness analysis in 2022 [25], some data elements are found in less than 50% of electronic health records in German hospitals. Presumably for this reason, 1 participant mentioned that the data quality was not good enough.

Accuracy of suggestions is an area with several influencing factors such as the type of trial, general accessibility of the data, and data quality. One reason for false positives can be that not all of the important criteria are accessible, leading to suggestions that are technically correct, although the patient is still not eligible for the trial. The same result is achieved when there are fuzzy criteria, which need to be judged by trial staff. This is a problem also identified by Li et al [26] in 2021. They described that different scopes of research can lead to different definitions. In order to address this problem, we included the trial personnel in the definition of filter criteria. However, we learned that some criteria have to be checked manually, such as the cause of a disease or life expectancy [26]. Penberthy et al [27] also identified a high rate of false-positive suggestions in the evaluation of their PRS. They concluded that this was due to incomplete information about the patients, which prevented the exclusion criteria from being fully checked. However, some people have mentioned that few false positives are possible. Nevertheless, it is unclear whether this observation is based on concrete numbers or on the expectations of the participants.

The population examined in clinical studies is often criticized as not being representative. Older adults, women, and ethnic minorities in particular are less frequently included in clinical trials than they are represented in the general population [28-30]. Especially with the possibility to access a broader pool of patients, these tools could be used to face the underrepresentation of different groups. The ability of research staff to identify additional patients from diverse hospital wards is a phenomenon that Penberthy et al [27] also observed in their PRS evaluation. Additionally, including persons from other wards can happen more often to reach patients who are primarily treated for a different disease or health issue than that addressed in the trial.

Half of the participants were able to integrate the PRS in their daily routine, while others stated that this would not be fully possible. On closer examination of all statements of these persons, we could identify potential reasons for the missing integration and could see that 2 of these persons also criticized that pseudonymized lists are not practical. One of them stated that the lists should be generated earlier in the morning, and another demanded that the full patient names be included in the list. It is possible that integration could be easier if these issues are worked on. Despite the lack of comprehensive investigation into the PRS requirements, the integration of a PRS into existing systems, such as the official HIS, is a topic that is frequently discussed in various academic publications. In addition to the findings of Fitzer et al [11], Dugas et al [31] were able to derive this conclusion from a case study, while Schreiweis and Bergh [14] reached the same conclusion through stakeholder interviews.

Features Already Implemented in KAS+

As mentioned above, the KAS+ system was not used with its full capabilities due to the study requirements. For each proposal, feedback was necessary, especially if it was marked as false positive—this was not possible with HIS integration. Therefore, this integration was not used for this study, which also disabled the connected features.

This is why some mentioned features are already implemented but have not been used, like the integration into HIS. Trial staff can access a screening list, which is constantly updated. Various filters can be applied to this screening list and electronic health records can be accessed directly from this list, provided that the user has sufficient rights. All suggestions are shown with a consent status that indicates, for example, whether they have signed an informed consent for this study, rejected, or withdrawn it.

Implementation of Requirements

We could identify 32 requirements from the analyzed interviews. It is not possible to say which of the requirements are specific to a trial center or medical discipline and which are valid for a broader field of users. We assume that requirements mentioned by more than one person are at least not specific to one process. From all requirements, 12 were expressed in at least 2 interviews and are listed in [Multimedia Appendix 4](#).

Adjustable Update Interval

Three of the requirements addressed the notification or update interval of the tool. By implementing adjustable intervals, all these requirements could be met. At least the features mentioned above should be available: weekly, daily, and real-time updates. It would be even better, especially with changing shift schedules, if the intervals could be chosen completely freely, that is, users could also specify certain weeks, days, or times when they want to receive notifications.

Integration in Workflow

Users want to be able to adapt the system to suit their needs, which correlates with the demand for a flexible PRS to be integrated into the daily workflow. This is particularly related to the demand for integration into the local HIS, which would

also reduce system discontinuities in the solutions. The lack of integration sometimes leads to time-consuming workarounds, mainly caused by typing information from one system into the other. Reducing this work would therefore mean that the use of the screening list would take less time.

The tools should be embedded in the daily work of the trial centers. Trial staff work in a variety of workflows involving different groups of people, departments, and information sources [11,32]. In order to implement a working integration into existing processes, it is necessary to know them in detail. To the best of our knowledge, there is as yet no publicly described preliminary work on which to build [32]. For this reason, it makes sense to perform a complete workflow analysis before developing and implementing a PRS in order to avoid system discontinuities and other application issues. Furthermore, it is advisable to integrate the PRS directly into existing information systems when feasible.

Broad Filtering Options

The filtering options when generating the list have to cover criteria, which are relevant for the identification of eligible persons. Several studies have been conducted to find out which data elements are necessary to check all the eligibility criteria. Therefore, the criteria were bundled into data element groups. The studies that examined this issue list a broad range of data elements and their frequency, which can be used as a guide for the first implementation of a PRS [20,21]. Additionally, we could show that the filtering for wards and the multiple presence of parameters is necessary in the eyes of our participants. The PRS can only consider those data elements that are present in the clinical systems. However, there are data elements that are not routinely collected or are not of sufficient quality. As a primary requirement for the implementation of a PRS, it is therefore necessary that the system has access to a data pool that is as complete and up-to-date as possible. Nevertheless, eligibility criteria can be highly specialized. Thus, a more flexible approach where data elements can be extended continuously would be a way to face these issues.

Pseudonymization

The screening list should always show enough information to find the persons easily in HIS in order to keep the effort in locating the patients as low as possible. We consider this as the reason for full patient numbers or patient names to be shown on the list. Patient data should be pseudonymized for authorized users before being displayed on the screening list. A similar observation was made by Butte et al [33].

Limitations

The main limitation of our study was the small number of participating trials: 10 trials at 3 different locations. Participants used a different PRS as already described above, and all locations had dissimilar local conditions, which might have had

an impact on the results. The investigated trials varied in type, design, and the duration for which the trial staff used the PRS. Also, the way the interviews were documented varied slightly; while 2 of the included sites transcribed the interviews, 1 filled the form stenographically. Therefore, there is no additional information for the bounded questions for 1 trial. As we did only a qualitative analysis and used only our participants' opinions regarding the false-positive and false-negative rates, we have no evidence that they always correlate with the quantitative numbers. Since the KAS+ test environment worked with daily generated PDF lists, many patients had already left the clinic when the trial staff checked the lists. Moreover, the KAS+ system would remove no longer suitable patients from the list, while this was not the case within the PDFs. This may have led to a higher false-positive rate.

Conclusion

The trial staff had a high workload with the recruitment of patients. Especially in retrospective recruitment, where often hundreds of files of a ward have to be searched manually, the time required can be enormous and files of other wards are not even included. If a filter system such as recruIT or KAS+ succeeds in generating a list in which this number can be reduced, time can be saved, even if there are false-positive entries in this list. Although the evaluated PRS does not actually yet meet all requirements, all participants would use the system again, at least for certain trials, which shows the need of any kind of support.

Participants stated that, even with more accurate suggestions, a manual control is crucial, as there will always be discretionary criteria or other aspects that need a human judgment, which cannot be done by a PRS. The recruitment efficacy of the system can vary across different trials. Nonetheless, it remains to be seen. In any case, participants do not want a support system for each and every trial, in particular, if there are already well-established processes in place or if the identification of a test individual depends heavily on the doctor's subjective assessment.

Our results are in line with test runs of comparable recruitment tools but also show that study personnel must be closely involved in the development to meet their needs like the filtering option for current wards or scheduled notifications. The next steps should be the exploration of the most needed parameters to increase the quality of the suggestions, the integration into HIS, and the implementation of an adjustable update and notification interval, as these are the most important aspects shown in this evaluation.

The future enhancement of the tools should be done in cooperation with the study personnel to create a tool that can easily be integrated into the workflow. To ensure this, future evaluations with a larger group of participants and a wider array of trials are necessary for a comprehensive analysis.

Abstract

Background: Research exploring perspectives on inpatient portals reports that patients desire the information affordances of inpatient portals, and clinicians recognize their value for improving patient experience but also express caution regarding sharing aspects of the medical record. This study contributed to the existing literature on inpatient portals by considering the psychosocial dimension of clinician resistance to information sharing with inpatients and the power dynamic associated with clinician-patient information asymmetry. Along with the information affordances commonly discussed in this area, this study explored perspectives on the novel option to audio record consultations via an inpatient portal.

Objective: This study aims to understand patient, proxy, and clinician perspectives on the value and impact of an inpatient portal within the Australian context. It explores clinician resistance and receptivity to sharing aspects of the medical record with patients and the power dynamic that characterizes the relationship between clinician and patient. It considers how an inpatient portal might assist in the transformation of this relationship such that this relationship could be characterized by greater information symmetry.

Methods: Interviews were conducted with patients (n=20), proxies (n=4), and clinicians (n=21) recruited from 3 areas within the Royal Melbourne Hospital, where the portal would later be implemented. A largely inductive reflexive thematic analysis was conducted.

Results: Patient and proxy participants reported that they wanted to understand what is happening in their care for peace of mind and that an inpatient portal could support this understanding. Clinician participants reflected on how they might transform their information-sharing practice to provide greater transparency in their relationship with patients. Participants considered the types of information that could be shared and how this information could be shared via an inpatient portal. Four key themes were generated: (1) affording the patient and proxy awareness, control, and reassurance through sharing accessible and meaningful information; (2) protecting the clinician and safeguarding quality health care in information sharing; (3) flexibly deploying the functions depending upon clinician, patient, proxy, and context; and (4) moving toward person-centered care: empowerment and equity via an inpatient portal.

Conclusions: An inpatient portal provides an opportunity to reconceptualize the medical record and how this information might be shared with patients while they are admitted to the hospital, such that they have more understanding as to what is happening in their care, which ultimately supports their well-being. The transition to a more transparent information-sharing culture in the Australian hospital context will take time. An inpatient portal is a critical step in facilitating this transition and creating more informational symmetry in the clinician-patient relationship.

Introduction

Background

Over the last decade, initiatives have been implemented across various countries to provide patients access to the medical record. Of these initiatives, Open Notes [1] is perhaps the most notable. Initiated in the United States in 2010, Open Notes is a call to action to provide patients access to their notes so that they can have more knowledge of, become more involved in, and have improved experience and outcomes in their health care. This initiative began as a pilot project to evaluate patient access to primary care notes [2]. As of 2021, it is now a US federal rule to provide patients access to their medical records [3]. Another key initiative is Planetree [4]. Founded in 1978, this international organization is dedicated to improving patient care from the patient perspective and has published numerous articles on the benefit of sharing the record with inpatients (refer to the study by Frampton et al [5]). Sweden's Journalen is also another noteworthy initiative. Implemented in 2012, this system offers anyone from the age of 16 years access to their outpatient records from hospitals, primary care, mental health care, and dental care [6]. Alongside these initiatives, studies from the last decade have focused on and have been motivated by the incentive to share medical records with inpatients via portals for the reasons outlined earlier, that is, to enable the patient, as the patient-centered or person-centered discourse puts it, to become more "empowered" in their care [7-16]. These studies all underlined the inpatient portal's beneficial impact on patient experience.

Studies (noted earlier) on the value and impact of sharing medical records with inpatients from both the patient and clinician perspectives are concentrated in the United States. These studies are generated from patient and clinician participant

perspectives on hypothetical patient access to components of the medical record or from the actual clinician and patient experience of the sharing of and access to components of the record. These studies reported that clinicians are generally accepting of providing inpatients access to their records due to the benefits they provide patients. Also in these studies, clinician participants convey innovative ways the record could be shared with inpatients. However, clinician participants generally express caution that patient access to their records during their hospital stay may result in patient misunderstanding and anxiety as well as potentially compromise the quality of care. Patients generally report wanting access to their records and appreciate the potential transparency and inclusion in their care that this information sharing could provide. Significantly, studies involving the patient experience of the inpatient record report a decrease or no increase in patient anxiety [9,10,13,14] and therefore suggest a misunderstanding from the clinician perspective of the patient experience and a possible reduction of this experience to a limiting stereotype [17].

Objectives of This Study

The motivation for our study was to explore patient, proxy (a nominated representative of the patient and in this study a partner involved in their care), and clinician perspectives of the MyChart Bedside inpatient portal within the Australian context before its future implementation. MyChart Bedside is an app by Epic Systems Corporation that extends the electronic medical record, providing patients access to aspects of their record (including notes, test results, and vital signs) while admitted to the hospital, via their smartphone or a hospital-provided tablet (Figures 1 and 2 show screenshots of the inpatient portal). To our knowledge, there are no studies of this kind exploring patient and clinician perspectives of patient access to their inpatient record in Australia.

Figure 1. Screenshot of inpatient portal with menu bar, notes, and recording features as displayed on a tablet (MyChart is a registered trademark of Epic Systems Corporation).

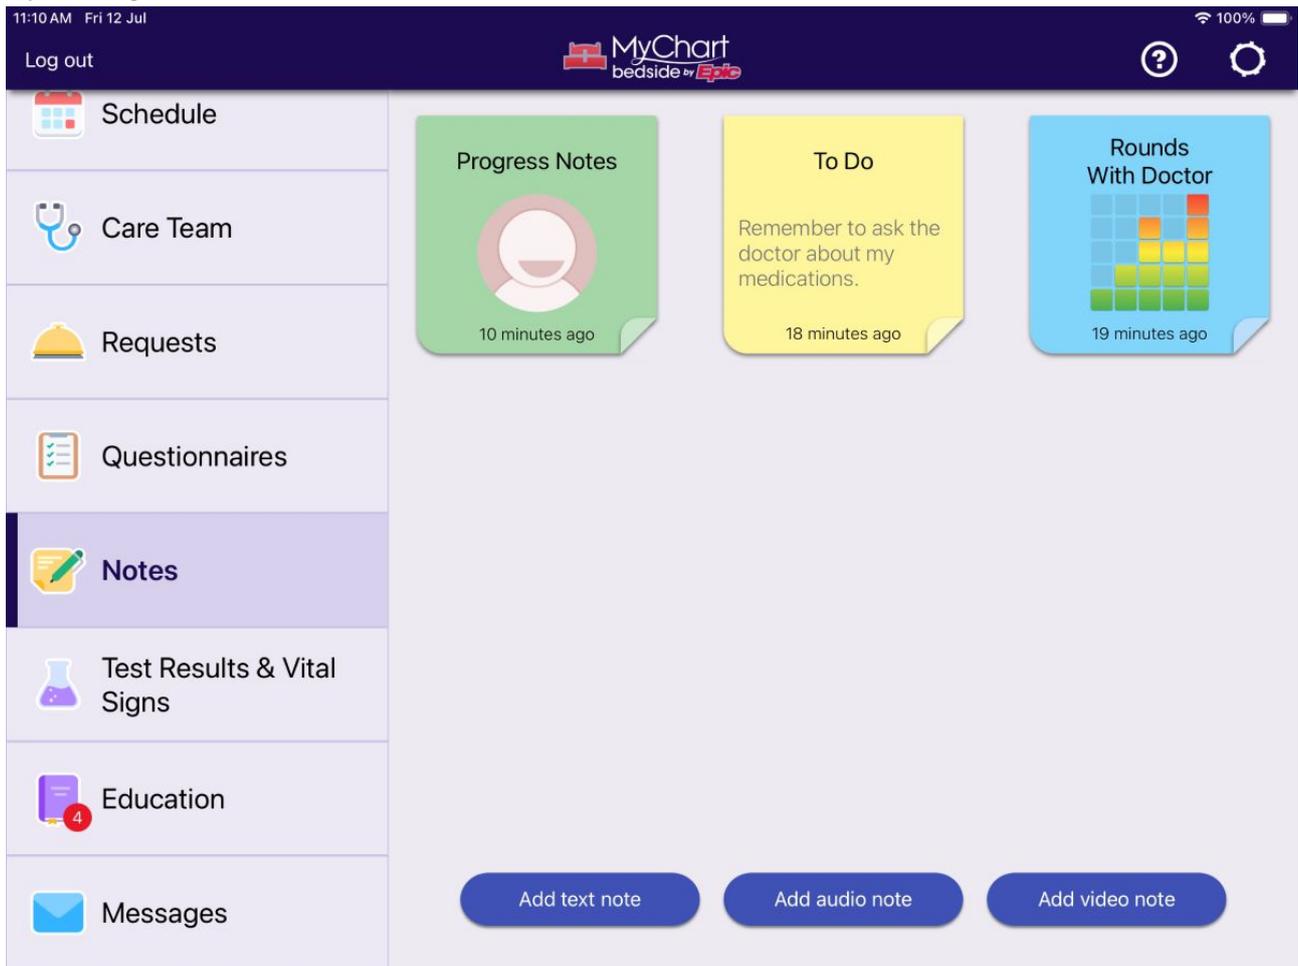

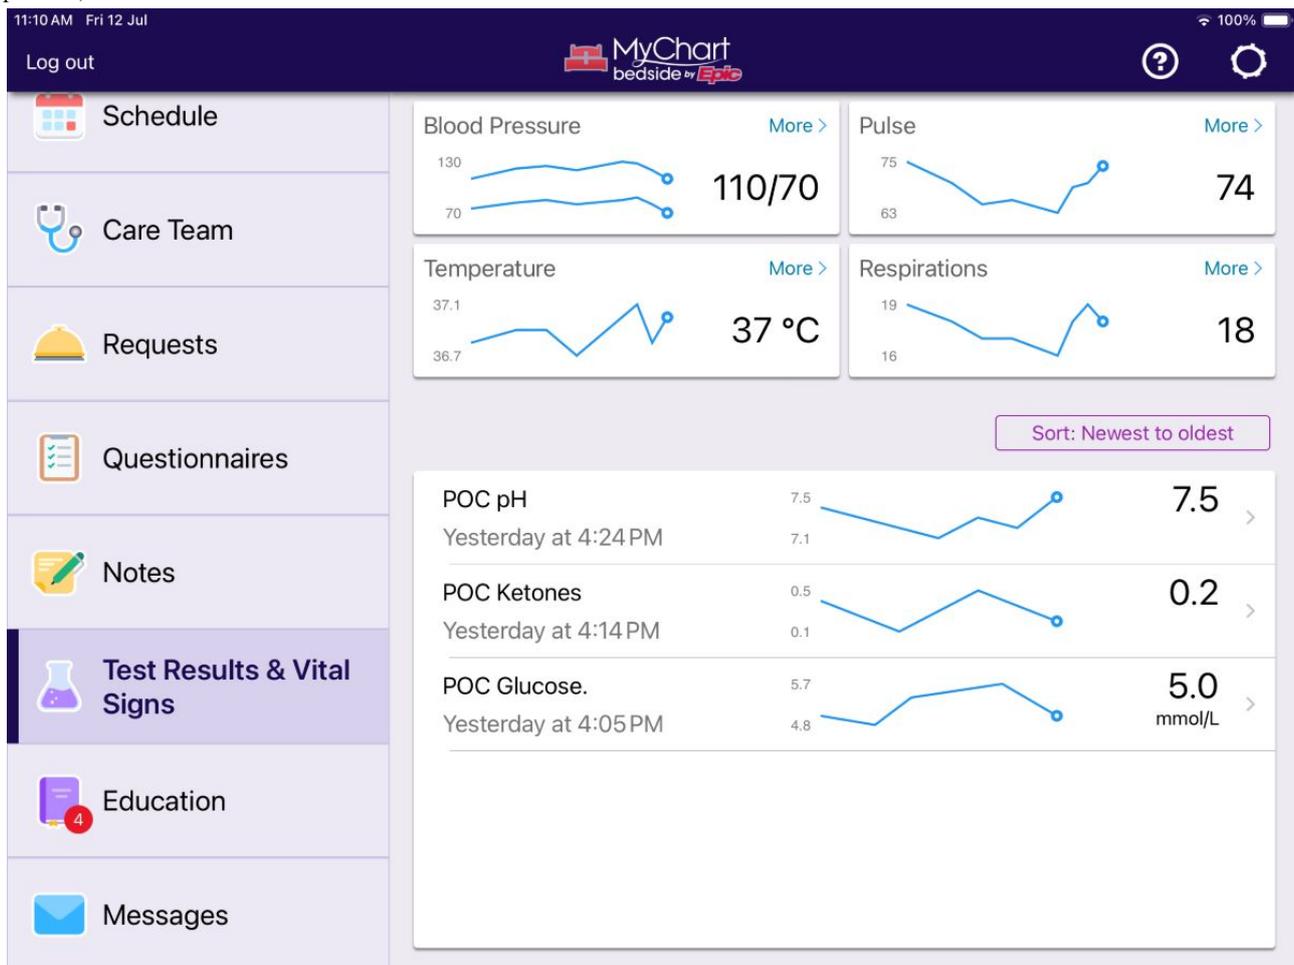

Figure 2. Screenshot of inpatient portal with menu bar and test result feature as displayed on a tablet (MyChart is a registered trademark of Epic Systems Corporation).

In this qualitative study, we used the term *person-centered*, as person-centered discourse acknowledges the patient as more than solely a patient with a set of symptoms to be diagnosed and acted upon, and it acknowledges the carer as not only a carer but as a person with unique preferences and needs [18,19]. Initiatives that provide patients access to their records and studies focused on sharing information with inpatients (cited earlier) are aligned with the ethos of person-centered care. This ethos calls for health care to move away from the traditional paternalistic model of medicine characterized by an information asymmetry, where the clinician withholds information from the patient and proxy and positions them as a passive recipient in health care, to move toward a more balanced relationship characterized by greater transparency in information sharing between clinicians and patients and proxies, supporting greater patient and proxy collaboration with the clinician in their health care.

A significant contribution of this study to the studies in this area is that it approaches not only the patient and proxy but also the clinician through a person-centered lens. In this approach, the clinician is understood not solely in terms of their clinical function but also as a person who, just like the patient and the proxy, although for different reasons, may be vulnerable in health care. This study pointed to how recognition of clinician vulnerability may provide insights into their resistance to information sharing, which is the common result in studies

exploring perspectives on patient access to their record. This study also shares with the person-based approach [20] the acknowledgment of the significance of the psychosocial dimension of its participants when exploring their perspectives. The person-based approach builds on user-centered and human-centered design and the principles of usability and acceptability and deploys a psychosocial lens to design and evaluate digital health interventions for behavior change and to enhance well-being. This study that has a different but related focus—an inpatient portal is also intended to enhance patient well-being—explored, where relevant, the psychosocial dimension of its participants when considering their perspectives and acknowledging their preferences about the acceptance of and vision of the sociotechnical system that the portal would generate.

This study was conducted within the context of the Royal Melbourne Hospital (RMH), a metropolitan, quaternary, and adult teaching hospital. Since August 2020, RMH has been offering its outpatients and their nominated proxies access to portions of their records, including select notes, test results, and medication lists via an outpatient portal (accessible via their smartphone or PC) referred to as “Health Hub.” The next logical step envisioned by RMH is to offer inpatients access to information pertaining to their hospital stay via an inpatient portal, MyChart Bedside. MyChart Bedside provides information affordances, including those that are the focus of

this study—access to notes, test results, and the ability to message the care team and audio record consultations during the patient’s hospital stay. The primary incentive of our study was to determine the levels of receptivity and resistance among the clinician, patient, and proxy population to these affordances before the portal’s future implementation throughout the hospital. The primary research question that guided our study was “What is the foreseen value and impact of an inpatient portal from the patient, proxy, and clinician perspective?” Patients, proxies, and clinicians were interviewed to understand their perspectives on the portal’s functions, and this paper presents a reflexive thematic analysis of their perspectives. The exploration of patient, proxy, and clinician perspectives on the prospect of patients recording their consultations provides a novel contribution to the existing literature on patient portals that does not discuss this function.

This study builds on the knowledge generated in previous studies with particular attention to the psychosocial and cultural dimension of information sharing within the context of a hospital and the power dynamics involved between the patient and proxy and clinician. More generally, it points to why, despite the patient’s and proxy’s desire for more information on their health care and the clinician’s understanding of the value of sharing information with the patient and proxy, the transition to a more transparent, symmetrical relationship through information sharing between clinicians and patients and proxies is complex. This study describes this complexity while suggesting ways it can be addressed such that health care contexts, such as that of Australia, can move toward more person-centered care.

Methods

Recruitment

Clinician, patient, and proxy participants were recruited for interviews from areas within the hospital where the portal would later be implemented. These areas included ward 7B (hereafter referred to as the leukemia ward), hospital in the home (HITH) subacute, and HITH acute. These areas care for patients with blood cancers, notably leukemia, and extend inpatient care to a patient’s home for patients recovering from such conditions as having a stroke (HITH subacute) or breast cancer surgery (HITH acute). In total, 5 patients and 1 proxy were recruited from each of the HITH areas; 10 patients and 2 proxies were recruited from the leukemia ward. Recruitment of patients and proxies was facilitated by the nursing unit manager from the leukemia ward, a nurse educator from HITH acute, and a clinical coordinator from HITH subacute. Potential participants were selected via convenience sampling, that is, based on their mental and physical ability to participate in an interview and provide informed consent, their fluency in English (interviews were conducted in English as the hospital operates within an English-speaking environment), and their willingness to be interviewed. Author SS phoned the selected potential participants, and those interested in being interviewed nominated a date and time for the interview. More details on patient and proxy demographic characteristics (including context recruited from, age range, the highest level of education, employment

status, comfort with technology, and understanding of their health condition) can be found in the Results section.

Nursing unit managers from the 3 areas and the chief medical information officer nominated the clinicians to be recruited. Their purposeful selection included a range of clinician types (including physicians, nurses, and allied health staff) and levels of seniority. A total of 9 (43%) of the 21 clinicians were recruited from the leukemia ward, 7 (33%) clinicians were recruited from HITH subacute, and 5 (24%) clinicians were recruited from HITH acute (refer to the Results section for clinician demographic characteristics, including context recruited from, clinician type, age range, level of education, and comfort with technology).

Generation of the Dataset

Interviews

Participants were interviewed for 30 to 60 minutes via a videoconference platform. A semistructured interview guide was used. The interview explored the portal’s following functions: (1) access to the notes, (2) access to the test results, (3) ability to message clinicians, and (4) ability to record consultations.

Participants were invited to consider whether and how these information affordances were useful and how they would impact care. Interviews were recorded and transcribed.

Analysis

Reflexive thematic analysis was used in the analysis of the dataset. In this qualitative method, researchers acknowledge their epistemological position, that they coproduce knowledge with participants, and that knowledge is not “found” but generated [21]. This study took a contextualist epistemological position, which located knowledge as generated by people’s experiences and perspectives from a particular context at a particular point in time. Author SS took a largely inductive approach in the analysis of the dataset and conducted semantic coding of the transcripts in NVivo (Lumivero), describing the dataset and staying close to the participants’ voices. The codes and the subsequent themes were outputs generated from the dataset rather than preconceived through a theoretical framework. However, in the generation of a dataset, its analysis, and reporting, there is always a level of interpretation involved. The disciplinary background of author SS in the humanities and particular interest in ethics of sociotechnical systems informed the interpretation of the dataset. The disciplinary backgrounds of authors AB (nursing and informatics), BB (nursing), and TF (medicine and informatics) informed their review of the analysis and its finalization.

Ethical Considerations

This study was approved as a quality assurance project by the RMH Office for Research in August 2022 (QA2022087) and required only verbal consent from participants. Participants received an information sheet detailing that their information would be deidentified in published material as well as in data storage. Patient and proxy participants were remunerated with gift vouchers.

Results

Participant Demographic Characteristics

The participant demographic characteristics are presented in [Table 1](#) and [Textbox 1](#). Patient and proxy participants were aged between 21 and 80 years, and clinician participants were aged between 21 and 60 years. Most of our patient and proxy participants had sound digital and health literacy: all patient

and proxy participants reported a good understanding or a very good understanding of their health condition, and most reported being comfortable or very comfortable with technology. The education levels of the patient and proxy participants varied. [Textbox 1](#) presents the clinician participant types recruited, grouped by each specific health care context. As can be seen, nurses were our most represented clinician participant type, followed by physicians.

Table 1. Demographic characteristics of participants.

- Physiotherapist
- Consultant

Hospital in the home acute clinicians

- Nurse educator
- 2 home visit nurses
- Pharmacist
- Consultant

Thematic Overview

In total, 4 themes were generated from the dataset as conveyed in [Figure 3](#): focused on the patient's voice, theme 1 formed a major part of the analysis. It was concerned with how the inpatient portal's functions can serve the patient and proxy, affording them awareness, control, and reassurance in their health care through accessible and meaningful information. After understanding what information the patient and proxy wants and the reason for it, we then need to understand how patient and proxy access to this information might impact the

clinician's practice. Theme 2 was focused on clinicians' concerns about how the portal's functions might impact them and their provision of care. Theme 3 considered how these functions can be flexibly deployed to serve the patient and proxy, protect the clinician, and safeguard quality care. Theme 4 presented an overall reflection on the value and impact of an inpatient portal from the patient, proxy, and clinician perspective, exploring the portal's perceived strengths and limitations in relation to key concepts in person-centered care: *empowerment* and *equity*.

Figure 3. Thematic overview.

Theme 1: Affording the Patient and Proxy Awareness, Control, and Reassurance Through Sharing Accessible and Meaningful Information

Overview

The most overwhelming factor generated in the patient and proxy interviews was that patients and proxies experience anxiety while admitted to the hospital due to the uncertainty about their situation. Patient and proxy participants explained that their anxiety is not so much a result of their health condition but their lack of awareness of what is happening in their health care. This theme was concerned with how functions that share meaningful information with the patient and proxy could bring them greater awareness of their situation and, by extension, a greater sense of control and peace of mind in their health care. Throughout this paper, *meaningful information* for the patient and proxy is understood as selective information regarding their health care that is tailored, relevant, and makes sense to them. Patients and clinicians conveyed the meaningfulness of information shared by the inpatient portal would depend upon the patient's understanding of this information and, if necessary, whether it can be made meaningful by the clinician in conversation with the patient. Participants also considered the meaningfulness of this information could depend on added explicatory summaries; patient-friendly language; the selection

of relevant information; and whether the patient wants this information generally speaking or at specific moments during their health care. Significant to this theme is the idea that the portal affords patients the ability to access information when they are ready because, as patient participants expressed, they experience periods of being unable to take information in due to the emotional and physical impact of their condition. This theme has been generated primarily from the patient and proxy perspective of functions that provide the option to share test results and notes and to record consultations. The clinician's perspective on these functions contributes to this theme in a secondary capacity in terms of its degrees of alignment to or divergence from the patient and proxy perspective. The themes mentioned subsequently are labeled with the function they address and a patient or proxy quote or paraphrased perspective conveying a common patient and proxy perspective on the benefit of the function.

Theme 1.1 Test Results: It's Good to Know Where You Sit Whether It's Good or Bad

Patient participants from the leukemia ward considered it would be valuable if the portal could afford them more timely access to their results, rather than them having to wait for their clinician to share this information:

As a leukaemia patient, the one thing you're always wanting to know is...your blood levels...those counts mean that...we're stuck in hospital or we can...become day patients, which is what we all aim for... First thing in the morning...pathology has already got your results, but you don't know what they are.... If it's on the app [portal...] you can...get the blood counts from...the night before. [Participant 38]

Patient participants more generally explained that access to their results helps them understand their health, and, as many expressed, this understanding reassures them. One patient expressed, "It's good to know where you sit; whether it's good or bad." Another stated that having access to these results would help them prepare for their consultations and feel more in control. Another explained that having access to their results could function as a kind of diary whereby they could track their health progress as they receive treatment. Accessibility was a key reason why patient participants were interested in having their results on the portal—having access to them whenever they needed them and being able to share this information with their care network (general physicians, family, and carers) was important to them. Some patient participants expressed the need for an explicatory summary or additional information to help them contextualize and understand their results:

It would be great to have...something that would explain...these results...It's valuable in the sense that you can see things out of range, but you can't put the context around it....You're like, "I'm not quite sure what they're looking for with that." [Participant 43]

Some clinician participants echoed the aforementioned perspective, stating that it would benefit patients to receive their results with an explanatory statement. A clinical coordinator stated the following:

I am on the health portal and love seeing my results, but I also know how to interpret them....If [they] came with explanations and general advice, I think that would be good.... Like what happens if my potassium is low? What do I do about it? My blood sugar is high. What do I do about it? [Participant 4]

A more common clinician perspective was that results should not be shared with patients before being discussed with their clinicians. A pharmacist explained the following:

If you don't have the skills to interpret it you shouldn't be given information without explanation.

However, there were clinician participants who had no reservations regarding sharing results with patients and made no mention of the importance of the clinician first discussing these results with their patient or providing an explanatory statement. Echoing a patient perspective cited earlier, an assistant nursing unit manager from the leukemia ward stated the following:

A lot of them actually wake up at about three o'clock...in the morning because they know that that's when results come back and they ask.... It would be good for them to just log on themselves and actually have a look, "Oh, I'm going to get some platelets

today. Oh, my white cells are—I don't think I can go home today," because they know. They're very well-informed. They know exactly what's happening. [Participant 12]

Theme 1.2 Notes: Knowing What Track You're on Gives You Peace of Mind

Patient and proxy participants were interested in access to their progress notes for a greater understanding of and to keep track of their health care and to have something to refer to, particularly at times when it is difficult to take in or retain information from consultations:

You know that this is the track you're on...you can...see if something's changed.... If there was something major coming up and then I'd forgotten about it or missed something, I could go back into the notes and go, "Okay, no, we've decided that this is what we're going to do".... It'll give you...peace of mind and definitely something to refer back to, because it can be so overwhelming. Sometimes you don't retain all that information. [Participant 22]

We would be able to look at the notes and if there was something that we just needed to reconfirm...or if...we didn't quite understand what the doctor said.... I need to know exactly how she's going, not only for her wellbeing but for mine...so I can do what I have to do as a carer looking after her. [Participant 11]

A proxy participant, who is also a nurse and so understands what the progress notes involve, explained why access to their partner's notes would have been helpful:

We couldn't really visit him very much in hospital because visiting hours are restricted, so it would really help us to have access to check that everything was okay.... I guess it would just be extra reassurance. [Participant 1]

However, some patient participants were aware that they would not be able to understand notes in their current form. A patient stated the following:

I was exposed to the hospital notes.... The language used is mainly for the medical department, so mainly it's a jargon...a bunch of numbers and blood counts that...I couldn't translate to tangible information for myself, so—yeah, it hasn't been useful, but I'd like some more transparency there. [Participant 22]

Some patient participants suggested a patient-friendly, summary record alternative to the clinician-facing notes, as they assumed the latter would be difficult to understand and therefore not useful.

Clinician participants were comfortable sharing admission and discharge notes with patients and proxies, but most were reluctant to share progress notes. Those open to sharing progress notes echoed the patient suggestion of a patient-facing note that could function as a summary record, filtering out aspects of the notes that could offend, confuse, or distress the patient. Some clinician participants considered how certain sections of the notes, such as those from the ward rounds and assessment notes,

could be of value to the patient. A physician stated the following:

If I say, "...the next couple of days, the plan is to do a CT...to give you some transfusions—" this and that...I don't think much of that would sink in.... I almost...want to give them a...a list to...say, "Okay, this is what's happening today. This is what's happening tomorrow."...That's what's captured in a ward round note.... If they have access to the ward round note, it'll be nice for them to see what's on the agenda...to understand what's happening for their illness.... [Participant 26]

A speech therapist stated the following:

If I did a swallowing assessment...and had a report, I would write it in a patient-friendly manner and...share it, whereas if it was just a progress note with no home therapy program...then I would maybe just keep that for the other clinicians. [Participant 17]

There was a minority (2/21, 10%) of clinician participants who were open to sharing notes and wrote them as if a patient could access them. A physiotherapist explained that this was how they were trained to write notes. A social worker explained that they write their notes as if a patient could read them but simultaneously expressed discomfort at the prospect of a patient reading their notes.

Theme 1.3 Recording Consultations: I'd Feel More Informed and Relaxed About My Care Because I Wouldn't Need to Remember Everything

Most patient and proxy participants were interested in recording their consultations due to similar reasons for wanting access to their notes—the view that it is difficult to take information in when you are unwell and that having this record of information would bring awareness, control, and reassurance in their health care. A patient stated the following:

I'd feel more informed...and more relaxed about my care, because I wouldn't need to remember everything. I've felt anxious some of the time because I figured I was being told something very important, but especially when I'd just come out of ICU...I could barely relate what had happened to me in terms of what the doctor had said.... I didn't feel confident...talking to the doctor. I needed someone else...there to take in what they were saying. [Participant 39]

This perspective conveys how the recording function could be beneficial for patients who do not have someone with them who can help them process information communicated to them. Another common reason for patient interest in recording consultations was to be able to share this information with their care network. Patient participants expressed that sometimes when they try to relay consultation information to their family, they are not always able to do so accurately, if at all. The following quote is from the proxy, who is also a nurse:

Because [he...] was unable to speak...he was unable to tell me what happened in those consultations....

That was really hard. He had a whole team of people come and see him, but he was unable to...relay that information. So it would be great to have them recorded. [Participant 1]

One patient participant stated that they would not need to record their consultations because they have “pretty good recall.” A proxy participant explained that they would not want this because they trust their partner’s clinicians. Formerly a police officer, this participant associated recording with surveillance.

Despite having reservations, many clinician participants could see the value in providing patients with the option to record their consultations. They considered it could function as a record for patients to return to or share with their care network if they were not proficient in English. They also considered it could be valuable as a form of education and echoing the patient participants, a record for when patients cannot take their consultations in, for when their recall is limited, and to share with families absent from consultations. A graduate nurse stated the following:

When the doctors come in...it can be quick.... They don't process the information a hundred percent....To have that...conversation recorded that they can go back and listen to...might be helpful because sometimes you need to hear information a few times to process it. [Participant 3]

There was a minority (2/21, 10%) of clinician participants who, due to their ethos of transparency, had no problem with patients recording their consultations. There were others—also a minority (3/21, 14%)—who were opposed to it, due to the vulnerability they felt in relation to it. Most (16/21, 76%) clinician participants had “mixed feelings” regarding this prospect.

Theme 2: Protecting the Clinician and Safeguarding Quality Health Care in Information Sharing

Overview

It was immediately apparent in the interviews that just as patients and proxies experience anxiety due to lack of awareness and therefore control in their health care, clinicians experience vulnerability in sharing information with patients. This vulnerability could be a result of the clinician’s level of seniority, expertise, training, experience, work culture, the medicolegal implications of their field, or a combination of all these factors. This theme focuses on the clinicians’ concern regarding patients recording consultations and accessing progress notes. Clinician participants considered how patient access to these information affordances might result in scrutiny of their practice, which could negatively impact them as well as compromise the quality of care provided. This theme is developed solely from the clinician’s perspective. The following subthemes are labeled with the function they address and a common clinician perspective.

Theme 2.1 Recording Consultations: This Would Make a Lot of Clinicians Uncomfortable

Clinician participants recognized that enabling patients to record their consultations would benefit patients but felt uneasy about

this. They explained that they did not want their words taken out of context to be misinterpreted, misappropriated, and vulnerable to any medicolegal implications. A speech therapist considered that if consultations were recorded, they (the therapist) might overwhelm the patient with information to safeguard themselves rather than giving the patient the information that is most meaningful for them at that moment in their health care. They stated the following:

We should be very aware of what we're saying, and...comfortable enough with what we're saying that we're happy...to be recorded....Some of the things that I probably said when I was working three or four years ago are no longer actually accurate because of new evidence so I think there would need to be some safeguards....What can happen with those recordings, where can they go? Is it just accessible through the app or is it going to be uploaded by the patient somewhere else? [Participant 31]

A physician considered the following:

It'll be helpful to play back those recordings and try and understand...things a bit better...and ask questions. So, I can see that that's pretty valuable. It does make me...nervous when patients say, "Can I record things?"...That is something that would make a lot of clinicians uncomfortable.... Perhaps, that is more of a reflection of us, and what we're worried about with our practice than what is best for the patient.... A lot of concern...would be the medico-legal implications of recorded information, and information, perhaps, being taken out of context.... [Participant 26]

Several clinician participants stated that they would support the recording of consultations if there was consent from the clinician and regulations to ensure information would not be misinterpreted and misappropriated. There was also the view that this function should only be deployed in certain situations where it was needed.

Theme 2.2 Sharing Progress Notes: I'd be Worried About the Self-Filtering That Might Happen and What Impact That Might Have on Clinician Communication and Patient Care

In their consideration of sharing progress notes, a speech therapist reflected as follows:

It's hard because it's like a culture in the hospital, you wouldn't expect for the notes to be shared, so it's a whole change of thinking. [Participant 17]

This perspective that sharing notes with patients would require a cultural shift and an evolution of thinking perhaps explains why many clinician participants were resistant to the idea of sharing progress notes. Importantly, several clinician participants understood why patients may want access to the notes and stated they would want access if they were patients; however, they also felt reservations about sharing these notes with patients when considering the clinician's perspective.

Clinician participants were generally concerned about how patient and proxy access to progress notes might negatively impact clinical practice and patients and proxies. Many clinician participants explained that these notes are a mode of communication between clinicians and include differential diagnoses, queries, social issues, and observations on mood and behavior that may confuse, offend, or distress the patient or proxy. They explained that if they were to share these notes, they would need to change the way they write, and this may impede communication with their colleagues and degrade the quality of care. A nurse explained the following:

I'd be worried about people not potentially fully documenting things [...because they are] worried what the patient might see or how they might react to what they've read.... That's certainly an area that's going to take...more exploration as the program unfolds. [Participant 2]

A dietician expressed the following:

I'd just be worried at the level of self-filtering that might in fact happen and what impact that might actually have on communication between teams and...patient care....There's perhaps a question about the purpose of why they might need access to everything when it comes to their notes.... [Participant 40]

As with the clinicians' perspective on recording consultations, there was the idea that it should be optional to share specific notes depending upon the patient, the clinician, and the situation, rather than a default sharing of all notes.

Theme 3: Flexibly Deploying the Functions Depending on Clinician, Patient, Proxy, and Context

Overview

Throughout the interviews, particularly when interviewing clinicians, it became clear that for the functions to be of value to and to have a beneficial impact on the clinician, patient and proxy, and health care context, they would need to be flexibly used. The flexible use of functions meant that they would not be used in the same way in every situation, but their use would depend upon the clinician, patient, proxy, and context. Rather than a one-size-fits-all approach, it was conveyed by clinicians that certain notes and results (rather than others) may be beneficial to share, and in some cases, recording consultations would be appropriate. The flexible use of functions would enable the clinician to adapt the information-sharing system according to their shifting levels of comfort, the shifting needs of the patient, and the particularities of the context.

This theme introduces a new function—the messaging function—and draws from both patient and clinician perspectives. The interviews conveyed that if the messaging function were to be implemented, it would need to be done flexibly, depending on the clinician, patient, and context. Furthermore, regulations would need to be put in place for its purpose and to set patient expectations regarding clinician response. Many clinician participants, particularly physicians, were opposed to this function due to the extra work it would

entail in responding to messages. Patient participants also expressed concern that this function would place too much burden on physicians. However, there were clinicians who could see how messaging could be an effective means of communication with patients in their respective roles as clinical coordinators, speech therapists, and occupational therapists from the HITH subacute context. There was unanimous agreement among patient and nurse participants from the leukemia ward that messaging would be an effective means of patient-nurse communication and would support quality care. The following subtheme is labeled with the function it addresses and a key patient perspective from the leukemia ward that was echoed by nurse participants from this same health care context.

Theme 3.1 Messaging: It Would Be So Good for Nurses and for Us as Patients Because Nurses Could Go to Where They Need to Be

Nurse participants stated after a patient buzzes them, they must go into their room to determine what they need, whereas messaging would immediately convey to them what patients need, and they would be able to determine who to attend to first depending upon the urgency of the situation. They stated messaging would be particularly useful in situations where they would otherwise need to put on protective wear to go into the patient's room, which takes time. One nurse explained the following:

On our busy days, our buzzers are just going off the hook [which...] adds...stress to the nursing staff. Having something like that to [...know] the things that are urgent and the things that aren't...would help. [Participant 12]

Another nurse stated the following:

If you could get a message on your rover [nurses' communication device] telling you exactly what they need...it would save time.... [Participant 3]

Patient participants shared the nurses' perspectives, adding the insight that messaging would be beneficial if they needed to let their nurse know that they were in a critical condition:

My temperature can be raging at 41 and I can be close to death, and I push the button, or I need a bottle of cordial, and I push the button. And the nurse...doesn't know whether I'm nearly dead or whether I want the bottle of cordial....I think the app would be brilliant.... It would be so good for the nurse, and so good for us as patients because then the nurses could go to where they really need to be.... [Participant 41]

The interviews made clear how messaging could improve patient-nurse communication in the leukemia ward, enabling nurses to more effectively manage their patients' needs and potentially reduce nurse and patient stress.

Theme 4: Toward Person-Centered Care: Empowerment and Equity Via an Inpatient Portal

Overview

This theme explores the perspectives of the patient, proxy, and clinician participants on the value and impact of an inpatient portal through 2 critical and related concepts in person-centered care: *empowerment* and *equity*. The adage *knowledge is power* was voiced throughout the interviews when considering the potential value of the portal's information affordances. The terms *empowerment* and *control* were often expressed—and were often expressed together—by participants when they considered the portal's value. A significant insight generated by the interviews was that if a person shifts from the position of the clinician to that of patient or proxy, they become disempowered in their access health care information. Within the discourse on person-centered care in digital health, as concerns the context of this study, the proposition is that an inpatient portal could facilitate greater equity for the patient and proxy in their relationship with their clinician and in their health care through providing patients and proxies with accessible and meaningful information. This theme explores this proposition and highlights the potential strengths and limitations of the portal concerning the concepts of empowerment and equity. The following subthemes are partially labeled with participant quotes.

Theme 4.1 The Portal Empowers Patients to Be More in Control Like an Equal Person in Their Care

Reflecting on the value of the portal, a nurse stated the following:

That's the thing that stood out to me the most...it would be really good for them.... It empowers them to be more in control and like an equal person in their care.

The term *empowerment* became especially poignant when clinicians considered when they had been patients and had experienced an immediate disempowerment in their role reversal. A physician explained the following:

When they change roles...from a healthcare professional to a patient, even though...they've done so many years of study and training, immediately...being a patient, just kind of disempowers them in a way that's very confronting....As the treating team, you have all the information...you just feel like, "Yep, we know what's going on." But as a patient, you are relying on someone to tell you what the results are and where you're at with your treatment.... To just feel like you're in control...that's what the app [portal] might help with. [Participant 26]

This perspective conveys the dramatic shift in access to information and, by extension, power that occurs when a clinician becomes a patient. The clinician knows what's happening (to a degree), and the patient depends on the clinician for this information. As the nurse who was the proxy participant in this study expressed, she would have wanted access to her husband's progress notes and the ability to record his

consultations, so she could have a better understanding of what was happening to him. This would have reassured her. This participant nurse did not hesitate in expressing her desire for this information, despite also being a clinician and therefore familiar with the Australian hospital information-sharing culture, which restricts patient access to such information. As the aforementioned quote conveys, perhaps the reason why there was no reservation in accessing this information, as is normally the case from the clinician's perspective, was because, in the position of patient or proxy, one is disempowered. Reflecting upon the value of the inpatient portal, a patient participant stated the following:

You'd just feel a little bit in control. At the time, we're totally out of control. [Participant 9]

Another explained the following:

I think it's empowering to know more about your condition. If you know more, you understand more, you can make better decisions.... When you know more, you're just more in control. [Participant 27]

Theme 4.2 The Portal Highlights and Marginalizes the Less Equitable Population

Considering the value of the portal, the proxy participant, who is also a nurse, reflected on caring for her husband, who is a physician and had just had a stroke:

I'm very aware that for us, as awful as it's been, it's been fairly seamless because we understand what's going on. I can't imagine how terrifying it must be for people who don't understand.... If people are...informed and they feel like they can ask questions, I think it [the portal] could only be a good thing. Knowledge is power and people feel better equipped to support their loved ones if they've got all the information because it's very intimidating, this whole talk about MRIs and CTs, and clot retrieval.... We have to embrace the technology.... It's easy for English speakers and people who don't have a pre-existing disability.... It's not that easy for everyone. [Participant 1]

This perspective raises the issue of equity of access for people who are not proficient in English or have a disability that impedes their intake of information. The fact that the portal would only be accessible in English concerned some clinician participants. Clinician, patient, and proxy participants were also concerned that the portal would not benefit older adults or those who were not technology proficient. A consultant considered the following:

Is it empowering? Yeah, if it gives the information in an accurate way.... But...there's still that bias towards the tech-savvy.... Older [people from] non-English speaking backgrounds [...this] population who would most benefit—one, would not be able to use it, and two, the materials we provide are not in their language of choice. So [it...] highlights and actually marginalizes the less equitable population. [Participant 10]

This perspective shared by several clinician and patient participants points to the limitations of the portal's affordances.

Discussion

Overview

This study's patient and proxy participants wanted health care information accessible via an inpatient portal to increase their control and, by extension, decrease their anxiety during their hospital stay. Clinician participants generally wished to support inpatient access to information via the portal but also expressed resistance and uncertainty in this area. Clinicians will need more experience in information sharing via inpatient portals in health care contexts like that of Australia to understand how it might impact care. A flexible deployment of the inpatient portal's functions could support exploration in this area. Clinician and patient participants shared ideas on how to reconceptualize the record such that it is accessible and meaningful to the patient and proxy. This study highlighted how an inpatient portal can help address the information asymmetry and power imbalance that characterizes the patient-clinician relationship.

All patients and proxies interviewed were highly interested in access to notes, and test results via an inpatient portal. All but one participant was interested the ability to record their consultations. Patient participants explained that, when unwell, it is difficult to process and retain information and having the option of accessing meaningful information—information that is relevant and makes sense to them—regarding their health care when they are ready to process it would be valuable. When considering information sharing via the inpatient portal, 3 key clinician perspectives were generated. The first 2 perspectives were held by a minority (5/21, 24%) of clinician participants. They involved either (1) an openness without reservation to sharing information with patients and proxies or (2) a complete resistance to sharing information with patients and proxies. The third perspective, held by most (16/21, 76%) clinician participants, involved an openness to information sharing with patients with reservations as to what, how, between whom, and in what context information should be shared. This perspective generated theme 3 focused on the flexible deployment of the functions depending upon the clinician, patient, proxy, and health care context. The importance of flexible deployment of the portal's information affordances, particularly in relation to high-risk situations, is noted elsewhere [22]. Furthermore, as another study has stated, when sharing health information, there should not be a one-size-fits-all approach, as different people need different information at different times and in different contexts [7].

This study contributes to existing studies on sharing medical records via an inpatient portal by acknowledging that how this sociotechnical system is configured will be determined not only by the individual patient's need for awareness, control, and reassurance in their health care but also by the clinician's need to protect their practice. Some clinician participants self-reflexively considered their attitude toward sharing inpatient notes or enabling the patient to record consultations. These participants, when reflecting on their attitudes toward information sharing, considered that these attitudes could be a

result of their education, their work culture, and the broader medicolegal implications of their field. The significance here is that just as patient and proxy anxiety is a critical component to consider in the case of the value of information sharing through an inpatient portal, clinician vulnerability and indeed, anxiety, in relation to this process must also be acknowledged. As 1 clinician participant conveyed sharing inpatient notes is not part of the existing culture of the hospital and requires a new way of thinking, and as another clinician participant expressed, it will need exploration.

Shifting hospital culture to accommodate new attitudes and exploring new approaches to information sharing with inpatients will take time. Indeed, in the American context, OpenNotes charts the evolution of information-sharing culture in health care over half a century [1]. In the Australian context, where the prospect of sharing the record with inpatients is still in its infancy, a flexible sociotechnical system is needed while clinicians adjust to the changing information-sharing culture and become more comfortable with becoming increasingly transparent with patients and proxies. However, clinicians will need a high level of awareness when making the decision not to share information with patients and proxies. They will need to know if this decision is motivated by a limited attitude toward the patient that disempowers them and excludes them from their health care, or whether this decision is motivated by concern for the patient's well-being or because of the complexity of the treatment that requires time before meaningful information can be conveyed to the patient [17,22]. It has been noted that policies are needed to guide clinicians in the sharing of sensitive information in this transforming information-sharing culture [12].

The evolution of health care information sharing will require clinicians to continually reflect upon their attitudes. As raised in the Introduction section, a common clinician perspective is that if inpatients have access to their notes and tests, they will become anxious. However, as noted previously in this paper, studies exploring the inpatient experience of such information have shown that patient anxiety does not increase and indeed, in some cases, decreases [9,12,14]. This common clinician misunderstanding that access to information will increase patient anxiety has been argued to be the result of reducing the patient to a stereotype, which in turn produces a *hermeneutical injustice*: where a person's right to understand their situation is impeded [17,23]. What is overwhelmingly reported in this study is that patient anxiety is the result of not knowing what is happening more so than knowing what is happening. As 1 patient participant so clearly stated, "It's good to know where you sit; whether it's good or bad."

This study has generated significant insights into how clinicians are inquiring into their current practice and reflecting upon why they may be resistant to certain forms of information sharing, despite understanding the value it would have for the patient and proxy. As a physician reflecting on clinician resistance to recording considered, "Perhaps, that is more of a reflection of us, and what we're worried about with our practice than what is best for the patient." This reflection highlights the tension between professional expectations and wanting to provide patients with greater access to information. This clinician

self-reflexivity is a critical component in the movement toward greater information symmetry and in addressing the power imbalance in the patient- and proxy-clinician relationship. As insights from clinician participants conveyed, the impetus for developing a more symmetrical relationship is most clear when the clinician places themselves in the position of the patient or proxy and understands the disempowerment the patient and proxy experiences due to limited access to their health care information. Indeed, compelling insights came from clinicians who drew from their direct experience of the reversal of roles and their recognition that the patient and proxy is disempowered in their relation to the clinician.

A perspective was raised in this study that the portal would highlight and marginalize less equitable populations, including older people and people who do not speak English. However, a study conducted in the United States has noted that less equitable populations benefit from patient portals the most: Black people, people who have low education levels, and those who do not speak English at home reported access to the record as more important than White people, people with high levels of education and native English speakers [24]. However, this idea is contradicted in a more recent study in the inpatient context that reported that African American patients used the inpatient portal less than White patients [25]. For our study, many of our patient and proxy participants had only a secondary school education, which indicates that a desire for health care information is not dependent on being highly educated. It is noteworthy that a patient who has difficulty speaking English or has low digital literacy may share their portal's information affordances with their care network, such as their family. This idea of the value of a digital platform being accessible by multiple parties involved in a patient's care is emphasized elsewhere [26].

A key insight generated from this study was that patients and proxies want access to information that is *meaningful*—information that is tailored, relevant, and makes sense to them. This perspective led to participants' conceptualization of how the record could be shared. Clinician participants considered what aspects of the notes would be useful to the patient, such as the ward round notes and assessments. Patient and clinician participants considered how the notes, if they were shared, would need to be in patient-friendly language and a summary form. This idea of the summary note has been raised in another study that reported that information sharing enabled by patient portals may call for a redesign of notes [7]. This idea of reconceptualizing the record has been highlighted in another study, which states the importance of clinicians "writing notes that patients will read" [22]. A patient participant from an earlier study exploring patient experiences on access to their records explained, "I read until I found technical stuff, and then I would jump over it...The parts I read, and I understood, were interesting and beneficial" [13]. This perspective is echoed by patient perspectives generated in this study that conveyed that unless patients understand the information, the information will not be useful. Likewise, clinician participants considered the importance of sharing useful information with patients; 1 clinician participant stated that information is not necessarily a good thing and could result

in information overload. As noted in a previous study, selecting information that is meaningful for the patient and that does not overwhelm them will require an exploration of how best to present this information to the patient via the portal's interface [12].

Another significant contribution of this study to the literature on inpatient portals is the exploration of clinician and patient perspectives on enabling patients to record consultations. Although these perspectives have been explored in studies focused solely on the topic of recording [27], the option to record consultations has not been explored as a function of the inpatient portal. Clinician participants considered how it would be valuable for the patient to record consultations if they were not proficient in English so they could return to the consultation or share it with their care network. Clinician and patient participants considered the recording function useful to capture the details of an intervention or education, to share a consultation with the patient's care network, and to give the patient time to process the information because when unwell it is difficult to take information in, particularly when one has, as several patient participants put it, "chemo brain." Most clinician participants expressed resistance to enabling this function, cautioning that before such a function could be implemented, there should be safeguards in place to protect the clinician from any medicolegal consequences that could result from such a practice. Research in health care recording in the Australian context details patient rights and legal responsibilities [28]. In Victoria, if the consultation is in person, the patient has a legal right to record it and does not require the consent of the health care provider; consent is advised to protect the patient-clinician relationship. However, for the patient to share the recording with others, clinician consent is legally required. To record and share telehealth consultations in Victoria, the patient is legally required to have the consent of the clinician [28]. Neither patient nor clinician participants in this study were aware of this legal framework. Perhaps if they were, the prospect of recording consultations would be normalized, rather than being a subject of desire from the patient's perspective and a subject of fear from the clinician's perspective.

This study enabled patient, proxy, and clinician participants to reflect on how they want information shared in the inpatient context and the type of person-centered sociotechnical system they want to create to support the well-being of everyone involved in the health care context but most importantly the patient. Within the Australian context, the transition to a more transparent patient-proxy-clinician information-sharing relationship is still very much in process. An inpatient portal is a valuable step in this process.

Principal Results

The participants' consideration of an inpatient portal involved a reconceptualization of the medical record and information-sharing practice within the hospital. Participants considered how the portal's potential influence on and redesign of information sharing could result in enhanced patient-clinician communication and more transparency in the provision of care, which could contribute to patient and proxy well-being. This study highlighted how the clinician-patient information

asymmetry correlates with the power imbalance involved in the clinician-patient relationship. Alongside the influence of an inpatient portal that initiates a rethinking of the medical record and how it can be shared with the inpatient, clinician self-reflexivity is a valuable step in addressing this power imbalance and information asymmetry. This study also underlined that clinician's vulnerability needs to be acknowledged in the evolving information-sharing culture and that the portal's functions could be flexibly deployed with the intention to protect the clinician's practice. Finally, this study reported the value of recording consultations from the patient and proxy perspective and the messaging function from the patient and nurse perspective within particular contexts.

Limitations

Study participants were recruited from only 3 contexts within the hospital; participants from other contexts may have provided different perspectives. Only patients and proxies fluent in English were included in the sample due to the need to conduct the interviews in English. Furthermore, all patient and proxy participants had a good understanding of their health, and most were comfortable using technology. This could be because the types of patients and proxies who agree to an interview focused on health care technology are usually people who have reasonable health and technology literacy. The study sample could therefore reflect how the less equitable patient and proxy population is excluded from the health care context.

Comparison With Prior Work

This study echoed results reported in previous studies: patients desire the information affordances of an inpatient portal to support their well-being, and clinicians understand the value of these information affordances but express caution regarding certain information sharing. This study has contributed to the knowledge of patient and clinician perspectives on inpatient portals through its exploration of the power dynamic that characterizes the patient-clinician relationship as well as drawing attention to clinician vulnerability in information sharing with patients. It considered how an inpatient portal might assist in transforming the hospital's information-sharing culture to support person-centered care. It provided a novel contribution to the literature on inpatient portals by exploring perspectives on the recording function. Finally, it explored perspectives on an inpatient portal from within the Australian context, pointing to how, in this context, health care is still in the process of transitioning to person-centered care.

Conclusions and Future Work

Participants explored how information could be shared via an inpatient portal. Patient and proxy participants expressed their desire for the portal's information affordances to support their well-being. Clinician participants reflected on their resistance and receptivity to information sharing with patients and proxies. Clinician participants expressed that there needs to be further exploration of information sharing via an inpatient portal to understand its value and impact. This study is the first stage of a 2-part research project; our next step is to explore the experiences of patients using the inpatient portal in a recent implementation in the leukemia ward. It is important to note

that this recent implementation of the inpatient portal in the leukemia ward has not been informed by the results of this study but was realized as an independent project, and this implementation does not include access to progress notes nor the recording or messaging functions. However, once the 2

stages of this study are published, their combined results will inform future implementations of the inpatient portal throughout the hospital and potentially lead to patient access to more comprehensive information affordances within the inpatient context.

Acknowledgments

The authors would like to thank Cameron Grant, Annie Robson Hammond, Janelle Walters, Bronwyn West, and Julie Wong for their assistance in participant recruitment. The authors thank Jessica Rixon for sending the patient and proxy participants gift vouchers and Julie Louie for sourcing inpatient portal images. The authors would like to thank Sarah Boltuk for facilitating Epic Systems Corporation's copyright permission for the portal images and Dr Simon D'Alfonso for reviewing this paper. The authors would also like to thank the study participants for their insights.

Data Availability

The datasets generated during and analyzed during this study are not publicly available to protect participant privacy.

Authors' Contributions

SS conducted the interviews and analysis and wrote the manuscript. All authors reviewed and developed the manuscript. All authors were involved in research design and recruitment.

Conflicts of Interest

None declared.

Abstract

Background: Good preconception health reduces the incidence of preventable morbidity and mortality for women, their babies, and future generations. In Australia, there is a need to increase health literacy and awareness about the importance of good preconception health. Digital health tools are a possible enabler to increase this awareness at a population level. The Healthy Conception Tool (HCT) is an existing web-based, preconception health self-assessment tool, that has been developed by academics and clinicians.

Objective: This study aims to optimize the HCT and to seek user feedback to increase the engagement and impact of the tool.

Methods: In-depth interviews were held with women and men aged 18 - 41 years, who spoke and read English and were residing in Australia. Interview transcripts were analyzed, and findings were used to inform an enhanced HCT prototype. This prototype underwent user-experience testing and feedback from users to inform a final round of design changes to the tool.

Results: A total of 20 women and 5 men were interviewed; all wanted a tool that was quick and easy to use with personalized results. Almost all participants were unfamiliar with the term "preconception care" and stated they would not have found this tool on the internet with its current title. User-experience testing with 6 women and 5 men identified 11 usability issues. These informed further changes to the tool's title, the information on how to use the tool, and the presentation of results.

Conclusions: Web-based self-assessment tools need to be easy to find and should communicate health messages effectively. End users' feedback informed changes to improve the tool's acceptability, engagement, and impact. We expect that the revised tool will have greater reach and prompt more people to prepare well for pregnancy.

Introduction

Overview

Preconception care aims to optimize the physical and psychological health of women and their partners prior to conception [1]. Good preconception health reduces the incidence of preventable morbidity and mortality for women and their babies [1,2]. In Australia, there is a need to increase awareness about the importance of good preconception health and access to preconception care [3]. This is evidenced by the high proportion of women entering pregnancy above a healthy weight, the low proportion of women taking folic acid before

conception, and the low rate of good prepregnancy glycemic control in women with diabetes [4-7].

Barriers to the delivery of preconception care include inadequate knowledge in the community about the importance of optimal preconception health and a lack of presentation to health care providers for preconception assessment [8,9]. Additional barriers include women from low socioeconomic backgrounds having lower levels of functional health literacy [10]. This is associated with lower rates of consulting a health professional for preconception care and worse preconception health behavior [10,11]. Women also identify lack of time and living in rural and remote communities as prohibitive factors to seeking preconception care [12].

Evidence suggests that people of reproductive age are keen to learn about preconception health and adopt positive health behavior change before a pregnancy. Most women of reproductive age report a preference for internet-based information sources [13] and use technology to find information on pregnancy health [13,14]. Digital health tools, such as web-based self-assessment tools, are a promising medium to increase knowledge and awareness about preconception health among people of reproductive age across geographical locations [15,16]. This includes increased understanding of the benefits of good preconception health, the risks of poor preconception health, and the opportunities to improve health before conception [17,18]. Impacts of web-based preconception health self-assessment tools include reduced rates of preconception alcohol consumption, improved uptake of folic acid supplementation [19], and also act as a catalyst for clients to initiate discussions with health care providers [17].

The Healthy Conception Tool

The Healthy Conception Tool (HCT) was an existing web-based preconception health self-assessment tool, developed by YourFertility, a Commonwealth-funded fertility health promotion program in Australia. The HCT asks questions about a person’s general and reproductive health from which people then get a personalized output of results. They are then encouraged to take the results to their doctor to discuss what they can do to optimize their health. The HCT contains a section for both women and men. The HCT was developed in 2017 in collaboration with academics, clinicians, and researchers at the Robinson Research Institute. Some feedback from users was used in the initial development of the HCT; however, formal

usability testing was not performed. Exploring usability can identify issues with how people engage and interact with a tool, and the findings can be used to improve experience to maximize the effectiveness and efficiency of the tool [20].

As the HCT is a potential enabler to promote the importance of preconception health, particularly for people in rural and remote areas who face additional challenges in accessing health care, optimization and usability testing can enhance a tool for these populations. This paper describes the process taken to engage with communities using a person-centered approach to assess usability and optimize an existing web-based preconception health self-assessment tool for people in Australia.

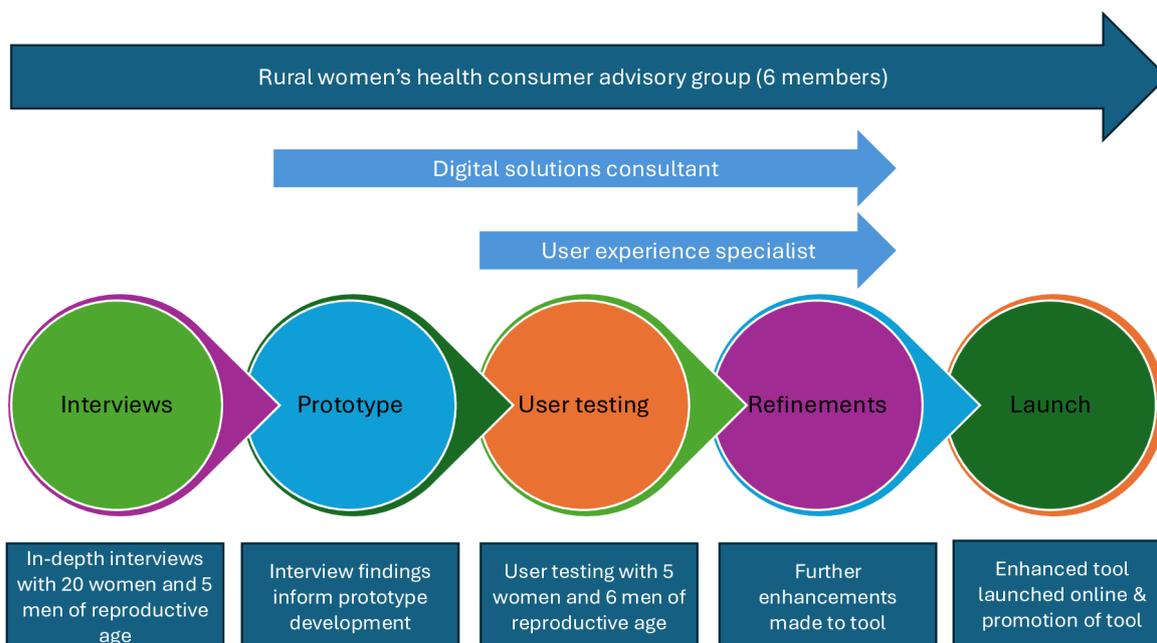

Methods

Overview

In-depth user interviews and usability testing were used to optimize the existing HCT (Figure 1).

A rural women’s health consumer advisory group (RWH-CAG) was established to oversee this body of work and ensure person-centered design in all aspects. A total of 6 women aged 19 - 30 years old, who resided in rural and remote locations in Australia, were selected from a pool of 17 applicants. Selected applicants had lived experience and demonstrated knowledge of issues around the access of sexual and reproductive services to rural Australian women, particularly in the areas of family planning and preconception care. The role of the RWH-CAG was to inform the study design and recruitment methods (Figure 1).

Figure 1. Process of optimizing a web-based self-assessment tool for preconception care.

Recruitment

People of reproductive age (18 - 41 years old), residing in Australia, who could speak and read English, were eligible to participate in both the interviews and user-experience testing. People of all relationship statuses were eligible to take part.

Recruitment for interviews was via social media with advertisements targeting regional and remote community parent groups and noticeboards. Recruitment for user-testing was coordinated through a user-experience agency (Nomat Australia) with an Australia-wide registered pool of user-experience participants. The participants meeting the recruitment specifications listed above were sent an invitation to take part.

Process

In-Depth Interviews

In-depth interviews to understand participants' experiences of using the HCT were performed from February to September 2021. In particular, what features of the HCT were most likely to increase their knowledge and influence behavior change, and to explore ways in which the tool could be improved. Given COVID-19 quarantine restrictions, interviews were conducted via telephone or internet-based videoconferencing at the participants' request. Before the interview, participants were required to complete the HCT. Interviews were recorded and transcribed, and data were analyzed by two researchers who have reproductive and public health expertise, using an inductive thematic approach [21,22]. Data were coded, manually without assistance of software programs, to identify consumer likes and dislikes across content and design features of the self-assessment

tool. These findings were further discussed among all members of the research team, and agreement was reached on key domains and features for optimization

Prototype Development

A series of strategy, planning, and design workshops were held with a digital solutions consultant (Sentius Australia). These workshops aimed to develop creative and digital solutions for the new tool design, informed by the interview findings. A prototype was developed by Sentius and the research team, with a list of features identified for user testing.

Optimization of Prototype With User Testing

The prototype underwent user-experience testing, conducted by a user-experience specialist to identify any usability issues and validate design changes that had been made from May to June 2022. Again, given the COVID-19 pandemic restrictions, the participants took part in a 1-hour videoconferencing call for user-experience testing. In this call, the participants completed the HCT in their chosen setting, to reflect their typical context. The participants shared their smart device screen so that their tool navigation could be directly observed. The participants completed the System Usability Scale (SUS) [23] and had the option to provide additional feedback on their experience. The SUS is a 10-item questionnaire to enable a standardized assessment of usability of an interface (Figure 2) and is an accepted tool to benchmark the usability of Digital Health Applications [24]. Usability problems were categorized as minor, moderate, or critical relating to the impact they had on tool engagement and completion (Table 1).

Figure 2. System Usability Scale [23].

System Usability Scale

© Digital Equipment Corporation, 1986.

	Strongly disagree				Strongly agree
1. I think that I would like to use this system frequently	1	2	3	4	5
2. I found the system unnecessarily complex	1	2	3	4	5
3. I thought the system was easy to use	1	2	3	4	5
4. I think that I would need the support of a technical person to be able to use this system	1	2	3	4	5
5. I found the various functions in this system were well integrated	1	2	3	4	5
6. I thought there was too much inconsistency in this system	1	2	3	4	5
7. I would imagine that most people would learn to use this system very quickly	1	2	3	4	5
8. I found the system very cumbersome to use	1	2	3	4	5
9. I felt very confident using the system	1	2	3	4	5
10. I needed to learn a lot of things before I could get going with this system	1	2	3	4	5

Table . Category definitions for identified usability issues.

Classification	Definition
Minor	Causes some hesitation or irritation
Moderate	Causes task failure for some users
Critical	Leads to task failure. Issue inhibits users from completing core tasks or may impact core business objectives

Prototype Refinement and Enhancements

User-experience testing results informed additional changes to the tool. Another round of planning workshops was held to decide on the final changes to the tool. These were tested amongst the research group for quality assurance.

Launch

When all changes were made, the enhanced tool was launched on the internet.

Ethical Considerations

This study was approved the University of Sydney Human Research Ethics Committee (2020/430; June 22, 2020). Verbal consent was obtained prior to the interview and user testing.

Table . Participant demographics.

Demographics	Interview participants (n=25), n	User testing participants (n= 11), n
Gender		
Female	20	6
Male	5	5
Pregnancy intention		
Planner	10	6
Nonplanner	15	5
Place of residence		
Metropolitan	11	9
Regional and rural	14	2

Interview Results

All participants completed the HCT prior to their interviews, using either a mobile device or laptop, with some completing the tool on both a mobile and laptop device. Attributes of the self-assessment tool, as identified from the interviews, are presented below.

General Features

Overall, participants were very positive about the HCT. Most participants liked that it was quick to use, taking on average 5 minutes to complete, and that it was a single source for multiple topics of pregnancy preparation.

Source Credibility

The participants expressed that it was important to know the tool was from a credible source. This was attributed to endorsement from reputable professional organizations such as academic institutions.

I look for does it come from a trusted source, is it from the Royal Children's Hospital website or is it from Breastfeeding Victoria's website, not just a mummy blog or a website that has obvious ads or links to creams that they want to sell you. [P19, female, regional, nonplanner]

Target Audience

Participants liked that the tool was inclusive of partners with information for both men and women.

Recruitment for both processes ended when no new data were obtained, and previously identified themes were repeating. Participants were given a Aus \$50 (US \$37.50) VISA gift card in recognition of their time.

Results

Overview

In-depth interviews with 20 women and 5 men, and user-experience testing with 6 women and 5 men of reproductive age were performed. The participants included people planning and not planning a pregnancy in the next 12 months, from metropolitan, regional, and remote locations in Australia. The participant demographics are shown in [Table 2](#).

I liked that it had a section for men and women, I think that's really good, that men are included in it as well. [P6, female, regional, nonplanner]

Finding the Tool

The participants identified that a good tool is one that is intuitive to find on a simple web-based search. Almost all participants stated that they would not have found this tool on the internet with its current title.

Information Gained

The participants liked the links to further information, particularly the multiple and varied topics that were collated together.

And I think the link that it had when you clicked on the little info icon, they took you to places, and there was like so much information in those places. [P6, female, regional, nonplanner]

Presentation of Results

The participants stated the presentation of their results was too general and that they wanted more personalized results. Consistently, the participants conveyed that the results must be meaningful to the individual to encourage behavior change.

User Experience

A total of 4 key domains for exploration in the user-experience testing were identified from the interviews:

1. User interface
2. Tool navigation
3. User experience
4. Results

A summary of the features for testing within these 4 domains is shown in [Table 3](#). More details on the interview findings relating to these domains and features are available in [Multimedia Appendix 1](#).

Table . Domains and features of a web-based self-assessment tool for preconception care to be assessed in usability testing.

Domain	Features to test
User interface

Mechanism to receive and keep results	<ul style="list-style-type: none"> • Email • Print

User-Experience Testing

All participants completed all questions in the prototype on their first attempt and responded well to its simplicity. The amount of information provided was considered appropriate, the supplied links were determined to be valuable, and information was perceived to be presented in a way that was easy to digest and use. The average SUS score was 91.82 (SD 4.62), which is a high score compared with an industry average in Australia of 68 (SD 12.5). The participants responded well to the given color scheme.

A total of 11 usability problems were identified, 4 moderate and 7 minor ([Table 4](#)).

Additional observations of significance were the impact of the organizational logos at the bottom of the tool. Without prompting, several participants commented on the organization logos and indicated that seeing this added credibility to the tool. New features to increase reach of the tool were also noted and included the option to share the tool with the user's contacts.

Additional refinements were made to the tool following user-experience testing to address the problems identified. Some key changes are shown in [Figure 3](#).

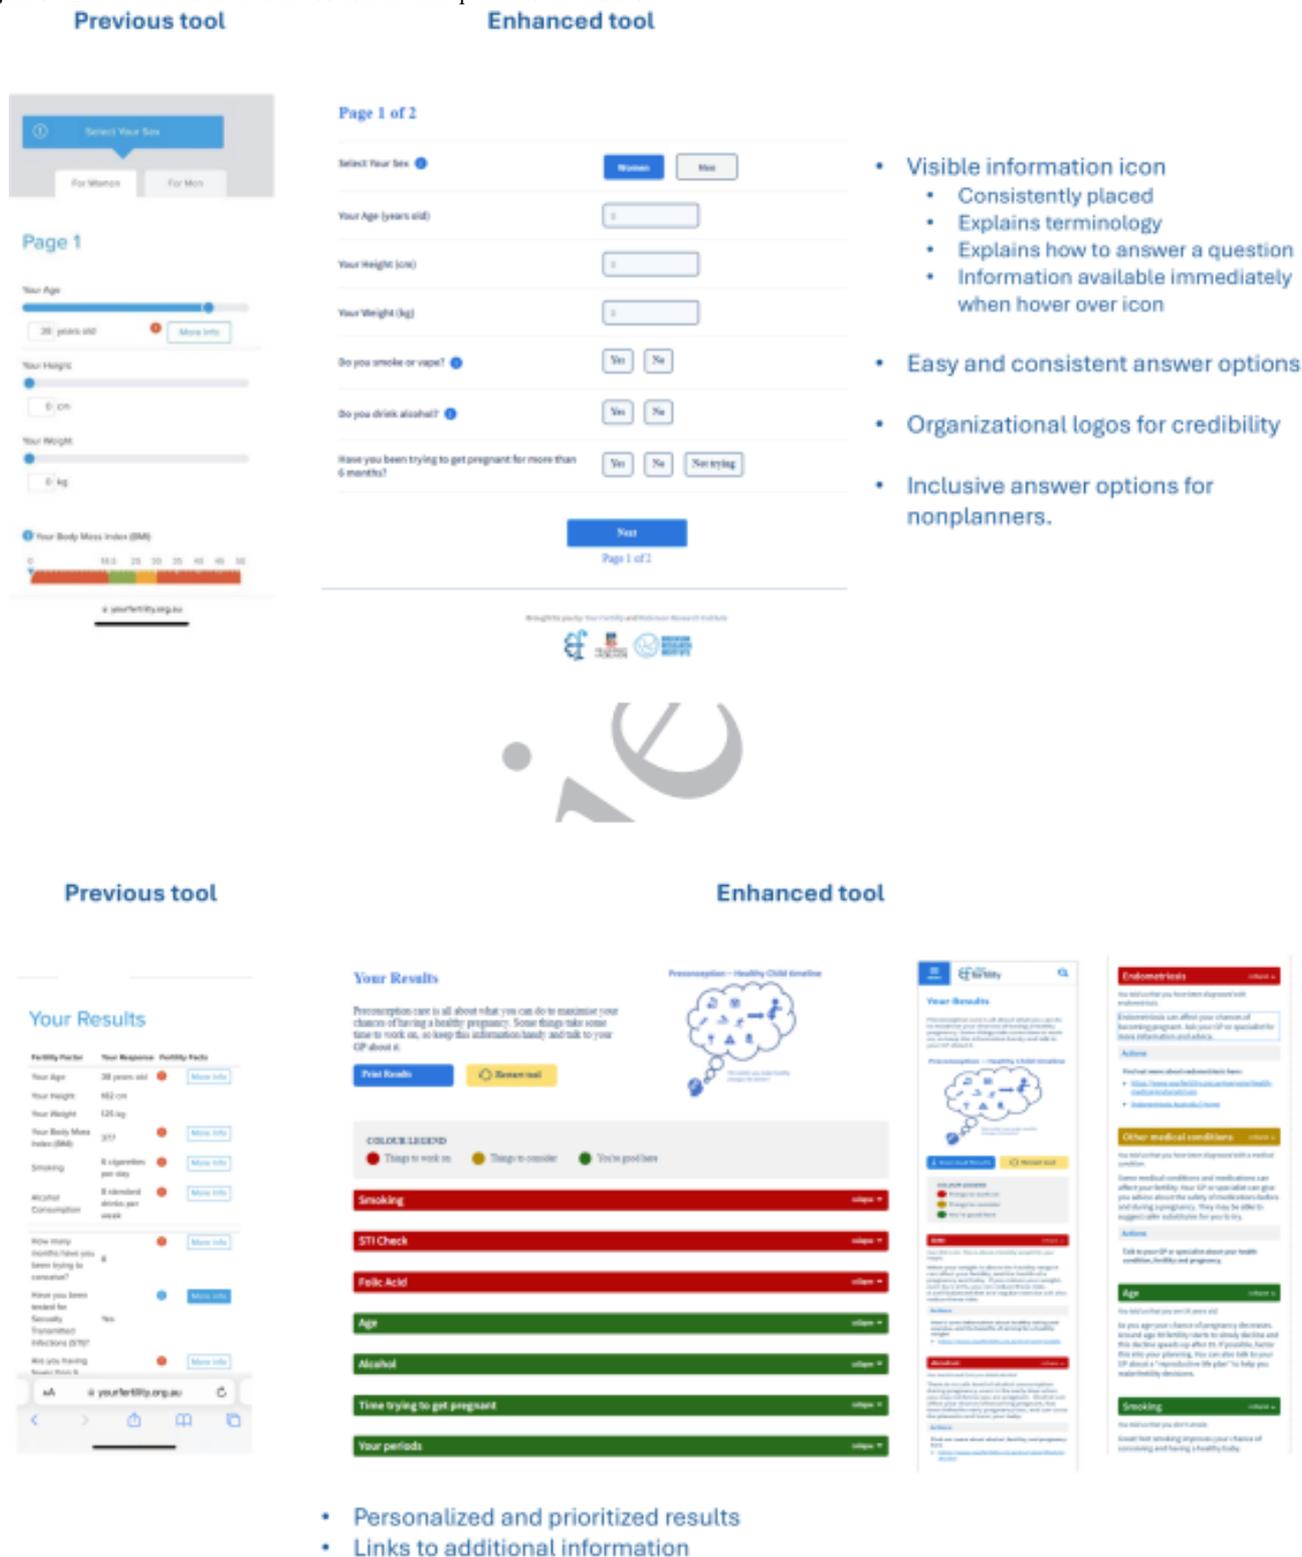

Table . The findings on user-experience testing for a web-based self-assessment tool for preconception care.

Issue	Observation	Recommendation	Severity
Results			
	Presentation of results—traffic light system colours		
		Consistently, the color coding on the results page was not obvious to participants. Particularly, the use of orange instead of red was misunderstood. <i>“I don’t understand why they’ve done that...maybe change the choice of colours to red, yellow and green? I would be fine with red”</i> (P36, male, planner, metropolitan)	Update to green, orange, red and introduce descriptive headings within the results page. Moderate
	Grouping preference		
		Consistently, participants indicated that they preferred the layout of the second version of the results page (order as per traffic lights). Specifically, participants suggested that grouping results led to increased understanding of the content grouping. <i>“Now it makes more sense to see the colours categorised in groups.”</i> (P28, female, non-planner, metropolitan)	Implement grouping of results as the standard. Moderate
User experience			
	Help icon: visibility		
		The help icon was deemed to be of value to participants, however it was not immediately obvious to all participants. The visual hierarchy needs to be increased, in order to prompt a higher use rate. <i>“No, I don’t recall seeing these help icons, that would have been good to know for this question [fertile window].”</i> (P26, female, non-planner, metropolitan)	Consider making the help icon 15% larger and changing the color to HEX #14c797 to increase prominence. Moderate

Issue	Observation	Recommendation	Severity		
Answer clarification: smoking and alcohol			For both the smoking and alcohol use questions, some participants answered "no" despite describing infrequent use. This indicated that just having 2 possible answers causes misreporting in some instances. <i>"It's a tad confusing, the smoking and drinking. It's a yes and a no answer but there's a lot of gradations in there...someone might have two glasses a week."</i> (P34, male, planner, metropolitan)	Include help icon to explain how to answer the question.	Moderate
Question clarification					
Chemicals			Participants often displayed confusion as to what kind of chemicals this question referred to. <i>"I don't know much about chemical exposure...maybe a Tefal pan? I'm not sure. That would have been a question I could use some extra information for."</i> (P28, female, nonplanner, metropolitan)	Include help icon text to expand on the types of household chemicals that could impact fertility.	Minor
STI check			On occasion, participants expressed surprise at the inclusion of the STI check question. Specifically, participants did not feel it was relevant to them if they were in a long-term relationship. <i>"Why is this question relevant to pregnancy?"</i> (P30, male, planner, metropolitan)	Include help icon text to explain the relationship between STI checks and future fertility. Reiterate STIs can be asymptomatic	Minor
Prescription meds			Participants indicated confusion around the types of prescription medication that would be included here. <i>"I'm on the mini [contraceptive] pill, but I wouldn't tick yes here."</i> (P27, female, planner, metropolitan)	Add help icon text to explain prescription medications	Minor

Issue	Observation	Recommendation	Severity		
Folic acid			Folic acid prompted some additional discussion from participants, with questions raised about what it was, the dose required, and the function it served. <i>"I would answer no to taking folic acid...I haven't even heard that mentioned. Now I wonder if that is important or not...I am not sure what it is."</i> (P33, female, planner, regional)	Add help icon text to give a brief explanation of the importance of folic acid. Mention that folic acid is included in pre-natal supplements.	Minor
Results page: BMI information			Participants indicated that the BMI information required additional context to be more effective. <i>"The BMI information is good, but you just want a quantified benefit. You always hear about eating healthy and being healthy...it just becomes noise. Unless there's a real benefit, what's the point?"</i> (P30, male, planner, metropolitan)	Expand results section to include specific statistics connecting BMI with fertility. Include more targeted exercise suggestions.	Minor
Language: male version			Throughout the text on the male pages, some of the wording occasionally confused male participants. Some male participants did not feel that this was relevant to them and questioned whether the results were actually targeted towards the male user.	Tailor copy for participant gender.	Minor
User interface					
Image: sperm regeneration			Without being prompted, male participants consistently drew attention to the sperm regeneration fact at the top of the results page. Participants indicated that this statistic was new to them, and that they valued having this information included.	On the results page, incorporate this information within the main content.	Minor

Figure 3. Enhancements to the self-assessment tool questions and results.

Discussion

Principal Findings

This work explored what features of a web-based self-assessment tool for preconception care are important to people of reproductive age. In particular, what features will increase engagement and completion of the tool, and what are

the best ways to present the results and information so that a user will act upon them.

Our findings showed that participants value a tool that is intuitive to find in a web-based search and is quick and simple to use. This is consistent with findings of other eHealth modalities, where ease of use and simplicity is a determinant in user engagement [25,26]. Clear information about what each question is asking was important to maintain engagement in the

tool. For questions that were not intuitive, or required explanation, an information icon was placed adjacent to the question text, in a different color to emphasize its presence. The information was visible by hovering over the icon, as participants indicated they did not want to be directed to an additional page, as this interfered with user experience. Having information presented in a way that is easily understood by the user has been identified as a key quality indicator of web-based health sites [27].

A key finding in both the interviews and user-experience testing was the need to have information clearly presented and easy to digest at an appropriate health literacy level. The International Reproductive Health Education Collaboration recently devised recommendations for developing and implementing tools to improve fertility literacy [28]. This included the recommendation to understand the target population and include user perspectives when developing education tools. In both the interviews and user-experience testing, there was a balance of planners and nonplanners (those not planning a pregnancy in the next 12 mo) to ensure the information presented was accessible and relevant to all people of reproductive age regardless of pregnancy intention. This also led to some key changes including to the title of the tool. Almost all of the interview participants would not have found the tool on the internet, and as such the tool was renamed with a plain English title as informed by participants of “Healthy you, Healthy baby.”

Another key feature for users was the personalized and ordered presentation of tool results. Results were grouped into categories that required the user’s attention and action. These were color-coded to convey visual priority and accompanied by explanatory text, in a positive tone to complement the color scheme.

The participants expressed the importance of knowing that a source is credible, and this is acknowledged by the inclusion of logos from trusted organisations. Trust in eHealth sites is a recognized determinant of user engagement with web-based health information sources [29]. Accreditation or endorsement with recognized logos from reputable institutions can increase trust in a platform [30].

eHealth platforms have been shown to be effective in improving user health knowledge, behavior change, and health outcomes [31,32]. Several eHealth platforms have been shown to be

effective for the communication of preconception health information [33-35]. A web-based app for people with sickle cell disease and sickle cell trait providing information about prepregnancy health was found to be acceptable and usable and increased consumer knowledge [33]. An eHealth lifestyle coaching program for women prior to pregnancy has been shown to increase healthy eating behaviours [34,35].

Studies have suggested improvement in eHealth intervention designs to increase their effectiveness [32]. This includes adopting a holistic approach to promote user engagement [36]. Our approach, informed by a rural women’s health consumer advisory group, of in-depth interviews followed by user-experience testing enabled a detailed understanding of our target audience needs and expectations. The opportunity to test the consumer, informed prototype, and validated design has delivered an enhanced tool for people of reproductive age in Australia.

Strengths

The use of both interviews and user-experience testing techniques are a strength of this study and provided additional iterations to enhance the self-assessment tool. The involvement of the RWH-CAG from conception to completion of this project also ensure a person-centred approach.

Limitations

The tool was only explored by people who can speak and read English, and therefore does not capture the preferences of people from culturally and linguistically diverse backgrounds. As these populations can face challenges with access to care, this is a priority area for future research. This study used the SUS as an instrument within the usability testing. Further enhancements may be achieved by using additional tools such as Nielsen’s guidelines in combination with the SUS [37].

Conclusion

As a web-based tool, “Healthy You, Healthy Baby” has the potential to improve knowledge among people of reproductive age about the importance of optimal preconception health, including those who experience health inequities, such as women and men in rural and remote areas. The tool can be adapted to other priority populations, including people from culturally and linguistically diverse backgrounds to further improve the delivery of preconception care.

Acknowledgments

The authors acknowledge the input of the rural women’s health consumer advisory group members for the invaluable contribution to the design and development of recruitment materials for this study. We also acknowledge the contribution of Renee da Silva and Joanna Anagnostou who were the Health Promotion Coordinators at YourFertility during the time of this research. The authors also acknowledge the collaboration with Kim Morrison and Mel King at Sentius for digital design, and with Chris Gray and Eliza Crisp at Nomat for user experience testing. This research was funded by the National Women’s Health Strategy Health Promotion Grants Scheme GO2745.

Authors' Contributions

ED contributed to the conceptualization, methodology, investigation, data curation, formal analysis, writing of the original draft, review and edits, visualization, project administration, and funding acquisition. KH performed the conceptualization; formal analysis; and the writing, reviewing and editing of the manuscript. RR contributed to the conceptualization and the writing,

reviewing, and editing of the manuscript. KIB performed the conceptualization; data curation; formal analysis; writing, reviewing, and editing of the manuscript; supervision; and funding acquisition.

Conflicts of Interest

None declared.

Abstract

Background: With the rise in people's living standards and aging populations, a heightened emphasis has been placed in the field of medical and health care. In recent years, there has been a drastic increase in nutrition management in domestic research circles. The mobile nutritional health management platform based on WeChat miniprograms has been widely used to promote health and self-management and to monitor individual nutritional health status in China. Nevertheless, there has been a lack of comprehensive scientific evaluation regarding the functionality and quality of the diverse range of nutritional miniprograms that have surfaced in the market.

Objective: This study aimed to evaluate the functionality and quality of China's WeChat nutrition management miniprogram by using the User Version of the Mobile Application Rating Scale (uMARS).

Methods: This observational study involves quantitative methods. A keyword search for "nutrition," "diet," "food," and "meal" in Chinese or English was conducted on WeChat, and all miniprograms pertaining to these keywords were thoroughly analyzed. Then, basic information including name, registration date, update date, service type, user scores, and functional scores was extracted from January 2017 to November 2023. Rating scores were provided by users based on their experience and satisfaction with the use of the WeChat miniprogram, and functional scores were integrated and summarized for the primary functions of each miniprogram. Moreover, the quality of nutrition management applets was evaluated by 3 researchers independently using the uMARS.

Results: Initially, 27 of 891 miniprograms identified were relevant to nutrition management. Among them, 85.2% (23/27) of them offered features for diet management, facilitating recording of daily dietary intake to evaluate nutritional status; 70.4% (19/27) provided resources for nutrition education and classroom instruction; 59.3% (16/27) included functionalities for exercise management, allowing users to record daily physical activity; and only 44.4% (12/27) featured components for weight management. The total quality score on the uMARS ranged 2.85-3.88 (median 3.38, IQR 3.14-3.57). Engagement scores on the uMARS varied from 2.00 to 4.33 (median 3.00, IQR 2.67-3.67). Functional dimension scores ranged from 3.00 to 4.00 (median 3.33, IQR 3.33-3.67), with a lower score of 2.67 and a higher score of 4.33 outside the reference range. Aesthetic dimension scores ranged from 2.33 to 4.67 (median 3.67, IQR 3.33-4.00). Informational dimension scores ranged from 2.33 to 4.67 (median 3.33, IQR 2.67-3.67).

Conclusions: Our findings from the uMARS highlight a predominant emphasis on health aspects over nutritional specifications in the app supporting WeChat miniprograms related to nutrition management. The quality of these miniprograms is currently at an average level, with considerable room for functional improvements in the future.

Introduction

With the intensification of the population's aging tendency, people pay increasing attention to the health of older adults. Specifically, nutrition management is of paramount importance for older adults, in that nutritional needs not only impact their

quality of life but also significantly influence overall health status [1]. Aging, a normal process, is accompanied by physiological changes such as a loss of muscle mass, reduction in bone density, and decline in metabolic rate; Therefore, it is of vital importance to adjust nutritional intake among older individuals, especially those with weak digestive systems [2].

Malnutrition among older adults is a significant universal concern. Senile malnutrition, characterized by inadequate and imbalanced nutrition, arises from various factors, such as inappropriate dietary choices, insufficient intake, absorption disorders, etc [3]. The aging demographic shift contributes to a rise in the population of older adults, and the health status of the older adults directly impacts societal sustainability [4]. Consequently, there is an urgent need for effective nutrition policies and intervening measures for older adults. Among them, nutrition education, promotion of a balanced diet, optimization of medical and health care systems are essential strategies to prevent and improve senile malnutrition [5].

Thus far, the government has issued a series of policies, including the “Healthy China 2030 Plan Outline,” which emphasizes the promotion of self-disciplined health behaviors and encourages balanced diets. Concurrently, the National Nutrition Plan (2017-2030) advocates for the integration of “Internet+nutrition and health” [6], endorsing the use of technology to manage public health and nutrition. Nowadays, this shift toward digital health management and intelligent nutrition support system for older adults reassure the growing emphasis on leveraging science and technology in health care. Through internet platforms and mobile apps, the dietary habits of older adults can be more effectively monitored, and personalized dietary recommendations can be provided to identify and address possible malnutrition issues promptly [7]. WeChat, an instant messaging software for smart terminals, was launched by Tencent on January 21, 2011, and it emerged in 2017 with its distinct advantages, including user-friendly miniprograms that do not require downloading, occupy minimal mobile phone memory, and include payment capabilities, circles of friends, public platforms, WeChat miniprograms, and other functionalities. All these features have contributed greatly to its widespread adoption among users [8].

Despite the growing number of mobile apps for nutrition guidance, there is remarkable variability among them due to a lack of specificity. Studies in China have predominantly focused on exploring the effects of interventions and the significance of nutrition research; yet, there remains a notable absence of scientific evaluation regarding the functionality and quality of commercially available nutrition miniprograms [9,10]. Accordingly, this study aimed to carry out a comprehensive search and assessment of relevant miniprograms using the User Version of the Mobile Application Rating Scale (uMARS) and develop WeChat-based applets for nutrition management.

Methods

Search Strategy

A keyword search for “nutrition,” “diet,” “food,” and “meal” in Chinese or English was independently conducted on WeChat by 2 researchers, and all miniprograms pertaining to these keywords were thoroughly analyzed. They personally experienced the relevant miniprograms registered on WeChat between January 2017 and November 2023. Screening for miniprograms strictly adhered to predefined inclusion and exclusion criteria.

The inclusion criteria were as follows: (1) the miniprogram’s functional content pertained to diet and nutrition, (2) it was available for free use, (3) its content was written in Chinese or English, and (4) it was compatible with mobile phones or tablets. The exclusion criteria were as follows: (1) it was never updated or maintained, (2) it was designed for commercial ordering and canteen services, (3) it was specifically for purchasing food, (4) it solely records data. During the screening process, the 2 researchers resorted to another researcher, if necessary, to resolve any discrepancies.

Sample Size

In this study, an observational research design was adopted to systematically search and quantitatively evaluate the function and quality of nutrition management miniprograms on WeChat. Using keywords such as “nutrition,” “diet,” “food,” and “meal,” a total of 891 miniprograms were initially identified. These miniprograms were then screened based on predefined inclusion and exclusion criteria. After the screening process, 27 eligible miniprograms were selected for detailed analysis.

Quality Assessment of WeChat Miniprograms Related to Nutrition Management

As described in a previous study [11], the uMARS was originally developed as an end user evaluation tool based on the Mobile Application Rating Scale (MARS), and it has been widely used for evaluating diverse categories of mobile health apps, which include those focusing on weight loss and nutrition, as well as the management of conditions such as rheumatism and ankylosing spondylitis [12].

As a comprehensive tool for evaluating the user experience of mobile apps, the uMARS was commonly used to gauge usability, user satisfaction, functionality, and other pertinent factors [13]. The 5 dimensions of the uMARS are engagement, functionality, aesthetics, information, and subjective quality, each dimension encompassing 3 - 5 questions and each question scored on a scale of 0-5 points (20 items in total) [14,15]. In the engagement dimension, the evaluator can evaluate the miniprogram’s entertainment value, level of interest, customization, interactivity, and target audience appeal. The functional dimension facilitates the evaluation of performance, ease of use, navigation, and gesture design. The aesthetics section focuses on layout, graphics quality, and visual appeal, and the information section assesses information quality, quantity visual information, and the credibility of the information source [16-18]. Notably, to ensure evaluation consistency, the subjective scale is not included in the assessment process due to the highly subjective nature of evaluators’ personal opinions and preferences.

Participants

Evaluation of the uMARS was conducted independently by 2 nutrition experts and 1 experimenter. Before the evaluation, each evaluator was required to read and further familiarize themselves with dimensions and items of the scale. All evaluators must comply with the consensus of the scoring criteria reached by the group discussion and evaluate each applet independently.

User Scores

User scores, a built-in feature of WeChat applets, are intended to assess users' overall satisfaction and experience, and a 5-point satisfaction scale is commonly used to measure people's satisfaction levels with the applets for research and surveys. Developers use these ratings to gauge the satisfaction levels of existing users and identify any areas for enhancement. If a feature of a WeChat miniprogram is not properly activated or if no users have participated in the rating, the default rating is set to 0.

Functional Scores

From among the 27 miniprograms selected, 16 functions were identified on the basis of registration and usage. Each miniprogram's functionality was evaluated by assigning 1 point for each aspect assessed, contributing to the cumulative total score. Feature scores ranged from 0 to 16, illustrating the comprehensiveness of the miniprograms' features.

Data Collection

Basic information regarding the 27 selected miniprograms was collected, encompassing metrics such as name, registration date,

update date, service type, user scores, and functional scores. Subsequently, the functionality and quality of these miniprograms were quantitatively assessed using the uMARS.

Statistical Analyses

The functional score of each miniprogram was collected and expressed as quantity and percentage values. uMARS scores were described as mean and SD or IQR values. All data were analyzed using SPSS (version 26.0; IBM Corp).

Ethical Considerations

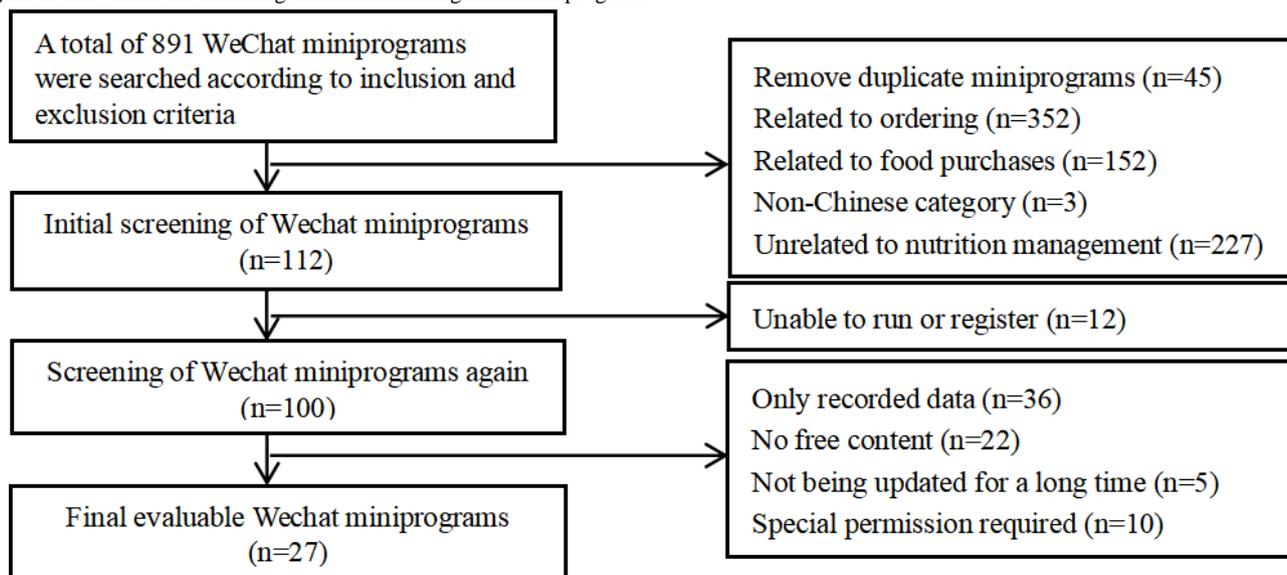

This study was approved by Zhongda Hospital affiliated to Southeast University (2024ZDSYLL194-P01).

Results

Screening of Miniprograms for Nutrition Management

We identified 891 miniprograms based on search terms (Figure 1). After removing the duplicate and unrelated miniprograms, 112 miniprograms were filtered. Ultimately, 27 miniprograms met the inclusion and exclusion criteria were selected for further study.

Figure 1. Flowchart for screening of nutrition management miniprograms.

Characteristics of Nutrition Management Miniprograms

We conducted a thorough search for miniprograms related to nutrition management through WeChat and used them after

registration. Interestingly, these miniprograms shared several common characteristics, including name, registration date, update date, service type, user scores, and functional scores (Table 1).

Table . Characteristics of the nutrition- related WeChat mini-programs^a.

Name	Registration date	Update date	Service type	User scores	Functional scores
Peppermint nutritionist	Nov 15, 2018	Feb 10, 2023	Health management, medical information, food and beverage, and health products	— ^b	10

WeChat Miniprogram for Nutrition Management

Following registration and use, the functional evaluation mainly focused on the nutrition management module of the miniprogram. This module encompassed 4 primary functions (diet management, weight management, exercise management, and nutrition education through class, video, or popular science content) and 12 auxiliary functions (Table 2). These auxiliary

functions encompassed specific features such as comparisons, analysis, and recommendations, along with capabilities for managing blood sugar, blood pressure, and sleep. Furthermore, it included features for nutrition assessment, questionnaire survey, dietitian consultation, access to a nutrition marketplace, generation of a nutrition report, monitoring of biochemical indicators, participation in nutrition-related social circles, and health assessment [19-21].

Table . WeChat miniprogram for nutrition management.

WeChat mini-program function	Miniprograms, n (%)
Main function	
Food record/management/analysis/clock in	23 (85.2)
Exercise recording/management/analysis/clock-ing	16 (59.3)
Weight recording/management/analysis/clocking	12 (44.4)
Nutrition class/video/popular science	19 (70.4)
Auxiliary function	
Food list	4 (14.8)
Food comparison	3 (11.1)
Food inquiry/analysis	8 (29.7)
Food/recipe recommendations	13 (48.1)
Blood pressure/blood sugar/sleep management	7 (25.9)
Nutrition assessment/questionnaire	8 (29.7)
Nutrition expert consultation	13 (48.1)
Nutrition mall	10 (37.0)
Nutrition report	7 (25.9)
Biochemical index	5 (18.5)
Nutrition sharing/friend circle/community	10 (37.0)
Health assessment	8 (29.6)

As depicted in [Table 2](#), the average functional score across all miniprograms was 6 points, ranging from 2 points in diet assessment to 10 points in peppermint nutrition food. Among the analyzed miniprograms, 85.2% (23/27) of them offered diet management features, facilitating the recording of daily dietary intake to assess nutritional status; 70.4% (19/27) of them provided nutrition knowledge and classroom teaching functionalities; 59.3% (16/27) of them offered exercise management capabilities, enabling users to record their daily physical activities; and only 44.4% (12/27) of them incorporated weight management functionalities.

In the functional evaluation, we conducted a comprehensive evaluation of the 4 main functions of each miniprogram. Simultaneously, we scrutinized and evaluated the auxiliary features to ensure that users could access comprehensive nutrition management services. Through this comprehensive assessment, we aimed to furnish users with detailed feedback, assisting them in selecting a high-quality nutrition management miniprogram, which was tailored to their requirements. Furthermore, this endeavor aimed to enhance users' health management practices and improve their overall and quality of life [22].

uMARS Quality Rating

An overview of the engagement, functionality, aesthetics, and information scores for the top 5 and bottom 5 miniprograms

was presented in [Table 3](#). Among them, the highest-ranking miniprogram was the WeChat applet mint health, with a uMARS score of 3.88 (SD 0.73), followed by AI (artificial intelligence) dietary dietitian, chestnut food diary, peppermint nutritionist, and sannuo health in turn. Notably, the user score approached 4.6 and the functional scores were 7.0. In contrast, the lowest ranking was WeChat applet-nutritionist world, with a uMARS score of 2.85 (SD 1.09), followed by diet evaluation, peppermint nutrition pro, nutritional meal companion, and long light nutrition diet therapy. In addition, the participation, function, aesthetics, and information scores of miniprograms are summarized in [Table 3](#).

The uMARS total quality median score, calculated on a scale of 5, was 3.38 (IQR 3.14-3.57), with an overall range from 2.85 to 3.88, indicating that most miniprograms achieved scores above 3 points. The uMARS score of engagement ranged from 2.00 to 4.33, with a median score of 3.00 (IQR 2.67-3.67). The functional dimension varied from 3.00 to 4.00, and the median score was 3.33 (IQR 3.33-3.67), with a lower score of 2.67 and a higher score of 4.33 outside the reference range. The aesthetic dimension spanned from 2.33 to 4.67, with a median score of 3.67 (IQR 3.33-4.00), and the informational dimension ranged from 2.33 to 4.67, with a median score of 3.33 (IQR 2.67-3.67; [Figure 2](#)). Detailed uMARS scores for all 27 miniprograms are provided in [Multimedia Appendix 1](#).

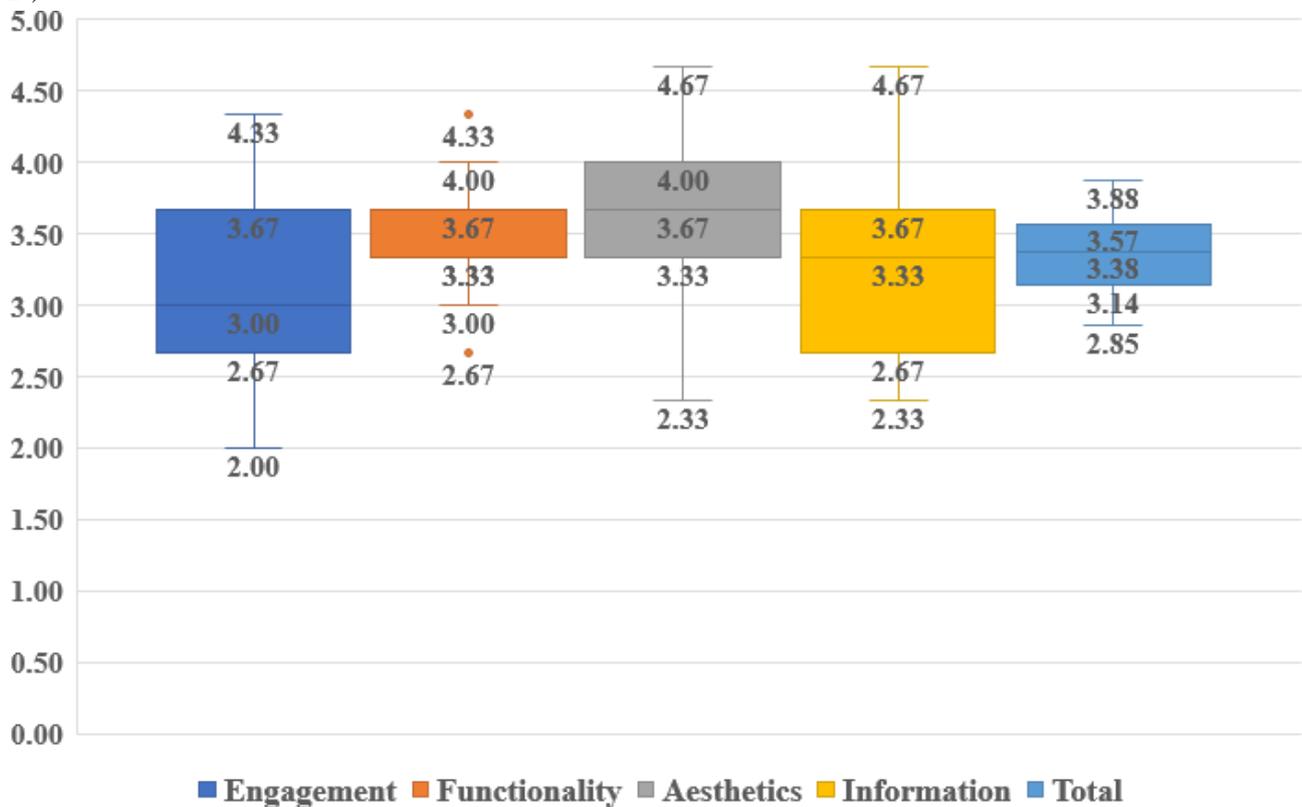

Table . The 5 highest- and lowest-scoring miniprograms (N=27) based on the User Version of the Mobile Application Rating Scale (uMARS).

WeChat applet	Engagement score, mean (SD)	Functionality score, mean (SD)	Aesthetics score, mean (SD)	Information score, mean (SD)	uMARS score, mean (SD)
Five highest-scoring miniprograms ^a					
	3.73 (0.96)	3.83 (0.72)	4.11 (0.33)	3.92 (0.67)	3.88 (0.73)
	3.73 (0.88)	3.67 (0.49)	4.33 (0.50)	3.83 (0.58)	3.85 (0.68)
	3.53 (0.92)	3.67 (0.49)	4.11 (0.60)	4.08 (0.79)	3.81 (0.76)
	3.47 (1.13)	3.67 (0.49)	4.00 (0.50)	4.00 (0.60)	3.75 (0.79)
	3.60 (1.12)	3.67 (0.65)	3.67 (0.50)	4.00 (0.74)	3.73 (0.82)
Five lowest-scoring miniprograms ^b					
	2.80 (0.86)	3.17 (0.58)	3.44 (1.01)	2.91 (0.79)	3.04 (0.82)
	2.73 (1.03)	3.08 (0.79)	3.33 (0.50)	3.17 (0.94)	3.04 (0.87)
	2.93 (1.22)	3.33 (0.49)	3.11 (0.93)	2.58 (1.24)	2.98 (1.04)
	2.93 (1.16)	3.33 (0.49)	3.11 (1.05)	2.50 (1.17)	2.96 (1.03)
	2.53 (1.89)	3.08 (0.90)	3.22 (1.09)	2.75 (1.14)	2.85 (1.09)

^aFive highest-scoring miniprograms: (1) mint health, (2) AI (artificial intelligence) dietary dietitian, (3) chestnut food diary, (4) peppermint nutritionist, and (5) sannuo health.

^bFive lowest-scoring miniprograms: (1) long light nutrition diet therapy, (2) nutritional meal companion, (3) peppermint nutrition pro, (4) diet evaluation, and (5) nutritionist world.

Figure 2. The User Version of the Mobile Application Rating Scale overall and section-specific scores of the nutrition management miniprograms (N=27).

Discussion

Principal Findings

A single user rating may not accurately gauge the quality of the miniprograms, and some existing evaluation systems for nutrition management miniprograms lack a scientifically grounded approach to promoting human nutrition. At present, the field of nutrition management miniprograms in China is still in its nascent stage and requires continual refinement of technique [18]. Analysis of functional scores revealed that only 18.5% of the miniprograms achieved scores above 8 points, indicating a need for improvement in their nutrition-related functionalities and health care. Among the identified issues, concerns were raised regarding the accuracy and comprehensiveness of the food database, potentially resulting in access to inaccurate nutrition. Furthermore, most miniprograms lack personalized services, consequently failing to offer tailored nutrition advice based on users' specific requirements and health conditions [23].

This study differs from prior research in several key aspects. First, many nutrition miniprograms now target specific disease types, tailoring diet management to the unique needs of patients. Second, some programs incorporate social circles to enhance user engagement, consequently fostering greater usage among patients [24]. Third, a subset of programs collaborates with the medical industry, engaging professional medical teams during development and establishing expert consultation platforms accessible via the WeChat miniprogram, tablet computer app, and computer software. Fourth, certain programs leverage data analysis and AI to deliver personalized nutrition advice and services, catering to individuals' specific needs [25]. Fifth, the seamless integration of these programs within WeChat enables direct access without the need for installation or downloads, ensuring faster and more convenient processes. Finally, developers continuously refine and expand nutrition management programs in response to evolving technological advancements and user preferences, thus integrating new functionalities and enhancing user experience to elevate program

quality and competitiveness [26]. Notably, our evaluation further revealed that the quality of nutrition management miniprograms varies significantly, with many exhibiting incomplete content, imperfect functionality, and limited individualization and intelligence [27].

Limitations

Although this study reports some interesting and significant findings, there are several limitations associated with the use of WeChat miniprograms. First, nutrition miniprograms on WeChat are still undeveloped and nascent compared to nutrition apps with high usage rates. Second, due to the inability to download WeChat miniprograms, relevant data such as download counts and software size cannot be fully obtained, limiting our analysis of the data displayed on the platform [28]. Additionally, our research focuses solely on analyzing the functionality and quality of miniprograms within the WeChat platform, resulting in a relatively narrow scope. Accordingly, future studies could expand their scope by conducting questionnaire surveys among users of the existing miniprograms or by integrating user feedback more effectively [29]. Simultaneously, encouraging active involvement from health professionals in the development of mobile health apps is crucial for ensuring their effectiveness and relevance in promoting better health outcomes [30]. Moving forward, the trajectory of development should prioritize the enhancement of quality, introduction of innovative features, and fostering of active participation of professionals, consequently providing more scientifically grounded and practical personalized dietary guidance and enriching research on domestic nutrition management miniprograms [31-33].

Conclusions

Our findings from the uMARS highlight a predominant emphasis on health aspects over nutritional specifications in the application of WeChat miniprograms related to nutrition management. The quality of these small programs is currently at an average level, with considerable room for functional improvements in the future.

Abstract

Background: The United States is experiencing a direct support professional (DSP) crisis, with demand far exceeding supply. Although generating documentation is a critical responsibility, it is one of the most wearisome aspects of DSPs' jobs. Technology that enables DSPs to log informal time-stamped notes throughout their shift could help reduce the burden of end-of-shift documentation and increase job satisfaction, which in turn could improve the quality of life of the individuals with intellectual and developmental disabilities (IDDs) whom DSPs support. However, DSPs, with varied ages, levels of education, and comfort using technology, are not likely to adopt tools that detract from caregiving responsibilities or increase workload; therefore, technological tools for them must be relatively simple, extremely intuitive, and provide highly valued capabilities.

Objective: This paper describes the development and pilot-testing of a digital assistant tool (DAT) that enables DSPs to create informal notes throughout their shifts and use these notes to facilitate end-of-shift documentation. The purpose of the pilot study was to assess the usability and feasibility of the DAT.

Methods: The research team applied an established user-centered participatory design process to design, develop, and test the DAT prototypes between May 2020 and April 2023. Pilot-testing entailed having 14 DSPs who support adults with IDD use the first full implementation of the DAT prototypes during 2 or 3 successive work shifts and fill out demographic and usability questionnaires.

Results: Participants used the DAT prototypes to create notes and help generate end-of-shift reports. The System Usability Scale score of 81.79 indicates that they found the prototypes easy to use. Survey responses imply that using the DAT made it easier for participants to produce required documentation and suggest that they would adopt the DAT if this tool were available for daily use.

Conclusions: Simple technologies such as the DAT prototypes, which enable DSPs to use mobile devices to log time-stamped notes throughout their shift with minimal effort and use the notes to help write reports, have the potential to both reduce the burden associated with producing documentation and enhance the quality (level of detail and accuracy) of this documentation. This could help to increase job satisfaction and reduce turnover in DSPs, both of which would help improve the quality of life of the individuals with IDD whom they support. The pilot test results indicate that DSPs found the DAT easy to use. Next steps include (1) producing more robust versions of the DAT with additional capabilities, such as storing data locally on mobile devices when Wi-Fi is not available; and (2) eliciting input from agency directors, families, and others who use data about adults with IDD to help care for them to ensure that data produced by DSPs are relevant and useful.

Introduction

Background

In 2019, more than 2 million adults with intellectual and developmental disabilities (IDDs) were living in the United States [1]. Many rely upon direct support professionals (DSPs) for assistance with activities of daily living, such as hygiene, dressing, taking medications properly, eating, accessing and navigating stores, learning vocational skills, participating in therapeutic activities, and socializing [2]. It is widely understood that the quality of life of adults with IDDs is significantly impacted by the quality of the support they receive from DSPs [3-11]. Unfortunately, there has been a shortage in the DSP workforce for more than a decade [7,12]. This shortage and a DSP turnover rate of 44.8% in 2017 led the President's Committee for People with Intellectual Disabilities to declare a crisis in the direct support workforce [13]. The DSP shortage and high turnover rate, each of which is associated with reduced quality of life for those served by DSPs [3,7], have both significantly increased since the COVID-19 pandemic [14]. Therefore, it is not surprising that the rate of COVID-19 infection among adults with IDDs was disproportionately high and that their quality of life decreased between 2019 and 2020 [15].

DSPs have indicated that generating required documentation is one of the least rewarding and most onerous aspects of their jobs [16]. Several factors make this task challenging, including difficulty recalling details of work performed many hours ago; fatigue; being rushed because employers require them to check out on a time clock at specific times to avoid overtime pay; fear of being accused of copying and pasting content from previous shifts; frequent interruptions by clients or other staff members; and, for some, challenges in writing in a nonnative language [16]. High turnover increases the communication demands on DSPs, including the need to generate detailed documentation to help bring new DSPs up to speed on their clients' needs. However, overworked DSPs who prioritize clients' medical and behavioral health needs may struggle to find time to document and share all relevant data during shift changes, unintentionally leaving their clients vulnerable to medical errors and inadequate support [14].

Technology enabling in-the-moment data collection can increase the efficiency of direct support staff and raise the quality of the data they produce, both of which can help improve care for their clients [17-19]. However, most data collection and reporting tools used to capture data about individuals with IDDs are targeted toward providers who work one-on-one with children [16] (eg, paraprofessionals or behavior technicians). These tools are not appropriate for DSPs who support multiple adults with IDDs during their shifts. In addition, the responsibilities of DSPs are much wider in scope than those of paraprofessionals and behavior technicians, who are typically not responsible for tasks such as administering medication and helping prepare meals.

DSPs' responsibilities are closer to those of home health workers who provide older adults or other adults with medical assistance and help with activities of daily living. Many high-income countries are already facing shortages of in-home health workers, while demand for them, as well as for DSPs, is expected to grow in many countries [20-22].

Recognizing that DSPs and the adults with IDDs who depend upon them could both potentially benefit from improved data collection and documentation, the research team used an established user-centered design methodology called Interaction Design and Engineering for Advanced Systems (IDEAS) [23] to design and pilot-test a suite of technology components called a digital assistant tool (DATs) to support data collection and reporting. This methodology relies upon frequent input and feedback from the target users, in this case, DSPs, to ensure that novel technology solutions will be useful, usable, and accepted by the DSPs [23].

Objectives

The primary purpose of the pilot study described here was to assess the usability of the DAT prototypes. The main objectives of the pilot study were as follows:

1. Identify design inconsistencies and usability problem areas of the DAT.
2. Observe representative users interacting with the DAT prototypes to help assess whether this technology could be effective, efficient, and well received by DSPs.
3. Establish baseline performance and user satisfaction levels in anticipation of more widespread testing of improved versions of the DAT.

Methods

Study Design

Overview

This project applied the IDEAS methodology, a user-centered participatory design approach that relies upon frequent input and feedback from target users to ensure that novel technology solutions will be useful, usable, and accepted by the users [23]. There are 6 steps in the IDEAS process: needs analysis, requirements generation, design and engineering, interface review, implementation, and evaluation. The first phase of this project included the first 2 steps; the second phase included the third, fourth, and fifth steps; and the third phase, which is the focus of this paper, comprises the last step.

Phase 1: Needs Analysis and Requirements Generation

To conceptualize the potential use of technology by DSPs, the research team sought to understand their perspectives on current data collection and documentation techniques and their ideas on how digital technology could be applied to support their work. The results of this exploratory descriptive research, which included focus groups, ethnographic observations, and a survey,

are described elsewhere [19]. Using the findings of this formative research, the team developed a list of design principles for our first set of prototypes, shown in [Textbox 1](#).

Textbox 1. Summary of formative research results and the corresponding design principles for the initial digital assistant tool (DAT) prototypes.

- Direct support professionals (DSPs) need to track and remember large amounts of information about multiple clients.
 - The DAT should automatically store notes, it should allow users to associate notes with specific clients, and it should provide access to notes on demand.
- DSPs must continuously monitor clients for safety while tracking behaviors.
 - The DAT should enable users to quickly and easily create notes while attending to clients, it should run on mobile and wearable devices, and it should not require a lengthy authentication process.
- DSPs must not allow clients to recognize when DSPs are creating notes about them.
 - The DAT should enable DSPs to create notes unobtrusively.
- DSPs are comfortable using smartphones but desire simple, easy-to-use data logging capabilities.
 - The DAT should prioritize usability—its user interfaces should be very simple, DAT log-ins should not time out during a shift, and the DAT should provide readable language.
- DSPs do not want employers to be able to access their notes.
 - The DAT should feature high levels of security and privacy and allow only DSPs to see their notes.
- DSPs must provide either chronological or categorically organized reports.
 - The DAT should time-stamp notes, it should allow users to associate notes with a topic or category, and it should allow users to sort and filter notes.
- DSPs must not copy text from prior days' reports into the current report.
 - The DAT should allow users to copy time-stamped notes into a clipboard or Word document to use to help write reports.

Phase 2: Design and Engineering, Interface Review, and Implementation

Once the research team had decided on the initial set of capabilities for the DAT, they designed a suite of technology prototypes that (1) enable quick and easy in-the-moment data collection; and (2) allow DSPs to access a private, secure web portal to review, sort, filter, and organize their notes to facilitate end-of-shift documentation. This suite includes 4 components: a mobile app that currently runs on Android smartphones; a private, secure web application that allows DSPs to access, review, and organize notes that they created with the mobile application; a cloud-based center that houses the data; and an

administrative website for creating and managing user accounts. As these components were being architected, researchers shared user interface design concepts for the mobile app and the web portal with DSPs to obtain their feedback. The initial wireframes for the mobile app included multiple screens that would allow users not only to create notes but also to review and edit them ([Multimedia Appendix 1](#)). After 4 iterations, the team settled upon a very simple single-screen note creation design for the mobile app, also called the Note Creation App; and a spreadsheet-like view of saved notes for the web application, also referred to as the Note Review App (both of which were implemented; refer to [Figures 1-3](#)).

Figure 1. The mobile app, used to create informal notes. This screen shows the touchscreen keyboard used to type new notes.

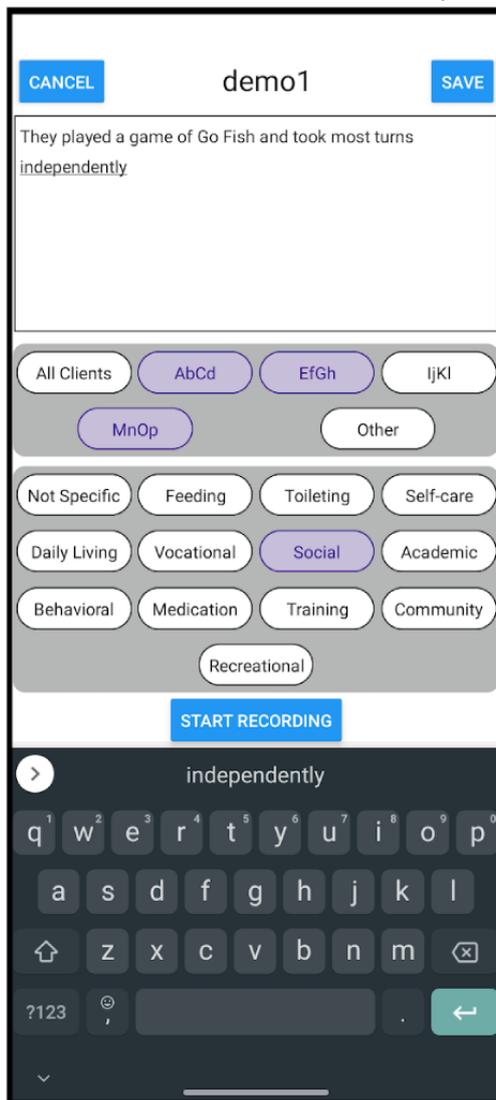

Figure 2. The mobile app, used to create informal notes. This screen shows the screen used for voice-based note creation.

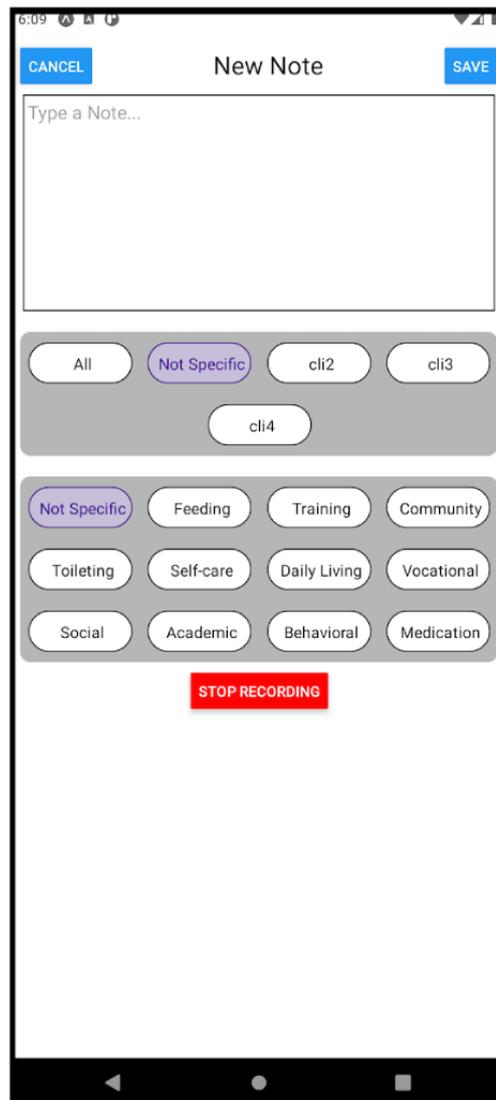

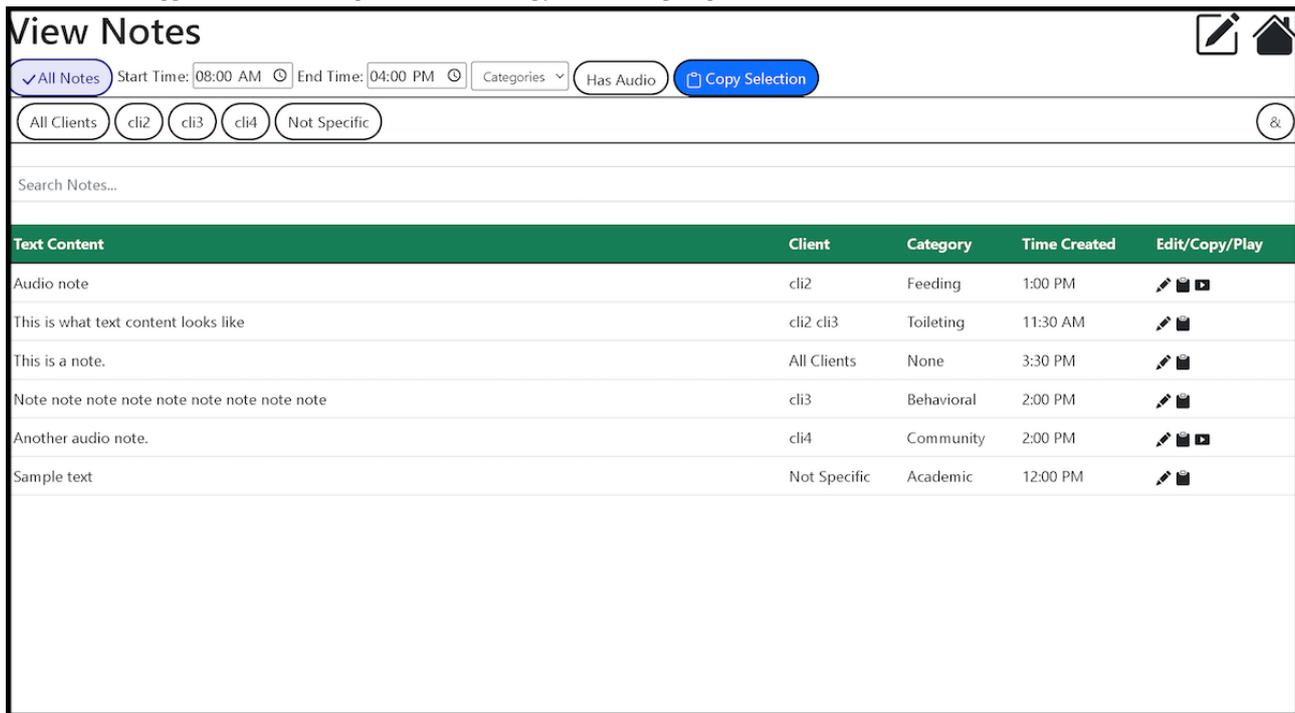

Figure 3. The web application, used to organize notes and copy data into report generation software. cli2: client 2; cli3: client 3; cli4: client 4.

Phase 3: Evaluation

Once the initial prototypes were implemented, engineering and psychology undergraduate students tested them in laboratory settings; the engineering students focused on performance testing, and the psychology students focused on providing usability feedback. After all known bugs had been fixed, and usability improvements had been implemented, the team began scheduling pilot tests.

Participants and Recruitment

Overview

The pilot study was intended to determine *proof of concept*; therefore, the number of participants was not determined based on traditional power analysis calculations. Guidance on how many participants to include in pilot studies varies, with some recommending between 10 and 30 [24,25] and others suggesting 12 [26,27]. Meanwhile, the System Usability Scale (SUS), the instrument used to measure baseline usability, requires at least 8 to 10 participants to produce reliable results [28]. The research team worked with 3 DSP service provider partners to recruit 16 participants with the goal of having at least 12 (75%) of them test the prototypes during multiple shifts.

The service providers’ senior management members notified their staff via email and during staff meetings that members of the research team would be bringing technology tools designed to be used by DSPs on specific dates. All staff who were working to support adults with IDD in the designated program for 3 consecutive shifts during the research team visits were eligible to serve as pilot test participants. Due to variability in testing sites, including staff characteristics, the level of support needed by clients served by the staff, and the timing of the staff’s work shifts, demographic data and results are reported separately for each test site.

Site 1 (Day Program)

The first pilot-testing site was a day program for adults with IDD where DSPs and clients were each assigned to 1 of 5 different rooms. Of the 10 DSPs who worked in this setting on the first day of testing, 6 (60%) were selected to serve as pilot testers; 2 (20%) were excluded because they were not scheduled to work 3 shifts in a row in the same setting, and 2 (20%) were willing but unable to participate because there were only 6 smartphones with the DAT mobile app installed available; thus, the first 6 DSPs who volunteered were enrolled. All 6 participants were native English speakers; 5 (83%) were women. Of the 6 participants, 2 (33%) were aged between 18 and 24 years, 1 (17%) was aged between 25 and 34 years, 1 (17%) was aged between 35 and 44 years, and 2 (33%) were aged between 45 and 54 years. All identified as Black or African American. Of the 6 participants, 1 (17%) had a high school degree, while the remaining 5 (83%) had taken some college classes but did not have college degrees. Experience working with adults with IDD ranged from 1.5 to >20 years, with an average of 8 years, 9.6 months. The amount of time they had held their positions ranged from 4 months to 3 years. Due to last-minute schedule changes, of the 6 participants, 2 (33%) used the DAT prototypes for 2 consecutive shifts, whereas the other 4 (67%) used them for 3 consecutive shifts.

Site 2 (Private Home)

The second test site was a private home that housed a single adult with a high level of support needs. Of the 12 different staff members who worked in this home, 4 (33%) were eligible to participate, based on their schedules, and all volunteered to serve as pilot testers. All 4 participants from this site were women and native English speakers; 1 (25%) was aged between 18 and 24 years, and the remaining 3 (75%) were aged between 25 and 34 years. Of the 4 participants, 1 (25%) identified as Black or African American, 1 (25%) as Hispanic, and 2 (50%)

as White. Of the 4 participants, 1 (25%) had a high school degree, 2 (50%) had some college but no degree, and 1 (25%) had a college degree. Their experience working with individuals with IDD ranged from 7 months to 7 years, with an average of 3 years, 11.4 months. The amount of time they had been working in the private home ranged from 3 months to 1.5 years.

Site 3 (Provider-Managed Group Homes)

The third test site included 3 group homes, all located in the same county, that housed 3 to 4 adults with IDD. Each of the 2 staff members in each of the 3 homes volunteered to serve as pilot testers. Of the 6 volunteers, 2 (33%) had work schedule changes that prevented them from using the DAT prototypes after their first shift and were removed from the study; the remaining 4 (67%) volunteers were included in the study. All 4 study participants were women and native English speakers. Of the 4 participants, 3 (75%) identified as Black Hispanic, and 1 as *other*; 1 (25%) had a college degree, and 3 (75%) had high school degrees and no college experience. Of the 4 participants, 1 (25%) was aged between 18 and 24 years, 1 (25%) was aged between 25 and 34 years, and 2 (50%) were aged between 45 and 54 years. The amount of experience they had working with adults with IDD ranged from 1 to 22 years, with an average of 11 years, 9 months. The amount of time they had held their positions ranged from 1 to 22 years, with an average of 7 years, 4 months. Due to last-minute schedule changes, of the 4 participants, 2 (50%) used the DAT prototypes for 2 consecutive shifts, whereas 2 (50%) used them for 3 consecutive shifts.

Materials

Each participant was provided with an Android smartphone (Motorola Moto G Power 2021 running Android version 11 RZBS31.Q2-14327-25) that had the DAT mobile app preinstalled. For testing at sites 2 and 3, each smartphone also had shortcuts to all study surveys (demographic survey, post-shift 1 survey, and post-final shift survey) located on its main screen. Shortcuts were not provided on the smartphones during testing at site 1 because the research team was present to provide links in person at that site. All participants used employer-provided laptops to access the DAT web application at the end of their shifts.

Procedure

On the first day of testing, the principal investigator (PI) obtained informed consent from each participant. She explained that they would be awarded gift cards at the end of the multiday test trial that would be credited with US \$75 per shift for their first 2 shifts and US \$100 for their third shift. Next, she asked participants to use a computer to complete a short demographic questionnaire, administered through Qualtrics (Qualtrics International Inc; [Multimedia Appendix 2](#)).

While participants were filling out the demographic survey, the research team used the administrative website to create user accounts and location-based shifts, which included the initials of the clients whom each participant would be supporting and relevant data categories for the DSPs who worked in this setting (eg, feeding, toileting, behavior, medication, and social skills). These categories were identified by asking staff supervisors to

select from a list of possible categories; they were also invited to add items not on the list.

After the participant finished the demographic survey, the researcher showed them the web application, which was populated with sample data previously entered by the research team. The researcher explained to the participant that this application would be used at the end of their shift to support writing the required reports. Subsequently, the researcher provided each participant with an Android smartphone, demonstrated how to use the mobile app, and invited the participants to try creating an audio note as well as a text-based note.

Participants were also invited to review, sort, and filter their sample notes using the web application during the training session. Once participants indicated that they knew how to use both the mobile app and the web application, they were given an opportunity to ask questions and informed that they could request help or address questions to the PI at any point during their shifts. They were then directed to use the smartphone that the research team had provided to log audio and text-based notes about their work while otherwise performing their job as usual throughout their shift.

Site 1 Testing

During pilot-testing in the day program, 2 to 3 members of the research team stayed on site during all 3 pilot-testing shifts. One research team member monitored the use of the mobile app through the administrative website, and 2 other members intermittently visited the rooms where the DSPs who were testing the DAT were assigned to work to observe or answer questions. In 1 room, the ratio of DSPs to clients was 1:3 on day 1 and 1:4 on days 2 and 3. In the second room, the ratio of DSPs to clients was 2:5 on day 1 and 2:4 on days 2 and 3. In the third room, the ratio was 2:3 on days 1 and 2 and 3:3 on day 3 (the third DSP in this room was in training and did not have access to the DAT). Finally, the fourth room, which was only included on day 3, had a ratio of 3:8, and only 1 DSP in this room used the DAT.

Throughout all their shifts, the participants used the mobile app to create short notes. They had the option to use voice or a touchscreen keyboard to enter text, and they could also use touchscreen buttons to associate notes with ≥ 1 clients or to indicate a specific category (eg, feeding, self-care, and medication).

Toward the end of the first day of pilot-testing, when participants were ready to start working on their required reports, a researcher helped them log in to the web application so that they could review and organize the notes that they had created during the shift. If needed, the researcher reviewed functionality, such as sorting, filtering, and copying 1 or multiple notes to a clipboard. The team then observed how the DSPs used the web application to help them create end-of-shift reports. Most of the DSPs (5/6, 83%) decided to paste their notes into either the clipboard or a text file and use 1 of these to draft the text portion of their end-of-shift report, rather than copying note content directly into the application that they use to submit their reports. Once the participants had finished their reports, they were

directed to use either the laptop used to create reports or the smartphone to fill out a web-based post-shift 1 survey ([Multimedia Appendix 3](#)). Participants were asked to rate 7 items, using a Likert scale ranging from 1 to 5, to indicate their level of agreement. Of the 7 items, 3 (43%) described their experience using the mobile app to log notes, their experience using the web application to review and organize the notes, and their opinions about the quality of the behavioral data and end-of-shift reports that they had provided that day. The items in this survey, which were also included in the final survey, were developed by the authors for this study and were not tested for validity or reliability.

At the end of days 2 and 3, the research team members were available to assist the participants, but all of them were able to access the web application and use it to help them with their reports independently. At the end of day 3, the participants were directed to fill out the final survey ([Multimedia Appendix 4](#)). The survey began with 17 items that were rated on a Likert scale ranging from 1 to 5 showing level of agreement. The first 7 items, which were about data collected and reports created, were the same as the first 7 statements rated after the first shift. The last 10 items were those included on the SUS survey, a well-established survey for assessing ease of use and user satisfaction [28,29]. Eleven open-ended questions followed the 17 statements. They asked participants to share their overall impressions of the mobile app and the web application, what they thought about the layout of the mobile app and the web application, what concerns they had about using the DAT, what it was like writing end-of-shift reports while using the DAT, and what additional feedback they wanted to share. These questions were designed to obtain feedback on existing functionality and elicit suggestions for changes or additions.

Once the final survey was submitted, the research team collected the smartphones, and the PI provided gift cards.

Site 2 Testing

As the private home housed a single adult, testing at this site was sequential, with only 1 (25%) of the 4 participants using the DAT prototypes on any given shift. In addition, only the PI visited this site when the DSPs who worked there participated in the pilot test. The PI met with each participant in the home approximately 1 hour before their shift started and obtained informed consent, provided the participant with a smartphone running the DAT mobile app, and taught them how to use the DAT mobile app and the DAT web application. Once training was completed, the PI placed shortcuts to the post-shift 1 survey as well as the final survey on the main screen of the smartphone and emailed the participant a private, secure link to the web application site where they could review and organize their notes. Finally, the PI answered any questions that the participant had, made sure the participant had a power cord and knew how to charge the smartphone with the mobile app, provided a phone number and email address to use in case questions or technical difficulties arose during their shifts, and departed. Although the research team members were not on site, they were able to monitor the use of the DAT mobile app and the DAT web application using the DAT administrative portal. All participants used the smartphone to create notes and accessed the web portal

at the end of their shifts without support from the research team. Toward the end of each participant's first shift, the PI sent a reminder email that contained a link to the post-shift 1 survey (which was also accessible via a link on the smartphone). Toward the end of the participants' third shift, the PI sent an email to confirm a meeting time to deliver gift cards and pick up the smartphones; the email also contained a link to the final survey.

Site 3 Testing

Two members of the research team visited each of the 3 group homes during the first day of testing at site 3 to obtain informed consent, hand out the smartphones with the DAT mobile app, and conduct training. The research team members had placed shortcuts to the demographic, post-shift 1, and final surveys on the home screens of the smartphones in advance. After training was complete, the research team members helped participants to create a bookmark to conveniently access the web application on the computers that the participants used to produce their end-of-shift documentation. The PI also emailed links to the surveys and a secure link to access the web application so that the participants could easily access the surveys and their private website for reviewing and organizing their notes from their computers. Next, the researchers gave participants an email address and a phone number that could be used to reach the PI and encouraged them to use these if they had questions or concerns while using the DAT prototypes. The researchers then departed. During the rest of this shift, the research team members monitored the use of the DAT mobile app and the DAT web application via the administrative website. Toward the end of the first shift, the PI emailed participants reminders to fill out the post-shift 1 survey; and toward the end of the third shift, the PI emailed reminders to fill out the final survey. After the third shift had ended for all participants, the PI visited each of the group homes to pick up the smartphones and chargers and distribute gift cards.

Data Preparation and Analysis

Survey data were extracted from Qualtrics. For each site, descriptive statistics for demographic data were summarized; and the frequencies of the Likert scale responses, except for the 10 SUS items, were computed. The responses to the SUS items from all 14 participants were used to compute a single SUS score, using established computations [29]. The research team members also analyzed open-ended responses from all participants thematically, using inductive open coding [30]. Following the 6-step method formulated by Braun and Clarke [30] as explained by Maguire and Delahunt [31], 2 members of the research team categorized different response types for each question and used these to establish codes; next, these researchers and the PI collaboratively identified high-level themes that ran across multiple questions. Finally, the research assistants independently coded responses to all open-ended questions using the final code set.

In addition, in keeping with the exploratory nature of this work, the research team members analyzed the notes that were collected using the mobile app to understand how DSPs used this technology. In particular, the team reviewed the number of text-based and audio notes that each DSP produced during each

of their shifts, the number of words in each type of note, and the number of notes that were started but canceled (not saved) by each DSP during each shift.

Ethical Considerations

This research complies with the American Psychological Association code of ethics and was approved by the Rowan University Institutional Review Board (PRO-2020-001085). Informed consent was obtained from each participant on the first day of testing. Regarding compensation, at the end of the multiday test trial, participants were awarded gift cards that were credited with US \$75 per shift for their first 2 shifts and US \$100 for their third shift.

Results

Note Logs

Data logs from 34 DSP shifts were imported into Excel (Microsoft Corp) for analysis. Across these shifts, a total of 373 notes were saved. Another 41 notes were started, but they were canceled (not saved). [Table 1](#) shows, for each site, the medians and IQRs of all saved notes per shift, audio notes saved per shift, text-based notes saved per shift, canceled notes per shift, notes created during a DSP's first pilot-testing shift, notes created during a DSP's second pilot-testing shift, notes created during a DSP's third pilot-testing shift, words per audio note, words per text note, and words per note.

Table 1. Types of direct support professional notes produced at each site during the pilot-testing.

Computation	Site 1, median (IQR)	Site 2, median (IQR)	Site 3, median (IQR)
Audio notes per shift	2 (1-9)	0 (0)	3 (2-5)
Text-based notes per shift	8 (4-14)	10 (7.5-14)	7 (4-12)
Total notes per shift	10 (5-12)	10 (7.5-14)	10 (2-16)
Canceled notes per shift	0 (0-1.5)	0 (0-3.5)	0 (0-1.5)
Notes created during first shift of pilot-testing	6 (4-12)	7.5 (6-9)	8.5 (5-12)
Notes created during second shift of pilot-testing	10 (5-12)	10 (5.5-14.5)	6 (2-10)
Notes created during third shift of pilot-testing	6 (8.5-12.5)	12.5 (6-16)	9.5 (7-12)
Words per audio note	9 (6-17)	N/A ^a	8.5 (8-14)
Words per text note	12 (6-22.5)	6.5 (3-9)	11 (8-15)
Words per note	10 (6-22)	6.5 (3-9)	10.5 (8-15)

^aN/A: not applicable.

Post-Shift 1 Survey Ratings Questions

The post-shift 1 survey began with 7 statements that were rated on a scale ranging from 1 to 5 to show level of agreement

(1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree). [Table 2](#) shows these statements as well as the frequencies of each of the ratings given to each statement.

Table 2. Frequencies of the post–shift 1 survey Likert scale responses for each test site. Response scale ranged from 1=strongly disagree to 5=strongly agree.

Statement	Site 1 (n=6), response; n (%)	Site 2 (n=4), response; n (%)	Site 3 (n=4), response; n (%)
I am confident that today's data sheets are accurate	<ul style="list-style-type: none"> • 4; 1 (17) • 5; 5 (83) 	<ul style="list-style-type: none"> • 5; 4 (100) 	<ul style="list-style-type: none"> • 3; 2 (50) • 4; 1 (25) • 5; 1 (25)

I believe today's session notes will be valuable to others (parents, supervisors, behavior analyst)	<ul style="list-style-type: none"> • 4; 2 (33) • 5; 4 (67) 	<ul style="list-style-type: none"> • 5; 4 (100) 	<ul style="list-style-type: none"> • 2; 1 (25) • 3; 1 (25) • 4; 1 (25) • 5; 1 (25)

Post–Final Shift Survey Ratings and SUS Ratings

All 14 participants who used the DAT during multiple shifts completed the post–final shift survey. [Table 3](#) shows the frequencies of responses to the first 7 statements.

The SUS score for the 14 participants was 81.79, which is quite high for an initial prototype; this score corresponds to *excellent* usability [32]. This score is also in the range where a product

is likely to be recommended by users to other potential users [33].

The final survey also contained 11 open-ended questions: 4 (36%) were about the mobile app, 6 (55%) about the web application, and 1 (9%) asked if any initial concerns that participants had about using the DAT prototypes had been alleviated after using them during multiple shifts.

Table 3. Frequencies of responses to post-final shift survey non-System Usability Scale Likert scale items.

Statement	Site 1 (n=6), response; n (%)	Site 2 (n=4), response; n (%)	Site 3 (n=4), response; n (%)
I am confident that today's data sheets are accurate	<ul style="list-style-type: none"> • 4; 1 (17) • 5; 5 (83) 	<ul style="list-style-type: none"> • 5; 4 (100) 	<ul style="list-style-type: none"> • 3; 1 (25) • 4; 1 (25) • 5; 2 (50)
I found it easy to record behavior data for all clients today	<ul style="list-style-type: none"> • 5; 5 (100) 	<ul style="list-style-type: none"> • 5; 4 (100) 	<ul style="list-style-type: none"> • 3; 2 (50) • 4; 1 (25) • 5; 1 (25)

Thematic Analysis of Open-Ended Question Responses

Overview

One-third of the question responses (5/14, 36%) were coded by each of the 2 coders. Inter-coder reliability was 92.56%. After coding was complete, the research assistants worked with the PI and identified the following 5 overarching themes in the survey response data.

Theme 1: Using the DAT Was a Positive Experience

Participants reported that the mobile app was easy to use and that it was helpful to be able to create notes in real time. Comments after using it for a single shift included "it's amazing" (Participant 4) and "I would use it on a daily basis" (Participant 12). The participants also provided predominantly positive feedback on the web application, such as "it's great," (Participant 2) "simple and easy," (Participant 7) and "organized and helpful" (Participant 6).

Theme 2: Using the DAT Made It Easier to Create End-of-Shift Reports

Survey responses also revealed that participants found that using the DAT facilitated writing end-of-shift reports. Their comments included "[The DAT] made it easy to keep track of everything throughout the day" (Participant 14) and "made [writing reports] a lot easier for me" (Participant 1). A participant wrote, "I had a great experience [writing reports] and I like [the DAT] very much" (Participant 7).

Theme 3: The DAT Helped Increase the Accuracy of End-of-Shift Reports

Participants indicated that using the DAT enabled them to create more accurate reports. One wrote, "It help [sic] to maintain accurate notes as the day goes along" (Participant 7); another reported that "It gives you the opportunity to keep the notes accurate" (Participant 9); and a third simply commented, "increases accuracy" (Participant 2).

Theme 4: Additional and Improved Features Are Desired

Although participants provided positive responses when asked about their experience using the DAT, they also noted that the tools could provide even greater benefit if they were enhanced. Suggestions included allowing users to access the web application to review and edit notes on their smartphone, improving the transcription accuracy; allowing users to store notes locally when smartphones are not connected to Wi-Fi; offering additional or more specific categories; and allowing users to copy time stamps when copying note text from the web application.

Theme 5: More or Better Training Would Help

The survey responses by 3 (21%) of the 14 participants suggested that they would have liked additional training. One of them noted that "it looks easy but when I'm by myself it's a different story" (Participant 12); the second wrote, "I wish I could get a better understanding" (Participant 11); and the third reported that "it would be easy if I get the hang of it" (Participant 12).

Discussion

Principal Findings

All 14 participants were able to use the mobile app without assistance during all shifts, but their ability to use the web application independently at the end of their first shift varied. All participants were able to use both the mobile app and the web application without help from the research team members during their second and third shifts. This result is consistent with an average SUS score of >80, indicating that the DAT prototypes are very easy to use. The hardest part about using the web application for most of the participants was typing in the URLs to access the private, secure notes review app. In future testing, aliases (shorter active links that take users to the same place as the longer URLs) should be set up to help avoid this problem. In addition, research team members should always help participants create a bookmark during training to make it easy to access the web application, a strategy that was not adopted until testing was conducted at site 3. All participants indicated that they found it easier to write reports at the end of their shift after using the DAT.

At site 1, all 6 participants were able to use the DAT prototypes for at least 2 successive shifts. These participants, whose ages were fairly well distributed across the range of 18 to 54 years, agreed or strongly agreed with 6 (86%) of the 7 survey statements after day 1. For the statement “I am confident today’s session notes contain all necessary information,” of the 6 participants, 1 (17%) selected *neither agree nor disagree*, and the remaining 5 (83%) all agreed or strongly agreed (Table 2). When given the same set of questions in the final survey, all 6 participants agreed or strongly agreed with all 7 statements (Table 3). This is consistent with the largely positive responses that these participants provided to the open-ended questions in the final survey. All indicated that they enjoyed using the DAT prototypes and would be interested in using future versions.

The site 2 participants were younger, with ages ranging from 18 to 34 years; therefore, they had less experience working with adults with IDD than site 1 participants. Their responses to the Likert statements also indicated a high level of agreement; after day 1, all 4 participants strongly agreed with 6 (86%) of the 7 statements; 1 (25%) participant selected *neither agree nor disagree* for the statement “I found it easy to write session notes today,” and the remaining 3 (75%) participants all strongly agreed with this statement. All 4 site 2 participants responded *strongly agree* to all 7 statements in the final survey. These participants also provided responses to the open-ended questions indicating that they enjoyed using the DAT prototypes and would be interested in using future versions. These 4 participants provided more suggestions for additional features than the participants from the other 2 sites.

Site 3 participants fell into 2 different age ranges. Of the 4 participants, 2 (50%) were aged between 18 and 34 years, and 2 (50%) were aged between 45 and 54 years. Compared to site 1 and site 2 participants, site 3 participants provided a wider range of responses to the 2 surveys. As can be seen in Table 2, after the first shift using the DAT prototypes, a participant disagreed with the statements “I am confident today’s session

notes contain all necessary information,” “I am confident today’s session notes contain only relevant information,” and “I believe today’s session notes will be valuable to others (parents, supervisors, behavior analyst).” Responses to the other 4 statements ranged from *neutral* to *strongly agree*. Responses to the final survey ranged from *neutral* to *strongly agree* for all 7 statements, indicating more variable sentiments among site 3 participants at the end of the pilot test than among site 1 and site 2 participants.

When we grouped the site 3 participants’ responses based on their ages, we found that those in the age category of 45 to 54 years (2/4, 50%) generally reported a less positive experience using the DAT prototypes than the other participants (2/4, 50%). In fact, a review of the data logs from these 2 participants revealed that they only used the mobile app at the end of their shifts. It seemed that they used the DAT mostly as a transcription service. As the DAT prototypes used a freely available web-based transcription service which was far from perfect, and time stamps are not helpful when all notes are created at the end of shifts, these DSPs would have been better off using a transcription app on the computers they used to create their end-of-shift reports.

While most of the test participants (12/14, 86%) indicated that they valued the ability to collect data about their work in the moment, several of them (6/14, 43%) noted that their ability to benefit from this capability was reduced because the mobile app prototype requires Wi-Fi to save notes. Even with this limitation, the DSPs were very enthusiastic about the DAT prototypes; 1 participant asked whether she could keep using them after the pilot test, and another asked when they would be available for daily use. Future work includes enabling the mobile app to store data locally so that it can be used to collect data while DSPs and clients are out in the community, which is a key part of some DSPs’ client interactions.

The average numbers of notes created per shift and canceled notes per shift was roughly the same for each site. The number of words per note averaged 6.5 at site 2 compared to approximately 10 at sites 1 and 3. To our surprise, audio notes had roughly the same number of words as text-based notes. While the number of words seemed low at first, this is consistent with the intent that note creation be quick, easy, and informal, helping jog memories during report creation. Meanwhile, the average number of notes that DSPs saved during their shifts increased for most DSPs across their shifts. We anticipated that the number of DSPs who created few notes initially would increase in subsequent shifts, and those who created many would create fewer as they learned which types of notes were most helpful. Although 1 DSP’s notes fit this pattern, it seems that the other DSPs created more notes as they became more accustomed to using the mobile app during their shift. In a few cases, participants did not include any content; they just created a note with a client and category selected, indicating that just having a time associated with a client and category would be useful when writing reports. In addition, participants indicated that being able to sort notes by category can directly help with writing reports that have specific requirements, such as detailing all instances of medication administration or all food intake during a shift.

Overall, the results from the pilot test are promising, suggesting that DSPs would be willing to use mobile devices to enable in-the-moment data collection, provided that the collected data facilitate efficient generation of required end-of-shift documentation. Feedback from the test participants suggests that technology such as the DAT could help to increase efficiency, effectiveness, and job satisfaction among DSPs.

Comparison With Prior Literature

Many sources, some more than a decade old, have warned about, or described, a shortage of DSPs in the United States [7,34-39]. Factors such as heavy workload, onerous documentation requirements, and burnout contribute to a high turnover rate, which exacerbates stress on DSPs [22,40-49]. Some of this literature points out that technology could potentially help to reduce the time DSPs must spend on their other responsibilities, such as documentation, so that they can spend more time on direct support [7,38].

Technology has been successfully applied to increase documentation efficiency and decrease workload in special education and clinic- and home-based therapy programs for children with autism spectrum disorder [17,18,50,51]. By enabling users to quickly and easily record in-the-moment data, these technologies help improve the quality of documentation they generate [52]. However, there is relatively little work that explores how technology could be applied to support direct support workers, such as DSPs and home health aides (HHAs), who provide care to adults [53,54]. Most of the research that addresses having direct support workers leverage technology is qualitative and focuses on workers who support patients without IDD [55-57]. One 2022 review paper identified only 1 study that created technology expressly intended to support the work of direct support workers [53]. This study, which also entailed creating a smartphone app to use to help create reports, was conducted in Japan nearly 2 decades ago. The authors who described this effort concluded that enabling direct support workers to use smartphones to create reports saves time and reduces costs [58]. Another 2022 review, which surveyed “the technological landscape” of direct support workers, noted that there is a paucity of evidence about how information and communication technologies can be used by these workers [57]. The authors of the review went on to assert that none of the existing technology-based interventions that could be used to facilitate home care were specifically designed to support the workflows of HHAs and concluded that “there is an urgent need for research that centers on the needs and perspectives of HHAs and using human-centered methods to engage HHAs in the design of technologies that truly support their essential caregiving work” [53]. The human-centered research reported here was specifically focused on developing technology for DSPs, but many of the design principles identified in [Textbox 1](#) are also relevant to creating technologies to support the work of direct support workers who care for individuals without IDDs, such as HHAs.

However, inserting technology that is intended to facilitate sharing data among many care providers does not always increase documentation efficiency or decrease workload. Consider the migration from paper to electronic health records

(EHRs), which significantly increased clinicians’ workload [59-62]. EHRs have also been associated with a decrease in the amount of direct patient support time [63-65]. In contrast to EHRs, many of which grew out of billing systems [66], the DAT prototypes were developed by following an established user-centered design methodology [23] that ensured that our team considered DSPs’ needs, goals, and constraints and obtained their feedback throughout our effort. As in the case of EHRs, a strong motivation behind creating the DAT prototypes helped to facilitate care for the individuals whose data are being logged electronically [67-70].

Multiple studies have pointed out that clinician burnout, which has been connected to the advent of EHRs, is correlated with decreased patient safety [71-74]. Similarly, DSP burnout and turnover are associated with poor health and quality of life for their clients [3,5]. Hence, technology such as the DAT prototypes, which are designed to reduce the burden of required documentation, improve job satisfaction, and reduce turnover among DSPs, can also help to improve the quality of life of adults with IDDs whom they support.

Limitations

Several limitations warrant mention. Our pilot test was limited to 14 DSPs working in 1 geographic region. However, different work settings, ranging from a private home with a single resident and group homes with 3 to 4 residents to a day program at a large agency, as well as the range of time that the DSPs who served as pilot testers had worked with adults with IDDs (<1 year to 20 years) increase the generalizability of our results. The pilot test length was also quite short, and we did not measure the amount of time spent generating documentation before the pilot test. These factors prevented us from assessing the impact of the DAT prototypes on documentation efficiency and quality. Nevertheless, the pilot test was long enough to establish feasibility.

Another limitation is that only 10 (71%) of the 14 pilot test volunteers were able to use the DAT prototypes for 3 successive shifts. Scheduling issues, often driven by staffing shortages that caused a staff member to be moved to a different location at the last minute, prevented several participants (4/14, 29%) from using the DAT as planned. In addition, we did not collect data about participants’ familiarity and comfort with technology, although our observations while on site during the first shift provided insights about these factors. The fact that the DSPs were paid to participate is another limitation, although responses to the open-ended questions suggest that at least some of the participants were interested in continuing to use the tools when they would not be paid.

In addition, while the qualitative data from the test users was generally very positive, the study did not use any instruments that assess the likelihood of user adoption, such as the technology acceptance model [75]. Future work on technologies to support DSPs should be informed by the framework developed by Venkatesh et al [76] for understanding user acceptance of IT and might also consider the strategies outlined by Sebastian et al [77] for increasing user acceptance of novel technologies.

Implications

The results of the pilot test are promising, suggesting that upgraded versions of the DAT prototypes or similar technologies have the potential to reduce the burden of completing end-of-shift reports, while improving the quality of data produced by DSPs. Making it quick and simple to produce time-stamped in-the-moment notes facilitates logging more accurate and more detailed client data. Better data about adults with IDD would enable family members, health providers, therapists, health providers, and behavior analysts to better support these adults. Long-term benefits of using the DAT could include (1) reducing DSP workload; (2) increasing the time DSPs spend interacting with adults with IDDs; (3) enabling DSPs to provide more consistent and appropriate support; (4) increasing DSP job satisfaction; (5) improving medical and behavioral support for adults with IDDs; and (6) providing a foundation for technology use that increases independence in adults with IDDs, thereby improving their quality of life. Digital documentation could also facilitate timely access to information about adults with IDDs for the diverse stakeholders who help support them.

However, there are risks associated with adopting technology-based data collection tools, including loss of data or an inability to log new data during technology failures. Moreover, to achieve the goal of capturing higher-quality data during work shifts, it will be necessary to allow users to customize the mobile app based on specific clients' support plans. This will add complexity, which could negatively impact user acceptance because many DSPs do not have a great deal of experience with technology. However, it is possible that supervisors or other employees at agencies that employ DSPs could learn to use an administrative portal to customize the mobile app based on clients' needs for support.

In any case, it will be important to obtain input from other stakeholders, such as behavioral supervisors, agency directors, and families, in future efforts, particularly as selection of suitable technology is likely the responsibility of the workspace and employer, and communication of data extends beyond DSPs. In the long term, technologies that support data collection will need to be integrated into existing report generation tools. Eventually, these technologies could even leverage artificial intelligence to create first drafts of DSPs' end-of-shift reports. If this sort of capability is developed, it will be very important to identify strategies for ensuring privacy and security and to consider the ethical implications of using artificial intelligence technologies [78,79].

Finally, while the DAT development effort focused on providing technology that supports DSPs, it is likely that many other types of direct workers could benefit from a similar platform (eg, HHAs, care workers, personal care assistants, certified nursing assistants, and nursing home assistants) [57,80-83]. This is significant because the United States is now facing a severe shortage across the entire direct support workforce [84,85] due in large part to the COVID-19 pandemic. As in the case with DSPs, the shortage in the direct support workforce is harmful to both these workers and those who rely upon them for support [86,87]. A report from the Centers for Disease Control and

Prevention revealed that in 2016 a total of 61 million adults (approximately 1 in 4) living in the United States had a disability that impacts major life activities [88]. Many of these adults do, or will eventually, depend upon direct support workers for assistance with activities of daily living.

In summary, future efforts should not only increase the capabilities and robustness of the initial DAT prototypes and consider the needs of family members, medical providers, behavior analysts, and others who would benefit from timely accurate data about adults with IDDs but also explore how these tools could be adapted to meet the needs of other types of direct support workers by eliciting information and feedback from these workers.

Conclusions

DSPs play a critical role in the care of adults with IDDs. Technology can help mitigate the high turnover rates, poor job satisfaction, and the burden of necessary data collection and documentation that negatively impact DSPs' ability to care for these adults. The user-centered research effort reviewed here produced proof-of-concept prototypes of tools intended to improve the effectiveness and job satisfaction of DSPs. The results of the pilot test indicate that these tools are likely to provide the intended benefits to DSPs and thus have the potential to help improve the quality of life of clients served by DSPs.

Future research should include testing more robust feature-enhanced versions of the DAT over longer periods in even more diverse settings where DSPs provide support to adults with IDDs. Additional work should also include identifying or developing an instrument to reliably assess report quality and time-motion studies of DSPs before and during longer trials to help quantify how much time DSPs spend generating required documentation. One time-motion study of physicians working on hospital wards found that the physicians believed that they were spending more time on documentation and other administrative tasks than they actually were [89].

In any case, the work reported here, despite its limitations, provides valuable insights into how technology could benefit DSPs and the people they support. Feedback from DSPs indicates that the highest-priority feature enhancement for the DAT prototypes is enabling the mobile app to store data locally to support in-the-moment data collection without Wi-Fi connectivity. Several other enhancements, such as shared task lists, were identified as part of the initial user needs analysis activities performed at the start of this effort [16]. In addition to adding some of these capabilities, future work should identify the needs and constraints of the service providers who employ DSPs to identify barriers to adopting data collection and documentation technologies, such as costs, adaptability in small operations, the need to protect confidentiality, minimizing potential technology damage, and preventing data loss. Such work could help enable future versions of the DAT to supply all caregivers and service providers with the information necessary for better overall service, outcomes, and quality of life for adults with IDDs.

Finally, this line of research needs to be expanded because it could have a profound impact on the health and welfare of

several other adults beyond those with IDD who are supported by direct support workers: older adults, individuals with physical disabilities, and individuals with severe mental illness. Furthermore, the direct support workers themselves could also benefit from technologies such as DATs that enable quick and easy in-the-moment data collection and facilitate end-of-shift reporting.

Acknowledgments

Funding for this work was provided by a grant from the New Jersey Department of Health Governor's Council for Medical Research and Treatment of Autism (CAUT2020APL016). The authors would like to thank the direct support professionals who participated in these studies for sharing their valuable experiences and perspectives, the leadership of the 3 organizations where we conducted the pilot tests, and Adam Jonas and Morgan Murphy for helping with the thematic analysis of the responses to the open-ended survey questions.

Abstract

Background: In Canada, adults with chronic noncancer pain face a persistent insufficiency of publicly funded resources, with the gold standard multidisciplinary pain treatment facilities unable to meet the high clinical demand. Web-based self-management programs cost-effectively increase access to pain management and can improve several aspects of physical and emotional functioning. Aiming to meet the demand for accessible, fully automated resources for individuals with chronic noncancer pain, we developed a French web- and evidence-based self-management program, *Agir pour moi* (APM). This program includes pain education and strategies to reduce stress, practice mindfulness, apply pacing, engage in physical activity, identify and manage thinking traps, sleep better, adapt diet, and sustain behavior change.

Objective: This study aims to assess the APM self-management program's feasibility, acceptability, and preliminary effects in adults awaiting specialized services from a center of expertise in chronic pain management.

Methods: We conducted a mixed methods study with an explanatory sequential design, including a web-based 1-arm trial and qualitative semistructured interviews. We present the results from both phases through integrative tables called joint displays.

Results: Response rates were 70% (44/63) at postintervention and 56% (35/63) at 3-month follow-up among the 63 consenting participants who provided self-assessed information at baseline. In total, 46% (29/63) of the participants completed the program. We interviewed 24% (15/63) of the participants. The interview's first theme revolved around the overall acceptance, user-friendliness, and engaging nature of the program. The second theme emphasized the differentiation between microlevel and macrolevel engagements. The third theme delved into the diverse effects observed, potentially influenced by the macrolevel engagements. Participants highlighted the features that impacted their self-efficacy and the adoption of self-management strategies. We observed indications of improvement in self-efficacy, pain intensity, pain interference, depression, and catastrophizing. Interviewees described these and various other effects as potentially influenced by macrolevel engagement through behavioral change.

Conclusions: These findings provided preliminary evidence that the APM self-management program and research methods are feasible. However, some participants expressed the need for at least phone reminders and minimal support from a professional available to answer questions over the first few weeks of the program to engage. Recruitment strategies of a future randomized controlled trial should focus on attracting a broader representation of individuals with chronic pain in terms of gender and ethnicity.

Trial Registration: ClinicalTrials.gov NCT05319652; <https://clinicaltrials.gov/study/NCT05319652>

Introduction

Background

The prevalence of chronic pain, including chronic cancer pain in adults, is estimated to be between 18% and 21%, with severe repercussions for all aspects of the lives of those affected, their families, and society [1-3]. Chronic pain affects patient-perceived health status and psychological functioning; decreases energy levels; and hinders engagement with physical, emotional, cognitive, and social activities [3-6]. These impacts can strain familial and social relationships and affect work performance [7]. Living with chronic pain often involves increased medical expenditures and detrimentally affects one's financial well-being [3,6]. In addition, the wait for services is not without added consequences to these repercussions, with long wait time (12-30 months) being associated with further deterioration in pain-related interference, psychological distress, and pain acceptance [3,8-10].

In Canada, adults with chronic noncancer pain face a persistent insufficiency of publicly funded resources, with the gold standard multidisciplinary pain treatment facilities being unable to meet the high clinical demand [1,2,11]. Since 2019, the Canadian Task Force has reaffirmed the necessity to implement equitable and innovative ways to deliver health interventions in a timely manner in the public network [12,13]. Web-based self-management programs that include exercise, sleep hygiene, pacing, and a healthy lifestyle are endorsed as part of the therapeutic considerations and recommendations for chronic noncancer pain management [14]. These programs have shown an impact on patients' pain intensity, pain interference [15,16], anxiety [15,17], depression [17,18], stress [18], catastrophizing, and self-efficacy [19].

The lack of accessible and reliable unguided web-based self-management programs tailored to French-speaking individuals with chronic noncancer pain is a significant yet solvable health services gap. Over the years, individuals with lived experience, organizations, and researchers have stressed the relevance and importance of actively involving patient partners in the health intervention development process [20-25]. Therefore, a novel French web-based self-management program for chronic noncancer pain developed in collaboration with individuals with lived experience could meet the specific needs of French-speaking individuals [26].

Objectives

This study aims to (1) assess the feasibility and acceptability of the *Agir pour moi* (APM) self-management program and trial procedures and (2) explore preliminary outcomes in individuals living with chronic noncancer pain.

Methods

Study Design

We conducted a mixed methods sequential explanatory study consisting of a single-arm, pre- and postintervention trial, followed by qualitative, semistructured interviews with adults experiencing chronic noncancer pain and awaiting services from a center of expertise in chronic pain management [27-29]. We registered the trial at ClinicalTrials.gov (NCT05319652) and followed the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) and guidelines for reporting nonrandomised pilot and feasibility studies [30,31].

Ethical Considerations

The University Hospital Centre (CHU) de Québec-Université Laval Research Ethics Board approved the study (#2023-6312).

Knowledge Users' Involvement

A total of 7 individuals with lived experience of chronic pain, 5 health care professionals with experience and expertise in chronic pain management, 3 medical students, and 1 graphic designer contributed to the program's codevelopment. We engaged in web-based, phone, or email conversations over a period of 1.5 years. All knowledge users could contribute to various aspects of program development, including its identity (eg, colors, logo, and name), structure (eg, lesson sequence, content organization, and navigation), content (eg, self-management strategies, theoretical content, and testimonials), and learning modalities and behavior change techniques (eg, personal plans, reflective activities, and interactive scenarios). These knowledge users were not further involved across the duration of the trial, but individuals with lived experience initially guided the team toward reducing the questionnaire burden to a minimum for the participants.

Study Setting, Participants, and Recruitment

We recruited participants from the center of expertise in chronic pain management waitlist at the CHU de Québec-Université Laval. This center provides superspecialized services intended for complex chronic pain cases requiring a technical platform and multidisciplinary team. Most individuals referred to such centers experience significant impairments, including high pain levels interfering with their daily life, moderate to extremely severe depression, and pain-related sleep disturbance. Most of them take prescription analgesic medication and have already consulted different types of health care professionals [2].

Using the center's assigned priority level, between June and August 2022, we sent 500 invitation letters to adults (aged >18 years) with chronic noncancer pain (for >3 months) unlikely to receive services within the next 6 months. Interested individuals were to email us to set an eligibility interview, confirming that they understood French, had access to a computer and high-speed internet, had not started a new treatment for pain

within the last 1 month and agreed to notify us before starting a new one, were available for the duration of the study, and were able to provide informed consent. We excluded individuals who participated in a chronic pain self-management program within the last year or those who were scheduled for surgical treatment within 6 months. Following the assessment for eligibility, a research team member explained the study procedures and recorded verbal informed consent.

Intervention

The codevelopment of the APM self-management program (thereafter APM or the program) is detailed [32] and available in the study by Marier-Deschenes et al [33]. Briefly, we designed a cognitive behavioral therapy (CBT)-centered, web-based self-management program that would enable

participants to develop their self-management skills autonomously (eg, goal setting), practice suggested self-management strategies (eg, pacing), and sustain new behaviors (eg, respect of limits). Despite the diverse nature of our targeted population, the proposed self-management strategies to explore and develop are mostly universal, spanning areas such as managing thoughts and emotions, gradually resuming physical activity, practicing pacing, and adopting good sleep hygiene. The program is self-guided (ie, unguided) in that it provides the same information as face-to-face programs offered in tertiary pain clinics but without therapeutic support from health care professionals [34]. It is structured around weekly lessons over an 8-week period with content that encompasses 26 different behavior change techniques [35] and a downloadable personal plan (Table 1).

Table 1. Summary of Agir pour moi (APM) program's topics and self-management strategies with associated content.

Week	Topics and strategies	Lesson headers
Foreword	What does APM offer?	<ul style="list-style-type: none"> • What is self-management? • Who is this program for? • Will you have less pain? • Key attitudes to adopt • How to navigate the program?
Week 1	Introduction	<ul style="list-style-type: none"> • What is chronic pain? • Are you ready for self-management? • How to set specific, measurable, appealing, realistic, and time-bound (SMART) objectives?
Week 2	Engage in well-being activities	<ul style="list-style-type: none"> • Reduce stress • Experience mindfulness
Week 3	Practice pacing	<ul style="list-style-type: none"> • Follow-up on last week's objective • Evaluate your energy expenditures
Week 4	Practice pacing, continued	<ul style="list-style-type: none"> • Follow-up on last week's objective • Planning your weeks
Week 5	Engage in physical activity	<ul style="list-style-type: none"> • Follow-up on last week's objective • Stretching exercises • Engage in physical activity that you enjoy
Week 6	Take care of your thoughts	<ul style="list-style-type: none"> • Follow-up on last week's objective • Identify thinking traps • Perceive the positive
Week 7	Revise your lifestyle habits	<ul style="list-style-type: none"> • Follow-up on last week's objective • Promote sleep • Adapt your diet
Week 8	Plan for the future	<ul style="list-style-type: none"> • Reflect on previous objectives and further goals • Sustain the change

The program incorporates a variety of media, including photos, infographics, interactive scenarios, tables, audio recordings, and videos. All content is fully narrated, with short audio clips accompanying written information in each lesson, ensuring accessibility in both formats. Interactive exercises such as quizzes, drag-and-drop questions, and real-life scenarios enhance understanding.

Participants were encouraged to set and track their own weekly objectives related to the topic in their personal plan, which

serves as our learner's workbook. This plan features reflective, observational, monitoring, problem-solving, and action-planning activities.

Participants were advised to allocate 60 to 90 minutes weekly for program activities. They had the flexibility to divide the lessons into multiple short sessions; completing each lesson in 1 sitting was not necessary. While participants were encouraged to follow the program sequentially, all 8-week content was readily accessible.

Following the program poses minimal health risks. The program incorporates low-intensity activities, such as stretching exercises, which might cause temporary discomfort when resumed. However, the risks associated with physical inactivity, including the development or worsening of chronic illnesses, outweigh those of gradually resuming physical activity.

Quantitative Data Collection and Outcomes

Overview

Participants were assigned a log-in user ID and password for the program's web-based platform. They completed self-reported questionnaires on the web at 3 time points: preintervention, postintervention, and 3 months after completing the program. We sent an email reminder to those who did not log in at least once a week or complete questionnaires at the appropriate time. Participants who completed all questionnaires were eligible for a random computerized drawing of 5 CAD \$75 (US \$55.89) gift cards. We provided participants facing technical difficulties with phone support. We used REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web application, for creating and managing surveys and databases.

As this was a feasibility study, we did not perform a power calculation on measures of effect but rather aimed at estimating

the number of eligible participants and the potential recruitment rate from the center of expertise in chronic pain management waitlist. Therefore, this study is not appropriately powered to assess APM's efficacy [36].

Feasibility and Acceptability Outcomes

We considered the following outcomes in assessing the feasibility of the intervention and research methods and the acceptability of the program: (1) feasibility of recruitment (number of referred adults who responded to the invitation and consented to participate in the study and number of interested adults excluded based on inclusion and exclusion criteria), (2) feasibility of data collection (rate of response to and completion of the questionnaires at each time point), (3) acceptability for those who engaged with the program (mean score to the Acceptability eScale, which includes dimensions of usability and satisfaction) [37,38], and (4) engagement (number of lessons completed). Participants completing at least 6 (75%) out of the 8 weekly lessons were defined as program completers.

Effects Measures

We opted for the French versions of the following self-reported measures based on the recommendations of the Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials [39] (Table 2).

Table 2. Self-reported measures.

Measures	Items, n	Constructs	Score range	High score meaning
Pain Self-Efficacy Questionnaire [40,41]	10	Individual's confidence to perform activities while experiencing pain	0-60	Better self-efficacy
Pain intensity subscale of the Brief Pain Inventory [42,43]	4	Worst, least, average, and current pain intensity	0-10	Worse pain intensity
Pain interference subscale of the Brief Pain Inventory	7	Impact of pain on general activity, mood, walking ability, normal work, sleep, relationships, and enjoyment of life	0-10	Worse pain interference
Anxiety subscale of the Hospital Anxiety and Depression Scale [44]	7	State of anxiety	0-21	Worst anxiety symptoms
Depression subscale of the Hospital Anxiety and Depression Scale	7	State of depression	0-21	Worst depressive symptoms
Pain Catastrophizing Scale [45]	13	Catastrophic thinking and maladaptive responses to pain	0-52	Worst catastrophizing
Patient Global Impression of Change Scale	1	Patient's rating of overall improvement	1-7	Greater change

Statistical Analyses

We performed descriptive statistics using means (SD) for continuous outcomes and frequencies (%) for categorical outcomes. We compared pre-, post-, and follow-up intervention scores for effect measures using repeated-measures linear models. All statistical analyses were conducted using R software (version 4.3.0; R Foundation for Statistical Computing) in RStudio (version 2023.06.0; Posit PBC) [46,47]. Models were fit using lme4 (version 1.1-33; R Foundation for Statistical Computing) [48]. Model fit evaluations and assumption checks were done through visualizations using performance (version

0.10.4) [49]. Effects were considered significant when the 95% CI for the estimates did not include 0.

Qualitative Data Collection and Outcomes

Overview

We formed a heterogeneous group of 20 potential participants using their Acceptability eScale and pre- and posteffect measure scores. We invited participants with positive and negative impressions of the intervention and those for whom we could observe the effects on functioning or not. From a practical perspective, we made the decision to not interview individuals who did not engage with the program at all, as they would not have been able to provide valuable insights into the program's

acceptability and feasibility. However, we conducted interviews with participants who did not complete the program; they were just not specifically selected based on this criterion. We conducted semistructured, audio-recorded, 40-minute phone interviews 5 to 7 months after the intervention. We achieved data saturation with 15 interviews (12/15, 80% women and 3/15, 20% men) and did not deem it necessary to conduct further interviews [50].

Data Analysis

We analyzed the transcriptions using inductive and deductive thematic analysis based on the motivational model for pain self-management [51]. The lead author read the interviews multiple times to obtain a detailed understanding, then coded them according to the research questions and with consideration for the model's components. According to the model by Jensen et al [51], the willingness to embrace pain self-management behaviors is influenced by 2 primary factors. First, it is molded by beliefs concerning the perceived importance of these behaviors, encompassing considerations of cost/benefit ratio, learning history, and current contingencies. Second, self-efficacy, denoting personal beliefs about one's abilities to accomplish a specific task, also plays a pivotal role in shaping the inclination toward behavior change. Furthermore, to ensure the validity of the analysis, a research associate coded and discussed 3 interviews. Then, the lead author further identified meaningful units and assembled them into descriptive categories. She analyzed, interpreted, and summarized categories into 3 explanatory themes that were then discussed among all coauthors [52].

Integration

We addressed our study's main objectives by integrating the quantitative and qualitative results, drawing on all relevant data. We opted for 2 approaches: a weaving approach through the narrative and 2 joint displays presenting categories and associated quotes explaining the quantitative data [53,54].

Results

Feasibility

From the 500 invitations sent, 74 (15%) individuals expressed interest, of which 65 (13%) were confirmed eligible. Of these 65 eligible individuals, 63 (97%) consented to participate (Figure 1). A total of 9 (12%) of the 74 participants were ineligible due to unavailability during summer, current services from a pain clinic or rehabilitation center, lack of belief in program helpfulness, absence of computer access, low literacy level, and being unreachable. Response rates were 70% (44/63) at postintervention and 56% (35/63) at 3-month follow-up. A total of 15 (24%) of the 63 participants exited the study for reasons mostly unrelated to the intervention. Missing data were attributed to connectivity problems with the REDCap platform.

Participants were almost exclusively White (61/63, 97%) and female (44/63, 70%), with a mean age of 54 (range 24-75) years. On average, participants experienced chronic pain symptoms for 12 (SD 13.6) years, and most (34/63, 54%) had chronic musculoskeletal pain (Table 3).

Acceptability

Among the 63 participants, 38 (60%) completed the Acceptability eScale. The average total score for these participants was 25.2 out of 30 (acceptability threshold=24). In [Table 4](#), we have presented the integrated results of the quantitative and qualitative phases. The mean score for each of the 6 items from the Acceptability eScale is listed in the first

column. Each item score ranges from 1 to 5, with higher scores reflecting higher acceptability. The interviews revealed a consistent theme: a program that is globally acceptable, easy to use, and engaging. Interviewees felt they could opt for what worked for them once they had experienced it completely. They would keep most of the program as is, with some potential minor improvements.

Table 4. Joint display of participants' perceptions of the Agir pour moi program's acceptability.

Quantitative results	Qualitative findings	Integrated analysis
Mean score of the ease-of-use item: 4.0/5 (SD 0.9); 5 (8%) of the 63 participants needed support at least once to log in	<ul style="list-style-type: none"> Ease of navigation <ul style="list-style-type: none"> "Everything is very easy. We can go forward, we can go back, we can resume, we can close, come back. No, everything is perfect." [INT^a 7] User-friendly, except for the platform hosting the web-based program <ul style="list-style-type: none"> "As I was saying, when you're a participant, and you're logged in, I think it is super user-friendly ... It's more when you get to the big link page, I believe that's a little less user-friendly." [INT 13] 	The program was user-friendly once logged in, but connecting to the hosting platform could have been more intuitive.
Mean score of the strategies' helpfulness item: 4.1/5 (SD 0.9)	<ul style="list-style-type: none"> Picking the tool you need <ul style="list-style-type: none"> "That's it, because if you don't have that resource, what do you do? On a day when things aren't going well, you brood, you grumble all day long; you're in pain, you're angry, and you lose your patience, so if you think a little bit after having followed the program, you go back and find the tool you needed in it. Because as far as I'm concerned, the program wasn't one singular tool; it was a toolkit, and then you take what you need." [INT 10] "I was happy to see all this in the program, because it helped me a lot personally." [INT 8] Adaptable to one's situation <ul style="list-style-type: none"> "It's good to have all the suggestions in there because, ultimately, we keep what suits us and works well for us. So there's something for everyone, for everyone's tastes, and it's not the same stuff that works for everyone." [INT 12] Developing further the strategies that suit you best <ul style="list-style-type: none"> "It's been like a springboard to the rest of my journey, to do some reading... .. it sure helps with the perception of managing what we're capable to manage on our own." [INT 6] 	Some strategies benefited many participants, while others only reached a minority. Interviewees latched on to at least 1 lesson that triggered something in them. They acquired something useful out of it, although not all appreciated the same strategy or strategies.
Mean score of the required time item: 4.2/5 (SD 0.7)	<ul style="list-style-type: none"> Objective-dependent efforts <ul style="list-style-type: none"> "I didn't think it was very demanding, and after that, the rest is up to you... then you do it at your own pace, so I thought it was very appropriate." [INT 13] Motivating and minimal effort required <ul style="list-style-type: none"> "Oh, for me, it wasn't that much effort, no. Perhaps the first week's lessons were a little longer than the others that followed. But no, it's really not...it didn't take me any effort, no. It was motivating." [INT 7] A little demanding yet tangible <ul style="list-style-type: none"> "I think that's what makes it interesting. Because just reading is okay, but afterward, when you do the exercise, you push yourself a bit on the spot; sometimes, you don't really feel like doing it, but it makes it more tangible." [INT 11] 	The time and effort required to follow the program and apply self-management strategies were adequate, but interviewees highlighted the necessity to reach a certain degree of readiness to change because taking action required some investment.

Quantitative results	Qualitative findings	Integrated analysis
Mean score of the use appreciation item: 4.3/5 (SD 0.7)	<ul style="list-style-type: none"> Adapting use to your schedule <ul style="list-style-type: none"> “As I said, we could follow it whenever we wanted. I chose the time of the day when I was in better shape. That was something I thought was very nice, you know, not having to connect at a fixed time.” [INT 15] Staying engaged <ul style="list-style-type: none"> “It went really well. Then, you know, you’d scroll, then you’d click, scroll, click, so that, you know, it kept you present; you had to be there... It’s not like a video you start and then lose focus. That’s very interesting too.” [INT 11] Fun program <ul style="list-style-type: none"> “it’s super fun.” [INT 13] 	Participants appreciated navigating the program at their convenient time. It was fun to use, and the need to scroll through the content kept them engaged.
Mean score of the comprehensibility item: 4.5/5 (SD 0.6)	<ul style="list-style-type: none"> Very simple explanation <ul style="list-style-type: none"> “It’s very...it’s simple. It’s very well explained.” [INT 7] 	The program presented well-explained, easy to understand information.
Mean score of the satisfaction item: 4.1/5 (SD 0.7)	<ul style="list-style-type: none"> Participants would recommend the program “I really enjoyed the program. I liked that there were videos, it made it more dynamic, I thought they were well done, well constructed ... I’d definitely recommend it.” [INT 12] Down-to-earth expectations, no promises <ul style="list-style-type: none"> “I thought the program was interesting... Knowing what’s in it, I’d do it again today... In the beginning, you don’t make any promises. In the program, it says ‘learning to live with chronic pain’, but there’s no promise; it doesn’t say: ‘Hey, when you get to the eighth week, you’re pain-free’.” [INT 10] “But I think the program doesn’t apply to me... You know, it’s like, geez, I thought I would discover something amazing. It’s been four years now, I’ve seen three internists, lots of doctors, and I went to a maxillofacial specialist back in September, and we’re trying to figure it out, but nobody knows what it is. I’m still waiting to find out.” [INT 2] 	All interviewees mentioned they would recommend the program to someone in a similar situation, reflecting satisfaction. Participants with high expectations for very specific problems might have been less satisfied.
Total mean score of the Acceptability eScale ^b : 25.2/30 (SD 3.0)	<ul style="list-style-type: none"> No change required <ul style="list-style-type: none"> “Well, it went well. I liked it a lot, I really liked the way it was put together, the way it was presented, gradually if you like. The program is super well done, I’m going to revise it, but I wouldn’t change a thing if you asked me if there was anything to change.” [INT 1] Use of multiple media <ul style="list-style-type: none"> “I loved it because there were testimonials. It wasn’t just reading. I put on my headphones, and I didn’t have to read. I listened. I like to listen, and then as I filled out my sheet, I’d make notes on the paper as I listened. Sometimes I’d take breaks, put it on pause and come back.” [INT 9] Promoting access for everyone <ul style="list-style-type: none"> “God, yes, it’s acceptable, and everyone should have access to it.” [INT 7] 	Overall, the program was well developed for our target users and proposed an appreciated gradual approach to the application of different strategies.
Of the 15 interviewees, 10 (67%) were still accessing the program or using the personal plan on an occasional to regular basis for >5 months after they finished it for the first time.		While the web-based format did not suit everyone, participants appreciated using it whenever they wanted and having the possibility to go back to previous lessons for a refresher. Not traveling to learn self-management strategies was a significant advantage. Had the program been offered through weekly classes at a specific time and place, some participants would have been unable to drive and attend.

Quantitative results	Qualitative findings	Integrated analysis
	<ul style="list-style-type: none"> Web-based content accessibility <ul style="list-style-type: none"> “It helps a lot that it’s online, so you can do it when it suits you. Because for me, if I’d had to travel, you know, appointments and things like that, I’d have had a lot more trouble because it’s hard for me to go on the road, whereas here, it was much more accessible, which is really great.” [INT 12] Possible punctual use once the program is done <ul style="list-style-type: none"> “Then again, it’s not a program that once it’s done, it’s done, and you can’t go back to it; you can go back and look. So you can continue to use it.” [INT 10] 	

^aINT: interviewee.

^bThe Acceptability eScale has 6 items with a total score ranging from 6 to 30. Higher scores represent a high level of acceptability.

Engagement

Of the 63 participants who consented to the study, 46 (73%) started the program, 29 (46%) finished at least 6 weeks’ lessons, and 26 (41%) completed all the lessons (Table 5).

Participants generally followed the lessons in order. Among the 19 noncompleters who did not withdraw from the study, 10 (53%) wrote back to us after receiving the email reminder. These participants provided personal reasons for not following the program according to schedule, including sickness or mental

health issues among close relatives, the death of a parent, estate management, and increased symptoms. Including participants who withdrew from the study, 21 (33%) out of 63 participants were not connecting weekly or stopped at some point for reasons external to the study or the intervention. Reasons related to the program included having already applied the proposed strategies and having trouble connecting. Of the 63 participants, 5 (8%) needed help logging in independently (n=3, 60% only required information by email and n=2, 40% received phone support and succeeded with a step-by-step explanation but did not connect afterward).

Table 5. Participants’ weekly lessons’ level of completion (N=63).

Weekly lessons	Completed the lesson, n (%)	Partially completed the lesson, n (%)	Never initiated the lesson, n (%)
Lesson 1	42 (67)	4 (6)	17 (27)
Lesson 2	37 (59)	6 (10)	20 (32)
Lesson 3	33 (52)	6 (10)	24 (38)
Lesson 4	32 (51)	3 (5)	28 (44)
Lesson 5	30 (48)	5 (8)	28 (44)
Lesson 6	29 (46)	3 (5)	31 (49)
Lesson 7	28 (44)	4 (6)	31 (49)
Lesson 8	26 (41)	4 (6)	33 (52)

Interviewees mentioned other factors potentially undermining the engagement in completing the program. Interviewees highlighted that timing and pain acceptance played an essential role in their perseverance or lack thereof. For example, understanding that no specific cause for her pain issue might ever be found was a turning point in a participant’s proactivity:

When I was still at the stage where I thought we would find a cause, it is something I really wouldn’t have been ready to do, the program... Doing the program, really, it sort of happened right at the time I got to the stage of realizing: ‘Okay, now I’m going to stay that way. What am I going to do with this?’ I felt a lot of psychological distress. Then, looking more into this (psychological) aspect through the program, it was as if I needed to do this. I’m not done, but it’s come a long way. And also, time matters; getting used to accepting. [INT 11]

For some interviewees, occasional or regular coaching would have been necessary to sustain motivation, answer questions, and revise their personal plan. Of the 63 participants, 2 (3%) mentioned their need for support and feedback:

There were ups and downs. There was no one to answer my questions. I found that very, very hard, especially the first few weeks. [INT 5]

I really need someone who’ll say, “Go, we’ll do this, we’ll do that.” In writing, I’ll read, and I’ll say to myself, “Oh my god, that’s wonderful,” but I’ll do it 2 or 3 times, and then I’ll give up... But I’ve always been like that; I’ve always needed someone to push me, not in everything, but especially since I’ve been ill. [INT 9]

There are participants who related less to parts of the program because their activity level was not adequately represented:

We always assume that people aren't physically active when in pain. Or if they are, clearly, it can't be too much. But you know, on my part, I will get injured before I stop [laughs]. [INT 11]

Furthermore, interviewees described factors mostly contributing to their engagement in completing the program. They expressed a connection to the program's content and felt more hopeful, supported, and less alone listening to the multiple integrated testimonials of individuals with lived experiences applying the strategies:

For me, it was seeing lots of testimonials from many people ... that's what really attracted me. To understand it better and to see that that's how it is: everyone's gone down exactly the same path I went through, and we all arrive at the same point, not being able to get out, not seeing anyone. It seemed like it was just me who was going through this. So, it gave me a boost. It also gave me a bit of confidence... I had the impression of being accompanied. [INT 14]

Moreover, a participant living far from a major urban area highlighted the appeal of these short videos:

Here, in my neighborhood, there's no program like that. I know there are places, there are meetings for people with chronic pain to chat, have a coffee, and things like that. We don't have that here. I found it fun to listen to them and know we're not alone in this. [INT 9]

On the one hand, interviewees thought the weekly connection and review of personal objectives supported their motivation and helped them stay focused:

I guess I needed to be held by the hand for a while, and to be guided through it... There was some kind of follow-up. So you weren't left to your own devices as much. [INT 12]

On the other hand, it might have been too much for some individuals:

There were too many things. Every week there was something to do, you know. You didn't have time to swallow the information and were already moving on to other things... Maybe it would have taken a week or two between each chapter. What made it easier was to stop for a few weeks, then think about all the information. [INT 5]

There is a fine line between what feels like a comprehensive program and what feels like an overwhelming task for unsupported participants. While most interviewees showed interest in all the presented topics and perceived the lessons' sequence as logical, gradual, and positive, specific strategies within these lessons might have lacked appeal to some participants. A suggestion was made that participants could start with their most appealing lessons after covering the pain education section. While we invited everyone to complete the tasks in order, the content was freely available and one could decide to skip parts of the program if desired.

Through the interviewee discourse, we could distinguish microlevel engagement, including the number of lessons they have followed, from macrolevel engagement, referring to the depth of involvement with the behavior change process, such as applying strategies consistently in a real-world setting [55,56]. Behavior change could be challenging, with participants facing expectations from others and their own. However, the program provided them with a better understanding of why it is beneficial to do so, and some participants made it a priority. Getting into the habit of doing something sometimes required broader or prior changes such as setting boundaries with the extended family. The notion of beginning with the easiest tasks was mentioned to underscore the initial challenge of implementing a strategy. Interviewees described the integration of certain habits into their routine as gradual, sometimes evolving over several months, without the participants realizing it. Over 5 months after finishing the program, interviewees described what they continued to apply and how some strategies became part of their routine:

Over the weeks, I really selected what had a positive impact on me. Then I do it regularly, almost every day. I'm into meditation, cardiac coherence, managing energy, stretching, and the gratitude journal. The other things, I can't think of anything else I could do more. [INT 6]

I still do so to this day, which is unusual for me. So, I thought it was really, really good... I'm more active now too, I do my exercises almost daily. I used to say to myself, "It's no use, I won't be able to do it. I don't have the energy. I'm in pain. I'm out of shape." Now I say, "Look, do it, even if it's just two minutes today, it'll at least be two minutes, you'll have done it." [INT 12]

Preliminary Effects Outcomes

We observed an indication of improvements over time in self-efficacy, pain interference, depression, and pain catastrophizing between baseline and postintervention (Table 6). The results of the linear model corrected for the individual (treatment effects) are presented in Table 7. In addition, 24 (56%) out of 43 participants reported some level of improvement on the Patient Global Impression of Change Scale after the intervention.

From a qualitative perspective, 14 (93%) out of 15 interviewees reported a different set of effects 5 to 7 months later. These effects included, among others, shorter and less frequent pain attacks, better management of pain, higher sense of control, less comparison with life before pain, improved psychological state, more patience, less frustration and irritability, forgiveness toward oneself, higher activity level, more self-care, and increased social life.

In Table 7, we have presented the integrated results of the quantitative and qualitative phases, with the overarching theme that the various effects observed were potentially influenced by macrolevel engagements.

The effects of the lifelong task of self-management might become noticeable over time. A participant mentioned

recognizing these effects several months after completing the program:

While I was going through (the program), well, you know, it was okay. In my case, it's really like it slowly

permeated me, but in a positive way, I mean. [INT 11]

Therefore, conducting the interviews 5 to 7 months after program completion was deemed appropriate.

Table 6. Mean scores for outcome measures at baseline, postintervention, and 3-month follow-up.

Measure	Subscale or construct	Baseline (N=63), mean (SD)	Postintervention (n=43), mean (SD)	3-month follow-up (n=34), mean (SD)
Pain Self-Efficacy Questionnaire ^a	Self-efficacy	26.9 (13.8)	32.4 (13.3)	32.5 (12.4)
Brief Pain Inventory	Pain intensity	5.5 (1.6)	4.8 (1.5)	5.0 (1.6)
Brief Pain Inventory	Interference	5.7 (2.0)	4.4 (2.0)	4.7 (1.9)
Hospital Anxiety and Depression Scale	Anxiety	9.0 (4.4)	8.4 (4.2)	8.2 (4.0)
Hospital Anxiety and Depression Scale	Depression	8.5 (4.0)	7.2 (3.9)	7.5 (3.8)
Pain Catastrophizing Scale	Catastrophizing	25.3 (10.9)	20.1 (12.2)	20.5 (13.2)

^aA higher score in the Pain Self-Efficacy Questionnaire indicates a high level of self-efficacy.

Table 7. Joint display of participants' perceptions of the Agir pour moi (APM) program's effects.

Quantitative results	Qualitative findings	Integrated analysis
<ul style="list-style-type: none"> Pain Self-Efficacy Questionnaire: the scores increased by 3.06 points on average after intervention (95% CI 1.26 to 4.85), $P=.002$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> Better self-efficacy <ul style="list-style-type: none"> "I'm less inclined to compare myself with my previous life. I see more of what I'm capable of doing today with the abilities I have. That's the main thing, I think." [INT^a 12] "Even though I've seen specialists who gave me medication, in the end, I think I got better by doing this on my own and saying to myself, Okay, I'm basically taking charge... I feel like I can control my pain peaks a bit more, and I know why I will have them." [INT 4] "Let's just say I've relearned how to gain confidence in myself and then say you're capable, go ahead, go take a walk, you can do it." [INT 8] 	Participants' belief in their capacity to do certain things to achieve their goal increased.
<ul style="list-style-type: none"> BPI^b pain intensity subscale scores decreased by 0.32 points on average after intervention (95% CI -0.55 to -0.10), $P=.007$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> No trend in pain intensity changes <ul style="list-style-type: none"> "I can say that my pain is less present and that it's not all I think about anymore. So yes, for my pain, it helped a lot." [INT 5] "It's just that instead of being in pain for nine hours at a time, well, not only have I hardly had any attacks for six, seven months, but when it happens, well the two times it happened, it lasted two, three hours or so, then it's stopped really suddenly, instead of lasting a whole night. So I tell you, it's not so bad." [INT 14] "But the pain remains the same. Sometimes when I'm doing your stuff, I've managed to get away for half an hour or an hour, but it comes right back." [INT 3] "I've done things, like mediation and all that, but it doesn't work." [INT 2] 	There were improvements for some interviewees and no improvements for others. While not measured with the BPI subscale, the frequency of pain crises decreased in some participants. However, as mentioned straightforwardly at the beginning of the APM, pain reduction is not the main objective of a self-management program.
<ul style="list-style-type: none"> BPI pain interference subscale: scores decreased by 0.78 points on average after intervention (95% CI -1.19 to -0.37), $P=.001$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> Less interference <ul style="list-style-type: none"> "I realize that the energy is coming back a little. It's coming back. It's not a complete crash like it used to be for me, and then I'd take a week to recover because I'd gone over the edge. Now, I don't do that anymore ... And in the end, I do a lot more than I used to do that way." [INT 12] "You know, I was more or less able to do some movements, some I couldn't do at all anymore. There are some that I've gradually managed to recover a little, it's not to the maximum here, but ... like putting on my shoes." [INT 15] "Well, I fall asleep faster when I do these exercises. Because I always try to go to bed at the same time, and sometimes sleep doesn't come. So I tell myself I'm going to bed anyway and do some breathing exercises. Then I fall asleep, which doesn't take long." [INT 15] 	Reducing pain interference translates into a gain in energy, a more stable ability to perform tasks, a new capacity to do movements, increased social activities, and better sleep.

Quantitative results	Qualitative findings	Integrated analysis
<ul style="list-style-type: none"> HADS^c depression subscale: scores decreased by 0.73 points after intervention (95% CI -1.21 to -0.25), $P=.005$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> Positive change in depressive state <ul style="list-style-type: none"> “It had been seven years since I’d stopped putting any effort into it and let myself fall, so it...no, no, it whipped me, and then I seemed to become a bit like myself again. I was letting myself go, then it was like: okay, go, I’ve been sinking for seven years, and now it’s time to get back on. It gave me a good boost. ... My mood has changed. I seem to be less, sorry about my French, but I’m less (swear) angry all day long.” [INT 14] Better mood <ul style="list-style-type: none"> “how can I put it, patience, my patience came back, better than when I couldn’t do my things. Yes, yes, that, I’ve made some gains.” [INT 15] “It’s also psychological, you know, like being less on edge in my head, I was a lot like (swears), I can’t do this anymore, I can’t. So I’m in a better mood with the kids. ... It also has a lot to do with irritability, because you know when you’re in pain, you’re always irritable, so if I’m in less pain, I’m less irritable, and I’m more likely to want to go outside with them.” [INT 11] 	<p>Most interviewees did not explicitly talk about depression but many reported being in a better mood, being less frustrated, and being less irritable.</p>
<ul style="list-style-type: none"> HADS anxiety subscale: nonsignificant score decrease of 0.37 points after intervention (95% CI -0.85 to 0.12), $P=.14$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> Anxiety <ul style="list-style-type: none"> “it’s really taken my anxiety level about it down a notch.” [INT 11] 	<p>Following the program does not appear to impact the anxiety state. Only 1 interviewee briefly mentioned a decrease.</p>
<ul style="list-style-type: none"> Pain Catastrophizing Scale: scores decreased by 2.83 points after intervention (95% CI -4.35 to -1.30), $P=.001$. No effects were detected when examining postintervention and follow-up metrics. 	<ul style="list-style-type: none"> Less panic <ul style="list-style-type: none"> “For me, what was a real game changer ... was also realizing that most people in this condition tend to have the same thoughts; thinking, for example, that there’s something perhaps serious hidden behind it, thinking that it will never stop, that you could die from it, and all that. It was good for me, because these are patterns I really have. Then, I thought of myself more like a normal person. ... The panic I used to feel about my pain has almost completely disappeared, and I realize how much I can change my situation myself.” [INT 11] 	<p>The testimonials and theoretical content helped normalize some participants’ catastrophic thoughts and guide them in confronting those and adopting more adapted views. Following the program can reduce catastrophizing.</p>

Discussion

Principal Findings

This paper described a pilot, mixed methods study assessing feasibility and acceptability and exploring the preliminary outcomes of a new self-directed, web-based program for chronic pain among adults awaiting superspecialized services. Collaborating with patient partners experiencing diverse types of pain was a key strategy enabling us to align the program closely with the varied needs and expectations of our wide-ranging audience. We opted for a simple yet attractive layout, providing clear instructions and features to aid those with attention and concentration challenges.

Feasibility, Acceptability, and Engagement

Chronic noncancer pain affects individuals in different ways and to different degrees. Those awaiting tertiary services in Canada experience severe impairments and present with a poor biopsychosocial profile [2]. To specifically recruit these individuals who are not yet patients at the center of expertise in chronic pain management, we could not directly reach out to them. The hospital’s archives had to send them invitation letters. Estimating the response rate in such a specialized context proved challenging because we lacked a benchmark for our expectations. However, a study by Thiblin et al [57], which involved a comparable internet-administered, CBT-based self-help intervention, achieved an 11% enrollment rate by

sending out 509 invitation letters. Considering the documented high dropout rates in similar trials [19,58], we anticipated that 500 invitations would suffice to ensure a minimum of 30 participants responding to questionnaires at all 3 time points. Our enrollment rate for a 3-month recruitment period was similar to or better than those of studies recruiting in tertiary pain treatment facilities [59,60]. The consent rate among potentially eligible adults was acceptable. However, because 4 (6%) out of 63 participants exited the study for surgery purposes and 3 (5%) others for significant changes in their medication, we might need to reconsider how we address these eligibility criteria during the phone interview. Furthermore, considering there are between 1000 and 1500 individuals awaiting services from the center of expertise and that they all would not meet our eligibility criteria, our response rate, although similar to those observed in other studies, would require conducting a future full trial across multiple centers.

Our study yielded comparable data collection results to other web-based intervention pilot trials with approximately 50% (35/63) of response at 3-month follow-up [61,62]. While studies with higher financial incentives (US \$25-\$80 per assessment) during visit assessments or initial motivational interviews had better response rates [60,63-66], we purposefully chose to stay as close as possible to real life where no incentives are offered. We received no negative feedback on the number or length of questionnaires. However, sending email reminders to participants who did not log in or complete the questionnaires at the appropriate time was suboptimal. Making phone calls in addition to email reminders might have provided us with reasons for disengagement and ensured participants received the reminders.

Some interviewees highlighted that the log-in process was not intuitive, leading us to consider modifying this aspect before conducting a full trial. The log-in was essential to the research project but is not part of APM itself and will not apply in real life. Once logged in, accessing APM at their most convenient time and place was a significant asset for our participants, consistent with patients' preferences [21].

APM's codevelopment with health care professionals and people with lived experience of chronic pain allowed a tailored approach to this population's needs and preferences in a web-based self-management program [32]. The interviewees' description of APM aligned with the acceptability score as a globally acceptable, easy-to-use, and engaging program. We based our 24 (80%) out of 30 threshold score for the Acceptability eScale based on the study by Tariman et al [38], suggesting that 80% of the highest possible summary score indicates good program acceptability. However, a score <24 would not automatically deem the program unacceptable. We must examine individual item scores to assess specific program weaknesses. All items scored ≥ 4 ($\geq 80\%$) out of 5, as show in Table 4, indicating no significant flaws requiring major modifications. Minor improvements we could make include adding testimonials from highly active individuals with chronic pain who learned to pace themselves and mentioning that lessons are preferably followed in order but can also be explored based on personal preferences after completing week 1. APM

effectively promoted behavioral change, guided participants in taking action, and served as a reference in the longer term.

While participants' weekly lessons' level of completion was lower than anticipated, it was consistent with what had been observed in other feasibility and pilot studies [62,67-69] and could be explained mainly by reasons external to the study. Our qualitative results alleviated concerns about potential flaws and did not point toward questioning the participant's appeal to the program. Overall, we are confident that the program and trial procedures are both feasible and acceptable.

Preliminary Effects

We explored pre- and postintervention effects as preliminary indications of potential changes in self-efficacy, pain intensity and interference, anxiety, depression, and catastrophizing. Findings yielded relevant results, but these should be interpreted cautiously.

Nevertheless, the qualitative interviews pointed in the same direction as our preliminary quantitative findings. Furthermore, these aligned with the results of a meta-analysis suggesting that following internet-delivered, CBT-centered interventions for chronic pain can lead to small significant improvements in pain interference and intensity, depression, anxiety, self-efficacy, and catastrophizing, with greater treatment effects in anxiety, pain interference, and intensity in guided compared to unguided interventions [34]. Therefore, depending on their perceived importance of change and self-efficacy, individuals with chronic pain may require additional support in reaching readiness to make sustainable changes.

Because we still did not know precisely what clinical, intervention, and study characteristics positively impacted the effects of unguided CBT-based self-management programs for chronic pain, APM offered several self-management strategies [70]. However, we did not expect participants to implement all of them once they completed the program. Participants used this program as a toolbox, as mentioned by an interviewee.

No adverse events were reported throughout the course of this study.

Limitations

This study has some limitations. First, we cannot make definitive statements regarding APM's effects without an appropriate control group, randomization process, and sample size. Indeed, we neither designed nor appropriately powered this feasibility trial to test a specific hypothesis [36]. Furthermore, while the participants presented various pain conditions, most of the female participants were White, as this is the case in similar trials [18,71,72], and were all attached to a single center. Recruitment strategies of a future randomized controlled trial should focus on attracting a broader representation of individuals with chronic pain in terms of gender, ethnicity, and health care institutions. In Quebec City, where our study was conducted, <10% of the population identified as members of a visible minority group in 2021. Expanding our research to cities with greater ethnic diversity could enhance our sociodemographic data and improve the relevance of our findings. Shifting to web-based recruitment methods might allow us to create tailored

invitation messages for specific demographic groups, using a casual design and images, instead of overwhelming potential participants with excessive written information. In our feasibility study, we had to use standardized letters to recruit participants from the waitlist of the center of expertise in chronic pain management. We acknowledge the need to adopt more flexible parameters for future large-scale studies. Furthermore, we might adjust our eligibility criterion, not limiting participation to those awaiting specialized services. This broader criterion could yield a more diverse sample, aligning with our aim to reach a wider demographic. However, we are mindful of the potential impacts on adherence and user satisfaction this broader criterion might pose. Nevertheless, these adjustments reflect our dedication to conducting a comprehensive and inclusive trial, ultimately contributing to a more nuanced understanding of chronic pain management. This may lead us to unforeseen modifications in our program.

Despite widespread internet access in Canada, disparities in internet speed, affordability, and digital literacy persist. APM, being exclusively web-based, poses a limitation in reaching individuals from remote regions and Indigenous communities as well as those in low-income households, older adults, and individuals with disabilities. These groups are disproportionately affected by the digital divide in Canada, making it challenging for them to access our program.

Future Direction

This study provides an initial understanding of APM's potential benefits for this group of individuals with chronic pain awaiting specialized services. Through the interviews, we acknowledged we had not captured the effects on the temporal aspect of pain, such as shorter and less frequent pain attacks, which were crucial

for some participants. Therefore, we could consider adding measures capturing these aspects in a future trial.

Developing a web- and evidence-based, patient-centered, free-of-charge, user-friendly, and French self-management program for chronic noncancer pain represents a potential response to the clearly expressed needs of individuals with this condition. Although the literature increasingly emphasizes the importance of personalization in eHealth, our limited financial resources hindered us from incorporating advanced features. We deliberately chose to focus on fundamental aspects and prioritize what we could offer and support in the long term, establishing the groundwork for a web-based program that could potentially evolve. As a result, the current version did not include personalized features, but it was still perceived as usable and useful. It will be essential to document how the program's implementation makes it possible to respond quickly and more equitably to some of the needs of patients waiting for services or who live far from large centers. APM is currently being used without restrictions in other French-speaking regions and countries. Anyone can use it freely, but a potential hurdle faced when using it abroad pertains to adapting to the accents in testimonial videos and Quebec-specific expressions.

Conclusions

The study findings provided preliminary evidence that the APM program and research methods were both feasible, as suggested by perceived acceptability and engagement. Furthermore, it provided preliminary indications of potential improvements in self-efficacy, pain intensity, interference, depression, and catastrophizing. The study yielded essential results to undertake a future complete trial.

Acknowledgments

The authors would like to thank Sergio Cortez Ghio, a biostatistician who performed the quantitative analysis. The authors would also like to extend their thanks to all those who contributed to the codevelopment of APM. PMD acknowledges support from a Frederick Banting and Charles Best Canada Graduate Scholarship Doctoral program from the Canadian Institutes of Health Research, a Leadership and Sustainable Development scholarship from Laval University, and a scholarship from the Strategic Research Development Fund from VITAM—Center for Sustainable Health Research. AMP holds the Chair in Educational Leadership on Chronic Pain—Medisca, which contributed to the development of the program. Additional funding for this study came from discretionary funds. The funders did not play any role in the design, management, analysis, interpretation, or writing of the manuscript.

Data Availability

The data sets generated during and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

PMD, AMP, and AL contributed to the study conception and design. PMD and AMP supported the details of recruitment and data collection. PMD, AL, and LJ analyzed the results. PMD and AL drafted the manuscript. All authors commented on and revised its previous versions before reading and approving the manuscript to be published.

Abstract

Background: Care partners of people with serious illness experience significant challenges and unmet needs during the patient's treatment period and after their death. Learning from others with shared experiences can be valuable, but opportunities are not consistently available.

Objective: This study aims to design and prototype a regional, facilitated, and web-based peer support network to help active and bereaved care partners of persons with serious illness be better prepared to cope with the surprises that arise during serious illness and in bereavement.

Methods: An 18-member co-design team included active care partners and those in bereavement, people who had experienced serious illness, regional health care and support partners, and clinicians. It was guided by facilitators and peer network subject-matter experts. We conducted design exercises to identify the functions and specifications of a peer support network. Co-design members independently prioritized network specifications, which were incorporated into an early iteration of the web-based network.

Results: The team prioritized two functions: (1) connecting care partners to information and (2) facilitating emotional support. The design process generated 24 potential network specifications to support these functions. The highest priorities included providing a supportive and respectful community; connecting people to trusted resources; reducing barriers to asking for help; and providing frequently asked questions and responses. The network platform had to be simple and intuitive, provide technical support for users, protect member privacy, provide publicly available information and a private discussion forum, and be easily accessible. It was feasible to enroll members in the ConnectShareCare web-based network over a 3-month period.

Conclusions: A co-design process supported the identification of critical features of a peer support network for care partners of people with serious illnesses in a rural setting, as well as initial testing and use. Further testing is underway to assess the long-term viability and impact of the network.

Introduction

Care partners of people with serious illnesses are often overlooked and poorly understood by health care professionals, lack support and educational resources, and are likely to experience significant challenges and unmet needs [1,2]. For many, the work of caring for a person with a serious illness can bring deep satisfaction and can also be challenging [3]. Care partners experience burdens in every area of their lives—emotional, physical, social, spiritual, and financial [2,4,5]. The death of someone with a serious illness (as well as the events leading up to it) also brings hardship, including stress related to loneliness, grief, trauma, role recognition, and self-identity [6-9]. Social isolation and grief are strongly correlated with subsequent depression and related symptoms in bereaved spouses, including sadness, appetite loss, and lower quality of life [5,10]. Bereaved care partners may also face challenges navigating household, financial, social planning, and legal affairs, as well as reintegrating into their local community [11] and accessing available resources. Addressing care partner needs has become a pressing health, economic, and social imperative [12].

Increasingly, care partners are joining online peer support networks to obtain emotional support, access information, and connect and share with others in similar circumstances [13-17]. While people often prefer connecting with health professionals for medical information, they prefer connections with peers over professionals for accessing emotional support or practical advice [18]. In the case of serious illness, when patients may not be well enough to use online peer support networks themselves, care partners are more likely to participate [19].

Previous research has demonstrated a number of variables that contribute to an online peer support network's success or failure [20-22]. Communities that have a clear, defined purpose; foster a strong sense of community; and have a high level of activity are more likely to be successful [20]. Additionally, sustained organizational and financial support for maintaining an online community from inception to maturity is essential, including support for a community manager who sets the tone for the community, creates content, conducts outreach, and fosters a sense of community [20,23]. Successful online networks also harness the interests and abilities of their users to strengthen the community. Networks with more active users are generally more successful [21] because they maintain a critical mass to allow for diversity in experiences and individual attributes,

allowing for the natural formation of relationships and answering questions.

Evidence on the impact of online peer support networks for care partners is promising [14,24-26]. For care partners of people with cancer, studies show evidence of decreased care partner emotional distress [27], negative mood [28,29], and sense of burden [29], as well as increases in quality of life and self-efficacy [27]. For care partners of people with dementia, online networks can lead to improvement in self-efficacy [30], decision-making confidence [31], and care partner and patient relationship quality [32]. Care partners also benefit from being able to freely express their sentiments and provide mutual support in a dedicated digital space apart from their loved ones [33,34]. Even people who observe network activity without participating report that reading about the experiences of others is empowering and informative [35,36]. Online networks offer certain advantages: 24/7 home access, flexibility (communication is often asynchronous), anonymity, and a wide range of expertise and experience not limited by geography [37-39].

Online peer support networks for care partners often target specific health conditions (eg, breast cancer and Alzheimer dementia) or stages of caregiving (treatment vs bereavement), but infrequently support care partners of people with diverse conditions or the transition between stages of caregiving. They may also fail to provide active facilitation and moderation; identify and vet regional resources and support from local peers; or provide the possibility of meeting in person. A co-design process can elicit those factors that matter most to the people for whom the network is intended to serve and ensure the successful adoption of the proposed solution [40].

The objective of this paper is to describe a co-design process and the resulting key functions and specifications for a regional, facilitated, and web-based peer support network that can meet the needs of active and bereaved care partners of persons with serious illnesses.

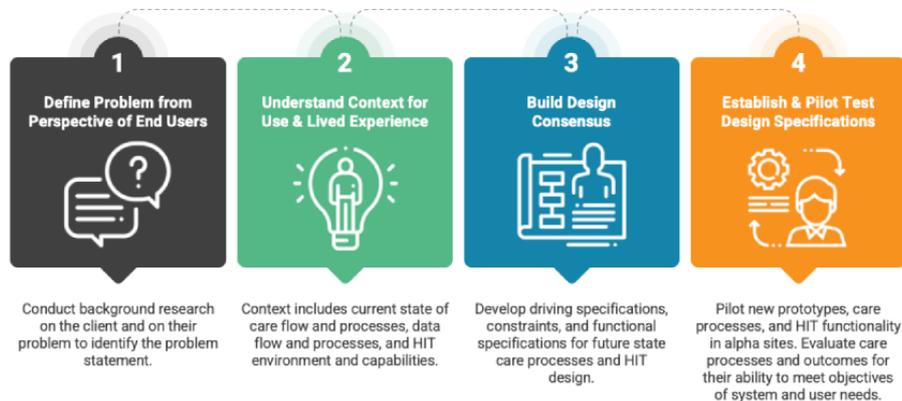

Methods

Overview

We applied a co-design framework (Figure 1 [41,42]), which combines human-centered design [43] and engineering design [44,45] processes, to create the specifications for a regional, facilitated, and web-based peer support network. The framework includes 4 stages: defining the problem, understanding the context for use, developing and building consensus around

functions and specifications that fulfill identified needs, and establishing and pilot-testing design specifications.

Figure 1. Co-design framework (reproduced from The Dartmouth Institute for Health Policy & Clinical Practice, which is published under Creative Commons Attribution 4.0 International License). HIT: health information technology.

Ethical Considerations

The study was approved by the Dartmouth College institutional review board (#2000907).

A waiver of written informed consent was used for the surveys, as the only link to the survey respondent would have been the written informed consent document. No identifiable information was collected and individuals were not paid for participating in human subjects research.

Target Population

The target population, hereafter referred to as end users, was defined as care partners (ie, informal caregivers or family members) supporting or providing care to adults (aged 18 years or older) with a serious illness and those who have experienced the loss of someone to a serious illness. The term care partner was chosen by the co-design team to reflect their role and relationship in partnering with a person with a serious illness. Serious illness has been defined as one that carries a high risk of mortality and either negatively impacts a person's daily function or quality of life, or excessively strains their care partners [46]. Care partners include relatives, spouses or partners, friends, neighbors, or others who have a significant personal relationship with, and who provide a broad range of assistance to, a person with a serious illness. We focused on care partners living in New Hampshire and Vermont, the catchment area for Dartmouth-Hitchcock Medical Center.

Participants

We formed an 18-member team to co-design the network. The team included 2 active and bereaved care partners of people with serious illness, 4 adults with serious illness, 6 interdisciplinary palliative care clinical team members, and 6 support service staff. Care partners and people with serious illnesses were recruited by our clinical team partners. Clinical team members were affiliated with Dartmouth-Hitchcock Medical Center, a rural tertiary care academic medical center in New Hampshire. Facilitation of the co-design process was led by researchers with expertise in co-design, evaluation, and quality improvement (EAO and ADVK). The design process was informed by consultation with an expert in human-centered design (EK) and a systems engineer (ISK). To ensure our design

aligned with best practices, we consulted with external advisors with expertise in facilitated support networks (DG and CY), met with regional health care and support partners, and obtained input from an external advisory committee with expertise in scaling innovations, business, and serious illness.

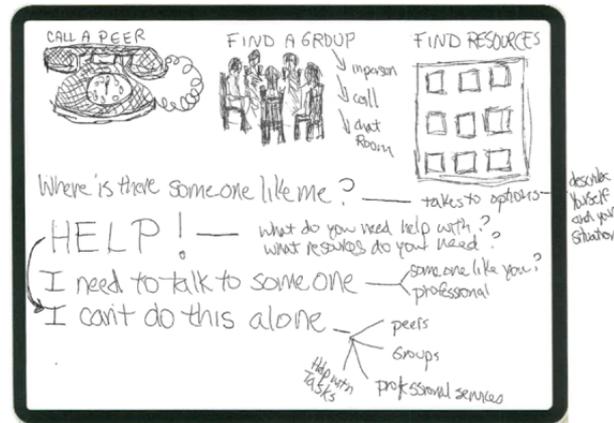

The co-design team met twice a month for 8 months (April to November 2019) to identify and prioritize the functions and specifications of the network and met monthly for 6 months (December 2019 to May 2020) to test prototypes.

Defining the Problem and Understanding Context for Use

We conducted human-centered design exercises [43] to elicit community needs and assets, define the problem, and understand the context for use. We drew upon stories of serious illnesses shared by care partners to identify needs arising from lived experiences. Design facilitators shadowed [43] outpatient palliative care visits and attended interdisciplinary palliative care team meetings to further understand the context of use; services provided by the care team; and the daily lives of people with serious illness, their care partners, and clinicians [47]. We developed empathy maps [43] to reflect and articulate what end users hear, see, say, do, think, and feel, and to identify points of pain and gain. We used a visual thinking exercise [48] to sketch ideas for an ideal support network (example, Figure 2). Design exercises were reviewed during design sessions to discuss critical functions and important features that fulfill and support these functions.

We supplemented design activities with surveys of potential end users. Between December 2018 and April 2019, we collected 28 surveys from a convenience sample of active care partners presenting at the Dartmouth-Hitchcock Medical Center outpatient palliative care clinic and 21 surveys from a convenience sample of bereaved care partners affiliated with the clinic or regional health organizations (eg, hospice) to elicit information on the challenges, needs, and desire for peer connection among active and bereaved care partners (surveys are provided in Multimedia Appendix 1). We used descriptive statistics to summarize categorical data, and thematic analyses to identify themes from open-ended questions.

Figure 2. Sketch of a serious illness community network, created by a co-design team member.

Building Design Consensus

We collated, organized, and systematically described the identified needs into a hierarchical list. We converted the highest-level needs into functions for the network to achieve. At the highest level, for example, “care partner need for information” was converted to “connecting care partners to information” and “care partner need for emotional support” was converted to “facilitating emotional support.” We identified potential specifications associated with each function of the network.

Co-design team members independently rated the importance of each specification using a five-item prioritization scale: (5) must have, (4) high importance (feasible without), (3) should have (very important), (2) could have (consideration), and (1) desirable (will not have at this time) [49]. Team members were provided an opportunity to describe their understanding and thought process for preference identification as a group. Scores were weighted and averaged by respondent type to ensure that patients and care partners, clinicians, and support service staff had equal participation weight (eg, scores from 6 clinicians were averaged to create 1 clinician average).

Pilot-Testing Design Specifications

We tested a series of prototypes to identify the importance of different network components. These included storytelling exercises, face-to-face group conversations, one-to-one matching of care partners, group videoconferencing, an online discussion forum, and a “Caregiver Day” event at the health center. Summaries are provided in [Multimedia Appendix 2](#).

After finalizing design functions and specifications, we identified potential vendors to host the network by conducting an environmental scan of web-based networks focused on people with serious illnesses and care partners and mapping desired design specifications to vendor capabilities. Four vendors provided demonstrations of their platforms between April and

May 2020. Vendor selection was driven by the vendor’s ability to provide the prioritized functions and specifications, the cost to build and maintain the network, and being a US-based company. Following vendor selection, the web-based network platform was customized by the design team to deliver upon design functions and specifications.

User acceptance testing was conducted between April and July 2021. Four care partners and 2 people who previously had a serious illness were invited to register as founding members of the network in April. These founding members were encouraged to invite care partners they knew into the web-based community to test the feasibility of enrolling members. Three clinical champions (physicians and social workers), a chaplain, and a staff member who manages complementary care programs referred care partners to the network. The research team met weekly with the vendor during the user acceptance testing period to resolve issues. The web-based platform remained available for registered members to use while issues were addressed. The network moderator met monthly with the design team to plan future improvements using a quality improvement framework [50].

Results

Problem Definition

The co-design process led to clarity around the objective of the network: to help care partners cope with the surprises that arise during serious illness and bereavement. The network, named “ConnectShareCare,” was intended to supplement existing services, to be provided outside of clinical encounters with the health care system or regional professional support and service organizations, and to tap into the wisdom of those with lived experiences.

If successful, the design team anticipated that the network would benefit 4 groups, as outlined in [Table 1](#).

Table 1. Anticipated impact of ConnectShareCare.

Audience	Anticipated objectives
Care partners	<ul style="list-style-type: none"> • Improve access to information that can guide decision-making • Improve sense of empowerment in making decisions and providing support • Decrease sense of distress and social isolation
Community partners	<ul style="list-style-type: none"> • Improve understanding of needs and gaps in service • Provide a system to share assets or resources
Clinicians or health care system	<ul style="list-style-type: none"> • Address gaps in services that are not currently met • Improve availability to see patients who seek services • Improve efficiency of health care encounters
Quality improvement leaders and researchers	<ul style="list-style-type: none"> • Improve understanding of the needs of care partners • Align services with care partners and community needs • Demonstrate a positive impact of the network over time

Context for Use and Lived Experiences

Our co-design process identified that active and bereaved care partners have different needs but have common interests in sharing information and providing or receiving support. Active care partners who completed an assessment survey were most challenged by emotional difficulties (eg, worry, uncertainty, or lack of control; 12/28, 43%), providing care and emotional support (7/28, 25%), and practical matters (6/28, 21%). Bereaved care partners were most challenged by loneliness (10/21, 48%), managing grief and emotional difficulties (6/21, 29%), and managing practical matters (5/21, 24%). Active care partners were most helped by support from friends, family, or other social connections (12/28, 43%), as well as by medical professionals (9/28, 32%), while bereaved care partners were most helped by support from friends, family, or other social connections (16/21, 76%) and by developing self-care strategies that led to personal resilience and growth (12/21, 57%).

Most active (18/27, 67%) and bereaved (18/21, 86%) care partners were interested in 1 or more forms of connecting with other people who have shared a similar care experience. Both active and bereaved care partners anticipated that a network could provide support, knowledge, and resources but anticipated challenges associated with time to participate and with forming personal connections.

The series of human-centered design exercises and interviews led to additional insights. First, active and bereaved care partners may benefit from connecting and sharing information with each other. Peer-generated information from care partners who have shared a similar experience feels more authentic, detailed, and actionable. Second, care partners wished to belong to a local support community that was connected through geographic proximity and could provide recommendations for local

resources. Third, a web-based network enables care partners to access information at any place or time, allows anonymity, improves access for people who are home-bound or grieving, and may reach an increased number of care partners. Fourth, trained staff who can moderate, promote, and manage the web-based community and volunteers who can recruit and engage users are important. Paid or volunteer moderators can play an important role in listening, making connections, and highlighting information, services, and programs. Fifth, a web-based network would benefit from supplemental opportunities for the community to meet face-to-face or through digital programming.

The design process also identified several potential risks and possible mitigation strategies. First, there was a risk of causing harm to vulnerable end users if the design failed to provide a safe and supportive environment, protect the privacy of sensitive information, or enact acceptable data ownership guidelines. Second, there was a risk associated with the usability of the network among end users who were less facile with web-based services. Third, there was a risk associated with the inability to form a personal connection with peers through a web-based network. Other potential risks included those associated with competition from other networks, inaccurate content or information, and care partners having minimal time to participate in a web-based support network due to other responsibilities.

Build Design Consensus

Two primary functions emerged from the design activities: to support care partners in (1) providing each other with emotional support and (2) exchanging helpful information and resources. We developed specifications related to these functions (Table 2), as well as the form of the network, including the user interface, data and security, and other considerations (Table 3).

Table 2. Prioritization ranking of design specifications associated with network functions (weighted average scores across patients and families [n=5]; clinicians [n=4]; clinical support service providers [n=5]; and network advisors [n=2]).

Network functions and prioritization ranking of associated design specifications	Ranking ^a
Function 1: provide each other with emotional support	
Must have	
<ul style="list-style-type: none"> Provide a supportive and respectful space <ul style="list-style-type: none"> Ability for established “Guidelines and Ground Rules” to be clearly visible to users Ability to protect individual identity (opt-out options for sharing personal information; opportunity to keep geographic location private) Allows moderator functionality for policing interactions and blocking users if necessary 	5.00
Should have (very important)	
<ul style="list-style-type: none"> Incorporate and help facilitate, one-to-one connections <ul style="list-style-type: none"> Ability to locate “true peer” (similar users) through the platform via matching on similar life circumstances (through backend algorithm or user profile details: type of loss, disease, time caregiving, or time since loss) Allow for private one-to-one messaging to facilitate a more personal connection, not monitored by an external entity 	3.27
<ul style="list-style-type: none"> Includes opportunity for storytelling based on personal user content or experience 	3.00
<ul style="list-style-type: none"> Provides an opportunity to share solutions 	3.00
Could have (consideration)	
<ul style="list-style-type: none"> Differentiate between whether people want to feel heard or want to hear solutions <ul style="list-style-type: none"> Ability for users to designate whether they are looking to hear solutions or feedback or simply share 	2.88
Function 2: exchange helpful information and resources	
Must have	
<ul style="list-style-type: none"> Provide connections to trusted and curated local, national, and international resources <ul style="list-style-type: none"> Ability to host webinars in order to share educational content Ability for newsfeed or wall that features newly published content Provide document or resource repository related to user needs Ability to highlight and share local events via calendar, bulletin board, or other Robust search function available to find targeted resources within the platform 	4.56
High importance (feasible without)	
<ul style="list-style-type: none"> Reduce the difficulty of asking for help by normalizing needing help <ul style="list-style-type: none"> Ability to add a button in various locations that asks “Having a hard time asking for help?” and that opens a new page that contains tips or guidelines on how to ask for help and what to expect when asking for help 	3.88
<ul style="list-style-type: none"> Provide frequently asked questions list and answers <ul style="list-style-type: none"> Site provides a list, or ability to create a list, of the most popular or frequently asked questions and answers (eg, “How do I cope with stress?”) 	3.76
Should have (very important)	
<ul style="list-style-type: none"> Ability to identify most common needs <ul style="list-style-type: none"> Ability to organize conversations around themes (or topics) and make it easy for someone with a specific question, topic, or theme to locate information pertaining to it Ability to “like,” (showing interest, support) posts, topics, or comments so that users can see which posts are popular and most useful Ability to follow a discussion thread, topic, etc. Once a user has “followed” something or someone, they can receive a notification when there is new content posted Ability to bookmark posts (to save content) that users would like to revisit 	3.47
<ul style="list-style-type: none"> Ability to be supported by local or regional expert moderator (community manager) 	3.38

Network functions and prioritization ranking of associated design specifications	Ranking ^a
<ul style="list-style-type: none">• Include the ability to publish videos related to the content of the network<ul style="list-style-type: none">• Allow users to record and post videos instantly (personal and other)	3.06

^aPrioritization ranking: (5) must have, (4) high priority (feasible without), (3) very important (should have), (2) consideration (could have), (1) desirable (will not have at this time).

Table 3. Prioritization ranking of the form of the network: user interface, data and security, and other considerations (weighted average scores across patients and families [n=5]; clinicians [n=4]; clinical support service providers [n=5]; and network advisors [n=2]).

Form of the network and its prioritization ranking	Ranking ^a
User interface	
Must have	
<ul style="list-style-type: none"> Simple or intuitive interface <ul style="list-style-type: none"> Provide support, guidance, and assistance with how to navigate and use platform (ideal: offer video tutorials) Passes Web Content Accessibility Guidelines (WCAG). Example: large font Ability to easily identify new content (since user's last login) 	5.00
<ul style="list-style-type: none"> Provides IT technical support (for members) 	5.00
<ul style="list-style-type: none"> Easy access to support user engagement <ul style="list-style-type: none"> Smooth and simple login process Optimized for mobile device Real-time information and comments available and accessible (not prescreened by community moderator) 	4.53
High importance (feasible without)	
<ul style="list-style-type: none"> Aesthetically refined <ul style="list-style-type: none"> Pleasing to the eye, organized, and appropriate imagery Symmetrical and aligned (looks modern) 	4.00
<ul style="list-style-type: none"> Appropriate use of pop-ups and other interactive elements 	4.00
<ul style="list-style-type: none"> Does not allow advertising <ul style="list-style-type: none"> Does not have advertisements on the platform itself Does not send any unsolicited promotional emails related to the platform or other 	3.76
Data and security	
Must have	
<ul style="list-style-type: none"> Secure platform or user privacy protected (Health Insurance Portability and Accountability Act [HIPAA] compliant) 	5.00
<ul style="list-style-type: none"> Public forum for information and resources, but opportunities for private discussion forums 	5.00
Should have (very important)	
<ul style="list-style-type: none"> Data are owned by the co-design team's institution (not the vendor) <ul style="list-style-type: none"> Establish terms and conditions for how information or data will be accessed, stored, and used No selling of data to for-profit or not-for-profit entities (pharmaceuticals or other) for financial gains 	3.47
<ul style="list-style-type: none"> Data access and analysis <ul style="list-style-type: none"> Provides actionable metrics related to user activity and engagement (including IP address) Data analysis capabilities available within local database Create an extract of selected data Ability to survey users 	3.00
Other considerations	
High importance (feasible without)	
<ul style="list-style-type: none"> Health-focused support network <ul style="list-style-type: none"> Network software is targeted to health-focused communities, has features and functions relevant to health, self-management, etc (eg, health needs assessment) and has experience working in peer-to-peer health care 	4.00
<ul style="list-style-type: none"> Sustainability (retaining users) <ul style="list-style-type: none"> Provides facilitation and network growth support (through designated pump primers, marketing, etc) Opportunity to offer member incentives (through badges, quality improvement initiatives: creating educational material, etc) 	4.00

Form of the network and its prioritization ranking	Ranking ^a
<ul style="list-style-type: none"> • Scalability <ul style="list-style-type: none"> • Interactive and responsive; ability to customize and add measures and functionality over time 	4.00

^aPrioritization ranking: (5) must have, (4) high priority (feasible without), (3) very important (should have), (2) consideration (could have), (1) desirable (will not have at this time).

The most highly prioritized specifications to support each function (Table 2) included providing a supportive and respectful space; providing connections to trusted and curated local, national, and international resources; reducing the difficulty of asking for help by normalizing needing help; and providing curated resources to address the most common concerns (eg, easy access to frequently asked questions and answers).

The user interface (Table 3) must be simple and intuitive, provide technical support for users, and be easy to access. It was highly important for the user interface to be aesthetically refined, include appropriate use of interactive elements, and not allow external advertising. The platform must be secure and protect user privacy. It must be available as a public forum for information but also allow participants to communicate via discussions not visible to others outside of the network. Other highly important considerations included hosting by a vendor with experience in providing health-focused networks and providing features that support sustainability and scalability (such as member incentives and the ability to customize or add functionality over time).

Pilot Test Design Specifications

Following the vendor selection process, we worked with CareHubs, an online health network vendor, to build the ConnectShareCare network. The network included (1) a single support community for active and bereaved care partners; (2) a short list of curated resources based on needs identified during the design (planning ahead, practical issues, emotional issues, communication issues, and family resources); (3) a calendar of online and in-person regional support programming; (4) a story from an end user about their experience as a care partner; (5) a roster with member profiles; (6) a help center; and (7) community guidelines. Screenshots are included in [Multimedia Appendix 3](#).

The initial feasibility of the network was demonstrated through the active participation of founding members, beginning in April 2021, with expansion to include 12 new care partner members in May 2021 and 15 new members in June 2021. During this period, the network had an average of 135 posts per month. A total of 16 members posted a message to the network, with an average of 11 members posting per month.

Discussion

Principal Findings

A co-design process generated a useful and feasible regional, facilitated, and web-based peer support network for care partners of people with serious illnesses. The co-design process ensured that all voices were heard, especially among people who

typically may not work together. Design decisions were made collectively and systemically, which allowed network functions and specifications to be identified and prioritized. By doing so, the co-design process ensured that the most critical decisions were responsive to regional needs and preferences. The resulting network connects active and bereaved care partners with peers to facilitate emotional support and exchange information related to caregiving for people with serious illness.

Comparison With Prior Work

Similar to other networks [15,33,51-62], ConnectShareCare has a clear purpose, includes mechanisms to foster a strong sense of community and support among regional care partners, and provides value to a variety of groups. The network builds on the resources, wisdom, and experiences of care partners. The inclusion of a moderator helps ensure a safe environment that is protected from misinformation, trolling, or cyberbullying. The moderator sets the tone and etiquette with members, modeling behavior and other preventative measures, as well as moderating posts, facilitating connections, and providing feedback to adjust member behaviors [20,23].

Our design process had several strengths. First, our process engaged people who would be end users of the network in making critical design decisions [40]. In contrast to asking end users about single decisions, our process allowed end users to make decisions in the context of all other design requirements and options. This led to a more systemic approach to engagement that ensures that decisions are optimized to fit together. Second, our process brought together people with different expertise (in being a person with serious illness or a care partner, in medicine, in health network design, and in community management and moderation) that may typically not work together to create services, and each had different needs to maintain the value of the network. The process also engaged people with engineering design [44,45] and user-centered design [43] expertise to ensure that the process was rigorous enough to produce a network tailored to the needs of end users. Third, our design was responsive to regional needs by addressing gaps in available services and drawing upon local assets. We intentionally worked with multiple health care and support organizations in the region to broaden our network and reach care partners most in need of support, regardless of where formal health care services were received. Care partners are a vulnerable population who often receive minimal structured support from the health system, yet they have significant knowledge to contribute on how to navigate health care systems, health and social resources, and losses at every stage (eg, relationships, identity, and freedom). This knowledge is often actionable by peers. Finally, our process may have supported growth in network participation due to health care and regional

support partners feeling heard and included in the design process.

Limitations

This project has certain limitations that should be considered by those wishing to adapt the methods and findings to different contexts. First, the project was built around a recognition that people who live in north-east rural areas can be particularly isolated and lack access to sources of support. It is unclear whether the network will meet the needs of people in other regions of the country. Second, similar to local demographic characteristics, our design team had limited racial or ethnic diversity. We do not know how greater racial, ethnic, or sociodemographic diversity would enhance or create barriers to its success. Third, the network is built around an asynchronous model. This can be very important because it respects the different schedules that people are on; however, it limits the opportunities for people to hear and see each other in real time. It is unknown whether a network that combines synchronous and asynchronous components would be useful in our context. Finally, while the design process requires extensive back and forth among participants and may not be feasible in other situations, it also represents a strength in creating a network that more closely reflects community needs. In our situation, the decision to create a new network was a result of the recognition that other solutions are not likely to fulfill the needs of our end users.

Conclusions

Care partners of people with serious illness often lack support and are likely to experience significant challenges and unmet needs. We followed a structured co-design process to collaboratively identify and prioritize the functions and specifications of a regional web-based facilitated peer support network to help care partners cope with the surprises that arrive during serious illness and bereavement. The network was designed to provide emotional support and exchange information related to serious illness caregiving. The coproduction of accessible peer-led information, resources, and support may extend the scope of services offered by a health system to support lay care partners—becoming part of a sustainable, person-centered value-creation system [63,64]. Opportunities exist to evaluate the feasibility of actively engaging community members and moderators in the network [65,66] and will be reported on in a publication under development. Moreover, there is a need to understand effective mechanisms to recruit and retain participants and provide a safe environment to people who are in vulnerable situations; to monitor the network life cycle through metrics related to activity and growth [20,22]; and to consider the creation of network subgroups to support care partners of people with particular illnesses (eg, cancer, dementia, and Parkinson disease) or people from specific minority populations. Finally, there is an opportunity to understand the impact of a regional support network on care partner quality of life, self-confidence, loneliness, and isolation [67,68]; and on health system reputation, use, and visibility.

Acknowledgments

The authors wish to thank the many other people who contributed to the design and implementation of the ConnectShareCare network and the many active and bereaved care partners who participated in and provided feedback on the network. Special thanks are given to Deadra Ashton, James Bowling, Mary Elizabeth Byrnes, Nancy Duhaine, Ellen Flaherty, Melissa Garland, Malavika Govindan, Amanda Hoggard, Marv Klassen-Landis, Jane Masters, Catherine Reed, and Donna Soltura for their feedback and contributions to the design of the network. In addition, the authors wish to thank the Upper Valley Elder Forum; Upper Valley Bereavement Partnership Group; Dartmouth-Hitchcock: Volunteers, Palliative Care Program, Arts and Humanities Program, and Aging Resource Center; Dartmouth Cancer Center; Visiting Nurse and Hospice of Vermont and New Hampshire; Lake Sunapee Visiting Nurses Association and Hospice Care; Bayada Home Care; CommunityCare of Lyme; Community Nurse Connection; Shire Digital; and CareHubs for their support of the ConnectShareCare network. This work was supported by the Gordon and Betty Moore Foundation (grant number 7485) and the Couch Family Fund at The Dartmouth Institute for Health Policy and Clinical Practice.

Abstract

Background: Multiple studies have examined the impact of deferral on the motivation of prospective blood donors, proposing various policies and strategies to support individuals who undergo this experience. However, existing information and communications technology systems focused on blood donation have not yet integrated these ideas or provided options to assist with the deferral experience.

Objective: This study aims to propose an initial gamified design aimed at mitigating the impact of the deferral experience by addressing the drivers of awareness and knowledge, interaction and validation, and motivation. Additionally, the study explores the feasibility of implementing such a system for potential users.

Methods: We conducted a literature review focusing on the dynamics of motivation and intention related to blood donation, as well as the deferral situation and its impact on citizens. Through this review, we identified weak donor identity, lack of knowledge, and reduced motivation as key factors requiring support from appropriate interventions. These factors were then defined as our key drivers. Taking these into account, we proposed a gamification approach that incorporates concepts from the MDA framework. The aim is to stimulate the aforementioned drivers and expand the concept of contribution and identity in blood donation. For a preliminary evaluation, we designed a prototype to collect feedback on usability, usefulness, and interest regarding a potential implementation of our proposed gamification approach.

Results: Among the participants, a total of 11 citizens interacted with the app and provided feedback through our survey. They indicated that interacting with the app was relatively easy, with an average score of 4.13 out of 5 when considering the 11 tasks of interaction. The SUS results yielded a final average score of 70.91 from the participants' answers. Positive responses were received when participants were asked about liking the concept of the app (3.82), being likely to download it (3.55), and being likely to recommend it to others (3.64). Participants expressed positivity about the implementation of the design but also highlighted current shortcomings and suggested possible improvements in both functionality and usability.

Conclusions: Although deferral is a common issue in blood donation, there is a missed opportunity in existing ICT services regarding how to effectively handle such experiences. Our proposed design and implementation seem to have captured the interest of prospective users due to its perceived positive usefulness and potential. However, further confirmation is needed. Improving the design of activities that currently rely heavily on extrinsic motivation elements and integrating more social components to create an enhanced activity loop for intrinsic motivation could further increase the value of the proposed project. Future research could involve conducting a more specialized and longitudinal design evaluation with a larger sample size.

Introduction

Blood Donation and Deferral Experience

Blood donation is an altruistic, socially responsible, and even a self-care activity. However, the commitment required to participate can be deterred by uncomfortable experiences, negatively affecting motivation to donate [1]. Preventing such experiences and reducing their impact could preserve the intention and willingness of citizens to continue donating blood.

One significant deterrent is the deferral experience [2], which means being disqualified from donating blood based on eligibility criteria. It is especially impactful in young and first-time donors, often resulting in abandonment [3]. Negative emotions are commonly reported during the deferral process [4]. Such negative experiences can deter potential donors when shared with their social circles [5]. Similarly, studies consistently identify negative interactions with staff, feelings of rejection, and confusion about deferral reasons as primary factors reducing return intention and motivation [6]. Some deferred donors misunderstand their deferral conditions, erroneously believing they cannot donate for longer periods or even permanently [7]. Communication and information gaps contribute to these misconceptions [8].

Challenges and Potential Solutions

To counter deferral effects, strategies such as enhanced communication, clear deferral information, and targeted recruitment show promise [4]. However, these solutions require substantial planning and resources, often unavailable to many blood centers. In that regard, information and communications technology (ICT) platforms, inspired by successful implementations in health promotion and telemedicine [9,10], could facilitate such support. As existing apps focus mostly on the donation itself and on supporting citizens for their next donation [11,12], there is an opportunity to offer unique value by tailoring systems to address the deferral experience. However, to that end, understanding the psychological responses and specific needs of deferred donors is crucial. Temporary deferrals necessitate motivation, health improvement, and eligibility [13], whereas permanently deferred donors (those unable to donate anymore) could still contribute indirectly through activities such as promoting donation.

Regarding the motivation topic, an approach that has gained notoriety is gamification, which involves the use of game-design elements in nongaming contexts [14]. Some blood donation centers worldwide use gamification, rewarding donors with badges, gifts, and certificates [15]. Furthermore, government blood donation apps in countries such as the United States and Canada have integrated gamified elements into their ICT services, aiming to boost donor motivation [16,17]. Although the impact on blood donation is yet to be studied, gamification has proven effective in therapy commitment and health

self-monitoring [18,19]. Considering this, gamification holds promise for increasing motivation in the blood donation context.

However, motivation is not the only factor to consider for a possible proposal. Previous studies have identified various deterrents, stemming from deferrals, health conditions, or environmental factors, which influence citizens' future intentions and behaviors [4]. In this study, we reviewed previous findings, as well as the results of a preliminary survey, to identify pertinent topics and form the foundation of our proposed design for an ICT system that aims to support (also) deferred donors.

Theory of Planned Behavior and Extensions in Blood Donation

The Theory of Planned Behavior (TPB) [20], an extension of the Theory of Reasoned Action, asserts that specific behavior is determined by intention, influenced by attitude, subjective norm, and perceived behavioral control. In the context of blood donation, the TPB proposed that positive evaluation of the act (attitude), social expectations (subjective norm), and belief in individual control over donation (perceived behavioral control) dictate the decision to donate.

Previous studies have found that the TPB explains between 32% and 50% of the variance in intention and 27% and 36% of the variance in behavior [21,22]. To enhance predictive power, the framework was extended due to the inconsistent link of the subjective norm [23]. In blood donation, additional constructs were incorporated based on psychological differences among nondonors, novices, and repeat donors. Moral norms, descriptive norms, past behavior, and self-identity were included as predictors [20,24,25].

Systematic reviews have shown that self-efficacy, donor identity, and anticipated regret have medium positive effects on both intention and behavior. Conversely, deferral has a medium negative impact, leading to a decrease in subsequent donations among experienced donors [26,27]. Past behavior or habit explains 19% additional variance in blood donation behavior for those donating 5 times or more [28]. Habit, suggested to be context bound, is viewed as an external motivator, whereas self-identity, which pertains to one's role in society as a blood donor, is defined as an internal motivator [29-31]. Both habit and self-identity significantly influence repeat blood donation behavior, with past behavior likely forming identity [23].

Self-Determination Theory and Motivation and Gamification

As the TPB applies mostly to situational-level intentions [32], blood donation studies primarily rooted in the TPB have expanded their scope to incorporate Self-Determination Theory (SDT) in the last decade [33,34]. SDT, a theory of human behavior and personality development, emphasizes social-contextual factors supporting human growth through satisfying basic psychological needs for *competence* (effectiveness of my actions in my current environment), *relatedness* (social involvement and relation with others), and

autonomy (internal need to be responsible for your own meaningful choices) [35]. It proposes that internally motivated behaviors persist, while external motivations can become internalized under appropriate socioenvironmental conditions [36].

SDT categorizes behavior on a continuum from amotivation (nonregulated behavior) to extrinsic motivation (external to integrated regulation) to intrinsic motivation (intrinsic regulation). Extrinsic motivation refers to acting in a certain way or doing a specific action because it leads to a separable outcome or reward. By contrast, intrinsic motivation refers to acting in a certain way or doing a specific action because the act itself is inherently satisfying. Integrating the TPB and SDT, studies have revealed that SDT's motivational orientations explained an additional 14% of the variance in blood donation intention compared with TPB-only models [37]. Amotivation had a negative direct effect on intention, while external motivation had no overall effect on intention but a positive effect on amotivation [38]. By contrast, introjected regulation had positive direct and indirect effects on intention, and autonomous motivation predicted intention directly and via attitudes, subjective norms, and perceived behavioral control [33,38].

Gamification Concepts and Frameworks

As SDT discusses the impact of motivation on behavior, it was considered the foundation for implementing gamification, as it does not aim to directly affect an outcome, but to change a target behavior (by affecting psychological factors) that can lead to that outcome [39,40]. To achieve this, the system can utilize its various design components, as outlined by the Mechanics, Dynamics, and Aesthetics Framework (MDA) [41], which served as the primary reference for our study. The framework comprises mechanics, which encompasses specific game components such as data representation and algorithms; dynamics, which refers to the interactions between these mechanics and player inputs over time; and aesthetics, which aims to elicit desirable emotional responses from players when they engage with the game system. These components are integrated to drive either extrinsic or intrinsic motivation, considering the targeted changes in human behavior [42-44].

Extrinsic motivation can drive behavior but may fade without external rewards, while intrinsic motivation leads to long-term positive effects on intention and behavior [45,46]. Thus, most gamified approaches recommend prioritizing intrinsic motivation in the design process. In that regard, users can be categorized according to the recognized characteristics and that drives them in the gamified implementations [47]: socializers (motivated by *relatedness*), free spirits (motivated by *autonomy*), achievers (motivated by *competence*), philanthropists (motivated by *purpose and meaning*), players (motivated by *rewards*), and disruptors (motivated by *change*). The players and disruptors categories can be further divided according to their behavior.

Considering the previous concepts and relationships of gamification and SDT, DiTommaso and Taylor [39] defined a framework in which they propose the following steps for design: discover the reason to gamify, identify players' profiles and motivational drivers, set up goals and objectives, describe skills

and desired outcomes, and playtest among others. Another design framework with similar foundations is the Six Steps to Gamification [48], which also takes influence from the MDA. It proposes the following steps: definition of business objectives, target expected behavior, description of players, design of activity loops, do not forget the fun, and deploy appropriate tools. Although not domain specific, these adaptable frameworks can guide gamification projects and were also used for reference in our study.

Deferral Experience and Effects in Return Rate

From the literature review, we chose to focus on recurrent and impactful issues related to the deferral experience, especially the ones that aligned with the constructs from the TPB and SDT. For example, the construct of self-identity (blood donor identity in this case) from the extended TPB can be associated with the negative feelings from a deferral. More specifically, a deferral, which can generate a feeling of rejection in the unsuccessful participant [13], can threaten the citizen's self-perception as a capable blood donor (identity), as the inability to participate diminishes their possibility of building experiences and forming a habit (especially in the cases of new and young donors). Similarly, confusion and misunderstandings in deferral make a successful blood donation seem more complex and difficult than it is, affecting citizens' perceived behavioral control (TPB construct). As indicated by Gemelli et al [1] and Hillgrove et al [13] negative experiences can reduce the motivation for future involvement, particularly for long-term or permanently deferred donors, eroding their sense of self-efficacy.

To further explore the relationship between the deferral experience and intention, we also took into account the findings of a preliminary survey involving Japanese citizens [49], in which a total of 208 participants were recruited. In the survey, the dependent variable was "Intention to donate again after deferral" (a 6-point Likert scale question with the values 1=not anymore, 2=not for a while, 3=I don't know, 4=maybe, after a while, 5=yes, unless rejected again, and 6=yes, I would). Citizens were asked whether they heard or knew about the concept of deferral and whether they had experienced a deferral case, as well as their future intention in a possible deferral scenario. The results implied a possible relation between deferral and reduced intention to donate (following previous studies). However, the data also suggested a positive relation between preventive awareness of the deferral experience and intention to donate. Donors and nondonors who had knowledge about the deferral concept indicated higher intention of future participation even after a possible deferral scenario.

Objectives

Considering the literature review, we focused on recurrent issues that could be addressed with a gamification approach, taking into account the connections between the deferral experience, their issues, and motivation. The topics we chose were as follows:

- Lack of knowledge about deferral: Some of the negative feelings appear because citizens are not knowledgeable of the topic, are not retaining the information, or have misunderstood it.

- Weak donor identity: citizens feeling rejected and lacking validation.
- Reduced motivation: citizens losing interest in addressing the deferral reason or losing interest in contributing to the future.

Additionally, considering the evaluated strategies to mitigate the negative impact of deferral from the analyzed literature [4,50], we defined the main drivers for our approach. First, to provide awareness and knowledge about deferral by making learning interesting to the citizens (*awareness and knowledge*). Next, to increase the scenarios of interaction and validation for deferred donors to nurture their identity (*interaction and validation*). Lastly, to provide motivational drivers for deferred donors to regularly engage in activities related to blood donation (*motivation*).

After that, we worked on the design of activities that could be implemented with the gamification framework while targeting the drivers selected regarding the deferral experience. After completing the initial design, we implemented a prototype with basic features and integration for a feasibility study, collecting feedback about the usability and receptivity of potential users to discuss the future value of the idea of offering a service regarding the deferral experience, our proposed design, and its implementation.

For this study, we explored the following research questions (RQs):

- RQ1: Will our gamified design that focuses on the previously mentioned drivers with regard to the deferral experience in blood donation have a positive reception from potential users?
- RQ2: Will our initial prototype implementation of the design be considered usable and useful in its current iteration?

Methods

Conceptualizing a Gamification Approach for the Deferral Experience

Overview

In this study, we are adopting an approach similar to the gamification frameworks mentioned previously [40,41,48], while also taking into account the unique requirements of individuals in blood donation. We have adapted the steps and elements of these frameworks to provide support specifically addressing the deferral experience and focusing on the main drivers mentioned.

Definition of Approach Objectives

We redefined our target users to include not only deferred donors but also regular donors and potential donors who might face deferral in the future. Our focus broadened to cater to anyone interested in the topic, aligning with our objective of providing deferral support. We concentrated on 3 main issues: lack of knowledge about deferral, weak donor identity, and reduced motivation, translating these into drivers for our

gamification approach: *awareness and knowledge, interaction and validation, and motivation*.

Target Expected Behavior

The next step was to define the citizens' expected behavior when interacting with our proposed gamification implementation. For our approach, we wanted the design to nurture the drivers, and as a consequence, possibly affect future intentions.

For *awareness and knowledge*, we expected users to engage in educational activities that both teach them about and test their understanding of the deferral experience and strategies for improvement. For *interaction and validation*, we expected users to get involved in discussions, in sharing experiences, and in supporting one another, improving the sense of community. In terms of *motivation*, our goal was to encourage users to access the system regularly, ideally once or twice per week, considering the prolonged pace between blood donations.

Description of Users

For our target group, while we initially expected to focus on the deferred donors, the results from the preliminary survey guided us to design the service as a preemptive one (including regular donors and nondonors), to nurture the identity of the users and prepare them against a deferral scenario. Designed primarily for young citizens (20-30 years) yet accessible to older individuals, the approach incorporated specific design elements reflecting the regional context (Japan). However, the core of the approach was intended to be adaptable, considering possible future adaptations for other regions.

In the context of the gamification approach, considering that the potential users (citizens) would not have the same goals or motivations (following the connection with SDT), for this study, we focused on targeting the players, the socializers, the free spirits, the achievers, and the philanthropists.

Design of Activity Loops

Macrolevel Progression Loops

The gamification approach aims to motivate citizens, particularly deferred blood donors, to stay engaged with blood donation-related activities. Although encouraging future donations is the ultimate goal, maintaining interest in the topic and promoting contributions to other related areas are also crucial. The design focuses on creating macrolevel progression loops for the drivers of *awareness and knowledge*, as well as *interaction and validation*.

Initial Outline

User progression is represented through levels. Levels increased based on experience points earned from various activities. Points earned could be exchanged for basic title characters. Special characters are unlocked as users progress, with higher levels requiring more points for unlocking. Higher user levels unlock additional activity options, which yield more points.

For the microlevel, we first defined some basic loops for the foundation of the design. For example, one of the initial hurdles considered was that, independent of any learning or social activity that could be designed, their value would not be

achieved if the users were not motivated to access the ICT system. In that regard, we considered a simple loop of providing a reward to initially push the user to use the system: if the user logs-in to the system, they receive a message about their current streak and earn some points. Users will earn more points according to how often they connect to the app and how high is their level. With regard to *awareness and knowledge*, we aimed to make the users both learn about deferral and review their current knowledge. For this purpose, the initial idea for this loop was that as users learn more, they can face harder challenges. And the more successful they are, the more complex information they will be taught. With regard to *interaction and validation*, we aimed to provide some activities in which users could interact with other users, and the more interactions and levels the user has, the more options of interaction would be available to them.

However, we needed to solidify the ideas for the microlevel. To achieve this, we opted to elaborate on the design with greater detail. We chose to do this by following the MDA framework, first from the user perspective, then transitioning to the designer perspective to finalize the activities' design.

Definition of MDA Aesthetics

For the driver *awareness and knowledge*, we aimed to nurture a habit in the users of learning about deferral. For *interaction and validation*, the expected behavior was to generate regular engagement in the users. To that end, specifically for the players, we first selected *submission*, which means the design would allow users to interact with the system as a pastime. Our goal was to present a variety of activities offering rewards and collectible items to enhance user enjoyment. However, this approach may heavily rely on extrinsic motivations, potentially overshadowing the altruistic aspect of blood donation. Thus, we needed to be cautious in its implementation to avoid solely focusing on rewards. To address this, we selected *fellowship* as a social framework to appeal to users who value social experiences.

We considered possible ways to make users interact with others, possibly in cooperation or competition. *Challenge* (experience as obstacle course), *discovery* (experience as uncharted territory), and *expression* (experience as self-discovery) were also chosen as they are more related to intrinsic motivations, which we wanted to favor over the extrinsic motivation, which was aimed to be used only as the trigger for the conduct of the users.

Definition of MDA Dynamics

We initially drafted dynamics outlines to connect the drivers and the aesthetics. For instance, in terms of *awareness and knowledge*, users could opt to heighten the difficulty of their learning process, introducing an element of risk that could generate a *challenge*. Additionally, we explored the possibility of randomizing the information users received, with variations based on their actions within the environment, thus fostering a sense of *discovery*.

By contrast, for *interaction and validation*, we aimed for users to be able to choose the type of recognition they would get, allowing for *expression*. They should also decide what they

could share with others and try to encourage them to perform certain actions, creating *fellowship*. From these initial ideas, we expanded into more detailed dynamics in the designer perspective iteration of the MDA.

Definition of MDA Mechanics

Generic mechanics are introduced, incorporating points, levels, and characters for onboarding. Points served as rewards for participating in different activities (the amount was adjusted per result), to create a sense of progression (the historical record was tracked to calculate the current level of the user), and to be used as a currency in the system. Levels were also used for progression. They increased according to the number of participations, providing recognition and incremental rewards. They were used as a certain multiplier in the activity rewards and to unlock new and special characters in the exchange store.

Characters were chosen as part of the representation and recognition of the users, being the main extrinsic reward of the gamification approach. However, they were integrated to appeal to both extrinsically and intrinsically motivated players, aiming to reduce the dependency on the extrinsic component. For example, with customization, they would target free spirits; if they were collectible, they would target players and achievers. As general rules, every registered user was provided with the same starting character; they could acquire more in the shop by exchanging the points they collected through the activities; they could also upgrade (defined as "evolve" inside the app) them by exchanging multiples of the same one. One character at a time could be selected to use it as their icon in their social activities, and characters would change their appearance if the user stood inactive in the system for more than a week.

Some social interaction components were included, such as a comment section and a simple feed wall for users' posts. Both of them had an upvote or downvote mechanism for users to indicate their relevance or popularity. A certain degree of user anonymity was incorporated to reduce possible social burdens of participants when creating content. However, for regular comments, the app showed their current character (and title) and their username. The main posts were put on hold until approved by an administrator, to reduce possibly harmful or misleading content; however, regular comments did not have this restriction. These mechanics aimed to engage the socializer, the free spirit, and the philanthropist types of users.

After this first iteration, we started with the designer perspective, in which we focused on linking all the previous concepts together, defining the more specific activities available in the system for the users.

MDA-Based Features and Feedback Loops

Finally, we describe the design of our proposed features for the gamification approach, integrating all the previous considerations and concepts.

The first feature we defined was the "Login Reward." Usage of blood donation apps tends to be low because of the timed nature of donating blood. However, to handle learning and engagement, as part of the onboarding, we chose to encourage users to interact with the system more often. To that end, we rewarded points if users log-in to the app regularly with up to

5 rewards per week, increasing the amount per consecutive access. We linked the reward to the level mechanic, providing additional points according to the level. Regarding the *awareness and knowledge* driver, we also included a message of advice and information regarding blood donation deferral. As dynamics, users could choose to access the app as usual or connect more times to increase their multiplier. Besides, as the level was linked to the rewards, users could choose to increase their level through other activities to receive more points. However, as users were not forced to read the advice message, we connected it with other activities to create the intended aesthetics and more complex activity loops.

The next features we defined, *quizzes* and *social poll*, were aimed to be connected with the broader activity loop and the *awareness and knowledge* driver. Quizzes have been implemented in other blood donation apps, so we included additional mechanics to make it less extrinsic, create new dynamics, and reach the intended aesthetics. We incorporated a life mechanic that resets daily, along with a difficulty level that becomes unlockable as users progress through levels, giving less incentive to guess the answer while also providing a higher risk-higher reward choice to more expert users. Additionally, feedback was provided according to the result, either congratulating the user for their right answer or guiding the user on the mistake. Furthermore, we connected the questions with the content shared through other features, so invested users will feel rewarded for learning on their own. Similar ideas were considered for the content of the *social poll*, but some mechanics that could allow for social interaction were included. Once per week, users could vote between different facts related to blood donation deferral, according to what they felt was the most interesting one. At the end of the week, users were notified of the most popular choice, and the ones who chose it were able to claim reward points. If desired, users could either discuss outside or through the app to try to get information about other users' preferences or to coordinate a specific choice for benefit. Additionally, previous results and facts were accessible, so users could review the content and discuss it for self-learning or connection with users.

The *news sharing* feature was also connected to the previous features and the *awareness and learning* driver, as content shared on the former would be used in the latter ones. Users could like their favorite entries and could comment about them. Comments or replies from administrative users had a special identifier while regular users had the default. Administrators would try to reply to important questions, but the content of the comments or discussions was up to the users, giving them freedom for communication.

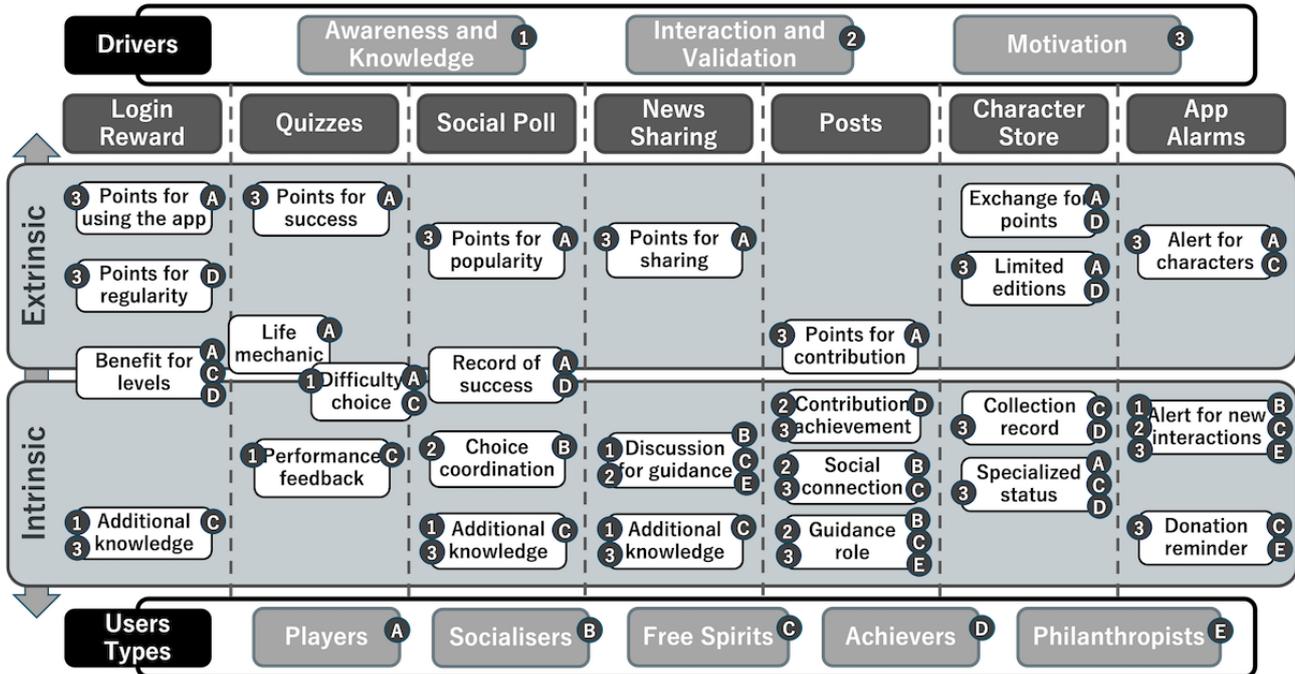

Similarly, to provide more options for the *interaction and engagement* driver, we defined the *posts* feature. Users could create posts for discussion (questions, anecdotes, suggestions, among others). If approved, the posts were shown in the app anonymously, displaying their current relevancy score. Every week, users who created new posts with high relevance would be rewarded points. While posts were defined to require approval by the administrator users, that restriction was not included in the evaluation. Posts would show in the user's feed, by order or relevancy and created date. We aimed to reward users for meaningful content, which in itself could motivate the participation of other users in the discussions. Besides, as the more relevant ones would be highlighted in the app feed, it could provide a sense of self-worth by knowing that one's content received a good reception from the community or that it provided value to the community, eventually motivating them to participate again in the discussions.

The next feature was "Application Alarms," aiming to provide users with some mechanics that could support their preferences. Users had the option to enable up to 3 types of notifications: notifications when new characters were implemented, notifications for news and discussions, and a reminder of the calculated end of the deferral period. The aim was for users to voluntarily choose to get informed about their topics of interest within the app.

Finally, for this initial scope of the design, we included features that, while not creating a proper loop by themselves, were required to connect the previous features and their loops. The first one is the "Character Store," in which users can exchange their points for available characters. The list of characters was updated in a regular schedule, with new characters being highlighted, while locked characters had a gray background. The store showed the required level, price, and current amount collected for each character. Characters being collectible were used as an extrinsic way to motivate the users to keep getting points through the other activities. By contrast, the upgrade option was linked to the title achieved by the user, which meant a special title for their effort. Users had the option to concentrate their points on either one objective or the other or to participate as much as possible to pursue both simultaneously. The other feature was the "Profile," in which users had access to their stats (level/points), their character collection (including the upgrades and selection), and additional settings for the account.

Some of the mentioned intended connections between the drivers, the users, the features, and their gamification elements can be seen in [Figure 1](#), which provides a more general outline of what we aimed to integrate as part of the activity loops.

Figure 1. Outline of connection between drivers, users, features, and gamification elements.

Deploy of the Concept

The proposed design was implemented in a basic mobile prototype, named as “Social Blood” app, to encapsulate the idea of a more interactive role from the citizens in blood donation.

For the icon and the other illustrations of the prototype, public domain images were selected from the Japanese web page Irasutoya [51] for the test deployment. The main screens of the app are displayed in Figure 2.

Figure 2. Screenshots of the main sections (Japanese version) of the prototype: (A) Home tab with the “Login Reward” as a pop-up; (B) Home tab screen; (C) Activity tab screen; and (D) Profile tab screen.

A welcome screen was created for user registration with either an email or Facebook account. An additional functionality (In-app Survey) not related to the design was included for data collection. The app would check for surveys requested by the researcher or the staff and ask the user to answer them. Once the pending surveys were completed, the user was redirected

to the main part of the app. If the user was accessing the app for the first time in the day, the “Login Reward” feature was shown to them.

A “Home” tab was created as the main interface available to the user. This section included features related to both learning and interaction, such as “News” and “Posts.” The user could

check the number of likes and votes of any entry on this screen. An additional option not related to the design, “Error Report,” was also considered in this screen, to let users notify the administrators if any issue was found during the use of the app. An “Activity” tab was created to include the features that support learning. Users can access the “Quiz” and “Social Poll” features on this screen. Users could create a discussion post on this screen. Finally, a “Profile” tab was also created to show to the user information regarding the gamified elements of the app. This section of the app connects to the “Character Store” feature and to the “Settings Screen” screen, which includes the “Application Alarms” feature.

Recruitment of Participants

To collect initial feedback regarding the prototype for its usability and acceptance by prospective users, a survey was performed with volunteers recruited on social networks. A digital flyer was posted with details of contact for the interested parties (Multimedia Appendix 1). Prospective participants were required to have an iPhone (Apple Inc.), be between 20 and 50 years old, and live in Japan for at least the last two months. Participants were recruited from June 17 to July 2, 2021. No incentives were used for the recruitment. Interested citizens received a Google Form (Google LLC/Alphabet Inc.) with the informed consent details and registration (Multimedia Appendix 2). If they signed up for participation, they later received an email with the following: a link to download the app, the user manual of the app (Multimedia Appendix 3), a list of main tasks to complete inside the app (Multimedia Appendix 4), and another Google Form link that contained an anonymous survey (Multimedia Appendix 5). Participants were asked to first download the TestFlight app from the Apple Store, and from there, install and use the approved version of the research prototype for a few days. They could then follow the tasks and complete the anonymous survey either through the app or through the Google Form once they deemed their test as completed. They could test the app and submit their answers to the survey until July 11, 2021.

Ethical Considerations

The study focused on collecting preliminary feedback (usability and acceptance), so no sensible information was stored, and no risk nor effect was involved for the participants. With those points in consideration, considering the guidelines of the Kyoto University Graduate School and Faculty of Medicine Ethics Committee, it was not required to apply for ethical approval.

Evaluation Details and Data Collected

Participants were instructed to attempt to complete the list of primary tasks outlined in the prototype app (Multimedia Appendix 4). Hereafter, these tasks are referred to as follows: Register and log-in (1. Log-in), fill out the survey (2. Survey), interact with news posts (3. News), interact in the discussion posts (4. Discussion), participate in the quiz activity (5. Quiz), participate in the weekly poll activity (6. Poll), submit a simple post (7. Post), acquire a new character (8. Buy), upgrade a new character in the Character Store (9. Evolve), select a new

character for your profile (10. Select), and finalize their session (11. Log out).

In the Google Form, participants were asked to answer the following sections: demographic questions (age and gender), difficulty of task completion (questions about the previously mentioned list of tasks), System Usability Scale (SUS), and follow-up questions divided into acceptance questions (a Likert scale of 5 items) and opinion questions (free-text answers). Further details of these questions are provided in Multimedia Appendix 5. Additionally, participants were given a contact email to ask for support in case they had issues during the testing.

Data Analysis

Statistics of mean, SD (σ), and standard error of the mean (σ_M) were calculated for the average of task difficulty and the final SUS results. The SUS score per participant was calculated according to the standard assignment of points per type of question, which included positive and negative values [52,53].

Qualitative answers were grouped and summarized (if possible) following a simple semantic approach: we grouped the answers for each question and summarized the main ideas according to positive or negative feedback regarding the topic of the question. For the questions regarding the status of the app, we used the labels interface, functionality, and gamification to group the answers. The same categorization was followed for the questions regarding suggestions and improvements. Additional comments were not segregated but were individually considered and described, provided they were not redundant.

The analysis of the questions was carried out after the submission deadline for participant results had elapsed. Only submissions that were completed and received before the deadline were taken into account for the final analysis.

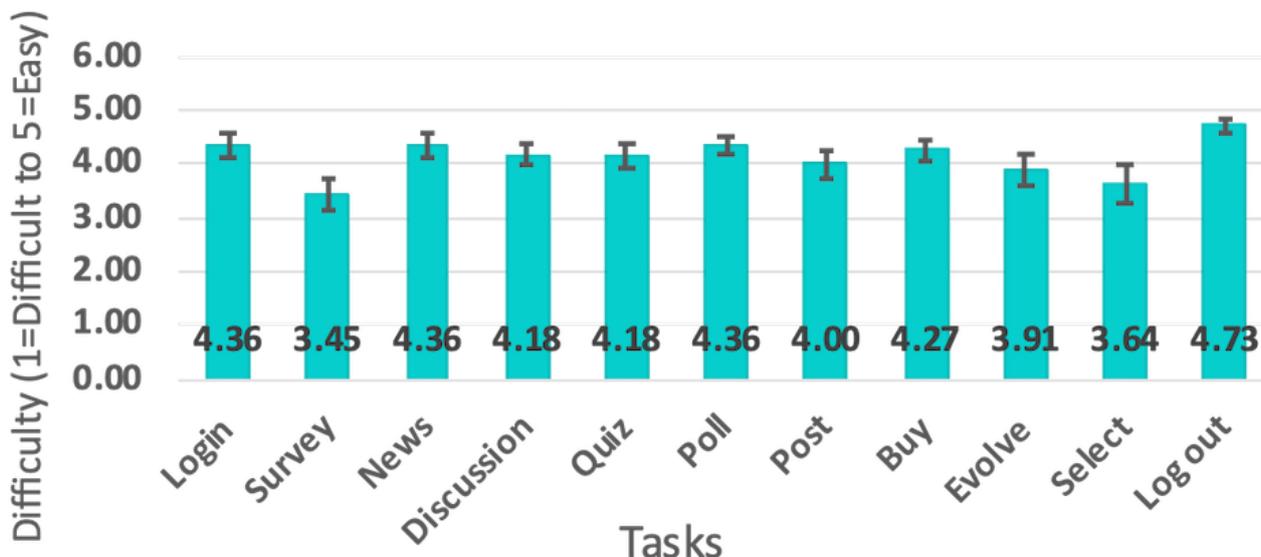

Results

Overview

From May 17 to July 2, 15 participants were recruited for the preliminary evaluation. A total of 13 participants created an account for the app and 11 participants submitted the final form. The full content of the answers is available in Multimedia Appendix 6. Participants ranged in age from 20 to 34 years. There were 10 male and 1 female participants. Descriptive statistics were used regarding the demographic variables of the participants.

Difficulty of Task Completion

Only 4 participants asked for support during the period of the evaluation. Questions were related to tasks 2, 7, 8, 9, and 10. Only tasks 9, 10, and 11 had 1 case each of not being completed. Regarding the difficulty level of each task, the results indicated that all of them were relatively easy to complete (4.13 average). The tasks that were considered the most difficult were task 2 (Completing the in-app surveys) and task 10 (Selecting a new character), as shown in Figure 3.

Figure 3. Subjective results of difficulty of each task.

System Usability Score

The SUS evaluation of our proposed app, as seen in [Multimedia Appendix 7](#), showed a final score of 70.91 (scale 0-100, with 100 being the best usability), slightly above the average SUS score of 68 (C grade, percentile range of 41-59). The highest SUS score received by participants was 95, while the lowest score was 30.

Regarding the score per question, item 1 (“I think that I would like to use this application frequently”) showed the average lowest score from all the lists, with a value of 3.18. The highest score was for items 3 (“I thought the application was easy to use”) and 7 (“I would imagine that most people would learn to use this application very quickly”), with a value of 4.00.

Follow-Up Questions

Acceptance and Qualitative Questions

Regarding the acceptance questions, participants responded positively to the app, expressing interest in its concept (3.82), likelihood to download it (3.55), and likelihood to recommend it to others (3.64).

For the qualitative questions, we summarized the answers for the main topics of the survey.

Goals of the App

Most participants considered a blood donation app concept useful or helpful. From them, 2 participants highlighted the possible impact of the deferral experience. The other 2 participants focused on the service being an app as a core value of the project.

Factors That Could Motivate Usage

Three participants emphasized that being aware of how they can contribute can help maintain their motivation; 3 participants mentioned interaction with others and popularity of the app as their motivation; 3 participants focused on the gamification aspects as one of their factors; 2 participants highlighted the social components as their drivers; and 2 participants indicated possible personal benefits for motivation.

Preferences About the App

Three participants liked the interactive possibilities of the app; 2 participants indicated the Quiz as their preferred feature; 3 indicated sharing and discussing as their favorite activities; 2 mentioned liking the activities involving characters; 1 participant indicated to like the interaction in general; and 1 participant indicated that they liked the aesthetic of the app the most.

Weaknesses of the App

Some participants recommended support of more languages so more citizens could benefit from the app. One participant indicated that the Quiz activity required improvement but did not specify reasons. Two participants indicated that the character functionality could be improved. One participant complained about the compulsory survey in the app because of its duration. One participant felt that not all the gamification features were connecting well with the goal of the project.

Current Status of the App

Only 1 participant mentioned that the current features might not be sufficient to support the goals of the app. They mentioned that while the app can be used to support deferred donors, it might not motivate them to promote blood donation. The other participants provided feedback regarding adjustments or fixes for the current version of the app ([Textbox 1](#)).

Textbox 1. Feedback regarding adjustments or fixes for the current version of the app.

1. Regarding the User Interface
Possibly change the color palette of the app or allow theme selection, as the red color might create discomfort. Implement support for the “Dark” mode, as it created issues with the color of text in the News and Post features.
2. Regarding Functionality
Reduce the length of the In-App Survey. If possible, implement support for more languages, as it could help international students who want to donate.
3. Regarding Gamification
Adjust the point requirement for characters, as it was too high in the test. Move the character selection option to a grid, so users can look at their whole collection when choosing. Add feedback messages in the Quiz about the points acquired.

Improvements and Suggestions

Participants were also asked about what they wanted to see for implementation in the future (Textbox 2).

Textbox 2. Participants’ expectations for implementation.

1. Regarding Functionality
Consider the inclusion of a feature to find locations for blood donations. Consider the inclusion of features to share the news and discussions on social networks. Allow to link or upload videos in the comments.
2. Regarding Gamification
Consider adding the creation of groups or friend requests. Consider adding a “Gacha” option to acquire exclusive characters. Consider adding a ranking or certificate, similar to what is implemented in “Duolingo” [54].

Additional Comments

Some concerns about the information allowed in the Post feature were mentioned, as it could be nonrelated or harmful to the users. The usefulness of the app would be higher if medical institutions could provide information within it. It was suggested to highlight to the users the core goal of the app during the registration. It was also suggested to allow donors to know when their blood is used, as it could help to motivate them to continue to donate blood.

Discussion

Principal Findings

Current ICT services in blood donation aim to improve the citizens’ experience but do not focus on the deferral experience and its effects on prospective donors. This paper contributes to the field by debating the viability of implementing a system focusing on deferral and proposing a novel design to expand the concept of contribution and identity in blood donation. Our study indicates a missed opportunity in current services related to deferral. Potential users seem interested in an app supporting them in this area, and social gamification could make the role of a blood donor more approachable. However, our results, although slightly positive, require further validation due to the limitations, leaving room for discussion regarding the gamified design and the implemented prototype.

Proposed Gamified Approach Reception and Shortcomings

- RQ1. Will our gamified design that focuses on the previously mentioned drivers with regard to the deferral

experience in blood donation have a positive reception from potential users?

Participants’ favorable responses (average Likert scale score of 3.82) and positive opinions about the proposed functionality gave us an initial indication that the proposed project could be beneficial for the community. These results seem to align with ideas and concepts previously discussed in other studies. Previous studies discussed the relationship between knowledge of blood donation and intention to donate blood. However, only a couple of reviewed studies evaluated the ratio of knowledge regarding deferral. From our preliminary survey in Japan [49], 33% of nondonors did not know about the concept of deferral, with an additional 11% also unaware of the concept. Similar results were shown in [55], in which 90% of the participants never heard about the “donor deferral” term. This unawareness regarding deferral could be related to the positive response from the participants in our project, as either it introduced them to a new but relevant concept or it emerged as a service that could be valuable because of the low level of current support, which can be considered from their answers in the open questions. Furthermore, as participants expressed their positive intention to download the app (3.55) and to recommend it to others (3.64), the results suggest that there could not only be an interest but also an emerged necessity that has not appeared before because of the lack of awareness.

However, the current data are insufficient to reach a proper conclusion about the project acceptance, not only because of the small sample but also because of the scope of the participants, as it is not a proper representation of the target population. Additionally, the positive reception from the users could have been influenced by the Hawthorne effect [56], as

the participants were aware of being part of an experiment, and the topic was related to a social contribution project. In this regard, a higher-scale study is required for further validation and analysis to decrease the effects of noise in the data and allow for more significant results.

Regarding the gamification aspect and its value, while the mentioned results were positive, their approval could have been related more to the goal of providing support. We delved into the comments of the participants about the design itself for possible conclusions. When asked about motivation to use the app and its best feature, some participants did indicate that the gamified aspects caught their interest and could even be driving motivators, highlighting the characters as part of it. These answers seem to suggest that the gamified components can play a role in, at least, capturing the interest of potential users. However, more detailed data are required to determine how beneficial is the integration of the gamified concepts in our proposed project. For example, asking participants for specific reasons why a gamification feature seems motivating to them or why it might feel discouraging. Besides, an additional evaluation regarding the impact is considered, as the value of the proposal can be confirmed if a positive effect can be determined. Comparing which features have more or less effect could also be important, as it could allow for the identification of factors to consider for future ICT-gamified implementations in blood donation.

Currently, while we discussed the importance of integrating the type of users, their motivations, and the MDA elements to nurture the drivers of interest, we have no specific data to indicate if our design has the desired effect or not. The data limitation becomes important with our goal of nurturing the intrinsic motivation of the citizens (prospective users), as we cannot recognize if the potential interest is related to the components that nurture the intrinsic motivation or the ones that do so for the extrinsic motivation. Analyzing some of the comments, most of the positive focus was on the *quiz* and the *characters*. These features, although designed considering an activity loop that could nurture intrinsic motivation, might not reach that goal in their current state. This weakness appears to be echoed in the feedback from 1 participant, who expressed dissatisfaction with the current state of the app, feeling that it falls short of achieving our design goals and lacks sufficient integration of features. As some participants showed interest in the social activities of the design (which are more related to intrinsic motivation), it might be worth it to redesign the current gamified activities to incorporate and integrate social components as part of the progress of the users.

We previously mentioned that some restrictions should be considered in a system related to blood donation, as some interactions could clash with the altruistic nature behind the donation act. To address that complexity, having a deeper understanding of game design itself is required. Learning from different and successful implementations of player interactions in game environments can lead us to a design that can properly nurture prospective blood donors' social motivation. From the case studies in *The Gamification of Learning and Instruction Fieldbook* [57], an interesting idea is the implementation of specific types of leaderboards that encourage various forms of

participation, thereby creating a stronger activity loop. Building on that concept, although we aim to steer clear of incentivizing competition in donation participation, we could adapt similar interactive mechanisms to enhance engagement in learning activities. For instance, in the Quiz activity, introducing a monthly leaderboard alongside corresponding achievements could offer users more personalized motivation compared with simply rewarding points. Another intriguing option could involve allowing users to accumulate questions they have answered correctly, which they could then use in a soft-competition interaction. In this scenario, users could anonymously challenge others using their question collections until their opponent provides an incorrect answer. With this revised structure, points serve as the initial incentive to engage with the Quiz feature. However, the interaction with others serves as an intrinsic motivator, encouraging users to strive for higher-difficulty questions to challenge others. Additionally, users may be motivated to continue learning or recalling information to avoid losing in these interactions.

Applying a similar rework infused with deeper game design insights could greatly enhance the experience for prospective users. However, before this step, gathering additional data on the project's reception and soliciting input from more citizens would be invaluable. This information will help define the direction for implementing gamification strategies to encourage blood donation participation.

Prototype Implementation Usability and Usefulness

- RQ2. Will our initial prototype implementation of the design be considered usable and useful in its current iteration?

Based on the initial average SUS score of 70.91, it seems that our proposed implementation is progressing in the right direction in terms of usability. Additionally, participants did not report significant issues regarding how to use the main options of the app, as they rated the difficulty level closer to "Somewhat Easy." However, similar to the reception, we cannot draw definitive conclusions due to the small sample size and the potential influence of the Hawthorne effect. Moreover, the scores may have been positively biased due to the presence of an instruction manual and the support provided. Taking these factors into account, we directed our attention to the individual responses for more in-depth discussion.

Regarding difficulty, the activities with lower scores were those related to managing the characters (*evolving and selecting*), as well as the added survey functionality. From the comments, it appears that the functionality for upgrading the characters to their additional forms is not intuitive. The issue may stem from the fact that the options are spread across different screens, making it challenging to locate and connect them. Consolidating all the actions related to character management onto a single screen, separate from the character acquisition process, could potentially make the interface easier to use. In the case of the survey, the only complaint received was regarding its length, with participants finding it too long to complete. However, it received the lowest rating among the activities, suggesting that other participants may have also encountered issues with it. We can hypothesize that, aside from the length of the activity itself, participants may have been dissatisfied with its mandatory status

rather than being optional. We could enhance the data collection process within the app by integrating it with gamification concepts, offering initial extrinsic rewards to users interested in participating. Ideally, we should also establish a loop that fosters participation through intrinsic motivation. This could involve designing activities or incentives that align with users' intrinsic interests, values, or desires for personal growth or contribution. Furthermore, from specific results of the SUS score, the participant who gave the lowest score (30) cited issues with the user interface. Taking this into consideration, future implementations of the proposed design should allocate adequate time for interface functionality and compatibility tests.

Another point for analysis from the SUS results is the average score assigned to item 1 ("I think that I would like to use this application frequently") of the survey. Although participants expressed positive sentiments regarding downloading the app and recommending it to others, the responses to item 1 indicated a nearly neutral position regarding the desire to use the app frequently. Indeed, the variation in results could stem from differing perspectives among user types. Nondonors might not use the app as frequently, even if they appreciate its concept. Similarly, donors with no deferral experience might use it for reference purposes, but perhaps not as frequently as deferred donors. Another possible and simple reason could be that participants might have had different interpretations of the term "frequently." Besides the inclusion of the "user category" variable, future survey evaluations could use a support question to help identify the regularity (if either daily, weekly, or monthly, as examples) of usage of our proposed implementation.

Further data collection is still required to obtain more detailed feedback about the current implementation, as there might be additional issues or shortcomings from the usability or the usefulness that were not captured because of the small number of participants.

Limitations

The study has multiple limitations that affect the reliability and generalization of the results. The small sample size of only 11 participants from Japan limits our ability to capture the true opinions of the various groups within the target population (prospective blood donors). Nondonors, donors, and deferred donors could have different perspectives and specific improvements regarding the design. Besides, although the recruitment was performed with Japanese material, we cannot confirm that only Japanese citizens participated in the evaluation. We have to consider that, although blood donation is seen as an altruistic and social activity in general, there can be differences in how individual values contribute to society according to one's cultural background.

Recruiting participants through social networks and including ownership of an iPhone as part of the criteria may have biased the sample toward individuals with higher levels of

technological literacy, potentially influencing the results of the SUS score. However, to mitigate this bias, consistent guidance materials and tasks were provided to ensure a similar starting point for all participants.

The final version of the prototype for evaluation was created within a limited timeframe and programmed solely by 1 (REC) researcher. This constraint impacted the resources available for implementing content and graphical user interface options. The workforce constraints also impacted the choice of the target system for development, leading to the selection of iOS for release due to the developer's familiarity with it. Additionally, while the introduction of elements and activities involving user donation was considered, the acquisition and integration of these data into the current iteration of the project proved infeasible due to limitations related to permissions, partnerships, and time constraints.

Not collecting quantitative results regarding the value of the gamification aspect of the proposed design represents a significant weakness in the evaluation. Furthermore, the anonymous nature of the responses prevented the possibility of soliciting more detailed explanations regarding certain qualitative answers or comments from participants about the gamified components of the app. Indeed, it is crucial to address these shortcomings in future evaluations. Planning for a recruitment process that ensures a sufficient number of participants and obtaining ethical approval are essential steps for conducting a more comprehensive evaluation.

Conclusions

ICT systems have gained significant recognition and reliability across various fields, including within the realm of blood donation. We sought to explore previous work related to deferred donors and identify areas for further improvement. In addition to providing automated services, certain ICT projects have prioritized enhancing user motivation by incorporating gamification into their design. However, upon reviewing the current literature, it became apparent that only a few, if any, of the existing systems have specifically addressed the experience of deferral or its implications. In this research, we introduced an innovative ICT gamified design and implementation aimed at addressing this overlooked issue. Additionally, we offered an initial assessment of the project's potential reception, usability, and usefulness. Further enhancements can be made to the design of activities, which currently rely primarily on extrinsic motivation elements, to incorporate more social interaction. This would create an enriched activity loop that fosters intrinsic motivation. Further research could involve a more specialized and longitudinal design evaluation with a larger sample size. Understanding which specific features or gamification elements influence citizens' intentions or behaviors regarding their role in blood donation could be crucial for future design endeavors. Moreover, it could serve as a reference point for official ICT implementations in blood donation services.

Acknowledgments

The authors thank the citizens of Kyoto for their participation and feedback regarding the prototype of the study. REC holds a Japanese Government (Monbukagakusho: MEXT) Scholarship for the Doctoral Program. This work was supported by JST (CREST grant JPMJCR21M1), Japan.

Authors' Contributions

REC performed the literature research, design of the study, development of the app, and data analysis. LHOS and YM reviewed and validated the steps of the study design, especially the preliminary evaluation of the concept. All authors contributed points for discussion and implications based on the results. Additionally, all authors participated in drafting and revising the manuscript.

Conflicts of Interest

Abstract

Background: Digital Mental Health (DMH) tools are an effective, readily accessible, and affordable form of mental health support. However, sustained engagement with DMH is suboptimal, with limited research on DMH engagement. The Health Action Process Approach (HAPA) is an empirically supported theory of health behavior adoption and maintenance. Whether this model also explains DMH tool engagement remains unknown.

Objective: This study examined whether an adapted HAPA model predicted engagement with DMH via a self-guided website.

Methods: Visitors to the Mental Health America (MHA) website were invited to complete a brief survey measuring HAPA constructs. This cross-sectional study tested the adapted HAPA model with data collected using voluntary response sampling from 16,078 sessions (15,619 unique IP addresses from United States residents) on the MHA website from October 2021 through February 2022. Model fit was examined via structural equation modeling in predicting two engagement outcomes: (1) choice to engage with DMH (ie, spending 3 or more seconds on an MHA page, excluding screening pages) and (2) level of engagement (ie, time spent on MHA pages and number of pages visited, both excluding screening pages).

Results: Participants chose to engage with the MHA website in 94.3% (15,161/16,078) of the sessions. Perceived need ($\beta=.66$; $P<.001$), outcome expectancies ($\beta=.49$; $P<.001$), self-efficacy ($\beta=.44$; $P<.001$), and perceived risk ($\beta=.17-.18$; $P<.001$) significantly predicted intention, and intention ($\beta=.77$; $P<.001$) significantly predicted planning. Planning was not significantly associated with choice to engage ($\beta=.03$; $P=.18$). Within participants who chose to engage, the association between planning with level of engagement was statistically significant ($\beta=.12$; $P<.001$). Model fit indices for both engagement outcomes were poor, with the adapted HAPA model accounting for only 0.1% and 1.4% of the variance in choice to engage and level of engagement, respectively.

Conclusions: Our data suggest that the HAPA model did not predict engagement with DMH via a self-guided website. More research is needed to identify appropriate theoretical frameworks and practical strategies (eg, digital design) to optimize DMH tool engagement.

Introduction

Background

Access to mental health support is poor, with barriers including mental health stigma and limited time, availability, and accessibility [1]. According to the National Institute of Mental Health, it was estimated that 57.8 million adults in the United States lived with a mental illness in 2021 [2]. Digital Mental Health (DMH) is seen as the next generation of mental health care, in that it is readily accessible to most, affords anonymity when appropriate, and can be used when a consumer needs it, rather than when a provider is available. It serves a particularly valuable role where services are scarce, with studies finding disproportionate use of online mental health screening tools in rural areas [3].

In general, engagement with DMH is poor [4-7]. When using mobile apps, consumers in 1 study disengaged in as little as 2 weeks [8], and another study found a median 15-day retention rate of 3.9% [9]. However, there is limited research on engagement with mental health focused websites, which likely have different usage patterns than other approaches to DMH, such as mobile apps or digitally mediated therapy. Mental health websites are typically free, usually used for short-term information gathering, and may include a wide variety of self-guided resources such as psychoeducation articles, self-administered screening tools for common mental health problems, links to find therapists, downloadable self-monitoring tools (eg, medication management charts), ways to connect with peer support groups, and interactive self-help tools (eg, cognitive reframing activities using artificial intelligence). One website developed and maintained by Mental Health America (MHA) [10] features all of these DMH resources contained within approximately 500 pages, is free and openly accessible, and is visited by 9-10 million people a year, with 6.5 million using self-administered screening tools and 3.5 million accessing other resources. However, resources other than screening tools are underutilized. In particular, those who self-administer mental health screening tools are unlikely to engage with the other valuable resources on the website. For instance, in 2021, only 70% of those who used the website to self-administer a screening tool visited a nonscreening-related page on MHA. Only 15% subsequently read any articles despite the valuable psychoeducation and other materials available that could help them improve their emotions and behavior (Mental Health America, unpublished data, January 2024).

We partnered with MHA to conduct collaborative research with the goal of increasing optimal engagement with DMH resources on their website. We defined optimal engagement with DMH as engaging with resources that are aligned with users' needs and interests and motivate users toward taking positive mental health actions. The Health Action Process Approach (HAPA) is a theoretical framework aligned with this goal. The HAPA model has been described in detail elsewhere [11-13], but here

we describe it as applied to DMH tool engagement. The HAPA model is separated into 2 phases: *motivational* (when *intentions* are developed) and *volitional* (when *health actions* occur). During the motivational phase, preintention factors shape behavioral intention. Several mechanisms operate to support or hinder progression through the HAPA stages of health behavior change. Movement from preintention to intention is influenced by *perceived need* to engage in a health action [14], *task self-efficacy*, the degree to which consumers believe that they can engage in behavior change, *perceived risks* of not acting, and *outcome expectancies*, the positive and negative anticipated consequences of engaging in a behavior. If consumers have a high perceived need for change, high task self-efficacy, positive outcome expectancies of engaging with a DMH tool, and high perceived risks of not acting, they are more likely to move through the 2 stages of the motivational phase: *preintention* to *intention*. If task self-efficacy, perceived needs and risks, or outcome expectancies are low, then the consumer will be unlikely to set intentions. The volitional phase describes the process by which a consumer moves through the action stages: *behavioral intention* to *planning* to *acting* (ie, implementing a health behavior; in this case, engaging with DMH). Consumers with high intentions are more likely to implement a health behavior if they engage in planning. Other mechanisms in the traditional HAPA model include *maintenance* and *recovery self-efficacy* (the belief in the ability to continue a health behavior in the face of challenges, or restart if stopped) and *coping planning* (plans for how to continue an action in the face of challenges). These mechanisms are less relevant for the current research because they are focused on ongoing maintenance of behavioral actions. The HAPA model has robust empirical support in predicting health behavior change, such as dietary behaviors and medication adherence [15,16]. For example, 1 study found that medication adherence was significantly predicted by intention, task self-efficacy, coping self-efficacy, and coping planning in a sample of patients with type 2 diabetes [16].

We aimed to assess the applicability of the HAPA model to DMH engagement on a mental health website. We conducted the current research to assess whether the HAPA model fit our data and to examine the strength with which HAPA model constructs (eg, self-efficacy, perceived need, and perceived risks) were related to DMH engagement. This information would be used to develop and test tailored engagement strategies that match stage (eg, preintention, intention) and mechanism (eg, self-efficacy, perceived need) to the individual to improve DMH engagement. Tailored nudges (ie, strategies using a cue, such as a message, to influence user behavior) using this language could be developed and tested to help consumers move through the stages of behavior change (ie, from preintention or intention into the volitional stage of acting) to act on health-promoting behaviors (eg, through self-help tools, therapy, and building social connections). For instance, upon completing a screening tool, an MHA website visitor who endorses low self-efficacy

could be shown language intended to increase self-efficacy to thereby increase their motivation to transition from self-administering screenings to initiating self-help or professional treatment.

There is precedent for applying the HAPA model to develop stage-matched interventions. Lippke et al [17] found that for intenders, but not preintenders, a physical activity planning intervention produced changes in intention and planning which were subsequently associated with increased physical activity. Self-efficacy, which was not targeted by the intervention, was not impacted by the intervention and not associated with physical activity. The authors concluded that interventions will be more successful when tailored to the participant's stage of change, with intenders being more receptive to volition-based interventions as predicted by the HAPA model. Similar findings have been found when developing interventions tailored to stage of change and HAPA mechanisms. A study on hand hygiene behavior in hospital units found that interventions tailored to empirically assessed HAPA components (eg, providing information on the risks of not acting for units that scored low on risk perceptions) were associated with a decrease in infections, whereas units that received untailored interventions did not experience a decrease in infections [18].

Previous work has described how the HAPA model can be adapted for ongoing digitally delivered psychotherapy [19], but the use of DMH self-guided websites is likely to have different engagement patterns and associations. Website usage is likely to be more sporadic, short-term, and used by people in the preintention and intention stages, as they are determining what kinds of actions they want to take. In addition, the operationalization of a health action on a DMH website includes actions such as clicking on a navigation page, reading an article about depression, or using a web-based single-session intervention. Planning a health action in this context may be a seamless and instantaneous process that is difficult to separate from intention. Intention to act, planning, and action (clicking a link) may occur within a time span ranging from seconds to minutes, rather than days to weeks as in usual applications of the HAPA model [12,20-25]. Furthermore, it is unclear whether or how principles of marketing (strong call to actions) or user design (color and placement) determine user behavior as compared with the HAPA model.

A meta-analysis of 95 studies using the HAPA model [13] provides a summary of empirical literature applying the HAPA model to a wide variety of health behavior outcomes, such as dietary behavior and physical activity [26]. Self-efficacy and outcome expectancies were moderately correlated with intention, and risk perception effect sizes were small but statistically significant. In the meta-analytic path analyses, self-efficacy, intention, and action planning significantly predicted outcomes. Due to the small and nonsignificant role of risk perception, the authors suggested that this mechanism may play only a minor role in predicting health behaviors.

Only 3 (3.2%) of the studies included in the meta-analysis used an observed behavioral measure. The remaining studies used self-report measures of outcomes, and none of the studies examined DMH. Because using self-report measures for all

HAPA constructs and outcomes is likely to inflate associations due to method bias, observable behavioral outcomes are necessary to reduce these biases [27]. In addition, most studies had a greater than 4-week time lag between the measurement of HAPA constructs and behavior. Whether the HAPA model is relevant for behaviors that occur with lags of seconds or minutes rather than weeks or months remains unknown.

An additional study not included in the meta-analysis examined the HAPA model in a DMH context and included both self-report and observed measures of engagement [14]. This study of engagement with a web-based intervention for trauma had mixed findings: self-reported engagement was associated with HAPA motivational constructs but observed engagement was not. These findings support the idea that self-reported engagement is more strongly associated with self-reported HAPA constructs than objective measures and that planning may be most effective for those with low self-efficacy.

In sum, several gaps exist in the HAPA model literature. Studies have relied primarily on self-report measures, with so few including observed or objective measures that a moderator comparison of self-report and objective measures could not be conducted in the meta-analysis. In addition, no studies applying the HAPA model to DMH were included in the meta-analysis because so few exist. We are aware of only 1 previous study that applied the HAPA model to DMH, which found attenuated effects when using an objective measure for engagement behavior [14]. Therefore, more research is needed to determine the strength of the HAPA model in a DMH context and which uses objective measures of behavioral outcomes.

Aim of This Study

The purpose of this cross-sectional study was to test whether the HAPA model predicted DMH engagement and to determine which HAPA model constructs were most strongly associated with DMH engagement. In doing so, this manuscript contributes to the broader literature on the HAPA model by focusing on DMH engagement, employing an objective measure of health behavior, and measuring outcomes within seconds or minutes between the motivational and volitional phases of the HAPA model. In addition to contributing novel insight toward understanding engagement with DMH via the HAPA model, these findings could be applied to strategies to increase engagement by focusing on HAPA constructs in website design.

Methods

Participants

Data were collected via voluntary response sampling. Participants were a naturalistic sample of people who self-administered a mental health screener on the MHA website between October 2021 and February 2022. The inclusion criteria were clicking on the "Next Steps" survey and completing it for their own needs (as opposed to reporting that it was completed for others, such as their children). The exclusion criteria were completing less than 70% of the Next Steps survey or taking the "parent test" or "youth screener" (Pediatric Symptom Checklist [28,29]); there was no age restriction. The final

analytic sample included data from 16,078 sessions (15,619 unique IP addresses from US residents) on MHA.

Procedure

Users of the MHA website can self-administer any of several evidence-based mental health screening measures for depression, postpartum depression for new and expecting parents, anxiety, attention-deficit/hyperactivity disorder, psychosis or schizophrenia-spectrum disorders, posttraumatic stress disorder, eating disorders, substance or behavioral addictions, and youth mental health (separate versions for youth or caregivers to complete). Participants could click on any of these tests and take the online screener; for example, clicking “Depression Test” showed users the Patient Health Questionnaire-9 [30]. This study focuses on data collected from the Next Steps survey, which was an option participants could choose among these screeners and was also provided via a link on the results pages for screening measures. Participants could complete as many screeners as desired. After completion of each screener, including the Next Steps survey, the participants were shown an optional demographics survey. Data submissions were chunked into sessions, which were defined as all website interactions via a unique IP address bounded by a gap of at least 30 minutes.

Ethical Considerations

All materials and procedures for this study were approved by the University of Washington Institutional Review Board (STUDY00010958). All data were protected under the University of Washington Institutional Review Board. Data sharing between MHA and the University of Washington followed a Data Security Protocol, which required data to be deidentified via random identifiers and stored securely on an encrypted institutional server accessible only by authorized research team members. The study’s external Data Safety and Monitoring Board oversaw study progress and participant safety. The Institutional Review Board and Data Safety and Monitoring Board determined that there were no anticipated risks for participants and no further application for ethical approval was required.

Measures

Demographic Survey

The demographic survey included items about age range, race, ethnicity, and gender identity. A checkbox was provided for participants to indicate whether they identify as transgender. If participants completed more than 1 demographic measure during a session and these values differed, which was rare (<3%), we report “more than 1 answer given,” which should be distinguished from “more than 1 of the above.” For instance, an IP address that completed only 1 demographics measure and endorsed “Asian” and “Black” was categorized as “more than 1 of the above,” whereas an IP address that reported “Asian” on 1 demographics measure and “Black” on another screener was categorized as “more than 1 answer given.” It is possible that multiple people (eg, in the same household) may have completed the surveys from the same IP address.

Next Steps Survey

The Next Steps Survey was developed by the research team at the University of Washington collaboratively with MHA (Multimedia Appendix 1). Because this was a naturalistic study and participants were not incentivized to participate, the team aimed to use measures that were pragmatic, brief, tailored to the website activities, and consistent with MHA’s values and approach. No existing measures were suitable, as studies using the HAPA model often apply individualized items due to the study-specific nature of the constructs. Therefore, items were developed by the study team by adapting existing items developed and tested in other studies of the association between HAPA constructs and behavior [13,14,20,22,31-34]. The resulting 22-item survey designed to assess HAPA model constructs in the context of DMH consisted of four 5-item subscales (outcome expectancies, intention, self-efficacy, and planning) and 2 single items for perceived risk and perceived need. The 5-item subscales comprised questions that asked about the five types of resources available on the MHA website: (1) learning more about mental health (LMH), (2) connecting with others (CO) who have mental health conditions, (3) learning about treatment options (LTO), (4) receiving mental health treatment (RMH), and (5) using online self-help tools (ONL).

Outcome expectancies were measured by participant ratings on their belief that the 5 types of resources would improve their mental health on a 4-point scale ranging from 0 (*Definitely won’t help*) to 3 (*Definitely will help*). Intention items assessed whether participants intended to act on the 5 resources on a scale of 0 (*I definitely will not do this*) to 3 (*I definitely will do this*). Self-efficacy items asked participants to rate their confidence in their ability to act on the 5 items on a scale of 0 (*Not at all confident*) to 3 (*Very confident*). Planning items were yes/no questions that asked participants whether they had a specific plan to take any of those actions.

Perceived need was measured on a scale of 0 (*No*), 1 (*I don’t know*), and 2 (*Yes*). Perceived risk was measured on a 4-point scale from 0 (*No, it will get better on its own*) to 3 (*Yes, it will get much worse*). If participants completed more than 1 Next Steps survey during a single session, we report on data provided during the first completion within that session.

Engagement With Web-Based Content

Choice to engage was a dichotomous outcome indicating that participants visited any web pages, excluding screening pages. To correct for extremely brief web page visits that did not represent true engagement, based on literature that shows that users evaluate website design within seconds [35], we defined engagement as requiring at least 3 seconds on the MHA website excluding time spent on screening pages.

We operationalized level of engagement with 2 indicators: number of pages visited, or engaged pages (EP), and total engaged minutes (EM). EP was computed by summing the total number of web pages visited on the MHA website excluding screening pages. EM was computed by summing the total amount of time spent on MHA’s website excluding time spent on screening pages. Because time spent per page was computed

from when a page on MHA was loaded to the time participants clicked on a link to another page on MHA, time spent on the final page viewed (eg, before closing a browser or visiting another website) could not be included in EM.

Analyses

The goals of these analyses were to examine whether the HAPA model predicted engagement with web-based resources and which HAPA constructs were significant predictors of website engagement. We did this by testing the model fit of the adapted HAPA model to our data using structural equation modeling (SEM).

Data were collected from 21,329 sessions in which participants took the Next Steps survey. Of these, 75.9% (16,179/21,329) completed the Next Steps survey for their own needs and did not take the Pediatric Symptom Checklist. Analyses included data from only those participants who completed at least 70% of the 22 Next Steps survey items (N=16,078). Because participants completed the Next Steps survey during each session and may have exhibited different engagement patterns after ≥ 30 minutes of inactivity on the website, IP addresses with multiple sessions (n=605) were retained in the analysis, with the number of sessions for any 1 IP address ranging from 1 to 10. Response categories with less than 10% endorsement were combined with the next adjacent response category for accurate parameter estimation. Following collapsing of response categories, proportions of endorsement for each of the Next Steps survey items were no greater than 58.9% for any 1 response option.

Prior to SEM, we examined correlations between the Next Steps survey items, EM, and EP. We used the weighted least squares means and variance-adjusted (WLSMV) estimator, which computes a tetrachoric or polychoric correlation matrix using pairwise complete observations. Next, measurement models using unidimensional confirmatory factor analysis (CFA) were assessed for each reflective latent construct (self-efficacy, outcome expectancies, intention, and planning) using model fit

statistics, with factor loadings as the parameters of interest. The measurement model for level of engagement was underidentified and model fit indices could not be estimated. The adapted HAPA model was tested by incorporating the HAPA constructs and their measured variables to form the theorized model (Figure 1). This model excludes maintenance self-efficacy, recovery self-efficacy, and coping planning, as these constructs are not relevant to individuals engaging with a website during a single session. Maintenance self-efficacy refers to one's belief that they can overcome barriers to taking a health action, and coping planning refers to identifying methods to cope with those barriers. These constructs were excluded because there were no foreseeable barriers to the health action (ie, clicking a link) in the context of this study. Recovery self-efficacy refers to restarting a health behavior once it ends, which in our study would be returning to the website after usage. This is less relevant to our study as our research question is focused on an immediate behavioral outcome.

The first model predicted choice to engage, and the second analysis predicted level of engagement for those who did engage. All parameters were modeled and allowed to freely vary, and models were assessed by examining model fit indices and path coefficients. EM was modeled as a censored variable to account for the unrecorded time spent on the final page visited. Assumptions of multivariate normality and linearity were assessed in MPlus. While SEM is robust to nonnormality, recommended values of acceptable skewness range from -2 to $+2$, and acceptable values of kurtosis range from -7 to $+7$ [36,37]. Skewness and kurtosis for both EM and EP were well out of the acceptable range (EM skewness=5.19, kurtosis=40.58; EP skewness=5.74, kurtosis=92.56), indicating nonnormal distributions. The highest proportion of values was at 0 (5.6%) for EM and 2 for EP (13.6%; Table 1). The WLSMV estimator is used to analyze ordinal response data, does not require the observed variables to be normally distributed, and assumes that the underlying latent response variable is normally distributed [38-41].

Figure 1. Hypothesized structural equation model based on the adapted Health Action Process Approach model.

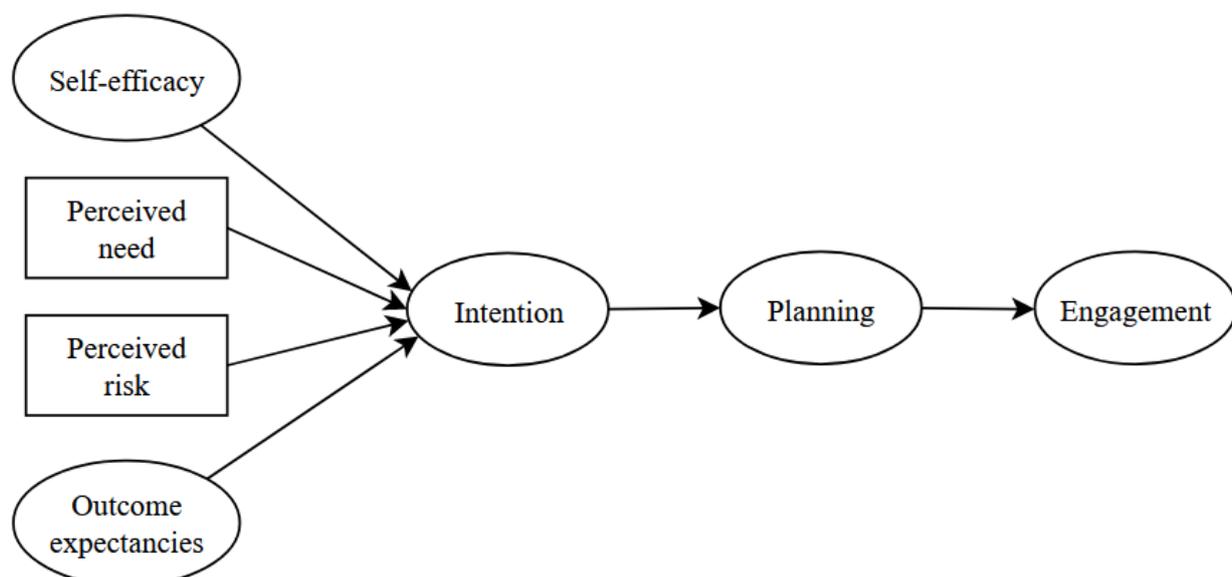

Table 1. Ranges, means, variances, and percentage of zeros for engaged minutes and engaged pages.

	Range	Mean	Variance	Percentage of zeros
Engaged minutes				
Full sample ^a	0-167.72	4.30	114.53	5.55 ^b
≥3 seconds ^c	0.05-167.72	4.56	120.27	— ^d
Engaged pages				
Full sample	0-202	6.92	80.33	4.60 ^e
≥3 seconds	1-202	7.32	82.34	—

^aN=16,078.^b892/16,078.^cn=15,161.^dNot applicable.^e740/16,078.

The WLSMV estimator uses pairwise deletion for missing data; the first and second models used data from 99.5% (16,003/16,078) and 93.8% (15,086/16,078) of the full analytic sample, respectively. The analytic samples exceeded the recommended sample size of 300 for CFA [42]. While there are no absolute standards for an adequate sample size for SEM, the sample exceeded recommendations of a sample size of 10-20 per estimated parameter or a range from 200 to 1000 observations for WLSMV estimation depending on model complexity [43-47].

There is evidence that traditional cutoffs for model fit based on the maximum likelihood estimator (eg, standardized root mean squared residual [SRMR] <0.08, comparative fit index [CFI] ≥0.95, and root mean square error of approximation [RMSEA] <0.06) may not be appropriate for models with censored, ordinal, and dichotomous variables, and alternative indices of fit are being explored in the SEM literature [48-52]. However, to the best of our knowledge, there is no well-accepted method for interpreting model fit for the WLSMV estimator. For the purposes of this analysis, we reported traditional model fit indices and used traditional interpretations.

Theoretically consistent model modifications informed by Mplus MODINDICES outputs were conducted as exploratory analyses to determine whether model fit could be improved. Planning was removed from the full models such that intention predicted engagement. Next, intention and planning were removed such that the motivational HAPA constructs (ie, self-efficacy, perceived need, perceived risk, and outcome expectancies) predicted engagement. Descriptive data were analyzed in R (version 4.3.2; R Core Team, 2023) [53], and SEMs were conducted using Mplus (version 8.4; Muthén & Muthén) [54].

Results

Descriptive Statistics

The analytic samples included data from 16,078 sessions and a subsample of sessions in which participants spent at least 3 seconds on MHA outside of screening pages (n=15,161). See [Table 2](#) for demographic characteristics. Correlations between the 22 Next Steps survey items, EM, and EP are shown in [Multimedia Appendix 2](#).

Table 2. Demographic characteristics.

^a“More than 1 answer given” includes participants who provided different responses in multiple sessions on Mental Health America.

^bThe original response options for gender identity included “female” and “male.” We report these as “woman” and “man”, respectively, to distinguish from sex assigned at birth.

^cPHQ-9: Patient Health Questionnaire-9 [30].

^dGAD-7: General Anxiety Disorder-7 [55].

Measurement Models

Self-efficacy, outcome expectancies, intention, and planning originally had 5 categorical items corresponding to the 5 types of resources: LMH, CO, LTO, RMH, and ONL. The CO items had the lowest loadings on self-efficacy, outcome expectancies, and intention ($\beta=.49-.55$; $P<.001$). The CO item (“Do you have a specific plan to connect with others who have mental health

conditions?”) was the third-lowest loading item for planning ($\beta=.61$; $P<.001$). To maintain consistency among the measurement models, all CO items were removed, and CFAs were conducted using the remaining 4 items (LMH, LTO, RMH, and ONL). Standardized coefficients and model fit indices for the final confirmatory 1-factor models are shown in [Table 3](#). All standardized factor loadings of each latent construct were significant ($P<.001$).

Table 3. Standardized coefficients and model fit indices for measurement models.

Structural Models

Predicting Choice to Engage

The first model predicted whether participants chose to engage with the MHA website. The model comprised the HAPA constructs and a dichotomous outcome variable, choice to engage (Figure 2). Model fit was poor: $\chi^2_{147}=40,022.3$, $P<.001$, CFI=0.81, RMSEA=0.13, 90% CI 0.129-0.131, and SRMR=0.14. Of note, the RMSEA is often inflated in models

with small *df* and should be interpreted with caution [56]. The strongest predictor of intention was perceived need ($\beta=.66$, $SE=0.02$, $P<.001$), and intention significantly predicted planning ($\beta=.77$, $SE=0.01$, $P<.001$). However, choice to engage was not significantly predicted by planning ($\beta=.03$, $SE=0.02$, $P=.18$). The model accounted for 83% of the variance in intention, 58.7% of the variance in planning, and 0.1% of the variance in choice to engage, although these estimates should be interpreted with caution due to poor model fit. See Table 4 for latent variable correlations.

Figure 2. Structural equation model predicting choice to engage. Chi-square(147)=40,022.3, $P<.001$, comparative fit index=0.81, root mean square error of approximation=0.13, 90% CI 0.129-0.131, and standardized root mean square residual=0.14. * $P<.001$. INT: intention; LMH: learning more about mental health; LTO: learning about treatment options; OE: outcome expectancies; ONL: using online self-help tools; PL: planning; RMH: receiving mental health treatment; SE: self-efficacy.

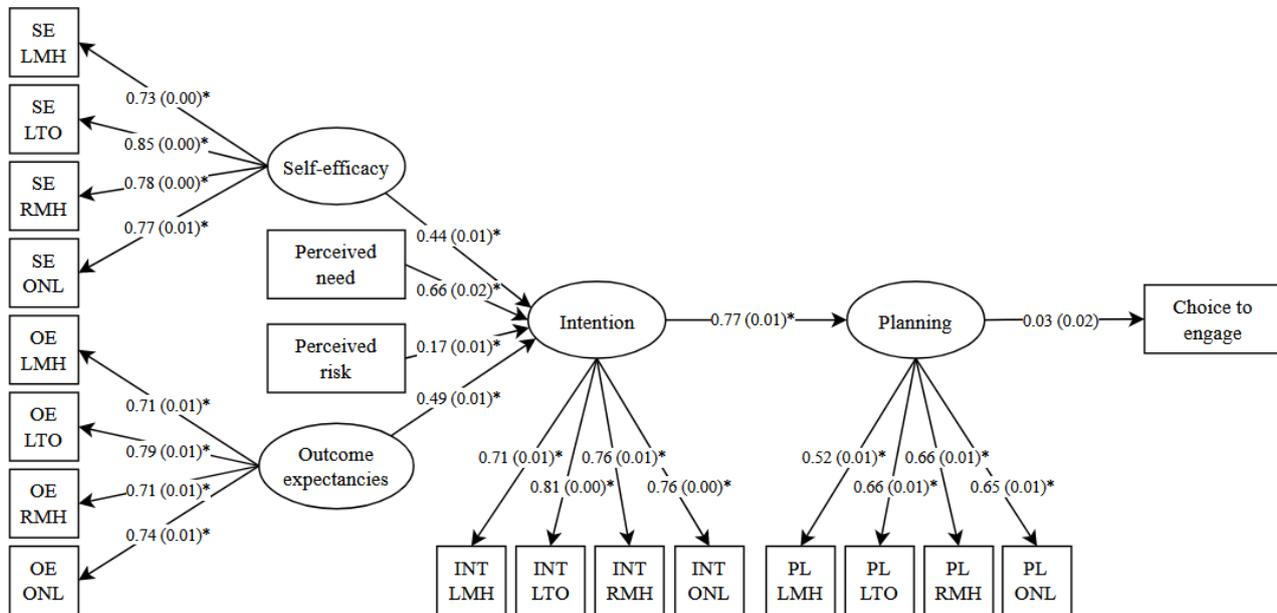

Table 4. Latent variable correlations.

	Intention	Self-efficacy	Outcome expectancies	Planning
Model 1: Predicting choice to engage, r (P value)				
Self-efficacy	0.77 (<.001)	— ^a	—	—
Outcome expectancies	0.79 (<.001)	0.68 (<.001)	—	—
Planning	0.77 (<.001)	0.59 (<.001)	0.61 (<.001)	—
Choice to engage	0.02 (.18)	0.02 (.18)	0.02 (.18)	0.03 (.18)
Model 2: Predicting level of engagement, r (P value)				
Self-efficacy	0.77 (<.001)	—	—	—
Outcome expectancies	0.79 (<.001)	0.67 (<.001)	—	—
Planning	0.77 (<.001)	0.59 (<.001)	0.60 (<.001)	—
Level of engagement	0.09 (<.001)	0.07 (<.001)	0.07 (<.001)	0.12 (<.001)

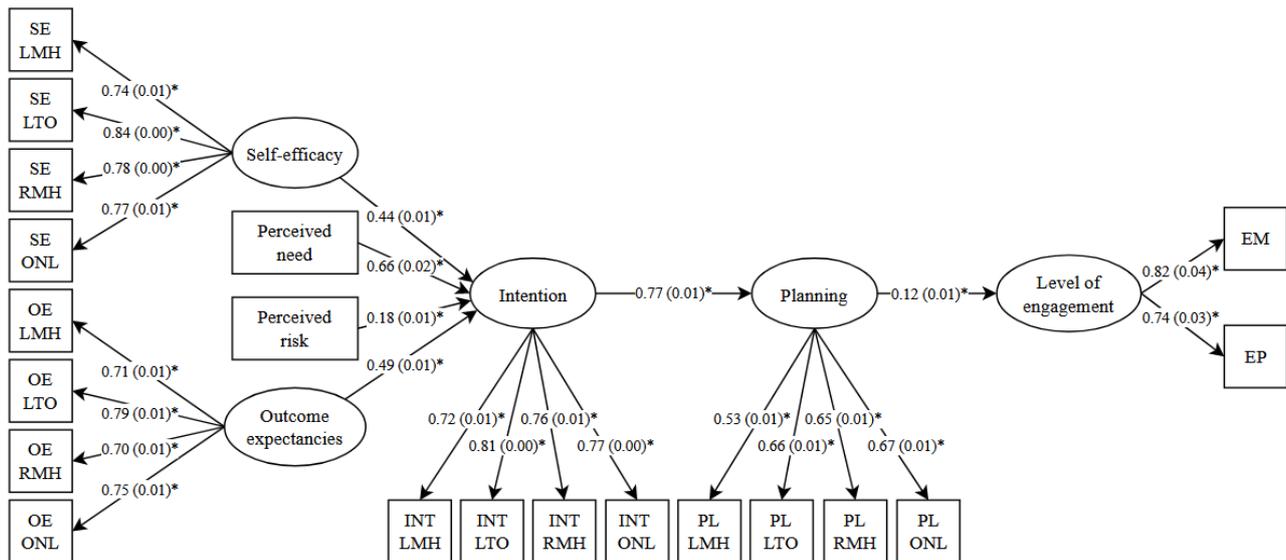

^aCorrelations on the principal diagonal of the correlation matrix and redundant correlations are not shown.

Predicting the Level of Website Engagement

Using the same structural model, we predicted level of engagement within the subsample of participants who engaged with MHA for at least 3 seconds (Figure 3). Similar to the first model, model fit was poor: $\chi^2_{164}=36,925.1$, $P<.001$, CFI=0.84,

RMSEA=0.12, 90% CI 0.121-0.123, and SRMR=0.14. The second model accounted for 83% of the variance in intention and 58.6% of the variance in planning. While the association between planning and level of engagement was statistically significant ($\beta=.12$, $SE=0.01$, $P<.001$), the model was able to account for only 1.4% of the variance in level of engagement. See Table 4 for latent variable correlations.

Figure 3. Structural equation model predicting level of engagement. Chi-square(164)=36,925.1, $P<.001$, comparative fit index=0.84, root mean square error of approximation=0.12, 90% CI 0.121-0.123, and standardized root mean square residual=0.14. * $P<.001$. EM: engaged minutes; EP: engaged pages; INT: intention; LMH: learning more about mental health; LTO: learning about treatment options; OE: outcome expectancies; ONL: using online self-help tools; PL: planning; RMH: receiving mental health treatment; SE: self-efficacy.

Sensitivity Analyses

The first sensitivity analysis was conducted by computing correlations between time spent on pages of different content types (navigation, condition, treatment, provider, connect, and DIY tool), the number of pages visited per content type, and the Next Step survey items. Time spent and number of pages visited by content type exhibited low correlations with the Next Steps survey items ($r=-0.08$ to 0.26). A second sensitivity analysis examined the second SEM predicting level of engagement with EM and EP winsorized at the 95th percentile. Model fit remained poor: $\chi^2_{154}=39,373.3$, $P<.001$, CFI=0.82, RMSEA=0.12, 90% CI 0.121-0.123, and SRMR=0.14.

Exploratory Analyses

Because planning had the worst model fit among the measurement models, it was removed from each structural model. The first exploratory analysis examined the model predicting choice to engage without planning (ie, intention predicted choice to engage). This model accounted for 88% of the variation in intention, but intention was not significantly associated with choice to engage ($\beta=.01$, $SE=0.02$, $P=.41$), $\chi^2_{86}=25,070.8$, $P<.001$, CFI=0.86, RMSEA=0.14, 90% CI 0.133-0.136, and SRMR=0.13. In the second model, planning was removed such that intention predicted level of engagement. Intention significantly predicted level of engagement ($\beta=.09$, $SE=0.01$, $P<.001$), and the model accounted for 88% of the variance in intention and 0.8% of the variance in level of engagement, $\chi^2_{99}=23,252.1$, $P<.001$, CFI=0.89, RMSEA=0.13, 90% CI 0.123-0.126, and SRMR=0.13.

Next, self-efficacy, perceived need, perceived risk, and outcome expectancies were modeled to directly predict the engagement outcomes. In the first model, perceived need ($\beta=.11$, $SE=0.04$, $P=.01$) and perceived risk ($\beta=.10$, $SE=0.02$, $P<.001$) were significant predictors of choice to engage, $\chi^2_{41}=8,015.8$, $P<.001$,

CFI=0.92, RMSEA=0.11, 90% CI 0.108-0.112, and SRMR=0.14. The path coefficients for self-efficacy ($\beta=.04$, $SE=0.03$, $P=.20$) and outcome expectancies ($\beta=-.03$, $SE=0.03$, $P=.26$) were not statistically significant. The model accounted for 0.9% of the variance in choice to engage. In the second model, level of engagement was significantly associated with perceived need ($\beta=.18$, $SE=0.03$, $P<.001$), perceived risk ($\beta=.09$, $SE=0.01$, $P<.001$), and self-efficacy ($\beta=.08$, $SE=0.02$, $P<.001$) but not outcome expectancies ($\beta=-.01$, $SE=0.02$, $P=.62$). Only 1.7% of the variance in level of engagement was accounted for by the model, $\chi^2_{50}=8,060.1$, $P<.001$, CFI=0.94, RMSEA=0.10, 90% CI 0.101-0.105, and SRMR=0.13.

Discussion

Principal Findings

This study found limited support for the HAPA model in predicting engagement with web-based mental health resources, although the adapted HAPA model was useful for understanding and predicting self-reported motivations, intentions, and planning. We found support for the HAPA model in the motivational phase, with a large percentage of explained variance in health behavior intention (83%) and planning (59%). Self-efficacy, perceived need, perceived risk, and outcome expectancies significantly predicted intention to engage. This is consistent with a meta-analysis, which found strong support for the motivational phase of the HAPA model [13]. The results also highlight the importance of perceived need, the strongest predictor of intention, when investigating engagement with DMH. Although referenced in prior studies of the HAPA model, perceived need is not often included as a construct in HAPA studies, including the meta-analysis. Our results indicate that perceived need may be an important construct to regularly measure in future HAPA research.

Consistent with previous work [57-59], we found evidence of the intention-behavior gap in predicting DMH website

engagement. Neither intention nor planning was a strong predictor of the engagement outcomes. Choice to engage was not associated with self-efficacy, outcome expectancies, intention, or planning. Latent variable correlations between level of engagement and self-efficacy ($r=0.07$), outcome expectancies ($r=0.07$), intention ($r=0.09$), and planning ($r=0.12$) were statistically significant, but effect sizes were trivial and should be viewed with caution because of the poor fit of the overall model and other limitations, such as the use of a self-report measure and measuring engagement using MHA's available metadata (number of pages visited and time spent on MHA, excluding the final page viewed). However, these coefficients are aligned with meta-analytic results, which found coefficients less than 0.18 for all HAPA constructs in predicting behavioral outcomes [13]. A number of studies examining the HAPA framework have also found evidence supporting the preintention-intention-planning phases but limited or no support for the association between planning and behavior [60-62]. For example, previous work demonstrated that HAPA constructs predicted intention and planning but did not find evidence for planning predicting behavior (physical activity) across samples of middle-aged, physically inactive women, adults with obesity, and walking duration in older adults [60-62]. One study of a 2-week web-based intervention similarly found greater support for the motivational phase than the volitional phase, as well as stronger associations between self-reported motivational HAPA constructs and self-reported behavior but weaker associations with self-reported motivational constructs and objective measures of engagement [14].

Assuming that our estimates in predicting DMH engagement are correct, we suspect that 1 reason our study had weaker estimates than those found in the meta-analysis may have been our use of objective measures of behavior rather than self-report outcomes. The stronger associations at the motivational phase of the model in our study and in the meta-analysis may be inflated by method bias, as all measures were self-reported except for engagement, though the context of DMH may also have played a role. Only 3 studies in the meta-analysis included objective measures of behavior, none focused on DMH, and none focused on extremely short time lags for measuring behavior [13]. While our findings align with those in another study that used an objective measure of engagement [14], the relative lack of objective measures in existing HAPA studies limits our ability to contextualize our findings within the larger HAPA literature. Due to this, it is unknown whether the lack of association with engagement in our study as compared with other studies was the result of the specific context of a mental health resource website, the use of an objective measure of behavior, or the short time lag of measurement.

These findings have important implications for researching and enhancing user engagement with self-guided mental health websites. Studies on various DMH forms, such as web-based interventions or digitally delivered psychotherapy, consistently show that real-world engagement is poorer than in controlled lab experiments. Future studies could focus on understanding the factors influencing small-scale engagement actions, such as split-second decisions to click on website resources. These actions may collectively contribute to more substantial,

long-term health behaviors. We suspect that website design, specifically strategies ensuring easy access and appeal of resources aligned with user needs, interests, and identity [63], may be a better predictor of health behavior in this context than the HAPA model. The sheer volume of materials on websites such as MHA can be overwhelming, making the quality, relevance, and visual appeal of resource links potentially more influential on DMH website engagement than constructs such as self-efficacy and outcome expectancies [64]. Tailoring links based on information from screening and demographic surveys is being explored in our ongoing research through a randomized trial of personalized website design.

Strengths and Limitations

Strengths of the study include a large real-world sample of participants across the United States seeking information on a broad spectrum of mental health conditions. Another strength was the application of SEM, a robust statistical technique, to a real-life DMH setting with a well-established theoretical basis for the hypothesized model. There has been little research on the mechanisms driving engagement with DMH websites, and to our knowledge, this study is the first to fill this gap in the literature by examining the HAPA model in the context of DMH website engagement.

This study has several limitations. The Next Steps survey, used as a self-report measure, is a proprietary tool that lacks psychometric evaluation and assesses simplified HAPA model constructs. Other studies of the HAPA model have distinguished, for example, between task self-efficacy, coping self-efficacy, and recovery self-efficacy, and between action planning and coping planning [16]. Nevertheless, this approach enabled the assessment of HAPA constructs in relation to the specific tools provided by the MHA website and aligns with the methodology of many other published HAPA studies, which also use study-specific measures without psychometric evaluation. In addition, this study did not examine these constructs across multiple time periods. The stability of these constructs over time in this context remains unexplored, leaving open the possibility that factors such as self-efficacy may fluctuate. However, our study assessed these constructs as closely as possible to the engagement behavior. Our measurement of engagement was limited to MHA's metadata, focusing on pages visited and time spent, excluding time spent on the final page viewed. While this approach may not capture the full spectrum of engagement behaviors, it was the only feasible approach for gathering a very large number of responses in a real-world setting. This study relied on a convenience sample, as participants self-selected into the survey. This could introduce bias, limiting the generalizability of our findings. Moreover, the exploratory models were iteratively honed and are likely overfit to the data. However, the modified models also resulted in poor model fit, suggesting that the adapted HAPA model did not fit the data.

Future Directions

Future research could address these limitations by using psychometrically sound measures, exploring temporal dynamics of HAPA constructs, broadening engagement assessments, and using more diverse participant recruitment strategies. The study

design could be modified such that the HAPA constructs are measured over multiple time points to examine change or consistency in appraisal-motivational factors over time. Researchers may also explore other frameworks that might be more appropriate for understanding and enhancing engagement with DMH (eg, Social Norms Theory [65], Health Belief Model [66], and I-Change Model [67]). We encourage future researchers to continue to fill these gaps, especially by including objective measurements of behavioral outcomes and by conducting additional research across the wide array of DMH approaches beyond website usage.

Conclusions

As online mental health services become increasingly popular, there is a growing need for standardized measures of online engagement with all DMH, including mental health resource websites such as MHA. Despite the recent proliferation of DMH tools, they are underutilized by the communities they intend to

serve, and few studies have examined factors impacting DMH engagement and how it can be optimized. This study aimed to identify whether and which HAPA constructs (self-efficacy, perceived need, perceived risk, outcome expectancies, intention, and planning) were significant predictors of DMH engagement. Despite some evidence supporting the motivational phase of the HAPA model in this context, the key finding was that there was insufficient support for the HAPA model in predicting engagement with DMH. The literature has yet to identify predictors of real-world DMH engagement, and doing so is an emerging and crucial research priority. It is possible that poor model fit was due in part to the study limitations. Researchers are encouraged to explore the HAPA model and other frameworks of health behaviors to identify predictors of DMH engagement. Understanding factors that optimize DMH engagement is urgently needed to inform evidence-based approaches toward tailoring DMH websites to better serve people seeking online mental health support.

Abstract

Background: Data dashboards are published tools that present visualizations; they are increasingly used to display data about behavioral health, social determinants of health, and chronic and infectious disease risks to inform or support public health endeavors. Dashboards can be an evidence-based approach used by communities to influence decision-making in health care for specific populations. Despite widespread use, evidence on how to best design and use dashboards in the public health realm is limited. There is also a notable dearth of studies that examine and document the complexity and heterogeneity of dashboards in community settings.

Objective: Community stakeholders engaged in the community response to the opioid overdose crisis could benefit from the use of data dashboards for decision-making. As part of the Communities That HEAL (CTH) intervention, community data dashboards were created for stakeholders to support decision-making. We assessed stakeholders' perceptions of the usability and use of the CTH dashboards for decision-making.

Methods: We conducted a mixed methods assessment between June and July 2021 on the use of CTH dashboards. We administered the System Usability Scale (SUS) and conducted semistructured group interviews with users in 33 communities across 4 states of the United States. The SUS comprises 10 five-point Likert-scale questions measuring usability, each scored

from 0 to 4. The interview guides were informed by the technology adoption model (TAM) and focused on perceived usefulness, perceived ease of use, intention to use, and contextual factors.

Results: Overall, 62 users of the CTH dashboards completed the SUS and interviews. SUS scores (grand mean 73, SD 4.6) indicated that CTH dashboards were within the acceptable range for usability. From the qualitative interview data, we inductively created subthemes within the 4 dimensions of the TAM to contextualize stakeholders' perceptions of the dashboard's usefulness and ease of use, their intention to use, and contextual factors. These data also highlighted gaps in knowledge, design, and use, which could help focus efforts to improve the use and comprehension of dashboards by stakeholders.

Conclusions: We present a set of prioritized gaps identified by our national group and list a set of lessons learned for improved data dashboard design and use for community stakeholders. Findings from our novel application of both the SUS and TAM provide insights and highlight important gaps and lessons learned to inform the design of data dashboards for use by decision-making community stakeholders.

Trial Registration: ClinicalTrials.gov NCT04111939; <https://clinicaltrials.gov/study/NCT04111939>

KEYWORDS

data visualizations; dashboards; public health; overdose epidemic; human-centered design

Introduction

Background

Data dashboards are tools, often published digitally on websites or dedicated apps, that present visualizations; they are increasingly used to display data about behavioral health, social determinants of health, chronic and infectious disease risks, and environmental risks to inform or support public health endeavors [1-4]. Dashboards can be an evidence-based approach used by communities to influence public awareness and decision-making and to focus the provision of resources and interventions in health care toward specific populations [2,3,5-8]. For example, local public health agencies across the nation have communicated health data about the COVID-19 pandemic through dashboards, using these as tools to generate awareness and motivate behavior change (eg, adherence to public health guidelines) [9].

Despite widespread use, evidence on how to best design and use dashboards in the public health realm is limited [1,9-12]. There is also a notable dearth of studies that examine and document the complexity and heterogeneity of dashboards in community settings. Experiences from the Healing Communities Study (HCS) provided an opportunity to empirically learn how dashboards and health data visualizations can be assessed to inform design and use, especially among community end users.

The HCS is implementing the Communities That HEAL (CTH) intervention aimed at reducing overdose deaths by working with community coalitions in selected counties and cities highly affected by opioid deaths in each state [13]. In January 2020, as part of the community engagement component of the CTH, 4 research sites followed a common protocol to develop community dashboards to support community coalitions in selecting evidence-based practices (EBPs) to reduce opioid overdose deaths in their respective communities. The protocol stipulated which key metrics to present to each community regarding opioid overdose deaths and associated factors that may contribute to their prevalence [14]. The CTH intervention protocol involved dashboard cocreation by HCS researchers

and community stakeholders from each community that incorporated the principles of user-centered design [15].

We define community stakeholders for this analysis as individuals in the community who are engaged in fighting the overdose crisis, including coalition members (eg, county public health officials and behavioral health practitioners) and community research staff. The CTH intervention envisioned community-tailored dashboards as a tool that coalition members would use to discuss and understand baseline conditions and trends, to inform EBP selections, and monitor research outcomes of interest to the community. Community research staff, often with preexisting ties to the community, were to support and lead coalitions through the use of data dashboards for decision-making and ongoing monitoring. These stakeholders were the anticipated dashboard end users who were not expected to have expertise in the use of dashboards, even though community research staff had additional training in community engagement and overall study protocols. Our research team oversaw the design, implementation, maintenance, and evolution of the dashboards used by these stakeholders.

The CTH dashboard cocreation involved, at a minimum, iterative show-and-tell sessions in which feedback from community stakeholders was provided on wireframes with the goal of refining the dashboard and its ability to align with specific objectives (eg, to address local challenges in fighting the opioid crisis and to highlight key performance indicators). Although the CTH intervention required the same specific core components of the dashboards (eg, use of predetermined metrics, annotations for metrics, and granularity of the data presented), communities could incorporate unique components based on preferences and resources, such as displaying local data (eg, county opioid overdose death rates) acquired by the HCS. Thus, dashboards varied in layout, interface, and content across the 4 sites.

Objectives

To elucidate lessons learned from providing dashboards to the coalitions and community stakeholders, we investigated the following questions on the CTH dashboards: Are the CTH dashboards usable and useful for community decision-making?

Are the dashboards easy to use and understand? Will the dashboards be used in the long term, and, if yes, for what purposes will they be used? Our study is novel because of four specific areas: (1) the use of a qualitative approach (instead of a quantitative approach) to expound on the technology adoption model (TAM) constructs, informing existing perspectives on dashboard usability; (2) the investigation of dashboard usability across 67 diverse communities; (3) the generation of themes and subthemes on the usability of a dashboard in the substance abuse domain; and (4) the identification of common themes on dashboard usability from a TAM and System Usability Scale (SUS) perspective [16,17] by comparing feedback from 4 unique applications of a dashboard that was tailored to the needs of end users. Our findings will be used to establish current perceptions of the dashboards and prioritize gaps in knowledge, design, and use that can be considered for future dashboard applications.

Methods

Ethical Considerations

Advarra Inc, the HCS's single institutional review board, approved the study protocol (Pro00038088). The HCS study is a registered trial (ClinicalTrials.gov NCT04111939).

Research Setting

Data collection and analyses were conducted as part of the HCS, a 4-site, waitlisted community-level cluster-randomized trial seeking to significantly reduce opioid overdose deaths by implementing the CTH intervention in 67 communities across Kentucky, Massachusetts, New York, and Ohio [13,18]. For the first wave of the HCS, each site created interactive dashboards with community stakeholder input to support local data-driven decision-making using community-level metrics for 33 communities randomized to receive the intervention (ie, wave 1 communities) from January 2020 through June 2022 [14]. Our analysis involved all wave 1 communities: 8 communities from Kentucky, 8 communities from Massachusetts, 8 communities from New York, and 9 communities from Ohio.

The CTH Dashboards

Common Components Across the Dashboards

More details about the cocreation of the dashboards and required core components can be found elsewhere [14]. Briefly, each site was responsible for developing a secure portal for each community receiving the CTH intervention. The portals contained downloadable intervention materials (eg, information on EBPs, community profiles, and community landscape data). Each portal had a CTH dashboard with data visualizations (eg,

bar and line graphs and tables) displaying metrics related to the HCS's primary outcome of reducing opioid deaths (eg, opioid overdose rates) and secondary outcomes connected to EBPs (eg, number of naloxone kits distributed and number of buprenorphine prescriptions filled).

Unique Components of the CTH Dashboards

Each site developed its CTH dashboard using different software, including Power BI (Microsoft Corp), Tableau (Salesforce Inc), SharePoint (Microsoft Corp), D3.js (Mike Bostock and Observable, Inc; Data-Driven Documents), Drupal (Drupal Community), and different types of visualizations, such as bar graphs, line plots, and tables with directional markers [14]. The 4 distinct dashboards displayed community-specific data that were accessible only to that community's stakeholders. Data acquisition and display were limited by site-specific data use agreements, which informed the timing of the data (lags), data suppression, and granularity (eg, aggregation by state vs county), as well as the requirement of user and password-protected access in some cases.

Study Design, Sampling, and Recruitment

Between June and July 2021, we conducted a mixed methods assessment of the use of the CTH dashboards. This period reflects the postimplementation phase of the second version of the cocreated dashboards (Figures 1 and 2) and was a stable time during which no fundamental revisions were made to the dashboards across the HCS. We administered the SUS to and conducted TAM-informed semistructured interviews with community stakeholders involved in the HCS. We collected sociodemographic data from participants to help characterize respondents. The interview data and SUS scores were concurrently examined to identify factors that influenced dashboard perceived use and usability.

Each site sampled and recruited participants. The sample was drawn from community stakeholders in the HCS communities who had a community portal account (ie, active users). Researchers from each site generated a roster of eligible participants from site server audit log files. Our research team worked with field staff to achieve a diverse participant pool of community stakeholder active users within each community. The sample included coalition members, including stakeholders in the HCS communities responsible for championing the use of a specific CTH intervention component, and HCS community staff who had the role of coordinating the use of data for decision-making. These active users were invited via email to participate in a group interview via Zoom (Zoom Communications, Inc) with up to 6 participants, although a few interviews were conducted individually due to scheduling challenges.

Figure 1. Mockups of the Communities That HEAL (CTH) dashboards: (A) CTH dashboard for Kentucky and (B) CTH dashboard for Ohio. Please note that any names of communities present are not real, and only synthetic data are used in the images. DAWN: deaths avoided with naloxone; EMS: emergency medical service; HCS: Healing Communities Study; MOUD: medication for opioid use disorder; OD: overdose; OUD: opioid use disorder; TBD: to be determined.

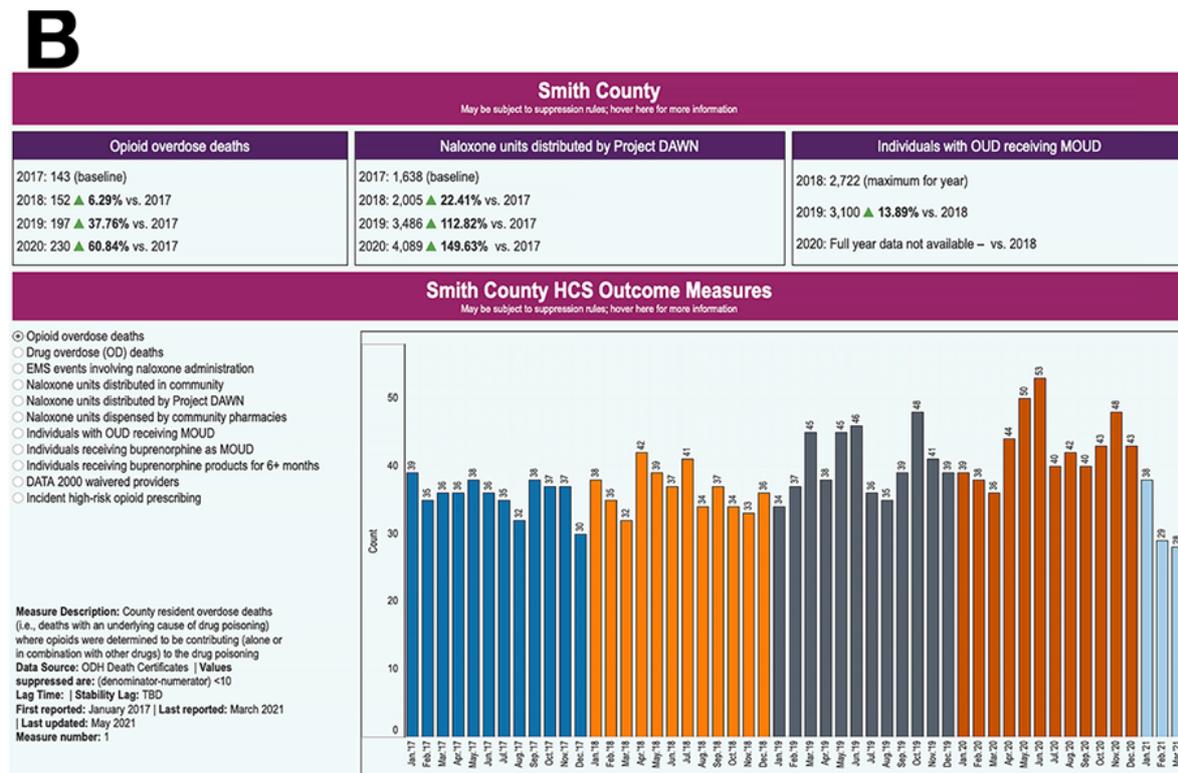

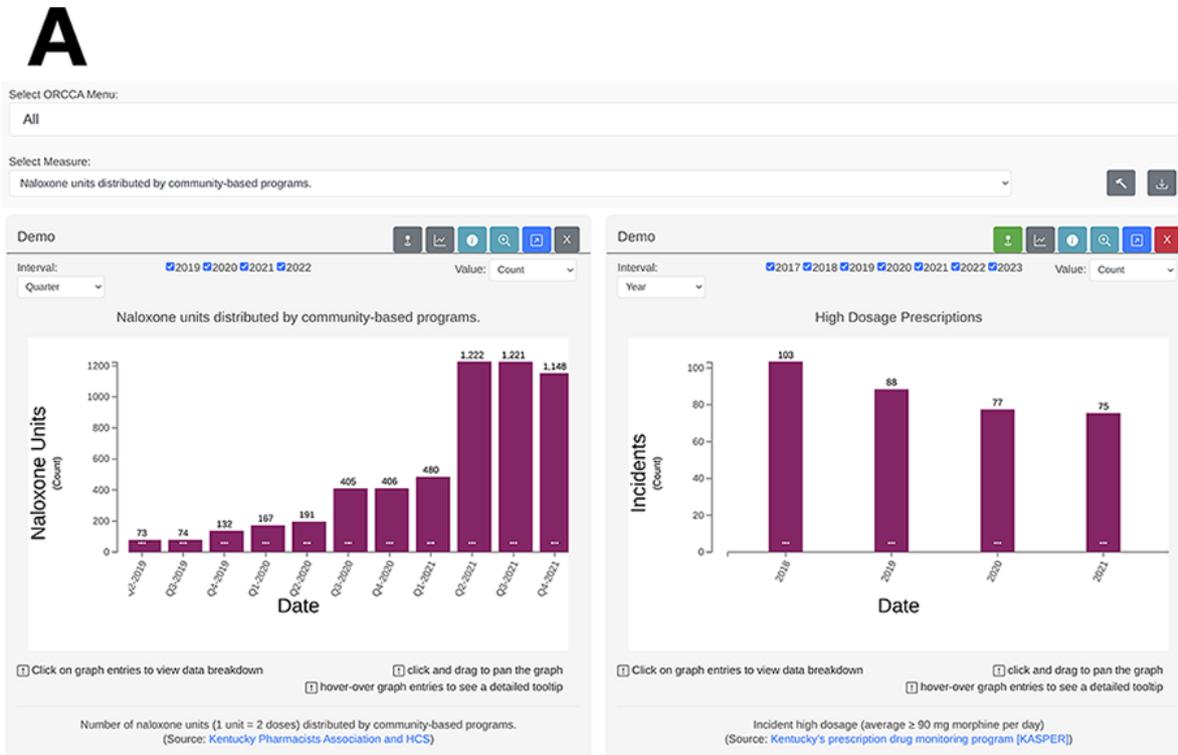

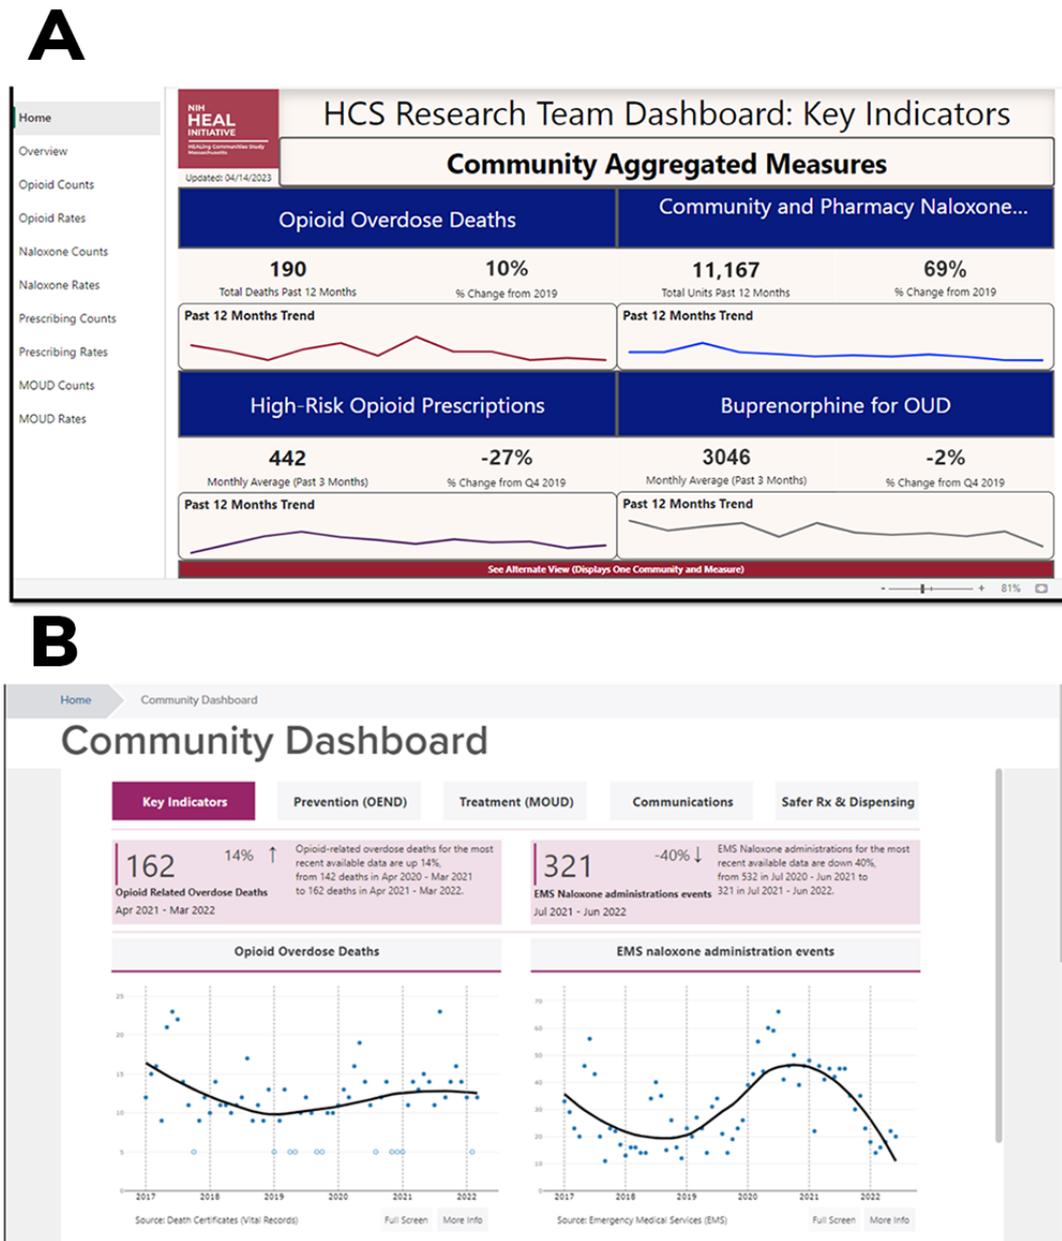

Figure 2. Mockups of the Communities That HEAL (CTH) dashboards: (A) CTH dashboard for Massachusetts and (B) CTH dashboard for New York. Please note that any names of communities present are not real, and only synthetic data are used in the images. EMS: emergency medical service; HCS: Healing Communities Study; HEAL: Helping to End Addiction Long-term; MOUD: medication treatment for opioid use disorder; NIH: National Institutes of Health; OUD: opioid use disorder.

Data Collection

Mixed methods evaluation data were collected by each site, which were then shared with the HCS data coordinating center (DCC) for analysis. Interviewers at each site first received common training on the research protocol, interview guide, and interviewing techniques. During the review, participants verbally provided consent and then were asked to individually fill out a short survey on REDCap [19]. The survey included sociodemographic questions and the SUS. After participants completed the survey, the research team displayed the site-specific CTH dashboard with synthetic community data to

reorient participants to the dashboard used in their community. Next, the research team asked participants semistructured, open-ended questions based on the TAM dimensions of perceived usefulness, perceived ease of use, intention to use, contextual factors (Multimedia Appendix 1). Table 1 provides operational definitions for each of the TAM constructs used to develop our interview guide questions. We focused on 4 constructs to explore how the dashboards were used for community decision-making, their ease of use, the intent for future use, and the context around dashboard use. Our interviews lasted approximately 1 hour and were recorded and transcribed.

Table 1. Technology adoption model themes and operationalized definitions^a.

Construct	Operationalized definition
Perceived usefulness	
Description	Alignment of the dashboard and its functions with the community stakeholder's expectations for goals and tasks
Benefits	How the dashboard positively influences the work and decision-making expectations of the community stakeholder
Drawbacks	How the dashboard did not meet the work and decision-making expectations of the community stakeholder
Perceived ease of use	
Description	Alignment of the technical functionality of the dashboard with the community stakeholder's workflow (needs and desires)
Barriers	Specific challenges faced with using the portal
Facilitators	Specific resources needed to support the use of the portal
Intention to use	
Description	The willingness of the community stakeholder to use the dashboard in the future, even if modified slightly
Acceptance	The approachability of the dashboard as a technological tool to accomplish work
Preference	Specific improvements, changes, or recommendations to the dashboard
Contextual factors	
Description	Circumstances (eg, social, cultural, and historical circumstances) that influence a community stakeholder's use of the dashboard
Community data orientation	Collective perceptions about how the community connects and works with data, including community data tools and approaches for decision-making

^aDefinitions derived from Davis [16].

Data Analysis

The validated SUS consisted of 10 five-point Likert scale questions. Each SUS item was scored (scale of 0 to 4), and their scores were summed and multiplied by 2.5 to assign a total score from 0 to 100 (lowest to highest usability). For the qualitative data, 1 research site constructed the codebook using an iterative constant comparative method [20]. Initially, the team created general codes using concepts from the TAM from the interview guide. Two researchers (RGO and YW) each coded an interview independently, compared coding, and discussed agreement and differences with a senior researcher (NF), creating a refined codebook with consensus codes and clarified definitions. The remaining interviews from this site were coded by these researchers, with review by the senior researcher. One researcher (RGO) working with the team inductively created subthemes for each TAM dimension, revised the codebook, and coded all the interviews from the site. The established codebook and coded interviews were then shared with the DCC. Two new coders from the DCC were trained by the experienced coders; each independently coded 6 test interviews and compared results in meetings with the experienced coders. Then, the DCC coders coded all remaining interviews (n=14) with weekly meetings to discuss differences and ensure alignment. The DCC coders then reviewed the original 7 interviews coded by the research site to confirm alignment across all data. After coding, the DCC conducted an exploratory analysis to better understand the emergent themes across different sites. Interview transcriptions were analyzed using NVivo (version 12; QSR International) [21].

The reporting of our qualitative methods and results adheres to the COREQ (Consolidated Criteria for Reporting Qualitative

Research) guidelines (Multimedia Appendix 2; Table 1) [22]. Altogether, scientific rigor was supported by the use of participant IDs and labels to ensure data were appropriately associated with participants across communities; encouraging consistency in data collection and the fidelity of the interview guide through mentorship and weekly meetings to ensure agreement and the reliability of codes and results; discussions with various experts in the data visualization field during the development of themes; and triangulation (data from multiple HCS communities and diverse roles) and parallel data collection (SUS and TAM) to achieve theoretical sufficiency for themes and diverse representation across sites [23,24].

Results

Descriptive Summary of Survey Respondents and Interview Participants

A total of 159 individuals from across all HCS sites were invited to participate in our study. Of them, 62 (39%) individuals enrolled and participated in interviews. We conducted a total of 17 group interviews (with an average of 3 participants per group) and 10 individual interviews (with an average of 7 interviews per site). Community coalition members represented 56% (35/62) of interviewees, with the remaining 44% (27/62) comprising community staff hired by the HCS to work with their specific community coalition (Multimedia Appendix 2; Table 2). At least 1 person was interviewed from every community. Participants from all sites typically had a master's degree, and a majority of participants from Ohio and Massachusetts were younger. Participants also typically identified as non-Hispanic White and female across sites (Multimedia Appendix 2; Table 3).

Table 2. Subthemes under perceived usefulness.

	Illustrative quotes
Benefits	
Knowledge dissemination	<ul style="list-style-type: none"> “I think it’s a terrific dashboard. I love the way that the information is on there. I think it really captures every aspect of what we’re seeing on the street” (Ohio). “Our subcommittee particularly likes to see in the slides [from dashboard data] what’s going on month by month. We usually give them an overall of how many [naloxone kits] we’ve distributed in total, but they also like to see how we’re trending. So that’s basically been our main use of it” (Kentucky). “When you dive into the data dashboard, I would say that the biggest use for it has been just displaying any recent data we have pretty much on a quarterly basis, and that mainly happens at subgroup meetings” (Massachusetts).
Decision-making tool	<ul style="list-style-type: none"> “[Deidentified person] can speak more to how data impacted our strategies. She was really helpful in the sense that like, she would give us the data, we would identify the issue, and then I would take that and talk to our partners to figure out how to move forward, but I wasn’t the one really digesting it, pulling the stories from it” (New York). “Yes, I do believe that it definitely helped when it came to those decisions because it helped the entire coalition know certain areas that needed extra help and what kind of help that they needed. It also helped us form...helped us do the problem solving in the original start of this coalition” (Massachusetts). “Because it helped us choose...There’s 10 strategies that you could have chose, but by looking at the data that’s available on the dashboard, then you say, ‘All right, these are the ones that we need to tackle here in our community, because it’s right here in front of our face. These are the important ones’” (Kentucky).
Access to more data	<ul style="list-style-type: none"> “So, we don’t see the practical application of this portal, but the information is on there. How to access it is, in my opinion, absolutely suited for any organization that would need that data that they don’t have access to normally” (Ohio). “But the Medicaid data, we never access that as the health department. I’m not entirely sure why but it’s a really helpful data source for us to be able to use because we serve a lot of, you know, medically underserved population. So, being able to have access to those numbers does help” (Ohio). “I got that from the dashboard, because I think that our sense was that there was more naloxone available than there probably was because there’s so many other sources now. I mean, it’s not just coming from harm reduction...And then we were trying to identify what was behind it because we were seeing that naloxone was a huge factor in deaths being down. I mean, that was something we had to really make sure was occurring. And if there was a distribution site, as it were, that was sort of flailing a little, we wanted to do something about that. So, that information came from the dashboard. I did not have a sense of that from the community” (Massachusetts). “[L]ike residents receiving buprenorphine. I don’t know where you’re getting that information, prescription drug monitoring programs. I wish we could get that like firsthand, but this is great to look at because I don’t get that data. And it’s current as of 2021” (New York).
Drawbacks	
Time constraints	<ul style="list-style-type: none"> “[G]iven COVID and everything that happened we just didn’t have [data] available, and the timeline really just didn’t align with decision-making, and I think that is just a fundamental issue with the study, like we talked about, but I do think that that makes it challenging” (Massachusetts). “Particularly since we’ve been working out of the office, there’s greater demands of people’s time and lower bandwidth available” (Kentucky). “But this has also just been a unique for us Wave 1 folks, a unique time, given the pandemic and everything. We have so many other things too...that are not typical. That some of the HEALing [Communities] Study...has just been a little bit extra so it’s just been kind of a hard time...” (Ohio).
Misalignment of the dashboard as a tool	<ul style="list-style-type: none"> “So, I would say that in [deidentified community], a lot of it is redundant. They already have access to this data. It’s already in a location where they feel comfortable going and know how to go to. So, they don’t want to use something new. If they don’t have to” (Ohio). “I think, you know, had we had it earlier, I think it would have been easier to incorporate it into the coalitions. I think now it’s just trickier” (New York). “We did not use the data from the dashboard largely because, I think, everyone around our virtual table already knew all the data from our community dashboards and understood. Everyone is there because they work in this space, and so they understand exactly where the trends are, where the issues are, and so forth” (Kentucky).
Disutility of data	<ul style="list-style-type: none"> “I think the factor is that the data is just so lagged, and the information that we need to work off of, we just need something way more current than what’s available...It’s just -- the data is just not very useful for us right now, unfortunately” (New York). “The problem is much bigger than what the numbers from [deidentified agency] can show us and so when we’re looking at it that way, it’s better to get that real time data from each other rather than rely on HCS to get old data that we’ve kind of already gone through” (Ohio). “Well, we’ve looked at the data, but I think we haven’t really used it, and the reason is two-fold. One, it’s too soon to be able to see much of an impact on the practices. We’re still rolling some of them out. And secondly, COVID, that has screwed up all the data, and we don’t, at the moment, have a good way to separate the impacts of the pandemic isolation and so forth from changes in practice in our community. Everyone right now is just kind of, with what’s going on, doing the best we can. We can’t read the data to detect impact of anything that we’re doing right now” (Kentucky).

Table 3. Subthemes under perceived ease of use.

	Illustrative quotes
Barriers	
Access to dashboard	<ul style="list-style-type: none"> “This might be a little petty, but just the fact that I have to use a password to access it. I think especially people on our coalition, they may not write down their passwords that they use for [the HCS^a] because it’s not their full-time job. So. if they forget the password, they’re less likely to go through the steps to retrieve it and get in there, so they may not use it as much if it were just open access” (Kentucky). “I remember my login info and its only because my computer remembers it. I think my username was given to me and it’s not what I normally use for things so I think if my computer didn’t hold my username and password, I would have had to fiddle with it every time I try to open it” (New York). “Another thing too, and this is my last thought is that it’s kind of odd who can have access and who cannot have access. It feels very gate kept in a way. And that’s going to be a barrier just anyway, so you know, we have our voting is set up for one vote per agency, which has led to just one representative per agency so that one representative for that agency is the only one who has access but their partner or a contact of theirs within their agency is the one emailing me for the information. They don’t have access to the dashboard. So that kind of does create a barrier as well and it’s definitely something that I don’t like about it. I don’t like there’s a password. I don’t like that you have to log in” (Ohio).
Data manageability	<ul style="list-style-type: none"> “[Describing barriers and challenges] first of all it’s not being able to download the data but also not being able to compare two different data sets” (Ohio). “[I]nitially, they wanted us to have a couple slides and go over overdoses every month, and all of us were like, ‘What? There’s so many different things, and it looks insane. I don’t know how to explain that.’ Once I felt more comfortable with filtering things out to make it digestible, it’s been more useful. But initially, it was kind of crazy to look at” (Kentucky). “I might add that, as a CDM [community data manager] in a cluster community, these communities don’t often combine their data, so on the data dashboard for...those aggregate counts, or that aggregated together from each community, so it’s really hard to see what’s working, although we want to break silos. They don’t identify together, so I think that’s been a little bit hard, not to be able to see that separate breakdown” (Massachusetts).
Unable to locate usable data	<ul style="list-style-type: none"> “I would say, a major barrier in [deidentified community], as well, are the suppression rules, you know, because we have such a small population” (Ohio). “[I]t’s a rural community or communities, and so often our data is suppressed for the variables that require suppression. So, I think that just based on it’s great to remain confidentiality and is hard to understand if there’s an increase from one to four, et cetera, or zero to four. So, the suppression in rural communities is that point” (Massachusetts). “And so, we were anticipating and we were being told over and over again, that this data is coming, wait to see the dashboard, and then behind the scenes, we would get contacted and say, you guys got to push this dashboard, you guys got to keep pushing it, and so I’ll go on the dashboard and there’s nothing to push” (New York).
Presentation of numbers and labels	<ul style="list-style-type: none"> “So, I’m assuming if any numerator is a one through 10 or a denominator’s one through 10, the data gets suppressed, but I guess I’m not 100% sure, and then...And then I noticed like on the overdose deaths for May of ‘21. There’s a zero value there. I don’t know if that’s like you know when there’s a zero on the dashboard. Are those true zeros or is it like a placeholder? Like do we really not have any overdose deaths in May at all. Which seems kind of, like it, you know not right, I guess” (Ohio). “Sometimes I wonder if, you know, the line across whatever the imputed data value [ie, values masked due to suppression rules] that is chosen for a particular measure, now that there’s the trend line, I wonder if just leaving off the imputed value all together, so it doesn’t show on the plot. Because I feel like if someone looks at it fast, they’re not looking at it close enough to be like, ‘Oh, why is March missing?’ They wouldn’t even notice that and that might clear up a bunch of confusion” (New York). “[On their naloxone administration event data] But yeah, it’s like on a five, it’s like five. And I remember somebody asking me like, ‘Why is it stuck at five instead of zero?’ I don’t know why. And I couldn’t explain that. So, like, if I can’t explain that, then like I don’t -- like then they look at me, and, you know, whatever, we’re all supposed to be experts and we all have degrees in-in, you know, in bio stats or data or whatever, we’re experienced and if we can’t explain that, then-then they question that” (New York). “My thing is super minor, and it’s a visual thing...On our specific dashboard, there’s the cover page, and the first one in the upper hand corner, it still says opioid overdose deaths, but if you click in it’s more like, I would say it’d be more accurate to describe it as opioid overdose events or related events, because it seems like, if someone were to click on it, they’d only be able to access the death data...When I present it, people were like, ‘Oh, I didn’t realize there was EMS data there too,’ so it’s totally a minor label thing” (Massachusetts).
Facilitators	

	Illustrative quotes
Additional support	<ul style="list-style-type: none"> “I think, just like before maybe HEALing Communities leaves our county...It might be nice to like have a refresher to some of our stakeholders about the dashboard and what information is out there. You know, maybe like a you know presentation, or something and how to get access to it and that kind of thing. I know that was done a while back, because I feel like...I’m even a data person and I, you know still kind of struggle with the dashboard of HEALing Communities so and there’s a lot on there obviously that I didn’t even know about” (Ohio). “It may be helpful just for me to have some kind of training on how to put the data together though. Because I can go in there and just mess with everything. But looking at the community profile, the dashboards, and how to build those specific charts and things, I’m not sure exactly the functionality of it. So maybe just a video or just being able to ask questions or something like that would be pretty helpful” (Kentucky). “I was going to say for troubleshooting too, I think we’ve run into that challenge. Of course, coalition members will come to us saying they’ve run into an error or whatever the case may be, and it’s just challenging to triage some of that, to be like, ‘Hold on. Let me get in touch, try to figure out what’s going on, and then I’ll try to get back to you as soon as possible.’ And I think everyone in [Organization] has been really responsive” (Massachusetts).
Data accessibility	<ul style="list-style-type: none"> “So, I do like that up at the top of the dashboard it has like where you are compared to 2017, it compares the various years to 2017 so that you see...the -- if it’s increasing or decreasing compared to that, like really steady fixed baseline. I also like that you can look at the data by month, by quarter, and by year, because I think that is also really helpful. Especially like with overdose deaths, where there can be some seasonality to that, it’s helpful to see that” (Ohio). “I like that you’re able to add more than one indicator to kind of look at how the trends have changed over the last couple of years and being able to put in more than one thing to get a graph and look at. Because it’s very helpful when it’s all in one place. Because I did a lot of data for a grant for that [deidentified] grant that I wrote a couple of years ago. And it was so hard to get all that data because you had to look at multiple different programs and now it’s just all on one program. So that’s really helpful” (Kentucky). “It’s quick, it’s like a bottom line, you know. If you, if you had to throw together a newsletter or a speech or a letter to the editor, you could, you know, you could glance over it and get some up to date, real time numbers, you know, for that area, pretty reliably” (New York).
Navigability	<ul style="list-style-type: none"> “I think the dashboards, I think they’re beautiful, I think you guys did a really great job...I think it looks great, it just -- the data is just not very useful for us right now, unfortunately” (New York). “It’s very easy to use and I’m kind of a very visual person. So, for me, being able to look at graphs makes it a lot easier. And so, I use a lot of graphs...having those graphs provides me with a very quick and easy picture of ups and downs is really valuable” (Massachusetts). “I like the charts. I think that as someone who...I mean not only do I write grants and those charts are really helpful to stick in there for the reviewer, especially when you have something that you want to really emphasize. But also doing presentations and reports and things like that for other people, it really helps them to be able to see the trend and understand you know that. So, I just like the fact that it makes really nice, simple, pretty charts” (Ohio). “One of the things that I liked about it is being able to go in there and see the trends. It’s like it’s talking about pharmacy dispensing, and naloxone dispensing in the community, whether that’s trending up and down. I thought that was pretty helpful. It’s a few months behind, but an accurate view of what’s going on in the community right now” (Kentucky).

^aHCS: Healing Communities Study.

Perceived Usability and Acceptance of the CTH Dashboards

Of the 62 participants, 58 (94%; Kentucky: n=13, 21%; Massachusetts: n=14, 23%; New York: n=15, 24%; Ohio: n=16, 26%) completed the SUS survey. The grand mean for overall SUS scores across all HCS sites was 73 (SD 4.6), indicating that the CTH dashboards were within the 70th and 80th percentile of SUS responses (Multimedia Appendix 2; Table 4). This score is recognized in the literature as being within the acceptable range [25,26]. The overall SUS score for the New York dashboard was the highest (mean 77, SD 11.4) and akin to the SUS scores of Microsoft Word and Amazon. The overall SUS score for the Ohio dashboard was the lowest (mean 67, SD 12.3), which was similar to the usability of a GPS system. The overall SUS scores for the Kentucky and Massachusetts

dashboards were 75.8 (SD 10.4) and 70.2 (SD 16.3), respectively.

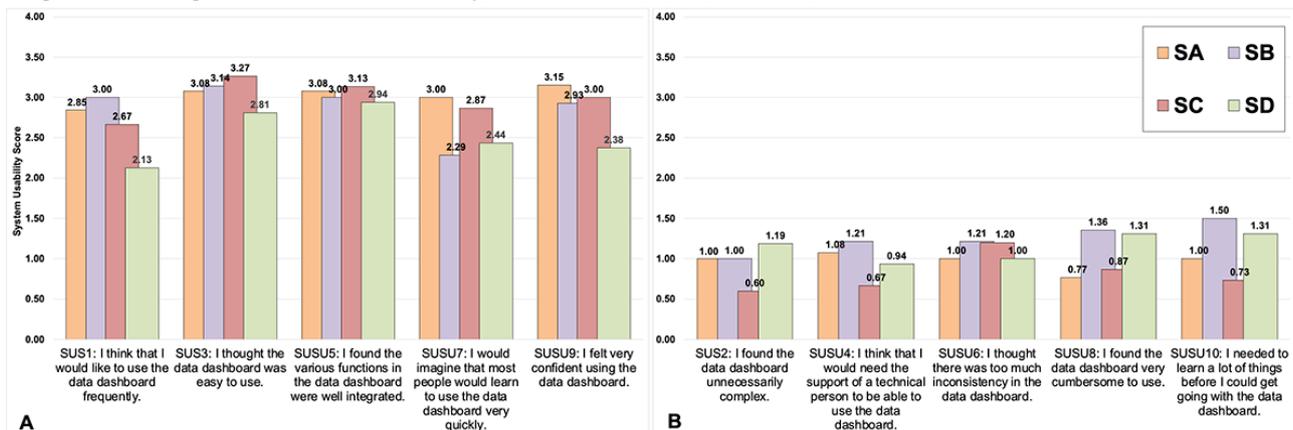

Figure 3 illustrates the breakdown of each SUS domain and contrasts the average scores by participants from each HCS site. The New York dashboard scored the highest across most of the SUS domains. Although Ohio participants did not score the dashboard as favorably as participants from the other sites across many of the domains, it should be noted that the responses were generally positive. The discussion that follows expounds on these SUS scores, with additional support from the data from our TAM-informed interviews. We link specific SUS dimensions around usability with closely associated TAM themes on usefulness. This novel approach highlights potential drivers of SUS scores based on design considerations elucidated by a specific set of TAM themes and subthemes.

Table 4. Subthemes under intention to use.

	Illustrative quotes
Acceptance	
Alternate data uses	<ul style="list-style-type: none"> • “We are always, always, always pushing data driven decision-making with the coalitions and more often than not, the coalitions have a lack of data that they can specify down to a county or even a municipality. And so, having access to something like this...can potentially tap into the [deidentified community] data and be able to use that data to justify a program need or a grant...” (New York). • “[W]e have opportunities...from new funding sources that we have never had before. So they’re coming towards us and kind of questioning where our gaps are and where we think that we could grow. So, I do think there’s things on the dashboard that we will probably be utilizing in the future” (Ohio). • “I’m doing a study for my dissertation actually on...overdose deaths and things of that nature, and trauma, retention and treatment. All sorts of things. So, I’ll definitely be looking at the numbers that you guys have because they’re recent numbers. I know it’s valid data and things of that nature” (Kentucky).
Future strategy monitoring and modification	<ul style="list-style-type: none"> • “Maybe the dashboard will become more relevant as time goes on because it’ll be a longer period of time that we’ll be looking at and so we’ll have more time to reflect on and we’ll have a bigger window of time that we’re looking at” (Massachusetts). • “So I think it’ll be even more important later on in the study after the community has been established, and the goals or your strategies have been in place for a while, and you can start seeing the effect” (Kentucky). • “Maybe as things change in terms of opioid response, there might be a need to start looking at some other forms of data, but the data supplied now are okay, thank you” (New York).
Use conditional on data changes	<ul style="list-style-type: none"> • [When asked whether they would use the dashboard next year] “So I feel, I feel like if the data is, if I can track the same data on the dashboard that my DC [data coordinator] is giving to us, then yes” (Ohio). • “[T]he reality is that the workload is very, very high and we’re frequently, and this won’t surprise you, we’re frequently coordinators and CEFs [community engagement facilitators] in a position of hurry up and do this today. And so it doesn’t allow for a lot of time for reflection and kind of that kind of thoughtful consideration...maybe it should be built into something a little bit more so that it is part of something” (Massachusetts). • “I think it would be good for a community like the HEALing [Communities Study] to have that presence long term and having it be a problem-solving person means it could be one person serving multiple sites and not just ongoing doing something, but really targeted to needs. I think would be very helpful” (New York).
Preference	
Content	<ul style="list-style-type: none"> • “If we could break it down like [deidentified participant] said earlier by zip code that would be phenomenal because you know we wouldn’t have to wait for the meeting, we’d be able to see it anytime” (Ohio). • “Well, I would love to see the information for the rest of the study in the community personally. I mean, I can understand why they limited it...I don’t mind comparing, you know, this one township to different counties and seeing how people are doing, you know...if the numbers showed something drastic, I would call over there and say, ‘What are you doing that we’re not doing?’” (New York) • “One is that it feels a bit, I don’t know, not really, doesn’t get that accurate. Maybe it just can’t. Maybe there’s no way for it possibly to give an accurate illustration of the communities that it is supposed to represent, and maybe there’s just no way to do that. Maybe it’s just because I know the community so well, and maybe if somebody didn’t know the communities at all, they would look at that and say, ‘Wow, this is really helpful’” (Massachusetts).
Function	<ul style="list-style-type: none"> • “I just wish it was publicly available, because if I could send a link to somebody on my coalition there’s much better chance they’d be able to see it and access it” (Ohio). • “It’s not accessible to general community or other groups that are not inside the [HCS^a] structure. So, I guess there’s that piece, so thinking about that. Is there a purpose and a reason to make it public?” (Kentucky) • “Something that has been frustrating for me, from some of the HCS data that we get is we get a lot of plots, but we never get the underlying data. And always what I want to do is be able to download it, download it into like visualization software that I use, add those like timeline components, and then present it in a way that I know my community will understand” (New York).
Aesthetics	<ul style="list-style-type: none"> • “My thing now is how can I make it into a Facebook post-type of thing to grab people’s attention; that we can start the conversation and engage them in the conversation. Having tools or in a format that we can say, ‘Let’s share this part and this part.’ Perhaps get some people engaged in talking about this issue or finding a champion about this issue. How can we make it usable like that?” (Kentucky) • “I think it could be structured a little bit differently. You know specific to Healing Communities Study, you know, if we, if we really intended EBP [evidence-based practice] selection and monitoring for these tools, then I think they would have been they should be structured a little bit differently. The dashboard is getting there. I know we have like an MOUD view and a safer prescribing view, which I think is really helpful and you know if that was more like the primary way of looking at it. I think that would really increase its use for what we hope it would be used for” (Ohio).

^aHCS: Healing Communities Study.

Figure 3. System Usability Scale (SUS) results by domain and study site (n=58). Raw SUS scores are presented. (A) SUS questions that were framed positively. (B) SUS questions that were framed negatively. Each SUS item is scored on a scale of 0 (strongly disagree) to 4 (strongly agree). A total of 4 participants did not respond to the SUS. SA: Kentucky; SB: Massachusetts; SC: New York; SD: Ohio.

Perceived Usefulness

Sites were generally positive in their reported perceptions about inconsistencies with the dashboards (SUS6); however, there was variability in the scores across states when it came to confidence in using the dashboards (SUS9). For example, participants from Ohio reported the least confidence, whereas participants from Kentucky scored the confidence domain the highest.

The alignment of the dashboards and community stakeholders' expectations may have influenced perceptions of confidence in using the dashboards and consistency in using the dashboards. On the basis of the TAM-informed interviews, 3 subthemes emerged regarding the benefits of using the CTH dashboards: *knowledge dissemination* (the dashboard was used to increase the awareness of activities in a community [eg, sharing data and validating existing assumptions]); *decision-making tools* (the dashboard was used for choosing EBPs in a community and evaluating EBPs strategies); and *access to more data* (broader and granular dashboard data about a community were available). In contrast, 3 subthemes emerged regarding the drawbacks of using the CTH dashboards: *time constraints* (the use of the dashboard felt time intensive, and other priorities distracted from its use); *misalignment of dashboard as a tool* (the use of the dashboard was not aligned with the HCS's goals and workflow); and *disutility of data* (dashboard data were not translatable to anything actionable). Table 2 provides illustrative quotes from the interviews for each of the primary themes under perceived usefulness.

Perceived Ease of Use

Around integration (SUS5), perceptions among all participants were generally positive. Participants from Ohio did not respond as positively about ease of use and complexity of use (SUS2 and SUS3). Participants from Massachusetts, New York, and Kentucky scored the dashboards higher in these areas. Participants from Ohio and Massachusetts also scored training, support, and the cumbersome nature of the system (SUS4, SUS7, and SUS8) less favorably.

The alignment of the technical functionality of the dashboards with users' workflows may be linked to the users' perceptions

of the dashboards' complexity and ease of use and the need for training and support. Our TAM-informed interviews revealed 4 subthemes around barriers to use: *access to dashboard* (participants faced challenges with accessing the dashboard); *data manageability* (accessing the data users needed was cumbersome); *unable to locate usable data* (data in the dashboard were not easy to find because of the lack of availability [due to lags in reporting or suppression rules] or because of navigation issues on the dashboard); and *presentation of numbers and labels* (the data were displayed in ways that made their use difficult for participants). However, we discovered 3 subthemes that facilitated the use of the dashboards: *additional support* (training or information that informed the use of the dashboard or data); *data accessibility* (the dashboard was useful because of aspects of the technology or the way it is displayed); and *navigability* (different ways in which the dashboard was easy to use and navigate and aspects of the dashboard that could be changed to make it better). Table 3 provides illustrative quotes for each of the primary themes under perceived ease of use.

Intention to Use

Scores of the SUS items on the frequency of planned use and the knowledge needed to use the dashboard (SUS1 and SUS10) were equivocal and lower across all the sites. Participants from Massachusetts reported that they wanted to use the dashboard frequently, but they needed to learn more about how to use it. Participants from Ohio provided the lowest score for the SUS item on the frequency of planned use of the dashboard and, similar to their Massachusetts counterparts, indicated the need to learn more about how to use the dashboard.

The willingness of community stakeholders to use the dashboard in the future may influence their desire to use the dashboard frequently and learn how to use it. During the TAM-informed interviews, participants provided several recommendations for improving the dashboard that could promote future use. A total of 3 subthemes emerged regarding the acceptance of the dashboards in the future: *alternate data uses* (data on the dashboard will be useful but for purposes not initially part of the focus of the HCS); *future strategy monitoring and modification* (the dashboard will be used as intended for HCS purposes, including for EBP strategy monitoring and data-driven

decision-making about these strategies); and *use conditional on data changes* (the dashboard will be useful if some conditions are met [to help with its use]). In addition, 3 subthemes emerged regarding preferences with desirable use over time: *content* (participants desired changes to the data on the dashboard, including the provision of different data, to improve the usability of the data and their interpretation); *function* (participants desired additional tools or different ways to navigate the dashboard and use data); and *esthetics* (participants described ways in which the appearance of the dashboard could be improved to effectively communicate information). [Table 4](#) provides illustrative quotes on recommendations for each of the primary themes under intention to use.

Contextual Factors

Collective circumstances may influence the dashboard's perceived usability and use. A total of 2 subthemes emerged regarding how the community connects and works with data (community data orientation): *comfort with data* (collective perceptions of the comfort with using tools such as dashboards that contain data to make decisions); *established tools and approaches* (perceptions that ranged from those of human-centered data sources [eg, existing relationship with a coroner's office] to technology-based sources that were community preestablished substitutes to the HCS dashboard). [Table 5](#) provides exemplary quotes for each of the primary themes under the community context that illustrate how dashboards and their use may have been perceived when implemented.

Table 5. Subthemes under contextual factors.

Community data orientation	Illustrative quotes
Comfort with data	<ul style="list-style-type: none"> • “[T]he treatment providers, they’re not necessarily data people, but there’s some of us that are looking at it and using it. I guess that’s all that matters in the long run. That’s something that we’re always going to be dealing with the people in the coalition that we have” (Massachusetts). • “I think it goes back to who your audience is...If you’re looking to speak to people who, you know, I kind of consider myself a middle person for that aspect, right, so if you’re trying to speak to community members who have no data background and things like that, they’re -- first of all, they’re not even going to notice that [a date] is missing...” (New York). • “[S]o we are planning on either in our August or September drug coalition meeting kind of...showing people how it works, showing people the data that’s in there, and hopefully getting people a little bit more oriented towards...looking at that dashboard to see if what we’re doing is making a difference, because I don’t think that we are, as a coalition I don’t think we are data oriented and enough really if that makes sense” (Ohio).
Established tools and approaches	<ul style="list-style-type: none"> • “I mean, I think the primary source or the primary...way that data is distributed in [the community] is really just through personal connections...I mean you know I think every coalition meeting we’ve had our health commissioner comes and has the...harm reduction clinic numbers, you know written down on the back of an envelope or a napkin or something and that was you know the you know the organizations are generally very good about sharing that individual level data...You know, to help, to help people” (Ohio). • “So, they’ve got their ODMAP [Overdose Detection Mapping Application Program] data that comes in through HIDTA [high intensity drug trafficking areas] and the police departments, and then they have the [Department of Health] data that shows how many Narcan saves happened and how many overdoses occurred. And then on top of that, you have things like coroner’s reports and coroner responses to actual deaths” (New York). • “I would say there’s a couple of places we’ll look depending on what it is. We use the KIPRC site a lot, Kentucky Injury Prevention. We use that depending on what they have. We also keep a data dashboard from the Health Department’s perspective on substance use and opioid disorder. So, we have a dashboard on ours that looks at things. We do a daily dashboard on overdose visits to the ED and EMS runs and things like that...Periodically, we might get things from the Office of Drug Control Policy, the state. We also have a local Office of Drug Control Policy, which pulls some local data for all of our counties as well. So, I would say those are probably our main sources of substance use data” (Kentucky).

Discussion

Principal Findings

Our assessment indicated that the community stakeholders in the HCS found the CTH dashboards to be usable, as measured by the SUS, and easy to use and understand, as indicated by the themes identified through our TAM-informed interviews. Some respondents indicated the usefulness of the dashboards, with many indicating areas for improvement. From these findings, we have synthesized and prioritized the following gaps and lessons learned for future consideration, which are generalizable to community stakeholders engaged in dashboard use. In the spirit of Chen and Floridi [27], our lessons learned are specifically about different visualization pathways for use in

dashboards among community stakeholders. Prior research has identified similar practices as supportive of the effective use (eg, greater engagement, cognitive alignment between end users, and decision aids) of dashboards. The lessons learned that we describe subsequently may help researchers design higher-fidelity dashboards that future scientific studies should consider when developing similar interventions and more general tools that integrate data visualizations for use among community stakeholders in community-oriented studies.

Prioritized Gaps in and Lessons Learned About Designing Dashboards for Community Stakeholders

Prioritized Gap: Cognitive Dissonance With the Dashboards

Many of the community stakeholders already had frontline knowledge of their community opioid crisis and its complexities. Hence, some community stakeholders may have seen the dashboards as tools simply providing hard data, which were secondary to their lived experiences within their communities and knowledge about contextual nuances with these communities. There may have been, arguably, a cognitive disconnect between what the community stakeholder expected from a dashboard and what the dashboard provided. This disconnect may have been exacerbated by factors such as adherence to the main HCS research protocol and purpose (eg, a brief timeline for development and programming before deployment and the prohibition of data downloads from visualization), use of suppression rules that masked values and contributed to the sparseness of data, lags in metrics due to reporting, and limited connections of the data with local resources for community stakeholders to act upon. Other challenges included balancing the need for “real-time” data with the validity of these data due to retrospective corrections.

Lesson 1: Use Storytelling via Dashboards

Cognitive and information science theories suggest the importance of aligning information representation formats provided by decision aids with mental representations required for tasks and cognitive styles of individuals [28-30]. We propose storytelling via dashboards as an effective, historically validated [31] approach to achieving this alignment. At a minimum, this involves providing basic data summaries in plain English, as done by the New York HCS site, and mixing and matching measures in graphs to allow the illustration of specific points, as adopted by the Ohio and Kentucky sites. Richer storytelling may involve multiple iterations or cocreations with community stakeholders that help craft the right set of qualitative contexts and information that situates quantitative data to evoke understandings that fit with internal mental models of the task and lived experiences [32,33]. Powerful stories could provide community stakeholders with structured templates to analyze, justify, and communicate data. Our findings suggested that there were indeed community stakeholders who were not comfortable with using data; individuals with such predispositions could find data presented as stories more meaningful, especially during decision-making processes.

Lesson 2: Link Actionable Insights to Useful Resources

Community stakeholders may require additional support with using insights garnered from dashboards. Dashboards can be seen as a mediator between data and a call to action to address specific issues. Moreover, dashboards can present structured sets of actions a community stakeholder can undertake, also known as an actionable impetus [34], as guidance on addressing a problem identified with the data [35-37]. For example, some community stakeholders in the HCS would have appreciated a set of recommendations for EBPs or resources within a local neighborhood that a coalition could have acted upon, given an

outbreak of opioid deaths. Design considerations could have made affordances (eg, alerts in the user interface) to create an impetus for action, which has been described as an “actionable data dashboard” [34]. Such actionable dashboards could provide important links to specific issues with the opioid crisis, such as the linkage of distribution centers for naloxone kits to community hot spots where there is unequal access to these kits based on factors such as race and ethnicity [38].

Prioritized Gap: Gatekeeping of the Data and Dashboards

Access to the dashboards was a noteworthy barrier under perceived ease of use. Some study participants indicated that this barrier hindered the use of data to facilitate decision-making among community members. Dashboard requirements limiting access to certain stakeholders was due to study protocol requirements to prevent communities from benchmarking data across communities. However, the user and password verification requirements were seen as inconvenient, and access control was seen as a form of gatekeeping that limited information sharing with key stakeholders who did not have dashboard access and were critical to decision-making in communities.

Lesson 3: Use Processes and Tools That Promote Access and Sharing

Arguments to enhance the use of data included approaches that facilitate human-human interactions in the sensemaking of data within dashboards and visualizations [3,39,40]. In addition to storytelling, other practices include improving how study insights are shared with communities and how communities are encouraged to share insights; permissible sharing includes dashboard export features or providing embedded codes so that data or narratives can be used in media, reports, presentations, websites, and social media content [41].

Prioritized Gap: Low Engagement With the Dashboards

Several themes (eg, data manageability, additional support, use conditional on data changes, and aesthetics) highlighted additional challenges to perceived ease of use and intention to use that could be represented by a broader concept used in the technological literature known as digital engagement [42-44]. The HCS missed opportunities to promote community stakeholder engagement with the CTH dashboards through which enhancements could have been made in areas such as dashboard training and clearer protocols around how community stakeholders used the dashboards during coalition meetings.

Lesson 4: Use a Multisector and Interdisciplinary Approach to Understand and Improve Engagement With Data Visualizations

The use of audit log file data or eye tracking to monitor and characterize use and user preferences (eg, line chart vs bar graphs) can inform design decisions and tailored interventions to foster behavioral changes that support the effective use of data among community stakeholders [44-46]. Our study, while recognizing early on that log files can support engagement, faced challenges with implementing a standard data model to track visual preferences and visit frequencies among community

stakeholders, a decision that could have supported systematic transformations to the dashboards. In addition, our findings demonstrated that the combined use of SUS scores and TAM-informed interview data was beneficial in obtaining a comprehensive perspective on how engagement, via usability, can be transformed. For example, prior research has indicated that barriers in usability may have been overlooked if only measured by a single approach, such as exclusively using the SUS [47].

The use of innovative training (eg, dashboard navigators and indexed videos) and workflow changes (eg, starting meetings with referencing insights from a dashboard) are 2 other practice-based examples that can foster engagement among community stakeholders by supporting the realignment of existing mental models and the building of new ones with visual representations to achieve specific tasks [48,49]. For example, the Massachusetts HCS site adopted “community data walks,” in which expert dashboard users provided active demonstrations to community stakeholders on how to use the CTH dashboards.

Our findings suggest that the fidelity of the cocreation process to develop the CTH dashboards had gaps. The HCS is one of the first large-scale applications of the cocreation process to design dashboards within the community context. The pragmatic, multisetting nature of the study reflects challenges to balancing a research agenda with the expectations of diverse communities. Interventions and strategies (eg, multiple plan-do-study-act cycles during the cocreation process) that can address gaps in fidelity in using cocreation could be adopted to ensure that the final outputs are indeed relevant to end users’ work and promotes higher engagement. There were no “checklists” to support our implementation at this level of complexity, and we hope that the lessons we learned establish the foundations for such an approach for future endeavors.

Limitations

Our definition of community stakeholders may be idiosyncratic to our study and parent study research protocols. However, the 4-site design provides a diverse sample of individuals who represent different professional roles and social and demographic

groups; the samples were not homogeneous across sites, including in terms of technology literacy, which was not assessed yet could shape end users’ experience with the dashboards [48]. The COVID-19 pandemic may have influenced perceptions of use of and intentions to use the CTH dashboards, given pandemic-driven competing demands, technology-mediated workflow, etc, experienced by the respondents. This may have resulted in conservative perceptions of dashboard usability; however, the public health domain is generally faced with competing demands and emerging situations, which might mitigate such notions. Our research study was relatively large in scope; hence, ensuring the fidelity of our assessment in general and the interviews specifically was challenging. However, as noted in the Methods section, we worked closely across sites to maintain rigor from study inception. We acknowledge that although the SUS is a validated tool, it may have lacked specificity for assessing CTH dashboards. Other TAM constructs (eg, external environment) and more updated versions of the TAM exist [50,51]. However, one of our original goals was to build a framework for dashboard use among community stakeholders; therefore, we chose to use a fundamental version of the TAM that had both the critical constructs for our focus and did not have other constructs that may have imposed a priori assumptions on dashboard usability from other fields and studies.

Conclusions

Data dashboards can be an evidence-based approach to support community-based public health decision-making. These technological interventions to visualize and interact with data can support transformations in community health, including during public health crises, such as the COVID-19 pandemic and the opioid epidemic. Our study is a novel assessment using both the SUS and TAM to examine the usability of dashboards among community stakeholders. Participants provided multifaceted perspectives on the usability of the CTH dashboards and their intention to use these dashboards. On the basis of our findings, we presented important gaps that motivated the consolidation of lessons learned regarding dashboard use among community stakeholders.

Acknowledgments

This research was supported by the National Institutes of Health (NIH) and the Substance Abuse and Mental Health Services Administration through the NIH HEAL (Helping to End Addiction Long-term) Initiative under the award numbers UM1DA049394, UM1DA049406, UM1DA049412, UM1DA049415, and UM1DA049417 (ClinicalTrials.gov Identifier: NCT04111939).

Abstract

Background: Advancements in technology offer new opportunities to support vulnerable populations, such as pregnant women and women diagnosed with breast cancer, during physiologically and psychologically stressful periods.

Objective: This study aims to adapt and co-design the World Health Organization’s Self-Help Plus intervention into a mobile health intervention for these target groups.

Methods: On the basis of the Obesity-Related Behavioral Intervention Trials and Center for eHealth Research and Disease Management models, low-fidelity and high-fidelity prototypes were developed. Prototypes were evaluated by 13 domain experts from diverse sectors and 15 participants from the target groups to assess usability, attractiveness, and functionality through semantic differential scales, the User Version of the Mobile Application Rating Scale questionnaire, and semistructured interviews.

Results: Feedback from participants indicated positive perceptions of the mobile health intervention, highlighting its ease of use, appropriate language, and attractive multimedia content. Areas identified for improvement included enhancing user engagement through reminders, monitoring features, and increased personalization. The quality of the content and adherence to initial protocols were positively evaluated.

Conclusions: This research provides valuable insights for future studies aiming to enhance the usability, efficacy, and effectiveness of the app, suggesting the potential role of a chatbot-delivered Self-Help Plus intervention as a supportive tool for pregnant women and women with a breast cancer diagnosis.

Introduction

Background

The growing awareness of the profound significance of mental health for individuals and society has spurred an expanding body of research to scrutinize global population trends and the strategies used to address this issue. Empirical evidence

consistently reveals an enduring surge in requests for psychological support, yet this burgeoning demand remains largely unmet due to scarce available resources and services [1]. Consequently, people’s needs remain unmet. The factors contributing to the challenge of accessing mental health services are multifaceted. In general, these impediments encompass issues such as suboptimal service quality, inadequate levels of

mental health literacy, pervasive stigma, and formidable cost barriers [2]. Within this context, developing and implementing strategies to fortify and enhance the health care system becomes increasingly imperative, rendering it more accessible to the population. Significantly, particular attention is being devoted to the prospective role of digital technologies, which can enhance the sustainability of the health care system by providing 24/7 support to patients and optimizing health care provider interventions [3]. These innovations aim to surmount the aforementioned impediments, advancing digital health as an integral and foundational strategy to foster equitable, affordable, and universally accessible mental health care [4]. A flourishing body of literature corroborates the potential of emergent technologies, encompassing telemedicine, mobile health (mHealth) initiatives, and digital therapies, in facilitating a seamless continuum of care, extending from clinical settings to patients' homes while embracing a staged care approach [3].

Furthermore, digital health may be particularly suitable for low-intensity mental health interventions [5]. This terminology refers to specific programs wherein the active engagement of health care professionals and specialists is not necessarily required. These interventions are grounded in empirically validated [6], evidence-based psychological practices seamlessly integrated into a self-help paradigm, whether guided or unguided. This intervention genre is conventionally designed to be transdiagnostic, offers facile adaptability across diverse contexts, and is readily implementable by nonprofessional operators. Given their structural attributes and overarching mission, low-intensity interventions represent a valuable conduit for augmenting access to pragmatic, evidence-based psychological treatments, catering to a broad spectrum of recipients. These encompass from individuals among the general population to those presenting with limited or mild symptomatic manifestations associated with distress and mental illness [6]. In summary, low-intensity interventions are positioned as a pivotal resource for addressing situations characterized by mild distress, in which failure to intervene effectively could potentially precipitate the escalation of these conditions into pathological states [7].

Psychological distress, encompassing stress, anxiety, and depression, frequently co-occurs with physical illnesses such as breast cancer [8]. Cultivating a more optimistic outlook has been demonstrated to play a role in disease management and recovery, underscoring the significance of holistically addressing physical conditions and mental health issues [9,10].

Even a completely different health condition from those mentioned previously, such as pregnancy, can expose women to similar psychological symptoms. Pregnancy is characterized by major transformations that significantly impact the woman physically, mentally, and socially. How the woman adapts to these changes determines the quality of her life and her levels of well-being [11]. Where adaptation is not functional, symptoms of psychological distress may occur; the most common conditions are anxiety, stress, and depression [11-14]. To date, psychoeducational interventions that promote women's psychological well-being during pregnancy are scarce and tend to focus mainly on samples of women with psychiatric symptomatology (eg, perinatal depression disorder) [15]. For

this reason, our study is part of the digital health framework to support health prevention strategies in the first 1000 days of life [16].

Evidence of the effectiveness of psychological interventions targeting pregnant women or women with breast cancer is increasing [17,18], but access to care services still presents several challenges. Many women face geographic barriers, with specialized centers often far from their homes. In addition, a shortage of qualified personnel, such as psychologists, further limits access to specialized care [19]. The stigma associated with mental health problems can also prevent women from seeking psychological support [20]. Therefore, in numerous instances, these target groups are excluded from accessing the requisite services. However, low-intensity interventions emerge as pivotal in addressing this lacuna, and the strategic combination with mHealth methodologies can yield an effective, sustainable, and inclusive framework for augmenting the scalability of mental health interventions.

This model is poised to cater to a comprehensive user base, encompassing prevention for individuals at potential risk of mental distress and intervention for patients grappling with mild to moderate mental distress [7].

Self-Help Plus

Self-Help Plus (SH+) is a low-intensity group intervention for stress management initially developed to target populations that are numerous or hard to reach by health care professionals under the principle of improving and facilitating access to health care interventions [21]. The SH+ package has been incorporated into the expanding array of low-intensity psychological interventions endorsed by the World Health Organization (WHO) [21]. By design, SH+ is a transdiagnostic intervention that is applicable, meaningful, and safe for people with and without mental disorders. SH+ is based on acceptance and commitment therapy (ACT) [22,23], a form of cognitive behavioral therapy [24,25].

The SH+ intervention package has 3 main components: a prerecorded audio course, a facilitator manual, and a self - help booklet for participants. This material has been translated into multiple languages and can be easily accessed on the web at the WHO website [26]. The audio material imparts key information about stress management and guides participants through individual exercises and small group discussions. The intervention is structured into five sessions focused on acceptance- and mindfulness-based techniques for stress management: (1) *grounding* (mindfulness), (2) *unhooking* (cognitive distancing), (3) *acting on your values* (value-based behavioral activation), (4) *being kind* (gratitude), and (5) *making room* (acceptance).

Preliminary studies report positive effects of SH+ with a potential impact on mental well-being; it had a significant long-term efficacy in a target population of refugees and asylum seekers exposed to stressful situations [27]. Other studies show a still debatable effect of SH+ when applied to health care professionals during the COVID-19 pandemic, whereas there emerges a need for further examining the potential role of the confounding effects of nonspecific factors [28].

This Research

This research fits into the landscape of WHO strategies by adapting the stress management intervention developed by the WHO itself, SH+, with two main goals: (1) to assess the viability of this intervention when targeting specific subgroups (women with breast cancer and pregnant women) and (2) to validate the applicability of the intervention as a chatbot-delivered and preventive action. This SH+ intervention, which has already been validated and tested on some specific vulnerable populations (eg, asylum seekers) [29], will be fully available to users through digital tools. In particular, it will be delivered through a mobile app and guided by a virtual assistant, ALBA. This research aims to assess the prototype of the ALBA app to gather feedback and needs from key stakeholders to further refine the app from a qualitative perspective of usability,

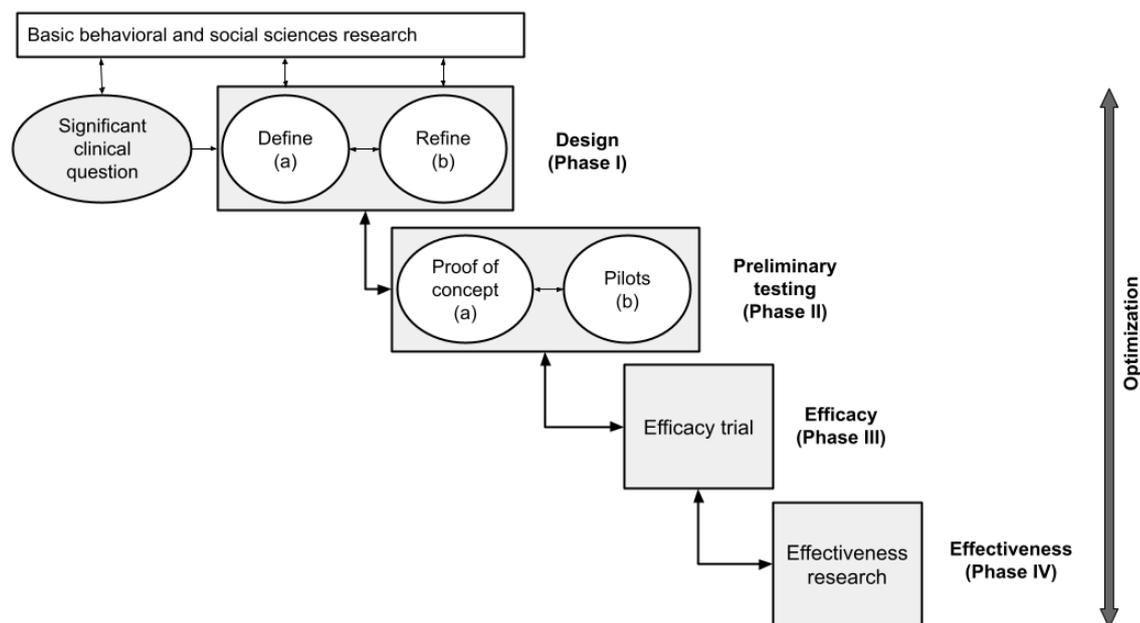

accessibility, and acceptability of the intervention delivered via a chatbot.

Methods

Overview

The stress management intervention was developed iteratively following the Obesity-Related Behavioral Intervention Trials (ORBIT) model [30], as illustrated in Figure 1 [30], which shows the pathway followed to translate a human-guided intervention into a possible digital therapy. In particular, the design and development process encompassed a multidisciplinary approach and continuous, systematic evaluation throughout, as the Center for eHealth Research and Disease Management (CeHRes) comprehensive road map approach recommended to improve the uptake and impact of eHealth technologies [31].

Figure 1. The Obesity-Related Behavioral Intervention Trials model.

The multidisciplinary project team, consisting of psychology, eHealth research, and communication experts, had biweekly meetings during the design and development phase. User-centered design methodologies ensured user involvement throughout the design and development process. Patient representatives, health care providers, and security experts were consulted throughout. The stress management intervention was developed in iterative processes through a combination of (1) intervention content development, identified and adjusted from the evidence-based cognitive behavioral stress management concept; and (2) iterative software development (phase 1—low-fidelity prototypes and phase 2—high-fidelity prototypes) and formative evaluation.

Intervention Content Development

A primary goal of this study was to adapt a validated stress management intervention, SH+ [21], into a new technology-based stress management intervention for pregnant

women and women with breast cancer. To do so, the development involved a wide range of expertise encompassing psychology, eHealth IT, interaction design, and specialized knowledge in pregnancy and oncology. A multidisciplinary team was assembled to address diverse user needs, ensure psychological coherence, and integrate technological requirements and user-centered design principles. The focus was on achieving adaptability of the proposed tools in the digital domain [31] guided by 2 pivotal methodologies: user-centered design [32,33] and service design [34].

The development process comprised the following stages: (1) literature review of WHO protocols and papers on digital mental health and the specific psychological needs of target populations; (2) exploration gathering insights from user representatives (eg, patients with breast cancer and pregnant women), health care providers, and eHealth experts (including designers and developers); and (3) content adaptation customizing SH+ intervention manual content addressing software development

and potential privacy and security issues. The intervention content was adapted and tailored by the entire research team through iterative processes to fit a 5 module–based intervention in electronic format. Adjustments were made to ensure easy language, short sentences, and focus on clear content for small screens.

This holistic approach, merging diverse expertise and user-centric methodologies, underscores the dedication to crafting a robust and efficient chatbot-driven intervention tailored for women dealing with breast cancer and pregnancy.

Phase 1: Iterative Development and Low-Fidelity Prototypes

The adaptation of the SH+ intervention through the implementation of the ALBA chatbot was based on a novel approach to delivering psychological support. Users can engage with a comprehensive and effective intervention through gamification, personalized sessions, reminders, and feedback. Therefore, a key aspect is represented by a multilevel structure to consider the different sections of the app and, simultaneously, to guarantee proper levels of user engagement, adherence, and overall impact on users' well-being. In the first iteration in 2023, a total of 3 psychologists and 2 communication experts tested and gave feedback on the prototype to ensure that the intervention program was logically built and would meet the stakeholder requirements.

On this basis, the following methodology was applied. The group of experts was divided into pairs, in which one person assumed the role of the chatbot whereas the other adopted the user's perspective, reading their respective segments of the dialogue aloud.

The pairs were reorganized for each of the 5 distinct modules to ensure a diverse spectrum of interactions and exhaustive coverage of potential dialogue scenarios and to avoid biases. This method facilitated the exploration of varied interaction dynamics and the collection of data on multiple communication styles. The oral recitation of dialogues served as a mechanism to evaluate several aspects of the chatbot's effectiveness, such as dialogue realism, rhythmicity and repetition of the texts, and communication fluency [35]. The verbalization process aids in gauging how seamlessly the chatbot replicates a humanlike

conversation, identifying any inconsistencies or unnatural responses. Thus, listening to the dialogue's progression allows for the assessment of the conversation's smoothness, which encompasses the coherence and pertinence of the chatbot's replies. Another function of this method was to identify any ambiguities or misinterpretations that might emerge during interactions with the chatbot [35]. Simulating the conversation enabled the experts to offer immediate critiques on every facet of the dialogue, contributing to rapid and focused content refinement.

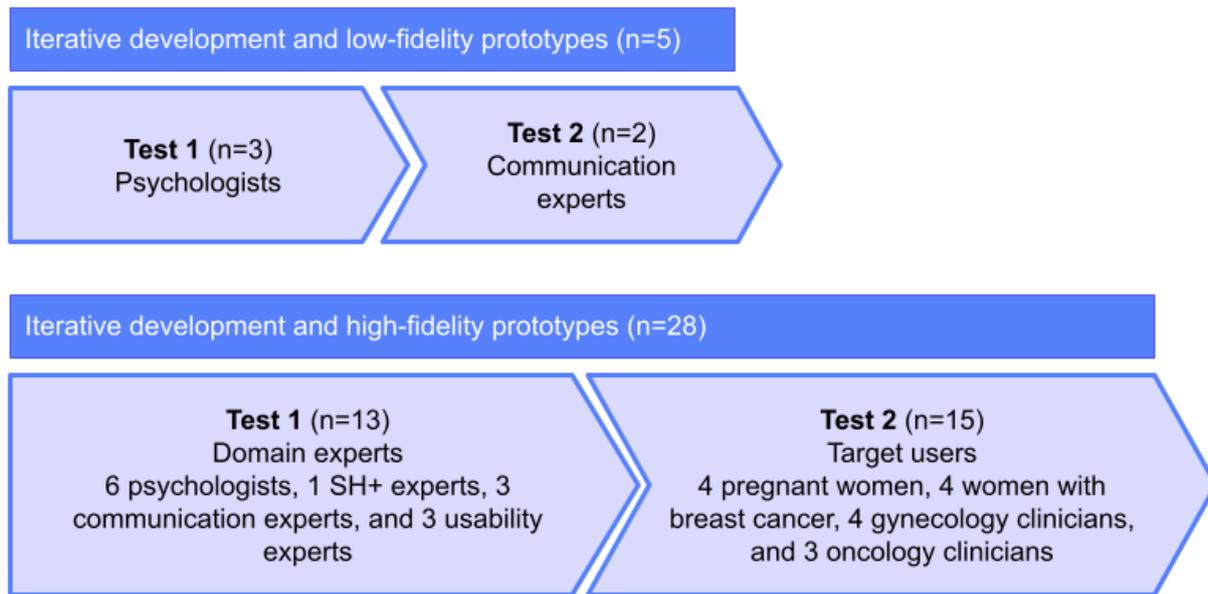

In a nutshell, this procedure aimed to analyze the chatbot's capability to engage in realistic, empathetic, and psychologically suitable conversations, leveraging direct feedback and expert psychologists' insights as key metrics for evaluation.

Phase 2: Iterative Development and High-Fidelity Prototypes

After minor adjustments, the paper prototype was implemented into an electronic format using the Landbot tool (HELLO UMI S.L.) [36]. Landbot is a chatbot generator that allows one to create, test, and deploy conversational chatbots via WhatsApp and other chat channels.

During the period spanning the end of 2023 and the beginning of 2024, a 2-phase evaluation of the ALBA prototype was conducted involving an overall sample of 28 participants, as elaborated on in Figure 2. In particular, of the 28 participants involved, 13 (46%) were domain experts (n=6, 21% psychologists), 1 (4%) was an SH+ expert, 3 (11%) were communication experts, 3 (11%) were usability experts, and 15 (54%) were users—8 (29%) target users (n=4, 50% women who were currently pregnant or had given birth within the previous year, 4/28, 14% of the total sample; and n=4, 50% women who were in current breast cancer disease status or follow-up from it, 4/28, 14% of the total sample) and 7 (25%) target clinicians (n=4, 57% gynecology clinicians [eg, obstetricians and gynecologists; 4/28, 14% of the total sample] and n=3, 43% oncology clinicians [eg, oncologists and case managers; 3/28, 11% of the total sample]). The recruitment of participants was based on personal contacts of researchers selected based on representativeness of the key target user groups addressed by the ALBA solution.

Figure 2. Software development and formative evaluation (N=37). SH+: Self-Help Plus.

Variable Identification

In an attempt to gather the necessary information, key variables were identified for investigation: communication, session structure, materials, engagement, functionality, esthetics, information, subjective and perceived impact, interaction, communication mode, involvement consistency, general comments, amelioration of technical implementation, and content adherence. The first 4 variables were assessed through the semantic differential tool [37], the following 5 were assessed through the User Version of the Mobile Application Rating

Scale (uMARS) [38], and the latter 6 were assessed through an ad hoc semistructured interview.

The semantic differential tool is an instrument consisting of a series of scales, each of which is composed of a pair of bipolar adjectives between which a rating scale (5 positions) is placed. Given the study’s variables, a list of subvariables was chosen to create ad hoc items for the research. Table 1 shows the chosen variables and their respective subvariables. On the basis of the target subject domain, each person was asked to evaluate and determine variables, as reported in Table 1 (single items are reported in Multimedia Appendix 1).

Table 1. List of variables investigated through the semantic differential tool and the people involved in evaluating the individual variables.

Variable and subvariable	Psychologists	SH+ ^a expert	Communication experts	Usability experts	Target group	Clinicians
Communication						
Empathy and listening	✓ ^b	✓	✓		✓	✓
Smoothness and fluidity	✓	✓	✓	✓	✓	✓

Materials						
Audio tracks	✓	✓	✓		✓	✓
Infographics and videos	✓	✓	✓		✓	✓

^aSH+: Self-Help Plus.

^bInvolved.

The uMARS questionnaire, on the other hand, evaluates mobile apps by covering 4 objective dimensions (engagement, functionality, esthetics, and information) and 1 subjective

dimension. Briefly, the questionnaire consists of 20 items covering the inquired variables as follows—engagement (n=5, 25%), functionality (n=4, 20%), esthetics (n=3, 15%), and

information (n=4, 20%)—and 4 items belonging to the subjective quality domain. A section on perceived impact (6 items) also assesses users' perceptions of the app's usefulness. Each answer is rated on a 5-point scale (1=inadequate, 2=poor, 3=acceptable, 4=good, and 5=excellent) measuring the usability of mHealth apps.

Interviews, instead, are suitable for a more in-depth investigation of users' attitudes and preferences regarding new technological solutions as open-ended discussions with users can help researchers better understand the issues and concerns related to the possible future adoption of these solutions [39]. [Multimedia Appendix 2](#) shows the list of topics and questions posed during the interviews.

Figure 3. Examples of personas.

	<p>Mara, 70 years old</p> <p>Background: Mara lives with her husband and has two adult children and five grandchildren. She is now in follow-up after a recurrence of breast cancer. She had the tumour for the first time about five years ago. Two months ago, she underwent chemotherapy and had to wear a wig again.</p> <p>Technological skills: Mara uses her smartphone a little during the day as she calls her grandchildren and friends by landline. She uses her cell phone more outside the home for phone calls and messages. She has a few apps installed and rarely uses them.</p>
	<p>Heloisa, 35 years old</p> <p>Background: Heloisa lives with her husband and two children aged 6 and 4. She is pregnant with twins and is in the 6th month of pregnancy. The twin pregnancy was a surprise for everyone.</p> <p>Technological skills: Heloisa uses her smartphone often during the day as she works in the communications sector. She also likes to show her children and husband her work and is slowly teaching her children to use the tool consciously.</p>

Focus on Experience and Expertise

This study aimed to involve experts from various fields and did not require all participants to respond to every specific ad hoc item of the semantic differential tool and questions of the semistructured interview. Usability experts were not asked to evaluate specific intervention content, whereas the SH+ expert was queried about the fidelity of the content to the original intervention during the interview. Clinicians, psychologists, and participants from the pregnancy context were asked questions relevant to that context, whereas those from the oncology field responded to questions specific to their area of work or direct life experience.

Procedure

All data were collected confidentially with participants' informed consent. Recruitment was conducted through word of mouth and direct acquaintance, clearly stating the study's objectives. Only volunteers aged ≥ 18 years were included. Before the study, participants received a privacy notice and

Context-Specific Methodologies

Personas

Personas are a user-centered and service design method used to create and visualize fictional representations of the target group [40]. Personas are an effective method for all project team members to better understand the target group for which the app is built. Personas in this study contained information about the pregnancy background, challenges, and technology use. [Figure 3](#) provides illustrated examples of study personas. Psychologists had to take the perspective of one of these personas before the reading.

consent form via Google Forms, allowing them to consent to participation and data processing.

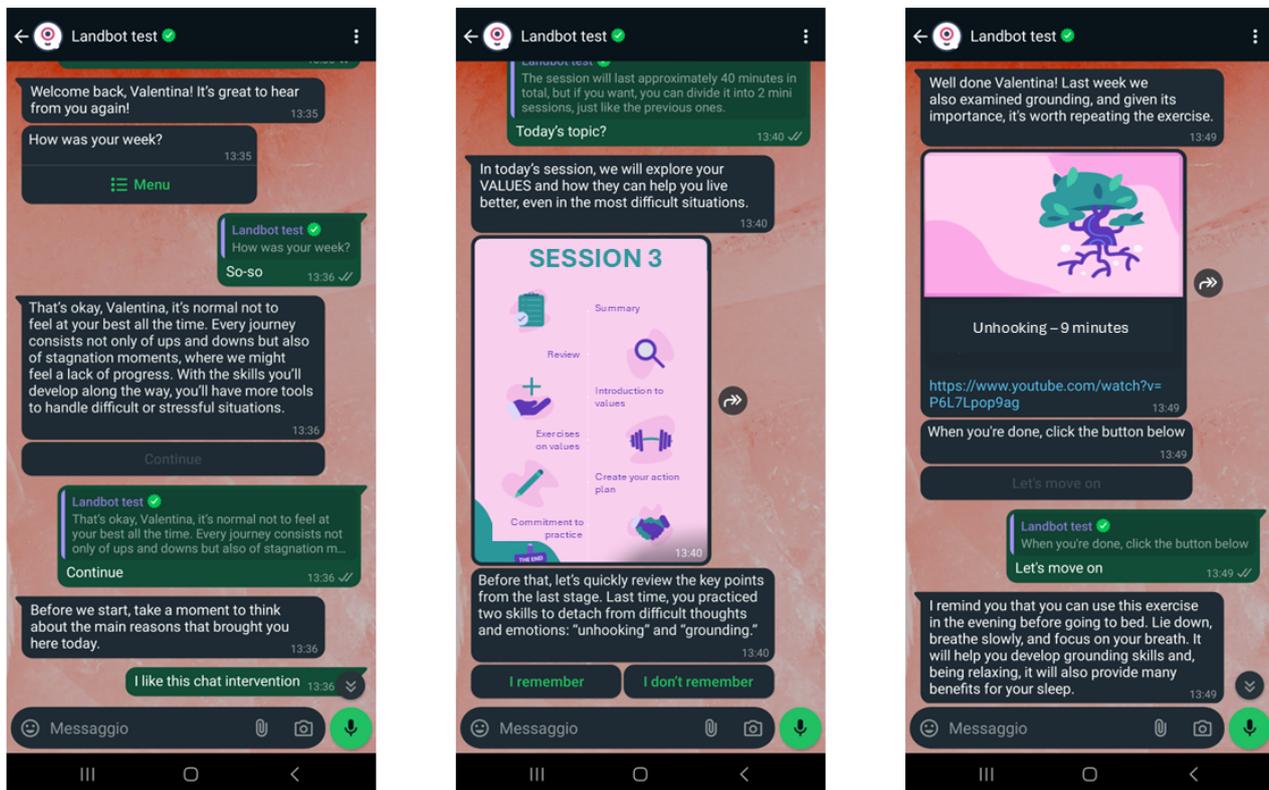

Operationally, the experimental procedure was structured as follows:

1. The information notice and informed consent were displayed.
2. Participants who decided to take part in the study were asked to fill out a questionnaire that collected some generic biographical information (age, schooling, gender, and employment status) and some information related to their knowledge and use of mobile apps.
3. Next, participants interacted with the ALBA app prototype for 6 weeks. Each session lasted approximately 40 minutes. During the study, the participants were asked to test the ALBA app on their phones; in particular, they had the opportunity to explore the interface and different sections of the app via mock-ups and read, listen to, and interact with the chatbot via WhatsApp during the dialogue session (see [Figure 4](#) for ALBA chat mock-ups). The session

- consisted of structured dialogues with predefined buttons for response options or free text. The text was not analyzed in this prototype phase as it was not the main purpose of this study. The dialogue was constructed to be as standardized as possible to maintain the already tested validity of the intervention. Participants were also informed about the future implementation of reminders and feedback for the activities proposed by the chatbot.
- Questionnaires were then presented to the participants regarding their overall experience with the system. In the final stages, participants were asked to evaluate the experience they had with the ALBA app by answering 2 questionnaires. Specifically, the semantic differential tool [37] and the Italian version of the uMARS [41] were used for the evaluation through questionnaires.
 - Finally, a brief semistructured interview was conducted. After the usability assessment, participants were invited to join a web-based interview to further report on their expectations, preferences, and concerns regarding the

ALBA solution tested. The interview questions were specifically designed ad hoc for our study, focusing on topics relevant to the evaluation of the app, such as interaction, communication mode, user involvement and consistency, technical implementation, and content adherence. The inclusion criteria for participating in the interview were having completed both the prototype test and the questionnaires as well as providing consent to participate in this additional phase. The exclusion criteria, on the other hand, were having dropped out during the test, not completing the questionnaires, or not providing consent for the interview. A total of 28 interviews were conducted by a researcher and audio recorded to enable a more detailed analysis of participants' responses. They were then analyzed and processed using qualitative tools. The interviewer initially provided a brief introduction to the interview objectives. Then, participants were asked to answer a series of semistructured questions regarding their expectations and preferences for using the app.

Figure 4. Examples of WhatsApp chat mock-ups. ALBA delivers content and monitors users' experiences by assigning tasks and providing motivational feedback. Through ALBA, users can interact, receive clear instructions, and access exercises and multimedia content.

To sum up, this study was divided into 2 main phases, each with distinct timelines and activities. Phase 1 focused on the iterative development of low-fidelity prototypes and spanned 6 months. Phase 2, dedicated to the iterative development of high-fidelity prototypes, lasted 4 months. Each step of phase 2 was carefully structured with specific time frames to ensure thorough data collection and analysis—10 minutes for informed consent completion, 15 minutes for pretest questionnaire completion, 6 weeks for app testing by participants, 20 minutes for posttest questionnaires, and 20 minutes for semistructured interviews.

Ethical Considerations

All data were collected in Italian and pseudonymized (deidentified) with participants' informed consent. Confidential audio recordings of semistructured interviews were used for data analysis, and participants were identified only by numeric codes. At the study's conclusion, participants can request the research outcomes from the research manager. Participants did not receive any compensation. This study was approved by the University of Padua Ethics Committee of Psychological Research on August 1, 2023 (reference 238-b).

Data Analysis

Data analysis for the quantitative results of the semantic differential tool and uMARS questionnaires was conducted using JASP and R (R Foundation for Statistical Computing) [42,43]. Due to the small sample size, nonparametric tests were used [44]. When applicable, the Wilcoxon signed rank test (W) was used as a nonparametric alternative to the 1-sample 2-tailed t test [44-46], and the rank-biserial correlation (r) was reported to indicate the strength of association along with its corresponding 95% CI [46]. All analysis results were considered significant with a critical P value set at .05.

The data collected during the interviews were analyzed using a qualitative method. A thematic analysis was conducted [47], organizing the themes into tables based on different contexts and participant types (eg, psychologists and clinicians). The responses were analyzed by grouping the most prominent themes emerging from the ad hoc initial topics (around which the questions were formulated) into subvariables to address thematic

redundancy within the participant sample. For this analysis, the interviews were first recorded and conducted by one author, whereas transcription and analysis were conducted by 2 other authors. Consensus on thematic relevance and redundancy was reached when both authors agreed; in case of disagreement, a third author was consulted to achieve a two-thirds majority. Finally, a comprehensive report was created highlighting the main findings with references to the specific groups where applicable.

Results

Phase 1: Iterative Development and Low-Fidelity Prototypes

Specifically, the app was designed to include 5 sections: *Chatbot*, *Exercises*, *Diary*, *Gallery*, and *Progress*. The first low-fidelity prototype version of the app was developed (Figure 5).

Figure 5. Low-fidelity prototype version of the ALBA app.

Functions of App Sections

ALBA assigns homework during the session delivery that the users should carry out during the following days, so the app *Diary* section supports self-monitoring of exercise progress and completeness of sessions, reinforcing users' empowerment. The completion of exercises is monitored in the evenings before the next session. All the exercises, divided week by week, are shown in the *Exercise* section. The *Gallery* page features all the multimedia material delivered by ALBA, such as educational videos, images, and intervention introductions. In addition, the app features a section called *Progress*, which provides users with an overview of their "journey" toward increased well-being. Using the journey metaphor, users can see the sticker badges earned by practicing exercises between sessions appearing on their suitcase illustration. These badges serve as long-term positive reinforcement and gratification for their efforts. Users receive badges for completion of exercises, and this is another way in which they can track their progress. Again, this gamification approach was selected to further reinforce empowerment and the sense of self-efficacy of the user.

Results of the Interaction With the Low-Fidelity Prototype

Regarding the interaction with the low-fidelity prototype in the co-design phase, 2 main themes emerged.

Communication

First, it was possible to review the communication style through role-play. To make the protocol more realistic, some parts of the dialogue were revised. The changes were made from a grammatical and syntactic point of view to make the text more fluid when reading. The changes also took empathy into account. This attention creates a feeling of trust in the relationship with ALBA. Through empathic communication, the person can feel in a safe space within which they are reassured and protected.

For example, after these changes, ALBA provides the option to skip a particularly sensitive answer. It also lets the user find a calm place before doing audio exercises, and moreover, it gives the possibility to review the concepts of the previous session.

Duration

A second critical result that emerged from the specialists who tested the low-fidelity prototype was allowing the user to divide the session into 2 mini sessions. Given that the time needed to complete a single session is approximately 40 minutes, which is generally considered an excessive time to dedicate to interaction with an app. For this reason, appropriate changes were made to the dialogue to provide a partial and optional closure after 20 minutes followed by a gradual resumption of the session on the subsequent day. Thus, to support adherence, the session can be divided into 2 mini sessions, preventing user fatigue and improving the usability of both the chatbot and the app itself.

Other Improvements

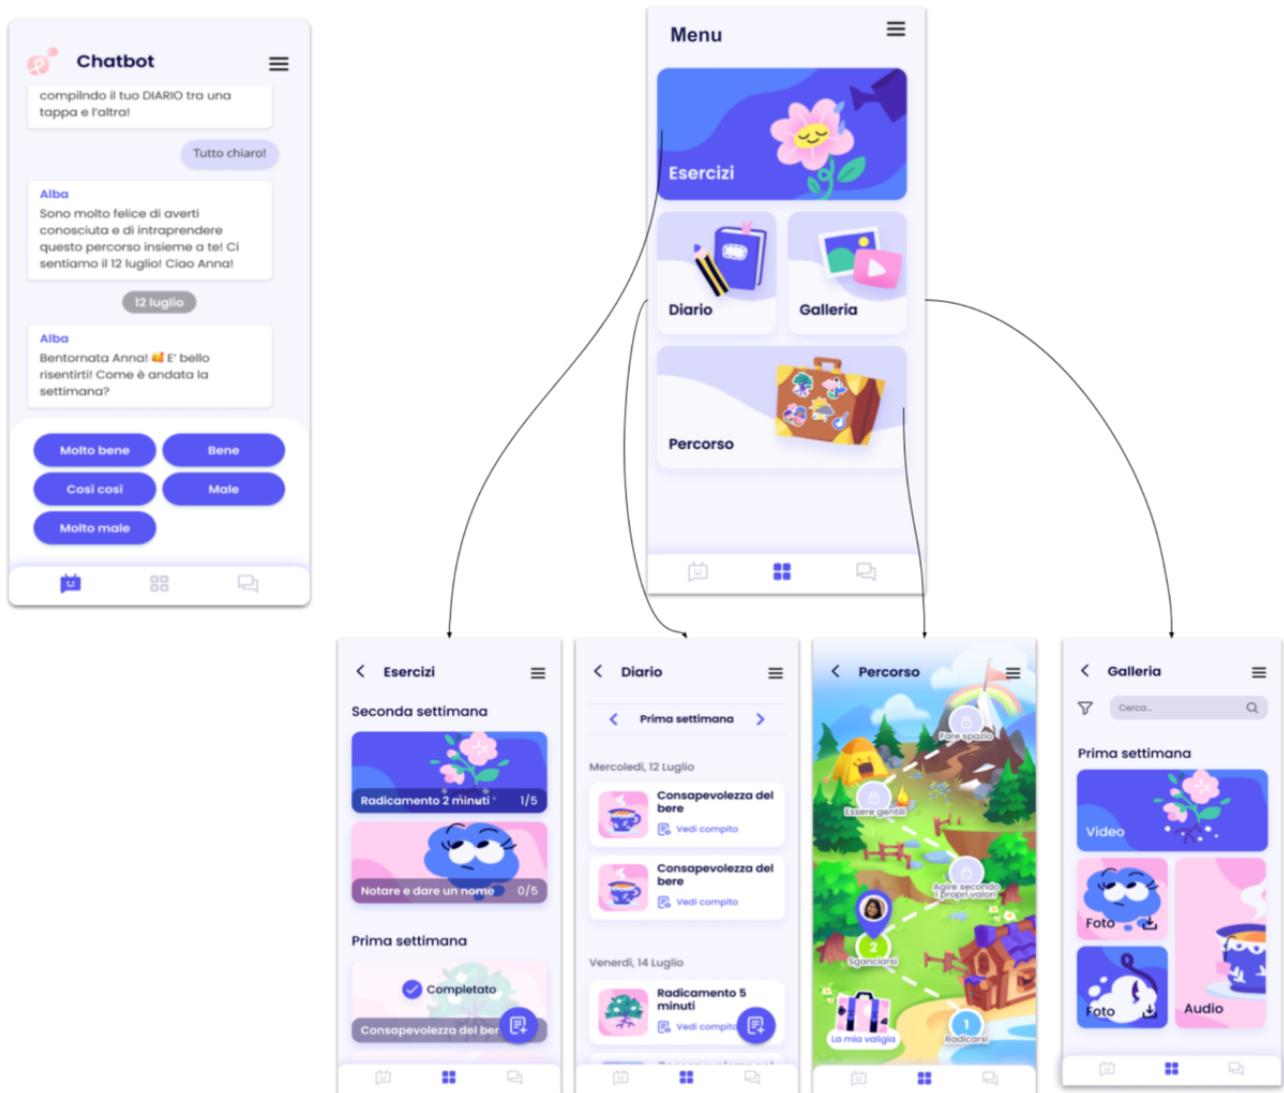

At the same time, writing errors were corrected, and the remaining parts of the original protocols designed for groups were adapted to the individual intervention. Mainly, attention was placed on the translation from group to individual gratitude exercises, the final exercise of each session.

Phase 2: Iterative Development and High-Fidelity Prototypes

Overview

To better understand the app and the entire intervention, more realistic mock-ups were created (Figure 6) after minor adjustments on the basis of the information gathered. This allowed users to better evaluate the app in its final appearance.

Figure 6. More realistic mock-ups of the ALBA app with its different sections.

In total, 28 individuals ($n=4$, 14% men and $n=24$, 86% women) participated in the pilot evaluation; the average age was 41.39 (SD 11.66; range 28-72) years. The average number of schooling years of the sample was 18.98 (SD 2.88; range 13-23).

Quantitative Results

Semantic Differential Tool

In this case, using a semantic differential-based questionnaire also facilitated the observation of the respondents' average

positioning with respect to the 3 macrovariables under investigation. In particular, concerning the subvariables, several significant results emerged from the Wilcoxon analysis, as reported in Table 2. The graphical representation of mean values derived from the semantic differential tool for each item is reported in Multimedia Appendix 3. As seen in this figure, a tendency toward the positive semantic pole (right pole) emerged in the feedback of this group of participants.

Table 2. Results of the semantic differential tool (N=28)^a.

	Participants, n (%)	Values, mean (SD)	Values, median (range)	W	P value	r (95% CI)
Empathy and listening	25 (89)	3.55 (0.67)	3.60 (2.40-5.00)	213.50	<.001	0.85 (0.64 to 0.94)
Smoothness and fluidity	28 (100)	3.89 (0.69)	4.00 (2.00-5.00)	266.00	<.001	0.93 (0.83 to 0.97)
Chatbot interaction	28 (100)	3.72 (0.55)	3.75 (2.50-4.50)	271.50	<.001	0.97 (0.92 to 0.99)
Lexicon	28 (100)	4.41 (0.61)	4.50 (2.50-5.00)	404.00	<.001	0.99 (0.98 to 1.00)
Session structure	28 (100)	2.95 (0.63)	3.00 (1.00-4.00)	64.50	.87	-0.05 (-0.54 to 0.47)
Audio tracks	25 (89)	3.97 (0.44)	4.00 (3.00-5.00)	300.00	<.001	1.00 (1.00 to 1.00)
Infographics and videos	25 (89)	4.08 (0.50)	4.00 (3.00-5.00)	300.00	<.001	1.00 (1.00 to 1.00)

^aFor the Wilcoxon test, the effect size is given by the matched rank-biserial correlation.

The results indicate that participants generally responded positively across various subvariables. Significant positive responses were observed for empathy and listening, smoothness and fluidity, chatbot interaction, lexicon, audio tracks, and infographics and videos. The session structure subvariable did not show a significant positive trend, indicating a neutral or mixed response. The effect sizes ranged from moderate to large,

suggesting varying degrees of impact for the different subvariables under investigation.

uMARS Results

The uMARS evaluated the respondents' average positioning in 4 key dimensions. Detailed results of the Wilcoxon tests are summarized in Table 3.

Table 3. Results of the User Version of the Mobile Application Rating Scale (N=28)^a.

	Participants, n (%)	Values, mean (SD)	Values, median (range)	W	P value	r (95% CI)
Engagement	28 (100)	3.55 (0.43)	3.60 (3.00-4.60)	300.00	<.001	1.00 (1.00-1.00)
Functionality	28 (100)	4.16 (0.51)	4.25 (3.00-5.00)	378.00	<.001	1.00 (1.00-1.00)
Esthetics	28 (100)	3.86 (0.49)	4.00 (3.00-4.67)	300.00	<.001	1.00 (1.00-1.00)
Information	28 (100)	4.20 (0.52)	4.25 (2.50-5.00)	405.00	<.001	1.00 (0.99-1.00)
Subjective items	28 (100)	3.20 (0.50)	3.25 (2.25-4.00)	233.50	.06	0.44 (0.02-0.72)
Perceived impact	28 (100)	3.66 (0.60)	3.83 (2.67-4.50)	264.00	<.001	0.91 (0.79-0.97)

^aFor the Wilcoxon test, the effect size is given by the matched rank-biserial correlation.

The results indicate consistently high ratings across all dimensions of the uMARS. Significant positive responses were noted for *Engagement*, *Functionality*, *Esthetics*, *Information*, and *Perceived Impact*. Effect sizes were uniformly high, particularly for the Wilcoxon tests, indicating a strong positive skew in user perceptions for each dimension evaluated. However, items such as "Customization" and "Interactivity" did not show significant positive trends in the *Engagement* scale, with "Customization" even indicating a negative effect size, suggesting variability or mixed responses from users.

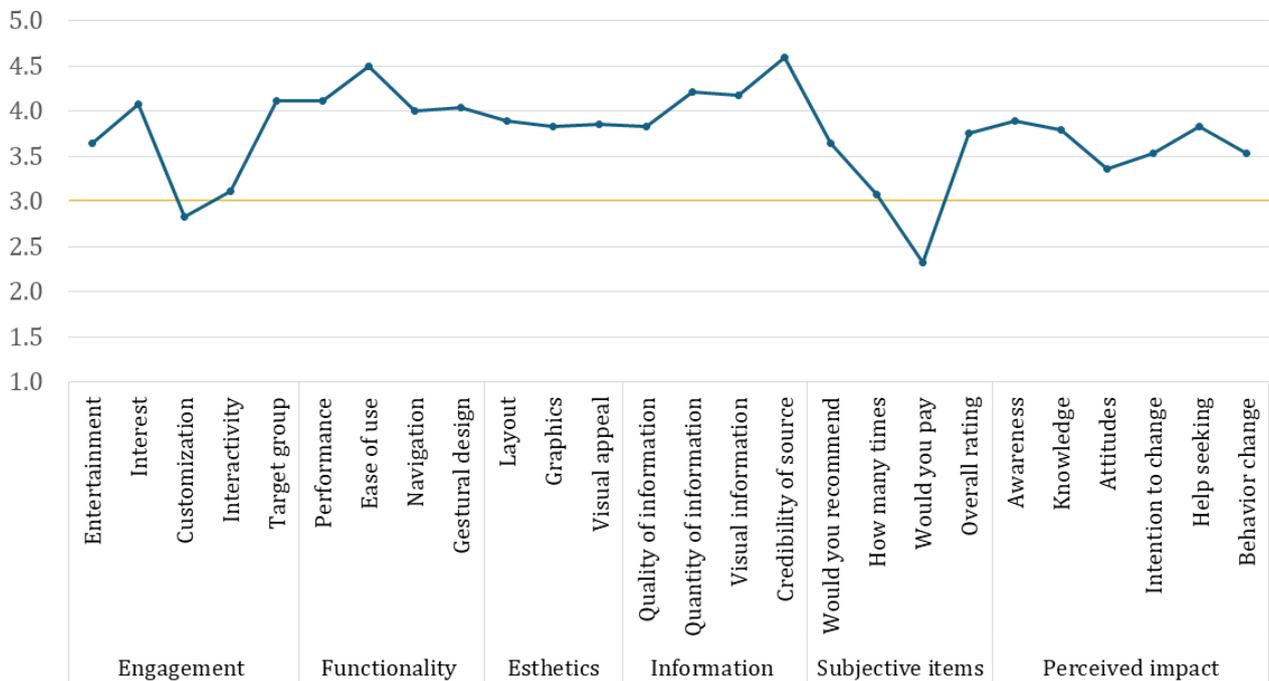

Considering the *Subjective Items* scale singularly (which did not show a significant trend), the items "Would you recommend" (median 4.00; SD 0.62; $P<.001$; effect size=1.00) and "Overall rating" (median 4.00; SD 0.52; $P<.001$; effect size=1.00) received a strong positive response. This suggests that most users would recommend the app to others, with a robust positive effect size indicating widespread satisfaction with the app's performance, utility, and perceived value. However, for the item "How many times" (median 3.00; SD 0.77; $P=.64$; effect size=0.13), responses were mixed regarding the frequency of app use, with no significant trend emerging. This indicates that users were likely to use the app on average

3 to 10 times in the following year. Moreover, for the item "Would you pay" (median 2.00; SD 0.72; $P<.001$; effect size=-1.00), there was a significant negative response, indicating that users were generally unwilling to pay for the app. The strong negative effect size underscores a consistent reluctance to incur costs for app use.

Regarding the relevant *Perceived Impact* scale of the uMARS, items such as "Awareness" (median 4.00; SD 0.74; $P<.001$; effect size=0.24), "Knowledge" (median 4.00; SD 0.79; $P<.001$; effect size=0.26), "Attitudes" (median 3.50; SD 0.73; $P=.02$; effect size=0.26), "Intention to Change" (median 4.00; SD 0.69; $P=.001$; effect size=0.26), and "Help Seeking" (median 4.00; SD 1.09; $P=.003$; effect size=0.23) were rated positively. This indicates that the app positively impacted users, although the effect sizes were lower compared with those of other items, suggesting a moderate consensus and some variability in responses. Conversely, the "Behavior Change" item result (median 4.00; SD 0.64; $P<.001$; effect size=0.88) highlights that the app had a significant positive impact on users, with a high effect size indicating strong agreement among users on the app's effectiveness in promoting behavioral modifications.

The mean and statistical significance for every item are reported in Multimedia Appendix 4. Figure 7 shows the graphical distribution of item scores.

Figure 7. Graphical distribution of User Version of the Mobile Application Rating Scale item scores.

Qualitative Results: Semistructured Interviews

One psychologist conducted the qualitative interview to gather additional information. Interviews were conducted and analyzed according to the identified thematic variables.

Set 1: Interaction

The interaction with the chatbot was generally well received. The clinicians appreciated the good overall interaction, pointing out the effectiveness of the videos and images as well as the presence of multiple response options. However, they found it difficult to go back to previous answers, noting repetitiveness and lack of novelty in the content. The communication experts praised the fluidity of the interaction and particularly appreciated the personality of the app but criticized the excessively fragmented design of the messages.

The SH+ expert highlighted the confidence given by the chatbot, which calls the user by name and provides relevant answers, but it was not clear when user responses could be expressed in free text (chatting and not pressing the default buttons) and expressed a preference for the human figure in the videos. The usability experts appreciated the guidance and psychoeducational support offered by the chatbot but pointed out the 1-way interaction and the excessive number of messages in a row.

Among the features preferred by those who tested the app were videos with exercises, the personality of the app, heterogeneous content, and images with goals and values. However, among the elements to be improved were some aspects of the videos. In particular, the psychologists pointed out that professional voices could greatly improve the effectiveness of the videos, which were nevertheless appreciated for their content. The SH+

expert, on the other hand, found the videos and audio a little too slow and monotonous but greatly appreciated the chatbot’s confidence and relevant answers. Finally, the usability experts found the videos and graphics useful but criticized the excessive length of the messages.

There was some discord regarding the possibility of correcting oneself and going back. In fact, the SH+ expert and psychologists considered it very useful and suggested that it should be included, whereas the communication experts did not find it particularly useful to go back. The usability experts did not find frequent errors, and the psychologists considered the consequences of errors to be not serious. On the other hand, the target group appreciated the practical examples provided during the sessions, which were considered important and highly functional to the objectives of the intervention. The variety of response options was also positively evaluated. However, it was suggested to reduce the length of the videos and messages as shorter and more focused content was deemed to improve the overall experience.

Set 2: Communication Mode

Concerning clarity and thoroughness, all categories of experts appreciated the possibility to better investigate concepts through examples and videos. In particular, the communication experts emphasized the clarity of the content, although they suggested using more concise answers. The same suggestion was made by the SH+ expert, who found some dialogues too complex and articulate. The clinicians disagreed, instead pointing out the simple and accessible language.

The usability experts also noted that the repetition of information was positive, especially for weekly use, but found the audio and video a little too slow and monotonous. Similarly, the

psychologists appreciated the repetition of videos to better explain concepts and suggested alternating text with images or videos to lighten the information load.

The language used by the chatbot was generally well received. The clinicians appreciated the simple language and short sentences, whereas the communication and usability experts praised the clear, appropriate, and friendly language. The psychologists and SH+ expert also found the language appropriate to the content and easy to understand. However, the SH+ expert considered the tone to be a little slow. It was suggested to keep the language simple but to consider more complexity and variety in the content using a more active and engaging tone.

Finally, the target group generally appreciated the appropriateness of the sentence length and the terminology used as the language was perceived as accessible and aligned with the needs of future users. In addition, the inclusion of emojis was seen as effective and realistic in conveying emotions. Users found these visual elements to be a helpful and engaging way to express their feelings. All categories of experts appreciated and found useful the visual mode of emojis, which was also considered effective by the usability experts. However, it was suggested to offer both emojis and words as a response option to accommodate different preferences. However, one area for improvement pointed out by the target group was the length of the written messages. Some users reported that, sometimes, the messages were too long and could become heavy to read.

Set 3: Involvement and Consistency

User involvement and consistency were strengths for some groups, whereas others experienced difficulties. The clinicians found the tone positive and encouraging and the communication fast. The SH+ expert found the communication engaging, whereas the psychologists found good engagement in the videos. However, the clinicians found it difficult to feel engaged without a physical person, whereas the usability experts found the interaction similar to reading a book, needing more interactivity and exchange. For these reasons, it was suggested that the level of personalization and interaction be improved to increase engagement.

The customization of the chatbot was considered good but with room for improvement. The clinicians appreciated the personalization through the use of the user's name and the space for personal choices but noted standard answers for all and the lack of specific personalization elements. The SH+ expert gave a score of 8/10 to personalization, whereas the psychologists noted that the answers were standard. It was suggested to offer the possibility to add photos and avatars and improve the customization of answers. The target group found the content engaging and motivating to continue, with good personalization using names. However, they noted that it became less engaging in the long term, with repetition feeling lengthy and tedious and the exercises sometimes being monotonous.

Set 4: General Questions

The communication experts noted that the timing should be personalized according to individual circumstances, emphasizing that some users might benefit more from reminders and progress tracking. Indeed, target users indicated that the chatbot could be helpful during times of high stress and change, such as during chemotherapy or radiation and after childbirth, but less useful immediately after diagnosis or in early pregnancy. In contrast, the clinicians suggested that the ideal time for chatbot use in oncology is during and after chemotherapy or radiation treatment, whereas during pregnancy, it is in the first and second trimesters. In addition, the SH+ expert expressed that the chatbot was generally useful but highlighted the need for it to be adaptable across different stages of treatment and pregnancy. The psychologists found consistency with the ACT model and good care in the messages but reported that negative responses were not always considered.

Set 5: Technical Implementation

Reminders and notifications were considered useful for maintaining consistency. However, it was emphasized that reminders should not be too intrusive. The communication experts emphasized the importance of sending reminders in a nondisruptive way, whereas the SH+ expert stressed the need for reminders to maintain consistency. The usability experts agreed with the clinicians but suggested integrating reminders and immediate feedback to enhance user engagement. In particular, the target group appreciated the overall coherence of the content with the topic addressed and the usefulness of reminders to maintain consistency in use. However, they also reported usability issues, especially when too many messages were received in sequence, which made them difficult to manage and slowed down interaction with the chatbot.

Concerning gamification aspects, the preference for gradual coloring of the stickers was expressed by most groups. The clinicians suggested that gradual coloring gives the idea of progress, whereas the communication experts preferred immediate gratification. The SH+ expert indicated a preference for receiving the sticker at the end, whereas the usability experts suggested giving the reward immediately to maintain engagement. The target group preferred a gradual color progression of the stickers as they completed the exercises. Indeed, this approach helps visualize progress, providing them satisfaction and motivation. At the same time, a lot of users also expressed the desire for immediate rewards and feedback to maintain engagement. Indeed, the use of pop-up positive feedback provides instant gratification and motivation.

Set 6: Content Adherence

The SH+ expert reported that, on a scale from 1 to 5, our intervention adhered at a level of 4 to the original intervention. In terms of content, the app takes them up and is coherent, yet it is very innovative in terms of the ways it is delivered.

[Table 4](#) briefly highlights key positive and negative aspects derived from the user interviews.

Table 4. Main positive and negative aspects that emerged from the user interviews.

Variable and subvariable	Positive aspects	Negative aspects (and suggestions)
Set 1: interaction		
General+alternatives for answers	Positive interaction (n=5) ^a ; multiple options for answers (n=10)	Limited alternatives in some cases (n=5); fatigue in going back to previous answers (n=2)
Best and worst features	Confident and personalized chatbot; interactive videos and images (n=9)	Long and sometimes monotonous videos (n=4)
Going back for mistakes	— ^b	Need for option to correct mistakes (n=13)
Set 2: communication mode		
Clarity	Clear language (n=10); suitable for all users (n=2)	Sometimes overly simplistic and repetitive (n=1)
Emojis	Visual and easy to express emotions (n=8)	Offer both emojis and words for responses to cater to different preferences (n=6)
Length of and terms used in messages	Terms appropriate to the content (n=13)	Messages can be too lengthy (n=5)
Set 3: involvement and consistency		
Engagement	Positive and encouraging tone (n=1)	Improve personalization (n=7)
Personalization	Use of user's name (n=4); space for personal input (n=3)	Lacks deeper personalization (n=6)
Set 4: general questions		
Concerns and criticism	Reflective questions after exercises (n=1)	Even if the user can read the message, they can still decide not to proceed (n=1)
Ideal time	Oncology: during (n=11) and after (n=8) treatment; pregnancy: second trimester (n=10) and after (n=12) childbirth	Not ideal immediately after diagnosis (n=5) or in early pregnancy (n=4)
Set 5: technical implementation		
Reminders	Helpful for maintaining consistency (n=22)	Ensure that reminders are supportive and not overwhelming (n=5)
Pop-up positive feedback	Provides instant gratification and motivation (n=17)	Offer immediate feedback but consider a weekly summary for sustained engagement (n=1)
Progress in stickers	Gradual coloring indicates progress and provides satisfaction (n=19)	—
Set 6: content adherence		
Adherence to SH+ ^c protocol	Generally aligns well with SH+ protocol (n=1)	Repetitive content (n=3)

^aNumbers in parentheses indicate the response frequency.

^bNo statements.

^cSH+: Self-Help Plus.

Discussion

Principal Findings

This study evaluated the adaptation of the WHO SH+ intervention for stress management. The first step involved developing the SH+ protocol, which was implemented through a mobile app with the support of the interactive ALBA chatbot. ALBA guides users through the 5-week program, corresponding to the 5 SH+ sessions, and facilitates navigation through various app sections. Notably, this adaptation introduced several innovations: the intervention was designed to further reinforce interaction and feedback to foster empowerment and self-efficacy, and it was tailored to female users, explicitly targeting 2 populations of interest in our study—pregnant women and women diagnosed with breast cancer.

The ORBIT and the CeHRes comprehensive road map approaches were adopted to evaluate the app, starting with a preliminary phase focused on refining the dialogues and low-fidelity mock-ups of the app's sections. This initial phase was crucial for developing coherent, accurate, and engaging dialogues and ensuring a reliable adaptation of the original SH+ content. Given that the protocol had already been validated, the chatbot's structured and standardized dialogues allowed for effective transmission of the proven content without the risk of artificial hallucinations, undertaken risks, or biases, which can occur with more advanced chatbot models based on large language models [48]. Giving value to the methodology adopted, regarding content adherence, the SH+ expert rated the intervention's adherence to the original at 4 out of 5, appreciating the innovative delivery methods while the core content was maintained. However, an explicit limitation of our chatbot emerged—the lack of flexibility in personalizing

responses and interactions, as highlighted by participants in phase 2. Indeed, it is worth noting that psychologists found consistency with the ACT model but noted that negative responses were not always considered by ALBA. This rigidity presents a double-edged sword—while it ensures the psychological rigor of the initial intervention, it also reduces the flexibility of personalized response options [49].

Additional relevant findings from the low-fidelity prototype review pertain to the app's organization, featuring a well-defined structure in sections evaluated during the second phase regarding usability. The integration of gamification and feedback aspects based on user progress monitoring to maintain engagement and immediate or delayed reinforcement from classic behaviorism to sustain motivation was also significant. The app provided customization in session management by proposing interruptions and clarification moments for the presented content, which users could accept or decline.

From the second phase of this study, further essential results emerged that will guide the iterative development of the app. Valuable insights were gathered by involving various stakeholder groups identified from both the pregnancy and oncology contexts. Both expert groups and target users, the final app users, provided quantitative feedback through the semantic differential tool and uMARS questionnaires and qualitative feedback through semistructured interviews. The evaluation of dialogues and mock-ups, following modifications from phase 1, confirmed a generally positive assessment of the app and the ALBA chatbot.

In particular, the semantic differential tool results indicated that ALBA's communication was empathetic and fluid, and the interaction with users was deemed appropriate and acceptable. In addition, the interview reports highlighted that the interaction with the chatbot was generally well received, although criticisms included difficulties in navigating back to previous answers, repetitiveness, lack of novelty, and fragmented message design. Specific feedback highlighted the chatbot's confidence, relevant responses, and psychoeducational support while suggesting improvements such as professional voices for videos and reducing video and message length. Overall, both the target group and experts acknowledged the strengths of the chatbot's interaction, particularly its engaging multimedia elements and responsive nature. However, their perspectives diverged significantly on several key aspects. The target group expressed a desire for more innovative content and a reduction in repetitiveness, emphasizing that fresh and varied interactions would enhance their experience. In contrast, the experts, particularly the communication and usability specialists, focused on the fragmented design of the messages and the overwhelming volume of content, suggesting that a more cohesive and streamlined message structure would improve interactive usability. Indeed, user satisfaction significantly improves when chatbots provide quick, relevant, and friendly responses [50]. This capability reduces wait times and enhances the perception of service efficiency. Moreover, positive interactions with chatbots not only increase short-term satisfaction but also contribute to long-term user loyalty as users with positive experiences are more likely to return and use the service again, thereby strengthening their relationship with the app [51].

Regarding the communication modality, from the semantic differential tool emerged that the language was clear and understandable. Experts valued the clarity and thoroughness of using examples and videos to investigate concepts, suggesting more concise answers and alternating text with images or videos. Thus, multimedia content, such as images, videos, and audio provided by the chatbot, was also positively recognized both in the semantic differential tool and interview outputs. While the chatbot's language was also praised for simplicity and clarity in the interviews, some found the tone slow and recommended a more active tone, and the use of emojis was well received, with a recommendation to offer both emoji and word response options; the target group found the terms satisfactory but suggested reducing message length. In comparing the perspectives of experts and the target group on communication mode, notable differences emerged. The experts emphasized the importance of clarity and the effective use of various communication modalities, highlighting the need for dynamic and engaging delivery. In contrast, the target group appreciated the overall clarity and accessibility of the language used but expressed concerns about the length of certain messages. While the experts focused on enhancing different communication modalities, the target group prioritized brevity and engaging content. This divergence in focus highlights specific areas for improvement, indicating that refining the chatbot's communication strategies could enhance user satisfaction and overall effectiveness.

Overall, the session structure was considered appropriately lengthy and moderately light in content according to the semantic differential tool results. The importance of using inclusive and comprehensible language in chatbots is increasingly recognized in academic literature, emphasizing how this can enhance user experience and engagement. Studies show that chatbots that use such language can significantly improve user satisfaction and accessibility, making interactions more effective and welcoming for a diverse audience [52,53].

Regarding the uMARS standardized questionnaire, equally encouraging results were obtained for the engagement, functionality, esthetics, and information variables. However, improvements are needed for customization and interactivity, which could have received a more clearly positive rating. In accordance with this, in the interviews, the usability experts appreciated the guidance and psychoeducational support from the chatbot but noted a 1-way interaction and too many consecutive messages. Indeed, the experts, including the clinicians, SH+ specialist, and psychologists, noted in the interviews the difficulties related to the lack of physical presence and the static nature of the interaction, which felt akin to reading a book. They emphasized the need for enhanced personalization and interaction to foster deeper engagement, with suggestions to include features such as photos and avatars. Additional insights on engagement from interview responses were mixed. Although personalization through the use of the user's name was appreciated by the target group, there was a need for more specific customization—while the content was initially engaging and motivating for the target group, it became less engaging over time, leading to suggestions for reducing repetition and monotonous exercises. This divergence highlights the experts'

focus on improving interaction dynamics and customization, whereas the target group prioritized sustained engagement and the need for variety to maintain interest over time.

Enhancements are expected in these areas by better integrating the *Diary* and *Exercise* sections with the chatbot's messages regarding weekly exercise management once the app is fully implemented. In addition, features such as reminders and feedback, which were not available to testers, are expected to improve the perception of app personalization. The literature emphasizes the effectiveness of engagement strategies and reminders in improving user interaction with chatbots. Recent research shows that chatbots that use personalized engagement techniques and timely reminders can significantly enhance user commitment over time and adherence to recommended actions, leading to better outcomes and increased user satisfaction [54].

Additional information from the interviews provides insights about future technical implementation. Both the experts and the target group recognized the utility of reminders and notifications but mentioned that they should not be intrusive, with preferences for nondisruptive reminders and maintaining consistency. Moreover, most groups preferred a gradual coloring of stickers to indicate progress, providing satisfaction and motivation, although the target group also expressed a desire for immediate rewards, indicating a nuanced understanding of how to balance engagement and consistency. The app's ease of use and the high perceived credibility of the source were 2 very positive aspects highlighted. Both results will be further investigated in future feasibility studies using standardized tools to measure app usability [55] and user trustworthiness [56].

A good overall rating emerged from the uMARS items regarding subjective impact and perception, with behavior-change and help-seeking initiatives aligning with the intervention principles. These results are promising for the app's effective use but should be considered with the potential bias from psychological experts who favor such interventions. In addition, participants indicated a reluctance to pay for the app hypothetically and suggested that they would use it 3 to 10 times per year. While the first point may seem moderate, the app will be provided for free by the health care system, and some willingness to pay adds value. The second point warrants further investigation as the app is designed for continuous use over 5 weeks and it is unclear whether further use throughout the year implies single accesses or restarting of the intervention. The interviews indicated that the app could be proposed to target women at various stages of breast cancer care or before or after childbirth in other contexts of interest. The clinicians suggested using the chatbot during and after chemotherapy or radiation for oncology patients and during the first and second trimesters for pregnant women. Similar ideas emerged from the target group. They indicated that the chatbot could be helpful during chemotherapy or

radiation and after childbirth and, in contrast, less useful immediately after diagnosis or in early pregnancy. This flexibility is due to the different triggers and timings of stress-related issues in both contexts [57,58].

Strengths, Limitations, and Future Directions

This study highlights several strengths, limitations, and future directions for the app. Among the strengths, the chatbot's structured and standardized dialogues ensured an effective delivery of the validated content, and the empathetic dialogues and integration of gamification and feedback mechanisms were positively received by participants. In addition, the app's ease of use and high perceived credibility of the contents coming from a validated WHO protocol were crucial for user adoption. However, notable limitations include the chatbot's rigidity in personalizing responses and interactions and some repetitive content.

There was also a clear need for more specific customization options and improving answer personalization. While initially engaging, the content became less motivating over time, prompting suggestions to reduce repetition and monotonous exercises.

Future directions involve enhancing the chatbot's flexibility and personalization by incorporating user-specific elements. Implementing reminders and feedback mechanisms is also expected to improve personalization perception. Furthermore, conducting future feasibility studies using standardized tools to measure app usability and user trustworthiness will be essential. Exploring the frequency and context of app use over a year will help better understand user needs and improve continuous engagement effectiveness in pregnancy and oncological contexts.

Conclusions

This research evaluated the adaptation of the SH+ intervention for stress management through a mobile app guided by the ALBA chatbot. The implementation of the protocol tailored for pregnant women and women with a breast cancer diagnosis showcased several innovations, including interactive elements, gamification, and personalized feedback mechanisms. Using the ORBIT and CeHRes methodologies, this study validated the structured dialogues of the chatbot for effective content transmission while acknowledging limitations such as rigidity in personalization. Despite these challenges, the app's organization, user-friendly interface, and perceived credibility were notable strengths identified through participant feedback. Moving forward, addressing customization shortcomings, enhancing engagement strategies, and conducting further usability studies will be critical to refining the app's effectiveness and user satisfaction across diverse health care contexts.

Acknowledgments

The authors extend their gratitude to all study participants who dedicated their time, shared their knowledge, and contributed with their invaluable personal and professional experiences to the research.

Abstract

Background: Homework is implemented with variable effectiveness in real-world therapy settings, indicating a need for innovative solutions to homework challenges. We developed Adhere.ly, a user-friendly, Health Insurance Portability and Accountability Act–compliant web-based platform to help therapists implement homework with youth clients and their caregivers. The initial version had limited functionality, was designed for youth clients and their caregivers, and required expanding available features and exercises to suit adult clients.

Objective: The purpose of this study was to better understand barriers and potential solutions to homework implementation experienced by therapists seeing adult clients and obtain their input on new features and exercises that would enable Adhere.ly to better meet their needs when working with this population.

Methods: This study used an exploratory, sequential mixed methods design that included 13 semistructured focus groups with mental health therapists and clinic leaders and a survey administered to 100 therapists. Analyses were performed using the NVivo qualitative analysis software and SPSS.

Results: The findings revealed common barriers, such as clients and therapists being busy, forgetting to complete homework, managing multiple platforms and homework materials, and clients lacking motivation. Adhere.ly was perceived as a potential solution, particularly its user-friendly interface and SMS text-message based reminders. Therapists suggested integrating Adhere.ly with telemedicine and electronic health record platforms and adding more exercises to support manualized therapy protocols and therapy guides.

Conclusions: This study highlights the importance of technology-based solutions in addressing barriers to homework implementation in mental health treatment with adult clients. Adhere.ly shows promise in addressing these challenges and has the potential to improve therapy efficiency and homework completion rates. The input from therapists informed the development of Adhere.ly, guiding the expansion of features and exercises to better meet the needs of therapists working with adult clients.

Introduction

Background

Mental health disorders affect approximately 20% of individuals in the United States and are associated with costly physical, social, and occupational problems [1-3]. Most evidence-based mental health treatments (eg, cognitive behavioral therapy [CBT]) involve introducing and practicing therapeutic mental health exercises during therapy sessions, assigning patients to practice those therapeutic exercises between therapy sessions, and reviewing that practice during the next therapy session [4,5]. This between-session practice, or homework, facilitates treatment processes, strengthens learning, and enables the skills learned in therapy to generalize to the client's everyday environment, leading to improved maintenance of treatment gains [6-8].

Despite its many benefits, homework is implemented with variable effectiveness in real-world clinical settings. Only 68% of general mental health care providers and approximately 55% of family care providers report using homework "often" to "almost always" [9,10]. Therapists report using homework in an average of 57% of sessions, and only 25% of therapists report using expert-recommended systematic procedures for implementing homework (ie, specifying frequency, duration, and location and writing down homework assignments for patients) [11]. A national survey revealed that 93% of mental health therapists estimate rates of client adherence to homework to be low to moderate [10], and studies generally report low to moderate rates of client homework adherence [12,13].

Previous research has outlined numerous barriers to the successful implementation of homework during mental health treatment [6,7,9,14-21]. In our prior work, we found that youth therapists often have difficulty consistently and effectively designing, introducing, practicing, assigning, and assessing homework exercises, especially given the time constraints and workload of everyday clinical practice. We also found that youth and caregiver clients often have difficulty remembering to complete assignments and understanding the rationale and practical implementation (ie, when, where, and how) of homework exercises [14]. As part of this prior work, we also explored potential health technology solutions to these barriers. Therapists and youth and caregiver clients suggested digitized therapeutic exercises with instructions for clients, automated SMS text message-based reminders to complete those therapeutic exercises for homework, behavior and symptom tracking, reports, and activity summaries. Therapists and clients also expressed beliefs that a health technology solution with these features would likely increase therapist use of and client adherence to homework and have positive effects on the therapeutic relationship, treatment efficiency, and treatment effectiveness [14].

Informed by these results and using an iterative, user-centered design approach, we developed Adhere.ly, a user-friendly, Health Insurance Portability and Accountability Act-compliant web-based platform to help youth therapists implement homework with youth clients and their caregivers [22]. Upon initial development, the major components of Adhere.ly were

designed to help youth therapists (1) *practice* digitized therapeutic mental health exercises (eg, relaxation, affect and emotion, cognitive, exposure, and parent-child activities) with their youth and caregiver clients in the session, (2) *remind* clients to practice homework between therapy sessions via automated SMS text message or email messages with links to those exercises to be opened and completed in the clients' smartphone or computer browser, and (3) *review* clients' homework completion and relevant data for certain exercises (eg, self-monitoring ratings and anxiety ratings during exposure exercises). Adhere.ly is accessed via computer, tablet, and smartphone browser and does not require any downloads by clients or therapists. Clients do not create accounts or need to log in to complete exercises assigned by therapists.

Objectives

The initial version of Adhere.ly included limited functionality and exercises designed solely for youth clients and their caregivers. Although therapeutic approaches with children and adults share many theoretical foundations, such as CBT, there are numerous developmental considerations that must be taken into account when providing therapy to children and adolescents [23,24]. Some of these include the focus and goals of the therapy (eg, individual vs systemic), the involvement of others (eg, spouses vs caregivers), and the way in which therapeutic concepts and techniques are communicated (eg, didactic vs gamified) [25]. As we sought to expand Adhere.ly to support therapists in treating adult mental health clients, we felt that it would be critical to obtain the input of these key stakeholders. The first step toward accomplishing this goal was to better understand barriers and potential solutions to homework implementation experienced by therapists seeing adult clients. Next, we sought to obtain their input on new features and exercises that would enable Adhere.ly to better meet their needs when working with this population.

Methods

Overall Design

We used an exploratory, sequential (qualitative then quantitative) mixed methods design to understand (qualitative) and prioritize (quantitative) (1) the challenges and goals of stakeholders relative to the use of health technology solutions such as Adhere.ly and (2) new features and exercises to support therapists delivering evidence-based therapy to adult clients. The qualitative component of this design included remote (ie, videoconference or telephone), ≤90-minute screen- and audio-recorded semistructured focus groups with mental health therapists and clinic leaders. The quantitative component included a survey among mental health therapists.

Ethical Considerations

This study was approved by the University of South Florida Institutional Review Board (STUDY002555). For the focus groups, we scheduled interested individuals and obtained individual verbal consent and demographic information before starting the group interview. For the survey, after following the link and completing a screener, participants clicked a button to indicate their electronic informed consent to participate. All

focus group and survey data were deidentified before analysis. Focus group participants received a US \$50 gift card for their time, and we compensated participants with a US \$50 gift card for their time upon completion of the survey.

Focus Groups

Participants and Recruitment

We conducted a total of 13 focus groups with mental health therapists (n=18) and clinic leaders (n=16) between September 1, 2021, and October 25, 2021. A range of 2 to 6 mental health therapists and exactly 2 clinic leaders were included in each of the 8 clinic leader focus groups, and therapists and clinic leaders were interviewed separately. We did not meet our initial recruitment goal of 24 mental health therapists and 24 clinic leaders due to recruitment challenges during the COVID-19 pandemic.

All focus group participants were English-speaking adults (aged ≥ 18 years). We included therapists who had obtained at least a master's degree in social work, counseling, clinical psychology, or a related field and carried active adult mental health treatment caseloads. We included clinic leaders who served in a supervisory, managerial, or ownership role for an organization focused on providing mental health treatment services. Research staff emailed mental health therapists and clinic leaders registered with Doxy.me, a commercial telemedicine platform, with information about the study and an invitation to participate.

Data Collection and Instruments

In total, 2 master's-level and 1 bachelor's-level research staff members trained in social and behavioral sciences research facilitated the focus groups, and all 3 are authors on this manuscript. The focus group facilitators were university employees and not employed by Adhere.ly, LLC. Facilitators were trained with a detailed semistructured interview guide and protocol, including a series of role-play exercises and strategies to minimize potential bias. The focus group semistructured interview guide was developed following the Consolidated Framework for Implementation Research (CFIR) codebook [26] and the Integrated Technology Implementation Model (ITIM) [27]. All the interview questions are included in [Multimedia Appendix 1](#). All focus groups were recorded and transcribed using the Dovetail transcription software (Dovetail Research Pty Ltd). Transcriptions were reviewed and edited to ensure accuracy while listening to the recordings.

The semistructured focus groups began with questions about challenges that therapists experience while trying to engage adult clients in homework during therapy and strategies that therapists have used to try to overcome those challenges. Next, participants viewed a 5-minute video tutorial on Adhere.ly and its current exercises and features. We then asked participants to share their perspectives on how Adhere.ly might address challenges to engaging clients in homework and for their input on changes that might be made to Adhere.ly to meet the needs of therapists treating adult clients, including the addition of new features and therapeutic exercises.

Data Analysis

The qualitative analysis was completed by a team of 4 research staff members, 3 of whom are authors on this manuscript. All research staff members had training in sociobehavioral sciences, including 2 with doctoral degrees in the social sciences (ie, clinical psychology and health and human performance), 1 with a master's degree in psychology, and another with a bachelor's degree in psychology. In total, 2 members of the analysis team also facilitated the focus groups. The researchers coded the focus group recordings using NVivo (version 11; QSR International), a qualitative analytical platform. Procedures followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) [26]. The team read through the transcripts line by line to identify sensitizing categories reflective of the data. Researchers used a hybrid deductive-inductive process using thematic analysis [27,28]. The researchers coded emerging categories based on prior work that informed the focus group questions [14,29-31]. The unit of analysis was meaningful phrases [27,28].

Specifically, the team completed an initial round of deductive coding using categories identified through (1) prior work evaluating barriers to implementing homework through telemedicine [14,25] and (2) the CFIR and ITIM frameworks [26,27]. Categories related to homework challenges and requested exercises and features were created using evidence from previous studies on the platform [14,25], including but not limited to motivational and internet access-related issues and care provider attitudes toward homework. Categories following the CFIR and ITIM frameworks included but were not limited to the adaptability, compatibility, complexity, efficiencies, and relative advantages of Adhere.ly.

Results of this initial round were used to develop survey questions that asked respondents to priority rank the therapist- and client-related barriers to homework and the requested features and exercises identified in the first round of coding.

During the second round of coding, researchers refined the codebook over 4 iterations of inductive coding to identify categories, and disagreements were resolved through consensus with the research team. The research team coded a third of the focus groups collaboratively until the Cohen κ was at least 0.61, indicating substantial agreement, and the remaining focus groups were coded independently. Focused coding was used to refine the coding and ensure that the data were coded completely with minimal redundancy [32]. A full list of categories and the number of associated references are provided in [Multimedia Appendix 1](#).

Survey

Participants and Recruitment

We administered the 15-minute, web-based survey among 100 English-speaking adult (aged ≥ 18 years) mental health therapists who had obtained at least a master's degree. Similar to the recruitment of focus group participants, research staff emailed mental health therapists registered with Doxy.me, including those who had participated in the focus groups, with information about the study, an invitation to participate, and a link to the

survey screener. Survey responses were collected between October 21, 2021, and December 21, 2021.

Data Collection and Instruments

We developed a 59-question survey using insights obtained from the focus groups and the literature on homework and process-based CBT [33]. The survey began with screening questions about age, specialty (eg, mental health counselor vs social worker vs psychologist), and education (ie, master's degree vs doctoral degree vs neither), followed by questions about personal (ie, sex, race, and ethnicity) and professional (eg, ages and disorders treated, practice type, primary reimbursement, and treatment paradigms followed) demographics. The survey then asked therapists questions related to their use of homework with their adult clients. These included questions about how often they asked clients to complete homework exercises using a 4-point Likert scale (ie, 1=*never*; 4=*most of the time*), how important they thought homework was to improving their clients' outcomes on a 5-point scale (ie, 1=*not at all*; 5=*extremely*), and how important it was for them to know the results of their clients' homework assignments (eg, whether they completed them and how it went) on the same 5-point scale (ie, 1=*not at all*; 5=*extremely*). The survey also included questions about the extent to which certain factors were a barrier to them using homework with their clients (eg, not knowing what or how to assign homework, forgetting, and being too busy) and their clients completing homework assignments (eg, not knowing why or how to do the homework assignment or what to do, forgetting, being too busy, and avoiding homework due to distress) using a 4-point scale (ie,

1=*not a barrier*; 4=*significant barrier*). Therapists then viewed a 5-minute video tutorial on Adhere.ly and its current exercises and features. Afterward, the survey asked them to rank a list of exercises (eg, relaxation, interpersonal, self-monitoring, and behavioral activation) and a separate list of features (eg, assessments, integration with telemedicine platforms, integration with electronic health record [EHR] software, and therapy guides) in the order in which they should be prioritized when added to Adhere.ly to meet therapists' needs when seeing adult clients. All survey questions are included in [Multimedia Appendix 2](#).

Data Analysis

We cleaned the survey data and used SPSS (version 28; IBM Corp) to calculate descriptive statistics. We averaged the rank order of the features and exercises and used mean rankings to determine relative priority.

Results

Focus Groups

Participants

The demographic characteristics of the focus group participants are shown in [Table 1](#). On average, participants were aged 47.97 (SD 13.21) years and were largely female (25/34, 74%), White individuals (23/34, 68%), and non-Hispanic or Latino individuals (31/34, 91%). As shown in [Table 1](#), demographic characteristics were similar for the therapist and clinic leader groups.

Table 1. Focus group participant demographics (N=34).

Demographics	Overall sample	Therapists (n=18)	Clinic leaders (n=16)
Age (y), mean (SD)	47.97 (13.21)	49.7 (15.80)	46.1 (9.60)
Sex (female), n (%)	25 (74)	12 (67)	13 (81)
Race, n (%)			
Asian	1 (3)	0 (0)	1 (6)
Black	8 (24)	5 (28)	3 (19)
Multiracial	2 (6)	2 (11)	0 (0)
White	23 (68)	11 (61)	12 (75)
Ethnicity (non-Hispanic or Latino), n (%)	31 (91)	16 (89)	15 (94)

The therapist and clinic leader focus groups were analyzed together, and these data were reported in a unified coding scheme comprising categories of responses. The number of therapists and clinic leaders that made statements relevant to each category is reported in [Multimedia Appendix 1](#). In addition, illustrative quotes are provided for each category. It should be noted that only therapists and clinic leaders were participants, so references made to client-related barriers are therapist and clinic leader perceptions of those client barriers.

Challenges to Engaging Clients in Homework

Participants identified 7 major categories related to challenges in engaging clients in homework (44 total references). Overall, most of the focus group participants reported challenges related

to therapists being too busy to complete, assign, or review homework (9/44, 20% of references) or perceiving that their clients were too busy to complete homework (8/44, 18% of references). However, the number of participants who made statements within both categories differed substantially between the clinic leader and therapist focus groups.

One participant commented the following:

We have not had much luck with getting anything returned to us, whether it's homework or releases of information...

Another participant stated the following:

...as an individual provider or even in a clinic, you don't have the time to be constantly checking in every day with all the clients to get them to practice what you're telling them to practice.

Most of the references associated with the category of therapists being too busy to assign homework and perceptions that clients were too busy to complete homework were from the clinic leader focus groups (7/9, 78% of references) as opposed to the therapist focus groups (2/9, 22% of references). Slightly more clinic leaders (5/8, 62% of references) than therapists (3/8, 38% of references) endorsed perceiving that clients forget to complete homework. While these were the 2 most common categories of responses in the clinic leader focus groups, neither was the most frequent in the therapist focus groups.

In addition, many focus group participants reported struggling to find the right platform or medium for homework (7/44, 16% of references). The number of relevant responses did not differ substantially between the therapist (3/7, 43% of references) and clinic leader (4/7, 51% of references) focus groups. Participants reported difficulty sending homework materials over telemedicine platforms as well as having to manage multiple web-based platforms and applications to meet their clients' needs.

One participant commented the following:

When I know that I'm going to be assigning homework assignments, I'll have the worksheet or paper in front of me so that I can give it to them. We use Doxy.me for our tele-health and it's a little hard, I can sometimes screen-share, but sometimes our tele-health is over the phone and I'm like, okay, just try and Google this on your own. Good luck. It makes it a little challenging.

The next 2 most frequently reported challenges included perceptions that clients lack motivation or discipline to complete homework consistently (7/44, 16% of references) and perceptions that clients receive insufficient instruction or rationale for completing homework (6/44, 14% of references). A comparable number of therapists and clinic leaders made statements that fell under these 2 categories.

One participant commented the following:

I think when it comes to giving a client an assignment, it's always a challenge as to whether they're going to follow through with it and utilize it. And also, I mean, at least they'll try it once and whether they're going to try it again, will depend on if it worked or not, or if it was so empowering to them that they're willing to keep using it.

Few participants mentioned challenges related to perceptions of clients avoiding homework due to anticipated distress (4/44, 9% of references) and clients experiencing external (ie, internet or phone access), educational, or cognitive functioning barriers to completing homework (3/44, 7% of references).

For example, one participant stated the following:

So, like you're in therapy and you're in the moment...and then in between sessions, you just sort of like, don't want to go there. So, you avoid.

Another participant stated the following:

I would also add that we have some resource barriers here sometimes. So, I'm in a fairly rural part of the country. And as a result of that, the ability to obtain a consistent internet or phone signal sometimes is really challenging. So, there's some technological barriers in that regard.

Related to educational or cognitive barriers to completing homework, another participant stated the following:

And then I also think the education and cognitive abilities of the person sometimes plays a role in making sure that the materials we're providing are appropriate for the person. So, if I try giving them really complicated interventions and I send them home with a sheet and their reading isn't strong enough to be able to comprehend what the sheet says that can also be a barrier in some situations.

While the category related to client avoidance was evident in both the therapist (1/4, 25% of references) and clinic leader (3/4, 75% of references) focus groups, the category related to socioeconomic status, rural versus urban location, educational level, or cognitive ability challenges was evident only in the clinic leader focus groups (3/44, 7% of references).

Overall, most clinic leaders emphasized therapists' and clients' busy schedules and perceptions that clients forget to complete their homework. Most therapists emphasized perceptions that clients lack motivation or discipline to complete homework consistently; however, the number of participants whose responses fell within these categories was more evenly distributed across categories in the therapist focus groups than in the clinic leader focus groups.

Current Strategies for Overcoming Challenges

Participants' responses fell into 5 categories of strategies or responses that therapists used to overcome challenges in engaging clients in between-session exercises (57 total references). Most participants referenced using motivational and reinforcement strategies to encourage homework completion during the sessions (23/57, 40% of references); however, nearly all the participants who mentioned this strategy were clinic leaders (19/23, 83% of references) as opposed to therapists (4/23, 17% of references):

We have to really just plan out how important the assignments are to their treatment, and just for them to know that if they want to get better and achieve the goals that we've set in therapy, then the homework assignments are a very important part of that, and they need to take it seriously.

Many participants also mentioned using multiple applications and web platforms to send and track homework (15/57, 26% of references). Similar to the previous category, most participants who mentioned this strategy were clinic leaders (13/15, 87% of references) rather than therapists (2/15, 13% of references):

...some of us have gotten creative. We realized that the paper homework doesn't work...or having the client record their thoughts on their phone or on a paper does not work. So, we get written permission from the client to share Google Drive, which is probably not the most HIPAA compliant activity to be doing. We have to go through the whole hassle of getting the client to sign that they're okay with this and that they're sharing that Google document. Knowing that the therapist is able to review it and see it in real time tends to have a little bit of an effect on compliance.

The third most frequently referenced strategy was adapting the treatment plan to “meet clients where they are at,” which largely entailed changing homework assignments or completing them in the session rather than continuing to give the same homework assignments that the clients had not previously completed (14/57, 25% of references). This category was equally referenced by clinic leaders (7/14, 50% of references) and therapists (7/14, 50% of references):

I don't penalize and you know, I don't shame or anything like that when people don't do their homework. However, like a good teacher, if you don't do your homework, you're doing it in class. And so, we just break out the pen and paper, I get silent, turn the lights down, if I need to, or the lights up, whatever is going to be conducive. But sometimes people, this is the one time they get a chance to really just be still and really think, cause they're on autopilot so much.

The last 2 strategies were referenced by only a few focus group participants and included having clients set their own reminders either electronically or in written form (3/57, 5% of references), which only emerged in the clinic leader focus groups, and providing accountability via email, SMS text message, or phone (2/57, 4% of references), which was mentioned by only 1 participant in the clinic leader and therapist focus groups each. For example, one participant commented the following:

...we've definitely had clients who forget things that we've had them put it in their calendar in their phone.

How Adhere.ly Might Address Challenges to Engaging Clients in Homework

Participants' responses to how Adhere.ly might address challenges to engaging clients in homework were divided into 11 categories (143 total references). Overall, the most common responses were that the utility of Adhere.ly would vary by client demographics and clinical needs (28/143, 19.6% of references), which was emphasized almost equally by therapists (18/28, 64% of references) and clinic leaders (10/28, 36% of references), and that Adhere.ly is easy to use and would appeal to a wide range of therapists and clients (27/143, 18.9% of references), which was emphasized by more therapists (12/27, 44% of references) than clinic leaders (15/27, 56% of references).

Regarding the utility of Adhere.ly varying by client demographics and clinical needs, participants mentioned demographics such as age, which they thought might influence attitudes toward technology, and smartphone use. Many

participants also mentioned generally taking the approach of seeing how specific clients responded to new interventions before they drew conclusions about effectiveness and being unable to comment on Adhere.ly until they had piloted it with their clients. A smaller subset of these participants mentioned that Adhere.ly may not be helpful for specific clinical populations, including those in crisis or with serious substance abuse problems:

I know a lot of my older people...my older ladies, high anxiety, depression, they're going to have difficulty understanding it. I mean, it's something that I think could be very useful to a certain group of folks.

I think this also speaks to a particular demographic. I see a fair percentage of Medicare patients, some of whom don't have smartphones, and some who are very smart about using their smartphone. So, you know, defaulting to that, it's enough of a challenge to get people, some of them, to do telemedicine. So, we'd have to look at whether this is a demographic that is comfortable doing things on the phone.

Regarding ease of use, participants mentioned that Adhere.ly seemed more accessible and efficient than other applications and platforms, which was mentioned by nearly the same number of therapists (12/143, 8.4% of references) and clinic leaders (15/143, 10.5% of references):

I definitely agree that even compared to some other apps...the user interface seems a lot simpler. I kind of poked around before and created an account and it actually moves pretty quickly and doesn't lag and it's just easier to navigate.

Many participants reported perceptions that Adhere.ly would increase the overall efficiency of therapy (23/143, 16.1% of references), which was mentioned by most participants across the therapist (11/23, 48% of references) and clinic leader (12/23, 52% of references) focus groups. Several specifically mentioned that Adhere.ly's reminder feature would improve homework completion rates (16/143, 11.2% of references), although this was primarily emphasized by clinic leaders (15/16, 94% of references) rather than therapists (1/16, 6% of references). One participant commented the following:

I think it reminds me of Fitbit. It's kind of the same concept of getting people to get up and move or exercise and, it's just, again, reinforcing a different habit.

Another participant stated the following:

...being able to know that there's some real practical, useful tools and automated support reinforces the fact that folks are getting what they need in between sessions. Cause it's absolutely difficult to have to start over again week by week because you feel like you lost what happened between the sessions.

Many participants also stated that the utility of Adhere.ly would vary by therapist demographics and theoretical orientation (12/143, 8.4% of references), although more therapists (18/143, 12.6% of references) emphasized this than clinic leaders (10/143, 7% of references). Some of these comments referenced

the association between age and attitudes toward technology or attitudes toward technology alone, as illustrated by the following quotes:

I have some [therapists] that are really tech savvy. And so, this is going to seem like a breeze, and it would be pretty easy for them to incorporate it. And I have others that wish that we didn't have electronic health records and wish we could still do pencil and paper for everything. And so, I would imagine this would probably align with comfort level in part, but as long as it was fairly user-friendly, I would imagine probably most of my clinicians would at least try it out.

I have staff under me who are in their fifties. I have staff in their thirties. So, I think it just varies. I can't speak to everybody's level of comfortability. That's the best answer I can give you.

Therapists also mentioned that Adhere.ly might be especially useful when implementing evidence-based CBTs over telehealth but might be less useful if using other interventions or doing therapy in person:

It's not as much a need for in-person services as for integrated CBT interventions on doxy.me. That feels like a need. Like, to me, that's the missing piece. I think I mentioned this in our first meeting, even as a clinical supervisor, if I have a very beginning therapist and I'm trying to teach her how to teach the cognitive triangle or how to teach a thought record, and I'm doing it over zoom, which I did for so long.

Some participants also mentioned that Adhere.ly would easily fit into therapists' in-session workflows (11/143, 7.7% of references), which was mentioned by slightly more clinic leaders (7/11, 64% of references) than therapists (4/11, 36% of references). Participants explained that therapists could easily set up Adhere.ly exercises with their clients at the end of the session, which would minimize the time they would need to spend doing homework outside the session:

Many times, we have patients back-to-back and so the ability to do it in between appointments isn't always there. I think if the provider saw the value in this, I would imagine they would incorporate it into the session on the back end as kind of a wrap up between that and the following session. I think if it was like an add-on that had to be done in between sessions, that could create some challenges only because of the learning curve and time commitments.

Other less commonly referenced categories included Adhere.ly's ability to capture treatment data (9/143, 6.3% of references) and the use of text-based communication (6/143, 4.2% of references) coming from their therapist as opposed to an external platform (5/143, 3.5% of references) to increase client engagement and homework completion. For example, one participant commented the following:

I like the tracking. I like the little charts that show you how they're doing.

Another participant said the following:

I like that it goes straight to their email or their texts without a log-on...if there's no login, I find that clients are much more likely to click on a link and then follow through.

Primarily clinic leaders emphasized the benefits of capturing treatment data (8/9, 89% of references) and the use of text-based communication (5/6, 83% of references), whereas more therapists emphasized the benefits of clients receiving direct communication from their therapist through Adhere.ly (4/5, 80% of references).

Suggested Features to Add to Adhere.ly

When asked which features should be added to Adhere.ly (63 references in total), a total of 7 categories emerged, although most of the references included in this account were from the clinic leader focus groups (52/63, 83% of references). The most common response was to add a demonstration video or other web-based walk-through for clients and therapists (14/63, 22% of references), and 86% (12/14) of these references were from the clinic leader focus groups. One participant stated the following:

...make an electronic training that actually sends the links to the clinicians so that they see what it's like, and they're sort of exposed to it from the client side.

This was followed by integration of Adhere.ly with EHR platforms and Doxy.me (12/63, 19% of references), which was only mentioned by clinic leaders. One participant stated the following:

I think the toughest part would be if people have to log into a separate platform...the more integrated it is into something you're already using or the easier it is to get in and out of, the more helpful it would be.

Other suggestions included enhancement of audiovisual features (ie, gamification and more color and visuals; 11/63, 17% of references), which was primarily mentioned by clinic leaders (8/11, 73% of references) rather than therapists (3/11, 27% of references):

There's got to be some type of draw that keeps somebody continuing to engage with electronic interventions...like gamification. For example, can they achieve ribbons or trophies or can go toward something that shows them that they're making progress? I know at least with some of the programs that I utilize now, that's what I really like about it.

Several participants also suggested expanding the reminder feature (ie, recurring notifications, customizations, and parent reminders; 10/63, 16% of references), which was equally mentioned by therapists (5/10, 50% of references) and clinic leaders (5/10, 50% of references). For example, a participant suggested adding "a way to set the reminder up for an open-ended period of time until it's changed, rather than every week having to get them there and change the reminder." Other suggestions mentioned by several participants included adding more options for registration (ie, self-registration and customized communication preferences, including more client identifiers and a feature for group, couple, and family registration; 8/63,

13% of references) and adding an e-consent form (5/63, 8% of references). One participant emphasized the following:

Share-ability! Where can I share the information? Is it with the client? Is it with their parent? Is it with a family member? Clinician share-ability I think goes a long way to making something useful.

Both of these features were only mentioned by clinic leaders.

There were several features that did not fit neatly into the other categories, all of which were referenced by only 1 participant, such as options for clients to provide feedback on exercises, a feature allowing PDF export of client results, and ensuring sixth- and seventh-grade reading level across the content. These features were also only requested by clinic leaders.

Suggested Therapeutic Exercises to Add to Adhere.ly

When asked which therapeutic exercises should be added to Adhere.ly, participants responded within 7 major categories (81 references in total), most of which were identified by therapists (47/81, 58% of references). These categories included the following: homework from evidence-based therapy protocols (40/81, 49% of references), homework for specific skills or strategies (17/81, 21% of references), homework for specific client demographics (6/81, 7% of references), homework for specific mental health conditions (5/81, 6% of references), personalized or custom exercises (5/81, 6% of references), and brief or single-item assessments (3/81, 4% of references).

Regarding homework for evidence-based therapy protocols, most therapists and clinic leaders identified the following interventions as useful additions: mindfulness-based approaches (11/40, 28% of references), trauma-focused therapies (ie, eye movement desensitization and reprocessing, cognitive processing therapy, and prolonged exposure; 8/40, 20% of references), dialectical behavior therapy (5/40, 12% of references), behavioral activation (4/40, 10% of references), safety planning (3/40, 8% of references), CBT (3/40, 8% of references), and acceptance and commitment therapy (2/40, 5% of references). One participant explained why they emphasized trauma-focused interventions:

Much of my focus is trauma. And so many of the approaches I use include things like EMDR and somatic experiencing. So...if I was going to assign anything to anyone, it would be related to developing self-regulation skills and somatic awareness skills to help them be able to cope with trauma symptoms. So that would be one way that I can see providing homework to people is to do something like that.

While mindfulness and stress reduction interventions were mentioned by an equal number of therapists (6/11, 55% of references) and clinic leaders (5/11, 45% of references), most of the remaining interventions were mentioned by more clinic

leaders than therapists, although the overall number of suggested interventions was greater for therapists than clinic leaders.

With respect to homework for specific skills and strategies, therapists most frequently requested journaling (7/17, 41% of references), creative activities (3/17, 18% of references), recovery plans (2/17, 12% of references), and strength-based activities and positive psychology (2/17, 12% of references). These distributions can be viewed in greater detail in [Multimedia Appendix 1](#).

One participant suggested the following:

I think those basic needs things like, are you sleeping? Are you eating? Have you had water today? For that kind of stuff, they need reminders because when they're really depressed, as we know, it's hard to remember those basic things.

Regarding homework for specific client demographics (5/81, 6% of references), some therapists referenced emotion regulation games that are engaging for children (3/5, 60% of references) despite the prompt to suggest interventions for adult users, as well as couples exercises (2/5, 40% of references). For example, one participant suggested the following:

...for clinicians working with couples...there are lots of lots of things like scanning for opportunities to express appreciation and respect...prompt them to initiate a conversation to show appreciation.

No clinic leaders suggested interventions for specific demographics or mental health conditions. The remaining categories, including homework for specific mental health conditions and personalized or custom exercises, did not have a pattern of minor categories and were only mentioned by a few therapists.

Survey

Participants

The demographic characteristics of the survey respondents are shown in [Table 2](#). On average, therapists were aged 45.6 (SD 14.23) years and were largely female (69/100, 69%), White individuals (79/100, 79%), and non-Hispanic or Latino individuals (85/100, 85%). Therapists were mostly mental health counselors (39/100, 39%), psychologists (28/100, 28%), and social workers (22/100, 22%) who worked in individual practice (55/100, 55%) and small clinic (33/100, 33%) settings and were primarily reimbursed via private (53/100, 53%) or public (32/100, 32%) insurance. Most therapists primarily saw adults (93/100, 93%) and adolescents (51/100, 51%) with anxiety (99/100, 99%), trauma- and stressor-related (90/100, 90%), and mood (85/100, 85%) disorders following the cognitive behavioral paradigm (69/100, 69%).

Table 2. Demographic and professional characteristics of the survey respondents (N=100).

Demographics	Values
Age (y), mean (SD)	45.64 (14.23)
Sex (female), n (%)	69 (69)
Race, n (%)	
American Indian or Alaska Native	1 (1)
Asian	3 (3)
Black	13 (13)
Multiracial	11 (11)
White	79 (79)
Ethnicity (non-Hispanic or Latino), n (%)	85 (85)
Highest degree, n (%)	
Master's	67 (67)
Doctoral	33 (33)
Specialty, n (%)	
Mental health counselor (eg, LMHC ^a or LPC ^b)	39 (39)
Psychologist (eg, PhD or PsyD)	28 (28)
Social worker (eg, LCSW ^c)	22 (22)
Marriage and family therapist (eg, LMFT ^d)	9 (9)
Other mental health therapist	1 (1)
Type of clinic or organization, n (%)	
Individual practice	55 (55)
Network of health care providers or small clinic	33 (33)
Hospital or large clinic	10 (10)

^cLCSW: licensed clinical social worker.

^dLMFT: licensed marriage and family therapist.

Perceptions on Homework

Most therapists (94/100, 94%) reported that they generally asked their clients to practice therapeutic skills and exercises for homework *some to most of the time* (mean ranking 3.51, SD 0.61). Most therapists (73/100, 73%) felt that homework is *moderately to extremely* important to improving their clients' outcomes (mean ranking 4.08, SD 0.93). Most therapists (69/100, 69%) also believed that it is *moderately to extremely* important for them to know the results of their clients' homework assignments (eg, whether they completed them and how it went).

Barriers to Therapists Using Homework With Clients

Therapists perceived having difficulty getting clients to complete assignments (mean ranking 2.66, SD 0.79), not wanting to overwhelm or distress clients (mean ranking 2.05, SD 0.93), and being too busy or not having time (mean ranking 2.01, SD 0.90) as *minor to moderate* barriers to them using homework with their clients. Therapists perceived forgetting to assign homework (mean ranking 1.84, SD 0.90), not knowing what to assign (mean ranking 1.72, SD 0.71), not knowing how to address clients not completing assignments (mean ranking 1.69, SD 0.84), not knowing how to assign homework (mean ranking 1.34, SD 0.59), and not being trained to assign homework (mean ranking 1.29, SD 0.59) as *minor* barriers to nonbarriers to them using homework with their clients.

Barriers to Clients Completing Homework Assignments

Therapists perceived clients having a busy or chaotic home life as a *moderate* barrier to clients completing homework assignments (mean ranking 3.00, SD 0.80). Therapists also perceived clients forgetting about homework (mean ranking 2.86, SD 0.94), avoiding completing assignments due to distress or symptoms (mean ranking 2.66, SD 0.71), receiving little reward or reinforcement for completing assignments (mean ranking 2.10, SD 0.88), and viewing assignments as boring (mean ranking 2.06, SD 0.81) as *minor to moderate* barriers to clients completing homework. Furthermore, therapists perceived clients not knowing how (mean ranking 1.91, SD 0.77), what (mean ranking 1.88, SD 0.81), or why (mean ranking 1.73, SD 0.75) assignments should be completed as *minor* barriers to nonbarriers to their clients completing homework assignments.

New Adhere.ly Features to Prioritize for Therapists Seeing Adult Clients

With respect to adding new features to Adhere.ly, therapists primarily suggested adding self-report questionnaires or assessments (mean ranking 6.76, SD 1.46), integration with telemedicine platforms (mean ranking 5.18, SD 2.26), and therapy guides or treatment protocols (mean ranking 4.64, SD 2.31). These were followed by the ability to edit text language in SMS text message or email reminders (mean ranking 4.47, SD 2.08), customized exercises for their practice (mean ranking 3.97, SD 2.92), integration with EHR software (mean ranking 3.94, SD 2.38), incentives or rewards for clients (mean ranking 2.69, SD 1.82), integration with wearables (mean ranking 2.68, SD 1.89), and integration with other treatment software (mean ranking 1.67, SD 1.97).

New Adhere.ly Exercises to Prioritize for Therapists Seeing Adult Clients

Regarding adding new therapeutic exercises to Adhere.ly, therapists suggested prioritizing relaxation (eg, breathing, muscle relaxation, mindfulness, and grounding; mean ranking 7.38, SD 2.20) and self-monitoring (eg, journaling, emotions, thoughts, and behaviors; mean ranking 6.57, SD 2.08). These were followed by coping and emotion regulation (eg, cognitive reappraisal and acceptance; mean ranking 5.49, SD 2.33), behavioral activation (eg, scheduling pleasant and important activities; mean ranking 5.04, SD 2.18), interpersonal (eg, social skill training; mean ranking 4.88, SD 2.45), and cognitive (eg, restructuring, flexibility and reappraisal, and modifying core beliefs; mean ranking 4.64, SD 2.71) exercises. Lower-priority exercises included problem-solving (eg, simplification, visualization, and planful problem-solving; mean 3.37, SD 2.24), behavioral (eg, contingency management, stimulus control, and shaping; mean ranking 2.87, SD 2.19), exposure (eg, building imaginal and in vivo exposure hierarchies; mean ranking 2.59, SD 2.32), and couple (eg, communication, compromising, and problem-solving; mean ranking 2.17, SD 2.85) exercises.

Discussion

Principal Findings

This mixed methods study explored common barriers experienced by mental health therapists when implementing homework with their adult clients. This study also explored potential solutions to those barriers, including health technology

such as Adhere.ly, a web-based platform designed to help therapists engage adult clients in homework. Therapists in this study provided their input on new features and exercises that would enable Adhere.ly to better meet their needs when working with this population.

Consistent with previous research, therapists reported facing substantial challenges when implementing homework with adult clients [6,7,9,14-21]. While most therapists rated homework as moderately to extremely important, only a small percentage reported consistent and successful implementation. These results align with previous findings [9-11]. The most used evidence-based therapy protocols, particularly cognitive behavioral interventions, rely on homework exercises, such as worksheets and coping skill practice [4,5], yet there are few solutions available to support therapists in carrying out this critical therapy component [14]. The significant barriers faced by mental health care providers and the lack of available tools to resolve these barriers have significant implications for the successful implementation of evidence-based therapies in real-world practice settings.

Common Barriers to Homework

Primary barriers to therapists using homework with their adult clients differed significantly between the focus groups and survey in terms of barrier rankings.

While therapists and clients being too busy to assign or complete homework, respectively, was the top-ranked barrier in the focus groups, difficulty getting clients to complete assignments was the top-ranked therapist barrier in the surveys. Therapists being too busy to assign or review homework was the third priority-ranked barrier in the surveys. The emphasis on busyness and competing demands aligns with previous research [14,15]. Even when clients are motivated, therapists and clients juggle numerous responsibilities, commitments, and in-session priorities, which are frequently cited barriers to completing, assigning, and reviewing homework [15]. In the focus groups, therapist and client barriers were merged due to statements often referencing both therapist and client busyness, which is the mostly likely reason for the different rankings in the survey and focus groups. Furthermore, primarily clinic leaders identified therapist busyness as a barrier in the focus groups, and the surveys did not include clinic leaders.

Similarly, therapist perceptions that clients forget to complete their homework was ranked second in the focus groups and in the survey. Previous research [14,15] has identified clients forgetting as a primary barrier and emphasized the need for solutions that remind and encourage adult clients to complete homework given their other responsibilities. In contrast with child and adolescent clients, adults have no external reinforcement to stay focused on their therapy goals aside from their therapist, whom they may see at most once a week. Low rates of homework completion might be expected given that these barriers are coupled with clients finding assignments boring and receiving little reward or reinforcement for completing them, which was the third-ranked client barrier in the survey. Given that adult clients also struggle to remember what to do for homework and how to do it, solutions that remind clients to complete homework while providing easy-to-use and

easy-to-access exercises with clear instructions have tremendous potential to overcome these common barriers to homework adherence.

The remaining barriers identified in the focus groups and the survey differed significantly. The third-ranked barrier in the focus groups was therapists struggling to find the right medium or tools with which to assign homework, followed by clients lacking the motivation to complete homework, clients receiving insufficient reinforcement for completing homework, clients avoiding homework due to distress, and other client barriers to homework (eg, lack of internet or smartphone or cognitive challenges). In contrast, the remaining survey priority-ranked categories were not wanting to overwhelm or distress clients and not knowing what to assign or how.

We attribute these differences to developing survey items using a combination of previous research [14,15] and a preliminary content analysis of the focus group results, using different samples for the focus groups and the survey, and the inclusion of clinic leaders in the focus groups who may have significantly different concerns from therapists (eg, emphasis on structural or administrative challenges). Furthermore, there is limited previous research in this area on which to base survey items, and prior work may not adequately capture barriers to implementing therapy homework. Indeed, the survey priority rankings were overall low for the client and therapist barrier question, indicating that the items selected for the survey were not representative of therapists' concerns. These discrepancies emphasize the importance of this mixed methods study given the critical role of homework in evidence-based therapy protocols. The qualitative findings will be used to develop future survey items that are more reflective of therapists' and clinic leaders' experiences in real-world practice settings.

Focus group participants reported that therapists' general therapeutic approach to addressing these challenges includes using motivational and reinforcement strategies to "meet clients where they are," including completing homework in the session and adapting homework assignments so that they are less time-consuming to complete. Therapists reported using multiple web platforms, mobile apps, and other materials (eg, paper homework) to create, assign, and remind clients of homework. For example, therapists often use phone reminders, paper materials, and various mobile apps to follow homework assignments prescribed according to specific therapy protocols. However, this approach results in therapists having to use several different platforms and mediums to implement homework, which can be inefficient and time-consuming for both the therapist and client, leading to frustration and lower homework adherence. Participants reported high perceived value of an all-in-one solution to support them in this process. This perceived value highlights the importance of adapting Adhere.ly for use with adult clients.

Adhere.ly as a Solution

Overview

Overall, participants viewed Adhere.ly as a potential solution to these challenges by offering a user-friendly, all-in-one solution. They felt that that Adhere.ly would likely reduce

inefficiencies, increase homework completion rates, and be easy to use. Participants most frequently showed interest in Adhere.ly's SMS text message or email reminder feature. This feature allows clients to simply click the link from their SMS text messages or email and complete brief therapy exercises.

Most participants stated that Adhere.ly would be helpful for a wide range of therapists and clients while also believing that its utility would depend on therapist and client demographics. The most frequently mentioned concern in this domain was that some populations might not have access to the internet or cell phones with data plans and some clients or therapists might need to be technologically savvy to use the platform. As a result, Adhere.ly may resolve barriers to homework for some but not all therapist and client populations. Some therapists suggested that generations who grew up around these technologies might find SMS text message-based reminders and exercises especially motivating and helpful. Therapists and clients who did not grow up around these technologies might find learning a new application burdensome or less engaging. Additional training and support resources, while alleviating some barriers, would not address underlying attitudes toward or existing patterns of technology use [34].

Suggested Features and Exercises

Although the survey and focus groups identified similar features and exercises to add to make Adhere.ly compatible with adult clients, there were significant differences in the extent to which these features and exercises were emphasized by both samples. Regarding features, the survey respondents ranked enhanced assessment, integration with telemedicine platforms (eg, Doxy.me), therapy guides, customizable reminders, and EHR integration as the top 5 most important features to add. Focus group participants emphasized a demonstration video to orient clients and therapists regarding the application, EHR integration, gamification, and custom reminders as the most important features to add. We suspect that these differences are largely due to the focus group sample including clinic leaders because all the focus group participants who emphasized the demonstration video and EHR integration and most of the participants who mentioned gamification were clinic leaders. In future studies exploring the utility of health technology to enhance the implementation of evidence-based therapies, we will include clinic leaders in both the surveys and focus groups and ensure that extensive demographic and professional information is collected in both samples.

Regarding requested therapy exercises, evidence-based therapy protocol homework assignments (eg, mindfulness-based therapies and trauma-focused interventions) were most frequently requested, followed by specific coping skill assignments (eg, journaling). Eye movement desensitization and reprocessing, cognitive processing therapy, and dialectical behavior therapy were the most frequently referenced interventions, reflecting a high need for trauma-focused homework solutions. The survey options were worded differently than the focus group exercise categories, but the results were fairly similar across the samples. Survey respondents also emphasized mindfulness and relaxation-based exercises, self-monitoring exercises, coping and emotion

regulation, behavioral activation, interpersonal skills, and cognitive exercises as the top-ranked exercises to add. Given that 69% (69/100) of the survey respondents identified as cognitive behavioral therapists, it makes sense that the most requested exercises aligned with second- or third-wave cognitive behavioral interventions. Focus group participants were more likely to discuss the overall need for including evidence-based therapy protocol homework with an emphasis on mindfulness-based and trauma-focused interventions.

Limitations

While this study offers valuable insights into common barriers faced by therapists to implementing homework with their adult clients and how health technology solutions such as Adhere.ly might help, there are some limitations to consider. This study included a small sample of therapists and clinic leaders for the focus groups and a separate sample of therapists for the survey. Recruitment was impacted by the COVID-19 pandemic, which led to smaller-than-recommended focus groups; however, this study was conducted during a period of unprecedented need for telehealth solutions, which we believe is a strength.

While efforts were made to ensure diversity in this sample, the findings may not reflect all mental health care providers, and true integration of the qualitative and quantitative findings would require at least some overlap in the survey and focus group samples. Furthermore, this study did not adequately assess therapist and clinic leader demographics to match the demographics collected in the survey, which will be corrected in future studies. Lack of inclusion of this information impacted our ability to assess how participants' contexts may have influenced their responses. Specifically, the therapists and clinic leaders who consented to participate may have greater comfort with or interest in health technology solutions than the average mental health clinician.

In addition, these data were obtained using focus groups and self-report assessments, which are subject to inherent biases and limitations. While we aimed to reduce the potential for researcher bias, as described in the Methods section, all researcher contributions are also subject to inherent biases and limitations. This study aimed to assess therapist and clinic leader perceptions on Adhere.ly's utility for adult-serving clinicians given that its utility for therapists serving children and families has been previously assessed. As a result, the findings cannot be generalized to therapists working across all populations and settings.

Conclusions

This study identified primary challenges that therapists face while implementing homework in adult-serving mental health outpatient treatment. The findings indicate that, with the additional features and therapeutic exercises requested by respondents, Adhere.ly has strong potential to address some of these challenges and increase overall homework completion rates, which would theoretically support improved clinical outcomes.

The results of this study were used to inform the user-centered development of the requested features and exercises, which can be accessed freely through the Adhere.ly platform. However,

the broader implications of this study are that it was conducted at a time of unprecedented need for telehealth solutions and, at present, evidence-based therapies are inadequately implemented in real-world practice settings due to the aforementioned challenges. There is incredibly limited research on evidence-based therapy homework implementation despite its clear implications for the implementation science literature.

Ongoing research is exploring the feasibility and effectiveness of using Adhere.ly in mental health therapy practice settings.

Specifically, we are evaluating its ability to contribute to improved homework implementation and adherence and, in turn, clinical and functional outcomes. Future studies will also address the limitations of this study through continued refinement of Adhere.ly and study methodology. Overall, this study contributes to a growing but still small body of literature on therapy homework implementation and highlights the importance of innovative technology solutions that address common challenges experienced by therapists.

Abstract

Background: Digitally supported self-management tailored to an individual's need, in addition to usual care, may reduce pain-related disability compared to usual care alone, and patients with low back pain (LBP) using mobile health (mHealth) solutions express positive experiences. Hence, implementing mHealth solutions designed to support self-management is desirable from a clinical and patient perspective. Easily accessible mHealth solutions that can support the self-management of patients with LBP are available, but interest may be subgroup specific. Understanding the characteristics and preferences of patients with LBP labeled as interested may help to reach relevant LBP patient groups and inform the development and implementation of effective interventions with mHealth for patients with LBP.

Objective: This study aims to explore the proportion of patients with LBP labeled as interested in testing an mHealth solution designed to support self-management in addition to usual care and to assess how these patients differ from those who were labeled as not interested.

Methods: This exploratory cross-sectional study analyzed demographic and patient-reported outcomes from the SpineData registry, a Danish registry of patients with LBP in an outpatient setting. Between February and December 2019, the SpineData registry was used to assess the preliminary eligibility of patients for a clinical trial (selfBACK). Patients were labeled as interested or uninterested depending on if they responded to an invitation to be tested for eligibility for the trial. Outcomes were selected from the International Classification of Functioning core set of LBP using a clinical approach. Associations were assessed in a backward selection process, and the proportion of variance explained was assessed with pseudo- R^2 statistic.

Results: This study included 843 patients, with 181 (21%) individuals labeled as interested in participating in the selfBACK trial. Notably, the cohort labeled as interested differed from their uninterested counterparts in two key aspects: age (36-65 years: 116/181, 64.1% vs 347/662, 52.4%; $P=.003$) and smoking status (smokers: 22/181, 12.5% vs 174/662, 26.6%; $P<.001$). Those aged 36-65 years had higher odds of being labeled as interested compared to individuals aged 18-35 years (odds ratio [OR] 0.43, 95% CI 0.26-0.71) and those 65 years or older (OR 0.77, 95% CI 0.53-1.15). Nevertheless, age accounted for only a modest proportion of variance ($R^2=0.014$). Smokers demonstrated lower odds of being labeled as interested (OR 0.39, 95% CI 0.24-0.64), with smoking status explaining a similarly small proportion of variance ($R^2=0.019$). Collectively, age and smoking status accounted for 3.3% of the variance.

Conclusions: Our investigation revealed that 181 (21%) individuals with LBP invited to participate in the mHealth solution trial for self-management expressed interest. Generally, the characteristics of those labeled as interested and uninterested were comparable. Of note, patients aged 36-65 years had a higher frequency of being labeled as interested compared to their younger and older counterparts.

KEYWORDS

low back pain; mHealth solutions; mobile health; characteristics; patient interest; transferability; representativeness

Introduction

Digital health interventions delivered with smartphones (mobile health [mHealth] solutions) are accessible to most patients across age, geography, and socioeconomic status. Thus, clinicians' expectations of mHealth solutions are significant, and the availability of new solutions on the commercial market every day also indicates a strong general interest in using mHealth solutions [1,2]. Nevertheless, many mHealth solutions have limited download rates, and if downloaded, the use can be scarce [3,4]. This discrepancy may indicate a need for a better understanding of potential users and their characteristics.

For patients with low back pain (LBP; not attributable to a recognizable, known specific pathology such as infections, fractures, or structural deformity), self-management support is recommended as the first line of treatment [5-8]. This may involve empowering patients to know when to consult for diagnostic assessment, symptom relief, or advice [9]. Digitally supported self-management may be delivered through smartphone apps or digital platforms to facilitate and enhance such self-management practices. Research indicates that the integration of such digitally supported self-management strategies, when combined with standard care, can lead to a reduction in pain-related disability [10]. Further, evidence supports that mHealth solutions designed to support self-management are accepted by patients with chronic LBP [9]. Therefore, there is a growing interest in implementing mHealth solutions designed to support self-management from both clinical and patient perspectives. However, despite the potential benefits, the level of acceptance and use of these interventions remains an area that requires further investigation.

However, studies on other patient groups using mHealth solutions report that lower age, higher education, higher income, higher BMI, and higher self-perceived health are associated with increased use [4,11]. In contrast, the cost of using these apps is a significant barrier [11].

Individuals with LBP who use mHealth solutions to self-manage may thus represent a specific subset within the general population. Therefore, this study aimed to investigate the percentage who expressed interest in participating in a trial evaluating an mHealth solution designed for self-management alongside standard care, as well as to evaluate potential distinctions between those who were labeled as expressing interest and those who were not.

Methods

Study Design

This exploratory cross-sectional study used demographic and patient-reported outcomes (PROs) from an internet-based multiuser clinical registry (SpineData) [12]. Reporting follows the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guidelines [13].

Setting

Data were collected at the Spine Centre of Southern Denmark, an outpatient hospital that performs clinical spine evaluations [12]. General practitioners or chiropractors typically refer patients to the Spine Centre, which performs a multidisciplinary assessment of its patients, with more than 10,000 new cases yearly.

Before patients are evaluated at the Spine Centre, they provide information in the local SpineData registry [14]. The registry is designed based on the biopsychosocial model of health, and information is collected across the health domains of pain, activity limitation, work participation, psychological factors, physical impairment, and contextual factors [12]. To mitigate nonresponse and missing information, SpineData uses a "waterfall" model (eg, patients in employment are not asked to respond to causes for unemployment). SpineData has an overall completion rate of 80% and approximately 60% of patients agreed to their responses being used for research [14]. The use of this registry allows for the comprehensive assessment of patients consulted at the Spine Centre and provides a rich source of data for research studies, such as the one presented in this paper.

Participants

Between February and December 2019, SpineData was used to identify eligible patients based on the following criteria: consenting to be contacted for research projects, proficiency in Danish, and experiencing LBP in the past 14 days that exceeded their leg pain in severity. Patients with previous back surgery, who were actively filing for a pension, or who were younger than 18 years were not invited. All patients matching the eligibility criteria were sent a letter of invitation to hear more about the selfBACK trial. One reminder was sent. The patients who did not respond to either invitation or reminder were labeled uninterested. The selfBACK trial investigated the effectiveness of the selfBACK digital decision support system that provided patients with LBP individually tailored digital support in an app format using three content domains: (1) physical activity, (2) education, and (3) exercise programs. The trial investigated the

additive effect of the selfBACK system in addition to usual care. Participants in this trial were recruited from primary health care such as chiropractors, physiotherapists, and general practitioners in addition to the Spine Center of Southern Denmark. Recruitment was performed in Denmark and Norway. The population within this study concerns the pool of patients seen at the Spine Center, who would have received an invitation to eligibility screening to the selfBACK trial based on their answers given in the SpineData clinical registry. In this study,

all patients who matched the preliminary eligibility criteria for the selfBACK trial were included [15].

Outcomes

The variables of interest were selected from the SpineData registry, based on the International Classification of Function core set for LBP and clinical reasoning [16]. The demographics and clinical characteristics comprised the domains of pain, activity limitation, work participation, and psychological and contextual factors (Textbox 1).

Textbox 1. Detailed description of the content and handling of included outcomes.

Sex

- Male or female

Age

- Patients were categorized into age groups ≤ 35 , 36-65, and > 65 years.

BMI

- The anthropometric variables of height and weight were used to calculate BMI (kg/m^2).

Smoker status

- Categorical variable that was dichotomized to smoker and nonsmoker strata. If a patient indicated cigarette use of any kind, they were categorized as a smoker.

Alcohol consumption

- Categorical variable that was stratified into two groups based on the consumption of more than 14 alcoholic beverages a week. The threshold was based on the recommendation of the Danish Ministry of Health [17].

Comorbidities

- This variable was based on four dichotomous variables: allergies, including medication; cancers; heart disease; and lung disease. If a patient replied yes to one of these variables, they were categorized as having comorbidities.

Current work status

- The work status variables consisted of different ways of participating in the labor market: working full- or part-time, flex job, in education, job training due to inability to maintain habitual job function, unemployed, early retirement, pensions, stay at home, and other. The variable was dichotomized to working or not by grouping patients indicating working part- or full-time, flex, and students in one group and the remainder in another group.

Multiple pain sites

- SpineData contains a freehanded pain drawing. The pain drawing was post defined into 46 anatomical regions. In this study, the regions were grouped into 9 areas: neck, shoulders, upper back, elbows, lower back, wrists/hands, hips/thighs, knees, and ankles/feet, inspired by Øverås et al [18]. Patients with two or more pain sites were considered as having multiple pain sites.

Average back pain

- The average back pain in the last 14 days was measured on a 0-10 numeric rating scale, with 10 indicating the worst imaginable pain.

S'TarT BaCK screening tool [19]

- The S'TarT Back scores categorize patients into three strata based on their risk of developing chronicity: low risk, moderate risk, and high risk of chronicity:
 - Low risk: < 3
 - Moderate risk: ≥ 4 and subscore ≤ 3
 - High risk: ≥ 4 and subscore ≥ 4

EQ-5D-5L-VAS [20]

- Numeric rating scale score spanning from 0 to 100, with 100 representing the best possible health state

Oswestry Disability Index (ODI) [21]

- The ODI is a questionnaire containing 10 items that are scored from 0 to 5. The maximum score is 50 points, which indicates that the patient is bedbound. The ODI has been found valid for patients with low back pain [22].
- To estimate the patients' functional level, the ODI Stata package was used. The ODI package allows for the imputation of data for one missing value. The missing values in one section were replaced with the average score for all sections.

Anxiety [23]

- Numeric score rating from 0 to 10, with 0 indicating no anxiety and 10 a high degree of anxiety

Social isolation [23]

- Numeric score rating from 0 to 10, with 0 indicating no loneliness and 10 a high degree of loneliness

Catastrophization (terrible pain that will never improve) [23]

- Numeric score rating from 0 to 10, with 0 indicating no catastrophization and 10 a high degree of catastrophization

Catastrophization (the pain is overwhelming) [23]

- Numeric score rating from 0 to 10, with 0 indicating no catastrophization and 10 a high degree of catastrophization

Risk of persisting pain [23]

- Numeric score rating from 0 to 10, with 0 indicating no risk of persisting pain and 10 a high risk of persisting pain

Feelings of sadness, depression, or hopelessness [23]

- Numeric score rating from 0 to 10, with 0 indicating no feelings of depression and 10 a constant presence of depression

Loss of interest or joy [23]

- Numeric score rating from 0 to 10, with 0 indicating no loss of interest or joy and 10 never feeling interest or joy

Fearing activity will damage the back [23]

- Numeric score rating from 0 to 10, with 0 indicating no fear that physical activity will damage the back and 10 completely agreeing that physical activity will damage the back

Fearing activity will increase the pain [23]

- Numeric score rating from 0 to 10, with 0 indicating completely disagreeing to avoid physical activity and 10 completely agreeing to avoid physical activity

Exposure

Patients were allocated into two groups based on their response to being invited for eligibility screening for the selfBACK trial. Those who responded positively to the invitation to be screened were labeled as interested in using the mHealth solution, whereas those who did not respond were labeled as uninterested.

Statistical Methods

The demographics and baseline characteristics of patients who were or were not labeled as interested in the digital mHealth intervention were assessed using the χ^2 test for categorical variables and 2-tailed Student *t* test for continuous variables. Baseline characteristics are reported as the proportion and percentage or mean and SD.

To assess the strength of associations between PROs and patients labeled as interested in mHealth or not, we used univariate and multivariate logistic regression analysis with an odds ratio (OR) and 95% CI. The associations were assessed in a backward selection process, and the proportion of variance explained was assessed with McFadden pseudo- R^2 statistic. Statistical analyses were performed with Stata statistical software (Release 17; StataCorp LLC). Missing information was handled using pairwise deletion. The ODI Stata package allows for data imputation for one missing value. The missing values in one section were replaced with the average score for all sections. To avoid overparameterizing the model, we aimed for a 1:10 patient-to-variable ratio.

Ethical Considerations

The Region of Southern Denmark was the data controller for this project, which is included in its records on personal data processing activities (file 21/13433). Data processing in the project was regulated by the Danish Act on Research Ethics Review of Health Research Projects section 14, subsection 2, which states that health research based solely on questionnaire surveys and registry data is exempt from the obligation to notify the committees. Following the Danish Health Care Act, we obtained approval for using hospital record data for scientific purposes from the council of the Region of Southern Denmark (file 21/25588). After merging, analyses were run on pseudonymized data, and the results presented in this manuscript do not enable the identification of single data participants. Hence, following national laws, no additional informed consent was collected and no remuneration was offered to patients.

Results

Overview

From February to the end of December 2019, 5796 patients (~80% of those invited) completed the SpineData registry before their diagnostic assessment at the Spine Centre. Of the total sample, 843 (15%) were invited to the selfBACK trial. The mean age of the cohort was 52 (SD 16.2) years, with an even distribution of sexes (male: $n=429$, 50.1%), and a mean BMI of 27.5 kg/m².

Of the 843 patients invited to the eligibility screen for the trial, 181 (21%) accepted the invitation and were stratified into the group who were labeled as interested in the mHealth solution.

Of the 21 included variables, 8 had complete responses, and none of the remaining 13 variables had more than 2.5% missing responses.

Comparison of Patients Who Were Labeled as Interested and Uninterested in an mHealth Solution

Patients labeled as interested in using the mHealth solution were aged 36-65 years ($P=.003$) and had a lower proportion of smokers ($P<.001$) compared to the patients labeled as uninterested. The remaining variables were not different between the patients labeled as interested and uninterested (Table 1).

Table 1. Baseline characteristics of patients labeled as interested in the mobile health solution compared to the uninterested patients.

Baseline characteristic ^a	Interested (n=181)	Uninterested (n=662)	P value
Female, n (%)	93 (51.3)	321 (48.5)	.49
Age (years), n (%)			.003
18-35	21 (11.6)	146 (22.1)	
36-65	116 (64.1)	347 (52.4)	
>65	44 (24.3)	169 (25.5)	
BMI (kg/m ²), mean (SD)	28.1 (5.8)	27.2 (5.0)	.05
Smokers, n (%)	22 (12.5)	174 (26.6)	<.001
<14 alcohol consumption per week, n (%)	173 (95.5)	636 (96.0)	.76
Has comorbidities, n (%)	84 (46.7)	208 (42.3)	.29
Working, n (%)	95 (52.4)	367 (55.4)	.49
Has multiple pain sites, n (%)	136 (75.1)	462 (69.7)	.24
Average back pain (score range: 0-10), mean (SD)	6.3 (2.0)	6.3 (1.9)	.91
STarT Back tool, n (%)			.34
Low risk	54 (29.8)	164 (24.7)	
Moderate risk	46 (25.5)	169 (25.5)	
High risk	81 (44.7)	329 (49.7)	
EQ-5D-5L-VAS (score range: 0-100), mean (SD)	59.0 (22.1)	55.2 (23.0)	.05
Oswestry Disability Index (score range: 0-50), mean (SD)	30.3 (15.6)	31.1 (14.9)	.50
Anxiety (score range: 0-10), mean (SD)	3.8 (3.0)	3.8 (3.1)	.99
Loneliness (score range: 0-10), mean (SD)	1.4 (2.4)	1.3 (2.2)	.67
Catastrophization (terrible pain that will never improve; score range: 0-10), mean (SD)	4.8 (2.9)	5.0 (3.0)	.48
Catastrophization (the pain is overwhelming; score range: 0-10), mean (SD)	3.7 (3.1)	4.1 (3.1)	.24
Risk of persisting pain (score range: 0-10), mean (SD)	6.8 (2.6)	6.8 (2.6)	.91
Sadness (score range: 0-10), mean (SD)	3.5 (3.1)	3.6 (3.1)	.71
Loss of interest or joy (score range: 0-10), mean (SD)	4.3 (3.3)	4.3 (3.2)	.88
Fearing activity will damage the back (score range: 0-10), mean (SD)	3.4 (2.9)	3.8 (3.2)	.08
Fearing activity will increase the pain (score range: 0-10), mean (SD)	4.8 (3.2)	4.4 (3.3)	.16

^aMissing: 8 of the 21 variables had complete responses, and none of the remaining 13 variables had more than 2.5% missing responses.

Our results suggest that patients aged 36-65 years were more likely to be labeled as interested in mHealth solutions compared to patients between 18-35 years (OR 0.43, 95% CI 0.026-0.711) and 65 years or older (OR 0.77, 95% CI 0.525-1.153) and explained a limited proportion of variance ($R^2=0.014$). Smoker (OR 0.39, 95% CI 0.244-0.636) and the association explained a limited proportion of variance ($R^2=0.019$). Combined, the

associations of age and smoking explained 3.3% of the proportion of variance.

These findings were supported by univariate regression analysis and a comparison of patients who were labeled as expressing interest in the mHealth solution to those who did not. The proportion of variance explained in the group of patients labeled as interested in mHealth solutions across the 21 selected

variables was 0.059, with age and smoking status accounting for 0.033 of the variance (Table 2).

BMI ($P=.05$), overall perception of health measured using the EQ-5D-5L-VAS score ($P=.05$), and fear that activity will damage the back ($P=.08$) were borderline significant.

Table 2. Associations to being labeled as interested and proportion of variance explained.

	Odds ratio (95% CI)	SE	Z	People invited, N	P value ($P> z $)	R^2
Age (years)				830		0.014
36-65 (reference)	—	—	—		—	
18-35	0.43 (0.02-0.71)	0.114	-3.17		.002	
>65	0.77 (0.52-1.15)	0.151	-1.48		.14	
Smoking				830		0.019
Nonsmoker (reference)	—	—	—		—	
Smoker	0.39 (0.24-0.64)	0.098	-3.72		<.001	

Discussion

Principal Results

This study aimed to explore the proportion of patients with LBP who were labeled as interested in using an mHealth solution designed to support self-management in addition to usual care and assess how these patients differed from those who were labeled as not interested. We found that 21% of the eligible patients were labeled as interested in using the mHealth solution. The groups had no statistically significant differences except that patients labeled as interested were more frequently within the 36-65 years age range and were nonsmokers.

Comparison With Prior Work

Previous evidence of the characteristics and associations of patients with LBP and their interest in mHealth solutions is limited. Contrary to Krebs and Duncan [4], we found a nonsignificant association between BMI and no association between being younger and labeled as interested in mHealth solutions. The key differences between Krebs and Duncan [4] and this study are the target populations (general population) and the type of mHealth solutions included (fitness apps or calorie trackers). Similar to our results, Philip et al [24] identified an association between higher age and increased use of mHealth solutions among patients with chronic pain. We suggest that the differences in results between Krebs and Duncan [4], Philip et al [24], and this study were due to differences between participants from the general population and patients with LBP or chronic pain. Three recent studies have assessed the characteristics and associations of users and nonusers of different mHealth apps, all using participants from the general population, but still lacking consensus. Walrave et al [25] identified no sociodemographic differences between users and nonusers of contact tracking alert apps, including the Belgian Corona alert app. A study of the general US population identified strong associations of age, gender, and education level with the use of fitness apps and calorie counters [26]. Lim et al [27] identified that female patients with higher education were more prevalent users of mHealth apps. Although this lack of consensus regarding patient interest could indicate a call for more research, it could also reflect that the interest in mHealth

solutions may be characterized by patients' preferences and perspectives on the relevance of mHealth solutions.

Strengths and Limitations

This study benefitted from several strengths. First, we had access to comprehensive information on the patients participating through the SpineData registry. Further, we benefitted from the fact that SpineData has been in routine use for several years and is frequently updated per clinician and evidence demand [14]. Thus, the PROs were collected using validated questionnaires or questions designed for the LBP population and International Classification of Function core set [14,16,28,29]. The included patients were identified using a computer algorithm, and patients were sent one invitation and one reminder invitation to be screened for eligibility. Thus, the risk of unconscious bias in the recruitment was eliminated. However, using a single data source (SpineData) also limited the variables available to investigate in the univariate model. Low education and economic status have been associated with limited use and adoption of mHealth solutions [26,30], but this information was unavailable in SpineData. Smoking is reportedly more prevalent among patients with a lower socioeconomic or sociodemographic status [31,32]. Further, the use of one registry meant we only had access to PROs, which may be affected by recall bias. The statistically significant difference between being labeled as interested in mHealth solutions by smoking status could reflect a difference in education level. Thus, education level is a parameter that could differentiate the patients labeled as interested and those labeled as uninterested in the mHealth solution, although this hypothesis remains unanswered. Patients referred to the Spine Centre usually have pain for extended periods and at a higher intensity than patients in the primary sector [33]. Thus, these patients potentially have more complex LBP issues than those with LBP who were not referred, which means that our study population may be a subgroup of the general LBP population. The terms "interested" and "uninterested" pose a challenge due to their vague nature. We recognize the distinction between demonstrating a "cursory" interest and moving toward actual participation. After extensive discussions among authors, we chose the terms "interested" and "uninterested." Despite their less-than-optimal nature, we believe these terms best suit the context where we categorize patients based on their response to an invitation, progressing

from screening to eligibility for participation in a trial evaluating an mHealth solution supporting self-management in patients with LBP. Further, some patients might be interested in testing an mHealth solution but uninterested in participating in a trial or vice versa. Further, those labeled as uninterested in the mHealth solution in this study might see advantages in mHealth solutions that they found more relevant like how to stop smoking or lose weight [34]. This study only addresses patient characteristics; however, investigating clinicians' perspectives on the use and adoption of mHealth solutions in LBP self-management will similarly inform on barriers to and facilitators of increased mHealth adoption in clinical practice. However, as the SpineData clinical registry only entails patient data, this perspective was not possible in this study. Thus, the results of this study should be interpreted with caution regarding generalizability, and future qualitative or mixed methods studies could explore patients' preferences and perceptions of the relevance of mHealth solutions. Another important area of research can be clinicians' acceptability of mHealth solutions

and the need for rigorous demonstrations of safety and efficacy to alleviate any reservations or hesitation among clinicians.

Conclusion

This study aimed to explore the characteristics of patients labeled as interested or uninterested in participating in a trial testing an mHealth solution designed to improve self-management. Our study identified that 21% (n=181) of eligible patients with LBP were labeled as interested in participating in the trial testing an mHealth solution to support self-management. Overall, the patients labeled as interested and uninterested, except for age and smoking status were similar. Interestingly, patients aged 36-65 years were more frequently labeled as interested in the mHealth solution. Thus, patients aged 36-65 years may be more interested in adopting mHealth solutions. How to increase interest in mHealth solutions among younger and older patients with LBP is an important consideration for future research and developers, especially as the findings of the selfBACK trial indicate an increased effect for older patients.

Authors' Contributions

AH, BSC, and KS conceptualized the study. AH, LFS, and NHSC acquired the data and data permissions. JAI performed the data analysis and drafted the manuscript, with support from NHSC, AH, and LFS. All authors helped draft and critically revised the manuscript for important intellectual content and approved the final version.

Abstract

Background: Home-based aerobic exercise in people with neuromuscular diseases (NMDs) has benefits compared to exercise in the hospital or a rehabilitation center because traveling is often cumbersome due to mobility limitations, and societal costs are lower. Barriers to home-based aerobic exercise include reduced possibilities for monitoring and lack of motivation. To overcome these and other barriers, we developed a mobile health app: Keep on training with ReVi (hereafter referred to as ReVi).

Objective: We aimed to determine the usability of the ReVi app.

Methods: Patients followed a 4-month, polarized, home-based aerobic exercise program on a cycle or rowing ergometer, with 2 low-intensity sessions and 1 high-intensity session per week supported by the ReVi app. The app collected training data, including heart rate and ratings of perceived exertion, provided real-time feedback on reaching target intensity zones, and enabled monitoring via an online dashboard. Physiotherapists instructed patients on how to use the ReVi app and supervised them during their training program. Patients and physiotherapists separately evaluated usability with self-developed questionnaires, including 9 questions on a 5-point Likert scale, covering the usability elements efficiency, effectiveness, and satisfaction.

Results: Twenty-nine ambulatory adult patients (n=19 women; mean age 50.4, SD 14.2 years) with 11 different slowly progressive NMDs participated. Both patients and physiotherapists (n=10) reported that the app, in terms of its efficiency, was easy to use and had a rapid learning curve. Sixteen patients (55%) experienced 1 or more technical issue(s) during the course of the exercise program. In the context of effectiveness, 23 patients (81%) indicated that the app motivated them to complete the program and that it helped them to exercise within the target intensity zones. Most patients (n=19, 70%) and physiotherapists (n=6, 60%) were satisfied with the use of the app. The median attendance rate was 88% (IQR 63%-98%), with 76% (IQR 69%-82%) of time spent within the target intensity zones. Four adverse events were reported, 3 of which were resolved without discontinuation of the exercise program.

Conclusions: The usability of the ReVi app was high, despite the technical issues that occurred. Further development of the app to resolve these issues is warranted before broader implementation into clinical practice.

Introduction

Physical fitness is an important health marker [1,2] and is strongly associated with daily life functioning [3] and independent living [4] at older age. People with neuromuscular disease (NMD) often have reduced physical fitness caused not only by the underlying disease but also by an inactive lifestyle [5-7]. Aerobic exercise is an important aspect of rehabilitation treatment for NMD, as it contributes to improved physical fitness [8]. The integration of exercise programs into everyday life was recently identified as one of the major research priorities for individuals with NMD [9].

People with NMD usually perform their aerobic exercise program in a hospital, rehabilitation center, or physiotherapy practice under the direct supervision of a physiotherapist. However, center-based exercise may be cumbersome for individuals with NMD, who are often limited in their mobility. Moreover, center-based exercise requires the availability of physiotherapy staff, whose number is often limited as many countries are reducing health care services [10,11]. This amplifies the need for alternative modes of exercise intervention delivery that maintain high quality and effectiveness [12,13].

Transferring aerobic exercise from the hospital environment to the home or community may be a beneficial way to reduce travel time and societal costs. A recently developed training guide called B-FIT is an example of a home-based aerobic exercise program specifically developed for NMD [14]. Feasibility of the B-FIT exercise program has been demonstrated for different types of NMD, and patients and physiotherapists were satisfied with its use [14]. A barrier to use B-FIT was that some patients experienced the program as insufficiently challenging. This requires attention because poor motivation has been reported as a major barrier to exercise in people with NMD [7,15]. Furthermore, physiotherapists perceived initiation of the program as time-consuming; most of the worksheets, including exercise testing results and the training schedules, needed to be filled out by hand. A more general concern regarding exercise in the home environment is the reduced possibility to monitor exercise sessions. This is particularly important for the vulnerable population of people with NMD, as it may put them at risk for under- and overtraining.

To overcome these barriers to home-based aerobic exercise for people with NMD, we developed a mobile health (mHealth) app called Keep on training with ReVi (hereafter referred to as the ReVi app). The ReVi app aims to improve patients' adherence to the B-FIT exercise program by (1) offering a structured exercise program, (2) providing insight into training progression, and (3) improving motivation through auditory encouragement. For physiotherapists, the ReVi app aims to improve their opportunities for supervision by enabling them to monitor progress and provide feedback from a distance and also to reduce the time investment to initiate the exercise program.

The primary aim of this study was to assess the usability of the ReVi app for assisting and monitoring home-based aerobic exercise according to the B-FIT training guide in people with NMD. We also evaluated the attendance rate, the time spent

within target intensity zones, and the occurrence of adverse effects.

Methods

Design

A multicenter prospective pilot study was conducted at the outpatient departments of rehabilitation medicine of 2 university hospitals and in 3 rehabilitation centers in the Netherlands. All centers were specialized in treatment of NMD. This study included 2 different cohorts; in one cohort, the ReVi app was applied as part of usual care at the Department of Rehabilitation Medicine at the Amsterdam UMC, location Amsterdam Medical Center (AMC). The other cohort consisted of patients using the ReVi app in the intervention group of an ongoing multicenter randomized controlled trial on the efficacy of a physical activity program, which combines the B-FIT aerobic exercise program and motivational interviewing coaching to improve physical fitness in people with NMD [16].

Ethical Considerations

The medical ethics review committee of the AMC waived the need for medical ethical approval for the usual care cohort, and approved the study protocol of the randomized controlled trial (NL62104.018.17). All patients provided informed consent.

Participants

The inclusion criteria applied to both cohorts were (1) diagnosis of a slowly progressive NMD, (2) age ≥ 18 years, and (3) possession of a smartphone or tablet. Exclusion criteria were (1) contraindication for being physically active, (2) inability to follow verbal or written instructions, and (3) insufficient competence in the Dutch language. In addition, patients in the randomized controlled trial had to be motivated to improve their reduced physical fitness and were excluded if they had participated in an exercise program for a period longer than 4 weeks in the past 6 months. For the purpose of this study, we included only data of patients who completed at least 12 of the 48 possible training sessions, to ensure sufficient experience with the use of the ReVi app to evaluate its usability. We aimed to include a total of 30 patients in this study.

Physiotherapists were included in the study if they supervised at least 1 patient. Physiotherapists that were already exposed to the B-FIT training guide followed a half-day training course to refresh their knowledge on the use of the B-FIT training program and learn the use of the ReVi app. Physiotherapists that were not exposed to the B-FIT training guide followed a full-day training course to learn both the B-FIT training program and the use of the app. Furthermore, they received an instruction manual with a step-by-step guide on the use of the app.

ReVi App

The ReVi app (Amsterdam UMC) was built by a company (everywhereIM BV) specialized in the development of medical apps. The app was available for iOS and Android and it was developed in the Dutch language. An expert group consisting of physiotherapists, rehabilitation physicians, exercise physiologists, patients with different types of NMD, and representatives of the Dutch Society of Muscle Diseases and of

the app builder actively participated in the development of the ReVi app. Expert group meetings were organized to discuss the aims of the app, to identify essential functionalities, and to provide feedback on so-called functional designs (on paper). The primary objective during this initial developmental phase was to create an app to assist a 16-week aerobic exercise regimen. If the study yields favorable results, the next developmental stage will be initiated to enhance the app's functionality and further explore the possibilities for offering longer-term support to home-based aerobic exercise. The data protection officer of Amsterdam UMC (location AMC) was also involved in the app's development process to ensure that personal data processing was organized in accordance with the General Data Protection Regulation (GDPR).

B-FIT Aerobic Exercise Program

The ReVi app was programmed with the B-FIT aerobic exercise program. This 16-week, polarized, home-based exercise program consisted of 2 low-intensity sessions below the anaerobic threshold (AT) and 1 high-intensity session above the AT per week. Patients visited the study center prior to the start, midway through, and after completion of the exercise program for a face-to-face meeting with their supervising physiotherapist. During each visit, an exercise test was executed. During the visits midway through and after completion of the exercise program, patients received feedback on training progress based on exercise testing results and based on data in the ReVi dashboard (see section App Description).

In the usual care cohort, target intensity zones were based on indirect assessment of the AT using ratings of perceived exertion (RPEs) during a submaximal exercise test [17]. In the randomized controlled trial cohort, target intensity zones were based on direct assessment of the AT during an exercise test through visual inspection of the gas exchange plots using the V-slope method [18]. If training based on heart rate was not feasible, for instance in patients using β -blocking agents, training was based on RPEs using the 6-20 Borg scale. Each training session consisted of several exercise intervals interspersed with recovery periods. Training sessions were performed in the home environment (eg, at home, in the gym, or at a physiotherapy practice) on a bicycle or rowing ergometer. A more detailed description of the B-FIT aerobic exercise program can be found in [Multimedia Appendix 1](#) [14].

App Description

Physiotherapists created a personal account for a web-based dashboard that was used to create and manage ReVi app accounts of patients they supervised. The dashboard could be

accessed using a desktop or laptop computer. Two-way verification using Google Authenticator (Google Inc) was required to sign in. The physiotherapists created patient accounts by sending a link to the patients' email addresses. Via this link, a password was created. Patients used the ReVi app on a mobile phone or tablet. Logging in to the ReVi app required their personal email address and password.

After signing in to the ReVi app, the home menu opened, from which 2 menus could be chosen: the Settings menu and the Training menu, which provided an overview of the program ([Figure 1](#)). Through the Settings menu the type of training could be chosen: training based on heart rate or based on Borg scale. For training based on heart rate, a Bluetooth connection with a heart rate monitor was established (in these cohorts, the device was the Polar H10; Polar Electro) and could be tested. Additionally, contact details of the physiotherapist were entered to enable patients to contact their therapists via the ReVi app.

The Training menu provided an overview of the training sessions ([Figure 2](#)). By selecting training sessions, the training protocol, including exercise intervals and recovery periods, was shown ([Figure 3](#)). During training sessions, the ReVi app guided users by illustrating their target intensity zones. In case of heart rate-based training, a heart rate chest strap was provided to the patient. The app was Bluetooth connected to the heart rate chest strap to continuously monitor heart rate ([Figure 4](#)). Patients rated their perceived exertion every final minute of the exercise interval or recovery period using the 6-20 Borg scale ([Figure 5](#)). During RPE-based training, patients rated their perceived exertion every minute. The ReVi app provided auditory feedback during training sessions. When patients trained within the target intensity zone, they were encouraged to continue. If the heart rate or Borg scale was not within the target intensity zone for at least 20 seconds, the ReVi app provided auditory instructions to increase or decrease the resistance. Directly after completion of the exercise session, an overview of the exercise results was shown ([Figure 6](#)).

Heart rate and Borg score data were saved by the ReVi app and sent to the web-based dashboard. Physiotherapists could access the training data of the patients they supervised; patients only had access to their own exercise data. The dashboard included, for each training session, a table with the percentage of time spent within the target intensity zones, the average heart rate for each exercise interval and recovery period, and the accompanying RPE ([Figure 7](#)). Additionally, a graph illustrated the actual heart rate or RPE with reference to the target intensity zones.

Figure 1. Screenshot of the ReVi app home screen.**Figure 2.** Screenshot of the exercise program overview.

Figure 3. Screenshot of the exercise session protocol; this is an overview of the intensity and duration of each exercise or recovery bout.**Figure 4.** Screenshot of the exercise session live screen; the actual achieved intensity (heart rate or rating of perceived exertion) and the target intensity zone during the exercise session are shown.

Figure 5. Screenshot of the Borg scale.

Figure 6. Screenshot of the exercise session results; the graph shows heart rate progression over time and the percentage of time spent within the target intensity zones.

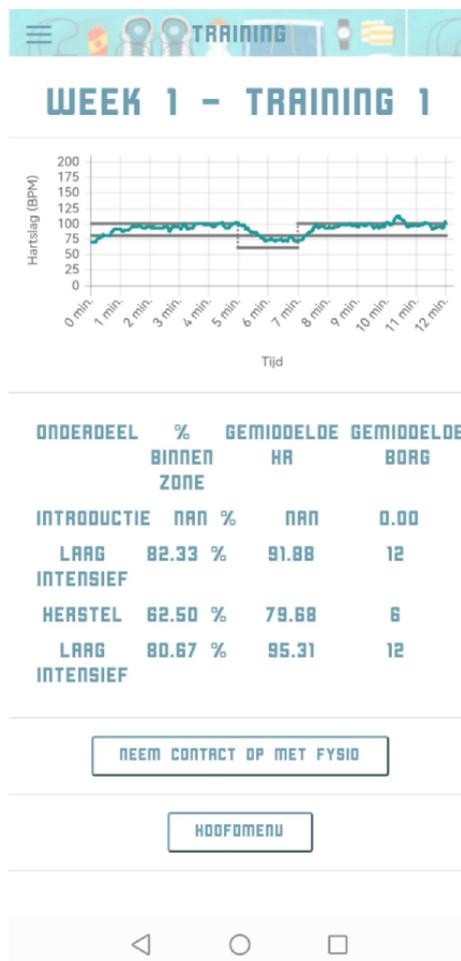

Figure 7. Screenshot of the ReVi app web-based dashboard. The percentage of time spent within the target intensity zones is presented in the table. The graph shows the heart rate during the training session (solid line), as well as the target intensity zones (grey dashed lines). The ReVi app dashboard is only available in Dutch, but for this paper the screenshot was translated to English. HR: heart rate.

Segment	% within zone	Average HR	Zone	Borg
Warming-up	99	84	70 - 93	9
High intensive	76	123	122 - 133	12
Recovery	62	94	70 - 93	10
High intensive	73	123	122 - 133	13
Recovery	45	96	70 - 93	11
High intensive	83	125	122 - 133	13
Recovery	36	98	70 - 93	11

Outcomes

ReVi App Usability

The primary outcome was the usability of the ReVi app, defined according to the International Organization for Standardization (ISO) as follows: “Usability is the extent to which a product can be used by specified users to achieve specified goals with efficiency, effectiveness and satisfaction in a specified context of use” [19]. Efficiency refers to the resources expended in relation to the accuracy and completeness with which users achieve goals (eg, ease of use, learning time, and additional effort of using the ReVi app during training sessions). Effectiveness refers to the extent to which the ReVi app has completed its goals to motivate patients and support patients to train within the targeted heart rate zones. Satisfaction assesses positive or negative attitudes toward the use of the ReVi app [20].

Self-developed questionnaires were used to assess the usability of the ReVi app among patients and physiotherapists. The questionnaires were developed by the study team, which consisted of researchers, rehabilitation physicians, and a physiotherapist. The questionnaires were reviewed by 2 patients and another physiotherapist before the final version was developed. The questionnaires contained questions pertaining to the 3 major aspects of usability: efficiency, effectiveness, and satisfaction. The usability questionnaires for patients and physiotherapists included 12 and 13 questions, respectively, of which 2 were open questions (Multimedia Appendices 2 and

3). Nine of the closed questions were scored on a 5-point Likert scale (1=strongly disagree; 2=disagree; 3=neither agree nor disagree; 4=agree; 5=strongly agree). Patients filled in the questionnaire after their last completed training session; physiotherapists did so after completion by the last patient they supervised.

Attendance Rate and Time Within Target Intensity Zones

For assessing attendance rates and the time spent within target intensity zones, we used data collected in the ReVi app dashboard. The attendance rate was defined as the percentage of followed training sessions. From the followed training sessions, we determined the percentage of time spent within target intensity zones for low- and high-intensity exercise intervals combined and separately.

Adverse Events

Adverse events related to the exercise program, such as severe muscle fatigue, joint pain, or muscle pain, were recorded. Patients were instructed to contact the physiotherapist to report adverse events. In addition, physiotherapists checked for adverse events during each patient visit.

Data Analysis

Descriptive statistics are used to present patient and physiotherapist characteristics. The data from the questions that were scored on a 5-point Likert scale were reduced by combining “agree” and “strongly agree” responses to form an “agree” category, and response options of “strongly disagree”

and “disagree” were combined to form “disagree.” Frequencies were calculated on the basis of the total number of responses to each question on the usability questionnaire and expressed as percentages. Data analysis was performed using SPSS (version 28.0; IBM Inc).

Results

Study Group

Between January 2020 and November 2021, 23 patients started their exercise program as part of the usual care cohort, of which 20 patients were included in the study. Three patients were excluded because they executed less than 12 exercise sessions. Reasons included technical problems with the ReVi app (n=1), medical issues (n=1), and a lack of motivation (n=1). Nine other

patients participating in the ongoing randomized controlled trial were also included and started between July 2021 and December 2021.

Patient characteristics are shown in [Table 1](#). Twenty-three patients were treated at the outpatient clinic of the Department of Rehabilitation of the Amsterdam UMC (location AMC), supervised by 6 physiotherapists. The other 6 patients were treated by 4 physiotherapists at Rehabilitation Center Klimmendaal (Arnhem; n=2), Basalt Rehabilitation Center (Leiden; n=2), University Medical Center Utrecht (Utrecht; n=1), and Sint Maartenskliniek (Nijmegen; n=1). Twenty-eight patients trained based on heart rate and 1 patient based on the Borg scale. Twenty-seven patients performed the exercise program using a bicycle ergometer and 2 patients used a rowing ergometer.

Table 1. Respondent profile.

Characteristics	Respondents
Patients (n=29)

^aSum score for muscle strength of the legs was calculated by adding 16 muscle groups. Each muscle group had a score between 0 and 5, and the sum score ranged from 0 to 80 [21].

Primary Outcome

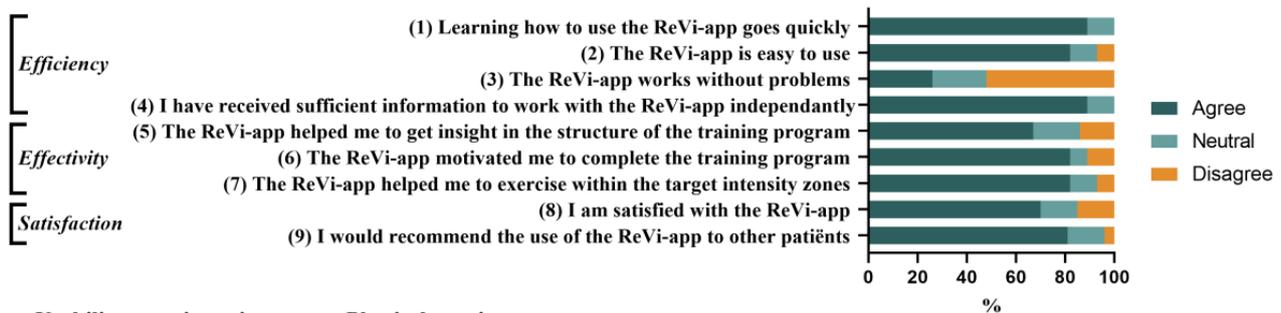

Usability

Twenty-seven patients and all 10 physiotherapists filled in and returned the usability questionnaire. Two patients did not return

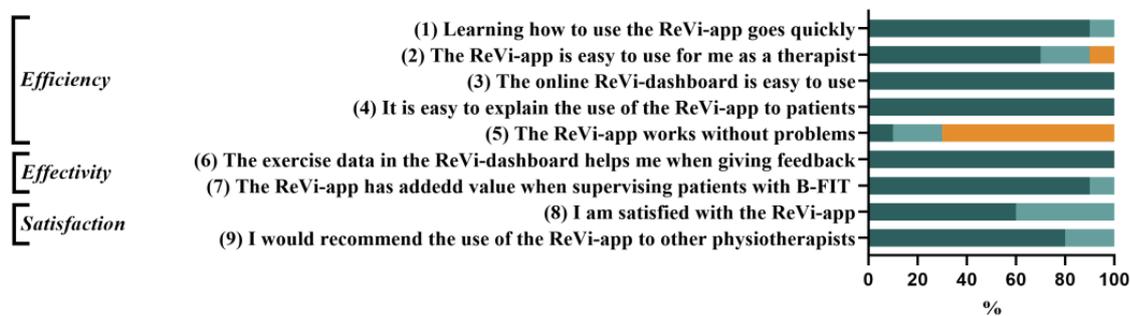

the usability questionnaire despite multiple requests. Questionnaire scores of patients and physiotherapists are presented in [Figure 8](#).

Figure 8. Statements and outcomes for the patient usability questionnaire (n=27) and the physiotherapist usability questionnaire (n=10). Scores are given on a Likert scale, ranging from 1-5 (1 = strongly disagree, 5 = strongly agree). Frequency data were reduced by combining “agree” and “strongly agree” responses to form an “agree” category, and response options of “strongly disagree” and “disagree” were combined to form “disagree”.

Usability questionnaire scores: Patients

Usability questionnaire scores: Physiotherapists

Efficiency

Twenty-four patients (89%) reported that learning how to use the ReVi app went quickly and 22 patients (81%) found that the ReVi app was easy to use. Seven patients (26%) agreed with the statement “the ReVi app works without problems.” In 16 of the total of 29 patients (55%), 1 or more technical issues occurred during the course of the ReVi app training program. The most-reported technical issues were connection problems with the heart rate monitor and a bug in the app that hindered saving of exercise data in week 11 of the exercise program.

The majority of therapists reported that the ReVi app was easy to use (n=7, 70%) and all therapists found the use of the app easy to explain to patients. Nine therapists (90%) experienced technical issues using the ReVi app.

Effectiveness

Eighteen patients (67%) reported that the ReVi app provided insight into the structure of the exercise program. Twenty-two patients (81%) agreed that the app motivated them to complete the program and that it helped them to maintain exercise within the target intensity zones.

All therapists reported that the web-based dashboard helped them to provide feedback to patients and that the ReVi app had added value for supervision. The most important benefit reported by the physiotherapists was that the ReVi app allowed insight into the number of sessions that were followed and the exercise intensity that was achieved during training sessions.

Satisfaction

Nineteen patients (70%) were satisfied with the use of the ReVi app and 22 patients (81%) would recommend the use of the ReVi app to other patients with NMD. The most important reasons to recommend its use to others were that the app provided structure, helped them to train within the target intensity zones, and motivated them to complete their training sessions. The most-reported reason for patients not to recommend the ReVi app to others was the occurrence of technical issues.

Six therapists (60%) reported that they were satisfied with the use of the ReVi app and 8 therapists (80%) would recommend the use of the app to other physiotherapists. Reasons to recommend its use to others were that it was easy to use, enabled monitoring from a distance, and provided data that could be used to give tailored feedback to patients. The most-reported reason to not recommend the ReVi app to others was the technical issues that occasionally occurred when using the app.

Secondary Outcomes

Attendance and Time Within Target Intensity Zones

Twenty of the 29 patients (69%) completed the exercise program. Reasons for discontinuation among the other 9 patients were technical problems with the ReVi app (n=4), medical issues (n=2), closing of the local gym due to COVID-19 measures (n=2), and a lack of motivation (n=1).

Figure 9 shows the attendance rate for each patient, as well as the time spent within the target intensity zones. The median

attendance rate was 88% (IQR 63%-98%). During the attended training sessions, patients spent a median of 76% (IQR 69%-82%) of the time within their target intensity zones (Figure

10). The median percentage of time spent within the low intensity zones was 85% (IQR 81%-92%), and in the high intensity zones it was 59% (IQR 45%-70%).

Figure 9. Attendance rates for individual patients ordered from most to least sessions, and the percentage of time spent within the target intensity zones during corresponding sessions. * patient trained based on Borg scale.

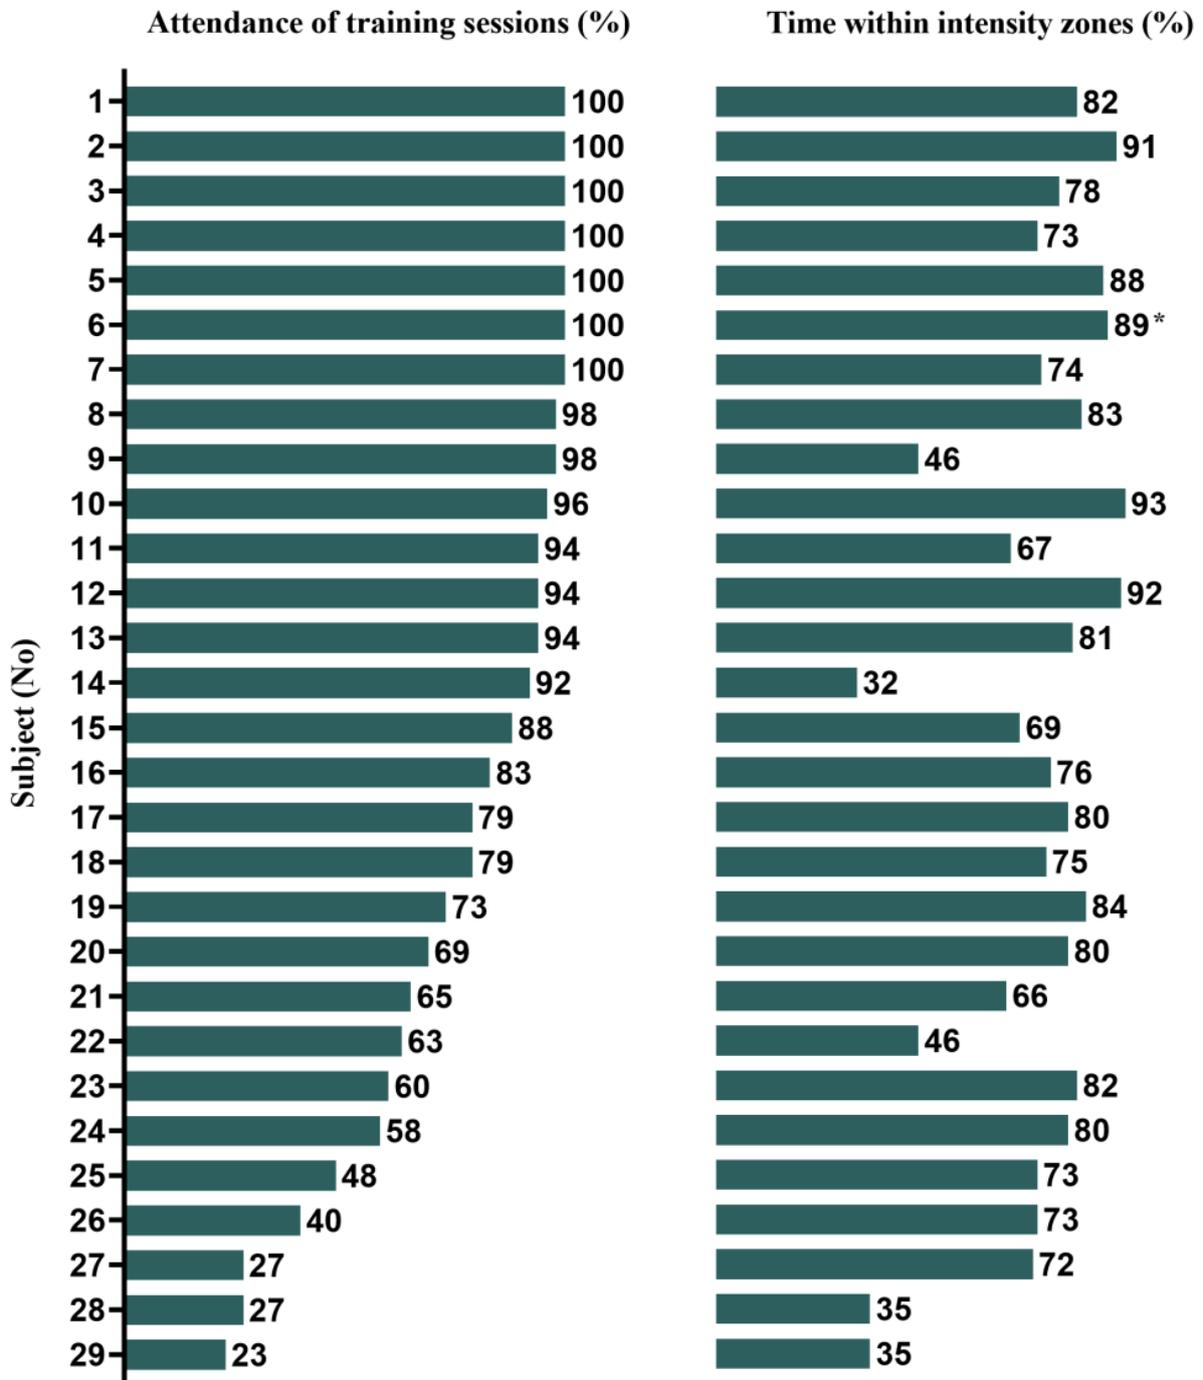

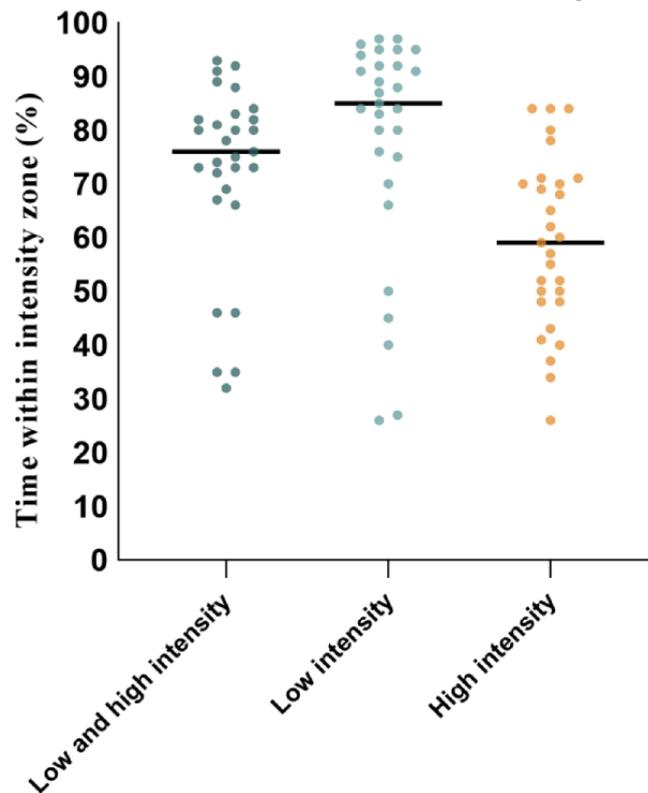

Figure 10. The percentage of time spent within the target intensity zones during A) both high and low intensity exercise intervals, B) low intensity exercise intervals and C) high intensity exercise intervals. Black lines indicate the median. Each dot represents a single patient.

Adverse Events

Four adverse events were reported: fatigue (n=2), knee joint pain (n=1), and high blood pressure during training (n=1). In the patient with high blood pressure during training, the rehabilitation physician and physiotherapist decided to terminate the exercise program. The other 3 adverse events were resolved without discontinuation of the exercise program.

Discussion

Principal Findings

This study provides insight into the usability of the ReVi app among people with NMD to support home-based aerobic exercise according to the B-FIT training program. The different components of usability, including efficiency, effectiveness, and satisfaction, were all judged as good by physiotherapists and patients, despite the occurrence of technical issues.

Patients were generally positive about the efficiency of the ReVi app due to its rapid learning curve and ease of use. Patients could independently work with the app based on the instructions that they received from their treating physiotherapist. Adequate instructions are known to be a key facilitator of patient engagement with mHealth apps [22]. With regards to its effectiveness, patients reported that the most important goals of the ReVi app were achieved: its use motivated them to complete the exercise program and helped them to exercise within their target intensity zones. These outcomes were supported by the findings that patients attended the majority of training sessions and spent most time within the target intensity zones. Patients were mostly satisfied with the use of the app,

which concurs with other studies on apps supporting home-based physical exercise programs in amyotrophic lateral sclerosis, which is a rapidly progressive type of NMD [23], and a variety of other patient populations [24-26].

Physiotherapists were positive about the efficiency of the ReVi app. This was mainly due to the rapid learning curve and its ease of use; a half- or full-day training course was required for physiotherapists to learn how to work with the app and the B-FIT training guide, depending on prior experience with B-FIT. In terms of effectiveness, physiotherapists reported that the most important goals of the ReVi app were achieved. They found the app helpful when monitoring patients during their home-based program, mainly because it enabled them to provide feedback based on exercise data. They were generally satisfied with the use of the ReVi app and would recommend the use of the app to other physiotherapists.

While efficiency, effectiveness, and user satisfaction were overall judged as positive, one of the efficiency items was clearly judged as insufficient: 55% (n=16) of the patients and 90% (n=9) of the physiotherapists experienced technical issues. Most of these issues were solved, but in all cases, this required the help of a physiotherapist, researcher, or software developer. Technical issues are known to negatively impact usability and decrease adherence and engagement with mHealth tools [22]. They often cause patients to stop their mHealth interventions, leading to high dropout rates, and they are reported as a main barrier to further implementation of mHealth or eHealth apps [22,27]. This is consistent with our finding that the most important reason for discontinuation of the exercise program was when the ReVi app did not function well. Therefore, resolving technical issues is an important concern for further

implementation of the ReVi app in clinical rehabilitation practice on a broader scale. This also underlines the importance of offering technical support when using mHealth tools such as the ReVi app [28]. Physiotherapists could play an important role in this, but that would require sufficient proficiency with mHealth. Moreover, considering the limited availability of physiotherapy personnel, it is essential for successful implementation of mHealth tools like the ReVi app to minimize technical issues and provide access to additional technical support for more complex problems.

The attendance rate, time within target intensity zones, and adverse events found in this study suggest that training in the home environment with the help of the ReVi app is a good alternative to center-based training. The attendance rate of 88% and time within target intensity zones of 76% are in line with adherence rates found in other studies evaluating aerobic exercise programs for NMD [29-37] that were mostly conducted in a hospital or rehabilitation center. Comparison of the attendance rate and time within target intensity zones between this study and past studies on exercise for NMD is hampered by incomplete or absent descriptions of adherence assessment methods in most other studies. In some studies, it is unclear if reported values are for attendance rates, the time spent within exercise zones, or training time. Moreover, some studies excluded patients who dropped out, leading to overestimated adherence. In this light, the attendance rate in our study may have been impacted by excluding patients who performed less than 12 exercise sessions and by the finding that some patients performed several training sessions without using the ReVi app. Despite these uncertainties, the attendance rate and time within target intensity zones found in our study seem to be in line with values reported in other aerobic exercise studies. The limited number of adverse events reported in this study also concurs with other studies on center-based aerobic exercise programs for NMD [32,38,39]. This further strengthens the notion that home-based aerobic exercise supported by the ReVi app may be considered a safe and feasible alternative for center-based exercise programs, which is in line with earlier research in telemonitoring of home-based exercise for amyotrophic lateral sclerosis [23].

Limitations

Patients with a positive attitude toward the use of mHealth may have been more inclined to participate in this study, causing selection bias and limiting generalizability to people with NMD and less affinity for mHealth. Also, most patients trained under supervision of a physiotherapist experienced in treating patients with NMD, which limits generalizability of our results to other health care settings, such as primary care physiotherapy practices.

Future Studies

Implementation of mHealth, such as with the ReVi app, in rehabilitation care presents some major challenges, such as the comfort of patients and therapists with the use of technology, legal and ethical considerations regarding patient monitoring and the protection of privacy rights, and integration of mHealth tools into current working protocols [40,41]. Additionally, specific application design requirements have to be considered for NMD patients who experience reduced hand functionality due to muscle weakness. These requirements may include sufficiently large buttons and input fields. As a consequence of these challenges, the scientific literature on telerehabilitation in NMD patients is still limited [42,43]. To enable the broader implementation of mHealth in clinical practice, research is warranted into other facilitators of and barriers to the implementation of mHealth specific to neuromuscular rehabilitation.

Conclusions

The usability of the ReVi app in terms of perceived efficiency, effectiveness, and user satisfaction is high, despite the occurrence of technical issues. Combined with the high attendance rate and time spent within target intensity zones and low number of adverse events, the ReVi app can be considered a promising tool to support home-based aerobic exercise in rehabilitation practice for NMD. Further development of the ReVi app to resolve technical issues is warranted before broader implementation into clinical rehabilitation practice.

Acknowledgments

We thank all participating patients and physiotherapists. This research project was funded by IPSEN Pharmaceuticals BV.

Abstract

Background: There is a great need for evidence-based antiracism interventions targeting mental health clinicians to help mitigate mental health disparities in racially and ethnically minoritized groups.

Objective: This study provides an exploratory analysis of mental health clinicians' perspectives on the acceptability of a web-based antiracism intervention.

Methods: Mental health clinicians were recruited from a single academic medical center through outreach emails. Data were collected through individual 30-minute semistructured remote video interviews with participants, then recorded, transcribed, and analyzed using content analysis.

Results: A total of 12 mental health clinicians completed the study; 10 out of 12 (83%) were female candidates. Over half (7/12, 58%) of the respondents desired more robust antiracism training in mental health care. Regarding the web-based antiracism intervention, (8/12, 67%) enjoyed the digitally delivered demo module, (7/12, 58%) of respondents suggested web-based content would be further enhanced with the addition of in-person or online group components.

Conclusions: Our results suggest a strong need for additional antiracist training for mental health clinicians. Overall, participants responded favorably to novel web-based delivery methods for an antiracism intervention. These findings provide important support for future development and pilot testing of a large-scale digitally enhanced antiracist curriculum targeting mental health clinicians.

KEYWORDS

acceptability; antiracism; clinicians; intervention; interview study; mental health; psychiatry residents; racism; social workers; web-based technology

Introduction

Racism or expressions of discrimination are often rooted in implicit bias and stigmatizing beliefs [1]. Currently, racism is known to be a key driver of mental health inequities in ethnoracially minoritized groups who may be victims of discrimination [2]. Such experiences often lead to negative mental health outcomes [2]. Current evidence suggests that Black, Indigenous, and people of color youth and adults experience highly disproportionate rates of delayed diagnosis and treatment of autism spectrum disorder, overdiagnosis of

conduct disorder, and underdiagnosis of attention-deficit/hyperactivity disorder [3], overdiagnosis of schizophrenia, overuse of antipsychotics with long-term medical consequences, and the underdiagnosis and treatment of depression [4]. Antiracism is the practice of actively opposing the effects of racism through institutional policies and individual behaviors [5]. Several recent systematic and scoping reviews on antiracism interventions in mental health professions have identified only one relevant randomized pilot study to date [5,6]. Of additional importance is that the authors found significant variability in training methodology, variability of intervention duration, and a lack of sufficient efficacy measurements to

evaluate existent antiracism interventions [5,6]. Thus, despite the strong need for evidence-based antiracism interventions targeting racial bias among mental health clinicians, such interventions remain underdeveloped and understudied in the literature. Within this context, evidence-based strategies, such as those based in cognitive-behavioral frameworks, have shown promise in addressing prejudiced thoughts, feelings, and behaviors but have yet to be applied to clinicians [4]. Notably, the delivery of tailored psychoeducational content such as this, has the potential to be greatly enhanced by digital design and delivery methods [3,7]. This is especially poignant given that web-based technologies are known to further augment interventional implementation structures with regard to both flexibility and sustainability [3,7].

Against the backdrop of a profound dearth of evidence-based antiracism interventions targeting mental health professionals, this study aims to explore aspects of the acceptability of a novel digitally delivered intervention of this sort [7]. Grounded in a strongly evidenced implementation science framework and through a dynamic and iterative process of evaluation, we explored facets of intervention acceptability regarding content, delivery, and implementation strategies [8]. Semistructured interviews were designed to elicit additional perceptions and attitudes among mental health professionals regarding gaps and opportunities in their current training on antiracism. Findings have the potential to be incorporated into future modifications of the intervention in order to optimize the feasibility and acceptability of large-scale randomized control pilot trials.

Methods

Overview

Participants were residents, fellows, and social workers specializing in mental health care. They were recruited from a single academic medical center in California through a remote method, which included outreach emails. Written, informed consent was obtained from all participants. Participants were compensated through US \$50 gift cards and water bottles. Data were collected through individual 30-minute semistructured remote video interviews with participants, which were recorded and transcribed for analysis. Semistructured interview questions were developed based on the clinical experience and literature review conducted by MOJ and TRB (Table 1).

The semistructured interview featured a presentation of a digital demo module of the cognitive behavioral therapy (CBT)-based intervention, which discussed core beliefs that may be harmful in the treatment of patients with mental health conditions. The module features real-world examples, teaches a key concept of intervention, presents examples of self-monitoring, and provides a visual outline of the engagement and reward components. Data were qualitatively analyzed using inductive coding and thematic analysis methods [9] using the Atlas.ti (Scientific Software Development GmbH) software by 2 independent coders (HA and DH). Identified codes and themes were reviewed and consolidated by the leading authors (MOJ and TRB) until consensus was achieved. The number of respondents mentioning each code or theme was reported.

Table 1. Semistructured interview questions and probes.

Domain	Questions	Follow-up probes
Sociodemographic information	<ul style="list-style-type: none"> What is your profession? Where are you in your training? 	<ul style="list-style-type: none"> How would you describe your race and gender?
Definitions and thoughts of antiracism	<ul style="list-style-type: none"> How would you define antiracism? What terms do you like to use to describe or discuss racism and antiracism? 	<ul style="list-style-type: none"> Are you comfortable talking with coworkers or supervisors about racism and antiracism?
Strengths of the current antiracism training	<ul style="list-style-type: none"> What are the strengths of your medical training thus far with regard to antiracism? 	<ul style="list-style-type: none"> What training, educational tools or courses have you benefited from in medical school or at the postgraduate level?
Weaknesses of the current antiracism training	<ul style="list-style-type: none"> What are the weaknesses of your medical training thus far with regard to antiracism? 	<ul style="list-style-type: none"> What additional support, educational tools, or resources would help elevate your clinical skills to provide equitable care to diverse populations?
Feedback on the demo module	<ul style="list-style-type: none"> How would you describe your experience going through the demo module? What format would you prefer for antiracism training (in person, online, zoom)? Would you have 10-15 minutes to dedicate to this specific type of antiracism learning? Would seeing a report of potential bias in your electronic health record make you more or less likely to complete antiracism training? Why or why not? 	<ul style="list-style-type: none"> What did you find helpful about the demo module? What would make it more helpful? How would you feel about your organization using digital means (online) in the form of self-directed modules to provide antiracism training? Would 10-15 mins, once per week, for 6 weeks seem manageable? A report of potential bias may include: <ul style="list-style-type: none"> Frequency of biased statements in notes Racial disparities in prescribing patterns

Ethical Considerations

This study was approved by the University of California, Los Angeles Institutional Review Board (IRB#22-001632-AM-00002).

Results

A total of 12 mental health clinicians (psychiatry residents, fellows, and social workers) completed the semistructured interviews. The participant characteristics included: female candidates (10/12, 83%), male candidates (2/12, 17%), and Asian (5/12, 42%), Black (2/12, 17%), Hispanic or Latinx (1/12, 8%), Middle Eastern (1/12, 8%), multiracial (1/12, 8%), White (1/12, 8%), and other (1/12, 8%) candidates.

The results of the content and thematic analysis are summarized in [Table 2](#), but major themes are highlighted as follows: the majority of participants (7/12, 58%) desired more robust antiracism training in mental health care. With regard to the demo module, the majority (8/12, 67%) enjoyed the module, (6/12, 50%) found it to be well-organized, and (11/12, 92%) felt the time commitment to be manageable. Many participants particularly enjoyed the CBT-based content (4/12, 33%), especially the daily self-reflection log (4/12, 33%). About 4 participants expressed a preference for an online self-directed structure, and 7/12 (58%) participants suggested that online content could be enhanced with an in-person or group component. Lastly, 4 participants communicated ways to improve participant engagement through the digital modality, including offering incentives, sharing personal experiences, and recording progress.

Table 2. Themes and representative quotes from semistructured interviews.

Question	Themes	Quotes
Discussions about race	<ul style="list-style-type: none"> Comfortable (5 mentions) Somewhat comfortable (2 mentions) Not very comfortable (4 mentions) 	<ul style="list-style-type: none"> I think so ... I have to admit that oftentimes in the face of authority figures, it can be challenging..., it can get tiring though, when you're one of the few faces of color, or if you're like, the only Black person in the room...
Definitions of racism and antiracism	<ul style="list-style-type: none"> Active advocacy against racism (11 mentions) Racism as all-encompassing and systemic (5 mentions) Self-awareness of antiracism (4 mentions) 	<ul style="list-style-type: none"> Antiracism, specifically, is a life-long journey, being aware of racial dynamics and disparities and power dynamics, I see it as, like, a modifiable factor.
Previous antiracism training	<ul style="list-style-type: none"> Beneficial, in-depth discussions and courses at some point (11 mentions) Limitations of training format and practicality (8 mentions) Strong training in residency (7 mentions) Minimal or no antiracism training (6 mentions) Insufficient institutional support (5) Beneficial scenario training (4 mentions) 	<ul style="list-style-type: none"> A lot of it is very theoretical; less of it is practical in the sense of, you know, in a specific situation. I feel like there's a lot of, like, resident-driven antiracism efforts ... justice, equity, diversity, and inclusion groups... Anti-racist work has been performative, ...there was too high a burden on faculty of color...
Antiracism training needs	<ul style="list-style-type: none"> More robust training and resources (7 mentions) Integration of representation and lived experiences (4 mentions) Accessible language (4 mentions) Integrate translational social sciences in curriculum (3 mentions) Increase cultural competency (2 mentions) Mitigate minority tax (2 mentions) 	<ul style="list-style-type: none"> Just hiring, you know, more faculty of color, I feel that the best ways I've learned have been when developing relationships outside of academia bubbles and being with people with lived experience. Having more, like, role-playing kind of activities might be great because for me, it's like if I'm in a situation where I have to speak up, my mind goes blank.
Digital demo module experience	<ul style="list-style-type: none"> Enjoyed digital module (8 mentions) Clear and organized web-based structure (6 mentions) Particularly liked CBT-based examples of core beliefs (4 mentions) Particularly liked online daily self-reflection logging (4 mentions) 	<ul style="list-style-type: none"> I really like the module. That's just like what happens at the hospital. It was clear and I thought the structure was very helpful and consistent while going through the four examples of core beliefs The good clinician one in particular led me to think about how there are so many ways the system rewards not thinking and not challenging biases, and I think it was nice that you provided that example.
Digital demo module time	<ul style="list-style-type: none"> Feels that 15 minutes/week of web-based intervention content for six weeks is manageable (11 mentions) 	<ul style="list-style-type: none"> Yes, I think we can definitely make that time.
Demo module digital format	<ul style="list-style-type: none"> Prefers online content with addition of in-person or group setting (7 mentions) Concerns about exclusively online, self-directed formats (5 mentions) Prefers self-directed online-only modules (4 mentions) Open to conducting over a Zoom call (3 mentions) 	<ul style="list-style-type: none"> In-person is generally always the most effective. I think we tend to have short attention spans, and it becomes just an online module you have to do. If you really want people to be an active participant and really engage with it, I don't know how good self-directed modules are ... I'm just like clicking through it.
Digital demo module improvements	<ul style="list-style-type: none"> Enhance resident participation and engagement in format (4 mentions) Include web-based incentive to track growth (2 mentions) 	<ul style="list-style-type: none"> I think that it might be helpful to allow us space to bring up our own examples, but I know that it takes a lot of vulnerability for us to sit there and reflect. If there's some sort of incentivization structure for people to check back in or record progress into, like a diary, I think that could be effective.
Potential report of EHR bias	<ul style="list-style-type: none"> Yes, it would be helpful (11 mentions) 	<ul style="list-style-type: none"> Yeah, it would overall. I think it would be cool, because in the same way that they make us look at how often we are prescribing benzos, why can't we also be explicit, you know, in terms of antiracism? Yeah, it would make me more wary. It would make me sit down and think.

Question	Themes	Quotes
Across questions	<ul style="list-style-type: none"> Minority tax (5 mentions) 	<ul style="list-style-type: none"> Everyone has the responsibility to care for, like, a language diverse community. It [shouldn't] just fall on certain individuals just because of their background. I remember there were some moments in medical school where I felt like there was too high a burden on faculty of color and also students of color.

Discussion

Overview

Using semistructured interviews with mental health professionals, our results indicate favorable acceptability of antiracist intervention content and digital delivery methods. The web-based demo module of the antiracism intervention received a high level of positive feedback, with participants finding it relevant, well-structured, and generally effective in teaching CBT principles. For example, participants enjoyed learning how to identify, react to, and consciously correct core beliefs that propagate racism in health care. Regarding acceptability, participants felt the time commitment would be feasible, especially the convenience of being able to access web-based modules for short periods of time over the course of several weeks. Online self-directed training was well-received, with a recommendation for the addition of a group, in-person, or zoom component to solidify and expand upon web-based self-directed learning. Participants also felt that this would improve engagement, especially with opportunities to share their own experiences. Such findings are in line with previous research suggesting that personalization and increased social connectedness facilitated by digital health intervention components can enhance user engagement [10].

In the context of existing literature, there is a need for targeted evidence-based antiracist strategies addressing the unique and specific needs of clinicians operating in any given health care specialty, as the needs of most mental health professionals will differ greatly from those of general health practitioners [11]. Unfortunately, most antiracism interventions to date have focused only on general health professionals, resulting in the existence of far less tailored interventions addressing a specific health care context or specialty. Furthermore, there are limited

discussions of methods for enhancing engagement in antiracism training other than mandating antiracism work [11]. Findings from this study fill this critical gap in the literature by investigating needed aspects of antiracist intervention dedicated to specialized mental health care, with the added benefit of using novel digital-based design elements promoting enhanced acceptability and participant engagement.

Limitations

Limitations include the fact that this study was conducted at a single academic center, which limits its generalizability to other institutions. However, this is a targeted approach to be applied to the study population of mental health professionals. A similar approach can be applied to other health specialty areas, using interviews targeting clinicians of interest. Such methods may further be used to tailor digital antiracism training to other clinical specialties. Another limitation is that the current study focuses on the acceptability of the intervention rather than its efficacy. Lastly, another important limitation lies in the lack of community engagement in the intervention design process, an aspect known to enhance the health equity of digital health interventions [12,13]. Future iterations will therefore aim to involve the systematic incorporation of the voices of community members served by mental health professionals.

Conclusions

Taken together, these results provide important guidelines for the implementation of a targeted intervention for mental health clinicians. They suggest favorable acceptability regarding the use of CBT principles in antiracism education and delivery in a web-based format. Such synthesized findings and insights from mental health professionals may be used to tailor and guide practical aspects of the further development and piloting of a future large-scale web-based antiracism intervention.

Abstract

Background: The enormous consequences of drugs include suicides, traffic accidents, and violence, affecting the individual, family, society, and country. Therefore, it is necessary to constantly identify and monitor the drug abuse rate among school-going youth. A geospatial dashboard is vital for the monitoring of drug abuse and related crime incidence in a decision support system.

Objective: This paper mainly focuses on developing MyAsriGeo, a geospatial drug abuse risk assessment and monitoring dashboard tailored for school students. It introduces innovative functionality, seamlessly orchestrating the assessment of drug abuse usage patterns and risks using multivariate student data.

Methods: A geospatial drug abuse dashboard for monitoring and analysis was designed and developed in this study based on agile methodology and prototyping. Using focus group and interviews, we first examined and gathered the requirements, feedback, and user approval of the MyAsriGeo dashboard. Experts and stakeholders such as the National Anti-Drugs Agency, police, the Federal Department of Town and Country Planning, school instructors, students, and researchers were among those who responded. A total of 20 specialists were involved in the requirement analysis and acceptance evaluation of the pilot and final version of the dashboard. The evaluation sought to identify various user acceptance aspects, such as ease of use and usefulness, for both the pilot and final versions, and 2 additional factors based on the Post-Study System Usability Questionnaire and Task-Technology Fit models were enlisted to assess the interface quality and dashboard sufficiency for the final version.

Results: The MyAsriGeo geospatial dashboard was designed to meet the needs of all user types, as identified through a requirement gathering process. It includes several key functions, such as a geospatial map that shows the locations of high-risk areas for drug abuse, data on drug abuse among students, tools for assessing the risk of drug abuse in different areas, demographic information, and a self-problem test. It also includes the Alcohol, Smoking, and Substance Involvement Screening Test and its risk assessment to help users understand and interpret the results of student risk. The initial prototype and final version of the dashboard were evaluated by 20 experts, which revealed a significant improvement in the ease of use ($P=.047$) and usefulness ($P=.02$) factors and showed a high acceptance mean scores for ease of use (4.2), usefulness (4.46), interface quality (4.29), and sufficiency (4.13).

Conclusions: The MyAsriGeo geospatial dashboard is useful for monitoring and analyzing drug abuse among school-going youth in Malaysia. It was developed based on the needs of various stakeholders and includes a range of functions. The dashboard was evaluated by a group of experts. Overall, the MyAsriGeo geospatial dashboard is a valuable resource for helping stakeholders understand and respond to the issue of drug abuse among youth.

geospatial; statistics; map; youth; drugs; dashboard; evaluation; drug abuse; monitoring; risk assessment

Introduction

Background

According to the United Nations Office on Drugs and Crime, over 275 million people used drugs globally in 2020, resulting in 36 million individuals with drug use disorders. From 2010, there was a 22% increase in people who use drug, with an 11% increase projected by 2030 [1]. The National Anti-Drug Agency Malaysia arrested 20,643 people addicted to drugs in 2020, showing a decrease of 20.8% from 2019. The agency provides information on awareness programs, medicine, intervention, and rehabilitation, creating hot spots for drug abuse activities. In 2020, people who use and are addicted to drugs accounted for 2% of adolescents aged between 13 and 18 years. A total of 59.4% of all people who use drugs had a secondary education, but a recent study reported that approximately 5.5% of Malaysian youths are lifetime people who use drugs, which is relatively high compared with previous findings [2,3]. To combat the increasing number of adolescent people who use drugs in Malaysia, the government has focused on implementing measures to reduce drug use [4-6]. Drug abuse severely affects individuals, families, and society [7]. Consistent monitoring of drug abuse rates among Malaysian school-going youth is essential.

The need for information and statistics about people addicted to drugs, accessibility, usage, effects, and prevention is vital for reducing drug abuse [8]. However, local communities lack effective prevention tools despite drug abuse reaching epidemic levels [4,9]. The increasing drug use among school students contributes to the spread of drug abuse epidemics [10]. To address this challenge, geospatial analytics can provide location-based tools with statistical charts to assess prevalence and risk factors associated with substance abuse, aiding stakeholders' understanding of the epidemic and promoting monitoring and prevention activities. Because of the substantial amount of assessment results that need to be compiled, it will be necessary to develop a digital system capable of managing, integrating, and synthesizing assessment data [11]. However, developing a user-friendly and effective dashboard can be a complex task that requires input from various stakeholders and careful consideration of user acceptance factors.

This paper is organized as follows. First, we provide a brief overview of the literature and related work. Next, we describe the methodology used in the study, including requirement gathering, pilot study, agile development, and data analysis. Then, we present the results of the study and discuss their implications. Finally, we conclude with suggestions for future research directions.

Related Work

A digital dashboard tracks, analyzes, and manages information to indicate key performance related to a monitored subject matter [12,13]. However, sometimes a simple design is insufficient for understanding a specific topic that requires spatial analysis instead of simple visual inspection [14,15]. A geospatial dashboard provides a solution with a web-based interactive interface that combines mapping, spatial analysis, and visualization with dashboard functions [16]. In the case of drug abuse, geographical location needs to be considered to explore the location and distribution [17]. Though several dashboards are introduced in other sectors [18-20], few dashboards are found in the drug abuse sector.

As Muhamad et al [5] reported, psychoactive drugs have become a burden on public health globally, causing social difficulties and intentional overdose fatalities [21]. The government must focus on reducing teens who use drugs, and a geospatial dashboard can help through monitoring and prevention activities. However, previous dashboards were either agency-specific or not practical. This paper reports developing a geospatial dashboard for monitoring drug or substance abuse in Malaysian schools.

Several tools are available to help monitor and manage drug abuse, each with its unique strengths (see [Multimedia Appendix 1](#)) [8,9,21-30]. One such tool is DrugTracker [9], which combines social media and geographic data to detect and monitor drug abuse in near real time. This tool can help identify emerging drug trends and monitor drug abuse hot spots. Another tool, the Drug Abuse Information System [8], is designed to improve the storage and reporting of drug abuse information in Tanzania, making it easier to manage and prevent it. The Drug Abuse Information System is particularly useful for providing detailed data and reports on drug abuse, making tracking trends and identifying at-risk populations easier.

The VISN 22 dashboard [21] is another powerful tool to help detect veterans taking high-dose opioids and monitor and control for concomitant suicide risk factors in the United States. The dashboard helps review references to high-dose opioids prescribed with psychiatric illness and suicide risk factors. The Dashboard for Substance Abuse Prevention and Control [25] is a tool that uses survey data to help monitor, evaluate, and manage strategic performance in Los Angeles. It is beneficial for its ability to provide up-to-date raw data on patient age, employment, and criminal status risk factors, helping to identify at-risk populations and prevent drug abuse. Clinical Dashboards for Addiction Treatment [26] is another tool that arranges and presents patients' data so clinicians can make informed, tailored

medical decisions. This tool is valuable for its ability to provide detailed patient data as a pilot study in a Midwestern substance use disorder treatment center, allowing clinicians to tailor treatment to individual patients.

The Drug Control Data Dashboard [27] is a tool that allows users to search topics by year, agency, drug, and, to a limited degree, geographic location, providing a machine-readable and interactive collection of drug data from many sources in the United States. This tool is particularly useful for its ability to provide a wealth of data on many specific drug topics. The opioid-related adverse drug events dashboard [28] allows hospitals to access their opioid-related adverse drug events and local benchmark data against national trends in the United States. The visual analytics dashboard [29] is another tool that presents hospital-wide electronic health record medication alerts in Philadelphia to help reduce alert fatigue and improve medication safety. Finally, the Substance Abuse InstantAtlas dashboard [30] presents data on the health impacts of alcohol and selected drugs concerning public health in Alaska.

However, there are also limitations to these tools, such as incomplete and shallow social media data, lack of risk assessment information, and concerns about design flexibility and the ability to feed up-to-date raw data. Also, they have limitations regarding the scope of data, such as only reporting data on specific substance categories or a limited patient population. It is also important to note that some of the tools discussed in our study have not undergone user acceptance testing. Acceptance testing is an essential component for evaluating the user acceptance of any tool or product. Without proper acceptance testing, it is difficult to determine whether a tool is easy to use, useful, and effective in meeting the needs of its intended audience.

MyAsriGeo, a geospatial drug abuse risk assessment and monitoring dashboard tailored for school students, addresses the shortcomings of previous related works by offering unique features specifically designed to monitor drug use in Malaysian schools. In contrast to existing tools, it overcomes limitations in data comprehensiveness, depth of analysis, and spatial relevance by providing dynamic visualizations and seamless data connectivity. The dashboard focuses on the Malaysian school context, coupled with innovative features, and ensures a more comprehensive understanding of drug use patterns. It is

validated using the Technology Acceptance Model (TAM), Post-Study System Usability Questionnaire (PSSUQ), and Task-Technology Fit (TTF) metrics. These assessments provided comprehensive insights into the ease of use, usefulness, interface quality, and sufficiency of MyAsriGeo. The process confirms that the geospatial dashboard transcends limitations, emerging as an innovative solution adept at meeting the diverse needs of users.

Overall, we provided a useful overview of different tools available for drug abuse detection and management, but it is important to carefully consider the strengths and limitations of each tool before selecting one for a specific use case.

Methods

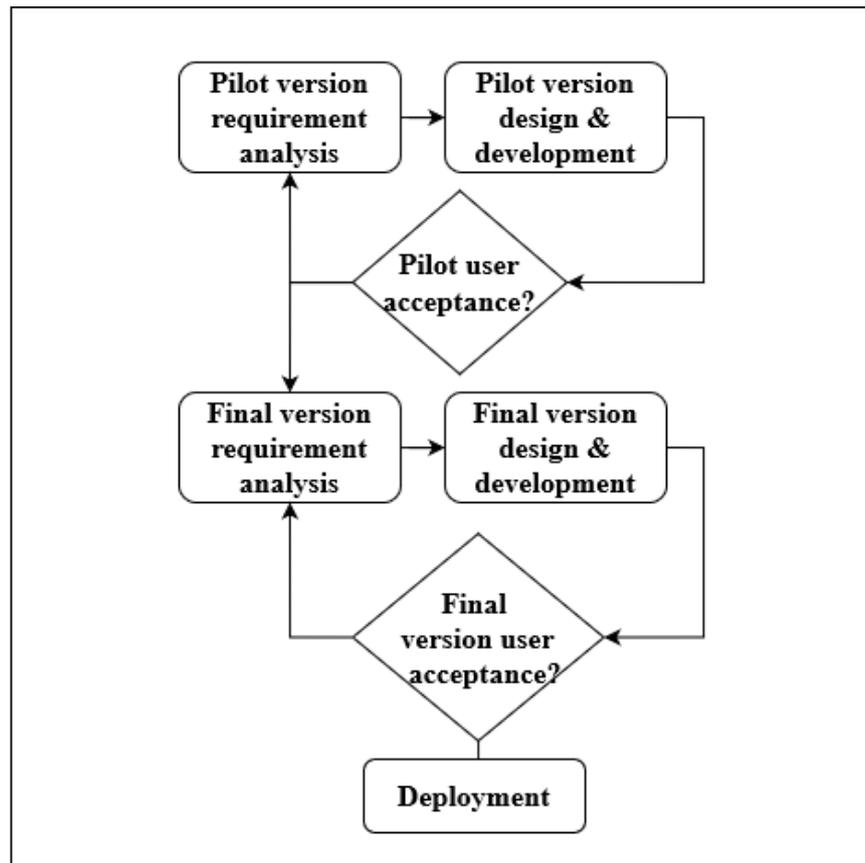

Procedures

The methodology for the MyAsriGeo dashboard was based on agile prototyping and included iterative cycles of requirement analysis, dashboard design, development, and acceptance testing [31,32]. The use of the prototyping technique in the agile development process is a common practice among various studies and is highly favored by the agile community; this technique is likely well suited to be implemented in this type of process [33].

A student survey on adolescent drug abuse in Malaysia was conducted in collaboration with 85 schools, the Ministry of Education, Universiti Kebangsaan Malaysia, and the National Anti-Drugs Agency, comprising psychiatrists, psychologists, counselors, and experienced practitioners, through the MyAsri platform of the SEGAR project. It highlights around 3000 students to understand risk factors, prevalence, and elements of trajectories among adolescents involved in polydrugs and amphetamine-type stimulants abuse at selected hot spots in Malaysia. Drug abuse surveys offer a valuable understanding of the sociobehavioral dimensions related to adolescent drug abuse activities in Malaysia.

The MyAsriGeo dashboard underwent 2 rounds of requirement analysis and evaluation, as shown in Figure 1. Experts from different fields, including medical, research, development, education, geospatial, and drug rehabilitation domains, participated in 2 rounds of focus groups and interviews and 2 rounds of user acceptance.

Figure 1. Methodology flowchart.

Ethical Considerations

With necessary approvals from relevant ethics committees (UKM PPI/111/8 JEP-2020-174(2)), parental consent was diligently obtained to ensure compliance with ethical standards. All data collected in this study were anonymized to protect the privacy and confidentiality of participants. Additionally, participants were compensated MYR RM20 (US \$4.29) for their involvement in the research.

Pilot Version Sprint

The pilot version of the MyAsriGeo geospatial drug abuse dashboard was designed and developed based on the basic requirements collected from the experts and stakeholders.

Pilot Version Requirement Analysis

The requirement analysis phase involved gathering comprehensive feedback from a diverse group of experts and stakeholders, including 20 experts spanning medical, research, development, education, geospatial, and drug rehabilitation domains. Aged between 30 and 59 years and possessing more than 5 years of experience in their respective fields, participants actively engaged in both focus group discussions and interviews, providing valuable insights. Thematic analysis was used during subsequent data analysis, systematically reviewing and coding detailed notes to identify recurring themes, patterns, and key insights, such as the selection of the contents of the results of the student surveys, demographics, notable trends in drug usage, specific challenges faced by students, and key points. This rigorous approach ensured a nuanced understanding of stakeholders' perspectives. The resulting feedback served as a

robust foundation for crafting the pilot version of the dashboard, strategically incorporating basic functionality to address critical needs identified in this collaborative and insightful process.

Pilot Version Design and Development

Based on the thematic analysis, the pilot version consisted of 3 pages, with no authentication or authorization system. The first page of the pilot version presented a basic view of the map, displaying the locations of schools without providing detailed summaries of key points. This page was designed to provide users with a simple and clear overview of the schools' locations. The second and third pages of the pilot version were used to display the student survey results and the drug and substance abuse in the form of charts. These charts provided an overview of the prevalence of drug abuse among students, the types of drugs used, and other related information. The charts were designed to be visually appealing and easily interpreted, giving users a clear understanding of the survey results.

Pilot Version User Acceptance

The first TAM questionnaire was conducted for the 20 experts and stakeholders to evaluate the pilot version's user acceptance such as ease of use and usefulness, and to identify areas for improvement. TAM is a theoretical framework used to predict how users will adopt and use technology. TAM suggests that usefulness and ease of use are important determinants of user acceptance and subsequent behavior. TAM has been widely used in various fields to analyze the adoption and usage of various technologies [22].

Initially, we crafted a survey using both a web and a paper-based questionnaire for individuals unable to access the online version. This survey aimed to explore the acceptance of the pilot version of the MyAsriGeo dashboard among the 20 experts and stakeholders, each with expertise in different specialty areas as mentioned earlier. The survey questions were designed, incorporating 5 items each for ease of use and usefulness (based on TAM). Responses were gathered using a Likert scale ranging from 1 to 5.

The feedback was used to refine the design and features of the dashboard. This process continued through multiple iterations until the MyAsriGeo dashboard was deemed effective in meeting the stakeholders' needs and goals and could effectively support their efforts to address drug abuse in their communities.

Final Version Sprint

Final Version Requirement Analysis

The feedback and acceptance results received from the experts and stakeholders who evaluated the pilot version were critical in identifying areas for improvement and ensuring that the final version of the dashboard met the needs of its intended users.

To define the end users and the new requirement for the MyAsriGeo dashboard, we conducted another focus group discussion and interviewed the experts and the stakeholders with our research team. During these sessions, we discussed the various demographic groups using the dashboard, including school-going youth, educators, and health care professionals. We also discussed the importance of including a variety of data and information on the dashboard, such as students' demography and the Mooney Problem Checklist [34]; information on drug and substance abuse; and the Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) [35].

Final Version Design and Development

Based on the thematic analysis of the second requirement analysis, the results were presented in the dashboard, which were crucial in providing a comprehensive understanding of the drug abuse problem and helping users make informed decisions. Additionally, experts were concerned about the importance of including information on economic affordability

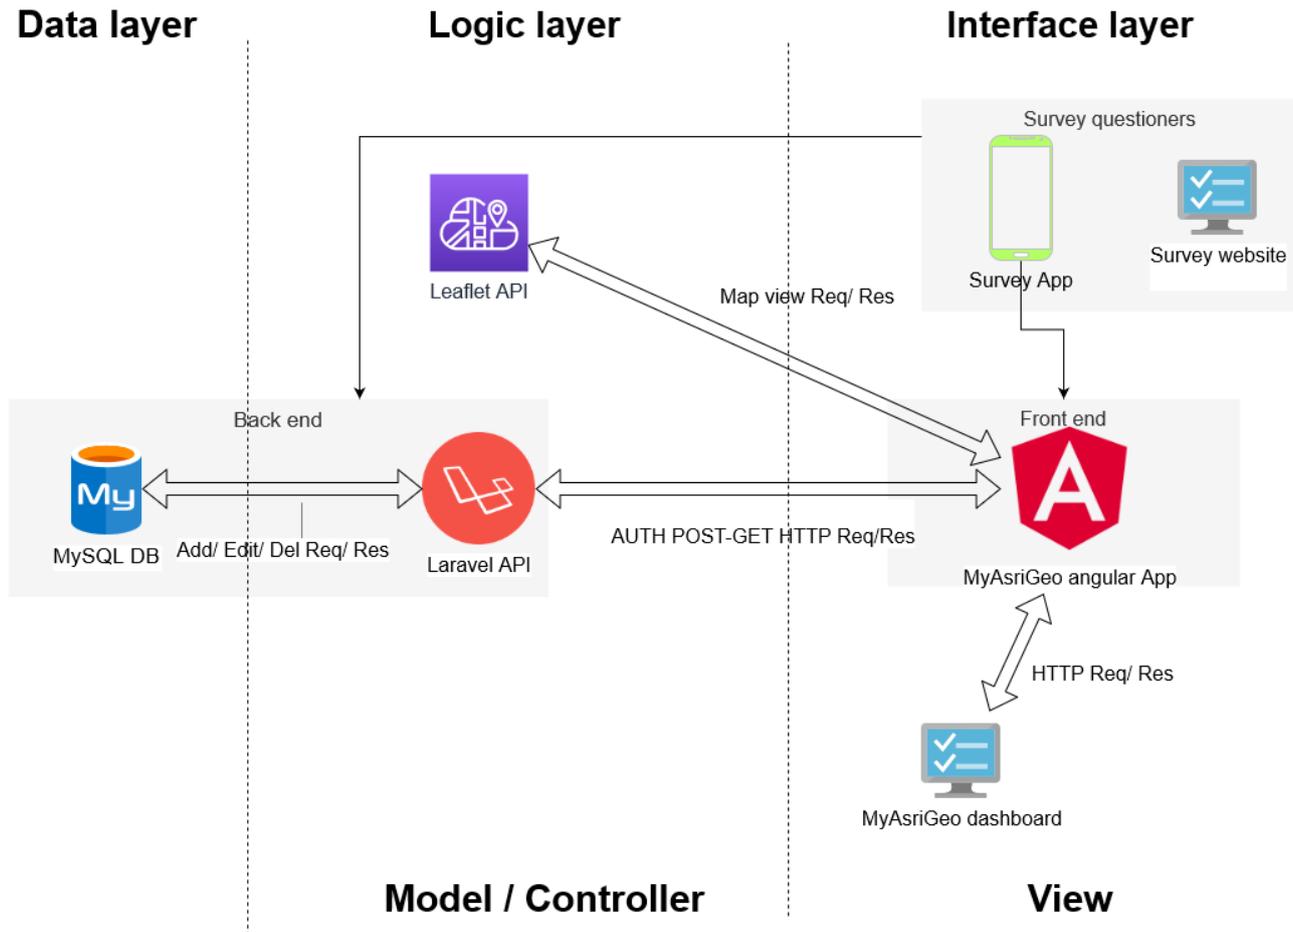

and types of drugs being used and data on the time and place of drug use. These factors are considered in designing the MyAsriGeo dashboard to ensure that it effectively addresses the issue of drug abuse among students. The dashboard design phase focused on refining the pilot version through iterative feedback cycles, testing, and refinement. The development phase involved implementing the design and building the dashboard features, with each iteration building upon the previous one.

MyAsriGeo Architecture

The MyAsriGeo geospatial dashboard was developed using the Angular framework and TypeScript for the front end, with the Leaflet application programming interface (API) used for geomapping locations (as shown in Figure 2). The dashboard includes in-app charts to display students' survey responses collected from mobile app surveys (which is not in the scope of this study), and aggregated data are stored in a MySQL database shared between survey applications and the Laravel API. The dashboard has a 3-tiered architecture, including the data, logic, and interface layers. The data layer holds geospatial and nongeographical data, and the logical layer contains models mapped to corresponding database tables in an object-oriented manner. The interface layer interacts directly with the client, communicating every client interaction with the logical layer containing the Leaflet API and Laravel API.

In crafting the MyAsriGeo architecture, our intentional choice to develop it as a web system is grounded in a forward-thinking approach, prioritizing future collaboration and sustainability. The incorporation of an API serves a dual purpose—facilitating seamless integration with external partners for potential collaborations and ensuring adaptability for future initiatives. The use of free services is pivotal for the project's sustainability, providing scalability and maintenance without imposing significant financial constraints. Furthermore, MyAsriGeo's tailored design specifically caters to the unique needs of drug abuse risk assessment for educational contexts, distinguishing it from other solutions. This strategic architectural approach positions MyAsriGeo as a versatile and enduring solution, adept at meeting the evolving demands of current and prospective stakeholders within the targeted field.

Figure 2. Architecture design of MyAsriGeo. API: application programming interface; DB: database.

Final Version User Acceptance

Finally, the second Acceptance questionnaire was conducted to evaluate the final version of the dashboard; 2 additional factors added based on the PSSUQ and TTF models were enlisted to assess the interface quality and dashboard sufficiency for the final version by end-users and stakeholders. PSSUQ is a widely used measure of the usability of a system [24], while TTF measures the extent to which technology helps users perform their tasks effectively and efficiently [23].

Similar to the pilot version, we initiated the user acceptance for the final version of MyAsriGeo with the aforementioned experts. The survey questions were designed incorporating 5 items each for ease of use and usefulness (based on TAM), 4 items for interface quality (from PSSUQ), and 4 items for sufficiency (from TTF). Responses were gathered using a Likert scale ranging from 1 to 5. Subsequently, we presented the finalized dashboard to the aforementioned 20 experts and stakeholders. They were instructed to interact with and test the dashboard. After this hands-on experience, we administered the designed questionnaire to gather their feedback and insights.

Results

Requirement Analysis

The student survey application had 4 contents: demography, Mooney Problem Checklist, information on drug and substance

abuse, and ASSIST. The first content, demography, gives an overview of the student's life, including name, age, area, school, race, gender, religion, and economic status. The second content, the Mooney Problem Checklist [34], helps adolescents and adults to express personal difficulties, which is useful in enhancing teachers' understanding of pupils and preparing children for counseling interviews. The topics of the checklist vary according to age group, health and physical development, home and family, morals and religion, romance, gender, and marriage. The third content, information on drug and substance abuse, identifies the information regarding drug and substance use, history, occurrence use, drug source, budget for drugs, medical history, prison history, abuse friends, and drug influencers of students. Finally, a multinational group of drug abuse researchers has created the World Health Organization's ASSIST to screen for psychoactive substance use and associated problems in primary care patients [35]. ASSIST was considered the fourth content of the survey. The risk and its representation on the geospatial map are the indicators with the result of the previous survey that will give a big picture of the whole drug abuse information.

Textbox 1 outlines the components of the initial version of the dashboard, incorporating selected results from a student survey conducted. This pilot version primarily includes demographic information, providing a comprehensive overview of students' demography, encompassing details such as name, age, area, school, race, gender, religion, and economic status. Additionally,

it features information on drug and substance abuse, offering insights into students' history, occurrence of use, drug sources, budget for drugs, medical history, prison history, associations

with friends who abuse substances, and key influencers in their drug-related decisions.

Textbox 1. Contents of the results of the student survey, which were presented in the pilot version of the dashboard.

1. Demography: Demographic information of the students.
2. Information on drug and substance abuse: Identify the information regarding drug and substance use of students.

Textbox 2 expands on the content integrated into the final version of the dashboard, building upon the initial selection. Based on the results of the second round of the focus group and interviews, additional features were incorporated. In addition to demographic data and information on drug and substance abuse, the final version includes the Mooney Problem Checklist [34] and the ASSIST tool. The Mooney Problem Checklist serves as a valuable tool to explore the problems students have experienced over the years, aiding in teachers' understanding of students and facilitating counseling interviews. The ASSIST tool, designed by a multinational group of drug abuse

researchers, is used to screen for psychoactive substance use and related problems in primary care patients [35]. These enhancements contribute to a more holistic understanding of the challenges faced by students, offering decision makers a comprehensive view of effective planning and intervention strategies. The inclusion of risk indicators and their representation on a geospatial map further enhances the dashboard's capacity to provide a comprehensive picture of drug abuse patterns, enabling informed decision-making based on the survey results.

Textbox 2. Contents of the results of the student survey, which were presented in the final version of the dashboard.

1. Demography: Demographic information of the students.
2. Mooney Problem Checklist [34]: Investigate the problems that students have experienced over the years.
3. Information on drug and substance abuse: Identify the information regarding drug and substance use of students.
4. The Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) [35]: It finds out the prohibited substances used by students in the last 3 months.

After the thematic analysis of the requirement analysis from the focus group discussion and interviews, we identified the

key users for the MyAsriGeo dashboard who will use the dashboard (**Textbox 3**).

Textbox 3. The key users for the MyAsriGeo dashboard.

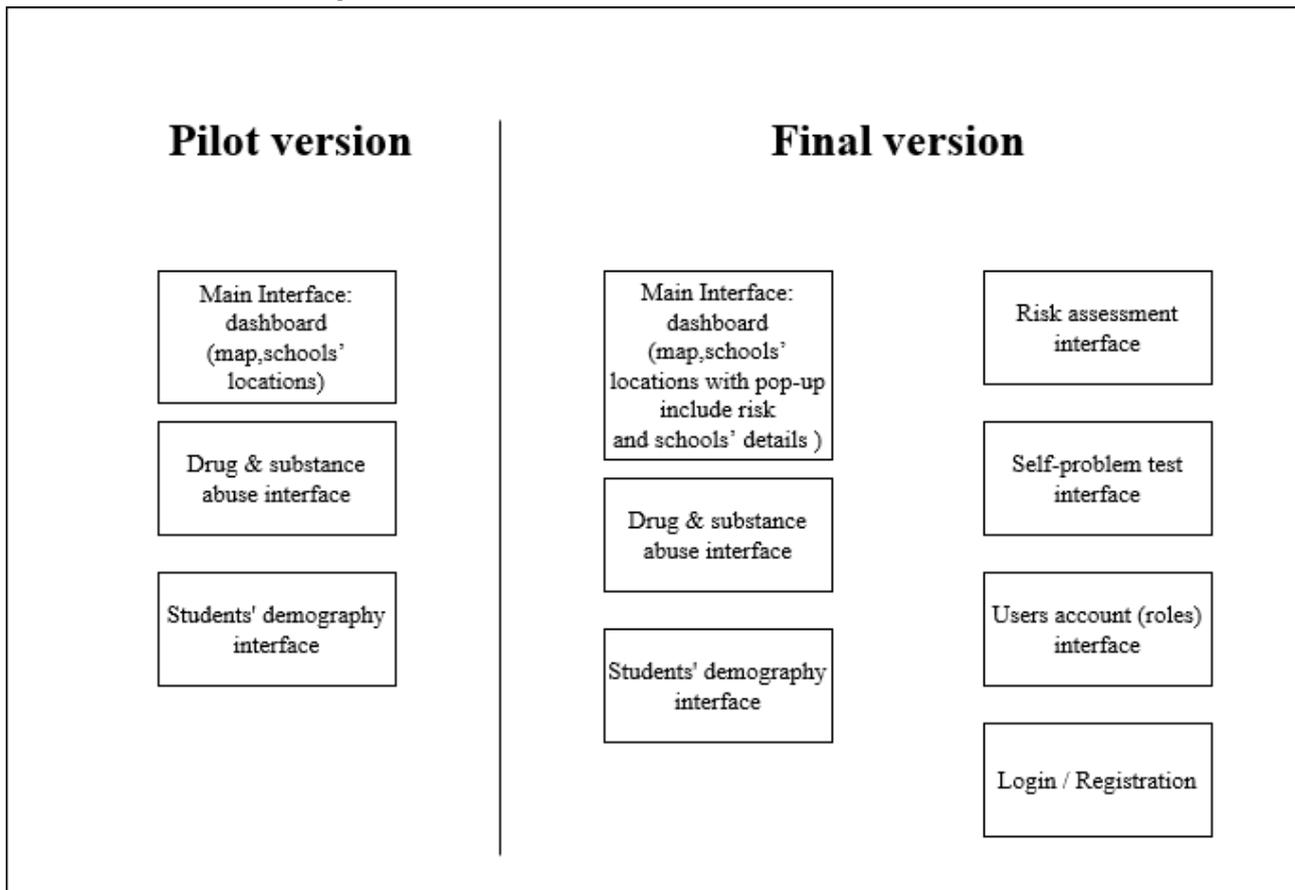

1. Researchers benefit from the ability to access and analyze data on drug abuse patterns and trends in schools, which is crucial in informing their research and studies on the subject.
2. Police: The dashboard allows them to identify hot spot schools concerning drug abuse and crime, aiding their investigations and targeted enforcement efforts.
3. National Anti-Drugs Agency: They can access detailed information on hot spot areas, schools, and nearby amenities through the dashboard to assess risk and evaluate the effectiveness of student intervention programs.
4. Community: By accessing information on drug abuse patterns and trends, they can increase their awareness and aid in prevention efforts.
5. Teachers: The dashboard provides access to information on drug abuse patterns and trends in their schools, which can increase their awareness and aid in prevention efforts.
6. Administrators: The dashboard gives them the ability to access, control, and manage confidential data, assign roles, and manage accounts, which ensures data security and compliance.
7. Decision makers: By accessing data and analyzing drug abuse patterns and trends, they can inform and support decision-making to minimize risk, increase awareness, and minimize crime rates.

MyAsriGeo Dashboard

The web application is structured with 7 distinct interfaces to effectively represent and interact with the collected data. In the pilot version (as shown in **Figure 3**), 3 primary interfaces are

featured: the dashboard main page, providing an overarching view of key information with a basic map of the hot spot schools; the drug and substance use page, focusing on details related to substance use among students; and the students page, offering insights into the student population.

Figure 3. Pilot versus final version comparison.

In the final version (as shown in Figure 3), the main page of the dashboard has been enhanced to include a dynamic map feature that provides detailed summaries of key points. This addition augments the visual representation of the data, allowing users to geospatially explore and analyze critical information. Additional interfaces are introduced to enhance the functionality of the application. The risk assessment page provides a detailed breakdown of drug abuse risks, allowing for a more nuanced understanding of specific challenges. The self-problem test page facilitates self-assessment for students, aiding in the identification of personal difficulties and contributing to a proactive approach to addressing concerns. The users page and authentication interface are incorporated to manage user access and permissions securely, ensuring the confidentiality and integrity of the data.

The synchronization of information from the main database back to the geospatial web across these interfaces strengthens the application's ability to provide a comprehensive and

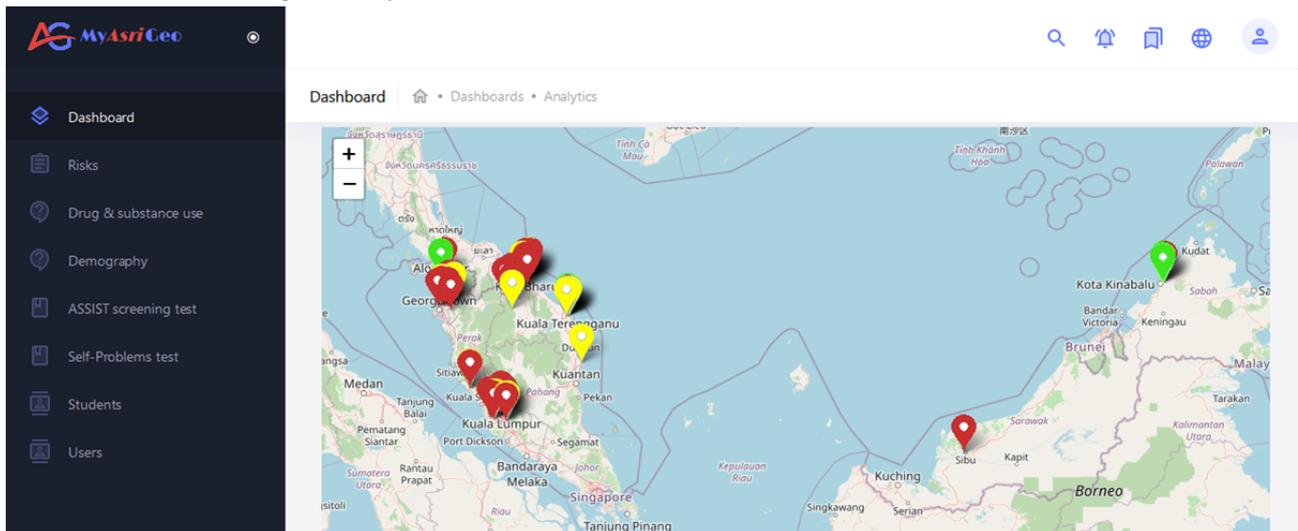

accessible representation of the survey results. Together, these interfaces empower users with the tools they need to analyze, understand, and respond effectively to the collected data, fostering informed decision-making and intervention planning.

Main Interface: Dashboard

The MyAsriGeo dashboard has a main interface (as shown in Figure 4) with a menu bar containing 7 options for easy navigation. The interface also displays a geolocation map of hot spot schools in Malaysia with markers colored red where at least one of the students is at a high risk for drug abuse, yellow where at least one of the students is at a medium risk, or green for otherwise. The pop-up for each school provides general statistics such as school name, student count, and school risk. The interface also includes a drop-down list to filter results by drug type. The school risk equation is displayed based on equation 1:

Figure 4. The main interface design of the MyAsriGeo dashboard.

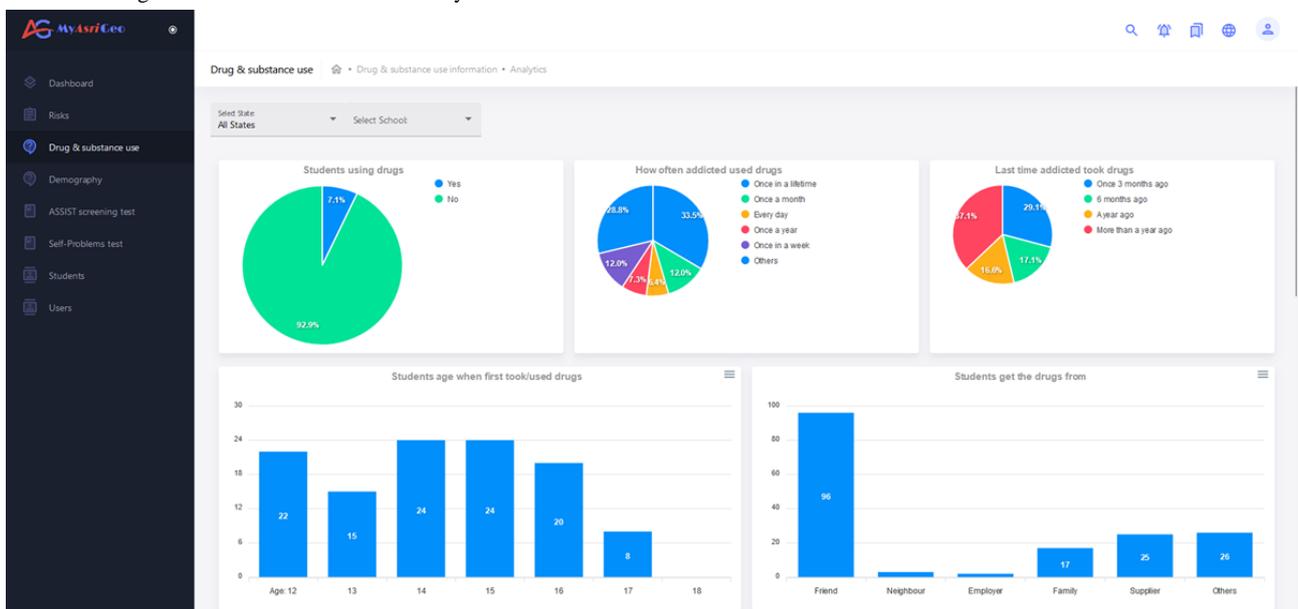

Risk Assessment Interface

The risk assessment page displays individual risks for different types of substance abuse in pie charts, which can be filtered by state and school using drop-down menus. The platform uses the ASSIST screening tool to assess the severity of substance abuse and assigns a numerical score to each question [35], which is then used to determine a low-, medium-, or high-risk level for each substance. Various factors such as family history and socioeconomic level are considered when assessing a student’s risk of substance abuse; we represent the calculation of student risk as follows [35]:

Drug and Substance Abuse Interface

The drug and substance abuse page of MyAsriGeo (as shown in Figure 5) displays charts related to drug and substance use, including students’ age, gender, medical history, parental marital status, financial status, frequency of drug use, age of first drug use, source of drugs, expenses of drug use, hospitalizations and imprisonment due to drug use, and drug-addicted friends. Users can filter the charts by state and school using drop-down lists. Pie charts and bar charts represent the data whereby the user can scroll down to view more charts.

Figure 5. The drug and substance use interface of MyAsriGeo.

Self-Problem Test Interface

This page presents the Mooney self-problem test result in bar charts with 2 state and school selection filters. Around 60 charts are presented here to cover the questions about money, communication, life, family, faith, job, school, future, and learning. The answers are categorized based on the options

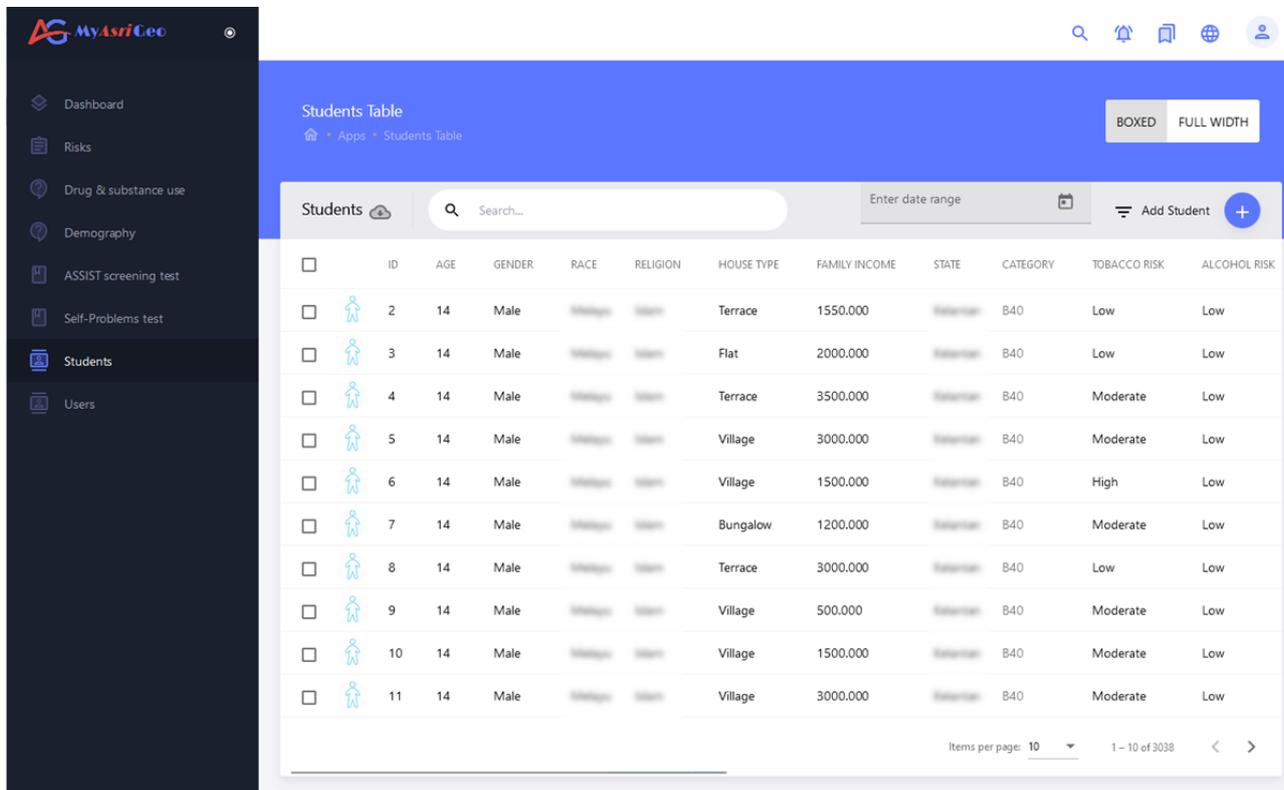

(strongly agree, agree, disagree, do not agree, and very not agree) given during survey data collection. The charts can be exported to CSV files, PNG images, and SVG vector-based images.

Students' Demography Interface

On this page (as shown in Figure 6), students' demographic information is listed in a table. Individual students' risk levels for each drug type can be viewed on this page. Each row has an edit and delete button to edit and delete the student

information. Apart from that, there is a button on the top of the table to search for any field type. The table can be sorted column-wise for each field. Ascending and descending options, including eliminating field columns, are also available. Options such as exporting tables in Excel form and adding new students are available on this page.

Figure 6. Students page of MyAsriGeo.

Users Account Interface

The MyAsriGeo system has 3 main user roles: administrator, country access user, and state access user. The roles determine the level of access to information and privileges granted to each user; the administrator has all the privileges, including managing user accounts by giving access to newly created accounts and editing and deleting accounts. The country access user can access everything except managing user accounts, while the state access user can access state-level schools, students, risks, and other information. A confirmation email is sent to new account holders to verify their email, and the administrator will review the account and assign appropriate access based on their assigned role. The users' information is listed in a table with add, edit, and delete buttons, search, and filters. The passport

token scope allows users to access information based on their role, ensuring that only authorized users can access sensitive data.

User Acceptance Results

Table 1 shows the statistical analysis results comparing the means of 2 factors (ease of use and usefulness) between the pilot version and the final version of a dashboard. For ease of use, the mean score was 3.77 in the pilot version and 4.2 in the final version. The 2-tailed *P* value of .047 indicates a statistically significant difference between the 2 means. The *T* value of -2.1 shows the direction and magnitude of the difference. The effect size, measured by partial η^2 , was 0.191, indicating a large effect size. This suggests that the changes made to the dashboard substantially impacted users' perception of its ease of use.

Table 1. Summary of the user acceptance results after the pilot prototype and the final version (N=20).

Factor	Pilot prototype, mean (SD)	Final version, mean (SD)	2-tailed <i>P</i> value	<i>T</i> value (<i>df</i>)	η^a
Ease of use	3.77 (0.93)	4.2 (0.55)	.047	-2.1 (19)	0.191
Usefulness	3.9 (1.09)	4.46 (0.43)	.02	-2.5 (19)	0.248
Interface quality	— ^a	4.29 (0.49)	—	—	—
Sufficiency	— ^a	4.13 (0.65)	—	—	—

^aNot applicable (these 2 factors were only designed for the final version evaluation).

For usefulness, the mean score was 3.9 in the pilot version and 4.46 in the final version. The 2-tailed P value of .02 indicates a statistically significant difference between the 2 means. The T value of -2.5 shows the direction and magnitude of the difference. The effect size, measured by partial η^2 , was 0.248, indicating a large effect size. This suggests that the changes made to the dashboard substantially impacted users' perception of its usefulness.

The table shows the mean and SD scores for 2 different measures of user interface quality [24] and sufficiency [23]. PSSUQ is a widely used measure of the usability of a system, while TTF measures the extent to which technology helps users perform their tasks effectively and efficiently. The mean score for interface quality on PSSUQ was 4.29, indicating that users generally found the interface to be of high quality. The SD for PSSUQ was 0.49, indicating that the ratings were relatively consistent. The mean score for sufficiency on TTF was 4.13, indicating that users generally found the system sufficient for their needs. The SD for TTF was slightly higher at 0.65, indicating that ratings were slightly more varied.

To conclude, these results suggest that the changes made to the dashboard between the pilot and final versions significantly impacted users' perceptions of its ease of use and usefulness. The effect size was large for ease of use and large for usefulness, indicating that the changes were meaningful and had a noticeable impact on users' experience with the dashboard. The scores for interface quality and sufficiency of the final version show that users are satisfied with the quality of the MyAsriGeo interface and have found its content sufficient.

Discussion

Principal Findings

Dashboards have become a popular tool in various health care systems to assist in making informed decisions about patient care by presenting a vast amount of information concisely and easily comprehensibly. Their implementation is on the rise as they enhance the quality and safety of care while reducing drug abuse [36,37]. The MyAsriGeo geospatial dashboard, developed to handle and analyze multivariate students' data regarding drug usage, is a valuable resource for stakeholders in Malaysia to understand and respond to the issue of drug abuse among youth. The development process involved continuous feedback from experts and stakeholders, ensuring that the dashboard was designed to meet the needs of all user types. The acceptance evaluation revealed that the dashboard was user-friendly and useful, indicating that it can be a valuable resource for stakeholders involved in addressing the issue of drug abuse among youth.

The high level of interface quality and sufficiency achieved by the MyAsriGeo dashboard is an important outcome, as a well-designed and well-functioning dashboard can greatly enhance the quality and usefulness of the tool [23]. By providing a geospatial map of high-risk areas, data on drug abuse among students, and risk assessment tools, the dashboard helps stakeholders understand the extent of the problem, identify areas of concern, and make informed decisions to address the issue.

The involvement of various stakeholders in developing and evaluating the MyAsriGeo dashboard is also noteworthy. By gathering the feedback and requirements of the National Anti-Drugs Agency, police, schoolteachers, students, and researchers, the dashboard was designed to meet the diverse needs of the users. It enhances the acceptance and adoption of the tool, as it is tailored to the specific needs of the stakeholders.

The evaluation results of the MyAsriGeo dashboard with experts and stakeholders suggest that the changes made to the dashboard between the initial prototype and the final version significantly impacted users' perceptions of its ease of use and usefulness [22]. Specifically, the results indicate that changes to the dashboard greatly affected users' perception of its ease of use and usefulness. The use of agile methodology and prototyping in the design and development of the dashboard allows for close collaboration with experts and stakeholders throughout the development process. This iterative approach facilitated identifying and incorporating feedback and requirements from these key stakeholders [38], which likely contributed to the dashboard's success.

The TAM, PSSUQ, and TTF were used to assess user acceptance of the dashboard. The TAM enabled the evaluation of key aspects of the dashboard's acceptance and provided insight into users' attitudes toward the dashboard. The involvement of 20 experts in evaluating the dashboard further supports the reliability and validity of the findings.

The dashboard supports enhancing decision-making abilities of decision makers, providing insights not only on which drugs are abused by students in hot spot locations but also on the impact those drugs have on the students' resulting health risk. Thus, it allows the decision maker to get precise information and use it accordingly [39].

The results of this study suggest that the MyAsriGeo dashboard, designed and developed using agile methodology and prototyping, is a promising tool for monitoring and analyzing drug abuse trends. The significant impact of the changes made to the dashboard between the initial prototype and final version on users' perceptions of its ease of use and usefulness highlights the importance of ongoing evaluation and refinement of such tools in collaboration with key stakeholders.

To ensure the effectiveness of the MyAsriGeo dashboard, continuous updates and improvements are necessary to keep up with the changing landscape of drug abuse among students. As such, future research can explore including more data sources and real-time data analysis to enhance the accuracy and effectiveness of the dashboard. It can include integrating social media data or information from drug rehabilitation centers.

The review highlighted several limitations of the tools, including incomplete and shallow social media data, lack of risk assessment information, concerns about design flexibility, and the ability to feed up-to-date raw data, and limitations regarding the scope of data they cover. Additionally, some tools have not undergone user acceptance, which is crucial in evaluating the effectiveness of any tool or product [21,25-30].

Therefore, before selecting a tool for a specific use case, it is important to consider its strengths and limitations carefully.

The review provided a useful overview of different tools available for drug abuse detection and management, but it is important to understand that no tool is perfect, and each has its own set of limitations. It is also crucial to conduct user acceptance to ensure that a tool is user-friendly, efficient, and effective in meeting the needs of its intended audience. Overall, the discussion emphasizes the need for a careful and critical evaluation of the available tools to make informed decisions about their use.

Additionally, the MyAsriGeo dashboard can be extended to cover other areas beyond drug abuse, such as cyberbullying, mental health issues, and academic performance. It can help stakeholders to identify potential risk factors that may contribute to drug abuse among students and take preventive measures.

It is important to note that the MyAsriGeo dashboard is not a stand-alone solution for addressing drug abuse among youth. A comprehensive strategy must complement it, including education, prevention, treatment, and law enforcement efforts [40]. The dashboard can provide stakeholders with the necessary information and insights to make informed decisions, but it is up to them to take action and address the issue of drug abuse among youth.

Limitations

The involvement of 20 experts in the evaluation provides some evidence for the reliability and validity of the findings; a larger

sample size would strengthen the generalizability of the results. Additionally, the study was limited to evaluating the dashboard's user acceptance, and future research could explore the impact of the dashboard on actual decision-making processes and outcomes.

Future Work

Future research could explore the effectiveness of the MyAsriGeo dashboard in detecting and monitoring drug abuse trends over time. Longitudinal studies could assess whether the dashboard provides decision makers with accurate and timely information to identify and respond to emerging drug abuse patterns. Additionally, future work could investigate the potential for the dashboard to be adapted and implemented in different contexts, such as other regions or countries, to assess its scalability and generalizability. Finally, integrating additional data sources, such as social media, could enhance the dashboard's ability to provide decision makers with a comprehensive view of drug abuse trends.

Conclusions

The geospatial drug abuse dashboard used in this study was developed and evaluated with the help of experts and stakeholders. The results showed that the changes made between the initial and final versions of the dashboard significantly impacted users' perceptions of its ease of use and usefulness. This study demonstrates the importance of geospatial dashboards for drug abuse monitoring and analysis among students.

Acknowledgments

This work was supported in part by the Ministry of Higher Education, Malaysia, under the Long Research Grant Scheme (LRGS/1/2019/UKM-UKM/2/7) and the Modal Insan Postdoctoral fund from the Centre for Research and Instrumentation Management, Universiti Kebangsaan Malaysia.

Authors' Contributions

AMA-A contributed to the investigation, methodology, development, and preparation of the original draft. SNHSA provided supervision, conceptualized the project, and was responsible for project administration, as well as reviewing and editing the manuscript. RI was involved in the conceptualization and administration of the project. KNAM offered supervision, project administration, and contributed to reviewing and editing the manuscript. LN took part in conceptualizing the project, preparing the original draft, reviewing and editing, as well as developing the methodology. KAZA was responsible for reviewing and editing the manuscript and contributing to the methodology. MCL contributed to the conceptualization and administration of the project. MLBT was involved in conceptualizing the project. SW contributed to conceptualization and administration of the project. ME was responsible for data curation.

Abstract

Background: Health care technology has the ability to change patient outcomes for the betterment when designed appropriately. Automation is becoming smarter and is increasingly being integrated into health care work systems.

Objective: This study focuses on investigating trust between patients and an automated cardiac risk assessment tool (CRAT) in a simulated emergency department setting.

Methods: A within-subjects experimental study was performed to investigate differences in automation modes for the CRAT: (1) no automation, (2) automation only, and (3) semiautomation. Participants were asked to enter their simulated symptoms for each scenario into the CRAT as instructed by the experimenter, and they would automatically be classified as high, medium, or low risk depending on the symptoms entered. Participants were asked to provide their trust ratings for each combination of risk classification and automation mode on a scale of 1 to 10 (1=absolutely no trust and 10=complete trust).

Results: Results from this study indicate that the participants significantly trusted the semiautomation condition more compared to the automation-only condition ($P=.002$), and they trusted the no automation condition significantly more than the automation-only condition ($P=.03$). Additionally, participants significantly trusted the CRAT more in the high-severity scenario compared to the medium-severity scenario ($P=.004$).

Conclusions: The findings from this study emphasize the importance of the human component of automation when designing automated technology in health care systems. Automation and artificially intelligent systems are becoming more prevalent in health care systems, and this work emphasizes the need to consider the human element when designing automation into care delivery.

Introduction

Delays in care can come from any number of factors that influence the health care work system, including technology and other automated computing tools that support patient care [1]. Understanding the dynamics between humans and technology, such as automated technology, allows designers to develop the appropriate equipment for completing patient care

tasks in different clinical environments. Advancements in technology (eg, artificial intelligence and smart medical devices) bring new applications in health care with the intent to improve the delivery of care [2]. New technologies that are currently being implemented in health care systems change the way hospitals maintain a patient's health record [3] and surgeons conduct surgery [4,5] and assist with patient mobility [6]. Advancements in smart health care technology have allowed health care work systems to become increasingly interconnected.

The adoption of electronic health records or electronic medical records opened communication pathways between patients and clinicians [7]. Videoconferencing capabilities have advanced the opportunities for remotely conducting appointments and inpatient communication [8]. With the increased use of technology within health care work systems, it is imperative to understand the short- and long-term effects of that technology.

One area where technology has made significant strides is with automation. Automation has been defined in many ways, but the consistent theme across the definitions is a technology completing a task for humans [9,10]. Parasuraman and Riley [10] stated as part of their definition of automation that “what is considered automation will therefore change with time.” The evolution of automation is portrayed through the types of technologies and industries integrating automation into daily workflows. However, in order for automated technology to be effectively used, it is important for the human user to trust the output of the automated system. Trust, like automation, has received many operational definitions depending on the context and field [11,12]. Development of trust in automation is a function of many factors including personality and system performance. However, humans are known to overtrust or become overreliant on automation, which has been known to cause unwanted outcomes [9]. Automation must be designed to promote trust in a way that adapts to its users’ needs while lending itself to allow for the appropriate amount of reliance [9,13]. Chiou and Lee [13] described the importance of designing adaptive and resilient automation to improve the trust dynamics between automation and its users. Automation errors occur when there are discrepancies between the amount of trust and the capabilities of the system [9].

There are several areas within the health care system that can benefit from automated technologies including high-risk environments, such as emergency medicine. Emergency medicine is a dynamic work environment, and there is a constant turnover of patients presenting with varying symptoms ranging in severity in emergency medicine. Health care providers use a triage system to prioritize arriving patients based on the severity of the diagnosis. Health conditions such as myocardial infarctions (ie, heart attacks) and cerebrovascular attacks (ie, strokes) require immediate medical intervention. A delay in care can have irrevocable effects on a patient’s health. Heart disease is a leading cause of death in the United States, and it is estimated over 800,000 people in the United States experience a heart attack every year [14]. Despite the prevalence of myocardial infarctions in the United States, the symptoms continue to be missed within emergency departments (EDs) [15]. Integrating automation into EDs capable of making an accurate assessment of a patient’s symptoms has the potential to assist one aspect of a clinician’s patient intake workflow.

Health care automation has the capability of improving clinical outcomes and hospital environments; however, for this to occur,

automation must be designed in a way that allows for seamless integration into the work environment. To improve both health care providers’ and patients’ acceptance of automated technology, automation must be designed to promote the appropriate level of trust within its users [9,13]. The first step to designing automation that promotes the appropriate level of trust is to understand which aspects of the technology enhance or detract trust in all health care providers responsible for operating or interpreting the results of automated technology (ie, physicians and nurses). While the health care providers are the primary user group when it comes to health care automation, it is vital to understand the patient’s perspective, as patients may have reservations for integrating automation into health care work systems [16]. Although health care consists of both providers and patients, there is little literature investigating the automation needs for both parties. Therefore, the objective of this study was to study the effect of automation mode on a patient’s trust in a cardiac risk assessment tool (CRAT). A secondary objective was to study the effect of the severity of symptoms on a patient’s trust in the CRAT.

Methods

Study Design

A within-subjects experimental study was performed to assess a patient’s trust in the CRAT. The CRAT was designed to have three automation modes: (1) no automation, (2) automation only, and (3) semiautomation. No automation was defined as a physician acting as the cardiac risk assessor without any technology, the automation-only condition was defined as a fully automated risk assessment tool that had no human intervention, and the semiautomation condition consisted of the risk assessment tool that was validated by the experimenter.

Participants

In total, 12 participants were recruited from undergraduate and graduate students at Oklahoma State University and the general Stillwater, Oklahoma community to participate in this study.

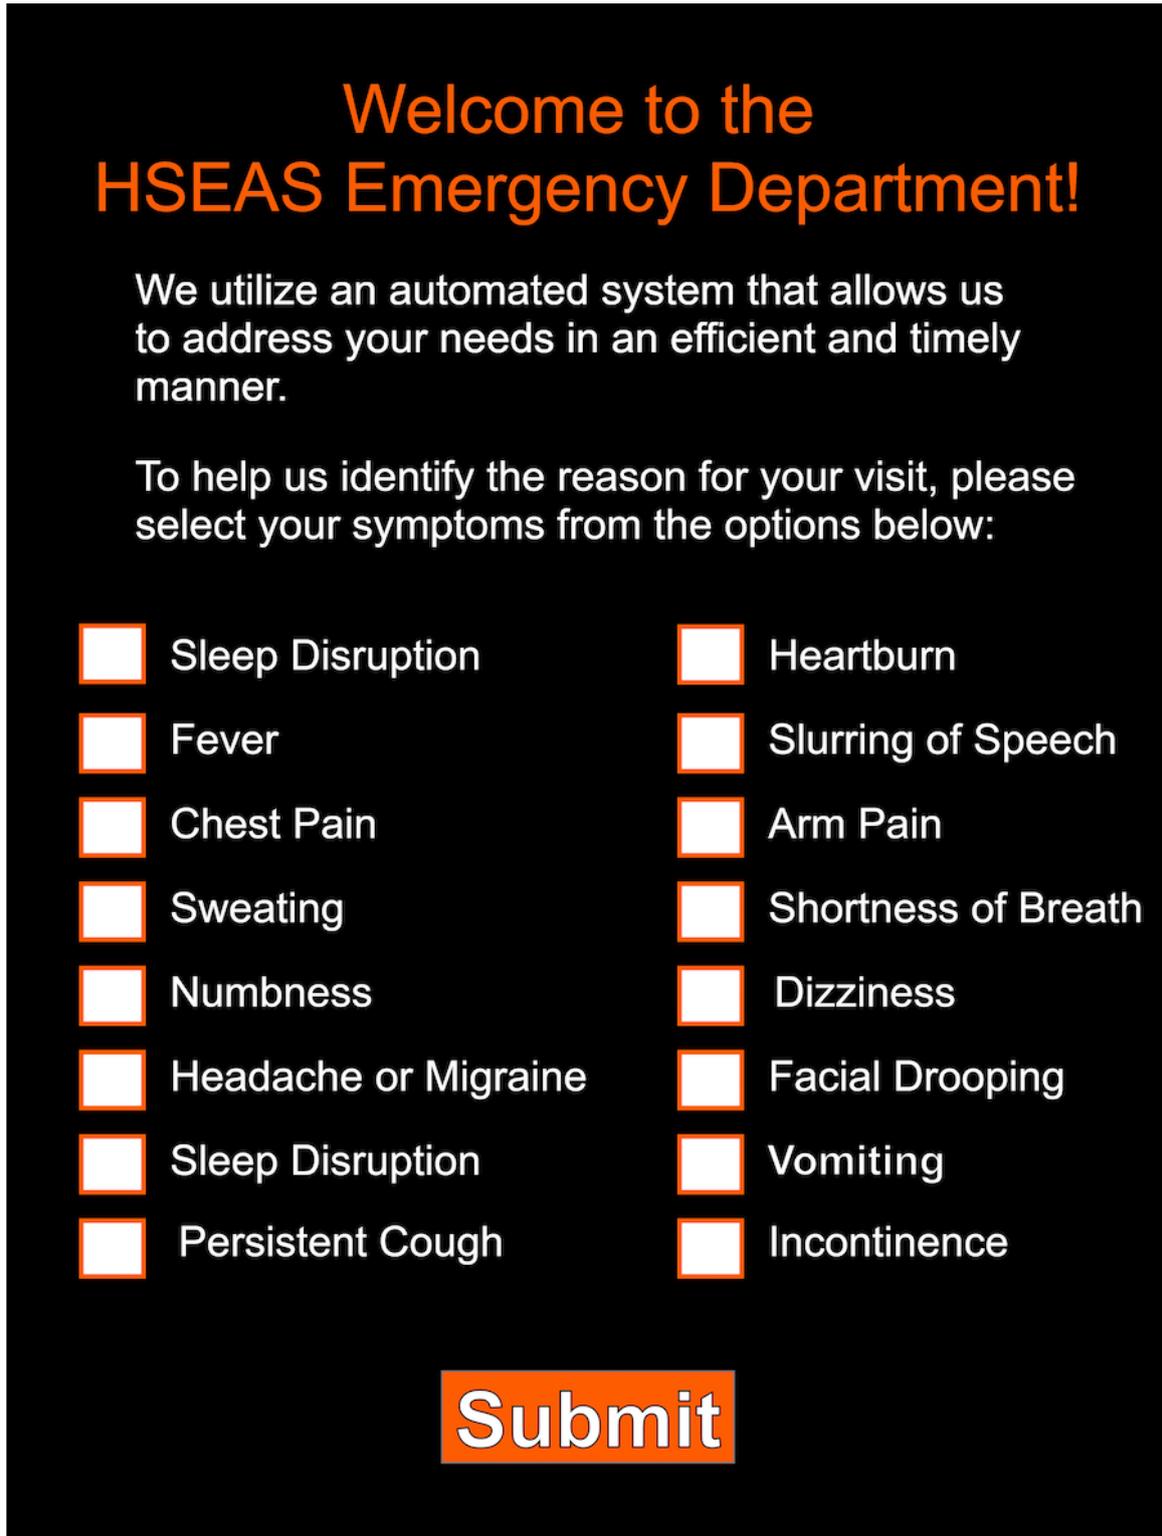

Ethical Considerations

This study received exempt status from the Oklahoma State University Institutional Review Board (IRB-22-391-STW). All participants completed the informed consent process with the experimenter, and all data were anonymized. Each participant received a \$10 Amazon gift card for their time.

Equipment and Materials

A digital application prototype was developed with Adobe XD (Adobe). The prototype displayed 16 potential health status symptoms with a touch-activated check box (Figure 1). Participants received a risk classification after checking their symptoms and selecting the submit button (Figure 2). Participants navigated the application using a Microsoft Surface tablet (Microsoft Corp).

Figure 1. Digital symptom application prototype showing 16 symptom options and checkboxes.

Submit

Figure 2. Digital symptom application prototype risk classification message for each risk classification level: (A) low, (B) medium, and (C) high risks.

Procedure

Upon arriving, the participants were welcomed to the Human-Systems Engineering Applied Statistics (HSEAS) Lab, and the informed consent process was completed with the participants. Participants were then seated at a table facing the computer monitor to complete the demographics questionnaire to collect data about the participants’ personal characteristics (eg, school status, age, and ethnicity), personal or family professional health care experience, experience as a patient or family member in an ED, the tendency to research medical information on the web, and subjective ratings on their quality of health.

Participants completed a training session on heart attack symptoms by reading a document titled “What are the warning signs of a heart attack?” [17]. This document ensured that participants understood the symptoms of a heart attack before completing the experiment. Participants were then relocated to a simulated waiting room area. For the remainder of the experimental session, the participant assumed the role of a patient arriving at the HSEAS Lab ED (ie, the simulated waiting room at the HSEAS Lab), and the experimenter performed the role of the health care provider. Each participant gave trust ratings for 3 different scenarios for each mode of information.

Automation mode (eg, automation only, no automation, or semiautomation) was presented across 3 blocks. In the automation-only condition, the participant used the tablet to independently submit their symptoms and only received their risk classification from the tablet. The semiautomation condition consisted of the patient (ie, the participant) working with the health care provider (ie, the researcher) to submit the correct symptoms and then receiving a risk classification from the tablet that was confirmed by the health care provider. Thus, the experimenter and the participant worked together to enter the symptoms. In the no automation condition, participants verbally stated their symptoms to the health care provider and were verbally provided their risk classification. The automation modes (eg, automation only, no automation, or semiautomation) were based on the trust in the automation framework presented by Chiou and Lee [13].

The order of the blocks, and thus automation mode, was counterbalanced across the participants. Participants were then classified as high risk, medium risk, or low risk based on the symptoms provided in the symptom severity scenarios (Table 1). Participants were provided the written scenario (ie, symptom severity scenario) that included the present symptoms and a subjective description of how they were feeling as a result of those symptoms. The risk levels were randomized within the block; therefore, each participant completed 9 different scenarios for each automation mode and risk level classification.

Table 1. Risk classification symptoms and subjective description.

Risk severity	Present symptoms	Lacking symptoms	Subjective description
High risk	<ul style="list-style-type: none"> Sweating Shortness of breath Severe chest pain Nausea 	<ul style="list-style-type: none"> None 	<ul style="list-style-type: none"> Feel “like an elephant is sitting on my chest”
Medium risk	<ul style="list-style-type: none"> Sweating Nausea Mild chest discomfort 	<ul style="list-style-type: none"> Severe chest pain Shortness of breath 	<ul style="list-style-type: none"> Feel “like there is a mild pain in my chest”
Low risk	<ul style="list-style-type: none"> Rapid heart rate 	<ul style="list-style-type: none"> Shortness of breath Sweating Severe chest pain Nausea 	<ul style="list-style-type: none"> Feel “like something is wrong because my heart is beating fast”

During this study, the prototype provided the correct risk classification for each symptom presentation scenario using a “Wizard of Oz” technique; thus, the automation was always correct in the risk classification. Participants were informed that there may be errors in the risk classification and that the submitted symptoms will help fine-tune the output of the CRAT. At the end of each scenario, participants were asked to provide their rating of trust in the provided risk classification on a scale of 1 to 10 (1=absolutely no trust and 10=complete trust); therefore, each participant had 1 trust rating for every combination of automation mode and risk level for a total of 9 ratings per participant. The participants’ subjective ratings of trust were collected following a similar approach presented in previous literature on measuring trust in automation via Likert scale ratings [18-20].

Data Analysis

A mixed effects linear regression model, with trust as the dependent variable, was fitted to the data, and stepwise deletion was performed until the best fit linear regression model was determined. Tukey contrasts were calculated to perform pairwise comparisons for all variables with multiple levels in the regression model. All statistical analyses were performed in

RStudio (version 2024.04.1+748; Posit Software, PBC) using the *lme4* package (version 1.1-26) [21] and the *multcomp* package (version 1.4-16) [22].

Results

A majority of participants identified as female (n=8), and the rest identified as male (n=4). The age of participants ranged between 18 and 52 (mean 24.56, SD 9.10) years. In total, 6 participants were current students pursuing either an undergraduate or graduate degree at Oklahoma State University, and 6 participants were members of the greater Stillwater community (ie, nonstudents). There was 1 participant who reported working in the medical field, and 7 of the participants reported having family members who worked in the medical field. A majority of 11 participants reported having been to a doctor in the past year with 10 participants having between 2 and 4 doctor visits in the past year. In total, 7 participants had previously visited an ED as a patient and 6 participants had visited an ED with a family member. Overall, 3 participants had visited an ED in the past year. The frequency for all trust ratings and the percentage of the total response are provided in [Table 2](#). The average trust rating overall across all conditions was 8.57 (SD 1.56).

Table 2. Summary of trust ratings by the frequency of occurrence (n=108).

Trust rating	Values, n (%)
0	— ^a
1	—
2	—
3	1 (0.9)
4	1 (0.9)
5	3 (2.8)
6	6 (5.6)
7	16 (14.8)
8	13 (12)
9	28 (25.9)
10	40 (37)

^aNot available.

The average trust ratings for automation modes and risk levels are provided in [Table 3](#). Between automation modes, the lowest trust ratings were provided for automation-only condition (mean 7.68, SD 1.42) and the highest trust ratings for the semiautomated condition (mean 9.08, SD 1.44). Overall, the

highest trust ratings were for the high risk level in the semiautomated condition (mean 9.58, SD 0.86), and the lowest trust ratings were for the medium risk in the automation-only condition (mean 6.91, SD 1.38).

Table 3. Summary of trust rating.

Automation mode and risk level	Average trust rating, mean (SD)	Overall average trust rating, mean (SD)
Automation only		
Low	8.08 (1.19)	7.86 (1.42)
Medium	6.91 (1.38)	7.86 (1.42)
High	8.58 (1.11)	7.86 (1.42)
Semiautomation		
Low	9.25 (1.01)	9.08 (1.44)
Medium	8.42 (1.93)	9.08 (1.44)
High	9.58 (0.86)	9.08 (1.44)
No automation		
Low	8.67 (1.93)	8.78 (1.53)
Medium	8.50 (1.38)	8.78 (1.53)
High	9.17 (1.07)	8.78 (1.53)

The mixed effects model showed that the random effect was nonsignificant in explaining any additional variability; however, to provide the most accurate representation of the data, the random effect was included in the final model. The results of

the final regression model are shown in [Table 4](#). The Akaike information criterion for the linear mixed effects model was 391.155. There was no interaction term included in this model.

Table 4. Linear regression table for the final linear mixed effects model.

Coefficients	Estimate (SE)	t test (df)	P value

Automation only	-1.222 (0.316)	-3.869 (92)	<.001
No automation	-0.306 (0.316)	-0.967 (92)	.34
High risk level	1.167 (0.316)	-3.693 (92)	<.001
Low risk level	0.722 (0.316)	2.286 (92)	.02
EDPatientYes ^a	-0.578 (0.351)	-1.647 (10)	.13

^aED: emergency department.

Automation mode (ie, automation only; $P<.001$) and risk level (ie, low and high risk; $P=.02$ and $P<.001$) were significantly associated with the participants' trust ratings. The Tukey pairwise comparisons for automation mode indicated that there were significant differences in the participants trust between no automation and automation only ($P=.03$) as well as automation only and semiautomation ($P=.002$).

Trust in the risk classification was also significantly lower when participants were classified as medium risk compared to a high-risk classification ($P=.004$). The Tukey pairwise comparisons showed no other significant differences between risk classification levels.

Discussion

Principal Findings

As automation becomes more integrated into health care work systems, it is important to understand the implications of automation on the patients and clinicians. Investigating patients' perceptions toward the use of automated technology, such as their trust, represents one such area of research. The purpose of

this study was to investigate patients' perceptions of an automated CRAT prototype developed to improve the triage process for patients with cardiac symptoms arriving at an ED. Findings from this study indicate that the factors significantly associated with trust were the automation mode and risk level.

Participants reported significantly higher ratings of trust in the risk classification when a human participated (ie, no automation and semiautomation conditions) in passing on the information to the patient compared to when the risk classification was only presented with the CRAT (ie, automation-only condition). These findings support the value of keeping the human, both patients and clinicians, involved when integrating health care automation into hospitals. Health care traditionally includes a close patient-provider interaction [2]; however, as technology has evolved, patient-provider interactions adapt to incorporate more technology into patient care. Unlike other industries where the roles of humans decrease with automation, health care technology requires more human involvement to properly monitor large amounts of data introduced during Health Care 4.0 [2].

There was a significant difference in trust ratings for the high-risk scenarios and the medium-risk scenarios. The high-risk scenario provided symptoms that were easily interpreted by the participants; however, the symptoms for the medium-risk scenario were more ambiguous. While the high-risk scenario incorporated all the traditional heart attack symptoms (eg, complaints of severe chest pain, shortness of breath, and nausea), the medium-risk scenario presented symptoms with multiple interpretations (eg, mild chest discomfort could be interpreted as heartburn). The difference in trust ratings between the high- and medium-risk scenarios suggests that there may be a relationship between the quality of information used by the automation to draw its conclusion and trust. Given a participant's lack of trust based on their individual differences, it is important to understand how ambiguous situations, such as the medium-risk scenario, can challenge their trust in the output [23,24]. It is possible that the participants trusted the automation more during the clear scenarios compared to the ambiguous scenario because of their own automation complacency or bias [25]. The medium-risk scenario may have been ambiguous since the participant could have interpreted the symptoms as more or less severe; therefore, it may have required more thought on whether the risk classification was correct. The ambiguity may have increased the level of doubt the participants experienced in the CRAT's output as trust is dynamic and constantly changing as different situations unfold [11,13].

All of the components of the health care work system are interconnected; therefore, this means that the performance of one work system element influences the other elements [1]. If we remove the human operator from the work system, there may be a negative effect on the care processes, which influence patient and organization outcomes. With hospitals focused on patient-centered care and patient outcomes, it is important to consider how patients perceive the technology used in care environments [8,26]. As new technology, such as artificial intelligence and automated technology, is integrated into health care work systems, it is important to appropriately design the interactions between humans and technology, especially designing for trust in automation [13].

The use of automated technology to assist in the intake and triage of patients has the potential to simultaneously support providers' work and the patient experience. The full extent of this potential is dependent on developing automation capable of providing trustworthy and accurate information to both parties. Chiou and Lee [13] described a framework where automation and the human operator were influenced by the context of repeated interactions between single human operator and one form of automation. In health care, interaction with automation may include simultaneous use effects for both patients and clinicians. Patients are primarily on the receiving end for treatments provided by automation, while clinicians are responsible for the actions that lead to automation-driven treatment outcomes. Given the clinician and patient are both involved in the treatment process, both parties experience consequences when errors occur. During one ED experience, patients may receive treatment from several devices from several clinicians, and clinicians may operate several devices while

delivering care to several different patients. Automation needs to be designed in a way to mitigate the risk of errors occurring due to the work pressures of clinical environments.

Limitations

This study emphasized the importance of humans in the development of automated technology for health care, and there are several areas of future work. The CRAT, while developed based on input from health care providers and material, was not validated as being a system that would be integrated into an ED, which means there is an opportunity to continue to develop the CRAT's viability and usability using ED provider feedback. Future work should also investigate the trust and perceptions of ED providers to understand how the use of automated technology such as the CRAT changes provider workload and care quality from their perspective as well as further investigations into patients' trust. This study focused on studying automation mode; however, individual differences, such as language, ethnicity, race, or cultural diversity, all of which may influence how a person trusts technology, may be important to study in future work. This study has a limited sample size of 12 participants, and we would like to continue this work with more participants in the future. Additionally, improving the diversity of future studies, such as expanding to a wider age range and number of participants, will provide the opportunity to gain more insights into the challenges of trusting automation.

To our knowledge, this is the first study investigating trust in a risk assessment tool such as the one studied here. The small sample size and simulated setting (ie, a simulated ED rather than a live ED) were selected to test the viability of this work while being able to remove the risk of negative impact on patient care in a live ED. Selecting heart attack risk as the diagnosis of focus for this study allowed for trust ratings to be gathered on an adverse health event, which has widely known consequences across the general populace. With that in mind, future work should investigate the trust in risk assessment tools for other adverse diagnoses (eg, neurological events). Furthermore, as automation is integrated into health care systems, designing for failures in automation (eg, misclassification of heart attack risk) should be studied in future work as well as the effect of automation failures on trust. Future investigation into the effect of automation failures is vital to understand how trust changes within a health care environment, where each care decision carries positive and negative outcomes for the patient and the provider. This work offers a foundation for trust in automation within health care to build on as future research with larger, more diverse sample sizes and greater ecologically valid environments to improve the generalizability of this work.

Conclusions

Automation and artificial intelligence are used to support clinical decision-making and ease the workload of health care providers. Using automation and artificial intelligence to support accurate and time-efficient decisions demonstrates new opportunities for advancing patient-centered care. Designing trustworthy automation can provide additional support when a clinical environment is understaffed or without access to specialty care such as rural clinics. This work represents an important first step at quantifying how patients trust automated technology

within health care. The results from this study indicate that patients trust technology most when there is a combination of human and automation interaction throughout the care process and when there is little to no ambiguity based on their symptoms. Keeping the human involved in the process enhances

the transparency of the automation with the patient, which can improve trust. Designing automation with the patient and clinician in mind is important when attempting to integrate automation into health care work environments, where errors can lead to irrevocable consequences such as patient death.

Abstract

Background: Patients with cancer who have recently been diagnosed have distinct requirements compared to cancer survivors. It is crucial to take into account their unique needs to ensure that they make informed decisions and are receptive to the care provided.

Objective: This study suggested a framework titled Effectiveness of Patient-Centered Cancer Care that considers the needs of newly diagnosed patients with cancer and related work system factors. This study investigated how work system factors influence the perceptions of patient-centered care, quality of care, and associated outcomes among newly diagnosed patients with cancer. Patient-centered care is defined in terms of workload and communication considerations, whereas the quality of care is assessed through indicators such as trust in physicians, satisfaction with care, and perceptions of technology.

Methods: This study used qualitative data collected through interviews with newly diagnosed patients with cancer (N=20) right after their first visits with their physicians. Thematic analysis was conducted to validate the 5 hypotheses of the framework, mapping the interactions among quality of care, patient-centered care, and work system factors.

Results: We found that workload and patient-centered communication impact the quality of care and that the work system elements impact the patient-centeredness (workload and communication) and the quality of care (trust in physicians, satisfaction with care, and perception of technology use).

Conclusions: Qualitatively validating the proposed Effectiveness of Patient-Centered Cancer Care framework, this study demonstrated its efficacy in elucidating the interplay of various factors. The framework holds promise for informing interventions geared toward enhancing patients' experiences during their initial visits after diagnosis. There is a pressing need for heightened attention to the organizational design, patient processes, and collaborative efforts among diverse stakeholders and providers to optimize the overall patient experience.

cancer; communication; trust; satisfaction; technology; workload; work system factors

Introduction

Background

Improving the quality of care (QOC), coordination, and quality of life are essential goals of chronic care [1]. Patient-centered care (PCC) is one of the approaches used to assure the primacy of the individual's health and life goals in their care management [1]. In recent years, the concept of having the person be the driving force in their health care decisions has evolved and gained momentum, and it is now largely considered the gold standard for health care worldwide [1,2].

The initial physician visits after a cancer diagnosis are a critical period in which patients face a range of challenges that can significantly disrupt their lives. Symptoms of the disease and the overwhelming decisions related to treatment can pose a threat to their physical, cognitive, and emotional well-being [3]. Patients often struggle to comprehend medical information and express frustration with prolonged waiting periods for prognoses and follow-ups [3]. This can lead to psychosocial concerns, including high levels of distress, emotional strain, uncertainty surrounding mortality, and disruptions to social life [3]. The cognitive and emotional burdens can be overwhelming, potentially leading to nonadherence to treatment plans [4].

PCC approaches are considered crucial for the delivery of high-quality care to patients. However, there is considerable ambiguity concerning the exact meaning of the term and the optimal method for measuring the process and outcomes of PCC [5]. Despite the concept's popularity in the past 30 years, there has been a slight argument of perspective in the literature about the definition of PCC [5]. It has been an evolving concept, originally presented by Balint [6], who described patient-centered medicine as understanding the patient as a unique human being, whereas for Levenstein et al [7], it is an approach in which the "physician enters the patient's world to see the illness through his eyes." In 1998, Delbanco et al [8] developed a self-described utopian vision for a patient-centered health care system called People Power. The relationship is supported by "computer-based guidance and communication systems." Don Berwick, a former administrator for the Centers for Medicare and Medicaid Services, has popularized the slogan Delbanco and his group adopted, "Nothing about me without me," acknowledging that PCC is not always evidence based. In his 2009 *Health Affairs* article, he emphasized that PCC relates to one's set of decisions and choices of circumstances and relationships in health care.

This concept has received increased attention since the 2001 Institute of Medicine report, "Crossing the Quality Chasm" [9], where health care quality and system-of-care improvement efforts were linked to the 6 core values: safe, effective, efficient, patient centered, timely, and equitable. Since then, myriad clinical, policy, and research initiatives have been launched to promote the study, advancement, and implementation of PCC. Research later presented 8 primary dimensions of the PCC model (respect of values, physical comfort, coordination and integration of care, information and education, access to care, involvement of family and friends, and transition and continuity) [10]. In 2015, the World Health Organization released its

framework on "people-centered health services" [11], emphasizing a focus on a system that adopts individuals', careers', families', and communities' perspectives into a trusted health care system.

PCC frameworks have proved to change the behavior of patients with cancer as they successfully engage the patient by incorporating his biopsychosocial support system into care delivery and ensuring sustainable development [12]. Involving patients with cancer meaningfully in the processes and responding to their emotions as part of PCC adoption have been linked to better health outcomes, more trust, and better engagement of the patient in their care [13]. Thus, to evaluate the effectiveness of PCC initiatives, the cognitive perception of patients with cancer needs to be studied in relation to their behavior within the care settings (eg, trust, satisfaction, anxiety, and engagement). On the other hand, achieving high-quality care is a complex pursuit in any setting, especially for cancer care. Improving the patient journey requires an integrated system of care and productive interactions among many system levels. By understanding the work system components, the design and integration of tasks, technology, and clinical processes can be reviewed to better support the needs of individuals while optimizing system performance. A supportive work environment and a highly engaged workforce correlate with improved quality of PCC and hospital performance [14]. Case managers, navigators, quality officers, and administrators may track patient outcomes at the population level. A study conducted in 2017 on postdiagnosis treatment communication with patients with cancer highlighted the importance of coordination among specialists, primary care, and other people involved in the care processes with patients to deliver necessary care as problems in coordination can lead to fragmentation in health outcomes and processes. However, existing initiatives and care-planning processes face barriers to adoption and implementation. To sum up, tools and initiatives designed to improve health care delivery through PCC need to be inspired by systems engineering principles as recommended by the Institute of Medicine and the National Academy of Engineering to identify, develop, and sustain best practices informed by the needs of survivors, caregivers, clinicians, organizations, and communities [13].

Due to the complex nature of the health care system, it remains hard to provide patients with care that meets their expectations without accounting for the work system in which they are receiving the care services [15]. However, to our knowledge, no framework focuses on PCC from a systems perspective. Human factors engineering interventions need to take into account issues across the whole system (system approach) with macro-ergonomic considerations, including organizational factors, to be more likely to significantly impact QOC. The Systems Engineering Initiative for Patient Safety (SEIPS) model of work system and patient safety, for example, emphasizes the principle of "balance" and focuses on system interactions that need to be considered to make significant progress in health care quality, linking the work system factors to health outcomes [16]. In addition, although many studies have focused on the workload of physicians and staff, no study has focused on the workload of patients with cancer. In this qualitative study, we explored the impact of work system factors on newly diagnosed

patients with cancer’s perceptions of PCC and QOC and the impact of PCC on the QOC outcomes among newly diagnosed patients with cancer following a suggested conceptual framework.

Theoretical Background

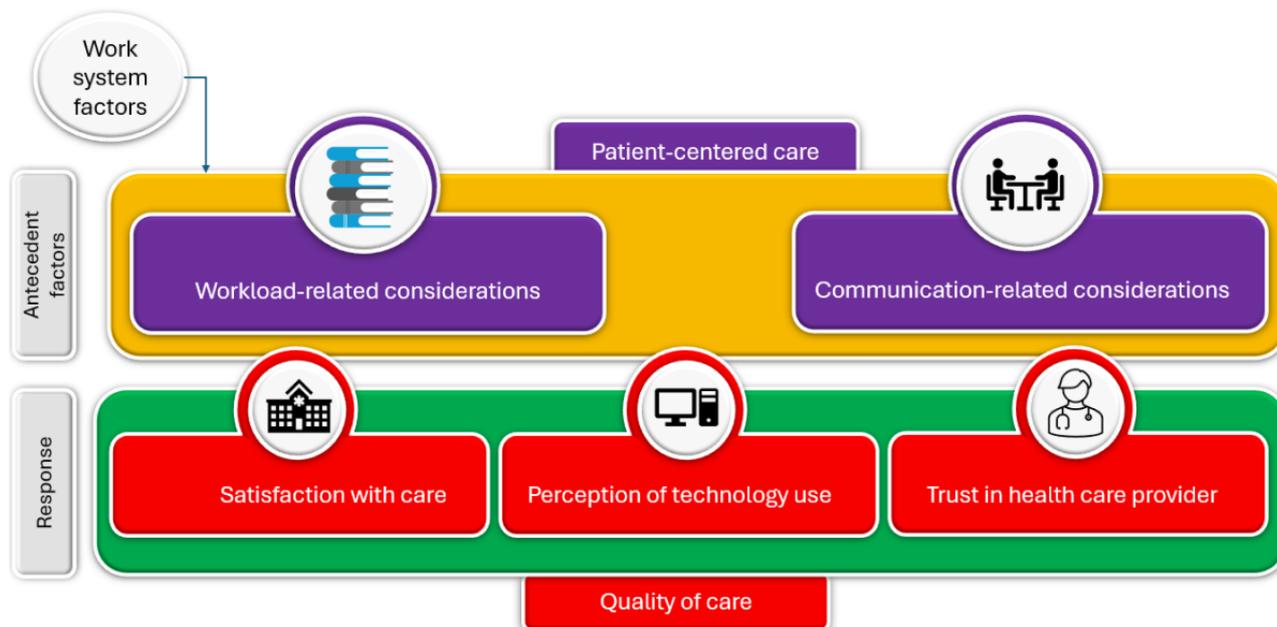

Overview

The framework built was inspired by different human factors models such as social cognitive theory [17], which conceptualizes the behavior of a person as a result of mental, personal, and social and environmental factors, therefore we considered behavior as a sum of a patient’s perceptual cognitive input (patient-centeredness perception) and the response. Our patient-centered effectiveness components were inspired by the patient-centered communication in cancer care that defines communication through 6 functions [18] and the technology acceptance model. The technology acceptance model links technology perception to the attitude of the user toward the perceived usefulness and ease of use and the external variables [19,20]. The last model that inspired our framework is the SEIPS [21]. From a sociotechnical perspective, patients’ experience, especially with chronic diseases, is a function of many coordination challenges [22]. Therefore, we need to go beyond the typical focus on a patient’s single health care

encounter and understand a patient’s journey from a broader perspective through their interactions with other stakeholders in a system where not only patients and physicians are actors but the work system and the tools used are also important impactors of the perceptions and decision-making processes. Thus, we look at the systems’ factors impacting patients’ perception of patient-centeredness.

Our framework in Figure 1 emphasizes the relationship between patients’ cognitive perceptions of patient-centeredness and QOC. We account for the impact of work system factors on these perceptions. We define patient-centeredness as a combination of workload support and communication and interrelationship support. Workload-related consideration characterizes the effective engagement of patients in their care experience. Communication and interrelationship improvement describes the communication effectiveness between patients and their providers. The dependent variables are related to the action tendency of patients: *satisfaction*, *perception of technology*, and *trust*. Exposure to the work system is considered a covariate in the model. To unpack this conceptual framework for evaluating patient-centeredness effectiveness, each independent variable has operational precedent in the human cognitive factors and behavioral economics literature.

Figure 1. Effectiveness of Patient-Centered Cancer Care framework.

Patient-Centeredness (Perceptual Cognitive Input)

Effective communication with patients with cancer can help meet information needs, improve physical and mental health, promote intimacy, and reduce burden [23]. In addition, patients diagnosed with cancer spend a lot of time and effort receiving treatment. Sometimes, patients have to deal with complex tasks related to medication taking and treatment in addition to rehabilitation activities that exceed their abilities, which engenders an overburden that has been proven to cause problems with adherence to treatment plans [24]. We define patient-centeredness in this conceptual framework as

workload-related consideration and communication and interrelationship-related considerations.

Workload-Related Considerations (Ensuring Effective Engagement and Task Load Improvement)

Patient ergonomics is the application of human factors or related disciplines to study and improve patients’ and nonprofessionals’ performance of effortful work activities in pursuit of health goals [16,25]. A central emerging concept of societal views of health care considers that patients actively perform “work” to achieve health-related goals and objectives [26]. This way, human factors position patients at the center of the work system,

aiming to improve their experience with the workload assigned [25,27]. In highly sensitive situations such as cancer care, this paradigm can help us better understand the dynamics among the 3 actors of the visits (physician, patient, and technology) and how their interaction can influence critical outcomes such as QOC, trust of physicians, and acceptability and perception of technology use. We define the role of patient-centeredness as a booster to the effective engagement and performance of patients in their care through *task load improvement perception*. Thus, the effectiveness is measured through task load improvement. Cognitive task load or workload is used in human factors or organizational psychology. It operationally refers to the levels of difficulty that an individual encounters during the performance of a task and is a measure of human performance [28]. Subjective methods commonly used in research include rating perceived task difficulty, engagement, or effort made by research participants [29]. There are 3 types of workload measurement: physiological, performance based, and subjective [30]. The physiological workload measures concern the continuous size of the body's physical responses [30].

Communication-Related Considerations (Communication and Interrelationship Improvement)

Compared to other health care settings, communicating information during oncology visits, especially initial ones, is critically important but can be particularly challenging due to the substantial amount of information provided, complex treatment decision options, involvement of multiple different providers (surgical, medical, and radiation oncology), and highly emotional situation with high patient workload [31]. Patients might not recall information accurately and might face difficulties understanding the information given. When information is particularly upsetting, many patients are too stunned to register further information [32]. Patients report leaving initial visits feeling that their informational needs (particularly about treatment, side effects, and prognosis) are not always met [32], which can lead to uncertainty, anxiety, and depression [31]. In one study with newly diagnosed patient with cancer–oncologist dyads, agreement on the content of the topics discussed ranged from only 37.5% for treatment side effects to 60% for prognosis [33]. Incomplete or inaccurate information about the disease process and treatment options increases the likelihood of patients receiving a suboptimal QOC [34]. Misunderstanding resulting from lack of communication has impacted health care outcomes such as decision-making, trust, and effective treatment [35]. Many countries have opened their accreditation, certification, and quality improvement programs for the past decade to examine physicians in training and communication skills [36]. Interpersonal and communication skills are 1 of the 6 general competencies for physicians identified by the Accreditation Council for Graduate Medical Education and the American Board of Medical Specialties in the United States [37,38]. “While communication skills are specific tasks and behaviors performed by individuals, interpersonal skills are relationship-oriented and process-driven, as noted by Duffy and colleagues” [39].

Response (QOC Perception)

Emotional distress is an average expected reaction to a cancer diagnosis. The diagnosis causes psychiatric complications (eg, anxiety, stress, and depression) induced by the patient's perceptions of the stigma commonly attached to cancer [40]. However, it is widely recognized that patient-centered interactions have the potential to influence patients' behavior and well-being [41-45]. Thus, we model patient-centeredness as an influencer of the behavior, which is patients' perception of QOC (*satisfaction with the care offered, perception of health IT use, and trust in health care providers*).

QOC Perception: Perception of Health IT Use

It has been long promoted that health ITs (HITs) will improve efficiency and QOC, support health care delivery, and reduce costs for the health care industry [46]. Much of the work has assessed how health care providers and organizations can use HITs to deliver health care services [47,48]. However, a growing awareness exists that consumers also want to participate in their health care [49]. For chronic disease settings such as oncology, patients must participate in the monitoring and managing of chronic diseases [50]. Several factors contribute to the widespread use of eHealth in chronic care; acceptance and capability of using ITs are vital components of understanding the disease and treatment options [51]. Advancements in digital communication and medical technologies have led to digitalizing health care [52,53]. The increasing adoption of various HITs has created new channels for physician-patient communication beyond the walls of physicians' offices. With the increased adoption and use rate of electronic health records in cancer care, oncologists can use the provided data in the critical decision-making process and support their workload [54]. In a study by Mazur et al [55], the enhancement of electronic health record systems' usability was associated with better oncologist cognitive workload and performance. However, little attention has been paid to technology support for newly diagnosed patients with cancer. Therefore, extending the existing knowledge base is essential to better understand how technology impacts newly diagnosed patients with cancer. Research on the mechanism of patient-centeredness shows that it is necessary to ensure patients' engagement with their health and their providers over the treatment time [56] as it impacts patients' lifestyles, quality of life, and behavior in the context of cancer care.

QOC Perception: Trust in Health Care Providers

Extensive literature supports the importance of trust in physicians for patients with cancer as it has been linked to improving QOC and other treatment outcomes such as adherence to treatment [57]. On the basis of a review by Hillen et al [57], trust is needed to ensure a good interaction between physicians and patients. Trust has also been shown to be impacted by communication among newly diagnosed patients with cancer [58]. Thus, we consider trust as one of the QOC factors affected by the communication and workload of newly diagnosed patients with cancer.

QOC Perception: Satisfaction With Care

Patients demand excellent care services from their providers. It is becoming a competitive edge in health care to control the quality outcomes and patients’ satisfaction with the services, the providers, and the organizations in which they receive care [59]. Satisfaction is an outcome of utmost importance in cancer care [60]. It was shown to be related to physicians’ ability to elicit the concerns of patients’ with cancer, consider their psychosocial needs, and involve them in treatment decision-making, which are the techniques of “patient-centered” care and communication [60,61]. We consider satisfaction with care to be the third main component of the framework.

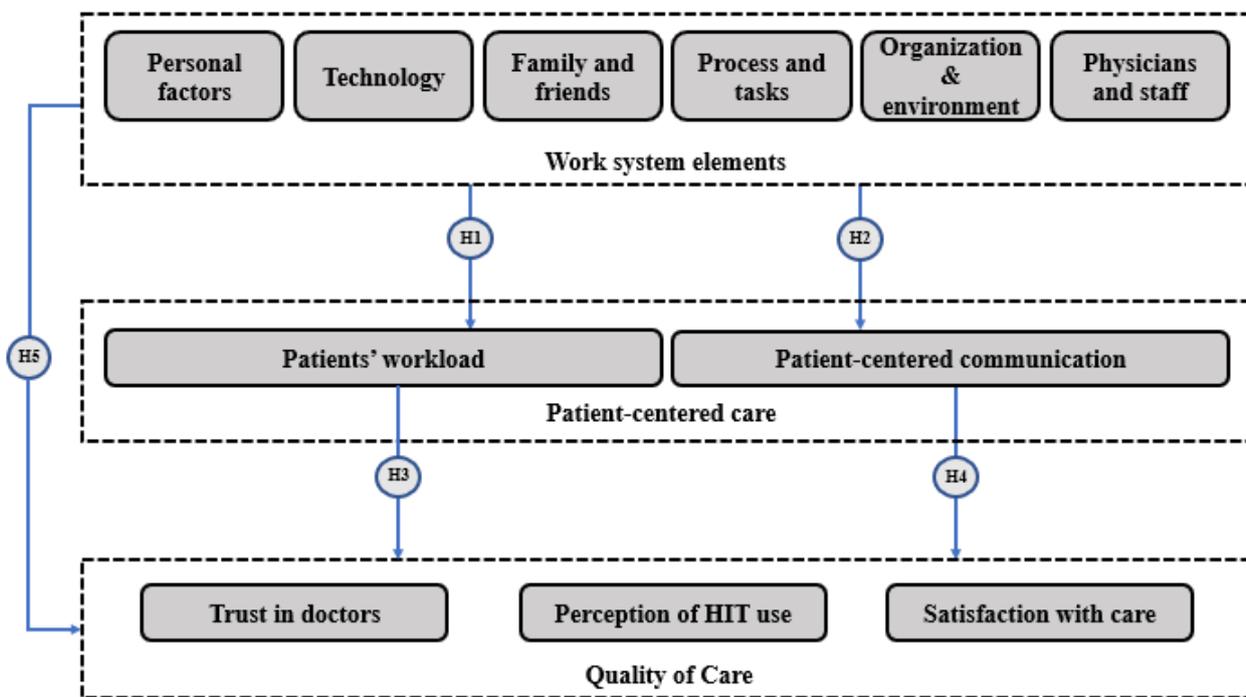

Hypotheses and Tests

Effective communication can prevent lapses in QOC and can mitigate harm when problems occur [62]. In cancer care, it is even more important to provide patients with the suitable communication needed [63]. Improving communication with patients with cancer in the first few visits requires a better understanding of patients’ experiences of breakdowns in care and their needs in the early stage of their experiences [64]. In addition, patients frequently experience high load and feel overwhelmed due to their confusion about the treatment plans and their uncertainties about their options, which compromises their perception of QOC [34].

The complexity of cancer care, typified by the financial, emotional, and physical challenges, makes patient care challenging [65,66]. In addition, the complexity of the cancer care work system is reflected in the multiple clinicians that are involved in the processes, the long therapies, and the uncertainty of the outcomes [66]. Thus, we considered the following hypotheses: (1) work system elements—work system factors impact newly diagnosed patients with cancer’s perception of their workload (hypothesis 1); (2) work system elements (communication)—work system factors impact newly diagnosed patients with cancer’s perception of their communication with physicians (hypothesis 2); (3) workload (QOC)—workload impacts newly diagnosed patients with cancer’s perception of QOC (trust in physicians, satisfaction with care, and perception of HIT use; hypothesis 3); (4) communication (QOC)—physician-patient communication impacts newly diagnosed patients with cancer’s perception of QOC (trust in physicians, satisfaction with care, and perception of HIT use; hypothesis 4); and (5) work system elements (QOC)—work system factors impact newly diagnosed patients with cancer’s perception of QOC (trust in physicians, satisfaction with care, and perception of HIT use; hypothesis 5);

We consider the following as work system factors: physicians and staff, organization and environment, family and friends, and processes and tasks. All hypotheses are summarized in Figure 2.

Figure 2. Hypothesis framework guiding the qualitative analysis. H: hypothesis; HIT: health IT.

Methods

Overview

This study used qualitative data from semistructured interviews to explore the impact of work system factors on newly diagnosed patients with cancer’s perceptions of PCC and QOC, as well as the impact of PCC on QOC and technology preferences. We

used semistructured interviews to facilitate candid disclosure of personal experiences. The interview questions used in this study were guided by the SEIPS 2.0 mode [26] and validated by existing literature. The full interview guide has been published elsewhere [67]. The SEIPS 2.0 model provides a framework that helps comprehend the work system (people, tools and technologies, tasks, working environment, and organization); process (clinical process, patient outcome, and

organizational outcome) in the health care domain [26]. It also helps assess and understand the complex interaction among work system elements [26]. The interview guide was developed iteratively with the research team. Subsequent revisions of the interview guide were informed by emerging themes and sensitizing concepts generated through data collection and analysis. We also revised the interview guide questions based on expert feedback and the results of quantitative research conducted previously in the same center as part of the same project. Our sample included patients who (1) had been recently diagnosed with cancer, (2) were in their first few visits to the cancer center where the study took place, and (3) were adults aged ≥ 18 years.

We conducted a total of 20 in-depth semistructured interviews. Sampling continued until theoretical saturation was achieved, defined as the point at which further interviews did not advance the conceptual depth of the developed categories or reveal new dimensions of the relationships among categories [68,69]. The interviews lasted approximately between 30 and 60 minutes and were facilitated by a trained expert in clinical research management. The length of each interview was determined by the patient's level of comfort in disclosing their perceptions and sharing their experiences. We completed 20 interviews, resulting in 989 minutes of recording that were used for data analysis. All participants provided informed consent for the interviews to be audiotaped and professionally transcribed.

Analysis of interview transcripts was iterative and used a deductive and inductive approach. The deductive approach used focused coding, applying predetermined codes or themes

resulting from the preset hypotheses made regarding the different interactions among the perceptions of work system factors, QOC, and patient-centeredness. Throughout the study, we incorporated memo writing to reflect on individual cases, interview settings, participants' responses, and emerging concepts and assess preconceived notions that were discussed weekly with the research team. The coding was done and visualized using a Microsoft Excel (Microsoft Corp) spreadsheet. We also prepared the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist and provided it in a supplementary file ([Multimedia Appendix 1](#)).

To mitigate the risk of bias caused by qualitative research, our study initially used a triangulation design with findings reported in different studies [3]. For more transparency and accuracy, different participants with different backgrounds reviewed and confirmed the transcripts and interpretations. In addition, a clear documentation of the analytical process was conducted.

Ethics Approval

This study received ethics approval (institutional review board ID 00011536) from the Stevens Institute of Technology and from Hackensack Meridian Health, John Theurer Cancer Center, New Jersey, where it took place.

Results

Overview

The distribution of demographics is shown in [Table 1](#). Most participants were female (12/17, 71%), White (9/17, 53%), and aged >40 years (15/17, 88%).

Table 1. Sociodemographic characteristics of the study sample (N=17).

Impact of PCC on QOC

This section presents the findings related to the testing of hypotheses 3 and 4.

Workload of Newly Diagnosed Patients With Cancer

Newly diagnosed patients with cancer expressed their perception of the workload and reported experiencing a high mental workload due to frustration and emotions when they were first diagnosed:

At first you're all nervous and upset with your condition. So you're like, I don't know how to do this. You're freaking out. [Patient 13]

The mental workload increases as patients are required to remember many details (eg, appointments, information, and medication) and are required to understand the results and options they are given with the little information shared with them:

There's a lot to remember. There's a lot you got to remember which medicine to take and when. [Patient 12]

I think sometimes the interpretation of the test results is challenging and a bit anxiety producing. [Patient 06]

In addition, patients experience high temporal and physical load as their tasks require a lot of effort and are time and energy consuming:

It's unfortunate that I have to get drawn so many time...You just get tired of sitting, you get tired of being in there. [Patient 02]

Very demanding. I go get the blood work done first, and then when my blood work is done, I go up and wait to see the doctor. Then I go to the infusion room when I'm done with him. [Patient 13]

Impact of Workload on Trust in Physicians

High workload negatively impacts newly diagnosed patients with cancer's trust in their physicians. For instance, patients who had less workload, felt cared about, were given enough time, or were less rushed were more likely to trust their physicians:

My doctor really care about me. I gage that because I'm not being rushed to leave right away. I see the attention that they pay attention to all my questions that I have, and also, I feel comfortable. [Patient 03]

I think they do help with my emotions because they are trying to address every question that I have. I am not getting very emotional; I'm not getting extremely upset. So what I'm trying to say is that they might not even see any emotional reactions from me because I do trust that the doctor said he will fix me and I know that he will. So, I'm not emotional. I'm going very strong because of their support and my knowledge that they are there, and they will fix the situation. [Patient 05]

Impact of Workload on Satisfaction With Care

The findings also showed that the workload perception among newly diagnosed patients with cancer impacts their satisfaction with the care services received:

As far as the demands, the time and effort it took to ensure the entirety of the visit was completed well in its entirety. Look, it was very effortless on my part. [Patient 06]

They just gave you time to digest and let you just sit there and think about what the doctor was saying, and that really does make a difference. So basing out the information across the appointment instead of just kind of ramming it all down your throat at the beginning and asking any questions, it always moves quickly. But I do think that the taking of time in between providing information and providing time to digest was very helpful. [Patient 12]

However, patients who felt that the care services were demanding of time or effort were less satisfied with their visits:

The treatment itself, when I'm there for chemo, does take a long time. That's like 4 hours at least. And then I'm on a pump for the next two days, so that does take a decent amount of my time. And then when I'm on the pump, I'm basically laying down because I really can't do much because I'm still getting treated. So, the treatments are demanding. [Patient 13]

Impact of Workload on Perception of Technology Use

Finally, the high workload impacts patients' approval of physicians using technology during the visits. Patients who felt that using technology made their tasks less effort, memory, and time consuming were more likely to accept it. They felt that having all the information available in one place saved them from looking for information everywhere and trying to understand it and share it again with the physicians:

Technology can help keep me cooperating with the doctors and the treatment without much effort...Usually the nurse has the computer and she's checking in that all the details are correct and verifying information with me before the doctor even walks into the room. And she can answer questions about when I start the next cycle, et cetera. Because she has all the information with her. That saves me time. I don't need to remember everything. [Patient 02]

It will impact only positively because I see an order, everything in one place in my app. I see my history, I see all my tests, I see all my appointments, all notes from the doctor, I see all the scans and everything is in one place. For me it's positive because again, I'm technology savvy and for me, that's great to be utilized, to have everything in one place. [Patient 05]

To conclude, these qualitative findings showed that having less workload (eg, physical, temporal, and effort based) helped newly diagnosed patients with cancer trust their physicians more, be

more satisfied with the care visits, and accept technology use during the visits (hypothesis 3 was supported).

Communication Needs and Impact of Communication on Trust in Physicians

The quality of the communication in cancer visits is critical. Physicians share a lot of information with patients in the first visit, and it is essential for them that physicians explain things clearly in an easy, comforting, and understandable way and that their questions are answered without being rushed. Good communication of the information needed made patients trust their physicians:

She made it very easy for me to understand very difficult, very complex procedures and explain to me clearly why, in my particular situation, she would recommend the clinical trial treatment that I'm on. And the appointment didn't last more than maybe 20 minutes, but in that time, I felt like I understood what I was getting myself into. She provided things for me to read when I got home and explained clearly that other options were not as good as this one...If I was concerned about something, she would try to reinforce that. Everything that she explained made sense because she was trying to keep me at ease and not worried about more than I should have. [Patient 02]

Our communication me and the doctor is genuine, accessible, nurturing, informative. [Patient 17]

Different patients also have different levels of understanding. Patients trust their physicians if they respect their pace and health literacy levels:

Yeah, basically pausing and making sure I understand things as she's saying them, making sure I'm caught up in the discussion, because you could go very fast over a lot of things and there's a lot of information to digest at an appointment like that. So she would take her time to pause and say, do you understand what I'm talking about? So that sort of thing helped. [Patient 17]

Another important communication factor that impacted patients' trust in their physicians was feeling like they were treated equally without any bias independent of the type of insurance they had or their age or race. Patients liked to be treated as human beings, not as numbers:

It felt good. I didn't feel like I was going to be just thrown in there and just done whatever, and then no explanation of anything, so it felt really good. And the mere fact that I have Medicaid and I didn't feel like a patient, that felt phenomenal for me. It was very powerful. Well, I mean, it seems that we get lost in the shuffle. We're just like, nobody basically. We seem to be like, I don't know, nobody, we're not treated like we just don't matter. I didn't feel that way at all. I felt like I have a chance just like everybody else who has like [insurance name] or whatever. So I just felt like they cared about me and the process was they were going to do whatever they had to do, no matter

what insurance I had. So that meant a lot to me. [Patient 07]

Furthermore, newly diagnosed patients with cancer like to be given full attention by their physicians, communicating both verbally and nonverbally, exchanging eye contact, and paying enough attention to every question they ask. This impacts their trust in physicians:

Well, they always examine me, obviously. They talk to me. They come up to me, and they look at me not everywhere in the room, just looking at me eye to eye, and explain to me exactly what happened this week...They look at me straight in the eyes, and for the time that we're there, her attention is focused on me. And when I ask the question, they usually don't mind repeating themselves, because sometimes when you're in treatment, you don't hear well. And I'm taking notes when I'm there. And I sometimes repeat questions that she may have already answered. And she is very happy to follow up and expand a little more so that I can understand in more detail what she's trying to tell me about follow up questions, answering follow up questions. [Patient 02]

Finally, patients want to be treated in a personalized way as a special person and to build a strong relationship based on empathy with their physicians by talking about their personal life and not only about treatment and visits:

My doctor is extremely approachable despite his busy schedule. He shared his cell phone number with me, but of course I'm not going to communicate to him. But those are things that you understand that you're not just a patient, you're a special individual for him and for his staff, and everything is personalized. I think that's my belief, honestly. [Patient 05]

I like that the doctor talks to me in general not only about my treatment. Sometimes we talk about family and things like that, really getting to know the doctor. He was very communicative; he keeps being positive and that helps. [Patient 01]

I think in particular, she has quite a good amount of empathy, which I think a lot of doctors don't. So she treats you like a human being and trying to think what else on the medical side. It's basically kind of explaining your condition well and giving you an idea of what's to come. [Patient 10]

In fact, patients who do not have a strong bond with their physicians and only talk about treatments without discussing their options may have low trust in the physicians' opinion and feel that they are treated in an unfair way:

Well, yeah, I feel that, but I think this is more and more interested in selling products that are profitable for the hospital than necessarily what care I need. She just seems obsessed with selling an expensive procedure that I'm not ready for. I'd like to see more programs tailored to my situation and some options. There's a lot of options and treatments available

today. And to say it's this or nothing, I don't think it's appropriate. [Patient 11]

Impact of Communication on Satisfaction With Care

The communication between newly diagnosed patients with cancer and their physicians also impacts their satisfaction with the care received during the visits. In fact, patients prefer to be told the truth about what is happening to them and for it to be stated that the physicians are doing their best:

Well, anything the doctor noticed, any concerns she has, she always meant that she just wants to be sure and just saying that she wanted to stay on top of things and that was pretty good to me. I would say I had really good care both in first visit and follow-up ones. [Patient 01]

They also want physicians to explain the goal of the visit clearly and to be walked through every step of the procedures. On the basis of patients' needs, physicians need to ask them whether they are satisfied or not and allow families to be part of the visit for more support:

When I have to come visit, they know exactly what happened before, and they can specifically tell me where we are today and what we need to do today. They also keep some time for me to ask questions, and if I don't understand something that she explained, she'll explain it again. My daughter participates in those visits as well, and she always has questions too. As long as we have questions. If we are all clear and everything's just a routine visit, then we need less time, I guess. But if we need more time to answer questions, they're willing to answer until we're satisfied...I like it when they explain things to me, even if they're technical, because I can look it up and kind of make sure that I'm getting the right information from my doctors and it's consistent with what the best health organizations treating cancer are doing. [Patient 02]

Although some prefer to be told everything, others do not understand much when it is too technical. Physicians need to explain things to them in an understandable way:

The communication was excellent. The answers that I was seeking were given and the questions that I had were answered. The care was given, felt comfortable. The doctor communicated with me in a way I could understand. [Patient 06]

However, paying attention to special cases is important to gain patients' satisfaction. Some patients have comorbidities and need to be taken care of in a more careful way. For example, one of the patients whom we interviewed was blind. It is more challenging to communicate with such patients:

I am blind, so they always print documents out for me though but they tell me everything verbally. To make sure I understand and then they tell me it's on the printout. [Patient 16]

Some other patients are skeptical about health care systems. It is important to know how to handle them and how to

communicate information to them without losing their trust not only in physicians but also in the system itself:

Cancer care is a profit center for these medical centers. The doctor is trying to push a very expensive procedure that's very invasive that I don't have the support network to do. And it seems to be like she wants an all or nothing for that procedure. So, I think I really need a second opinion on this stuff. Well, like I said, I think that the cancer centers seem to be out to maximize profits because I see them advertised all over. I don't know, that's just what I seem to find out. [Patient 11]

Finally, despite the focus on visits being very important, follow-up needs to cover home care for the first visits as patients need more support at the beginning of their experience and building a bridge of communication with them beyond the care visits would help them feel more cared about:

So, the communication during the treatment and while I am in the hospital is really good and I feel that I can ask any question and I always get the answers. As for communication when I am at home, I think I am still learning the system. After my first treatment, I had some adverse effects. I did document and I did write up my observations. Science in me did that. But I didn't know how to communicate that to the doctor until my next follow up with the doctor. And then we did discuss those adverse effects and they did adjust my dosing regimen. [Patient 05]

Impact of Communication on Perception of Technology Use

Newly diagnosed patients with cancer need their physicians to communicate with them without any distractions:

No, no them using a computer is of no distraction at all. The doctors still attend to me.... They always check my blood work and put it on the computer and if there is anything they communicate after the visit. They always call. [Patient 01]

If patients are made the center of the visits and the computer is used for documentation purposes, patients feel satisfied with its use by physicians:

I don't think technology is disturbing my communication because they are still there. It's not that we are communicating through computers only. They are still there in the room they are personally discussing with you. But then they document everything in the computer. And I think at this time and era, you do expect that everything will be documented on the computer? That's my expectation. [Patient 05]

She occasionally doesn't always use the computer, but occasionally does to look at test results. But I never really found it distracting, and I don't feel like she was paying attention to the computer more than me. It was just there as a tool as part of the

appointment. Never did I feel like it was computer first, patient second sort of thing. [Patient 12]

However, if the use of technology made patients feel that they could not communicate well with their physician, they were not happy with it being used during the visits:

Not every time, but yeah it was distracting, sometimes. Actually, now that I think about it, I think that was where I could see a few instances where that was where their focus was. I think I would ask a question and there would be like a two-minute pause because he was in the middle of typing stuff on the computer and then he would answer after. So, the doctors was distracted with whatever he was doing on the computer. [Patient 08]

I would prefer them not to be on their computer and rather making eye contact and communicating directly with the patient rather than typing. So I didn't feel as connected with the doctor. [Patient 17]

To conclude, these findings showed that, if the communication between physicians and patients is built in such a way that patients are the center of the care and using technology does not distract physicians from building a bond with their patients, technology use during the visits is accepted and not judged as distracting. Thus, hypothesis 4 is supported.

Impact of Work System Factors on Communication

The work system factors in health care impact patients' communication with physicians. In fact, patients were more satisfied with the communication with health care staff when they felt that the organization was empowering nurses to intervene and raise issues related to their health. Thus, the *organization and environment* impact the communication perception among newly diagnosed patients with cancer:

There was a nurse, also a night nurse, who noticed that there was fluid in my lung and she put a note in for the doctor to see if they could remove it because she thought it was too big. The day after I got in from the emergency room and the nurse was the one who raised the flag to the doctors and the next day they removed the fluid. So I think they're empowered, but at the same time looking she didn't have to go back and look at the X rays in my lung because she was surprised that I was breathing so badly. So, she was just curious and checked in and brought it to everyone's attention. I also like that they called me directly to check on me. They make sure that we are cared about and that we know everything about our situation. [Patient 02]

In addition, frequent follow-ups can help patients share their concerns and issues with their physicians and help them communicate well in a continued way, which shows the impact of the *processes and tasks* on communication for newly diagnosed patients with cancer:

So, I think follow-ups are very important, especially after the first treatment. When my first treatment was very miserable, I felt very miserable afterwards, I had very significant adverse effects to the drugs. And then

in a week I had follow up with the doctor and we had really good communications for the second treatment. [Patient 05]

The way in which physicians, nurses, and staff interact with patients impacts their perception of communication. For instance, patients were more satisfied with physicians and other staff if they felt cared about and if their questions were answered. In addition, allowing family members to attend visits may help patients feel more reassured:

The people in the lab are amazing. They understand that we get pinched a lot, and they try to work with you, and they help each other, too, because they have to get the results stat, how they like to say. And they look thoroughly at the request from the doctor. And if I have questions about what they're doing, they'll answer them intelligently...When I first saw my doctor, she knew the record just as well, but she asked me to tell her my experience so she would know firsthand from me how I was feeling now and what had happened in the past. So, I felt very well taken care of and the communication between my doctor and me was excellent really. [Patient 02]

My daughter participates in those visits as well, and she always has questions too. [Patient 02]

Thus, we conclude that the work system elements impact the perception of newly diagnosed patients with cancer regarding communication, which supports hypothesis 2.

Impact of Work System Factors on the Workload

The work system elements impact patients' workload. In fact, the process of detailed documentation in the records and providers accessing that information easily also reduces patients' mental workload and frustration. Patients also like being guided through every step at the clinic as it helps them feel better:

I do feel supported, even though we meet for short periods of time...I felt that in every visit, in the few minutes that she was maybe 15 minutes that she's in the room, she knows everything about what happened the previous weeks. I don't know how she does it, but if I forget to tell her about something that I was feeling the week before, she would ask me about it. So, I understand. However, they do it to go into the room and remember exactly this patient in particular, it makes me feel very reassured that they've done their homework when they walk into the room to talk to me.... I think they have a pretty good system. Once you register, they have someone already greeting you, walking you over to do any lab tests that you need. They kind of wait around and guide you to the elevator so that you can go up to the waiting room waiting area. [Patient 02]

You come and you get greeted by a person that sits on the first floor. Then you go to lab. In the lab everyone is very attentive. Sometimes you have to wait a couple of minutes, but usually it's not very long wait time and they are very attentive to ensure that they are doing very good. [Patient 05]

However, the long waiting time in the process makes patients anxious and nervous, which adds more workload to the physically demanding processes and procedures that they are experiencing:

I just wait in between seeing the nurse and the doctor a little bit too long, I thought. So, the wait was a bit lengthy, a bit long. That was nervous for me. And not only that, but we had to leave at a certain time because we had to go pick up my nephew after school. So that was my appointment was at I think it was at 110, and I didn't see the doctor to, like, almost 230 or something like that. [Patient 07]

I sat there, and I waited, and I waited, and I waited for my first biopsy results and to get them at 02:00 p.m. I was calling and calling and calling, trying to see if anything came in...It's a lot and it takes a toll on you. [Patient 13]

To reduce this load, physicians and staff members need to explain matters clearly to their patients to comfort them, reassure them, and make them feel cared about through personalized services:

I would say the doctor knew how much information I needed to avoid being overwhelmed. Just telling me the options of what we need to do and I think that pretty much helped. Not feeling overwhelmed, it's like, let's do this and get past it. So that was pretty much my feelings. [Patient 06]

I was very nervous about what the nurse had told me that was going to happen once. I didn't want to need to have a tube in my lungs. But luckily, before we got to the procedure, they had already taken care of that and she put it in capital letters so that the radiologist didn't miss it, that they didn't need to put it too, because the treatment would resolve that over time. So, I think reassurance is what they tried to do and being attentive to the details, which in medicine, I think is very important because each case is a different case. And I felt very comforted that I'm not just a number, I'm a patient that they're trying to get out of the hospital. [Patient 02]

What I do when I am overwhelmed is I call the nurses all the time, and they're so helpful. I was calling them multiple times a week, and whether it was a new side effect, or I just had follow-up questions. So, I definitely have been utilizing them, and they've been so incredibly helpful. [Patient 08]

In addition to the health care actors, the organization impacts patients' workload. Patients need a relaxing, calm, clean, and organized environment. Using comforting colors and decorative signs that motivate patients can also give them more hope and reduce their load:

So, when we look at the physical layout of it and all those processes, it's very nice, very organized place, very relaxing when you have to wait, so it's no problem.... Everything was very comfortable. No noise

at all. Very calm and especially very accommodating. [Patient 01]

The environment is really good. Everything flows nicely. Everything is nice and clean. Everything the colors and the walls and everything is very calming. As far as decorations and stuff like that, there's like a passageway that sometimes I'll pass through that I see like puzzles of past people that I have done from cancer. They do like these jigsaw puzzles, and they've hung them all across this hallway that I pass, which I find very endearing when I pass, and I see that. So pretty much in the sitting areas and everything where everyone sits and waits nice, valid and everything like that. [Patient 03]

Construction work, long walking distances between the rooms, parking, and many other issues may cause patients to experience more physical and temporal load:

Let's be honest here. Like, it's completely overbooked, and I know they're under construction or what have you, which is stressful to have that many people crowding in the hallway.... Like if I was upstairs and I couldn't make it down in time, they would call and say, hey, she's running late. And it was accommodated. But it's definitely overwhelming to navigate. [Patient 17]

You can build a bigger parking lot if you have room. Yesterday, yeah, I was riding because the appointment was at 01:00 at that time was all packed. They had to drive around all the way up to the roof and start coming down...there are definitely not enough spots there. [Patient 09]

Furthermore, family and friends can help support patients in their tasks, which reduces their workload by facilitating processes:

My daughter is there for me. I moved in with her so that she could drive me to my appointments, and I can have support when I'm not feeling so good.... It makes things way easier. [Patient 02]

Wife, family, friends, taking me to the treatment, stopping by and visiting me, phone calls. Just a lot of support. [Patient 08]

My husband is always next to me. I am 90% self-cared, but sometimes I need his help to move around. For example, during the chemo to go to the bathroom. [Patient 05]

On the basis of these findings, we showed that work system elements impact patients' workload. Thus, hypothesis 1 is supported.

Impact of Work System Factors on Satisfaction With Care

The work system elements impact patients' perceptions of QOC. They impact patients' trust in their physicians, their perception of HIT use, and the satisfaction with the care received during the visits. In fact, patients appreciated nurses checking on them

frequently and being nice to them, which made them feel more satisfied with the care received:

I think specifically the nurses in the infusion center, they were so kind and so nice, and they definitely were always asking how I was feeling during the infusions. They come check on me every ten minutes, pretty much. So, they were very accommodating and made me feel very comfortable. [Patient 08]

Before seeing the doctor, you see the nurse nurses always welcoming even the staff that you go for copy or just approach to announce that you arrived. They are very attentive. You can see that they are feeling your pain. And that's very comforting, let's say... Usually my chemo is very long. So, the people who delivers lunch are so attentive to every single person. They are taking time for every single patient to repeat whole menu and convince you that this is very delicious to take. It's really warm and nice atmosphere. So I think they are taking extra steps to make you feel as comfortable as possible given the heaviness of the disease. [Patient 05]

Receiving less attention from physicians would make patients unsatisfied with the visits:

My doctor is very busy. He's the head of the cancer center and he has tons of patients. But I would have liked to see him maybe sometimes not at the end of the treatment, but also in the middle of the treatment. [Patient 05]

In addition, having a good organizational environment increases patients' satisfaction with care. Patients want to be in a well-designed environment where they can access better care services:

So, I think all is very accessible, very well designed, that you stop by first in the lab, then you can immediately pick up your pharmacy needs and then go to the second floor to visit the doctor and then move to the chemo center. So, I think everything was designed well. I love the sunny side and shady side of the infusion room. They have all these blankets, very nice people always asking what you want, more water, more anything to make you feel better. I think, as you say, from the organizational and structural perspective, is designed very well. [Patient 05]

Impact of Work System Factors on Trust in Physicians and Staff

When physicians provide them with personalized services that are not based on generic information and that speak to their needs and situations, patients tend to trust them more:

It's just from reading the reports that the doctor gives me after the visit summary, I can tell that it's not generic. It's definitely speaking to my condition. I can see that what they're writing, and my evaluations are definitely about me, and I can see the reports, and it's definitely very much personalized. [Patient 12]

The mix of personal and professional interaction makes them trust their physicians and the nurses delivering the services. Patients need people who listen to them, a friendly environment, and practices in which the main goal is to deliver the safest care to them:

What I did notice you have very good clinical practices that when the nurse has to introduce chemotherapy, they have second pair of eyes verification, which speaks of high quality and regulatory compliance of your organization, and that is incredible to see. [Patient 05]

Every time I have a discrepancy, they always double-check. Either the nurse in the infusion room double-checks with the research nurse, the research nurse double-checks with the doctor, and everybody double-checks to make sure that we're doing it the right way, and that gives me comfort as well. [Patient 19]

I think it's a good team. They listened to their own people, and they acted on it. That makes me trust the whole thing. So, I'm like I said, very professional and very personable. I really like that. It sums it up so beautifully. Like the two pieces in health care. Professional yet personable. I really do like that.... The hospital has great practice, and we have a number we can call. Twenty-four, seven. And they told us exactly how to behave and where to go when we got to the hospital. So that kept me more of these. But I was very scared. It was a Sunday night, so the doctor didn't physically come, but the emergency doctor had spoken to her. He knew my case. [Patient 02]

They had a social worker contact me, which was nice to see if I had any opportunities or anything. I thought that was a good guess here. Any helping hand is an essential hand. [Patient 11]

In addition, more trust is built among patients if the team's communication is healthy and professional:

The communication between the staff, I see that it is good and very professional. And the place is amazing. They walk with me and make sure I have all what I need to start the next step. The infusion, I prefer the one where I get sun and they already know that. [Patient 02]

Impact of Work System Factors on Technology Perception

If physicians let themselves be distracted during the visits or do not pay enough attention to patients, patients may consider technology as a source of distraction and disruption to the visit:

The doctors was distracted with whatever he was doing on the computer. [Patient 08]

Finally, the organized process of the visit, the good collaboration between nurses and physicians, and note-taking to make patients the center of the visits made patients trust their physicians more,

be more satisfied with the visits, and accept the potential that technology may have in the success of the care processes:
