This paper has addressed a gap in research describing emergency nurse patient flow management. We have identified numerous work system elements that shape emergency nursing work. These work system elements are theoretically linked to patient flow outcomes, but more research is needed to verify and measure their impact. The presented SEIPS model should therefore serve as a guiding framework for future studies that investigate the facilitators, barriers, and motivators to emergency nursing patient flow management.

This SEIPS work system analysis further demonstrates the complexity and difficulty of patient flow management. Patient flow researchers and health care administrators should embrace the study of human factors to support health care delivery. Increasing scholarly attention to the work of emergency nurses may offer new strategies to improve patient flow.

Impact Statement

The work of emergency nurse patient flow management has been poorly described. This nursing research study has used a human factors model to analyze the work system of emergency patient flow management. Study findings offer a theoretical framework to further investigate the impact of emergency nursing work on patient flow outcomes and identify novel patient flow solutions.

Conclusion

The SEIPS model has been applied in many health care projects and sectors to investigate care delivery [24]. Findings from this inductive, qualitative study provide further empirical support for the validity and usefulness of the SEIPS model. The unique contribution of this paper is the integration of the SEIPS model with the expertise of emergency nurses to describe their work system. There are many opportunities to better support emergency nurses in the complex, dynamic work of patient flow management.

Acknowledgments

The authors wish to thank Drs Cynthia Jacelon, Hari Balasubramanian, and Shannon Roberts for their guidance and support. This research was supported by a Beta Zeta at-Large grant from Sigma Theta Tau International Honor Society of Nursing.

Conflicts of Interest

None declared.

Abstract

Background: Currently, 30 million children are experiencing acute malnutrition, and 8 million children are severely underweight.

Objective: This study aimed to develop a stunting super app, a one-stop app designed to prevent and manage stunting in Indonesia.

Methods: This study consisted of three stages. Stage 1 used a 3-round Delphi study involving 12 experts. In stage 2, 4 experts and a parent of children with stunted growth created an Android app containing stunting educational materials. In stage 3, a pilot study involving a control group was conducted to evaluate parents' knowledge about stunting prevention through the app and standard interventions.

Results: In the Delphi study, 11 consensus statements were extracted; arranged in three major themes, including maternal health education, child health education, and environmental education; and applied in the form of the Sistem Evaluasi Kesehatan Anak Tumbuh Ideal (SEHATI) app. This app was assessed using a content validity index, with a cumulative agreement of $\geq 80\%$ among the 5 individuals. The pilot study showed an increase in the knowledge of mothers of toddlers with stunted growth before and after the educational intervention ($P=.001$).

Conclusions: The SEHATI app provides educational content on stunting prevention that can increase the knowledge of mothers of toddlers with stunted growth.

stunting; stunting prevention; mobile app

Introduction

Stunting is an effect of malnutrition characterized by suboptimal physical growth caused by malnutrition in the first 1000 days of life, which can affect children's development and cognitive abilities [1]. Currently, >30 million children in 15 countries (ie, Afghanistan, Burkina Faso, Chad, Democratic Republic of the Congo, Ethiopia, Haiti, Kenya, Madagascar, Mali, Niger, Nigeria, Somalia, South Sudan, Sudan, and Yemen) are experiencing acute malnutrition, with 8 million of them being severely underweight [2]. In Indonesia, the Basic Health Research data show that the prevalence of stunting in toddlers in 2018 reached 30.8% [3]. Further, based on the Indonesian Toddler Nutrition Status Survey, the prevalence of stunting in 2021 was 24.4% (5.33 million children) [4]. This proves that the prevalence of stunting in Indonesia is still a public health issue because the figure exceeds the limit set by the World

Health Organization, which is <20% [4]. The prevalence of stunting is increasing, owing to the lack of knowledge on the importance of meeting a balanced diet for toddlers during their golden age; the lack of awareness of primary caregivers, particularly mothers, in monitoring their food; and poor public knowledge on the early prevention of stunting [5]. Early stunting prevention can be started by increasing the understanding and role of the community in stunting prevention and increasing early detection programs in toddlers, which are expected to directly reduce this issue [6,7]. If inappropriately managed, stunting can lead to short- and long-term risks, such as decreased cognitive, motor, and language development, which will affect school performance, learning capacity, and other child potentials [8]. This can also incur high health expenditures and more frequent requirements for childcare, which will ultimately increase morbidity and mortality [9,10].

Currently, governments have implemented various national programs to ensure the health of mothers and children, including (1) specific intervention activities for giving iron tablets as a supplement to adolescent girls, brides-to-be, and pregnant women; (2) the promotion of exclusive breastfeeding and breastfeeding assistance; (3) classes for pregnant women; (4) information on a balanced diet; and (5) the Healthy Living Community Movement, which consists of increasing physical activity, vegetable and fruit consumption, and early disease detection [11]. At present, the prevalence of stunting in Indonesia is still very high and thus must be addressed through more innovative and creative interventions [12]. Currently, the most widely offered intervention is the use of IT, which offers easier access to health information anytime and anywhere.

The use of digital technology for health has become a popular practice when compared with other ways [13]. This is supported by the increasing use of mobile phones, as evidenced by global mobile user data reaching more than two-thirds (67.1%) of the world's population [14]. A form of technology usage in the health sector is the use of a smartphone app, which is commonly presented as a mobile health or eHealth app and can be further developed into a super app. A super app is a holistic app concept that has recently gained popularity, particularly in transport and other services offered by start-up companies such as Gojek, Grab, and Shopee. However, its use in the health sector remains unexplored. eHealth, or a super app, uses the interactions among medical informatics that are expected to reduce the prevalence of stunting in Indonesia, by referring to health services and information delivered or improved through technology [15]. In addition, assessment through this app is expected to be able to detect stunting early, monitor the condition of toddlers with stunted growth easily, and bridge stunting education to parents.

Preventing stunting is important to ensure the growth and physical development of children [16]. Having an app that aims to prevent stunting can improve the parents' and the community's knowledge about nutrition [17]. It can also provide easily accessible and relevant information and easily monitor the growth and development of children.

Several studies have evaluated the role of eHealth in stunting prevention. For example, Permana et al [18] took advantage of the use of "Nutrimo" or nutrition monitoring. Rianti et al [19] developed an app to prevent babies from being born underweight, which focuses on the health of pregnant women during pregnancy, particularly to comply with taking iron tablets. Kasjono and Suryani [20] developed Gerakan Anti Stunting (GASING, antistunting movement), an app for the delivery of information on a balanced diet and the promotion of clean and healthy living behaviors. Utario and Sutriyanti [21] developed an offline app for stunting management for Integrated Service Post task forces. However, current apps are neither comprehensive nor integrated into one platform and do not focus on stunting prevention. Therefore, this study is interested in developing a stunting super app, a one-stop app that can help prevent and handle malnutrition and thereby facilitate the eradication of stunting in Indonesia.

Methods

Study Design

Overview

This study consisted of three stages. In the first stage, content development related to stunting prevention education was performed using the Delphi study. The Delphi study is a method used to create context and collect opinions from experts on a particular topic [22]. In the second stage, the app was developed, which was later named Sistem Evaluasi Kesehatan Anak Tumbuh Ideal (SEHATI). In the final stage, a knowledge assessment was performed before and after the health education using this app with standard educational media.

Stage 1: Content Development by Experts

In stage 1, a classic Delphi study and web-based Delphi study were performed in 3 rounds for content development. This study involved 12 experts who met the inclusion criteria: expert educational backgrounds in medicine, nursing, nutrition, or physiotherapy who had experience with stunting for >2 years in Indonesia or parents who had children with stunting. In the first round of the Delphi study (first questionnaire), a classical Delphi study was performed by distributing a questionnaire with open-ended questions. Participants were asked, "What do you think can be done to prevent stunting?" The questionnaire was sent as a Google Form via WhatsApp version 2.24.23.78 (Meta Platforms). The answers obtained on the first questionnaire were collected and analyzed.

In the second Delphi round (second questionnaire), the analyzed answers were then sent back to the experts and scored using a 4-point Likert scale: highly relevant, relevant, irrelevant, and highly irrelevant. The answers were analyzed with a cumulative agreement indicator of $\geq 80\%$. In the third Delphi round (third questionnaire), answers that obtained a cumulative approval of $\geq 80\%$ were returned for final validation, and expert approval was achieved by assessing the appropriateness of each answer component based on the Likert scale. These stages generated the final consensus.

Stage 2: App Development by IT Experts

IT experts developed the app based on the consensus obtained in the first stage. The content validity index (CVI) test involved 5 experts, who were not the experts employed in the previous stage, with the CVI standard of $\geq 80\%$. These participants were experts in nursing, medicine, IT, or language and a parent who had toddlers with stunted growth.

The app was developed beginning with understanding the needs of the target audience through stakeholder meetings with health care professionals and potential users. We defined the app's core features, such as growth monitoring, educational content, and consultation tools. We then chose Flutter 3.13.0 (Google) for its responsive and visually appealing user interface, and then we moved on to designing and prototyping using human-computer interaction principles like accessibility, usability, and user experience. Wireframes were created using Figma 24.33.0 (Figma) to outline the app's layout, and detailed designs were developed focusing on user experience and

navigation. An interactive prototype to simulate how the app will work and gather feedback from stakeholders to make improvements was then built. The app was then developed using Flutter and Dart 3.3.0 (Google). Flutter allowed for a responsive and attractive user interface, while Dart was the programming language used for app development. Firebase was set up for back-end services, including data management and real-time updates, and Firebase Authentication was implemented to manage user log-ins and security. We continuously tested the app to find and fix any issues. This included unit tests for individual parts and integration tests for how different features worked together. The app was prepared for launch by submitting it to the Google Play Store, ensuring it met all guidelines. After the launch, we continued to support the app by fixing bugs, adding new features, and improving performance based on user feedback.

Stage 3: Stunting Super App Evaluation

A pilot study was conducted to evaluate changes in parents' knowledge about stunting prevention after intervention using SEHATI. Knowledge assessment took place using the contents developed in stage 1. In this stage, the pilot study involved 30 participants selected based on the inclusion and exclusion criteria. Inclusion criteria were participants who could use a mobile phone and mothers who have children younger than 5 years. Meanwhile, the exclusion criteria were participants who use iOS software on their mobile phones. In the pilot study, the recommended sample size was at least 12 participants [23]. Changes in knowledge of stunting prevention were assessed, and changes attributed to the use of SEHATI and other educational media were compared. Parents (1) with toddlers aged <2 years (2) who possessed and could operate a smartphone (3) and were willing to participate in the study were enrolled.

The app was given once to respondents, starting with an explanation of the manual book by the research team. After the app was installed and respondents could use the SEHATI app, respondents were given educational interventions to prevent stunting through the app. Respondents could access the app anytime and anywhere because it could be used offline, so it was also suitable for use in rural areas that have limited internet access.

Data Analysis and Statistical Test

Descriptive statistical tests were used to assess the characteristics of the respondents. The results are displayed as mean, SD, and percentage. The results obtained from the consensus of the experts were integrated into an app, and the CVI test was taken with expert judgments. The CVI indicator was considered valid if the value was ≥ 0.78 . Furthermore, bivariate analysis was performed to assess the increase in knowledge in the group using the nonparametric Wilcoxon test and Mann-Whitney test. All data were analyzed using IBM SPSS Statistics for Microsoft Windows version 21 (IBM Corp).

Ethical Considerations

This study received Health Research Ethics Commission approval (#126/UN4.6.4.5.31/PP36/2023). Before the study, all experts received a consent form, which explained the purpose, procedures, benefits, confidentiality, risks of the research, and the right to refuse or freely withdraw participation in the study. All expert data were anonymized. Participants were given compensation in the form of internet data vouchers (US \$18.84).

Results

Delphi Study

The educational theme for mothers consisted of 4 contents with a cumulative agreement presentation of $\geq 80\%$, including preparing prepregnancy nutrition, meeting nutritional needs during pregnancy, routine pregnancy checks, and regular intake of vitamins during pregnancy. Meanwhile, the educational theme for children that met the cumulative agreement presentation of $\geq 80\%$ had 4 contents, namely, exclusive breastfeeding, provision of complementary feeding, routine monitoring of children's growth and development, and complete immunizations. Meanwhile, the theme for environmental health education included 3 contents, with a cumulative agreement presentation of $\geq 80\%$, including environmental cleanliness, parenting, and socioeconomic support.

In stage 1, the Delphi study was conducted to develop a stunting prevention educational app involving 12 experts, and the 11 contents identified were grouped into three major themes, namely, educational content for mothers, children, and the environment (Table 1).

Table . Table 1. Result of stage I of the Delphi study: educational contents for stunting prevention.

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Maternal health educational contents						
Preparing prepregnancy nutrition	Brides prepare nutrition before pregnancy (prepregnancy) by consuming a balanced diet (carbohydrates, vegetables, animal proteins, vitamins, and minerals) and iron tablets at the age of 12 - 18 years with a dose of one tablet per week. Mothers also need to take height and weight measurements to monitor BMI.	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)
Meeting nutritional needs during pregnancy	<p>Pregnant women must meet their nutritional needs by consuming macronutrients and micronutrients.</p> <p>a. Macronutrients</p> <ul style="list-style-type: none"> • Carbohydrates such as rice, cassava, corn, sweet potatoes, and others • Proteins from plants such as beans, tofu, tempe, and others • Proteins from animals such as meat, chicken, eggs, and milk, and others <p>b. Micronutrients</p> <ul style="list-style-type: none"> • Multivitamins contained in vegetables and fruits • Minerals such as calcium, folic acid, iron, and iodine 	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Routine pregnancy check	Mothers routinely undergo pregnancy checks at least six times during pregnancy, as follows: <ul style="list-style-type: none"> • First trimester (gestational age 0 - 12 weeks): 1 time • Second trimester (gestational age >12 - 24 weeks): 2 times • Third trimester (gestational age >24 - 40 weeks): 3 times 	0 (0)	0 (0)	2 (17)	10 (83)	12 (100)
Routine vitamin consumption	Mothers routinely: <ul style="list-style-type: none"> • Take folic acid tablets once a day after meals during pregnancy • Take one iron tablet every day during pregnancy, for at least 90 tablets, to prevent blood deficiency (anemia) and start as early as possible 	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)
Children's health educational content						
Exclusive breastfeeding	Mothers give breast milk exclusively to newborns up to 6 months of age.	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)
Complementary feeding	Mothers feed complementary foods that are adjusted to the age (month) of the child	0 (0)	1 (8)	1 (8)	10 (84)	11 (93)

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Routinely monitor children's growth and development	Mothers routinely monitor the growth and development of children by weighing and measuring the length or height at each visit to the Integrated Service Post with the following frequency: <ul style="list-style-type: none"> • Monthly visit for toddlers aged 0 - 12 months • Every 3 months for toddlers aged 12 - 24 months • Every 6 months for toddlers aged 24 - 72 months • Every 3 months for head circumference measurement at the age of 0 - 12 months • Every 6 months for head circumference measurement at the age of 18 - 72 months 	0 (0)	1 (8)	1 (8)	10 (84)	11 (93)
Complete immunization, vitamin A, and deworming		0 (0)	1 (7)	3 (22)	8 (71)	11 (93)

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
	<p>Mothers routinely take their children for complete immunization, vitamin A supplementation, and deworming with the following schedule:</p> <ul style="list-style-type: none"> • From birth to 24 hours old: hepatitis B, BCG^a, and polio drops 1 • 1 month old: BCG and polio drops 1 • 2 months old: DPT-HB-Hib^b 1 and polio drops 2 • 3 months old: DPT-HB-Hib 2 and polio drops 3 • 4 months old: DPT-HB-Hib 3, polio drops 4, and injectable polio vaccine • 9 months old: measles-rubella • 18 months old: continued measles-rubella and DPT-HB-Hib • Administration of blue vitamin A capsule once at the age of 6 - 11 months • Administration of red vitamin A capsule once every 6 months at the age of 12 - 59 months • Deworming from the age of 12 months, taken twice a year or every 6 months 					
	Environmental educational content					

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Keeping the environment clean	Sanitation, clean latrines, stay away from cigarette smoke and wear proper clothing.	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)

Topic	Prevention components	Likert scale responses (n=12), n (%)				Cumulative agreement, n (%)
		Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Parenting	<p>Parenting plays an important role in preventing stunting. Parenting is divided into <i>asah</i>, <i>asih</i>, and <i>asuh</i>.</p> <ul style="list-style-type: none"> • <i>Asah</i> refers to the stimulation of children's intelligence, such as the provision of educational tools that help them become smarter • <i>Asih</i> refers to efforts to develop a child's affection, spirituality, independence, and need for a sense of security and comfort • <i>Asuh</i> encompasses physical and biological needs, including nutritional requirements, immunization, personal and environmental cleanliness, medical care, and physical activity and play 	0 (0)	0 (0)	3 (25)	9 (75)	12 (100)
Socioeconomic support	<p>Parents must be aware that economic support plays an important role in helping children obtain their nutritional needs. One of the things that can prevent malnutrition is to save money during pregnancy, locally known as <i>Tabungan Ibu Bersalin (Tabulin)</i>. It can be started at the beginning of pregnancy to meet maternity needs and the initial needs of the baby at birth.</p>	0 (0)	1 (7)	3 (29)	8 (64)	11 (93)

^aBCG: Bacillus Calmette-Guérin.

^bDPT-HB-Hib: diphtheria, pertussis, tetanus, hepatitis B, *Haemophilus influenzae* type b pediatric unspecified.

Stunting Super App Development: Content Validity

In the second stage, the validity of the super app contents was evaluated. The contents were assessed by 4 experts from various

disciplines (nursing, medicine, IT, and language) and a parent of children with stunted growth (Table 2).

Table . Quantitative evaluation of SEHATI^a app contents.

Assessment items	Likert scale responses (n=5), n (%)				Cumulative agreement, n (%)
	Highly irrelevant	Irrelevant	Relevant	Highly relevant	
Simple design for easy use	0 (0)	0 (0)	1 (20)	4 (80)	5 (100)
Uses language and sentences that are easy to understand	0 (0)	0 (0)	2 (40)	3 (60)	5 (100)
Provides features based on user categories	0 (0)	0 (0)	1 (20)	4 (80)	5 (100)
Combines images with text	0 (0)	0 (0)	0 (0)	5 (100)	5 (100)
Avoids distracting elements (such as excessive accessories or styles)	0 (0)	0 (0)	2 (40)	3 (60)	5 (100)

^aSEHATI: Sistem Evaluasi Kesehatan Anak Tumbuh Ideal.

There were 13 scoring items using 4 Likert scales (highly irrelevant, irrelevant, relevant, and highly relevant). The validity limit of the app contents was set to a cumulative agreement of $\geq 80\%$, and if the evaluation value was $< 80\%$, then adjustments

were made to the app content. All items in the CVI test met the cumulative agreement presentation ($\geq 80\%$). In addition, the results of the qualitative evaluation of SEHATI are shown in Table 3.

Table . Qualitative evaluation of SEHATI^a content.

Reviewer field	Comments of the reviewers
Nursing	<i>This app has provided educational needs from every critical stage for stunting prevention starting from before pregnancy in mothers until 1000 days after giving birth. In the future, there needs to be regular content updates and addition of information needed by users according to the latest developments in child health issues. [Reviewer Ar]</i>
Medicine	<i>The app is very good; however, it is necessary to add information for adolescent girls and pregnant women and monitor growth and development based on BW/BH, BMI/A, MUAC, and HC. [Reviewer Aj]</i>
IT	<i>The interface of the system is already decent and has met the needs of the users. It needs to consider space and memory upgrade to anticipate increasing users. [Reviewer U]</i>
Indonesian linguist	<i>This app benefits parents to avoid stunting. Its clear and communicative language makes this app easy to use. The design and important information regarding the health of the mother, child, and the environment are displayed very well. This app also has a consultation feature, which makes it easier for users to consult their health if they experience symptoms. Hopefully, it can be useful for the public given its simple operation and economical use. [Reviewer M]</i>
Mother of toddlers with stunted growth	<i>This app is good enough because it covers all stages of development starting from the womb, after birth, and subsequent development. Even so, several components must be added such as myths and facts related to pregnancy and children, foods to be avoided, dos and don'ts, and traditions that may ruin child development. [Reviewer R]</i>

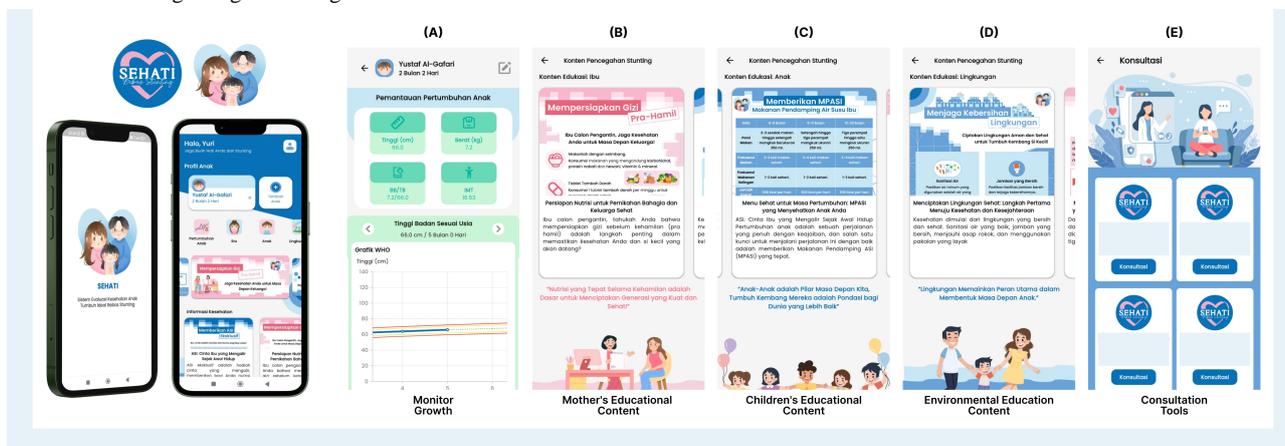

^aSEHATI: Sistem Evaluasi Kesehatan Anak Tumbuh Ideal.

The results showed that content must be updated regularly according to the development of the latest child health issues (nursing). Also, additional information is necessary for adolescent girls and pregnant women and for growth and development monitoring (medicine), and space and storage upgrades are required if the number of users increases (IT). The app language was clear, communicative, and economical in its use (linguist); provided consultation features; and covered all

stages of development. However, some components must be added, including myths and facts about pregnancy, childhood, and inappropriate traditions (mother; Table 3).

This app was named SEHATI (Sistem Evaluasi Kesehatan Anak Tumbuh Ideal, ie, Ideal Growth Child Health Evaluation System), which means a comprehensive, one-stop health intervention app for stunting prevention and management. The features of SEHATI are summarized in Figure 1.

Figure 1. Sistem Evaluasi Kesehatan Anak Tumbuh Ideal (SEHATI) app features. SEHATI is an app designed to simplify child growth monitoring and includes stunting information. Parents can track their children’s growth and ensure their well-being with an easy-to-use interface. (A) Track and display a child’s growth through charts: weight-for-age, length/height-for-age, weight-for-length/height, and BMI-for-age. (B) Informational resources that focus on maternal health to guide mothers in making the right health decisions. (C) Learning materials to support a child’s development and improve health awareness. (D) Information on environmental factors that have an impact on children’s growth. (E) Users can consult with health experts for personalized advice regarding a child’s growth.

Based on the results of the observations and interviews with researchers, the experience of users of this app was good. Respondents were happy because the app contained health

information on stunting prevention that could be accessed easily at any time. This app was helpful for mothers in monitoring child growth, and because the app was equipped with growth

charts, data could be input by mothers themselves every month. In addition, there was a consultation feature that was helpful for mothers in dealing with their children's health.

Pilot Study: Increasing the Knowledge of Stunting Through SEHATI

This stage was conducted to track changes in the knowledge of mothers of toddlers with stunted growth regarding stunting

prevention. A total of 30 mothers who had babies or toddlers and could operate smartphones and the SEHATI app received educational intervention. Their knowledge was evaluated twice: once before education (pretest) and once after education (posttest). The average age of mothers was 29 years and the average age of the children was 6 months. Most participants had a bachelor's degree ($n=20$, 66.7%), with the dominant occupation being a housewife ($n=20$, 66.7%; [Table 4](#)).

Table . Characteristics of the respondents by age, education, and occupation.

Characteristics of respondents	Values
Age of mothers (years; $n=30$)	
Mean (SD)	29 (5.240)
Min-max	17 - 39
Age of children (months; $n=30$)	
Mean (SD)	6 (7.617)
Min-max	1 - 38
Education ($n=30$), n (%)	
Primary school	1 (3)
Junior high school	2 (7)
Senior high school	7 (23)
Undergraduate degree	20 (67)
Occupation ($n=30$), n (%)	
Housewife	20 (67)
Government employee	9 (30)
Self-employed	1 (3)

The statistical test used to determine the difference between pretests and posttests was a 2-tailed t test because the data was normally distributed. The results showed a significant difference after participants received stunting prevention education using

the SEHATI app ($P=.001$), which means there was an increase in maternal knowledge after participating in education with the app ([Table 5](#)).

Table . Differences in knowledge before and after stunting prevention education.

	Mean test score (SD) ^a	SE	P value ^b
Scores ($n=30$)			.001
Pretest	14.63 (1.326)	0.242	
Posttest	16.20 (1.495)	0.273	

^aThe number of pretest and posttest questions was 20.

^bA paired sample, 2-tailed t test was done to determine significance.

Discussion

Preparation of Stunting Prevention Education Contents

Initially, the Delphi technique was used in a series of studies by the RAND Corporation in the 1950s [24]. It is one of the methods that the group used to survey and gather the opinions of experts on a particular topic [25]. In this study, a combination of classic and web-based Delphi techniques were used, which began with open questions to experts, and the study was conducted in three rounds. The classic Delphi used an

open-ended questionnaire administered in three rounds, whereas the web-based Delphi used Google Forms distributed through WhatsApp [26]. The Delphi study was conducted in 3 rounds as adapted from Abrar et al [27].

The preparation of the app's contents involved 12 experts, who were selected based on education level, work experience, and stunting training certificates, and they extracted three major themes, namely, maternal, child, and environmental health educational content. In addition [28], the authors involved parents who had experience in caring for toddlers with stunting, provided information about caring for toddlers with stunted

growth, and gained knowledge on preventing children from experiencing the adverse effects of stunting again [29].

A total of 11 themes on stunting prevention were identified in the Delphi study. This is in line with the component of needs regarding stunting prevention in terms of maternal health in the study by Ekayanthi and Suryani [30]. In their study, the nutrition and health of pregnant women were improved by meeting the requirement for macronutrients and micronutrients, giving nutritional supplements (iron tablets), and regular monitoring of the health of pregnant women.

Stunting prevention based on children's health is carried out by good parenting, exclusive breastfeeding, intake of appropriate complementary foods, immunization, provision of a psychosocial stimulus to children, and basic health care [31]. Environmental education also contributes to stunting prevention by practicing clean and healthy living behavior, increasing access to clean water and sanitation facilities, and maintaining environmental cleanliness [32].

Content Validity Evaluation of SEHATI

In the second stage, the validity of the app was tested by expert judgment. The authors chose Android as the educational medium because of its effectiveness as an information tool and its increasing use for educational media [24]. According to Putra et al [33], the use of Android-based educational media is an effective medium to increase public knowledge and attitudes toward stunting. In line with this finding, Fitriami and Galaresa [34] found that Android is a comprehensive means that helps improve maternal nutritional behavior.

In this study, all items in the CVI assessment component on the SEHATI app met the cumulative agreement percentage ($\geq 80\%$), and they recommended updating the contents regularly so that mothers have easy access to the latest information regarding child development issues and stunting prevention [33]. Further, young women need additional information to prepare them for the next stage of life as mothers so that stunting can be prevented [35]. In addition, more content about pregnancy myths and facts must be considered to prevent fetal stunting in mothers believing such myths [36].

In addition, the SEHATI app's sustainability plan is that the development team will collaborate with health stakeholders for sustainable maintenance. Funding and maintenance of the

SEHATI app will be charged to stakeholder institutions. SEHATI is designed to complement existing stunting prevention programs in Indonesia through comprehensive growth monitoring features and easy access to educational materials. SEHATI also strengthens the government's efforts to monitor and improve the nutritional status of children. The app supports existing systems by providing structured, real-time growth data that can be accessed by relevant parties for further analysis under certain conditions. SEHATI also allows users to consult directly with health experts, facilitating coordination and early intervention in high-risk cases.

Change in the Level of Knowledge

The results showed that the participants demonstrated an increase in knowledge after using the SEHATI app. The urgency of disseminating knowledge has been stated in the Regulation of the Minister of Health of the Republic of Indonesia No. 67 of 2016, which focuses on increasing true and comprehensive knowledge regarding prevention, transmission, treatment, and a clean and healthy lifestyle [37]. The app is considered effective because it is associated with efficient use of time and energy in providing education to parents who have malnourished toddlers [29]. In addition, Android apps can be accessed by phone and by everyone, allow for multitasking, and easily notify parents or the community [34]. Regarding app use by parents, a reliable, up-to-date, and evidence-based app is crucial, particularly when using apps in the context of routine care for children [38].

Limitation

The limitation of this study was related to the sampling approach, in which experts were chosen based on the researchers' judgment. Thus, to prevent this bias, a purposeful sampling technique was used in the selection of expert panelists, who were clinically competent and participated voluntarily.

Conclusions

The Delphi study resulted in 11 consensus themes for stunting prevention. The results were integrated into the SEHATI app, which was assessed using the CVI and the cumulative percentage of agreement from 4 experts in nursing, medicine, IT, language, and a parent of toddlers with stunted growth was $\geq 80\%$. SEHATI as a stunting prevention educational app contributes significantly to the increase in stunting knowledge for mothers who have toddlers with stunted growth.

Acknowledgments

The authors thank all who participated in this study. The authors also wish to thank their colleagues at the Faculty of Nursing who have helped in this study and the Hasanuddin University Research and Community Service Institute.

Authors' Contributions

KAE, NF, AIL, NH, AJ, HA, and AB all equally participated in the preparation of proposals, research processes, and preparation of the final report.

Abstract

Background: Integrating health information into university information systems holds significant potential for enhancing student support and well-being. Despite the growing body of research highlighting issues faced by university students, including stress, depression, and disability, little has been done in the informatics field to incorporate health technologies at the institutional level.

Objective: This study aims to investigate the current state of health information integration within university systems and provide design recommendations to address existing gaps and opportunities.

Methods: We used a user-centered approach to conduct interviews and focus group sessions with stakeholders to gather comprehensive insights and requirements for the system. The methodology involved data collection, analysis, and the development of a suggested workflow.

Results: The findings of this study revealed the shortcomings in the current process of handling health and disability data within university information systems. In our results, we discuss some requirements identified for integrating health-related information into student information systems, such as privacy and confidentiality, timely communication, task automation, and disability resources. We propose a workflow that separates the process into 2 distinct components: a health and disability system and measures of quality of life and wellness. The proposed workflow highlights the vital role of academic advisors in facilitating support and enhancing coordination among stakeholders.

Conclusions: To streamline the workflow, it is vital to have effective coordination among stakeholders and redesign the university information system. However, implementing the new system will require significant capital and resources. We strongly emphasize the importance of increased standardization and regulation to support the information system requirements for health and disability. Through the adoption of standardized practices and regulations, we can ensure the smooth and effective implementation of the required support system.

Introduction

In recent years, there has been a growing body of research highlighting the profound impact of health and well-being on students' academic achievements [1]. Numerous studies have documented the significance of maintaining good physical and mental health in order to support students' overall well-being and optimize their educational outcomes [1-3]

One particularly alarming trend is the increasing prevalence of stress, depression, and anxiety among students. These mental health challenges have been shown to have detrimental effects on students' physical health and their academic performance

[1]. Consequently, it has become essential to address these issues and implement effective strategies to support students' well-being throughout their educational journey [4].

Furthermore, students with disabilities and special needs form an integral part of university life. Inclusive education is not only a moral imperative but is also mandated by standards and regulatory requirements. However, students with disabilities often face unique challenges that can hinder their full participation in academic and social activities on campus. Navigating the complex landscape of campus resources, overcoming the stigma associated with invisible and physical

disabilities, and combating feelings of isolation are just a few of the obstacles that these students encounter [5-7].

In light of these challenges, it is crucial to explore and address the role of health information technologies in supporting the health and well-being of university students. Despite recent advancements in health information technologies, there is a noticeable gap in research focusing on health information and university information systems. These systems play a central role in managing various aspects of university life, including academic support, administrative processes, and campus resources. However, the incorporation of health information into these systems remains relatively unexplored.

Recent studies highlight the vital role of information and communication technologies (ICTs) in supporting students with disabilities in higher education. Fichten et al [8] discuss how, despite generally adequate support on campuses, significant gaps exist in home and e-learning environments. Sharby and Roush [9] propose a decision-making model tailored to the needs of allied health students, emphasizing tailored accommodations and maintaining academic integrity. Stein et al [10] show how a knowledge-based system can effectively support disability accommodations under the Americans with Disabilities Act (ADA), enhancing institutional support and compliance. These insights reveal an urgent need for universities to improve ICT integration and support to foster inclusivity and aid students with disabilities. Furthermore, these gaps underline the necessity for better adaptive technology access off campus and increased faculty training in disability accommodation practices.

Understanding the potential benefits and challenges associated with integrating health information into university information systems is essential for enhancing the overall support and

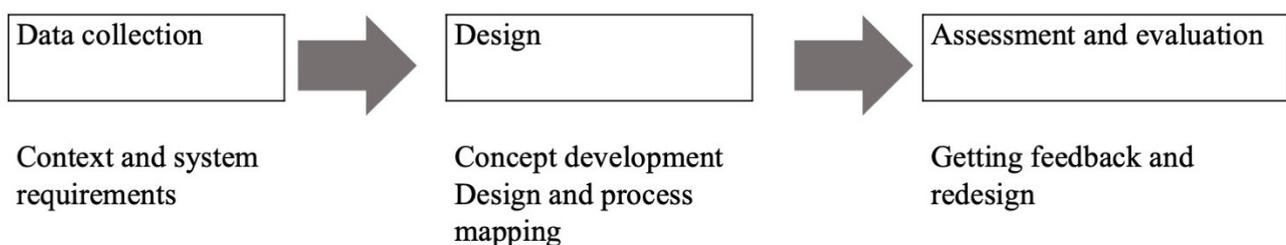

well-being of students. By leveraging the capabilities of modern information systems, universities can better address the unique health needs of their student population, promote inclusivity, and empower students to achieve their full academic potential. The analytical decision-making model proposed by Sharby and Roush [9] offers a comprehensive theoretical framework for integrating health information into university information systems. This model's systematic approach to accommodating diverse needs can be adapted to evaluate how health data are integrated into university information systems, ensuring these systems meet the varied requirements of students, faculty, and staff effectively. By applying this model, universities can better identify gaps and implement tailored solutions that enhance accessibility and functionality within their health information ecosystems.

Therefore, the aim of this study is to investigate the current state of health information integration within university information systems and provide design recommendations. By examining the existing system and stakeholders needs, this study seeks to shed light on gaps and opportunities for integrating health information technologies into university systems. The findings of this research will contribute to the growing body of knowledge in health information technologies and inform the development of strategies and interventions aimed at improving student well-being in higher education settings.

Methods

In this study, we used a user-centered approach to integrate health data into the university information system [11,12]. The methodology consisted of data collection, design, and assessment and evaluation [13] (Figure 1). The following subsections describe each phase in detail.

Figure 1. Summary of the study design steps describing each phase.

Data Collection

To gather comprehensive insights and users' requirements for the system, a series of interviews and focus group sessions were conducted with stakeholders. The interview phase involved engaging with a diverse group of participants, including 3 academic advisors, 3 administrative staff working on student affairs related to health and academic performance, 2 physicians/health counselors, 3 health professionals, and 4 teaching faculty members. The participants' experience ranged from 6 to 13 years. These stakeholders were chosen based on their expertise and previous involvement in activities and cases related to students' health information. In the methodological design of this study, we considered content saturation to be achieved within the 15-participant sample, as no additional

unique insights were observed beyond this point. Consistent with findings from the usability testing literature, studies such as that by Faulkner [14] have shown that increasing the sample size from 5 to 10 participants can capture up to 95% of usability issues, thus providing a robust basis for our sample size decision and ensuring comprehensive data collection for system evaluation.

Additionally, 2 focus groups were conducted with 10 students. All students were undergraduates, and their age ranged from 19 to 24 years. The aim of these focus groups was to understand students' perspectives and needs.

Before the interviews, participants were given introductory information about the research project. Participation was voluntary, and they were allowed to skip questions, withdraw,

or end the interview at any time without any conditions. No compensation was offered for participation. Prior to initiating the interview, participants were briefed on the study's scope and provided their informed consent. The interviews were unstructured, and probing questions were introduced as needed (Multimedia Appendix 1). The main areas covered during the interviews are described in the following sections.

Background and Context

We sought to understand the stakeholders' roles and responsibilities, as well as their relationship to the student health information system being developed.

Goals and Objectives

Our aim was to identify the stakeholders' primary goals, objectives, and desired outcomes related to the system. This included understanding what they hoped to achieve or improve through the use of the system.

System Requirements

We gathered requirements from stakeholders regarding the desired functionalities, features, and capabilities of the health information system. This included understanding the specific data elements, information flows, and interactions that are important to stakeholders.

Use Cases and Workflows

We examined the typical use cases and workflows of stakeholders within the context of the health information system. This involved understanding how stakeholders interact with the system, the sequence of steps they take, and any dependencies or constraints they encounter.

Data Privacy and Confidentiality

This involved discussing stakeholders' concerns and requirements related to data privacy, confidentiality, and compliance with relevant regulations. This included understanding their expectations for data protection, access control, and confidentiality.

Initial Phase and Workflow Analysis

During the initial phase of data collection, the focus was on gathering system requirements, as well as understanding the use cases, flow of information, restrictions, and other pertinent factors. The interviews and focus groups were guided by open-ended questions and prompts to encourage participants to provide detailed insights and suggestions.

The data collection process also included an analysis of the existing workflow and an artifact analysis. The artifacts included the existing forms, screenshots, templates, instructions, and guidelines used for data gathering and communication.

Design

Following the data collection phase, thematic analysis was conducted to identify patterns, common themes, and user requirements [15]. This analysis informed the design phase, where a conceptual design of the workflow was developed. The design process involved translating the gathered requirements into system functionalities and a workflow. In addition, an artifact analysis was conducted to examine existing forms,

templates, and guidelines related to the workflow. This analysis involved systematically reviewing and coding these documents to identify recurring themes, inefficiencies, and opportunities for improvement. The artifacts were evaluated based on criteria such as clarity, efficiency, and alignment with the workflow.

To establish a holistic approach, the design phase was informed by the systems model of Bowman and Marzouk [16] for implementing the ADA in higher education. Their model, based on general systems theory, encompasses a comprehensive structure with input, throughput, and output subsystems. By adopting this systems model, the workflow design addressed core components such as accessibility, learning resources, and quality control.

To enhance the design methodology, insights were incorporated from previous studies to provide a broader understanding of user requirements and system functionalities. Fichten et al [8] contributed valuable information on variables related to how well the ICT needs of students with different disabilities are being met at institutions of higher education, at home, and in e-learning contexts. Their work also explored the disciplines and programs pursued by students with varying disabilities and the specialized ICTs used. Stein et al [10] provided a knowledge-based system design to assist university administrators in meeting the requirements of disability-related legislation. This ensured that the proposed system was comprehensive and aligned with compliance standards. Finally, Sharby and Roush [9] delivered an analytical decision-making model for addressing the specific needs of allied health students with disabilities, offering accommodations that are both practical and inclusive.

Assessment and Evaluation

Once the conceptual design was drafted, participants were presented with the proposed design and concept. Their feedback and suggestions were collected to ensure their perspectives were considered in the development process. An iterative and agile approach was adopted to incorporate the feedback received from participants.

Ethical Considerations

The study was approved by the ethical review committee at Jazan University (REC-45/11/1100). Participation for both staff and students was entirely voluntary, and no compensation was provided to participants. Participants were allowed to withdraw at any time without any conditions. Informed consent was obtained and all data collected were anonymized to ensure the privacy and confidentiality of participant information.

Results

Current System

Based on our analysis, we have identified several systemic challenges and shortcomings in the existing system, which are summarized in the following sections.

Variation and Inaccuracy of Student Information

We found that the information entered by students varies in nature and is often incomplete or inaccurate. This creates

additional work for university staff and committees, who must gather more information and assess individual cases. Students tend to understate or overstate their conditions, further complicating the process.

Absence of University Health Care Center Representation

Currently, the university health care center is not involved in the process. When students require medical reports for absences or other requests, they upload the report from their accounts. This lack of integration creates inefficiencies and delays in the system.

Exclusion of Academic Advising Unit

The academic advising unit is not part of the process, which means that advisors cannot proactively identify or address students' needs unless a request is specifically referred to them by a staff member. This disconnect hinders effective support and guidance for students.

Neglect of Disability-Related Accommodations and Student Needs During Registration

The current system does not adequately consider disability-related accommodations and students' individual needs during the registration and enrollment process. There is no distinction made between different classrooms or labs, nor is there information on the availability of relevant resources. This oversight can lead to accessibility issues and hinder students' academic experience.

Design Considerations

Our results identified several requirements that need to be taken into consideration for integrating health-related information into the student information system. We categorized these needs into the following 4 categories: privacy and confidentiality, timely communication, workload and automation, and disability resources.

Privacy and Confidentiality

Our results revealed that students' health information requires a particular degree of privacy. Disseminating such information indiscriminately among all stakeholders encompassed within the system or involved in the process may not align with best practices. To overcome this challenge, we proposed a system that empowers the student advising unit. This system allows for the evaluation of received information, assessment of specific requirements, and addition of labels, tags, or notes detailing students' needs. This will enable the effective safeguarding of the privacy of students. Additionally, in scenarios where medical reports are needed by the university administration or external committees for request assessments or legal matters, exceptions can be formulated to ensure appropriate sharing.

Timely Communication

Our interviews with stakeholders highlighted recurrent instances where students had a low attendance rate due to health conditions that required regular hospital visits, such as sickle cell anemia or cancer. We found that these students were sometimes reluctant to address their needs openly. Many were only discovered during the consultation session with the

student's advisor after being called for a low attendance rate. Providing detailed health information about students early on in their academic journey can help student advisors support them better.

Workload and Automation

In our study, we discovered that a significant portion of the tasks related to managing health information were being carried out manually. This manual approach posed several challenges, including inconsistencies and variations in practice, as well as an increased workload for staff members. To address these issues and streamline the process, the proposed workflow emphasizes the importance of automating certain activities. For example, by implementing automation, we can effectively match students' needs to appropriate classrooms; ensure the availability of necessary equipment and infrastructure; send timely notifications for attention; calculate students' health measures, such as stress, depression, and anxiety; and provide tailored advice and recommendations to support students in overcoming difficulties. By leveraging automation, we can alleviate the burden on staff members and enhance the overall efficiency and effectiveness of managing health information for a large number of students.

Disability Resources

While some university systems contain sections for disabilities, information regarding specific health conditions or academic needs are not always incorporated into academic information systems [17]. Moreover, the inclusion of disability information is not fully streamlined or integrated in the workflow, such as by automated flagging and registering of students with a disability that need specialized resources and accommodations in unequipped rooms or laboratories. These needs span from relatively minor adjustments such as left-handed tables to conditions that may need wheelchair accessibility or technological aids for visual and auditory impairments. The integration of health conditions within the academic information system is recommended to empower administrators and registrars in the seamless allocation of classrooms and laboratories suitably equipped to address these distinctive needs.

Data and Information

Based on the interviews, it is evident that the design of student information systems needs to consider various aspects of students' health. In this study, we categorized the types of information required into 3 categories, which we describe in the following sections.

Information Related to Disabilities and Special Needs

This category pertains to students with disabilities; examples include physical and mental disabilities, as well as vision and hearing impairments. It is crucial to consider the specific needs of these students to ensure an inclusive educational environment. Understanding their disabilities and special needs allows educational institutions to provide appropriate accommodations and support services, promoting equal opportunities for learning and participation.

Information Related to Health and Chronic Conditions

This category encompasses both preexisting chronic health conditions that may impact a student's educational journey and health-related events that might affect their attendance. Our results suggest that students with chronic health conditions face unique challenges in maintaining academic progress, managing their health, and navigating the educational system. Incorporating information about these conditions into students' information systems enables educational institutions to provide interventions, accommodations, and support tailored to individual needs.

Information About Continuous Health Measures

While the previous 2 categories focus on students with specific health issues, we propose that continuous health measures should

be included for all students. These measures may involve assessing stress, anxiety, and depression levels. This can be very valuable for monitoring and addressing mental health concerns in educational settings to enhance overall well-being, academic performance, and retention rates. Collecting data on continuous health measures can facilitate early intervention and the implementation of appropriate support systems.

Workflow Description

To design the workflow, we separated the process into two different processes: (1) a health and disability system and (2) quality of life (QoL) and wellness measures (Table 1).

Table 1. Description of the data needed and frequency of collection.

Process and data	Collection frequency
Health and disability system	
Information related to disability and special needs	Entered once at the beginning of enrollment and updated as needed
Information related to health and chronic conditions (preexisting chronic health conditions)	Entered once at the beginning of enrollment and updated as needed
Information related to health and nonchronic conditions (health-related events)	Entered as needed
QoL^a and wellness system	
Information about continuous QoL and wellness measures including stress, depression, and anxiety	Systemic collection, once every semester

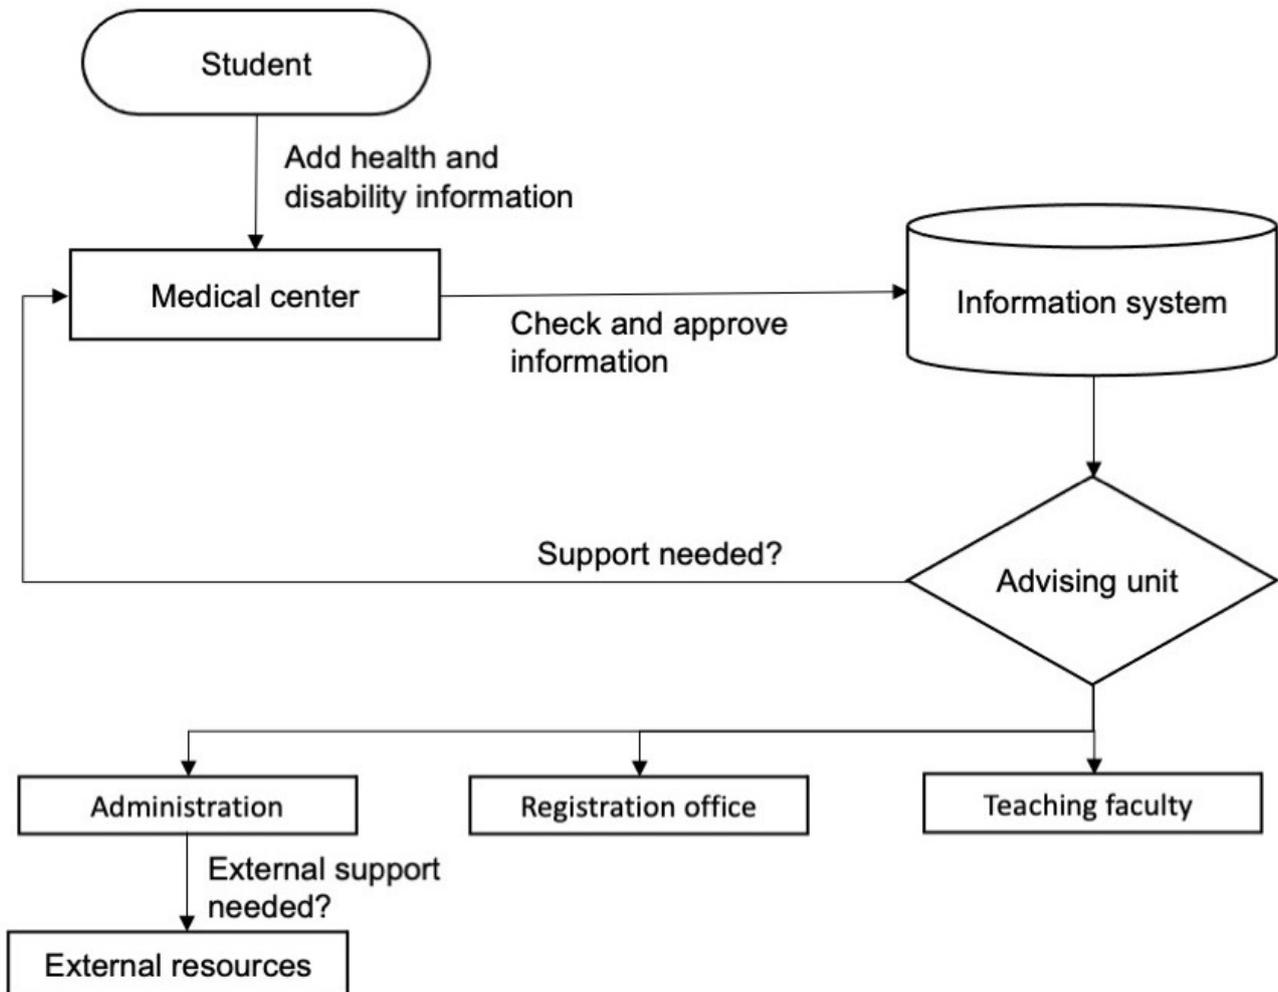

^aQoL: quality of life.

Health and Disability System Workflow

Information related to disability and special needs are entered by students for health center review and approval (Figure 2). The university health center approves and enters the students' health-related information. Based on the type of disability selected, the system suggests a classroom or laboratory based on the availability of necessary accommodations that the student

may need, including academic, technological, or administrative needs. The advising unit receives notification of registrations that have a mismatch between disabilities and resources for further attention. If needed, the student advising unit identifies the necessary accommodation that a student may need and sends messages to communicate with the registration office, administration, and teaching faculties.

Figure 2. Health and disability system workflow.

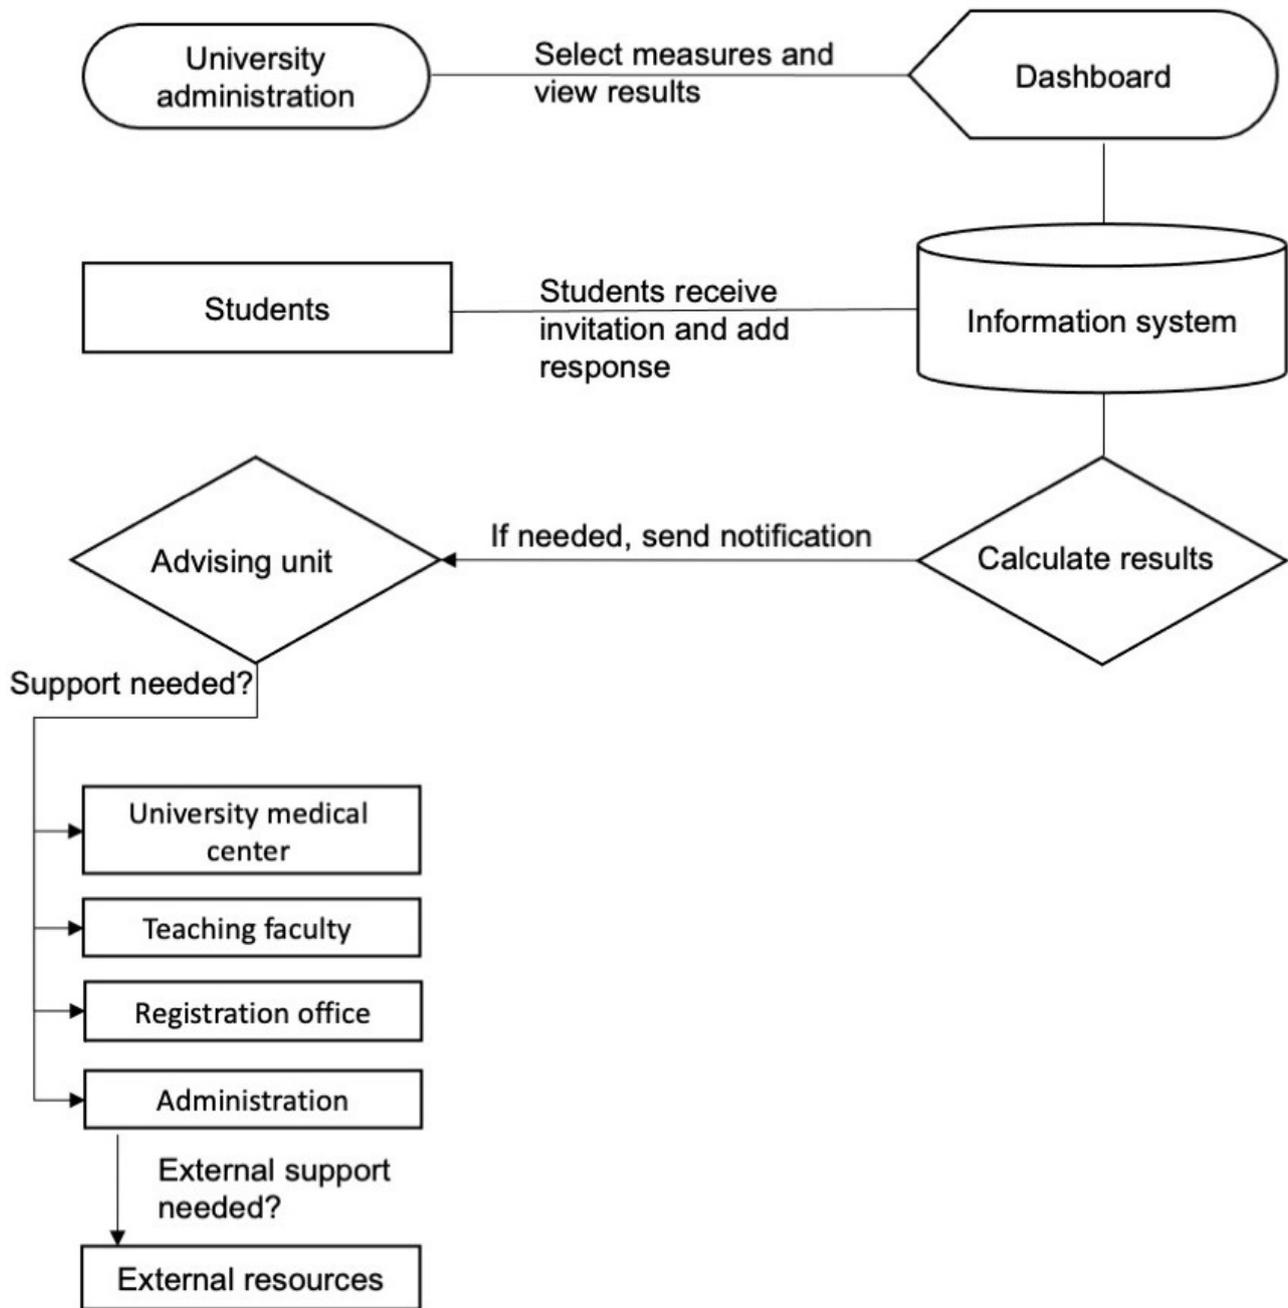

QoL and Wellness System Workflow

The university administration selects the health measures they are interested in and specifies the frequency of measurement (Figure 3). Students receive the invitation and complete their responses. The university administration uses the dashboard to

view the results, including summary information and a data overview. Responses with low scores that needs attention are identified by the system, triggering a notification that is sent to the advising unit for attention. The advising unit reviews the triggered student response and takes the necessary action.

Figure 3. Quality of life and wellness system workflow.

Discussion

Principal Findings

In this study, we investigated the current status of integrating health and disability information within university systems, identified the existing gaps, and provided design considerations. Using a user-centered design approach, we assessed the impact of these design considerations on students' success and inclusion. Our findings revealed several challenges. These challenges include privacy concerns, underidentification of stress, anxiety, and depression, and reluctance among students with hidden disabilities to disclose their conditions due to fear of stigma and discrimination. Our user-centered design approach addressed these issues by emphasizing the role of advising units in maintaining privacy and facilitating support. Additionally,

the design focused on resource allocation to meet the diverse needs of students with various disabilities, ensuring accessibility and adaptive learning support. By incorporating health and disability information into university systems, the proposed design aims to enhance inclusivity, improve resource allocation, and promote better academic outcomes for all students. In the subsequent sections we discuss these findings and provide recommendations for future work.

Incorporating health and disability information is crucial for promoting students' academic success. However, effectively integrating this information into existing systems remains challenging. To address this challenge, there is a need to incorporate the use of health and disability information into the academic process and daily activities. The appropriate inclusion and use of health and disability information within university

information systems offers a promising approach to integrate these data into daily tasks and processes, leading to enhanced effectiveness and improved outcomes. In our study, we adopted a user-centered approach to design the integration of health and disability information into university information systems. This approach prioritizes the needs and perspectives of users, ensuring that the system is tailored to their requirements and preferences. By considering the user experience and incorporating user feedback throughout the design process, we designed a system process that effectively incorporates health and disability information, ultimately enhancing its usability and impact on student success.

Our study uncovered many challenges in the existing system. Among these challenges was the privacy and confidentiality of students' health information. While obtaining knowledge about students' health events is essential for providing adequate support and accommodation, some students were reluctant to share their health information due to concerns about privacy breaches, stigma, or fear of discrimination.

Another significant challenge was the underidentification and underdisclosure of psychological conditions such as stress, anxiety, and depression among students. Many students perceive stress and anxiety as a normal part of the academic journey and may not seek professional help to differentiate between healthy stress and unhealthy stress. The systematic collection of stress, anxiety, and depression data via validated measures offers great potential for timely interventions and support. Furthermore, students with hidden disabilities often encounter barriers that hinder their university experiences [18]. Due to a desire to avoid the label of "disability," many students with invisible disabilities choose not to access the supports they are entitled to, which can hinder their academic success [18,19].

To address these challenges, the proposed design emphasizes the role of student advising units in facilitating support while maintaining students' privacy. Advising units can play a crucial role in creating a safe and supportive environment where students feel comfortable sharing their health information and accessing the necessary support services [20,21]. By establishing trust and providing guidance, advising units can help students navigate the system while respecting their privacy needs.

One of the key use cases found during interviews was the allocation of resources to meet the diverse requirements of students with disabilities. It was evident that different types of disabilities present unique needs and challenges. For instance, students with hearing or vision impairments may require special technological resources to facilitate their learning experience [22,23]. On the other hand, students with physical disabilities require accessibility measures, such as wheelchair access, that should be available in various locations across the campus.

Furthermore, the interviewees emphasized the importance of addressing the adaptive learning needs of students. This includes considering students with conditions such as cognitive disabilities and other health conditions that may impact their attendance [21]. While the specific needs may vary in each case, being aware of these needs is crucial for effective preparation and support.

By incorporating health and disability information into the university information system, administrators and faculty members can gain a comprehensive understanding of the diverse requirements of students. This knowledge enables them to allocate resources more effectively and provide appropriate support, ultimately promoting inclusive education and enhancing student success [20,21].

In order to ensure comprehensive inclusion and accessibility, it is crucial for accreditation bodies and policy frameworks to address the needs of individuals with disabilities. While physical accommodations such as wheelchair access, left-handed writing tables, and disability-friendly bathrooms are typically addressed in these standards, there appears to be a significant gap in incorporating disability-related information into IT standards and guidelines. Despite the growing reliance on IT in various domains, there is a lack of explicit guidance on how to handle disability-related information and promote its integration into IT systems. This oversight is concerning given the potential of IT to enhance accessibility and empower individuals with disabilities. By failing to address the inclusion of disability-related information, accreditation bodies and policy frameworks miss an opportunity to ensure equal access and participation for all.

While the current academic accreditation includes requirements related to students' disabilities in the physical environment, such as wheelchair access, it does not address requirements related to student information systems [24]. To address this gap, it is essential for accreditation bodies and policy guidelines to recognize the importance of incorporating disability-related information into IT standards. This could involve establishing guidelines for designing accessible user interfaces, ensuring compatibility with assistive technologies, and promoting the provision of alternative formats for individuals with sensory impairments. Additionally, the safe handling and protection of disability-related data should be emphasized to safeguard the privacy and confidentiality of individuals with disabilities.

By actively addressing the inclusion of disability-related information within IT standards, accreditation bodies and policy frameworks can contribute to a more inclusive and accessible society. This proactive approach will enhance the usability and effectiveness of IT systems, promoting equal opportunities and empowering individuals with disabilities to fully participate in various aspects of life.

Limitations and Future Work

The proposed design offers potential solutions to address the issue of late discovery of health-related cases through systematic data collection and communication with student health clinics. However, challenges persist due to students' reluctance to disclose their health information out of concerns related to privacy breaches, stigma, and fear of discrimination.

The potential side effects of health information disclosure are a crucial area that requires careful attention. The threat of privacy breaches, stigma, and discrimination needs to be carefully assessed, and risk management strategies should be established to ensure the protection of students' privacy and prevent any negative consequences.

Although the design process described here incorporated user input, our study was limited to a relatively small sample size. For future work, we recommend prototype usability testing and evaluation of the redesigned model with a larger and more diverse group of users. This would provide a broader range of perspectives, facilitating further evaluation and improvements to the design. In addition, interpretation of our findings should be approached with caution, as the homogeneity of the participant pool, all drawn from a single institution, may limit the generalizability of our results

Future studies should also explore strategies to address privacy concerns, enhance security measures, and develop clear communication strategies to alleviate students' fears regarding the disclosure of their health information. Additionally, assessing the impact of the proposed design on student outcomes, such as academic performance and well-being, would provide valuable insights into its effectiveness and usefulness.

Conclusion

In conclusion, our study has identified several shortcomings in the current process of handling health and disability data. Based on our findings, we recommend implementing a new, redesigned process that addresses these issues. Effective coordination among stakeholders is crucial for the success of this process, and redesigning the university information system is essential for organizing and streamlining the workflow.

While implementing these changes will require significant resources and commitment, we strongly advocate for increased standardization and regulation to support information system requirements related to health and disability. By adopting standardized practices and regulations, we can ensure that the necessary information system is in place to effectively support these needs.

Acknowledgments

The author would like to thank all participants who participated in this research. The author also extends their appreciation to the King Salman Center for Disability Research for funding this work through research group KSRG-2023-237. The funding agency had no influence on the design or outcome of this work.

Abstract

Background: Low back pain (LBP) is a costly global health condition that affects individuals of all ages and genders. Physical therapy (PT) is a commonly used and effective intervention for the management of LBP and incorporates movement assessment and therapeutic exercise. A newly developed wearable, fabric-based sensor system, Motion Tape, uses novel sensing and data modeling to measure lumbar spine movements unobtrusively and thus offers potential benefits when used in conjunction with PT. However, physical therapists' acceptance of Motion Tape remains unexplored.

Objective: The primary aim of this research study was to evaluate physical therapists' acceptance of Motion Tape to be used for the management of LBP. The secondary aim was to explore physical therapists' recommendations for future device development.

Methods: Licensed physical therapists from the American Physical Therapy Association Academy of Leadership Technology Special Interest Group participated in this study. Overall, 2 focus groups (FGs; N=8) were conducted, in which participants were presented with Motion Tape samples and examples of app data output on a poster. Informed by the Technology Acceptance Model, we conducted semistructured FGs and explored the wearability, usefulness, and ease of use of and suggestions for improvements in Motion Tape for PT management of LBP. FG data were transcribed and analyzed using rapid qualitative analysis.

Results: Regarding wearability, participants perceived that Motion Tape would be able to adhere for several days, with some variability owing to external factors. Feedback was positive for the low-profile and universal fit, but discomfort owing to wires and potential friction with clothing was of concern. Other concerns included difficulty with self-application and potential skin sensitivity. Regarding usefulness, participants expressed that Motion Tape would enhance the efficiency and specificity of assessments and treatment. Regarding ease of use, participants stated that the app would be easy, but data management and challenges with interpretation were of concern. Physical therapists provided several recommendations for future design improvements including having a wireless system or removable wires, customizable sizes for the tape, and output including range of motion data and summary graphs and adding app features that consider patient input and context.

Conclusions: Several themes related to Motion Tape's wearability, usefulness, and ease of use were identified. Overall, physical therapists expressed acceptance of Motion Tape's potential for assessing and monitoring low back posture and movement, both

within and outside clinical settings. Participants expressed that Motion Tape would be a valuable tool for the personalized treatment of LBP but highlighted several future improvements needed for Motion Tape to be used in practice.

low back pain; physical therapy; physical therapist; wearable sensor; technology acceptance model; motion tape; kinesiology tape

Introduction

Prevalence and Impact of Low Back Pain

Low back pain (LBP) is one of the world's leading causes of disability [1-3]. In 2019, there were approximately 568.4 million prevalent cases, 223.5 million incident cases, and 63.7 million cases of years lived with disability owing to LBP reported globally [4]. LBP affects all ages and genders, but its prevalence increases with age, peaking at the age of approximately 45 to 54 years [4]. Approximately 70% to 85% of adults are expected to experience at least 1 episode of LBP in their lifetime [5]. Once predisposed to LBP, individuals are twice as likely to experience recurrent episodes of LBP [6]. Annually, LBP in the United States results in 149 million missed work days [7]. The total costs of LBP worldwide amount to approximately US \$100 billion a year, with two-thirds of this amount owing to lost wages and decreased work productivity [8].

Treatment of LBP With Physical Therapy

Physical therapy (PT) is a common, effective, evidence-based treatment for LBP [9,10]. Specifically, active interventions including exercises prescribed by a physical therapist are effective for prevention and treatment of LBP [11,12]. During an initial examination, a physical therapist can identify musculoskeletal and neuromuscular impairments associated with the LBP problem by conducting assessment of the patient's posture and movement. Then, the physical therapist and patient can work together to promote strength, stability, and mobility with in-clinic sessions and an assigned home exercise program with the goal of decreasing pain and disability [10,13]. Monitoring the patient's posture and movement can provide a basis for determining individualized factors associated with the LBP problem, which can then be addressed through targeted interventions.

Incorporation of Technology in PT

Whether at home or at work, specific movement patterns that are performed repeatedly have been identified as a significant risk factor for the development and persistence of LBP [2,14,15]. These movement patterns of the low back region can be characterized by evaluating the angle, velocity, and acceleration [16] and can assist in LBP diagnosis, treatment, and prevention. There are several approaches to monitoring spine posture and movement. Generally, when conducting a PT examination, clinicians visually monitor posture and movement or use tools that measure the range of movement such as goniometers or inclinometers [17], but an alternative approach is to use technology to help better quantify the objective measures of spine posture and movement and offer potential benefits such

as remote monitoring [16,18,19] while the patient is away from the clinic.

Technologies for Monitoring LBP

To date, existing technologies used to measure spine posture and movement in research and practice include optical motion capture, inertial measurement units (IMUs), and other wearable sensors [20-22]. Despite the variety of systems available, they generally present ≥ 1 limitation. Optical motion capture systems offer great precision and accuracy in monitoring human movement. However, their applications are limited owing to space needs, cost, and level of expertise needed. IMUs are portable devices that measure metrics such as acceleration and orientation [23] and include a variety of wearable sensors such as accelerometers, gyroscopes, and magnetometers, making them ideal for collecting data in a free-living environment. However, when used for monitoring human movement, IMUs have several limitations including decreased accuracy and precision for measuring slow movements [24,25], difficulty with measuring the axial plane movement accurately, inability to account for the multisegmented nature of the spine [26], and the need for multiple IMUs to triangulate posture and movement of a segment that can be cumbersome to the wearer [27].

Motion Tape

Owing to the limitations of existing sensor systems for measuring spine posture and movement, there is a need to explore new sensor innovations to address this issue. Ideally, such an approach would be wearable, unobtrusive, and usable in a clinical environment during PT sessions and in a person's natural environment to support home-based care. Another desired requirement would be high accuracy while collecting posture and movement data for a prolonged period.

Motion Tape, developed by Loh and Lin [28], is a disposable, self-adhesive skin-strain sensor system made using graphene nanosheets coated onto commercially available kinesiology tape (also known as K-Tape) [29-33]. Motion Tape has piezoresistive properties based on the deformation of the integrated graphene nanosheets in the tape that makes it sensitive to strain [33]. In previous studies, Motion Tape has demonstrated stable performance under cyclic strains [33,34]. In addition, the Motion Tape sensor system has been tested on human participants [33,34], displaying accuracy in measuring skin strains and angles across biceps, knees, shoulders, wrists, and various other body regions when compared with IMUs and skin strains estimated using optical motion capture systems [35]. Overall, Motion Tape offers noninvasive, comfortable, and practical skin-strain measurements and can comprehensively capture complex movements and muscle engagement, especially when applied as a network of sensors [35].

Motion Tape for a Low Back Use Case

When used for a low back use case, Motion Tape provides a means to capture the lumbar spine's multisegmental nature and multiplanar movements [36]. Motion Tape's low-profile and stretchable nature allows it to be worn throughout the day for all human shapes and sizes, and it could be suitable for use in an individual's natural environment with minimal interference to their daily activities. Motion Tape provides unique sensing streams that can be used in machine learning and artificial intelligence models to optimize inferences related to the management of LBP. Specifically, Motion Tape for a low back use case can address several key issues in a physical therapist's management of LBP, including the following: expanding on the level of detail available during the clinical assessment of posture and movement, assessing spinal posture and movement in a free-living environment, use for the promotion of engagement and adherence with and precise performance of a prescribed home exercise program, and using the patient's response to treatment to make informed decisions for future treatment or other patients [37]. Although there are several potential benefits that Motion Tape may add to personalized health care for LBP, the acceptability of Motion Tape among physical therapists has yet to be assessed.

Physical Therapists' Acceptance of Motion Tape

The success of this device is dependent on user acceptance or one's belief that the device will help them perform their work better (ie, perceived usefulness) and that the device's performance benefits outweigh the effort of using the device (ie, perceived ease of use) [38]. Thus, it is vital to understand physical therapists' perspectives about Motion Tape and their willingness to use it in their practice, to inform future developments and improvement of the technology.

Problem Statement

The primary aim of this research study was to evaluate physical therapists' acceptance of Motion Tape for the management of LBP. The secondary purpose was to explore physical therapists' current needs and recommendations regarding future development of Motion Tape.

Methods

Device Description and Stage of Development

In this study, licensed physical therapists evaluated a prototype of Motion Tape and examples of data streams from the app for a low back use case. The Motion Tape samples evaluated in this study included the Motion Tape sensor system with conductive wire leads connected to both sides of the sample (Figure 1).

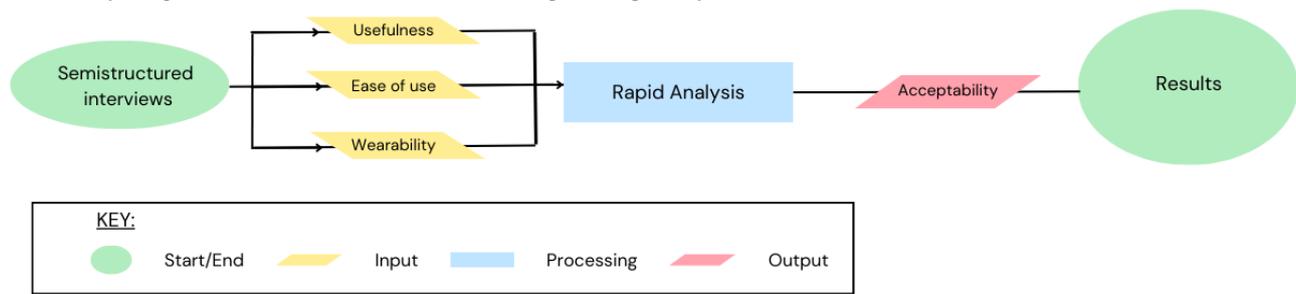

Figure 1. Motion Tape sample with conductive wire leads given to the physical therapists for evaluation.

Study Design

This exploratory, qualitative study was designed to explore physical therapists' acceptance of Motion Tape to provide a basis for future device development (Figure 2). The study was conducted from a constructivist point of view, with the goal of gaining insightful accounts and narrations of clinicians' lived

experiences with technology and patients, rather than identifying an absolute truth [39]. We used semistructured focus groups (FGs) that incorporated human factor considerations to uncover real-world needs and obstacles and to ensure that the development of the sensor system can be informed by real-world PT clinical needs.

Figure 2. Study design overview—the evaluation of Motion Tape’s acceptability.

Theoretical Framework and Constructs

The Technology Acceptance Model (TAM) framework was used in this study to assess two determinants of user acceptance of or willingness to use a technology: (1) perceived usefulness and (2) perceived ease of use [38,40]. An additional factor of wearability was also assessed to examine physical therapists’ perceptions about patient-centered issues that would affect whether the device would be worn [41]. Recommendations for future improvements were also investigated to collect insight into data, device, and app developments that clinicians would like to see for Motion Tape.

Perceived usefulness was defined as the degree to which the use of Motion Tape would enhance the physical therapists’ management of LBP [39-42], and this was assessed using the following constructs: (1) productivity, (2) effectiveness, (3) ability to make their job easy, and (4) benefits to PT treatment and recovery. Perceived ease of use was defined as the degree to which the use of Motion Tape would be effortless when used for managing LBP [39-42], and this was assessed using the following constructs: (1) how easy it would be for physical therapists to learn how to use it, (2) what level of instruction would physical therapists need to use it, and (3) how clear and understandable Motion Tape was in its current state. Wearability was defined as the degree to which Motion Tape would fit well and be comfortable for patients to wear on their back [42], and this was assessed based on (1) adhesion, (2) fit, (3) feel, and (4) how comfortable physical therapists would feel about applying and prescribing Motion Tape.

Participants and Setting

This study was conducted at the American Physical Therapy Association’s (APTA’s) Combined Sections Meeting (San Diego, California) on February 24, 2023. Participants were

recruited by sending study information via email to physical therapists who were members of the APTA Academy of Leadership Technology Special Interest Group. Members were also offered an opportunity to participate when they attended the Technology Special Interest Group in-person meeting at the APTA Combined Sections Meeting. Individuals were included in this study if they were a licensed physical therapist and were excluded from participating if they were unable to respond to questions in English. In total, 8 physical therapists were eligible and agreed to participate in 2 FGs of 4 clinicians each. A sample size of 8 people, in 2 FGs, was considered sufficient for this qualitative study to provide adequate variability and data saturation [43] and to provide a basis for device improvement. In addition, after data from the 2 FGs were collected and analyzed, the data were deemed saturated (ie, no new themes or codes were generated) and no further FGs were needed.

Ethical Considerations

The study protocol was considered to be exempt from ethics approval by the San Diego State University institutional review board. Each participant provided written consent before participating.

FG Methods

An FG guide (Multimedia Appendix 1) was used to lead the group’s discussion. The FG guide was developed by investigators (AL, PD, and SG) to be semistructured with open-ended questions to explore the participants’ perspectives about the usefulness, usability, and wearability of Motion Tape and to collect insight into future improvements for the sensors and data visualization (Textbox 1). A template of the FG guide was piloted with a Doctor of Physical Therapy student and a physical therapist at San Diego State University to ensure credibility [44]. General domains for each construct were prespecified to correspond with each interview question. Domains were defined based on the TAM framework and included perceived usefulness and perceived ease of use. An additional domain of wearability also was assessed.

Textbox 1. Guiding questions from the focus group guide.

Perceived wearability (W)

- How secure do you think the Motion Tape adhesive will be? (W-adhesion)
- To what degree do you think these sensors would fit your patients' anatomy (ie, their low back)? (W-fit)
- To what degree do you think your patients would feel the sensors on their back? (W-feel)
- How do you predict the Motion Tape Sensors would feel when being removed? (W-feel)

Perceived usefulness (U)

- To what degree would the usage of Motion Tape sensors affect how quickly you can assess your patient's posture, movement, or exercise performance? (U-efficiency)
- How effective do you think the Motion Tape sensors will be to capture valid data on your patients in the clinic? (U-effectiveness)
- How effective do you think the Motion Tape will be to capture valid data on your patients in their daily routine and normal environment? (U-effectiveness)
- To what degree would the usage of Motion Tape sensors affect the level of difficulty of your job as a clinician/physical therapist? (U-make job easier)
- What features, if any, would make the Motion Tape more useful to you? (U-useful)

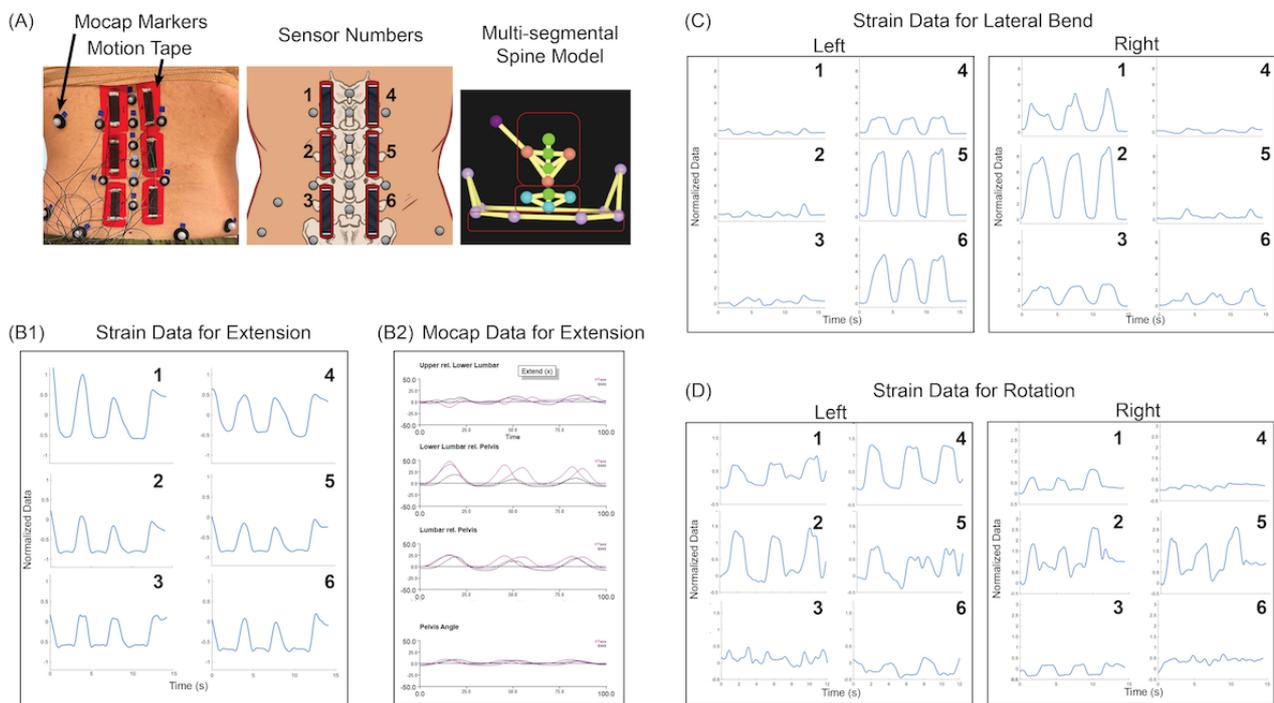

Perceived ease of use (EU)

- How easy do you think it would be to learn how to use Motion Tape? (EU-easy to learn)
- How comfortable would you feel prescribing Motion Tape to a patient to monitor their movements at home? (EU-comfort in usage)
- What level of knowledge do you think a clinician/PT would need to use the Motion Tape? (EU-clear and understandable)
- How easy/difficult do you think it would be for a clinician/PT to apply the Motion Tape to the patient's back? (EU-easy to use)
- What features, if any, would make the Motion Tape easier for you to use? (EU-easy to use)

FGs were conducted by AL (a female Master of Science student investigator) and PD (a female PhD student investigator). Reflexivity was maintained by the research team by discussing assumptions and biases that may influence how the clinicians responded to the FG moderators, who were not licensed physical therapists. As SG is a licensed physical therapist and member of APTA, she was able to provide valuable insight during the development of the interview guide, analysis, and interpretation to ensure credibility of the findings [44].

FGs were anonymized, and each participant was assigned a color as a name to ensure confidentiality. Each FG lasted approximately 1 hour and was recorded using digital voice recorders (Olympus Voice Recorder; WS-853). Before asking the participants questions, the investigators gave each participant a sample of Motion Tape. Participants were then oriented to a poster that displayed the Motion Tape placement and app data output streams (Figure 3).

Figure 3. Poster of Motion Tape placement and app data output for a low back use case. (A) The laboratory setup with 6 pieces of Motion Tape and several optical motion capture markers on anatomical landmarks of the lumbar spine. (B) The graphs display the following: (1) blue—the normalized strain data for extension, captured by the 6 Motion Tapes, and (2) purple—the kinematics for extension in degrees, captured by the optical motion capture system (reference standard). (C) The normalized strain data for right and left lateral bending obtained from the 6 Motion Tapes. (D) The normalized strain data for right and left rotation obtained from the 6 Motion Tapes.

Data Processing and Analysis

All FG audio data were downloaded to a HIPAA (Health Insurance Portability and Accountability Act)-compliant laboratory server, accessible only to the research staff, and removed from the digital voice recorder. The recordings were then transcribed, first using computer-based transcription (Word; Microsoft Corp). An investigator then checked and verified each transcription by listening to the original audio and reviewing and correcting the computer-based transcription.

Considering the need for timely feedback in the sensor development process, we adopted a rapid qualitative analysis (RQA) approach to explore themes regarding the acceptability and wearability of Motion Tape [45]. RQA was conducted by 3 investigators to assess the FG responses effectively and efficiently and to identify major themes. Codes and themes for RQA were deductively developed based on the TAM framework and the study objective [41]. We then used an inductive approach to generate RQA codes and themes, allowing for quick sorting of FG dialogue.

To ensure rigor and consistency of the method, a constant comparative approach with investigator triangulation was used at each stage [46]. First, the 3 investigators independently completed a summary report for each FG, with quotes and relevant topics under the respective themes and codes. Once the individual coding and summary reports for both FGs were completed, the investigators consolidated them into a combined rapid analysis summary report for each FG, unifying themes and reconciling discrepancies by consensus through discussion.

The summary reports for each FG were then transferred into a matrix in which each row was a participant quote and each column was a domain. From this matrix, investigators identified the underlying themes and subthemes between the 2 FGs.

Results

Overview

In total, 8 physical therapists (n=5, 63% men and n=3, 38% women), with a mean age of 47.5 (SD 5.6) years participated in this study. Participants reported obtaining PT degrees ranging from a bachelor's degree to a Doctorate in Physical Therapy and had, on average, 20 (SD 8.5) years of clinical practice experience, and most reported practicing in an outpatient orthopedic setting. Of the 8 participants, 5 (63%) reported having advanced doctoral degrees (3/5, 60% PhD; 2/5, 40% EdD).

The qualitative results from the FGs were organized using the TAM for the acceptance of Motion Tape [38,40-42]. Data were organized based on the 3 main domains relevant to user acceptance (perceived wearability, perceived usefulness, and perceived ease of use) and 21 subthemes (Textbox 2). Subthemes were further designated using *positive*, *negative*, and *neutral* valences. Positive valence indicates that the FG participants perceived the Motion Tape attribute as positive. Negative valence indicates that the FG participants perceived the attribute as negative. Neutral valence indicates that the FG participants perceived the attribute as neither positive nor negative.

Textbox 2. Themes (n=3), subthemes (n=21), and valences of user acceptance of Motion Tape.

Theme 1: perceived wearability

- Positive
 - Motion Tape has a small, universal fit.
 - The feeling of Motion Tape on the skin would decrease over time.
- Negative
 - Patients may feel Motion Tape's wires snagging or sensors rubbing on clothes.
 - Motion Tape does not consider people with skin sensitivities.
- Neutral
 - Motion Tape adheres for 3-4 days but may adhere less owing to external factors.
 - The feeling of Motion Tape being removed depends on the physical therapist.

Theme 2: perceived usefulness

- Positive
 - Motion Tape could increase specificity of physical therapy management of low back pain (LBP).
 - Motion Tape could be effective for the diagnosis, management, and monitoring of low back pain (LBP).
 - The feeling of Motion Tape and the awareness of Motion Tape monitoring would increase adherence to a home exercise program.
 - Motion Tape would be beneficial in telerehabilitation and hybrid sessions.
 - Motion Tape could increase the physical therapist's awareness of the pain source.
- Negative
 - Motion Tape brings legal concerns with data responsibility.
 - Motion Tape's reliability could be affected by external factors.
- Neutral
 - Motion Tape could increase the efficiency of assessments, but set up could take more time.

Theme 3: perceived ease of use

- Positive
 - Motion Tape would be easy for a physical therapist to apply.
- Negative
 - Motion Tape has a lot of data to sift through.
 - Motion Tape data are hard to interpret in their current state.
 - The self-application of Motion Tape would be difficult.
 - Motion Tape is designed for single use.
- Neutral
 - The prescription of Motion Tape is subjective to many factors.
 - The user interface would dictate how much knowledge would be needed to use Motion Tape.

Domain 1: Perceived Wearability

Regarding perceived *wearability*, all physical therapists were familiar with commercially available kinesiology tape. Thus, their thoughts about perceived wearability reflected their experience with kinesiology tape. For example, the physical

therapists expected Motion Tape to last about 3 to 4 days. A physical therapist mentioned the following:

Oh, I've used the K-Tape for four days before it started peeling off. Sometimes it lasts more than five days actually. Three to four days I think is average.
[FG1]

However, some physical therapists clarified that the *longevity* of Motion Tape's adhesion depends on several factors. For example, 2 of the physical therapists expressed the following:

How secure it is depends on a lot of factors, like moisture on the skin. It depends on not just moisture, but how clean your skin is and how much hair is on the skin. [FG2]

Some of them, specifically on the low back, tend to have more oily skin, and that depreciates the life of the tape. [FG1]

Regarding the *fit* aspect of wearability, physical therapists also believed that Motion Tape's size was sufficiently small to be universal to the wearer and the placement location. They expressed the following:

In my experience with tapes like this, it fits most of the clientele that I've worked with, both inpatient and long-term post-acute. [FG1]

If it was that little strip, I think it would be great to use anywhere. [FG2]

Regarding the *feel* aspect of wearability, generally, physical therapists felt that patients would feel Motion Tape at first when applied but would become less aware over time until the tape starts to peel off:

They'd know that they're there, and they'd probably become less aware of over time. [FG1]

However, physical therapists generally felt that with Motion Tape's current design, patients would *feel* the wires snagging or the sensors rubbing on clothing. A physical therapist explained it as follows:

So contraptions with wires will always have that uncomfortable feeling. Always. But if you go the wireless route, then probably after two days, the patient will be more comfortable until the tape starts peeling off. However, what I'm wearing right now, something that goes above my PSIS, if I go to the bathroom or do something, I'm going to, it's gonna move around, it might get pulled on it by my clothes. [FG1]

When removing Motion Tape, physical therapists said that patient feelings about the removal process would be quite variable. Some physical therapists felt that it was subjective to how the therapist removed Motion Tape and how much hair or oil the individual has on their skin. A physical therapist explained it as follows:

I'm just thinking of whoever is taking it off. You know, like, it depends on you, like, some people just rip. And some people are just gentle. So subjective. So it depends on the training of the therapist and concern if they're empathetic to our patients. [FG1]

The physical therapists mentioned some wearability concerns during the FGs. A concern was about how patients with skin sensitivities would be able to use Motion Tape. A physical therapist asked the following:

For those with skin allergy. Can you put an under wrap under this? [FG1]

Domain 2: Perceived Usefulness

Physical therapists expressed mixed feelings about whether Motion Tape would increase their efficiency with assessments of lumbar spine posture and movement. Some expressed that if all they had to do was apply the tape, then there would be increased efficiency:

If it's easy to objectively document, by understanding the graph, I think it's a night and day difference versus getting into the goniometers and doing manual assessment. Instead, you put on the tape, ask the patient to rotate their trunk, lean forward, reach forward, extend their back. And then if I have it digitally by email or direct messaging, it would save a bunch of time. [FG1]

However, others felt that it would reduce efficiency. A physical therapist explained the following:

Regarding the speed of assessment, I would be a little doubtful. I think by the time that you took this and you put it on the patient, you hooked up all the wires to it, you did the calibration, if you need to do a calibration, it might take just as long as doing an assessment. I would have concerns around the accuracy of this, to give you a number, an accurate range of motion, particularly for things like rotation. But if the data was convincing that everyone, if it was validated for everyone that gave you an accurate number, I think it could improve the quality of assessment. [FG1]

A physical therapist felt that for the in-clinic assessments, Motion Tape would improve specificity:

I don't feel like it [Motion Tape] would improve speed, it would improve specificity. [FG2]

Physical therapists also mentioned that they could envision Motion Tape as a useful tool for self-management and remote monitoring when used in combination with in-clinic PT. A physical therapist mentioned that the ability to monitor patients outside the clinic would be very meaningful:

That's the best place to actually observe them, their normal environment. If they're in therapy, they're being observed, coached, cued by a skilled clinician. Their performance is definitely going to be different. So if they're at home, and we're able to monitor them at home, I think the treatment will be more, and your adjustment and progression will be more meaningful. [FG1]

Some physical therapists suggested that having patients wear these sensors would increase their awareness of being monitored and thus increase engagement with and adherence to the home exercise program:

I think that what it has to offer is improving...adherence with our programs. I think that's your potential. [FG1]

When you tell someone, I'm looking at your posture right now, you change [gesturing to posture]. If they think you are watching, they'll do better. [FG1]

Physical therapists expected patients to have a phenomenal experience with Motion Tape when used in a hybrid setting:

I think to his point that if it's applied properly in the clinics, it's hybridized, and you can take a call, and there's no technical involvement on the patient side, and all they do is open up the app, they'd have this really phenomenal experience. [FG2]

Specifically, several physical therapists expressed that Motion Tape would help with the identification of postures and movements in free-living environments that provoke pain, allowing for more meaningful interventions:

I think for it to be very useful. It would have to compare with the app where you've got user input as to what's going on...where he's got these flags and the data that was pain here, pain here, pain here, and you can look, you know, to the periods of time before that. [FG2]

Some physical therapists did have some concerns about the usefulness of Motion Tape. A physical therapist expressed legal concerns regarding data responsibility:

As long as you collect data, someone's then responsible for it. So who's going to look at it? What's the liability then that person takes on by having that information?...if something goes wrong, and the therapist hasn't looked at the data, I'd like to know, are they liable? [FG1]

Another concern was knowing what external factors affect Motion Tape's signal and data reliability, mentioning that the use of Motion Tape in practice was "gonna depend on the reliability of the data" (FG2).

Several physical therapists felt that there were a variety of variables that might affect the reliability of the signal or data. They expressed the following:

And what other factors affect them, the sensors, as far as humidity, water, other environmental factors that might affect it? You know, what if they have a compression garment around the trunk, for example, does that affect the sensors? [FG2]

Whether, getting it wet and getting so some things on it changes the conductivity, and therefore the calibration over time. [FG2]

You get variability in the readings based on amount of tension that people put on it when they applied it. [FG2]

Whether that's different from person to person because of different makeups morphology. [FG1]

Domain 3: Perceived Ease of Use

Physical therapists felt that it would be easy to apply Motion Tape, given their background knowledge in human anatomy. A physical therapist stated the following:

You would need to know basic clinical knowledge of the application for where to look for the muscles, you know, right. So, they need to be clinician to have knowledge of the body. [FG2]

When asked whether they would feel comfortable using Motion Tape with their patients, there were mixed responses among physical therapists. Some mentioned that it would depend on "cost and buy-in" (FG2) or how it was going to be "incorporated into the plan of care" (FG1). A physical therapist even explained the variability as follows:

Depends on the situation, honestly. I mean, I have some families that I'll show them how to do the application. And I'll see them three weeks later, and they've reapplied four times and done it great. And then I've seen others that I'm like, "Oh, no! This is nope." [FG2]

There were also several concerns about the ease of use. Some physical therapists felt that they would have challenges with ease of use, specifically regarding interpretation of the data:

I think in its current form, easy to apply. Hard to interpret. [FG1]

It depends on the interface and how much it interprets the points. The tape will be easy, but it's all the other pieces. [FG2]

Additional concerns about the ease of use included that the amount of data presented was excessive and the type of data displayed was difficult to interpret. The physical therapists expressed a desire to see the range of motion displayed in degrees rather than resistance in ohms:

I think I'm probably realistically just correlated with what they report has been painful. Because I don't know that I've ever been so interested in all of that. Like, it might be too much data. For a patient, like I don't necessarily need to know their range of motion during every single activity, I need to know when it is relevant to them. And when it is impacting whatever condition they're here for. [FG1]

And again, I think for a clinician, it's going to have to be meaningful data. It's gonna have be Range of motion data not ohms. [FG1]

So then, conceivably, would it be helpful instead of giving you normalized strain,...if they could interpret it, would convert this over to degrees of rotation and flexibility? [FG2]

If you could get range of motion kind of information, I think that would be great. [FG2]

Another concern was about how challenging the self-application would be for patients:

How are people actually going to apply this on their own, someone that doesn't know how? [FG2]

Finally, another concern was that Motion Tape is a single-use product. A physical therapist explained the challenge of a single-use product as follows:

Okay, now how about waste? So it's like a single use thing? Now I'm gonna throw in a whole planet into this is single usage. Or can you reapply? [FG2]

Future Recommendations

Future recommendations from the physical therapists were organized into 3 categories (Textbox 3): data, physical features, and app features.

Textbox 3. Themes (n=3) and subthemes of future recommendations for Motion Tape.

Theme 1: Data recommendations

- Motion Tape data should be easy to read at a glance.
- Motion tape data should account for differing patient morphology.
- Physical therapists should be aware of factors that affect Motion Tape data.

Theme 2: Physical feature recommendations

- Motion Tape should be made wireless or with removable wires.
- Motion Tape should be reusable.
- Motion Tape should be customizable in length.

Theme 3: App feature recommendations

- Motion Tape app should include BMI input.
- Motion Tape app should include input for a patient's change in activity.
- Motion Tape app should allow flagging events.
- Motion Tape app should include comparative data.

Regarding the data *recommendations*, physical therapists expressed that data should be summarized in the form of an at-a-glance graph with 1 overall meaningful number, reflecting the range of motion. They would also like to know how the data change from person to person owing to morphology and how external factors (water, application stretch variability, and skin movement) affect the data. Additional data that would be useful for their job included comparative data, graphs with a color scale, and information about muscle activation. Participants in an FG expressed the following:

Take a baseline and have them rotate from that position and determined by the volume strain, whether they are tension either degrees, or even if it's yellow, green, yellow, red, like if they're moving within if they can't pinpoint it specifically, but you know, within a range, would that be helpful? [FG2]

I think even just having comparative data would be helpful, right? Because, you know, I keep telling my students, "Don't tell me, 'I want to increase range 10 degrees.'" Because that doesn't tell me, "Can they walk?" Right? But, "Are they doing better now than they were doing when we started?" That's useful. So even if we get baseline data that could be translated into amount of motion and then follow up data that says, "hey, it's more, it's more fluid, it's better, it's whatever." I think that can be really useful. Now I know the payers are gonna want, how much rotation did you get? How much lateral flexion did you get? [FG2]

And I think beyond the range of motion, I work in neuro. I think just like muscle activation would be interesting, you know, like, how much activation did

you get today, for example, versus six weeks ago, post stroke or, you know, spinal cord or something? I think that would be really interesting just to see the firing muscle activation. And on the flip side, and I don't know if that's possible, but looking at specificity. Could that be something to monitor changes in specimen specificity? Post- X Y & Z intervention, right? That could also be interesting. So it's not really about range of motion, we're also activity known as firing or not? [FG2]

Regarding *physical feature* recommendations, physical therapists wanted a way to mitigate the wires, either by moving to a wireless system or making them removable. Physical therapists were also concerned about the limited stretchability of the short pieces of tape, as it would not be long enough in length for typical kinesiology tape use, and recommended making the length customizable to the physical therapists' needs. Physical therapists were also concerned about Motion Tape's single-use design and were curious about whether it could be reusable to reduce waste:

Again, I'm thinking like, in the future, no wires, you've got a strip of graphene that you could customize length to, with those couple millimeters around the edge. And if we wanted a whole length, we cut whole lengths. And if we want segments, we can cut segments. And it feeds the data to the app somehow tailor it to someone's body. [FG2]

So you can imagine that maybe something like this could be a roll of tape. Yeah, the width of duct tape. And there's actually two pieces on this roll. There's one section, that's the conductive piece, that you can cut it to length, and then next to it there are maybe

there's a wire section, that's conductive tape that you can pull off and put on the ends of whatever you choose. So you get one roll of tape. And then one of them is the is the graphene is the other piece that you tear off to the appropriate length is the conductive tape that connects it to the box. And then it's a solution, you can customize length and you have your conductive piece and then your graphene. [FG2]

Regarding future *app feature* recommendations, physical therapists expressed a need for the capability to input factors such as BMI, activity changes, “flags” for events, and changes in pain to help label, compare, or contextualize the data.

Discussion

Overview

There is a gap in the research between rehabilitation device development and evaluation of clinicians' acceptance of such devices. Most existing studies have considered patient or user satisfaction [47,48], whereas others that consider the clinician's perspective have not specifically evaluated sensors for measuring spine posture and movement [49,50]. In this study, several themes relating to physical therapists' perspectives about Motion Tape's wearability, usefulness, and ease of use for a low back use case were identified.

Domain 1: Perceived Wearability

One of the most common challenges for wearable sensors is ensuring that they are unobtrusive to the wearer's natural movement and environment [39]. The small form and fit of Motion Tape was considered by physical therapists to be ideal for a wearable sensor. However, similar to previous studies, the wires in the current design were considered to be not ideal [37]. Studies have shown that wireless technologies tend to be more widely used in many fields, especially in the field of wearable devices for health care [51]. Thus, a future iteration of Motion Tape without wires would be considered optimal. On the basis of feedback obtained from physical therapists, wearability for people with skin sensitivities also should be considered. Previous studies have shown that skin irritation is the most common concern when using kinesiology tape for extended periods of time [52,53]. Thus, future studies should explore whether a medium or substrate can be used under Motion Tape to mitigate skin irritation, possibly as an extension of recent research that integrated Motion Tape with elastic fabric for respiration monitoring [54].

Domain 2: Perceived Usefulness

There were mixed feelings among physical therapist participants about how efficient Motion Tape would be in the clinic. Overall, most physical therapists felt that Motion Tape would increase the specificity of their assessments, a characteristic that has been shown to be beneficial for LBP diagnosis and treatment [55]. Furthermore, Motion Tape's ability to monitor the patient's movements remotely was considered beneficial, as this feature

may increase adherence to home exercise programs, which is an important component of effective treatment for LBP [56,57].

Domain 3: Perceived Ease of Use

On the basis of physical therapists' perspectives, Motion Tape would be easy to apply, but data would be difficult to interpret. Creating a device that is easy to use and understand is crucial because it predicts consumer use behavior [38,41]. Recommendations included presenting the data in units that physical therapists are more familiar with (ie, degrees of range of motion) and creating an app that requires minimal time for the physical therapists to use. These changes may promote increased device use and acceptance in PT.

Future Recommendations

On the basis of clinician feedback, Motion Tape appears to be a promising new technology that could be used for monitoring lumbar spine posture and movement in the management of patients with LBP. Future device development will be needed to address clinician recommendations obtained from this study in the domains of wearability and ease of use. In addition, future studies will be needed to validate Motion Tape in laboratory, clinical, and free-living environments and to investigate patient acceptance of Motion Tape.

Limitations

A limitation of this study is that participants were physical therapists who were part of a Technology Special Interest Group and are likely to be more receptive to using technology in practice. Thus, this study's results regarding Motion Tape's acceptability may be biased in favor of Motion Tape's ease of use, usefulness, and wearability. Future studies should also assess the acceptability of Motion Tape for clinicians who do not regularly use technology in their practice. Another limitation is that the physical therapists were not presented with active samples of Motion Tape with live data streams in the app. Instead, participants were given inactive samples of Motion Tape and presented with a poster with examples of app data streams. Future studies should provide an opportunity for physical therapists to apply Motion Tape to a person and use it with the app interface. Finally, there was a potential for investigator bias in the interpretation of the results, as several investigators of this study are actively working on the development of this device. However, 2 of the 3 investigators who conducted data analysis were outside the primary research team.

Conclusions

Physical therapists expressed overall acceptance of Motion Tape for its potential to monitor and assess low back posture and movement, both within and outside clinical settings. Physical therapist participants expressed that Motion Tape would be a valuable tool for personalized treatment of LBP but highlighted several future improvements needed for Motion Tape to be used in practice.

Acknowledgments

The authors would like to thank Nicolette Jaghab for her assistance with qualitative data analysis. This study is part of the Multi-Sensor Adaptive Data Analytics for Physical Therapy project and was supported by US National Science Foundation (award IIS-2205093).

Conflicts of Interest

KJL is a cofounder of JAK Labs Inc, a company that may potentially benefit from the study results. JAK Labs intends to commercialize Motion Tape for the physical therapy and rehabilitation market, among other markets. The terms of this arrangement have been reviewed and approved by the University of California San Diego in accordance with its conflicts of interest policies.

Abstract

Background: Physicians are currently overwhelmed by administrative tasks and spend very little time in consultations with patients, which hampers health literacy, shared decision-making, and treatment adherence.

Objective: This study aims to examine whether digital agents constructed using fast-evolving generative artificial intelligence, such as ChatGPT, have the potential to improve consultations, adherence to treatment, and health literacy. We interviewed patients and physicians to obtain their opinions about 3 digital agents—a silent digital expert, a communicative digital expert, and a digital companion (DC).

Methods: We conducted in-depth interviews with 25 patients and 22 physicians from a purposeful sample, with the patients having a wide age range and coming from different educational backgrounds and the physicians having different medical specialties. Transcripts of the interviews were deductively coded using MAXQDA (VERBI Software GmbH) and then summarized according to code and interview before being clustered for interpretation.

Results: Statements from patients and physicians were categorized according to three consultation phases: (1) silent and communicative digital experts that are part of the consultation, (2) digital experts that hand over to a DC, and (3) DCs that support patients in the period between consultations. Overall, patients and physicians were open to these forms of digital support but had reservations about all 3 agents.

Conclusions: Ultimately, we derived 9 requirements for designing digital agents to support consultations, treatment adherence, and health literacy based on the literature and our qualitative findings.

Introduction

Motivation

Consultations are less productive than what physicians and patients would wish [1,2], which hampers health literacy, shared decision-making, and treatment adherence. The recent rise of generative artificial intelligence (AI), such as ChatGPT, has sparked the interest of digital health developers, as they explore how this technology can improve shared decision-making,

physician-patient communication, adherence to treatment, and health literacy. In this study, we sought to discover what physicians and patients expect from digital agents (functional requirements) and how this functionality should be provided (nonfunctional requirements). A user-centric perspective is essential for guiding the development of digital agents because it prepares physicians for changes in their consultation methods and allows patients to understand what the new technology can offer.

Through in-depth interviews (refer to the Methods section), we described 3 digital agents to physicians and patients, analyzed their impressions and expectations (refer to the Results section), and deduced a set of design requirements (refer to the Discussion section). An introduction to the related work and concepts for the 3 different digital agents is provided in the following sections.

Related Work and Concepts

Relevant Medical Concepts

Overall, four medical concepts are essential when supporting medical consultations with digital agents: (1) shared decision-making, (2) physician-patient communication, (3) adherence to treatment, and (4) health literacy.

Consultations involve a participatory process between patients and physicians to reach an agreement regarding treatment goals and their implementation [3,4]. “Shared decision-making” has emerged as the gold standard for this participatory process [5-10] as it strives to reach a mutual agreement about therapy [6,7]. However, a systematic review of shared decision-making regarding clinical decisions found that the humanistic aspects of physician-patient communication were rarely assessed [11]. Good “physician-patient communication” is not only about technique or process but also involves understanding the whole person, finding common ground, and enhancing the patient-physician relationship [4]. In this way, physician-patient communication can have a therapeutic effect and influence health benefits [12].

The therapeutic process continues after the patient has left the consultation [3]. Once at home, it is up to the patient to implement the therapy plan, and the extent to which this occurs is referred to as “adherence to treatment” [13]. Adherence focuses on patients taking responsibility for their treatment and physicians collaborating more with their patients [14,15]. However, despite some progress, adherence to treatment remains insufficient [13,16-18]. First, there is a lack of “health literacy” when following the given instructions. Physicians may explain medical issues and treatment options during consultations, but their time is limited, and they must convey as much information as possible. Second, patients are in a stressful situation, which restricts their ability to absorb and hinders their recall [19-24]. Third, physicians may use medical terminology [25] with the following consequences: patients either do not understand or quickly forget what was discussed [26,27]. Brochures and leaflets are typically used to support health literacy, and modern approaches include video, multimedia, computer-assisted learning, mobile apps, and other web-based aids [28-32].

Digital Agents

Digital agents are computers that undertake tasks previously performed by humans. As such, they function autonomously, react to environmental situations, initiate actions, communicate with humans or machines, and behave intelligently [33]. An increasing volume of digitized data, improved algorithms, and better hardware has vastly enhanced the range of tasks that digital agents can perform. The most noticeable aspect is the recent success of generative AI. Nevertheless, the expanding capabilities of digital agents also raise concerns about AI in

general and digital agents in particular [34]. Examples include their potential misuse, how they can be controlled, and whether they exhibit bias [35]. Besides these general concerns, researchers are interested in understanding exactly how digital agents interact with humans. Although humanlike behavior may be helpful in some situations, task performance may be impeded by excessive humanness [36,37] such as in situations where humans prefer a digital agent with a background function. This issue is critical in institutional settings [38], where professionalism is vital.

Discussion about the capabilities of digital agents and their suitability has also reached the medical domain [33,39,40]. Conceptually, the dyadic physician-patient consultation becomes triadic [41-44] if a digital agent is included. The presence of digital agents changes the consultation dynamics [45,46] and alters how patients and physicians behave [41]. Despite such insights, the discussion lacks a clear conceptualization of the digital agent’s role in the professional context of physician-patient consultation. Consequently, discussing what physicians and patients expect from digital agents during and between consultations has not been possible.

Current Digital Support for Consultation, Adherence to Treatment, and Health Literacy

Physicians use electronic medical records (EMRs) and encounter patient decision aids (PDAs) during consultations, which provides patients access to their data through patient portals. Patients may also store data in their personal health records (PHRs) and take advantage of mobile health (mHealth) apps between sessions.

EMRs support physicians in documenting medical history, including physical examinations and laboratory results. They are intended to reduce costs, improve patient safety, increase efficiency [47], and safeguard data [48,49]. As EMRs are designed primarily for documentation purposes [50], it is the physician’s responsibility to determine how to use them in patient interactions. Proper use of EMRs by trained health care professionals can improve health literacy and adherence to treatment compared with paper-based records [51], for example, if physicians share their EMR screens with patients during consultations [52,53]. However, when used ineptly, physicians lose control of the consultation owing to increased gaze shifts and multitasking, which hinders their medical reasoning [47,54]. In the presence of a computer, preexisting positive and negative communication skills are amplified [55,56].

Encounter PDAs support physician-patient consultations by providing decision-related information and choices [57-61]. Although they tend to be simple in design [61], physicians complain that lack of training and experience and insufficient content and format impede meaningful use of encounter PDAs [57,58]. Another challenge is keeping encounter PDAs updated with the latest information [60].

Patient portals provide patients with access to their data stored in EMRs [62]. In such tethered patient portals, the responsibility for maintaining the data lies with the physician. To be understood by patients, information from EMRs must be

translated [62], and this applies to language, graphs, and other multimedia material.

Unlike patient portals, in electronic PHRs, patients themselves enter and maintain their health data [63]. Although PHRs can accumulate more information than patient portals, quality control and manageability are challenging. There is a consensus that more needs to be done (eg, patients also need to understand what they get from the PHR and need to act on what they understand) to enhance health outcomes or treatment adherence than just providing patients with access to their data [64,65]. Better-informed patients are not necessarily healthier patients [64], but there is (1) value and (2) potential in patient portals and PHRs. First, patients want access to their data to review it again at home, discuss it with their families, and use it as a starting point for further online research [62,64]. Second, there is evidence suggesting that patient portals and PHRs are more effective when they are interactive, when they are combined with other services such as reminders or interactive decision support, and when physicians actively promote their use [62,64].

Digital interventions based on mHealth apps promise to support patients' health literacy and adherence to treatment. In 2017, >300,000 health apps were available in online app stores [66]. Not all are considered effective, convenient, or of high quality [67-69], and many have low success rates and high dropout rates [70-72]. Nevertheless, despite their limitations, mHealth apps appear to support patients effectively in treatment adherence [67,73,74]. If they pass the medical quality requirements, they can even be prescribed in the same manner as medicine [75,76]. Physicians are best placed to assist with their use, but this requires their integration into workflows and EMRs [74,77,78], and the security of patient data must be guaranteed [79].

Digital Agents to Support Consultation, Adherence to Treatment, and Health Literacy

Overview

We conceptualized 3 general roles for digital health agents, which tie together the modern medical concepts and previous studies of digital agents with current digital support for consultation, adherence to treatment, and health literacy. These served as a basis for our empirical study, when introducing our selected physicians and patients to digital agents.

A digital agent can be a "digital expert" that provides the right aids at the right time or offers a second opinion about diagnosis and treatment. It can stay in the background of the consultation as a "silent digital expert" or actively participate in the consultation as a "communicative digital expert." Alternatively, it can be a "digital companion" (DC), which supports the patient between consultations. DCs provide patients with comprehensible information about diagnosis and ongoing treatment.

Silent Digital Expert

This is an extension of EMRs, providing the physician with contextual and real-time advice and additional information. The silent digital expert is designed to free the physician from searching vast information sources and allows more time for

face-to-face consultation, thereby improving physician-patient communication [4,12]. For example, the silent digital agent can alert physicians to different diagnoses and drug interactions or offer prompts for further questions. The silent digital agent also supports diagnosis and suggests appropriate treatment in a shared decision-making process [5-10]. It acts as an aid to the physician and is visible and accessible only to the physician, and with patient consent, it can record, transcribe, analyze, and summarize the consultation.

Communicative Digital Expert

As the third party in a triadic consultation, the communicative digital expert offers the same functionality as the silent digital expert. However, it actively participates in the consultation by extending the functionality of EMRs and encounter PDAs through an agency. It may be physically represented as a humanlike robot, smart speaker, or device of any shape. As the third party, the communicative digital expert can be invited to comment about the decision-making process of physicians or patients [5-10] and become active in explaining medical topics, thereby improving health literacy [80-83]. As such, it can be considered as a physician's assistant or patient's advocate, thus improving physician-patient communication [4,12]. For example, it might interrupt the dialogue if a physician is very brief or dominant, thereby providing both parties with further information, diagnosis considerations, and treatment recommendations. It acts in an empathetic, patient-centered manner and is capable of identifying and taking patient preferences into consideration.

Digital Companion

This agent is intended to support patients *between* consultations by extending patient portals and PHRs and combining them with an mHealth app. It relies on data from EMRs and supports patient treatment behavior. Its primary goals are to improve the recall of recommendations and information, promote health literacy [80-83], and support treatment adherence [12-18,84]. DC captures the critical points of the physician-patient consultation, translates them into everyday language, enriches them with multimedia elements (audio, picture, diagram, and video), and makes them conveniently accessible to patients or their families at any time. It also provides the patient with curated additional information and interactively supports their health care education based on individual preferences. Using sensor data from various devices (eg, smartphones, smartwatches, pedometers, and blood glucose monitors) and patient's interaction with DC, adherence to the treatment plan is measured, analyzed, and fed back to the patient (and with the patient's consent, to the physician). DC provides context-specific, adaptive interventions [85-88] based on adherence measurement, individual treatment agreement, and patient preferences. For example, adherence support might include diet recipes, exercise instructions, morale-boosting talks, and so on.

Methods

Research Approach

This study aims to understand what physicians and patients require from digital agents. These requirements should be grounded not only on technical vision but also on current consultation practices, with a focus on problem-solving.

Our research approach was inspired by the practice-oriented approach popular in computer-supported cooperative work (CSCW). CSCW is an interdisciplinary field of research involving, among others, computer science, psychology, and sociology, to analyze the potential and the shortcomings of digital assistance in consultations [89-91]. CSCW mainly uses qualitative methods and focuses on how human collaboration can be supported by technical means [89,92]. As these means must be applied within a professional context, this also involves studying work practices from the perspective of those involved [93,94].

Our study embraced this tradition by following an exploratory paradigm, striving for deep, contextualized insights [95,96]. We conducted an interview-based qualitative study with 47 participants—22 (47%) physicians and 25 (53%) patients. Our analysis combined bottom-up thematic analysis and interpretive research, allowing for both broad coverage and deep insight.

Overall, the chosen methodological approach respected the need to understand patients' and physicians' perspectives regarding their work practices and the potential use of technologies. We addressed variation and triangulation, whereby multiple researchers conducted the interviews with different patients and

physicians. We ensured audit throughout the process by mutual control among researchers and by assigning a quality manager role to one of the authors. The first author was directly engaged in data collection during a preliminary study [97] and guided data collection during this study to ensure adequate engagement in data collection activities. In summary, the study used various strategies to ensure the reliability and validity of the presented results [98] and followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines for reporting qualitative research [99].

Ethical Considerations

The Ethics Committee of the Zurich canton confirmed that this study was not subject to the Swiss Human Research Act (Business Administration System for Ethics Committees [BASEC]–Nr Req-2018-00847). Nevertheless, written informed consent was obtained from all participants before their interviews according to the World Medical Association Declaration of Helsinki [100].

Sampling and Recruitment

Exploratory studies require a variety of opinions, but they do not seek to be representative. To ensure variety, we interviewed both physicians and patients. We also relied on purposive sampling using a maximum variation strategy [101], which allowed us to search for a broad range of physicians and patients. Given that 5 interviewers acquired the patients and physicians independently, we can assume the coverage to be better than that of strategies involving sampling through a single researcher. Table 1 shows the demographic characteristics of the study participants.

Table 1. Demographic data of the interviewed physicians and patients.

Characteristics	Physicians (n=22)	Patients (n=25)
Sex, n (%)		
Male	12 (55)	14 (56)
Female	10 (45)	11 (44)
Age (y), mean (SD; range)	50 (14; 25-66)	46 (19; 20-86)

Of the 22 physicians, 13 (59%) are active in primary care, and the others work in hospitals; 11 (50%) are general practitioners or specialize in internal medicine. Other specializations include pediatrics, gynecology, radio-oncology, and dentistry. The educational background of the 25 patients ranged from unskilled workers to professionals and academics. The patients presented a broad spectrum of conditions, including diabetes, multiple sclerosis, heart conditions, tick-borne encephalitis, and epilepsy.

We conducted 46 in-depth interviews that resulted in audio recordings with 32 hours of interview time, amounting to an average length of 42 minutes and 46 seconds (SD 13 min and 47 s). Of the 46 interviews, 45 (98%) were conducted with 1 interviewee per session, and 1 (2%) involved 2 respondents. The sample size assured data saturation—the topics emerging in the interviews began to overlap after about 18 to 20 interviews for each group [102]. Consistent with the practice for purposive sampling and maximum variation [101], we used various channels to establish the initial contact with the interviewees

(email, face-to-face, and telephone). After confirming the time and date for a potential interview and giving their consent, no one dropped out of the study.

Data Collection

In total, 5 researchers conducted in-depth interviews based on the respective interview guides—separate guides for patients and physicians [96]. The interview guides were developed based on the literature about physician-patient communication; adherence to treatment; existing solutions in the field of medical informatics; and the authors' own experiences in the medical domain, including their research background. The overall structure of the interviews was informed by CSCW practice-oriented studies [93,94]. The interview guides were pretested in a preliminary study (with 11 health care professionals and 7 patients) published elsewhere [97]. Interviews for this study were conducted between January 2019 and May 2019, with patient interviews being conducted mostly in their homes and health care professional interviews in their

professional setting. Before the interviews, all researchers underwent interview training sessions to ensure that they had the same understanding of the questions and knew how to conduct the interview. The interviews were structured around 3 areas: current situation or practice (format of and preparation for a consultation), future developments (expectations from and attitudes toward digital health care), and closure (other points that were not already covered).

When discussing about digital developments, we suggested potential ideas because users often lack the necessary imagination when asked about future products or services [103]. Nevertheless, when prompted, many users can express helpful, subjective opinions about specific ideas [103]. Therefore, in the spirit of design thinking [104], we exposed the users to key design ideas by describing the digital experts and DC and asking for their perceptions, expectations, and preferences regarding digital agent support. As is typical in design thinking, the discussion focused on the desirability of critical capabilities but did not include a detailed discussion about feasibility.

Data Analysis

All the interviews were audio recorded and transcribed. The analysis combined deductive thematic research and interpretive research, allowing for broad coverage and deep insight simultaneously. During the top-down analysis, the transcripts were coded according to a codebook derived inductively from a small preliminary study [97]. A professor of nursing science cross-checked the codebook. Again, all researchers attended a training session to ensure that they had the same understanding of the codebook. All interviews were then deductively coded using MAXQDA (VERBI Software GmbH) [105]. The designated quality manager conducted quality assurance activities by controlling all code assignments and correcting them to ensure a consistent basis for analysis. We achieved thematic saturation—all themes from the specified coding schema appeared in the data with high frequency (the most frequent code was assigned 274 times and the least frequent was assigned 25 times; overall, we had 1954 assignments across all codes) [102]. Finally, all interviews were summarized by code; for each theme, we obtained a summary of participant opinions related to the code. These summaries formed the basis for further analysis, and the results were then used for interpretation.

To interpret the data, we organized 2 interpretation workshops involving the authors. The workshops aimed to establish a shared and consistent understanding of the most essential insights between the authors. The interpretive process involved iterative restructuring of the summaries along various dimensions, with 2 dimensions emerging as crucial for forming a consistent data view. First, we differentiated the problems, current practices that emerged to mitigate those problems, and potential technological solutions to address the problems that occurred during the interviews. Second, we observed that the issues aligned with the phases of a patient's journey: (1) consultation, (2) "transition" between consultations and period between consultations, and (3) actual period between consultations. These differentiations provided the framework for reporting our results, and the proposed structure covered all the challenges and problems identified during coding.

In our presentation of the results, we refer to the frequency of specific challenges because, after identifying the framework and distributing the significant challenges for each element in the framework, we returned to the coded data to classify the coded passages. In the following section, we have presented the quantified data about the frequency of passages pertaining to the challenges. However, it is important to clarify that we do not assert the representativeness of these figures, as the analyzed population was not chosen to be representative of the broader population. Instead, the numbers ensured the thematic saturation mentioned previously.

Results

Through analysis, we categorized the results into 3 steps in the patient journey: first, the consultation; then, incorporating information from the consultation into their lives; and finally, the time between consultations.

Problems and Agent-Based Solutions During a Consultation

During consultation, the main challenge, according to physicians and patients, is conveying complex information in minimal time to laypeople with various backgrounds, expectations, and abilities while building or maintaining a relationship of trust. [Table 2](#) summarizes the problems voiced by physicians and patients, current practices (as presented by the interview partners), and envisioned solutions offered by the 2 different versions of digital experts.

Table 2. Problems and solutions suggested during a consultation, along with the number of mentions in interviews.

Problems during the consultation	Current practices	Solutions offered by the silent digital experts	Solutions offered by communicative digital experts
Time pressures (physicians: 5/22, 23%; patients: 3/25, 12%)	— ^a	<ul style="list-style-type: none"> Physicians can concentrate on a thorough and engaging consultation using digital situational information 	<ul style="list-style-type: none"> Physicians can concentrate on a thorough and engaging consultation using digital situational information
Medical information is complex (physicians: 9/22, 41%; patients: 18/25, 72%)	<ul style="list-style-type: none"> Physicians use graphics, visualizations, videos, and 3D models from brochures, books, and online sources (physicians: 14/22, 64%; patients: 7/25, 28%) Physicians draw illustrations themselves (physicians: 13/22, 59%; patients: 4/25, 16%) 	<ul style="list-style-type: none"> The digital expert provides physicians with the following: <ul style="list-style-type: none"> The right visual aid at the right time Graphic templates or blank drawing areas that they can use for their own drawings 	<ul style="list-style-type: none"> The digital expert suggests text, images, audios, and videos tailored to individual patient needs
Not all patients respond to medical advice and information in the same manner (physicians: 12/22, 55%; patients: no matching question)	<ul style="list-style-type: none"> Most physicians try to approach patients individually by adapting their language to a patient's educational background or medical knowledge (physicians: 4/22, 18%; patients: no matching question) 	<ul style="list-style-type: none"> The digital expert provides visual aids tailored to a patient's educational background, numerical ability, or language skills 	<ul style="list-style-type: none"> The digital expert intervenes if it determines (eg, through sentiment analysis [106]) that a patient does not understand the physician
Patients expect more transparency and control over the treatment process (physicians: 2/22, 9%; patients: 21/25, 84%)	<ul style="list-style-type: none"> Many patients engage in conversations with physicians and take responsibility for their treatment (patient: 3/25, 12%), and physicians try to support this (physicians: 4/22, 18%; patients: 5/25, 20%) 	—	<ul style="list-style-type: none"> The digital expert intervenes when physicians do not give their patients enough time to talk, and it can empower patients to take more control
Some patients do not agree with the proposed treatment plan (physicians: 4/22, 18%; patients: 6/25, 24%)	<ul style="list-style-type: none"> Physicians respond with more intensive explanations (physicians: 8/22, 36%) Physicians protect themselves by documenting the conversation Physicians do not enforce treatment 	<ul style="list-style-type: none"> The digital expert offers arguments, statistics, and figures to support the physician's point of view 	<ul style="list-style-type: none"> The digital expert advocates for the patient (by putting the physician's thoughts or guidelines into perspective) or for the physician (by supporting the physician's thoughts or guidelines)
The computer distracts the physician and interrupts communication, and use of computer amplifies inferior communication skills	—	<ul style="list-style-type: none"> The user interface of the digital expert is designed to be self-explanatory and user-friendly Instead of the physician, the digital expert searches for information and offers context-related content 	<ul style="list-style-type: none"> The digital expert supports the physician and the patient, for example, through active listening It will only interfere by assisting an already impaired conversation

^aNothing mentioned in the interviews.

Regarding current practices, patients and physicians report that there is very little time for a thorough and engaging conversation:

I just felt like I was being processed. Quick assessment with the question: What's the problem? And I felt that I couldn't even say what I had because it was already clear to the physician. After a quarter of an hour, I was out of there again, and I was no wiser. [Male patient; aged 60 years; D07]

I frequently make lifestyle recommendations. Costs time too, by the way, cannot be done in a 20-minute consultation that's just long enough for issuing a prescription. [Male general practitioner; aged 64 years; hospital; ST09]

Most physicians in this sample practice shared decision-making. Some use the explicit term during the interview, whereas others simply implement shared decision-making without labeling it as such:

Then I say, we could try pharmacy, we could try herbs, we could try acupuncture or this or that. I'll let the patient have a say. Because then the patient's adherence is also much better. [Female general practitioner; aged 65 years; medical office; MA10]

All interviewed patients favored a silent digital expert as an aid to the physician; they did not object to physicians using online sources to obtain additional information during a consultation:

I don't like having a doctor who introduces him- or herself as "I am the all-knowing one." For me, that

tends to inspire confidence when a physician says: I don't know, I have to work with the exclusion procedure. [Male patient; aged 74 years; F01]

However, patients expect uninterrupted attention, which requires a sufficiently high level of expertise by the physician in using the computer:

He kept asking and reading to me while he was writing and asking me if that was correct. This was great for me because then I knew what he was writing. [Female patient; aged 52 years; S10]

Most physicians in this study would welcome a silent digital expert to facilitate multitasking, and some already use drug interaction assistants, risk or score calculators:

You can't read through the books in the evening. That would mean an insane amount of time or such a head. That's why these are important tools, I think for rare conditions it's certainly a good idea. [Female gynecologist; aged 35 years; hospital; MA02]

However, the benefits of a digital expert are assessed differently by those in different medical disciplines. A physician was concerned about the transfer of responsibility to the digital expert, whereas another physician worried about a decline in interprofessional communication. A young physician was concerned that this would cause them to acquire very little experience and self-confidence:

You rely too firmly on that afterward. Then you believe too firmly in that. Then it takes over your task, so to speak. [Female dentist; aged 29 years; dental surgery; MA03]

Most patients in this sample view communicative digital experts positively. Those against them are concerned that they might be disruptive or could be manipulated by the physician:

I do not know what the physician can enter there, and then it is clear that the computer represents the opinion of the physician. [Female patient; aged 51 years; S07]

The opinions of those in favor of it differ. Some consider a communicative digital expert as helping less skillful physicians and others consider it as helping competent physicians. Some would like a digital expert to be a physician's assistant, whereas others consider it as a patient's advocate:

As a patient, you are always subordinate to the physician, in that sense. I don't think it's a bad thing when someone else is on my side. [Female patient; aged 28 years; S06]

Approximately two-thirds of the interviewed physicians reject the communicative digital expert. For them, credibility, decision-making authority, and their patients' trust are at stake. Some consider empathy between the physician and patient as essential for patient adherence to treatment and, therefore, do not believe that a digital expert can help. A physician found communicative digital experts annoying but assumed that physicians and patients would get used to them over time:

In principle, I say, there is still an interpersonal level that artificial intelligence cannot comprehend. [Female general practitioner; aged 48 years; medical office; MA08]

Problems and Agent-Based Solutions for Transitioning From Consultations to the Period Between Consultations

Problems during the consultation may also hinder treatment because poor consultations can impair health literacy and adherence to treatment. Table 3 provides an overview of the voiced consultation issues that affect the time between consultations and the envisioned solutions offered through an interaction of the digital expert and DC.

Table 3. Problems and envisioned solutions for transitioning from consultations to the period between consultations, along with the number of mentions in the interviews.

Problems resulting from the consultation	Current practices	Solutions offered by the digital experts connecting to the digital companion
Patients cannot remember everything that the physician says (physicians: 0/22, 0%; patients: 10/25, 40%)	<ul style="list-style-type: none"> Patients do the following: <ul style="list-style-type: none"> Bring companions to the consultation Consult brochures or online sources (patients: 2/25, 8%) Use reminders on smartphones (patients: 2/25, 8%) Take notes (patients: 6/25, 24%) Physicians do the following: <ul style="list-style-type: none"> Repeat (physicians: 2/22, 9%) Use active listening techniques 	The digital expert records, transcribes, and summarizes the conversation for the patient (quality assurance)
Identifying and introducing clinically relevant mHealth ^a apps is time consuming and difficult	<ul style="list-style-type: none"> Patients search for apps themselves, but use dropout rates are high 	The digital expert suggests quality-assured mHealth apps or equivalent features of the digital companion

^amHealth: mobile health.

Most physicians in this sample see potential in automated recording and transcription. A physician hoped that digital experts would give them more time to communicate with

patients. However, physicians doubt whether a computer can separate relevant statements from irrelevant ones and produce relevant summaries. Some physicians stress that the notes they

make for themselves about the case cannot be directly shared with the patient but need to be translated. Others insist on control over the information that is shared with patients:

Therefore, the software must either be able to guarantee this or otherwise it is legally difficult to prove that the patient has been informed correctly.

[Male radio-oncologist; aged 35 years; hospital; MA01]

Besides technical difficulties, the interviewed physicians see another reason to avoid automatic summaries—subjective perceptions are often only discussed verbally or communicated via telephone owing to fear of litigation:

Certain things, incidents and so on, or special experiences or special stories that are told that could have legal relevance. I don't list them in the computer.

[Male general practitioner; aged 62 years; medical office; ST02]

Another physician takes precisely the opposite position. They would appreciate transcripts of complex consultations in which, for example, discussions about child protection or off-label prescriptions of medication are involved. A physician did not

believe that a consultation's significant first and last seconds would be transcribed with the necessary weighting.

Patients also have different opinions about digital experts. Only a few patients in this study raised data protection concerns regarding the consultation transcripts and other information recorded during the consultation. Some patients indicated that they would benefit from this evidence of what was said in the event of disagreement or malpractice. A patient was worried about a decline in care because physicians were afraid of malpractice lawsuits:

I tend to think I get worse treatment because most physicians have way too much fear of someone coming in afterward and saying, "I'm going to sue you – you told me something wrong." [Male patient; aged 61 years; S02]

Problems and Agent-Based Solutions for the Period Between Consultations

The consultation cannot cover all the questions and issues arising between consultation appointments, and patients must rely on their own judgment or a tool that assists them during this period. [Table 4](#) presents the problems that arise between consultations that lead to poor adherence and the solutions offered by DC.

Table 4. Problems and envisioned solutions for the period between consultations, along with the number of mentions in the interviews.

Problems arising between consultations	Current practices	Solutions offered by DC ^a
<ul style="list-style-type: none"> Patients lack information because of the following: <ul style="list-style-type: none"> Insufficient time for explanations during the consultation (physicians: 5/22, 23%; patients: 3/25, 12%) Poor recall of the consultation (physicians: 3/22, 14%; patients: 11/25, 44%) More questions arising later (physicians: 0/22, 0%; patients: 11/25, 44%) 	<ul style="list-style-type: none"> Patients do the following: <ul style="list-style-type: none"> Use online sources, but they are skeptical, and some distrust online forums in particular (physicians: 6/22, 27%; patients: 6/25, 24%) Read brochures (patients: 3/25, 12%), attend public lectures, or even attend anatomy courses Physicians provide brochures to guide patients away from online self-diagnosis (physicians: 2/22, 9%). 	DC provides curated content and web links tailored to the patient's diagnosis. This reduces misinformation and false self-diagnosis. In addition, it fosters more trust in health care information.
<ul style="list-style-type: none"> Patients lack clear instructions and specific information but instead experience information overload (physicians: 0/22, 0%; patients: 8/25, 32%) 	<ul style="list-style-type: none"> Physicians provide paper-based instructions regarding medication, exercises, and lifestyle changes (physicians: 3/22, 14%; patients: 8/25, 32%) 	DC tailors content to patient preferences, contexts, and specific circumstances. This includes content presentation in different formats (simple or sophisticated text, images, audios, and videos).
<ul style="list-style-type: none"> Patients are on their own between consultations (physicians: 3/22, 14%; patients: 1/25, 4%) 	<ul style="list-style-type: none"> Patients report little interaction with their physicians between consultations Some use email but only sparingly (physicians: 2/22, 9%; patients: 7/25, 28%) 	DC provides low-barrier access to the physician between consultations. A chatbot covers part of the conversation to protect physicians from huge workload.
<ul style="list-style-type: none"> Patients are overchallenged when taking their medication (physicians: 2/22, 9%; patients: 8/25, 32%) 	<ul style="list-style-type: none"> Medication apps can support complicated medication regimes (physicians: 1/22, 5%; patients: 2/25, 8%) 	DC supports adherence by providing the patient with individualized interventions that consider patient preferences, contexts, and specific circumstances.
<ul style="list-style-type: none"> Treatment success or failure goes unnoticed (physicians: 4/22, 18%; patients: 0/25, 0%) 	<ul style="list-style-type: none"> Physicians ask patients to maintain diaries or journals, mostly paper based (physicians: 8/22, 36%; patients: 3/25, 12%) 	DC offers easy-to-maintain diaries and journals, including data captured from digital devices (eg, wearables). The collected data can be shared with physicians (with the patient's consent).
<ul style="list-style-type: none"> Measuring adherence is difficult 	<ul style="list-style-type: none"> Adherence is rarely measured, and often, it is only based on the purchase of medicines (physicians: 1/22, 5%; patients: no corresponding question) 	DC offers adherence measurements in an easy-to-understand format.

^aDC: digital companion.

Most patients in this study would welcome a DC; however, a few are skeptical or undecided. Patients are open to using electronic tools and online services regarding current practices. However, this is not always helpful to physicians:

People practically come with a diagnosis, and after that, we first have to come back to the symptoms. And I have to say, "hey, we have to start all over again."
[Male general practitioner; aged 66 years; medical office; ST01]

Many physicians who were interviewed could see the potential of a DC. Some hoped this would improve adherence to medical advice, whereas a physician saw a significant benefit in making the DC genuinely personalized and tailored to an individual patient's needs. Regarding monitoring patient behavior between consultations, less than one-third of the physicians reported adherence measurement (which is usually based on the purchase of medications):

That's why I'm very happy when the patients order medication from us because then I can see on the

computer when they have picked up their medication. I don't see that when they buy medicines from the pharmacy. [Female general practitioner; aged 48 years; medical office; MA08]

Most physicians in this sample are open to receiving and interpreting monitoring data from patients and their mobile devices. However, they have the following reservations. First, there is an unmanageable number of mobile apps. Second, they fear data overload and being forced to respond to monitoring results, which requires additional time that physicians do not have. Third, physicians see a risk that such monitoring will negatively influence patient behavior. A physician raised the possibility that neurosis could result from constant introspection. Another concern was that patients would abdicate responsibility for their condition by transmitting data and threshold violations. Despite these concerns, confronting patients regarding their threshold violations encourages them to reflect on their condition and possible lifestyle changes. Therefore, patients can become "experts" on their condition:

Because that is certainly one aspect when patients think about it: Why did my sugar do that now? That's the most instructive. And the goal is that they become the "expert" and I coach them. [Female general practitioner; aged 39 years; hospital; ST08]

Discussion

Overview

Problems in physician-patient interaction that ultimately hamper treatment adherence can be classified into 3 categories: problems regarding the consultation itself, problems from the consultation but appearing between consultations, and new problems arising between consultations. These problems overlap and, therefore, need to be addressed using integrated support systems. On the basis of the scenario, a support system consisting of digital agents assisting in the consultation and a companion for the periods between consultations is proposed. To qualify for the task, these agents need to meet the expectations of physicians and patients and improve health outcomes. In the following sections, we discuss design recommendations for the 3 digital agents that are active in the consultation and act as the patient's companion between consultations.

Requirements for Digital Experts During the Consultation

Digital experts reveal their capabilities during the consultation by integrating and extending the functionalities of EMRs and encounter PDAs with the characteristics of digital agents [33]. These include autonomous and intelligent behavior, reactions to environmental situations, and communication with humans or machines.

The Digital Agent Should Make Its Role in the Triadic Consultation Transparent

Our interviews asked for opinions about including medically skilled digital agents as part of a physician's EMR [45,46]. These can facilitate conversations between physicians and patients or offer second opinions regarding diagnosis and treatment. In such cases, the digital agent functions as an additional physician. Although most patients would welcome this triadic consultation, some fear that physicians could manipulate their DCs. These reservations arise from an understanding that digital agents could adopt the role of a second physician and a trusted family member, spouse, or friend [41,42]. Such roles include informational or emotional support (eg, taking notes, ensuring understanding, and reassuring patients) [42]. Accordingly, the role of a digital agent in consultation must be clearly defined and transparent to patients. Further studies might explore what patients require to trust and benefit most from these digital agents in the role of a second physician, family member, spouse, or friend.

The Digital Agent Should Encourage Trust and Support the Physician-Patient Relationship While Safeguarding the Physician's Credibility

The literature and interviews with physicians and patients agree on the importance of trust and good relationships between physicians and patients in a medical setting [4,12]. Although

traditional health IT (eg, EMRs and encounter PDAs) does not seem to interfere with patient-physician relationships [53], the situation changes when digital agents act as medical experts or DCs during a consultation. Most interviewed patients like the idea of a digital agent and do not think it will harm the physician-patient relationship. At the same time, many physicians have an opposing view, fearing loss of credibility and decision-making authority. Therefore, a challenge for DC is to foster trust and support, rather than undermine, the relationship between physicians and patients. Such digital agents must support patients but not unduly contradict physicians or disrupt the natural flow of conversation. This means that digital agents must recognize whether a piece of medical advice will strengthen or damage the relationship.

The Digital Agent Should Help Physicians to Focus on the Patient During the Consultation

The interviewed patients expect their physicians' full attention even when interacting with a computer. In a traditional practice setting, computer screens create a barrier between patients and physicians and can be a serious distraction [47,54]. However, digital agents act independently or are triggered by voice control to provide information or document the conversation, requiring less attention from the physician. The form of digital agents integrated into the conversation can range from shared screens or smart speakers to humanlike robots. Technological advances have brought such user interfaces and digital agents more close to reality. Further studies should indicate what patients and physicians are most likely to accept.

The Digital Agent Should Support Physicians by Taking Over Administrative Duties

Administrative duties prevents physicians from doing what they were trained to do (at considerable expense) and reduces their job satisfaction. The time pressure resulting from these administrative duties is a well-known problem that affects patient health outcomes [1,2,12]. This issue surfaced in the interviews with physicians and patients who were dissatisfied with their treatment. Therefore, a significant role for digital experts is to relieve physicians from as many administrative duties as possible. However, it is essential for physicians that their medical reasoning is considered as something more than mere administration. Recording, transcribing, and summarizing the conversation is necessary, but it is not the whole story. Digital experts should support medical reasoning of physicians and ask for it if not already done, rather than impeding it.

Requirements for Handover From Digital Experts to DCs

To ensure a seamless patient experience, information collected and discussed during the consultation must be passed from the digital experts supporting the consultation to a patient's DC.

The Digital Agent Should Tailor Information and Patient Education to Individual Patient Needs and Preferences

In supporting consultation, digital experts could, for example, provide appropriate information at the appropriate time. After consultation, DCs could continue patient education between consultations, which is tailored to their information needs and

preferences. This can give physicians extra time during consultations [1,2] and assist patients in recalling recommendations and information [19,23,24]. In contrast to reading widely circulated brochures, leaflets, and generalized online sources [28,29,31,32,107], patients receive personalized information matching their specific circumstances and treatment plans. This saves time by reducing the need to guide patients away from potentially incorrect self-diagnosis [30].

Our interviews indicated that physicians effectively tailor information to their patients' needs and backgrounds. Therefore, digital agents in the form of digital experts and companions must keep up with or even outperform physicians to add value. To achieve this, digital experts should either be able to draw on predefined patient profiles or interpret and assess patient preferences and backgrounds correctly. Physicians understandably insist on maintaining overall control as they are liable for the information they give their patients. A suboptimal solution would require physicians to verify the information they provide patients via the DC. In contrast, a better solution would ensure (in a trusted manner) that the information offered was consistent with the physician's directions.

Requirements for the DC in the Period Between Consultations

DCs support patients as digital agents between consultations by integrating and extending the functionalities of patient portals, PHRs, and mHealth apps.

The Digital Agent Should Offer Adaptive Interventions for Behavior Change

In conventional lifestyle change treatment, adaptive interventions are standard, and physicians and patients adapt and agree about the treatment every few weeks or months, ideally in a shared decision-making process [3,4,6,7,9]. However, adjustment cycles are dependent on consultation cycles, and in the meantime, patients may treat themselves incorrectly or discontinue a treatment owing to a lack of corrective measures. Here, digital agents in the form of DCs can shorten the cycle considerably. Depending on a patient's mood, context, experience, and feedback, the DC can adjust the treatment within days, hours, minutes, or even seconds [85,86]. In our interviews, patients welcomed the idea of such functional flexibility. However, the challenge for the digital agent is to offer adaptive interventions that align with the respective physician's recommendations, comply with medical device regulations, and fulfill safety and performance requirements. Further studies must demonstrate that this type of adaptive intervention will improve treatment adherence.

The Digital Agent Should Measure and Monitor Patients' Adherence to Treatment and Provide Physicians With Easy-to-Read and Easy-to-Interpret Summaries

Measuring patients' adherence to treatment is a prerequisite for adaptive interventions [13]. Our interviews indicate scope for improvement regarding the measurement of treatment adherence—particularly for exercise and lifestyle changes. DCs are well suited to measure adherence based on objective data

from sensors and subjective data such as chatbot conversations with patients. The interviewed physicians indicated that they would accept patient behavior monitoring if DCs aggregated the monitoring results and communicated them directly to EMRs. The literature also calls for this type of workflow integration [62,74,77,78]. However, the DC must be able to recognize red-flag situations and respond appropriately because the responsibility and workload of constantly monitoring the results cannot solely rely on physicians.

Further studies are needed to determine how patients respond to behavioral monitoring. The interviewed physicians anticipate positive effects, such as patients becoming "experts" on their condition, and adverse effects, such as patients relinquishing responsibility for their actions. Therefore, digital agents must monitor patients in a supportive manner and report the results in a form that assists rather than overloads the physician.

The Digital Agent Should React to Feedback and Questions From Patients in the Period Between Consultations

The more sophisticated the DC's communication and interaction skills are, the greater the expectation patients have for them to react appropriately. It is insufficient to simply give patients access to information through patient portals or PHRs [62,63] or have chatbots handling patient questions and feedback. In certain circumstances, patients still wish to talk to their human physician. In such cases, a triage mechanism might involve physicians only when necessary. However, the associated liability issues affecting the physicians (eg, in the case of suicidal intent) must be resolved.

Requirements for the Integration of Digital Experts and DCs

Only the integration of digital experts and DCs can unlock the full potential of these agents to support the entire consultation process for the mutual benefit of patients and physicians.

The Digital Agent Should Integrate Consultation Support (Digital Experts) and Patient Apps (DCs)

Integrating digital experts and DCs closes the loop from one consultation to the next and synergistically increases the benefits of both agents [108]. From a digital expert to a DC, personalized information about the diagnosis and treatment is transmitted immediately at the end of the consultation. This avoids media discontinuity, overcomes the problem of poor recall of recommendations or information, and allows patients to implement correct therapy immediately. Some of this functionality is already part of patient portals or PHRs [62,63]. However, making this information available in an mHealth app supported by digital agents allows for better interactivity, adherence support, and measurement. As access to information alone has not proven to be effective [64,65], the mHealth approach promises greater effectiveness. Adherence measurements are fed from the DC to the digital expert based on sensor data and patient-reported outcome measures (eg, diary entries and chatbot threads). This allows physicians to prepare for the next consultation and saves time because patients do not have to report verbally what they have already entered into the app. The interviewed physicians and patients welcomed this

focus and time-saving measure, and the literature also calls for workflow integration along these lines [77,109-111].

Limitations

We derived the requirements for the design of digital agents to support consultation, adherence to treatment, and health literacy solely based on the statements obtained from our in-depth interviews with patients and physicians. Therefore, the 9 resulting requirements cannot be described as exhaustive. In particular, many necessary nonfunctional requirements are still lacking.

Furthermore, this study was conducted in Switzerland, which has one of the most expensive health care systems in the world. According to participating physicians, the standard consultation time is 20 minutes, which is significantly longer than that in many other countries. The responses from patients and physicians in other places and cultures might differ considerably. Further limitations may have arisen from the nature of a qualitative study based on a purposive sample. Although such a study results in a broad picture and deep insights, it may not be representative, not even for Switzerland. In addition, it is impossible to quantify the importance of the issues, suggested solutions, participant feedback, or the derived design requirements. For such purposes, surveys based on the insights obtained from this study are better suited. In addition, we cannot draw any conclusions related to specific user groups or medical disciplines. The fact that interview partners from very diverse backgrounds made similar observations and judgments indicates that our findings could be applied to various disciplines and user groups.

Conclusions and Future Studies

With the introduction of generative AI such as ChatGPT, the time for digital agents to support consultation, adherence to treatment, and health literacy may have arrived. There is enormous potential for patients and physicians to benefit from this new technology. Through in-depth interviews, both parties revealed their opinions about a silent and a communicative

digital expert to support consultation and a DC to accompany patients between consultations. Their responses are synthesized into the following 9 requirements for the design of digital agents to support consultations.

The digital agent should do the following:

1. Make its role in the triadic consultation transparent
2. Encourage trust and support the physician-patient relationship while safeguarding physician credibility
3. Help physicians to focus on the patient during the consultation
4. Support physicians by taking over administrative duties
5. Tailor information and patient education to individual patient needs and preferences
6. Offer adaptive interventions for behavior change
7. Measure and monitor patient adherence to treatment and provide physicians with easy-to-read and easy-to-interpret summaries
8. React to feedback and questions from patients in the period between consultations
9. Integrate consultation support (digital experts) and patient apps (DCs).

Some recommendations for future studies were also offered in Requirements for Digital Experts During the Consultation section and Requirements for the DC Between Consultations section in the Discussion section. In addition, we suggest the following:

1. Obtain a complete set of requirements for the design of digital agents for consultation; a full requirement engineering approach would need to be followed and explored in the field. This would include an analysis of the technical feasibility and economic viability [104] of the system, with the results of this study serving as a starting point.
2. Depending on where the digital agents are to be deployed, this study could be replicated with local patients and physicians.

Acknowledgments

The authors thank Andrea Koppitz Prof Dr, Professor of Nursing, for reviewing the codebook and assisting them with their profound health care knowledge. Furthermore, the authors would like to thank Dominik Spescha and Daniel Degenhardt for their support in conducting, transcribing, and analyzing the interviews.

Authors' Contributions

AF was involved in conceptualization, methodology, validation, investigation, data curation, writing the original draft, review and editing, visualization, and project administration. CS was involved in writing the original draft and review and editing. PHS contributed to the investigation. MD was involved in conceptualization and review and editing. GS contributed to conceptualization; reviewing, editing, and rewriting some sections; and supervision.

Abstract

Background: Men who have sex with men (MSM) are disproportionately burdened by poor mental health. Despite the increasing burden, evidence-based interventions for MSM are largely nonexistent in Nepal.

Objective: This study explored mental health concerns, contributing factors, barriers to mental health care and support, and preferred interventions to improve access to and use of mental health support services among MSM in Nepal.

Methods: We conducted focus groups with MSM in Kathmandu, Nepal, in January 2023. In total, 28 participants took part in 5 focus group sessions. Participants discussed several topics related to the mental health issues they experienced, factors contributing to these issues, and their suggestions for potential interventions to address existing barriers. The discussions were recorded, transcribed, and analyzed using Dedoose (version 9.0.54; SocioCultural Research Consultants, LLC) software for thematic analysis.

Results: Participants reported substantial mental health problems, including anxiety, depression, suicidal ideation, and behaviors. Contributing factors included family rejection, isolation, bullying, stigma, discrimination, and fear of HIV and other sexually transmitted infections. Barriers to accessing services included cost, lack of lesbian, gay, bisexual, transgender, intersex, queer, and asexual (LGBTIQ+)-friendly providers, and the stigma associated with mental health and sexuality. Participants suggested a smartphone app with features such as a mental health screening tool, digital consultation, helpline number, directory of LGBTIQ+-friendly providers, mental health resources, and a discussion forum for peer support as potential solutions. Participants emphasized the importance of privacy and confidentiality to ensure mobile apps are safe and accessible.

Conclusions: The findings of this study have potential transferability to other low-resource settings facing similar challenges. Intervention developers can use these findings to design tailored mobile apps to facilitate mental health care delivery and support for MSM and other marginalized groups.

Introduction

Gay, bisexual, and other men who have sex with men (MSM) have poorer mental health and experience more mental distress than their cisgender heterosexual counterparts [1-3]. Studies have shown a high proportion of MSM's experiences such as mood swings, disordered eating behavior, anxiety disorder, depression, suicidal ideation and behaviors, substance abuse, and body image disorders [4-7]. A recent systematic review and meta-analysis found that the prevalence of depression among MSM in Asia was 37% [6]. These mental health issues experienced by MSM are often linked to stressors triggered by a homophobic environment, particularly due to their sexual orientation [8].

In the context of Nepal, homosexuality is not criminalized, and the rights of MSM are guaranteed by the constitution [9,10]. Despite these legal safeguards, the prevailing cultural norms and societal attitudes pose significant challenges. Traditional and cultural values emphasize heterosexual marriages and family structures and traditional expectations of relationships, and a lack of family support often marginalizes individuals with diverse sexual orientations [11]. These social and cultural characteristics create a heteronormative and stigmatizing environment for MSM, which is detrimental to their mental health. Past studies have found that a very high number of MSM in Nepal had clinically significant depression (54%) and lifetime prevalence of suicidal thoughts (26%) [12,13]. Despite these dire mental health statistics, MSM encounter barriers in accessing health care, particularly mental health services, due to social stigma, discrimination, financial constraints, and insensitivity among health care providers [11,12,14-17]. These barriers to seeking mental health and psychosocial support among MSM, who not only have the highest needs but also the highest unmet needs, give rise to health disparities in this population. In order to reduce these disparities, improving access is crucial for advancing their overall health and well-being.

Mobile health (mHealth), especially mobile apps, offers a promising solution to bridge this gap. It can offer tailored and cost-effective interventions without the need for in-person contact and can provide convenience, improve mental health literacy and easy accessibility, eliminate travel hassles, and encourage help-seeking behavior [18,19]. With Nepal experiencing significant growth in mobile phone ownership of 96% and over 70% using the internet through smartphones, mobile app-based interventions tailored to the needs of MSM in Nepal are potentially feasible [20]. Recognizing the potential of mHealth, we conducted this study to (1) identify the mental health challenges and barriers to accessing mental health and psychosocial support services among MSM and (2) understand their preferences for smartphone apps (eg, functionality, format,

design, and attributes) that could enable their access to mental health and psychosocial support services access.

Methods

Study Setting and Recruitment

This qualitative study is part of a larger HIV biobehavioral survey that was conducted among 250 MSM participants in Kathmandu, Nepal [13]. Five focus group (FG) sessions were conducted with MSM participants in January 2023. Four of these sessions included 6 MSM participants in each, while the remaining session had 4 participants (N=28). FG sessions were conducted until a point of theoretical saturation was achieved. Eligibility criteria for participation included: (1) 18 years or older, (2) self-identified as cisgender MSM, and (3) proficiency in Nepali or English.

Participants were recruited using respondent-driven sampling, a network-based sampling method often used for hard-to-reach populations. The recruitment chain was initiated with 5 MSM "seeds," purposively selected based on recommendations from a community-based organization providing services to MSM. Each seed who completed the interviewer-administered questionnaire was given 5 recruitment coupons to recruit potential peers. Subsequent participants were, in turn, given 5 coupons to recruit additional peers. In total, 28 (~11%) of the survey participants were randomly selected for the FG sessions.

Study Procedure

FG sessions were conducted inside the community-based organization's office and lasted about 90 minutes. A semistructured FG topic guide with appropriate probes was developed that guided the discussion. A trained facilitator led the FG sessions, and a cofacilitator took the notes. Both the facilitator and cofacilitator identified themselves as MSM.

Before the discussion, participants completed an interviewer-administered Qualtrics survey that included sociodemographic, sexual health, alcohol, smoking, violence, and mental health-related questions. The participants' exposure to violence was assessed using the 4-item Hurt, Insult, Threat, and Scream screening tool, using a 5-point frequency format (scores 4-20). Final scores were classified as normal (0-10) or violence (11-25) [21]. Depressive symptoms were evaluated with the Patient Health Questionnaire instrument, scoring each of the 9 *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition, criteria (0-3). A composite score of 0-27 was computed, with a score exceeding 10 indicating moderate to severe depressive symptoms [22].

The FGs involved questions and discussions about traumatic life events. Participants were made aware that they did not have to answer any questions that they felt were distressing and could leave the FG session at any time if they felt uncomfortable. A

study team member was also present at all 5 FG sessions to refer to a counselor or provide any additional support needed in the case of a distressing situation. While conducting the FG sessions, a trained facilitator approached participants sensitively, respecting moments of silence and their willingness to continue discussions—statements like “I am fine” or “we can continue” followed silence. Despite the sensitive topics discussed, none of the participants requested support, including speaking with counselors. At the end of all FG sessions, participants also disclosed that they were glad to have had the opportunity to share their experiences.

Data Analysis

SPSS (version 29.0.0 software; IBM Corp) was used to calculate descriptive statistics (frequencies and percentages) for the variables collected via a Qualtrics survey. FG transcripts were transcribed and checked for accuracy before coding. The 2 coders (KG and CA) read and reread transcriptions to identify key ideas and recurring themes. A codebook was developed with mutually agreed-upon codes derived from the FG transcripts, and coding was completed independently by 2 researchers (KG and CA). To ensure reliability, codes were constantly compared for agreement and discussed between the coders, and the senior author (RS) cross-checked all codes. Dedoose (version 9.0.54) was used for data management and analysis. The themes were gathered as child codes and then placed into a broad category as root codes. Each theme with its qualitative quotes to best illustrate the findings are presented in the results section.

Ethical Considerations

The study protocol was approved by the institutional review boards at the University of Connecticut (H22-0039) and the Nepal Health Research Council (2391-2022 P). All the participants provided verbal informed consent before their participation. Participants were explained the importance of maintaining the confidentiality of FGs and requested not to discuss the experiences and comments shared during the FGs with others. All the sessions were conducted in Nepali and were audio recorded, transcribed, and translated. Participants were compensated NRs 1000 (~US \$8) for their time and participation. FG transcripts were deidentified before the analysis, and the survey data were anonymous.

Results

Participant Characteristics

Table 1 provides information on participants' characteristics. The mean age of study participants was 25.3 (SD 6.1) years. Most of the 28 participants were Hindu (n=22, 79%), had a high school or higher degree (n=21, 75%), and identified as gay (n=22, 79%). A total of 21% (n=6) of participants had depressive symptoms, and 14% (n=4) had experienced violence in their life. A little over half (n=15, 54%) of participants had used health-related mobile apps, and almost 90% (n=25) used digital devices to search for health-related information.

FG Results

Overview

Throughout the data analysis, 3 overarching themes emerged in the codebook with their own subthemes ([Multimedia Appendix 1](#)): (1) mental health challenges, (2) barriers to accessing mental health services, and (3) preference for mental health mobile apps with desired features and attributes.

Mental Health Challenges

Mental health challenges faced by the participants involve a multifaceted interaction of factors, including sexual orientation, emotional distress, stigma, discrimination and victimization, and social exclusion. Moreover, they frequently encounter barriers to accessing support services that could enhance their mental well-being. Participants not only vividly described their day-to-day challenges but also shared insights into the collective experiences of the lesbian, gay, bisexual, transgender, intersex, queer, and asexual (LGBTIQ+) community. Their comprehensive perspective underscored the profound impact of prevailing societal biases on their mental well-being ([Textbox 1](#)).

A constant fear of societal judgment and family pressure to conform to traditional gender norms has intensified issues like anxiety, depression, and suicidal thoughts. Participants in all FGs highlighted the pressure to enter heterosexual marriages, causing emotional turmoil as they navigate their identities and societal expectations ([Textbox 2](#)).

Participants disclosed coping mechanisms, such as drug use, drinking alcohol, smoking, engaging in sexual risk behaviors (eg, multiple sex partners), and self-harm. These strategies were described as providing temporary relief from the immense emotional turmoil they experience.

I have personally known someone who started risky sexual behavior from a young age because that was how they felt validated. They wanted others to make them feel better. So, they would often engage in multiple sexual encounters, thinking it would help them cope with their struggles... I also know people who turned to drugs and alcohol to cope with themselves. [18-year-old participant from FG1]

...due to tension and mental pressure, it was tough for me to control myself, so I started to cut my hands with a razor; I did it many times. I was also thinking of taking tablets for suicide. [30-year-old participant from FG3]

Several participants talked about and shared their experiences of intense anxiety and fear surrounding the possibility of contracting HIV and other sexually transmitted infections following sexual encounters with their partners.

I have extreme fear about whether I contracted it [HIV] or not... even the close friends I know have contracted HIV, and because of that, I also have a fear and anxiety of whether I contracted HIV or not after the sex is done. [21-year-old participant from FG1]

Textbox 1. Social acceptance and lack of family support heighten mental health challenges.

- "...there is no one, and when we open up there is no family support. Family supporting queer people, it is like gold which is rare. We only open out in this [LGBTIQA+] community; You can imagine how bad is our mental status and the situation." [26-year-old participant from FG2]
- "...because of my sexuality, sometimes I suffer from social anxiety, 'are they judging me because of my looks, voice or the way I dress.'" [24-years-old participant from FG5]
- "I study in 12th grade, and most of the time, I am bullied by my male classmates... even the teachers ask, "Why do you act like a girl?" And most of them do know I use TikTok, and everyone knows about me, so I think bullying is also another part, and I think mental health or stress is a common occurrence for everyone in LGBTIQA+ people." [22-year-old participant from FG1]

Textbox 2. Mental health challenges from societal pressure and identity concealment.

- "...if I have to be 'me' or do something feminine, then there is a fear of being judged by other people, so I have to pretend as a closeted man, I have to pretend masculine, have a masculine voice, and all the stereotypes and stigmas the people in the community have kept, which fuels the anxiety." [22-year-old participant from FG1]
- "I faced immense pressure from my family about marriage, being the only son. I kept my sexual orientation hidden, making it harder in our community. The talks of marriage became unbearable... I felt so distressed that I left home and was even suicidal. My relatives found out, but the misunderstanding about my identity remained... these struggles took a toll on my mental health, forcing me to search for ways to cope and maintain my well-being." [28-year-old participant from FG3]
- "I was so low that all I had in mind was suicide." [29-year-old participant from FG2]

Participants also shared that they fear the potential disclosure of their HIV status because they anticipate that others may treat them differently after learning their status.

When it comes to HIV, if a person status has HIV, he is afraid that if his status leaks, then people will look differently. [23-year-old participant from FG4]

One participant recounted how their colleague, upon learning their HIV-positive status, tragically died by suicide, underscoring the emotional toll and mental health challenges.

There was one colleague of mine who died by suicide as soon as the HIV test result came back positive. [25-year-old participant from FG1]

Barriers to Accessing Mental Health Services

Participants shared that many gay, bisexual, and MSM do not seek mental health services because they perceive themselves as mentally healthy and believe their lives are going well, leading them to overlook the need for such support.

The reason I believe that our community members do not seek mental health services is because they think they are alright, that their life is just going on, they think they are fine and healthy and feel they don't need such services. [25-year-old participant from FG3]

Participants also shared that individuals tend to become more open and willing to seek help if they are aware of mental health services like counseling and therapy.

...if people are aware of counseling and therapy, people will be more willing to go there. [24-year-old participant from FG2]

Participants discussed that individuals still closeted about their identity find it challenging to trust others, creating a communication barrier. Their hesitancy to trust stems from a history of hiding aspects of themselves, hindering open communication and sharing true feelings and experiences.

It is hard for people to trust. There is also a communication barrier because they are still closeted and grew up hiding things from the beginning. If the person themselves is not trusting them, then how can they trust the person in front of them. [35-year-old participant from FG2]

Stigma and discrimination associated with mental health and sexuality were major concerns for participants. Many participants brought up fears of being labeled "pagal" (a pejorative that is closest to "crazy" in English) as a barrier to accessing mental health services.

...there is a stigma against mental health, that is the reason we do not seek mental health services. If we visit a health care center, then people will talk about it, and the peer groups and society will think of us as pagal (crazy); they will say that this person is taking medicines, so that is another reason we do not visit mental health care centers. [26-year-old participant from FG3]

Others discussed the impact that homophobia can have on MSM seeking mental health services. Homophobia and heterosexism still exist in Nepal's society and can have significant impacts on MSM decisions.

A stereotypical saying "how can men like men?" is still prevalent in society, so, to not get judged by others, people don't attend these [mental health] sessions. [29-year-old participant from FG2]

Many participants expressed their frustration with medical professionals who, instead of addressing their health concerns seriously, tend to label them, dismiss their issues, and attribute symptoms to perceived psychological factors such as overthinking, thereby hindering their access to necessary services.

Often, the doctor calls us with names, gives us a tag, they do not give us a priority, they only say "there's

nothing wrong with you, it's only because you overthink" which has an impact on seeking services. [26-year-old participant from FG3]

Many participants expressed the financial strain posed by mental health services for MSM in Nepal. The consensus was that the cost associated with psychiatrist visits, along with their limited financial resources, significantly affects MSMs' ability to access the necessary mental health services.

The main reason is finances because it is still very expensive, like we have to pay NRs 800 to 1000 (approximately US \$8 to 10) per visit. It is expensive, even more so in private clinics. [23-year-old participant from FG5]

Several participants across all FG sessions expressed concerns about time limitations and transportation challenges when it came to accessing mental health services. In an FG, a majority of participants agreed on the considerable difficulty that MSM faces in securing transportation to be able to go to a physical mental health appointment. In another session, everyone unanimously agreed and nodded in agreement with the following statement:

I think so too, because not everywhere has access to transportation, and for some places, we might even have to walk a lot to reach there. [27-year-old participant from FG2]

When it comes to time constraints, participants talked about the difficulty of scheduling mental health appointments within the confines of work or school hours. They highlighted the difficulty of taking leave from work or school to attend counseling sessions during times of need.

I can go frequently, but the counseling appointment has to be time-friendly. Some of us are employed from 10 am to 5 pm or even 6 pm. If the counseling session is around that time, then I might come for a few days, taking a leave from work, but if my office does not allow me, then even if I had a mental health support need, I would not be able to attend. [26-year-old participant from FG3]

Solution: Mental Health Smartphone Apps With Desired Features and Attributes

Overview

Participants expressed a preference for a smartphone app with a variety of features and attributes compared to traditional clinical settings. They foresaw that such an app could enhance understanding of mental health, offer convenience, improve accessibility, reduce the necessity for travel and associated expenses, and deliver services in a confidential and nonjudgmental setting.

During our young age, we didn't have any type of apps to help with our issues or any sort of networking apps like Grindr, but now people are more open to using apps, so creating an app to help solve the mental health issue and counsel can be a great idea. [35-year-old participant from FG2]

Desired Features of the Mobile App

Participants recommended using creative approaches, such as fun activities to assess individuals' mental health for early detection, moving away from more direct approaches.

Something creative, not a direct approach, but through games or other ways we could assess the mental health status of the people for early detection. [25-year-old participant from FG3]

Participants emphasized the importance of using the app to schedule regular counseling appointments with mental health professionals for those requiring assistance. There was a strong preference for using Zoom over platforms like Viber and WhatsApp for digital counseling, citing its widespread use during the COVID-19 pandemic.

...those who are in need of mental health services should get counseling appointments from a professional by selecting them once or twice a week in the app. [29-year-old participants from FG4]

Rather than Viber and WhatsApp, Zoom is good for e-counseling, as in COVID many people are using it. [18-year-old participants from FG4]

All participants underscored the importance of mental health and psychosocial service providers being qualified, friendly, and supportive of the LGBTIQ+ community. They stressed the need for an environment where individuals feel safe and comfortable to share their concerns.

First of all, they should be very friendly towards LGBTIQ+, no matter whether they are a community member or not, and we have to feel safe and able to share everything. Is qualified and has studied the related field. [23-year-old participant from FG5]

Some participants had suggestions that would help make MSM more comfortable in participating in digital counseling, such as making cameras not compulsory.

We can do it through audio calls. Zoom counseling sessions are fine, but opening cameras should not be necessary or compulsory. [21-year-old participant from FG5]

An additional recommendation included providing convenient hours, allowing users of the app to secure digital counseling appointments relatively quickly. This would accommodate individuals who work or go to school, ensuring continued accessibility to the services.

People will schedule according to their needs and how big their problem is, if you are having a problem now and get an appointment for a session after a month, it is not possible. [21-year-old participant from FG2]

Participants suggested incorporating a toll-free helpline number within the smartphone app. They shared their experiences with toll-free helplines that did not function as intended in the past. Additionally, they provided suggestions for improving the toll-free helplines within the mobile app.

We can use a Toll-free helpline number, but even I tried to use toll-free service every time it was busy. So, the missed call system [call back system] is good. [21-year-old participant from FG5]

Several participants suggested including a feature to message counselors in addition to the toll-free helpline that could help those who do not want to or cannot talk over the phone.

Some might not want to speak; they could talk through chat. [30-year-old participant FG3]

Several participants shared their difficulties in finding friendly mental health and psychosocial service providers. To address this issue, participants suggested having a directory of LGBTIQ+ friendly providers on a mobile app that would help show MSM where to go when they require help.

I searched, and I came to know. It took me a lot of effort, and it was hard to find psychosocial counselors. [29-year-old participant from FG2]

Participants also suggested to include mental health educational resources, especially in the form of videos.

Many are hidden, they do not even want to come out of the house, because of the fear of society. But they use mobile apps, they could connect to the app, and even with information and educational videos, we could reach them. [21-year-old participant from FG5]

Many participants suggested a feature to connect with peers and other members of the MSM community through a communication channel within the app. They highlighted the importance of such a platform for sharing experiences and emphasized the value of peer support.

I think a discussion forum would be a good addition. The forum can help you share and make you feel like you are not the only one who is going through the same trauma and hardships, and we will be sharing with each other. [21-year-old participant from FG1]

Attributes of the App

Many participants suggested placing special emphasis on the privacy and confidentiality of data collected by the app. They recommended that app developers and health care providers should commit to privacy and confidentiality clauses in their contracts, with strict consequences for any breaches of information.

The staff, app developers, and providers should sign on privacy and confidentiality in their contract. If leakage of information is found, they need to know that strong steps will be taken. [26-year-old participant from FG3]

When discussing the user interface and colors of the app, several participants suggested that the mobile app should not overtly appear targeted exclusively at the LGBTIQ+ community. The participant expresses a desire for the app to have a discreet appearance, in contrast to the distinctiveness of dating apps targeted toward LGBTIQ+.

Through application maybe, the application should not look like for only LGBTIQ. It must look normal, not like Grindr. [23-year-old participant from FG5]

Participants showed a strong interest in an engaging activity for user engagement and retention, particularly one that incorporates entertainment. One participant mentioned:

There has to be an environment in the mobile app so that I feel like going and using it again. [26-year-old participant from FG3]

Discussion

Principal Findings

This study revealed a complex interplay between mental health challenges, including depression, anxiety, and suicidal behavior, among MSM in Nepal. The findings further highlight the barriers to accessing mental health care and support services among Nepali MSM due to factors such as insufficient mental health literacy, privacy concerns, financial strain, stigma, and discrimination. This underscores the urgent need for tailored and accessible mental health interventions. Participants overwhelmingly preferred smartphone app interventions to address the identified barriers and challenges, emphasizing their preference for accessible and confidential mental health support through digital platforms.

The major concern among MSM, where individuals perceive themselves as “all right” without the need for mental health services and less help-seeking attitudes, likely indicates a lack of mental health literacy, which is similar to the findings from studies among men and other minority populations [23-27]. Participants in this study expressed a preference for mental health resources and screening tools integrated into the app. Few studies have demonstrated that a smartphone app with an easily accessible and comprehensive mental health education module, resources, and engaging screening tools has the potential to combat this issue by fostering a proactive attitude toward mental well-being, the importance of seeking support, and the early detection of mental health problems [28-30].

The stigma and discrimination faced by MSM, both within society and health care settings, contribute to hesitancy in seeking mental health support. This fear of stigma and reluctance aligns with the findings from studies of various marginalized populations [26,31-33]. In response to this, participants expressed a preference for features within the mobile app that could link participants with LGBTIQ+ friendly mental health professionals through video sessions, automated text messages, or phone calls, emphasizing the crucial role of trust and understanding in the provider-patient relationship. Few interventions have integrated such features into digital interventions [34,35]. This feature could help to overcome this barrier by connecting individuals with LGBTIQ+ friendly and supportive mental health professionals and fostering a more inclusive, judgment-free, and accessible mental health support system.

In line with a substantial body of research, the findings emphasize that various stressors, particularly those related to societal biases, discrimination, fear of HIV, and other sexually

transmitted infection results, contribute to psychological distress, and these influence maladaptive coping behaviors among MSM [7,8,36-38]. By incorporating features such as mental health resources, coping strategies, and peer support discussion forums, the app can have the potential to empower MSM to navigate these challenges more effectively.

The privacy and confidentiality concerns expressed by MSM underscore the need for a sensitive approach to mental health support. This apprehension aligns with findings from studies of various minority populations [39-42]. Participants in this study articulated the desire for a mobile app that explicitly addresses these concerns through robust consent forms, privacy features, and secure messaging platforms. The app could have features that aim to ensure privacy and confidentiality, potentially fostering MSM trust and addressing barriers related to sharing personal mental health information. Integrating these features into app design could significantly contribute to alleviating privacy concerns and establishing a secure environment that encourages seeking mental health support.

The cost of accessing mental health services was a major concern for participants in the study, which aligns with previous research on the cost of mental health in Nepal [43]. It is important to address financial strain in any intervention that is created to help MSM in Nepal with mental health [44-46]. Studies have found that, by reducing travel expenses, mHealth interventions help allow access for sexual minority individuals to mental health care [47,48]. This not only addresses the financial challenges faced by Nepali MSM but also alleviates the transportation struggles [35].

Strengths and Limitations

This study is of particular value due to the lack of participant involvement in the development of mental health interventions,

with LGBTIQ+ consultation being notably rare when it comes to the creation of health interventions, policies, or guidelines [49,50]. Using FGs, the participants' perspectives can be used to create a more tailored and effective digital health intervention. However, this study has its own limitations. One of these limitations is the presence of social desirability bias, which is a common occurrence in FG discussions. This bias can influence participants to express socially acceptable opinions rather than their true thoughts and feelings. Additionally, it is worth noting that the study was done in Kathmandu, Nepal, which can differ in culture and access to mental health services than other areas of Nepal, limiting the transferability of the study findings mainly on the challenges and barriers. Finally, it is important to consider that the desire to participate in a given intervention does not automatically guarantee its real-world adoption. Evaluating the actual usage and effectiveness of the intervention in real-life scenarios is crucial to fully understand its impact and potential benefits. Therefore, it is necessary to evaluate real-world usage.

Conclusions

The study highlights the mental health challenges encountered by MSM in Nepal and the barriers they face in accessing mental health support services. The participants' direct quote, "invisible in the corner of the room," captures the hidden nature of their struggles intimately tied to the intersectional stigma surrounding mental health and sexuality. Emphasizing the potential of mobile apps, our findings suggest that incorporating user-friendly features like accessible resources, mental health screening tools, and digital counseling with LGBTIQ+-friendly providers can bring visibility to the mental health challenges of MSM. The mobile app has the ability to establish an open and supportive space, breaking down barriers and offering a pathway for MSM in Nepal to identify and address their mental health concerns with ease and confidence.

Abstract

Background: The transition from hospital to home after orthopedic surgery requires smooth communication and coordination between patients and their team of care to avoid fragmented care pathways. Digital communication is increasingly being used to facilitate easy and accessible asynchronous communication between patients and health care professionals across settings. A team-based approach to digital communication may provide optimized quality of care in the postoperative period following orthopedic surgery and hospital discharge.

Objective: This study was divided into two phases that aimed to (1) explore the perspectives of patients undergoing orthopedic surgery on current communication pathways at a tertiary hospital in Denmark and (2) test and explore patients' experiences and use of team-based digital communication following hospital discharge (eDialogue).

Methods: A triangulation of qualitative data collection techniques was applied: document analysis, participant observations (n=16 hours), semistructured interviews with patients before (n=31) and after (n=24) their access to eDialogue, and exploration of use data.

Results: Findings show that patients experience difficult communication pathways after hospital discharge and a lack of information due to inadequate coordination of care. eDialogue was used by 84% (26/31) of the patients, and they suggested that it provided a sense of security, coherence, and proximity in the aftercare rearranging communication pathways for the better. Specific drivers and barriers to use were identified, and these call for further exploration of eDialogue.

Conclusions: In conclusion, patients evaluated eDialogue positively and suggested that it could support them after returning home following orthopedic surgery.

Introduction

Across the health care system, digital communication is being implemented as an addition to traditional communication pathways [1,2]. Digital communication is a form of eHealth [3] that facilitates asynchronous 2-way text messaging between patients and health care professionals (HCPs). Digital communication is typically facilitated through email [4,5]; secure text messaging in patient portals [2,6]; or as a feature in mobile health apps developed for specific purposes, for example, postoperative monitoring [7,8] and neonatal tele-homecare [9,10]. Establishing the effects of using digital communication is still challenging [11,12]; however, an increasing number of studies suggest that it can support patients in taking care of their own health [12] and address unmet communication needs after hospital discharge [13,14]. When digital communication is used with the purpose of facilitating team-based communication across settings, studies indicate that it may contribute to improving continuity of care (COC) in transitions from hospital to home [14-16]. COC is essential for patients undergoing complex and long-term procedures [17]. Patients who receive care across time and settings are susceptible to fragmented care, and the absence of consistent professional support and communication may lead to neglect that ultimately affects patient safety [18-21]. Because of the growing population in need of orthopedic surgery, workforce shortage [22], and optimized surgery techniques, patients undergoing orthopedic surgery are discharged earlier [23]. Day surgery is increasingly used, and even patients undergoing complex treatments are

hospitalized for a shorter time. Common to patients undergoing orthopedic surgery is a need for continuing rehabilitation across settings, supported by adequate communication and home symptom monitoring between follow-up visits [24,25]. Even so, only a few studies have addressed the use of team-based digital communication involving patients and HCPs across settings, and primarily in other patient populations, such as patients with cancer [14,15,26] and children with cerebral palsy [27]. To our knowledge, no studies have investigated the use of team-based digital communication after hospital discharge in orthopedic surgery, although these patients often have long periods of rehabilitation, where cross-disciplinary and cross-sectoral communication is pivotal [28].

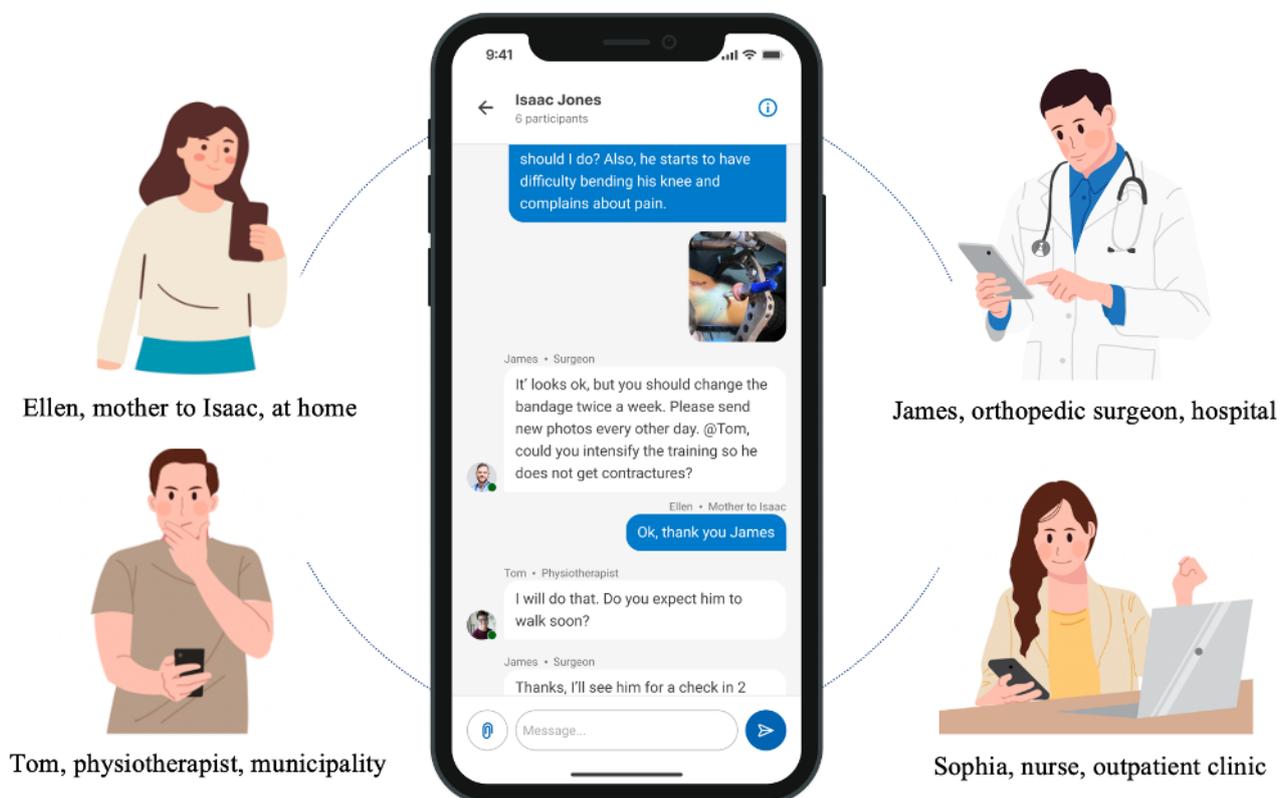

Therefore, the aim of this study was to explore the perspectives of patients undergoing orthopedic surgery on current communication pathways (phase 1) and to subsequently test and explore their experiences and use of a team-based digital communication solution (eDialogue) to evaluate whether the solution can support their needs after hospital discharge (phase 2).

Methods

The eDialogue Intervention

The technical solution used in this study was a simple General Data Protection Regulation-compliant solution, developed for team-based communication, that lets users chat directly with each other with texts and photos ("LetDialog" by Visma) [29] (Figure 1).

Figure 1. Illustration of the team-based digital communication (eDialogue) used in this study, where patients and health care professionals across settings could text and send photos to communicate about postdischarge issues.

The solution was accessed through an app for smartphones or through a website. Users could choose how they accessed it individually. To ensure compliance with the current legislation, user profiles were created with a digital signature (NemID), and the digital dialogues were stored in a secure cloud-based solution. A data processor agreement was made among the North Denmark Region, Aalborg University Hospital, and Visma before this study.

The features were basic asynchronous text messaging and exchange of photos. Photos could be taken directly or uploaded and sent through the solution for review by the health care team. Team-based digital communication was organized in teams, defined by the individual patient, in a shared chat. Notifications were sent to all the participants when there were new posts. Key HCPs from the orthopedic surgery department at the hospital were identified and recruited for participation before the study (surgeons, nurses, and physiotherapists). Other HCPs from municipal or private settings were recruited ad hoc and based on patients' wishes (eg, physiotherapists from the municipality).

Study Design

The study was exploratory, using a triangulation of qualitative data collection techniques, including document analysis, participant observations [30], semistructured interviews [31], and use data, with the purpose of obtaining in-depth knowledge of patients' perspectives and the context.

Theoretical Framework

The theoretical framework for this study was inspired by the concepts of COC [17,32], which is used as a measure of quality of care in health care transitions. COC includes *informational continuity*, described as the use of medical or personal information to provide appropriate care over time; *management continuity*, which refers to the provision of timely, coordinated, and complementary services that are responsive to patients' needs to connect care over time; and *relational continuity*, which involves the consistency and quality of relationships between patients and providers as a means of connecting care over time [32]. All 3 dimensions should be integrated to achieve COC, and thus, COC is maximized when planning for patient-provider continuity, information exchange, and seamless coordination of services in the period of transition from hospital to home [32-34]. For this study, COC has inspired the data collection and analysis of interviews and observations as well as the use of team-based digital communication to prevent fragmented care experiences after hospital discharge.

Participants and Setting

The study was conducted at the Orthopedic Surgery Department of Aalborg University Hospital, Denmark. The recruitment of participants began in May 2021 and ended in November 2021. The final follow-up interviews were conducted 2 months later in January 2022.

In phase 1, participants were recruited consecutively based on predefined inclusion criteria: (1) patients, or their parents if the patient was aged <15 years, undergoing deformity correction (DC) surgery or anterior cruciate ligament (ACL) reconstruction; (2) those who were able to read and write Danish; (3) those who

were discharged to their own home and had planned follow-up in the outpatient clinic; and (4) those who owned a smartphone and had access to a secure digital signature. The exclusion criteria were (1) those who were not able to understand Danish and (2) those who were not cognitively able to participate in interviews.

The 2 patient groups, DC and ACL, were selected because they represent 2 different orthopedic surgical care pathways. Involving both patient groups allowed us to gain an insight into the different needs of patients undergoing orthopedic surgery. ACL is performed as a day surgery (ie, discharge on the same day), whereas patients in the DC group most often have longer hospitalizations and prolonged treatments.

The same recruitment procedure was used for patients undergoing DC or ACL. The patients were approached by secretaries at the hospital with an invitation to participate. If the patients agreed to be called by phone with information about participation in the study, the first author (LWHJ) would call them to provide oral participant information. Written participant information was then sent by email, and the patients were given time to consider participation. One patient did not want to participate after receiving oral information due to a lack of mental capacity to participate in the interviews. Another patient could not be contacted by telephone after he had initially registered his telephone number. Both patients were from the ACL group.

In phase 2, patients and parents (if the patient was a minor) were onboarded to eDialogue on the day of discharge. The orthopedic surgeon, who had performed the surgery, was invited to join the patients' dialogue, as were nurses from the outpatient clinic and physiotherapists across sectors who were involved in the patient's care and rehabilitation after discharge. Thus, the patients were connected with known HCPs and were able to use eDialogue as needed from the day of discharge until 2 months after discharge. The patients could send texts and photos whenever it suited them, but they were told that a 24-hour response time on weekdays (Monday to Friday) would be aimed for. As such, messages sent during weekends and holidays would be responded to on the next weekday. It was pointed out, both verbally and in the participant information letter, that in case of emergency, patients should not use the solution but instead call, as they usually would have done before access to eDialogue. Thus, eDialogue was an addition to traditional communication channels (eg, telephone calls and email) and an extra opportunity for communication after discharge.

Data Collection

A triangulation of data collection techniques was performed to achieve exhaustive knowledge of current communication pathways, patients' perspectives, and their experiences with eDialogue.

Phase 1

First, document analysis was performed on documents and guidelines for postdischarge communication between patients and HCPs followed by participant observations of workflows (n=16 hours). The aim of the document analysis was to obtain knowledge of the policies and context of the study. The aim of

observations was to document the current communication pathways for patients following hospital discharge. Participant observations were performed by LWHJ and followed a predefined observation guide [30]. Observations were carried out at the orthopedic surgery ward and the outpatient clinic at the hospital and documented in Word files (Microsoft Corp). This involved, for example, secretaries' handling of incoming phone calls from patients, registration of patient inquiries, procedures for passing on messages to nurses and orthopedic surgeons, and HCPs' calls with patients. In addition, existing systems for communication with discharged patients were reviewed, including written communication to patients via "E-box," (a secure digital mail system for communication from Danish authorities) correspondence between HCPs across hospitals and municipalities in the local electronic health record, and interprofessional communication related to patients' phone calls.

Second, semistructured interviews were conducted at the point of inclusion for each participant (N=31). The aim was to explore patients' and parents' perspectives on current communication pathways. Interviews were performed using video 5 to 7 days before surgery for patients from the ACL group (n=14) and physically at the ward for patients and parents from the DC group (n=17) because they were all hospitalized in connection with their operation. All interviews were conducted by LWHJ based on a predefined semistructured interview guide (Multimedia Appendix 1). The guide was developed based on the theoretical framework for this study and combined with exploratory questions. It was pilot-tested in 2 patients similar to the study participants and revised accordingly. The interviews were carried out until data saturation had been reached, defined by the point where no new insights into participants' responses occurred, indicating the achievement of a comprehensive understanding of the participants' perspectives [31]. The interviews were audio recorded using a digital voice recorder (DM-450; Olympus) and lasted for 40 to 60 minutes. They were continuously transcribed and documented in Word files. During and at the end of each interview, key points were summarized to ensure the credibility of the meanings expressed.

Phase 2

Semistructured follow-up interviews were performed with the same patients and parents 2 months after hospital discharge (24/31, 77%). The aim was to explore their experiences of using eDialogue for team-based communication in the postdischarge period. The interviews were performed by LWHJ, audio recorded, and followed a predefined interview guide that was pilot-tested (Multimedia Appendix 1). The interviews were

conducted until data saturation was reached for each patient group [31]. They lasted between 30 and 60 minutes. Both users and those who did not use eDialogue after getting access were interviewed. A total of 6 patients (DC: n=3; ACL: n=3) were reached by phone, their experiences were discussed, and a short report was written. Nothing new emerged from these conversations. One parent of a child from the DC group was lost to follow-up as she did not return our calls. Interviews were performed face-to-face at the ward or digitally based on the preferences of the participants. Participants were most likely to choose web-based interviews due to convenience and distance to the hospital, and data collection was conducted at the same time as the COVID-19 pandemic.

Use data of eDialogue was collected through registration of events and manual counts of messages exchanged in all digital dialogues. Data included the total number of messages exchanged in eDialogue during the 2-month study period, the number of text messages and photos sent by patients or parents, and the number of text messages that actually needed a reply from HCPs. In addition, the distribution of text messages per week per patient group was collected and displayed to show the differences between groups. Content analysis [31] of the messages sent by the patients and the parents was performed to provide insight into question categories as well as how they were distributed between the patient groups.

Data Analysis

Data analysis was carried out in NVivo (version 20.6.2; Lumivero), inspired by Brinkmann and Kvale [31], with the aim of achieving an in-depth understanding and connection of the participants' expressed perspectives on current communication pathways (phase 1) and experiences using eDialogue (phase 2).

Separate data analyses were carried out for phase 1 and phase 2 and for each patient group (DC and ACL), all involving 3 steps: meaning coding, meaning condensation, and meaning interpretation (Textbox 1).

In phase 1, observational data were integrated into the data set to enhance the understanding of existing communication pathways for patients in need of postdischarge contact.

Use data from eDialogue were analyzed and presented using simple descriptive statistics and basic content analysis to present the overall question categories.

The reporting of this study followed the Consolidated Criteria for Reporting Qualitative Research checklist [35].

Textbox 1. The process of the thematic analysis.

Meaning coding

- Coding of the transcribed interviews was initially performed individually by 2 of the authors (LWHJ and REKL) by randomly selecting 4 interviews from each patient group and from each phase. Coding was conducted with an inductive approach with the aim of reflecting the meanings expressed by the participants.
- To achieve intersubjectivity before and during the analysis, interviews were individually read and reread by LWHJ and REKL, notes were made for initial ideas for codes, and these were then compared and discussed until agreement. In phase 1, this resulted in 21 codes in the deformity correction (DC) group and 18 codes in the anterior cruciate ligament (ACL) group. In phase 2, we identified 18 codes in the DC group and 15 codes in the ACL group. LWHJ continued the data analysis of the remaining interviews by applying the same codes to the entire data.

Meaning condensation

- The codes were then reread and condensed in discussion with REKL and the last author (BD) through several iterations, and this process resulted in 12 codes for the DC group and 8 codes for the ACL group in phase 1 and 11 codes for the DC group and 7 codes for the ACL group in phase 2. We merged and we left behind codes that did not directly address the research questions or were only described vaguely by 1 participant.
- The remaining codes were then discussed with all authors to achieve further condensation and to define and name subthemes and themes that would capture the essence of the data. It was clear to the authors that the 2 patient groups had expressed similar perspectives on the phenomena of interest, and therefore, codes could be merged between the 2 groups in this step. Theme generation was based on a systematic identification and organization of recurring patterns, topics, or concepts within the data set. This process resulted in 3 overall themes and 6 subthemes for phase 1 and 3 overall themes and 3 subthemes for phase 2.

Meaning interpretation

- Themes were defined and described narratively, and data extracts were chosen for presentation in the manuscript before writing the findings.

Ethical Considerations

Before the study started, the Ethics Committee of Northern Jutland was approached, and it was found that the study did not require approval, as eDialogue was an extra opportunity for patients to communicate directly with their team of HCPs across sectors. This was confirmed by email on March 18, 2021 (2021-000438). The study was registered with the Regional Committee on Health Research and approved (ID number 2021-057). All participants received thorough oral and written information and guidance in the use of eDialogue before discharge. The study followed the Helsinki Declaration, and the participants signed an informed consent form and were able to leave the study without explanation or effects on usual care. All patients or parents had access to eDialogue for 2 months after hospital discharge. If they wanted, patients were allowed to keep the possibility of eDialogue with their team of HCPs after 2 months and until their follow-up in the outpatient clinic was completed. An administrator from the project group was passively present in all dialogues to continuously observe whether the patients used the solution for emergencies against the given advice.

Results

Participants' Characteristics

Table 1 provides the baseline description of the 31 patients included in this study. The patients were recruited from 2 different subgroups of orthopedic surgery: DC (17/31, 55%) and ACL (14/31, 45%).

The patients in the DC group were, for example, patients with malalignment or limb length discrepancy, and they were all hospitalized for >1 day. The patients in the ACL group were all treated with ACL reconstruction, and they had the procedure performed as day surgery. Of the 14 patients with ACL injuries, 7 (50%) had a concurrent meniscal injury.

Across the groups, most patients were male (22/31, 71%), and patients ranged in age from 1 to 59 years. Patients from the DC group were discharged from the hospital after an average of 6.1 (range 1-9) days, and patients from the ACL group were all discharged on the same day of surgery (<9 hours of admission). All the included patients were discharged to their own home. Of the 31 patients included, 14 (45%) had previously undergone orthopedic surgery at Aalborg University Hospital, and thus, they were able to reflect on previous experiences with postdischarge communication during the initial interviews in phase 1. In the DC group, 5 patients lived outside the North Jutland Region.

A total of 42% (13/31) of the patients were children aged <15 years, and thus, their parents were the primary users of eDialogue. Therefore, the baseline characteristics of all users of eDialogue are presented in [Table 2](#).

The table shows 33 users in total because 2 patients aged 16 and 17 years had a parent joining the dialogue with them. Of the 13 parents who were users of eDialogue with or on behalf of their child, 77% (10/13) were female (mothers). The mean age of the parents was 43 (range 37-48) years on the day of discharge. All users of eDialogue used a smartphone on a daily basis.

Phase 1: Perspectives on Current Communication Pathways

Themes and Subthemes

Through the initial interviews, 3 themes and associated subthemes were revealed across the groups. Overall, patients

and parents from the DC and ACL groups had similar experiences of, and perspectives on, current communication pathways. However, some subthemes were more prominent in one group than the other. This is illustrated by showing how many patients and parents from each group expressed experiences related to the specific subtheme (Table 3).

Table 3. Themes and subthemes of patients' and parents' perspectives on current communication pathways with HCPs^a after hospital discharge (N=31).

Themes and subthemes	DC ^b (n=17), n (%)	ACL ^c (n=14), n (%)
Difficult communication pathways		
Doubts about who to contact and when	8 (47)	7 (50)
Withhold questions or forget to ask	7 (41)	9 (64)
Lack of information due to inadequate coordination of care		
Knowledge is not shared sufficiently	8 (47)	6 (43)
Hard to be "the messenger" between HCPs	9 (53)	5 (36)
Relations and communication provide "peace of mind"		
Relational continuity matters	15 (88)	4 (29)
Contacts provides a sense of being cared for	10 (59)	2 (14)

^aHCP: health care professional.

^bDC: deformity correction.

^cACL: anterior cruciate ligament.

Difficult Communication Pathways

Most patients and parents expressed frustrations related to difficult communication pathways when they needed contact with HCPs. They were in doubt about who to contact regarding specific issues both before and after surgery and discharge:

It was like a week after discharge, and I didn't know who to ask. Should I contact the department, the outpatient clinic or my own physician? I didn't know that. They kept telling me to call a new location.
[Mother of patient 2, DC]

The patients also described how they would often forget to ask questions at the outpatient clinic or they would withhold questions because they found it difficult to assess whether their issues were "severe enough" to take up HCPs time. A patient explains how it had previously led to concerns and worsening of symptoms:

I couldn't lift up my leg like I had been able to before...The next morning, the knee was barely visible due to swelling. Well, I should probably have done something the day before, but I didn't. You just know that when you call the hospital, you must go through several people, and I don't want to be a nuisance either. [Patient 4, DC]

Lack of Information Due to Inadequate Coordination of Care

Patients in the ACL group highlighted a lack of information before surgery. Similarly, they described missing information in the first weeks after discharge, before their postoperative follow-up visit, and before starting rehabilitation with a physiotherapist:

Actually, I didn't know what I was supposed to do. Maybe I didn't ask enough questions before discharge. The first week (after discharge) I didn't do anything. I was wearing this DonJoy bandage and I didn't put stress on my leg or anything. And it turns

out that I really should have done that. [Patient 1, ACL]

They had questions about rehabilitation and restrictions associated with the operation, and this led to Google searches, which usually left them more confused:

I felt like I was in a no man's land and didn't really know what to do. [Patient 3, ACL]

In the DC group, the patients and the parents described how knowledge is not shared across sectors in a sufficient and timely fashion. The fact that HCPs in the municipality did not have specialty-specific knowledge, as did those from the hospital, was perceived as unsafe and uncertain. They described situations in which home care nurses or physiotherapists had little or no experience with their treatment and care. That placed a massive burden on the patients or the parents to be in "control" of everything. Lack of information and coordination across sectors also led to confusion regarding the rehabilitation, for example, when the physiotherapist understood the rehabilitation plan differently than the patient remembered it. The patients and the parents from the DC group pointed out how they become the "messengers" and thus responsible for passing on information between the hospital and municipal providers. They viewed this as burdensome, expressing insecurity about accurately conveying all crucial information:

It's the fact that it is our interpretation of what is heard. You know, it is not necessarily medical language that we pass on to the next professional.
[Mother of patient 13, DC]

The physiotherapists often ask questions like "what did the surgeon say?" But when you have no professional knowledge, and you are busier with being there for your child, then there might be things I do not remember or consider as being important.
[Mother of patient 12, DC]

Relations and Communication Provide "Peace of Mind"

Patients and parents from both groups highlighted the importance of the relationship and communication with HCPs.

However, they had different perceptions of their actual needs. For the patients in the ACL group, the most important thing was that the HCPs were “competent.” This was also valid in the DC group, but they unanimously expressed that the relationship and contact with known HCPs were just as important to them. The mother of a boy, who had been through several operations throughout his childhood, described what the relationship between her son and the HCPs at the hospital meant:

It gives, well, it gives you peace. It gives peace of mind even before you have to leave home (to attend surgery or follow-up visit). He can say: “Well, now we’re going home to Aalborg again soon,” and people will say “You don’t live in Aalborg, do you?.” And then he would respond: “Well, a lot of my time, I do.”
[Mother of patient 7, DC]

The same perspective was elaborated by the mother of another boy:

I think it’s about safety, trust, and recognizability, and we don’t refer to it as the “doctor;” we say we’re going to see him (the surgeon) or her (the nurse).
[Mother of patient 15, DC]

During the initial interviews, it became clear that some patients undergoing long-term treatments in the DC group already used

email or SMS text messaging for communication with the orthopedic surgeon or the physiotherapist. This was described as a workaround because traditional communication pathways did not meet their needs, such as calling the secretary, who would leave a note for the nurse or the surgeon to call the patient. The patients and the parents expressed that it made them feel supported, and thus, they largely understood the intention of eDialogue. When asked about their expectations of eDialogue, most patients and parents who had previous experiences with orthopedic surgery expressed that they wished they had had the opportunity of team-based digital communication the first time. Thus, they expected that their previous experiences of “being a patient” would minimize their need for eDialogue at this time.

Phase 2: Experiences With, and Use of, eDialogue After Discharge

Themes and Subthemes

All 31 patients or their parents included in this study were given access to eDialogue for 2 months after discharge with their team of HCPs across sectors. Interviews with 77% (24/31) of the patients and parents led to 3 overall themes and associated subthemes identified across the groups. As in the initial interviews, some subthemes were more prominent in one group than the other and thus highlighted in the table (Table 4).

Table 4. Themes and subthemes of patients and parents’ experiences of using eDialogue with HCPs^a after discharge (n=24).

Themes and subthemes	DC ^b (n=13), n (%)	ACL ^c (n=11), n (%)
Digitally enhanced coherence and proximity		
A sense of security at home	13 (100)	7 (64)
Sharing knowledge between patients and HCPs	9 (69)	5 (45)
Drivers and barriers to use		
Recognizable, informal tool and easy to use	11 (85)	8 (73)
To “be invited” to dialogue by HCPs allows use	6 (46)	4 (36)
Worry about overburdening HCPs	10 (77)	2 (18)
eDialogue rearranges communication pathways		
Reduces the need for phone calls	12 (92)	6 (55)
Text messages and photos are adequate	9 (69)	7 (64)

^aHCP: health care professional.

^bDC: deformity correction.

^cACL: anterior cruciate ligament.

Digitally Enhanced Coherence and Proximity

Across groups, patients and parents unanimously reported that the possibility of easy and direct communication with HCPs after discharge provided them with a sense of security at home. Although eDialogue was used sparingly by some patients, the possibility made them feel at ease during the rehabilitation period. For the patients who used eDialogue more, it was expressed that it helped them get through the first period after discharge because they felt “closer” to the HCPs and as if they had a constant “back up”:

For me, it is very much about security, I almost feel that I have the surgeon by my side all the time. The first time (of surgery and discharge), I felt that he was far away. [Patient 4, DC]

The patients in the ACL group appreciated the opportunity to ask questions, but the need for communication was most evident in the first weeks after discharge and before the first clinical follow-up and exercise sessions with physiotherapists:

Before my first checkup, I encountered some problems that I really wanted answered, so that I didn’t have to go and wait and worry if there was something

wrong. It was solved immediately in eDialogue.
[Patient 8, ACL]

For the patients and the parents in the DC group, eDialogue specifically helped HCPs share important information across sectors. They described how no longer being responsible for passing on information between the surgeon and the physiotherapist at the municipality brought relief and was highly appreciated:

Then we could see that they had the dialogue and then we knew that when we showed up for training next time, the physiotherapist knew it, so we didn't have to explain, which we found difficult anyway.
[Father of patient 10, DC]

In other cases, the patients described how municipal HCPs would use eDialogue indirectly to keep updated with the patient's progress just by reading the messages exchanged between the HCPs from the hospital and the patient. This provided a basis for a common point of view at the patient's next training session.

The parents of minor children described how they used eDialogue to calm their child or explain the treatment plan to them by reading them messages from HCPs.

Drivers and Barriers to Use

In both groups, the patients and the parents agreed that eDialogue presented as a recognizable and informal tool that was easy to use and that this promoted their use. The short response time was also highlighted as a main reason to use eDialogue:

I don't remember a day has passed, more like minutes or hours. So, it's been cool. It would never have been the case if I had to call. [Patient 1, ACL]

Few patients experienced a late or no response. If it happened with their first question, they explained that it made them lose courage to use eDialogue another time. In general, the patients and the parents felt that the use of eDialogue was less intrusive than calling, but they also expressed worry about overburdening the HCPs. By contrast, they expected HCPs to manage their working hours themselves and assess when they had the time to respond:

To begin with, I thought that I would not burden the system unnecessarily...but it probably became a little more urgent and I worried about the way he was feeling, so I texted them and got a reply shortly after.
[Mother of patient 12, DC]

No patients expected answers out of hours, but some sent messages at these times to be relieved. However, they all emphasized that they could have waited for a response until the next weekday. A patient from the ACL group described her reflections about sending a message on a Friday night:

And of course, I thought, Oh no, now I hope he doesn't feel obliged to answer, but I also thought that they must be professional and decide for themselves.
[Patient 11, ACL]

Some patients and parents described how, before discharge, some HCPs would urge them to use eDialogue if needed and that the feeling of being invited made them more inclined to use it after coming home. The patients from the ACL group also described how eDialogue opened up the possibility to ask about "minor issues," which they might not have called about.

Among nonusers or those who used eDialogue sparingly, it was expressed that they simply did not have the need, as everything went as planned. Nonuse was also attributed to having frequent follow-ups at the outpatient clinic or attending physiotherapy several times a week.

eDialogue Rearranges Communication Pathways

The patients and the parents highlighted how the use of eDialogue had prevented phone calls or additional physical attendance after discharge; this was particularly prominent for the patients in the DC group:

Well, to start with we used eDialogue quite a bit I would say. As soon as we had any questions, we texted them and did not need any other forms of communication. [Mother of patient 8, DC]

In a few cases, messages in eDialogue developed into a need for phone calls or an extra checkup in the outpatient clinic. The time of the phone call or attendance was then arranged through eDialogue. However, digital communication was perceived as adequate in most cases. There were instances where follow-up questions from HCPs were necessary, yet patients quickly felt understood and equally comprehended the answers they received:

Although we have not spoken on the phone, I have received sufficient information and I also feel that I have managed to communicate well. [Mother of patient 1, DC]

A patient from the ACL group described how eDialogue was used as an extra contact for a him to "fully guard" himself. He was in doubt if the photo sent in eDialogue could show his concerns regarding the surgical site clearly enough, and therefore, he contacted his general practitioner and texted the team in eDialogue at the same time:

There was a situation where I had sent a message in the morning, and so, I thought I might as well, while there was still phone time at the GP, call to see if he had an available appointment. Then I came to my GP, and actually got exactly the same answer as I received on the phone (eDialogue) an hour later. So, it wasn't something that was needed as such, but now that I had the opportunity, I thought I might as well do it.
[Patient 8, ACL]

No patients expressed feelings of being misunderstood in their communication with HCPs in eDialogue. They experienced digital communication as being sufficient for their needs; however, they reflected on the risk of misunderstandings when communicating via texts:

I think it's a much more optimized way of doing it, because I don't need a physical conversation by phone. I'm fine with texting, but obviously there can

be some misunderstandings or something that can go wrong and then you have to call. [Mother of patient 15, DC]

The use of photos was mentioned as being very important to support texts. A few patients explained that they lacked the possibility of sending and receiving videos; however, they emphasized that it was not a necessity for their use:

If I hadn't been able to send photos, then maybe I would have had to explain something visual by phone, and then I would have had to come in for a checkup, and then I would have wasted a whole day. [Patient 1, ACL]

Video could be nice, but then again, the photos could effectively illustrate how the position of her leg is and show how much she has actually been able to stretch, in what positions it hurts, and so on. [Mother of patient 17, DC]

The mother of a minor patient explained how she used eDialogue as a photo diary to keep the HCPs across sectors updated on the progress of her son's surgical wound:

So, when she (the home care nurse) came and changed the dressings, we took some photos before she put on new ones, and then we kind of had it (photos) from time to time and could follow how it progressed...It was smart as hell, and when it wasn't the same home care nurse coming by, we showed them the photos and at the same time kept the surgeon at the hospital up to date. [Mother of patient 15, DC]

Use of eDialogue 2 Months After Discharge

The need for support and communication for both patient groups after discharge was expressed through the actual use of eDialogue (Table 5).

Table 5. Patients' and parents' use of eDialogue 2 months after hospital discharge.

	Total number of messages, n	Average number of messages per patient, n	Maximum number of messages per patient, n
DC^a (n=17)			
All text messages exchanged ^b	338	19.9	54
Text messages sent by patients	189	11.2	34
Actual questions that needed a reply ^c	128	7.5	20
Photos sent by patients ^d	127	7.5	53
ACL^e (n=14)			
All text messages exchanged	126	9.0	36
Text messages sent by patients	68	4.9	19
Actual questions that needed a reply ^f	55	3.9	14
Photos sent by patients ^c	13	0.9	6

^aDC: deformity correction.

^bThe total number of text messages exchanged between patients and health care professionals (HCPs) 2 months after discharge.

^cText messages sent from the patient or their parents to the HCPs in eDialogue. The minimum number of messages or photos sent per patient was 0, as some patients did not use eDialogue at all.

^dActual questions that needed a reply from the HCPs are the number of individual text messages from patients or parents that were formulated as a question; thus, this does not include the back-and-forth 2-way communication that 1 question could lead to (eg, saying thank you).

^eACL: anterior cruciate ligament.

^fPhotos refer to the number of photos taken by the patients or parents and sent for review by the HCPs.

Of the patients or their parents, 88% (15/17) in the DC group and 79% (11/14) in the ACL group used eDialogue to ask questions to HCPs after discharge. In the DC group, 13 (87%) of the 15 active users used photos, and in the ACL group, 5 (45%) of the 11 active users sent photos to support communication. Upon inclusion in the study, the patients and the parents were informed that they could expect a response time of 24 hours during the weekdays. This was complied with in 96.2% (176/183) of the cases where a message that required a response from HCPs was sent, and the distribution was equal across groups.

Among users of eDialogue in the DC group, the minimum number of per-patient questions that needed a reply from HCPs was 2, and the maximum was 20. For the ACL group, there was a minimum of 1 and a maximum of 14 questions that needed a reply in 1 dialogue. Thus, there was a marked difference in the individual's use of eDialogue during the study period in both groups.

Most of the communication took place from Monday to Friday; thus, 84.7% (155/183) of the questions that needed a reply from the HCPs were sent and replied to during the weekdays.

The patients and the parents in the DC group used eDialogue throughout the 2 months (Figures 2 and 3), and 15 (88%) of the

17 patients requested to keep on using it after the data collection stopped at 2 months. The patients in the ACL group primarily used eDialogue for the first 2 to 3 weeks after discharge (Figures 2 and 3), and use then faded. Only 2 (6%) of the 31 patients or parents expressed a need to continue with eDialogue after 2 months.

restrictions, concerns about symptoms and complications, medication, psychological support, interdisciplinary and cross-sectoral dialogue, coordination and practical needs, updates and gratitude, HCP ask for feedback. The categories were identified across groups; however, some categories were more prominent in one group than the other (Multimedia Appendix 2).

Content analysis of the messages in eDialogue revealed 9 overall categories, including treatment-related issues, rehabilitation and

Figure 2. The number of individual text messages sent from patients or parents to the health care professionals in eDialogue per week 8 weeks after discharge. ACL: anterior cruciate ligament; DC: deformity correction.

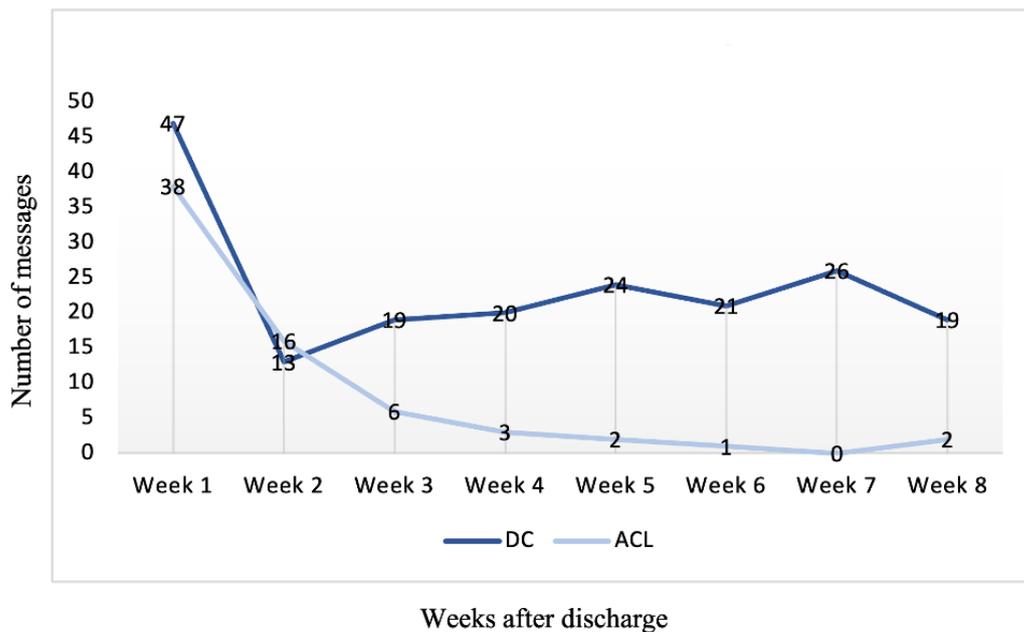

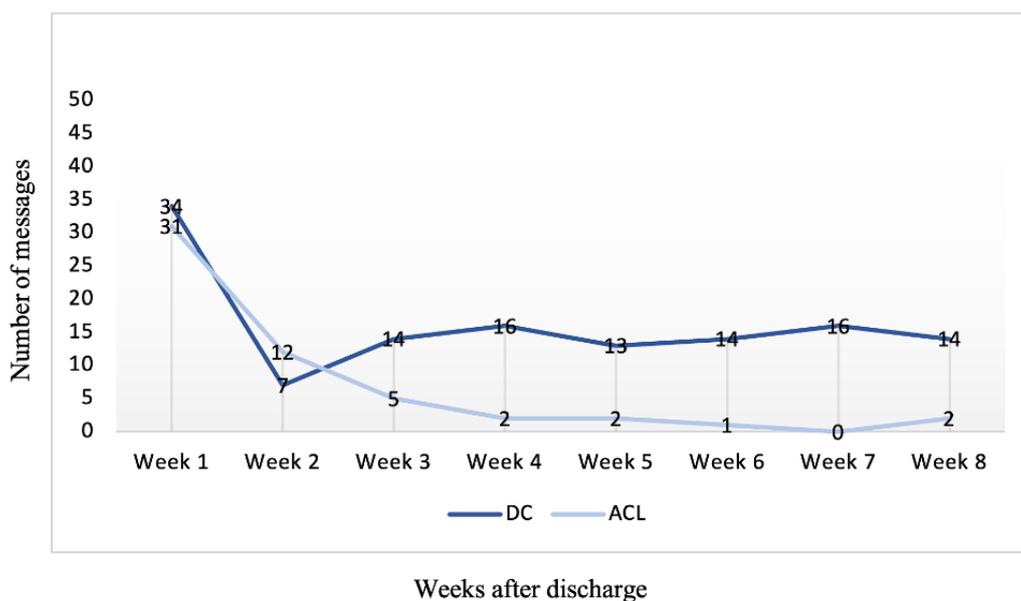

Figure 3. The number of messages sent by patients or parents that required a response from health care professionals, that is, messages phrased as a question, per week 8 weeks after discharge. ACL: anterior cruciate ligament; DC: deformity correction.

Discussion

Principal Findings

Overview

This study explored the perspectives of patients undergoing orthopedic surgery on current communication pathways (phase 1), and their subsequent experiences of using eDialogue after discharge, as well as the actual use of the solution (phase 2).

In phase 1, we identified unmet needs among patients regarding communication with HCPs after discharge. The themes involved perspectives of difficult communication pathways, lack of information due to inadequate coordination of care, and that relation and communication provide “peace of mind.” In phase 2, the participants were set up to use eDialogue for 2 months after surgery and discharge, providing them access to direct digital communication with their individual health care team across settings. Through follow-up interviews, they articulated the following themes: digitally enhanced coherence and proximity, drivers and barriers to use, and that eDialogue rearranges communication pathways. Use data of eDialogue supported the experiences expressed in the interviews and provided an overview of the actual use. These findings will be discussed with the theoretical framework of COC and previous research.

Signs of Improved COC With eDialogue

Through initial interviews, the patients and the parents expressed a need for more clear communication pathways after discharge. A patient expressed that it felt like being in a “no man’s land.” As such, they lacked communicative support at home as well as optimized sharing of knowledge between the HCPs involved in their treatment and care across settings, indicating that informational and management COC is under pressure [32]. Similar findings are described in other studies on patients’ experiences of the transition from hospital to home following surgery [24,28], and this emphasizes the need to address communicative challenges around hospital discharge.

The patients and the parents in complex and long-term orthopedic treatments (DC) experienced a greater need for continuous contact with their known health care team than those undergoing day surgery (ACL). Thus, the relationship, trust, and mutual understanding with the HCPs were described as being of great importance for their experience of security. For these patients, access to eDialogue was particularly useful, suggesting that eDialogue may play a role in facilitating relational COC. The patients in the ACL group, despite still having an unmet need for information, expressed that “less” would have been suitable for them. As digital communication becomes more prevalent in health care [1,2,4,5,7,9], comprehensive evaluations are crucial, including efficiency and optimal resource use considerations. Some patients may find less resource-intensive options, such as automated text message interventions, sufficient [36].

Through follow-up interviews, the patients and the parents across groups highlighted that eDialogue provided easy access to relevant HCPs and facilitated coherence and proximity after

returning home, leading to “a sense of security.” These findings corroborate previous studies [14,37] and support our assumption that team-based digital communication may contribute to improving patients’ experiences of COC in transitions from hospital to home [32]. Other studies have also highlighted that COC is one of the factors that can be positively influenced by the use of team-based digital communication [15,16]. Voruganti et al [15] evaluated the feasibility of integrating a web-based communication tool for collaborative care in a pilot randomized controlled trial and found evidence indicating an increase in COC scores in the intervention group; however, the study was unpowered to show the effect statistically. Another study by Lindkvist et al [16] described how access to and use of an eHealth device for text-based communication, image exchange, and data reports between HCPs and parents of preterm infants or pediatric surgery was experienced positively in the transfer period from hospital to home. Moreover, they reported that parents felt it gave a sense of “shared responsibility,” which was also expressed by the patients and parents in this study. Thus, they highlighted that eDialogue facilitated the sharing of information, so they no longer had to be the ones passing on information and knowledge between HCPs. This was a role that they often disliked or mistrusted that they could fulfill adequately. The findings from this study indicate, in line with other studies [14-16], that digital team-based communication has the potential to set the framework for interdisciplinary and cross-sector collaboration that supports COC following hospital discharge. Whether team-based digital communication can actually enhance levels of COC to an extent where it can be measured remains to be investigated.

Patients Want to Communicate Digitally

As seen in other studies on digital asynchronous communication [15,16,38], use data demonstrated that most patients and parents across groups used eDialogue (26/31, 84%). The drivers to use eDialogue involved that the tool was recognizable and easy to use. Employing a messenger-like tool, made available to patients on their own smartphone, was a strength, as we did not encounter technical challenges as described in other studies, where devices were newly developed and delivered to participants [16]. The simple solution only allowed for communication in text and photos, and it may lack other options for patients who cannot use the text-based medium. Although previous studies involving text-based digital communication for health care purposes show that patients largely adopt this form of communication across settings and needs [4,10,37,39], digital inclusion in eHealth interventions is important to acknowledge both in regard to the hardware as well as patients’ ability to use the solutions [40]. As such, if the patients cannot use the tool, no value has been added. Other studies have integrated several means of communication into their solutions, including text, video, photos, and voice recordings, and found that video communication was especially useful [16,41,42]. This is in contrast to our findings, where patients expressed that the text-based medium was sufficient for them in the postoperative period. However, we acknowledge that eDialogue, as used in this study, may not be sufficient for all patients. When designing and implementing digital communication solutions, considering patients’ literacy and eHealth literacy becomes

crucial to ensure equal access to health care [40,43]. Integrating multiple communication modalities within a single solution could serve as a means to achieve this goal.

A driver mentioned in this study was the informality of the solution, and that it felt less interrupting than calling by phone. Similar results have been found in other studies of digital text-based communication [16,37], and this indicates a high degree of acceptance and usability of the solution from the patients' perspectives. With an increasing level of smartphone use in the general population, digital communication becomes a more natural choice when patients need to contact providers. Thus, statistics show that the use of smartphones worldwide is increasing significantly, and in Denmark, it is estimated that 90% of all households own a smartphone [44]. As a barrier to use, the patients expressed concerns about wasting the HCPs' time. This is important to consider when implementing solutions for digital communication. Our findings indicate that this may be offset by a more inviting approach from the HCPs, as some patients and parents expressed this as a facilitator to their use. Previous studies have pointed out the importance of clearly communicating response times when using digital communication [16,37]. Similar findings were highlighted in follow-up interviews of this study, where patients and parents described quick response times, or alternatively late responses, as a driver and a barrier, respectively.

Across groups, the patients and the parents expressed that eDialogue, despite only being an addition to existing communication channels, had rearranged the communication pathways significantly. This became obvious as the patients and parents described a reduced need to call the hospital, as they found eDialogue adequate and exhaustive for their needs. These findings corroborate previous studies showing a potential decrease in phone calls to the hospital after discharge when digital communication is being used [16,45]. By contrast, another study reported, in line with our study, that some questions asked by patients in a digital communication tool were not something they would have called about and thereby indicate that access to digital communication may contribute to an increased consumption of health care resources [16]. To evaluate the effect on resource use, a randomized controlled trial should be performed. Future studies designed to demonstrate the effects on health resource use are desired to shed light on whether digital communication actually reduces patients' use of other forms of communication channels or adds on. In addition, it should be considered whether digital communication provides better quality, for example, defined as COC, patient satisfaction, and security for patients.

This study adds to the knowledge of patients' perspectives on current communication pathways and the sparse evidence of their experiences and use of digital team-based communication, specifically in an orthopedic surgery setting. This may inform future interventions of team-based digital communication, from its application in clinical practice to organizational and management levels.

Limitations

The study has limitations that may affect the interpretation of our results. First, inclusion criteria were participants who owned

and used a smartphone and could speak and write Danish well enough to send text messages. Second, we explored the perspectives of 2 selected groups of patients undergoing orthopedic surgery. Therefore, the external validity of the results is unknown for other groups of patients undergoing orthopedic surgery, than the ones we explored.

In planning the study, we decided that initial interviews with patients and parents in phase 1, who were subsequently recruited to use eDialogue after discharge, were appropriate to identify patients' perspectives on current communication pathways. However, some patients found it difficult to express themselves about this, as they had no or little previous experience of an orthopedic surgery context. In addition, there was a risk that the use of initial interviews combined with follow-up interviews within a short timespan (2 months) may have influenced the patients' expressed attitudes in favor of the intervention in the follow-up interviews. Reflecting on this, it might have been better to perform initial interviews with a group of patients who were not given access to eDialogue afterwards.

In this study, we did not use log files to summarize the use data, as other studies have done [16,26], and this may be perceived as a limitation. However, we argue that log files, which report the number of log-in attempts, database entries, messages sent in total and the like, would not show the actual use as it presented to the participants in clinical practice. Therefore, manual counts were used to remove messages saying "thank you" or similar, as these are not considered relevant to the use of eDialogue in a health care setting.

Overall, the 24-hour weekday response time was met in this study and some patients reported extremely fast responses from HCPs. This finding must be interpreted with caution, as we cannot rule out that it is due to the Hawthorne effect, which suggests that people behave better when they are observed [46]. Conversely, it can also be an expression of the flexibility that lies in the digital asynchronous form of communication, giving HCPs the possibility to answer when they have the time for it, or it may simply reflect that the HCPs replied instantly (when able to) not to forget it. Nevertheless, an exclusively positive interpretation of compliance with the response time in this study may result in blindness toward the possible pitfalls that can occur in the real world if eDialogue is implemented. Insights from the perspective of HCPs can reveal this.

Conclusions

The findings from this study indicate that the patients and the parents experienced an unmet need related to communication and collaboration following hospital discharge. eDialogue was overall evaluated positively, and the patients and parents perceived team-based digital communication as correspondent to their needs and suggested that it provided a sense of security after returning home. COC may be enhanced by assembling the team of HCPs in a simple digital communication solution with patients. However, eDialogue should be further evaluated and tested. Future research has to explore HCPs' perspectives on the solution as well as establish the effects and organizational and economic incentives to use team-based digital communication in the context of orthopedic surgery care pathways.

Acknowledgments

The authors would like to thank all patients, parents, health care professionals, and management from departments across hospitals and municipalities in Northern Jutland, Denmark, who agreed to participate in this study. The study was partly funded by the Research Fund of Danish Health Region North (2021-0019). Visma, the company who owns the technical solution used in this study ("LetDialog"), had no role in the design of the study; collection, analyses, or interpretation of data; or in the writing of the manuscript or the decision to publish the results.

Abstract

Background: Approximately 262 million people worldwide are affected by asthma, and the overuse of reliever medication—specifically, short-acting beta2-agonist (SABA) overuse—is common. This can lead to adverse health effects. A smartphone app, the Asthma app, was developed via a participatory design to help patients gain more insight into their SABA use through monitoring and psychoeducation.

Objective: This pilot study aims to evaluate the feasibility and usability of the app. The preliminary effects of using the app after 3 months on decreasing asthma symptoms and improving quality of life were examined.

Methods: A mixed methods study design was used. Quantitative data were collected using the app. Asthma symptoms (measured using the Control of Allergic Rhinitis and Asthma Test) and the triggers of these symptoms were collected weekly. Quality of life (36-Item Short-Form Health Survey) was assessed at baseline and after 3, 6, and 12 months. User experience (System Usability Scale) was measured at all time points, except for baseline. Furthermore, objective user data were collected, and qualitative interviews, focusing on feasibility and usability, were organized. The interview protocol was based on the Unified Theory of Acceptance and Use of Technology framework. Qualitative data were analyzed using the Framework Method.

Results: The baseline questionnaire was completed by 373 participants. The majority were female (309/373, 82.8%), with a mean age of 46 (SD 15) years, and used, on average, 10 SABA inhalations per week. App usability was rated as good: 82.3 (SD 13.2; N=44) at 3 months. The Control of Allergic Rhinitis and Asthma Test score significantly improved at 3 months (18.5) compared with baseline (14.8; $\beta=.189$; SE 0.048; $P<.001$); however, the obtained score still indicated uncontrolled asthma. At 3 months, there was no significant difference in the quality of life. Owing to the high dropout rate, insufficient data were collected at 6 and 12 months and were, therefore, not further examined. User data showed that 335 users opened the app (250/335, 74.6%, were returning visitors), with an average session time of 1 minute, and SABA registration was most often used (7506/13,081, 57.38%). Qualitative data (from a total of 4 participants; n=2, 50% female) showed that the participants found the app acceptable and clear. Three participants stated that gaining insight into asthma and its triggers was helpful. Two participants no longer used the app because they perceived their asthma as controlled and, therefore, did not use SABA often or only used it regularly based on the advice of the pulmonologist.

Conclusions: The initial findings regarding the app's feasibility and usability are encouraging. However, the notable dropout rate underscores the need for a cautious interpretation of the results. Subsequent studies, particularly those focusing on implementation, should explore the potential integration of the app into standard treatment practices.

Introduction

Asthma is a common chronic inflammatory disease, which is estimated to affect 262 million people worldwide [1]. Step 1 of medical treatment involves the prescription of short-acting beta2-agonist (SABA) as a reliever medication. In contrast to inhaled corticosteroids (ICS), SABA does not have an anti-inflammatory effect on the respiratory tract [2,3]. In 2019, step 1 was modified in the Global Initiative for Asthma guidelines [2]. Specifically, the option of a low dose of ICS-formoterol, as needed, was added because asthma control is often suboptimal [3-5]. According to guidelines, using SABA more than twice a week indicates suboptimal, uncontrolled asthma [3]. Approximately half of the patients with asthma have uncontrolled asthma [5-7]. The overuse of SABA is linked to an increased risk of asthma exacerbations, which are associated with damage to the respiratory tract, asthma-related hospitalization, and visits to the emergency department [8-12].

The overuse of SABA is common for different reasons. First, individuals often overuse their SABA instead of taking ICS to achieve a rapid relief from an asthma attack [13-15]. Second, individuals may lack knowledge about the medication and insight into the actual frequency of medication use [13,16]. For example, the REcognise Asthma and LInk to Symptoms and Experience study [17] found that 80% of the participants thought they had controlled asthma, although 40% had used their SABA ≥ 3 times during the past week. A post hoc analysis of the Dutch participants from this study showed that 60% of the patients with asthma overused their SABA in the previous week [18].

Previous studies have shown that self-management apps can help reduce the frequency of SABA use, increase SABA-free days, and improve overall asthma control [19,20]. These apps can also boost individuals' confidence in managing asthma and improve their quality of life (QoL) [21-23]. Often, these self-management tools include education, self-monitoring, and feedback to support the end users in managing their disease daily [21,22,24,25]. Most apps are developed using state-based models, such as the Waterfall Model, and agile methods [26]. These traditional methods do not engage end users in the development process, which may result in lower usability and adherence of end users [27]. Therefore, an app was developed in collaboration with end users and other relevant stakeholders (eg, health care professionals) using a participatory design. This design can be used to engage relevant stakeholders during the development process, which may improve the usability and adherence to an app. The objective of the app is to help patients gain more insight into their SABA use while also promoting responsible SABA use. This may eventually decrease SABA overuse. In a previous study, we described the development process of the Asthma app [28].

This pilot study, using a mixed methods design, aims to examine (1) the feasibility and usability of the app in people with asthma

and (2) the preliminary effects of using the app after 3 months on decreasing asthma symptoms and improving QoL.

Methods

Design and Population

The pilot study had a mixed methods design. Initially, the study was purely quantitative, with data collected through questionnaires administered in the app to examine the usability and preliminary effects of the app. Individuals were eligible to participate if they (1) were aged ≥ 18 years and (2) had asthma. Individuals who did not meet these inclusion criteria were excluded from the study; however, they could still use the app. The study period for the participants was 12 months. The study was conducted from January 15, 2021, to December 6, 2022; however, user data were collected until December 31, 2021. User data collection was stopped earlier because the costs for collecting these data increased after 2021, and this could no longer be funded.

During the study, we noticed that most participants used the app only in the first week after downloading. Owing to the high dropout rate, an additional qualitative study was conducted to examine the feasibility and usability of the app in more detail. Individuals who use, had used, or had downloaded the app once were included in the semistructured interviews. Individuals who participated in the qualitative interviews did not necessarily participate in the quantitative study. Qualitative interviews were held until data saturation was reached; data saturation was expected after 6 to 12 interviews [29,30]. Data were collected between November 7, 2022, and December 13, 2022.

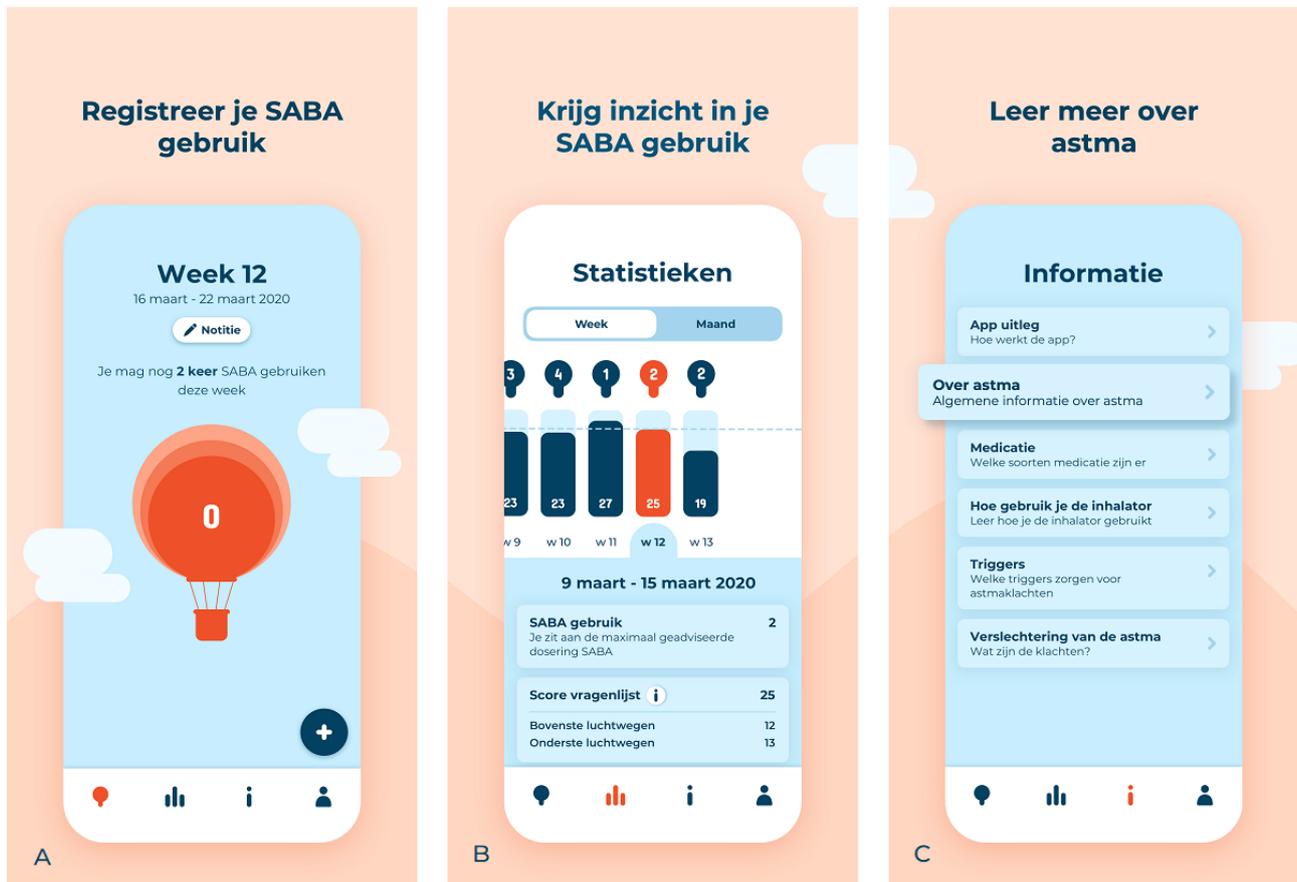

Ethical Considerations

According to the Medical Ethics Committee of the Leiden University Medical Center, this study did not fall within the scope of the Dutch Medical Research Involving Human Subjects Act (N20.103). Subsequently, a declaration of no objection was obtained from the Medical Ethics Committee. Participants provided informed consent and were able to opt out (see the *Procedure* section). The quantitative data were collected anonymously, and the qualitative data were collected pseudonymously.

Asthma App

The Asthma app (a Dutch app developed by the Leiden University Medical Center and Innovattic; [Figure 1](#)) allows end users to register their SABA use. Moreover, users can register asthma symptoms weekly (they receive a notification to do so), and they can register the triggers of these symptoms at any time. A graph shows how SABA use, asthma symptoms, and their triggers are related. The amount of SABA used was compared with the existing guidelines [2,3] or, when applicable, with health care professional's advice. Psychoeducation is also included, covering topics such as *what is asthma* and *types of medication and their function* [28]. The app was available free of charge in the App Store and Google Play Store.

Figure 1. Visuals of the final version of the Asthma app: (A) landing page where users can register their short-acting beta2-agonist (SABA); (B) the graphical overview or statistics (in Dutch statistieken) where users can get insight into their SABA use, asthma symptoms, and asthma triggers; and (C) psychoeducation or information (in Dutch informatie) where users can learn more about their asthma and the app. On the landing page, users can receive three different messages based on the number of registered SABA compared with the prescription: (1) “You can still use your SABA # times this week,” (2) “You are at the maximum recommended dose of SABA for this week,” or (3) “You needed more SABA this week than advised.” After downloading the app, users receive an explanation on how to interpret the graphical overview, and this explanation can also be found in the informational part of the app.

Procedure

Quantitative Data

Different channels were used to announce the app's go-live and to recruit participants. Relevant organizations (eg, Lung Foundation Netherlands and National eHealth Living Lab) posted the information on their website and social media, or only on their website or social media, and the closed Facebook group *Asthma and Peers* in the Netherlands published the information as well. The information was further communicated through publications (ie, via the COPD Asthma General Practitioners Advice Group in a magazine for pharmacists assistants and in a national newspaper in the Netherlands). Moreover, flyers were distributed via general practices.

After downloading and installing the app, individuals were asked 2 questions to determine their eligibility for the study (ie, whether they were aged ≥ 18 years and had asthma). Eligible individuals were given information about the study and could decide whether they wanted to participate by signing an informed consent form in the app. In the app, participants could view the informed consent form and withdraw from the study at any moment if they wanted to. If individuals chose to withdraw their consent, they could continue using the app.

Next, participants were asked to complete the demographic and clinical characteristics questionnaire and the baseline questionnaire about QoL (ie, 36-Item Short-Form Health Survey [SF-36] [31]) and intentions to change behavior (ie, a short version of the Theoretical Domains Framework [32]). Asthma symptoms were measured weekly using the Control of Allergic Rhinitis and Asthma Test (CARAT) [33,34]. The triggers of the asthma symptoms, such as dust mites and hay fever, were asked at the end of the CARAT, and the user could also enter additional triggers throughout the week. At 3, 6, and 12 months, user experience (ie, System Usability Scale [SUS]; [35]) and QoL were assessed. No compensation was provided for completing the questionnaire.

Qualitative Data

To gain more insight into the usability and experiences with the app, the following recruitment text was used: “NeLL is looking for (former) users of the Asthma app to get more insight into the usability and experiences with the app, during a one-time interview.” We recruited participants for the semistructured interviews via relevant organizations (eg, Asthma Association of the Netherlands and Davos and National eHealth Living Lab) that posted the information on their website and social media, or only on their website or social media; the information was also posted in the closed Facebook group *Asthma and Peers* in

the Netherlands. To increase the interview response rate, participants were recruited via the personal channels of the researchers. When a participant was recruited via personal channels, the researcher did not conduct the interview.

Interested individuals could contact the researchers via email. Subsequently, 1 of the researchers (LNvdB and AEV) would contact them to determine whether they were eligible to participate (ie, aged ≥ 18 years, having asthma, and [at least] having downloaded the app). Eligible individuals interested in participating received the informed consent form via email. The participants could sign the informed consent form digitally via Castor (ie, a digital, secure research environment) [36]. After signing the informed consent form, the participants received an email invitation to schedule the semistructured interview. We aimed to enroll individuals who use the app and former users (ie, those who had at least downloaded the app).

An interview protocol was developed (Multimedia Appendix 1) based on the Unified Theory of Acceptance and Use of Technology (UTAUT) framework [37]. These interviews were conducted to better understand the perceived usability and feasibility. Interviews were conducted web-based via Microsoft Teams and lasted between 30 and 45 minutes. The participants received a gift card of 30 euros (US \$31.2).

Outcome Measures

Demographic and Clinical Characteristics

General information about the participants and their asthma was obtained, including gender, age (birth year), level of education, type of asthma, degree of asthma control, and type of medication. Multiple answers could be selected when answering the question about the type of asthma (ie, allergic asthma, nonallergic asthma, exercise asthma, severe asthma, and do not know) and medication (ie, SABA, ICS, long-acting beta2-agonist (LABA), ICS+LABA, do not know, and no medication use). Furthermore, the participants were asked whether they had received specific advice from their general practitioner on how much SABA they could use per week. When the participant had not received specific advice or did not know whether they had received specific advice, the existing guideline of a maximum of 2 SABA intakes per week was used. When the participants received specific advice from their general practitioner on their SABA use, they could indicate how much SABA they could use per week.

The question “How much SABA did you use last week?” was used as a baseline measure of SABA use. To examine whether

an individual’s asthma was stable or unstable during the last week and differed from their average SABA use, an additional question was asked: “How much SABA do you use on average per week?”. In the app, individuals could register their weekly SABA use by clicking on the plus sign shown on the home screen.

The Intention to Change Behavior

The intention to change behavior was assessed using 3 items of the subscale “Intentions” of the Theoretical Domains Framework questionnaire [32]. The original subscale consisted of 4 items, but 1 of the items did not apply to this study and was, therefore, omitted. Items were answered on a 7-point Likert scale ranging from strongly disagree (1) to strongly agree (7). An example of an item is “In the next three months, I intend to use my SABA as prescribed.” A higher score (with a maximum of 21) signified more intent to use their SABA as prescribed in the next 3 months.

Feasibility and Usability

Different types of user data in the app were collected via an analytics platform (ie, PIWIK), namely, (1) which pages are visited in the app (ie, home screen, psychoeducation, user settings page, questionnaires, and the graph) and (2) events (ie, when the app is opened; SABA registrations; number of user clicks on notifications; and, when applicable, made changes in the maximum intake of SABA as advised by the health care professional).

The usability of the app was measured quantitatively using the 10-item SUS [35]. The items were rated on a 5-point Likert scale ranging from strongly disagree (0) to strongly agree (4). The scores were multiplied by 2.5 to obtain the total score ranging from 0 to 100. A higher score indicated that the app was more user-friendly.

A qualitative assessment of the feasibility and usability was conducted through interviews. The interview protocol was based on the UTAUT framework [37], which identified four main factors that influence the intention and use of technology (in this case, an app): (1) performance expectancy, (2) effort expectancy, (3) facilitating conditions, and (4) social influence. [Textbox 1](#) presents an explanation of these factors. Moreover, the UTAUT framework includes four moderating factors: (1) gender, (2) age, (3) experience, and (4) voluntariness of use [37]. These factors and moderating factors were discussed during the interviews.

Textbox 1. Explanation of the factors within the Unified Theory of Acceptance and Use of Technology framework.

Description

- Performance expectancy: the general benefits associated with app use and feasibility of the app
- Effort expectancy: ease of use and usability of the app
- Facilitating conditions: having sufficient resources and knowledge to use the app
- Social influence: the influence of other people (eg, family, friends, and acquaintances) to start and keep using the app and whether they would recommend the app to others

Preliminary Effects

Asthma symptoms and triggers of these symptoms were measured using the 10-item CARAT [33,34]. An example item is “During the last week, because of your asthma/rhinitis/allergy, how many times, on average, did you experience sneezing?” Items were rated on a 4-point scale ranging from 0 (never) to 3 (almost every day). All items were reverse scored, and the total score ranged from 0 (minimal control) to 30 (maximum control). A score of 24 or higher indicated controlled asthma. In addition to the total score, 2 subscales were calculated: a score of the upper airway and a score of the lower airway. The upper airway score ranged from 0 (minimal control) to 12 (maximum control), and the lower airway score ranged from 0 (minimal control) to 18 (maximum control). An additional question was added to identify the symptom triggers: dust mites, animals, smoke, weather, hay fever or pollen, air pollution, smells, and exertion or exercise. Participants were able to select multiple triggers.

Participants’ health and health-related QoL were measured using the SF-36 [31]. The SF-36 consists of 2 main categories: physical and mental health [38]. Physical health entailed the physical components and consisted of the following subscales: physical functioning (10 items), role limitations due to physical problems (4 items), bodily pain (2 items), and general health perceptions (5 items). Mental health entailed the mental components and consisted of the following subscales: social functioning (2 items), general mental health (5 items), role limitations due to emotional problems (3 items), and vitality (4 items) [31,39]. All items were recoded into scores ranging from 0 (the poorest level of physical or mental health) to 100 (the best level of physical or mental health) [40], with higher scores indicating better health and higher QoL.

Statistical Analysis

All quantitative data were analyzed using SPSS (version 25.0; IBM Corp) [41]. Descriptive analyses (eg, means, SDs, and percentages) were used to describe the demographic and clinical characteristics of the participants, intention to change behavior, user experience, QoL, and user data (eg, frequency of weekly SABA use). A mixed model was used to determine the change in asthma symptoms over time from the first week of using the app to 3 months after baseline. QoL at 3 months was compared

with baseline data using Wilcoxon signed rank tests. The effects at 6 and 12 months were not examined because of the high dropout rate during the study period (88.2% at 3 months and more dropouts beyond that).

Interviews were audiotaped for subsequent analyses, and all audio records were transcribed intelligent verbatim by 1 researcher (AEV). Qualitative data analyses were performed by 2 researchers (LNvdB and AEV) according to the principles of the Framework Method [42] using Atlas.ti (version 22.0) [43]. The Framework Method is a systematic and flexible approach often used for the thematic analysis of semistructured interview data. Following transcription, the 2 researchers immersed themselves in the interviews to gain a comprehensive understanding. Subsequently, a deductive approach was adopted to code the interviews based on a predefined concept codebook developed beforehand based on the UTAUT framework [37]. The coding process was conducted independently by the 2 researchers, followed by a comparison of the codes. Additional codes were incorporated into the codebook, where applicable. A framework matrix was used to organize the data comprehensively, featuring relevant quotes from the participants. Finally, the characteristics and distinctions within the data set were identified. Throughout the process, the steps and data were discussed with the researchers CH and AV.

Results

Demographic and Clinical Characteristics

In the quantitative study, 485 individuals participated at baseline. Of these 485 individuals, 373 (76.9%) reported that they used SABA. Only these individuals were included in the analysis. Most of the participants were female (309/373, 82.8%) with a mean age of 46 (SD 15) years, had a secondary vocational education or higher (316/373, 84.7%), and had allergic asthma (187/373, 50.1%). At baseline, participants stated that they used, on average, 10 SABA per week and 10 SABA in the week before using the app. Moreover, the mean intention to change behavior was 17.1. This indicates that the participants wanted to use their SABA as prescribed for the next 3 months. [Table 1](#) shows an overview of the demographic and clinical characteristics and the intention to change behavior.

Table 1. Baseline demographic and clinical characteristics of the participants and the intention to change behavior in the quantitative study.

Characteristic	Values
Gender (n=373), n (%)	
Male	63 (16.9)
Female	309 (82.8)

^aThe birth year of 2 participants was missing. These participants were excluded from the calculation of the mean age.

^bParticipants were able to select multiple answers.

^cSABA: short-acting beta2-agonist.

^d51 participants only used SABA and no other inhalers.

^eICS: inhaled corticosteroids.

[†]LABA: long-acting beta2-agonist.

^gThe maximum number of SABA inhalations per week, as prescribed by the participant's health care professional.

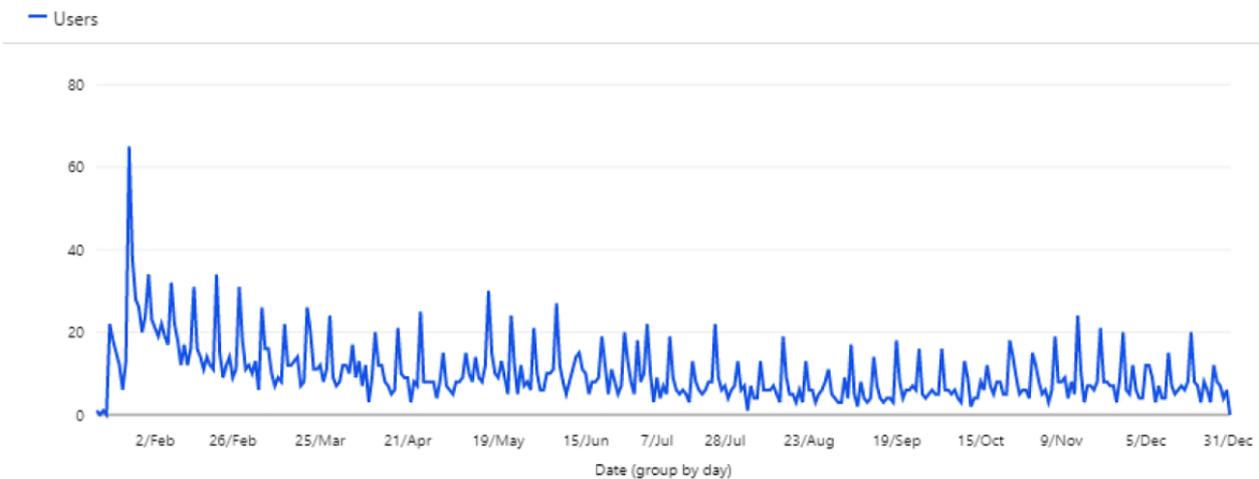

In the qualitative part of the study, among the 6 to 12 participants that we planned to recruit, only 4 participants could be included and interviewed. Half of the interviewed participants were female (2/4, 50%), with a mean age of 55 (range 21-78) years. One participant completed senior general secondary education, 1 completed secondary vocational education, and 2 had higher professional education. Two participants stated that they still used the app: they had both been using it for 1 year and 5 months. Regarding *social influence* from the UTAUT framework [37], the app was recommended by the hospital to

one participant, and the other participant found it via the asthma association. Two participants stated that they no longer used the app but had used it for approximately 1 or 2 weeks. They both started using the app after the recommendation from a family member.

Feasibility and Usability

User data showed that 335 unique users opened the app, of which 250 (74.6%) were returning visitors, with an average session time of 1 minute. An overview of the number of users during the study period is shown in Figure 2.

Figure 2. Number of users during the study period (January 15, 2021, to December 31, 2021).

Most users opened the app via their smartphone (303/335, 90.4%), followed by a tablet (27/335, 8.1%) and a phablet (4/335, 1.2%). On average, the users had 5 events (ie, starting the app, adding SABA, removing SABA, changing the maximum amount of SABA, and clicking on 1 of the

notifications) per session. Registration of SABA (ie, add-function) was most often used (7506/13,081 times, 57.38%). An overview of the events used per week is shown in Figures 3 and 4. At 3, 6, and 12 months, users registered an average of 5 SABA intakes per week (Table 2).

Figure 3. Unique events used per week: “add” means registering short-acting beta2-agonist (SABA), “remove” means removing a SABA registration, “set-max” means changing the maximum amount of SABA, and “start” means starting the app after giving informed consent and filling in the first questionnaires.

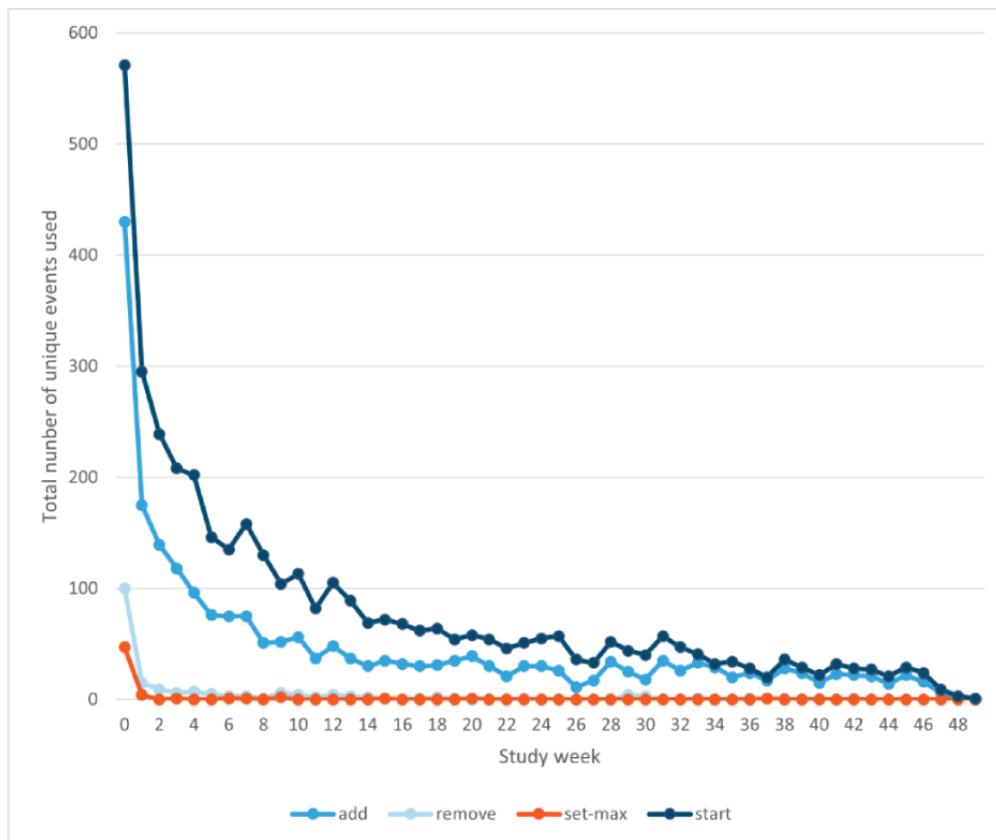

Figure 4. Events used per week, whether participants opened the app via 1 of the notifications: “open-intake-registration-reminder” is the notification users received when they did not register any short-acting beta2-agonist before the end of the week (Sunday); “open-review-questionnaire-reminder” is the notification for the questionnaires used at 3, 6 and 12 months; and “open-weekly questionnaire-reminder” is the notification for the weekly Control of Allergic Rhinitis and Asthma Test.

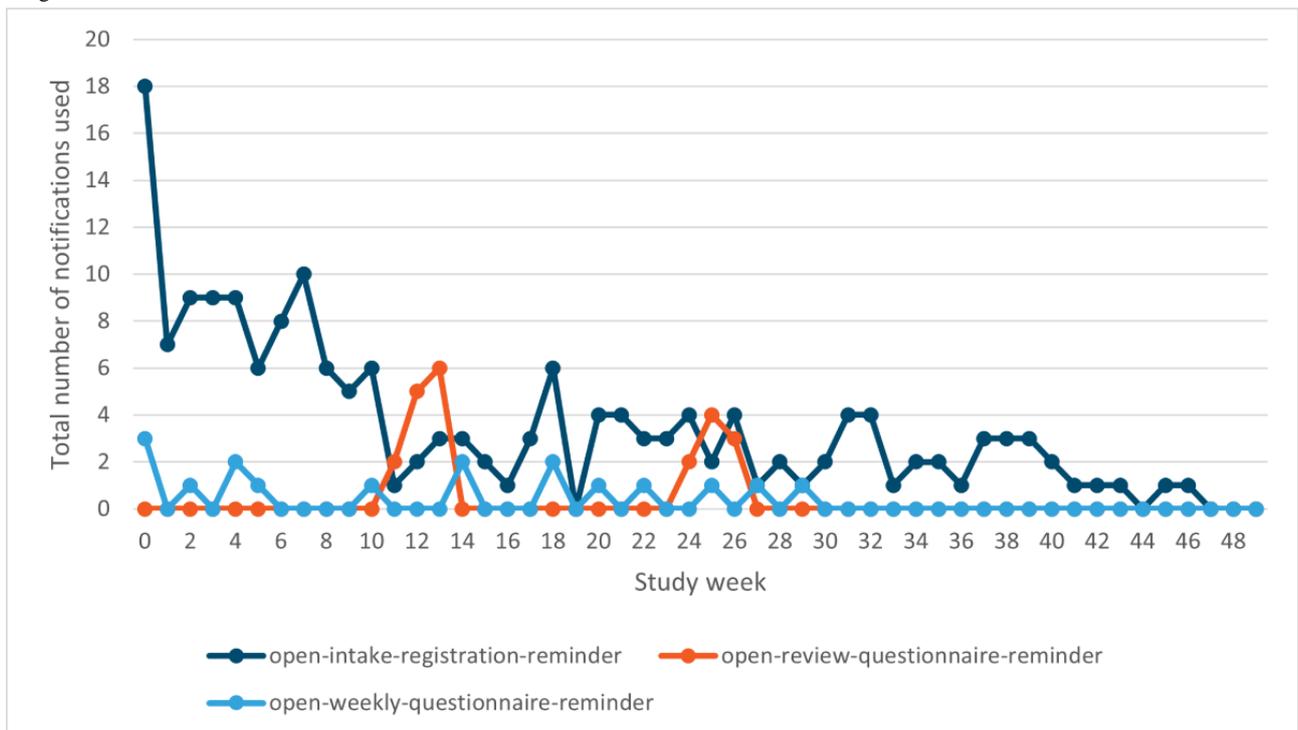

Table 2. Registered short-acting beta2-agonist use per week.

Time point	Values, mean (SD; 95% CI)
Baseline (n=373)	
Baseline questionnaire	10.5 (0.5; N/A ^a)
3 months (n=19)	
12 weeks after baseline	4.67 (2.5; 1.64-13.29)
6 months (n=11)	
25 weeks after baseline	4.82 (2.6; 1.68-13.81)
Latest time point^b (n=2)	
48 weeks after baseline	5.24 (3; 1.71-16.09)

^aN/A: not applicable.

^bMeasures ended within 1 year (mid-January 2021 until the end of December 2021).

Usability of the app, as assessed with the SUS, was good over the entire study period: 82.3 (SD 13.2; n=44) at 3 months, 84 (SD 13.6; n=26) at 6 months, and 82.3 (SD 13.4; n=11) at 12 months (Table 3).

Table 3. Questionnaire results regarding usability and quality of life.

Questionnaire	Baseline	3 months	6 months	12 months
Usability				
Values, n (%)	N/A ^a	44 (100)	26 (100)	11 (100)
Values, mean (SD)	N/A	82.3 (13.2)	84 (13.6)	82.3 (13.4)
Quality of life: physical health				
Values, n (%)	373 (100)	44 (100)	26 (100)	11 (100)
Values, mean (SD)	53.6 (22.4)	56.1 (23.9)	57.6 (21.8)	54.9 (24.7)
Quality of life: mental health				
Values, n (%)	373 (100)	44 (100)	26 (100)	11 (100)
Values, mean (SD)	57.4 (21.2)	62.9 (22.3)	59.4 (20.1)	67.8 (18.1)

^aN/A: not applicable.

Qualitative data showed that 3 (75%) of the 4 participants had experience using other health apps. The users mentioned that they wanted to use health apps that were fun and useful:

[...] I only want apps which I like or which are useful.
[Male user, 78 years old]

The participants found the app acceptable and clear in terms of *performance expectancy*. Three participants stated that gaining insight into asthma and its triggers was helpful. Another participant explained that it was not helpful at the moment because he considered his asthma to be controlled. This was for both participants who no longer used the app. One participant did not use SABA often, and the other participant only used it regularly based on the advice of his pulmonologist:

First impression was, well, I think, it looks clear. It was pretty clear to me on my own what I could do with it. After using it, yeah, I think it just looks like a nice app, not too old-fashioned. But just fairly new, as you expect from an app in this day and age. And it was also very quickly clear to me exactly what I could do with it. [Male user, 21 years old]

As very useful; you open the app and click on the plus icon how many times if you use it at that time. And also very nice that you get a notification every now and then like, "hey, it is the end of the week; make sure you fill in the amount." Especially if you forget to fill it in. That is nice. [Male user, 21 years old]

Regarding *effort expectancy* and *facilitating conditions*, 3 participants stated that the app is easy to use and straightforward and does not require much effort to register SABA use. One of these participants also stated that the app was well written and easy to read. The fourth participant did not say anything about ease of use. However, 1 participant experienced difficulties in interpreting the questions and answering the possibilities of the CARAT:

So with a few questions, I got, well you already noticed that I have some difficulties with choosing the right one. [Male user, 78 years old]

Of the participants who continue to use the app (2/4, 50%), they use it multiple times per week, with a minimum frequency of once per week and often 2 or 3 times per week. Opening the app was, for 1 participant, mostly completed after receiving a

notification. A former user mentioned that he would use the app once a week to fill in all the SABA intakes for that week.

Multiple possibilities for improvement were mentioned during the interviews. One participant wanted to be able to fill in triggers that were not listed in the app and also wanted to have the possibility to add more types of medication. Another participant missed contact with other patients with asthma in the app to discuss, for example, medication use. Someone else would change the CARAT based on their experienced difficulties. The last participant missed more background information about SABA use and why SABA should not be used more than twice a week:

There is one question that I do not understand. I filled it in good conscience in, and it immediately gave a number that should be decisive, but that I think “yes, but this does not apply to me.” In the app, it asked “how many times a night do you wake up?” [...] I do wake up but with a different cause [...] I personally think, but that is my opinion, there should stand “Do you wake up at night, because of your asthma?” [Male user, 78 years old]

Further exploring *social influence* showed that all the participants would recommend the app to others because they experienced that it provided more insight into their medication use and they received more information about the complete picture of asthma. One participant had already recommended the app to an acquaintance, who also started using the app. The 2 former users would specifically recommend it to certain patients: people with severe asthma or uncontrolled asthma or people who do not take their reliever medication as intended. Furthermore, 3 participants also found it useful to show the app to their health care professional during a consultation:

I would recommend it, especially to people who do not really have a case like mine. I would also not recommend it to people who, like me, only use salbutamol for sports. Yes, I do not know those people who just do it for sports just like me. Then it does not make much sense to keep track of how often you use it. You just know how often you exercise, and if you first use salbutamol then you know “hey, I use it so often.” But for people who use it often, it seems to me that is a very handy app, especially if you can see in that graph how often you have used it per week and in which week more and in which week less. [Male user, 21 years old]

Preliminary Effects

At week 1, the mean CARAT score was 14.8. This indicated that the participants' asthma was uncontrolled. Their CARAT score improved significantly to a mean score of 18.5 after 12 weeks (ie, 3 months; $\beta=.189$; SE 0.048; $P<.001$); however, this mean score still indicated that their asthma was uncontrolled. This was also the case for both the upper airway score, which significantly improved from a mean score of 6.8 to 7.7 after 12 weeks ($\beta=.073$; SE 0.027; $P=.009$), and the lower airway score, which significantly improved from a mean score of 8 to 10.8 after 12 weeks ($\beta=.121$; SE 0.037; $P=.002$).

The top three asthma triggers reported in week 1 were (1) weather (321/435, 73.8%), (2) exertion or exercise (305/435, 70.1%), and (3) smoke (197/435, 45.3%). After 12 weeks (ie, 3 months), the top three triggers were (1) weather (25/37, 68%), (2) exertion or exercise (19/37, 51%), and (3) hay fever or pollen (17/37, 46%).

At 3 months, there was no significant difference compared with baseline regarding the mean physical and mental health scores ($Z=-0.074$; $P=.94$ and $Z=-0.117$; $P=.91$, respectively; [Table 3](#)).

Discussion

Principal Findings

This study aimed to determine the feasibility and usability of a newly developed app, the Asthma app. Furthermore, the preliminary effects of using the app after 3 months on decreasing asthma symptoms and improving QoL were examined. The quantitative data showed that the usability was good. This was also found in the qualitative data: the app was considered easy to use, and it did not take much effort to register SABA. Furthermore, most participants stated that the app was useful for gaining insight into asthma, triggers, and medication use, and therefore, the app was considered feasible and usable. Multiple improvement possibilities were mentioned during the interviews, such as adding additional personal triggers next to the existing standard list of triggers and the availability of a social support network to contact others with asthma easily. In addition, former users, who no longer used the app, stated that they would recommend the app to people with severe asthma or uncontrolled asthma or people who do not take their reliever medication as intended.

As for the preliminary effects, an improvement in asthma symptoms was found after 3 months; however, the mean asthma symptom score still indicated that the asthma was uncontrolled. Improvement in asthma symptoms was also found in other eHealth studies [19,20]. The mean asthma symptom score in our study, indicating uncontrolled asthma, could be explained by the low intensity and noninvasive nature of the intervention (eg, users could use the app whenever and how often they wanted). A systematic review [44] also found that asthma control did not significantly improve in other studies. They proposed additional well-designed studies to gather more robust findings on what is necessary to achieve optimal asthma control [44]. In terms of QoL, no significant improvement was observed after 3 months. No effect was observed because poor asthma control was associated with worsened QoL [45,46]. The average uncontrolled asthma scores at week 1 and 3 months after baseline can be related to the low QoL scores at the same time points. Moreover, a systematic review [47] demonstrated that eHealth interventions have an inconsistent impact on QoL in people with asthma. The systematic enhancement of clinical outcomes such as QoL was mostly observed within the whole-systems approach, taking into account patient, professional, and organizational elements.

The data from this study should be interpreted with caution because of the high dropout rate, which resulted in insufficient

data for conducting analyses at 6 and 12 months. Although a high dropout rate is frequently seen in studies investigating digital applications, we envisioned that the dropout rate would be lower in this study, considering the participatory design process [28]. The dropout may be explained by the higher probability of dropout in people with chronic diseases when they are impacted physically and mentally by the condition [48]. Most of the participants in this study had uncontrolled asthma and, therefore, more symptoms throughout the day and night. This could have resulted in lower or no app use, which was directly linked to the withdrawal from the study. Another explanation for the high dropout rate could be, as described in our previous study [28], that only a minimal viable product was evaluated. Not all features recommended by the patients, such as registering additional controller medication, were implemented. Therefore, the app might not fit the needs of all the users and cause them to stop using the app.

Using the UTAUT framework [37], performance expectancy was positively associated with the use of the app for the current users. The app will help them gain more insight into asthma, triggers, and medication use. Performance expectancy was lower for former users who stated that their asthma was controlled; therefore, the aim of the app did not align with their needs. Effort expectancy was positively associated with both the intention to use and the actual use of the app, largely because of its user-friendly interface, minimal effort required for SABA registration, and language simplicity. The only aspect that was negatively related to the effort expectancy factor was difficulty with one of the questionnaires by a former user. Facilitating conditions were positively associated with the use of the app. The participants had the appropriate knowledge and resources to use the app. Technical support was not discussed during the interviews; however, clarity regarding the appropriate contact for technical issues could enhance user experience. Finally, social influence played an essential role in intention and use; all interviewees initiated app use through social media discovery or recommendations from health care professionals or family members. They would also recommend the app to others, and 1 participant had already recommended the app to an acquaintance. However, in future studies, this could be further explored in relation to voluntariness of use, which was not thoroughly explored in this study. This is also the case for other moderating factors such as *gender* and *age*. The sample size was too small to explore the associations between the moderating factors, factors, and intention and use of the app. Notably, prior experience with health apps positively influenced the intention and use of the app in this study, and current experience was positively influenced by effort expectancy, facilitating conditions, and social influence for current users.

Strengths and Limitations

This study has several strengths and limitations. A notable strength was the use of a real-life setting for evaluating the Asthma app, allowing a comprehensive understanding of its feasibility and usability. In addition, interviews with both current and former users provided a nuanced perspective on user satisfaction and the factors influencing app use.

In addition to the previously mentioned high dropout rate, another limitation was that the questionnaires were exclusively offered in the app environment. Therefore, former users were no longer able to complete the study questionnaires, thus limiting the availability of their data at later time points (ie, after baseline). To obtain the perspectives of former users on feasibility and usability, they were included in the qualitative interviews. Nevertheless, the recruitment of this group was difficult, and only 2 former users could be included.

Finally, the intended target of 6 to 12 interviews to achieve data saturation [29,30] was not attained. This was partially attributed to the difficulty in reaching former users who may have lost interest in the app or study. Despite the small number of interviews conducted, similar findings were found during data collection between the 2 users and the 2 former users.

Implications for Future Research and Practice

A minimal viable product was examined in this study. During the next development round, feedback gathered during the cocreation of the app could be re-evaluated [28], or new cocreation sessions could be organized to further enhance the app. In future studies, with a newer version of the app, the outcomes of this study could be further examined with more data at more time points, and clinical outcomes, such as the impact of the app on medication adherence, could be explored. A smart asthma inhaler [49,50] could also be linked to the app to gather real-time objective data instead of self-reported registration, which is more sensitive to biases.

This study has a high dropout rate. Renzi et al [51] stated in their review that reminders are often used to improve medication adherence in eHealth interventions but that this improvement is reduced over time. Typically, after 6 months, users tend to revert to their previous behaviors as the novelty of the eHealth intervention wanes [51]. This could also be the case in this study, especially because of the anonymous nature and the use of in-app questionnaires. In future studies, it would be advisable to collect data pseudonymously and send questionnaires via email to achieve a higher response rate. In this way, participants will also be less likely to withdraw from the study and stay involved for longer.

In the new version of the app, additional information about the treatment guidelines should be implemented, such as the fact that users should follow the advice from their health care professional if they receive any. It should be clarified that the app is specifically for people with asthma who only use SABA (and not ICS), which has been the first step of treatment for decades. Potential users could be reached via general practitioners, specialized practice nurses, or pharmacists when they prescribe or distribute SABA. Currently, the Asthma app is a stand-alone app, which means that it is used by patients without the involvement of health care professionals. However, involving health care professionals via “blended care” could improve the quality of care [52]. Moreover, health care professionals can offer additional education and guidance based on the data from the app [53]. To incorporate the app into standard treatment, it is necessary to develop a plan together with asthma associations and health care professionals. A designated implementation team can improve the success rate

of the implementation [54], and it is important to explore context-specific strategies that align with the implementation process phase [55]. Certain barriers (eg, technical issues, time and attention requirements for use, low engagement from health care professionals, and shortage of funding) and facilitators (eg, stakeholder engagement and enthusiasm, minimizing workflow interruptions, and access to information about the app) should be taken into account when implementing the app in standard care [27,56-58]. In addition, more education about SABA overuse could make health care professionals more aware of the risks, which could prioritize the use of the app.

Conclusions

This study evaluated the feasibility and usability of a new app for people with asthma. The initial results regarding usability were positive. Nevertheless, it is essential to exercise caution when interpreting these results because of the high dropout rate in this study. Two former users would recommend the app to people with severe asthma or uncontrolled asthma or people who do not use their reliever medication as intended. Future (implementation) studies could evaluate the potential of incorporating the app into standard treatment practices. Moreover, the actual impact of the app on clinical outcomes, such as medication adherence, should be further examined.

Acknowledgments

This study was funded by Astra Zeneca (no grant number). The authors would like to thank Andrea Sellink and Eva van den Berg who contributed to the review of the manuscript.

Authors' Contributions

LNvdB, CH, NHC, and AV contributed to the conceptualization and reviewed and edited the manuscript. LNvdB and AEV prepared the original draft and conducted the quantitative and qualitative analyses. LNvdB provided the visualization (preparation, creation, and presentation of the published work, specifically visualization or data presentation). LNvdB, CH, and AV contributed to the methodology, validation, investigation, resources, and data curation. CH, NHC, and AV supervised the project and acquired funding for the project. AV was responsible for the project administration. All authors have read and agreed to the final version of the manuscript.

Abstract

Background: Sjögren's syndrome (SS) is the second most common autoimmune rheumatic disease, and the range of symptoms includes fatigue, dryness, sleep disturbances, and pain. Smartphone apps may help deliver a variety of cognitive and behavioral techniques to support self-management in SS. However, app-based interventions must be carefully designed to promote engagement and motivate behavior change.

Objective: We aimed to explore self-management approaches and challenges experienced by people living with SS and produce a corresponding set of design recommendations that inform the design of an engaging, motivating, and evidence-based self-management app for those living with SS.

Methods: We conducted a series of 8 co-design workshops and an additional 3 interviews with participants who were unable to attend a workshop. These were audio recorded, transcribed, and initially thematically analyzed using an inductive approach. Then, the themes were mapped to the Self-Determination Theory domains of competency, autonomy, and relatedness.

Results: Participants experienced a considerable demand in the daily work required in self-managing their SS. The condition demanded unrelenting, fluctuating, and unpredictable mental, physical, and social efforts. Participants used a wide variety of techniques to self-manage their symptoms; however, their sense of competency was undermined by the complexity and interconnected nature of their symptoms and affected by interactions with others. The daily contexts in which this labor was occurring revealed ample opportunities to use digital health aids. The lived experience of participants showed that the constructs of competency, autonomy, and relatedness existed in a complex equilibrium with each other. Sometimes, they were disrupted by tensions, whereas on other occasions, they worked together harmoniously.

Conclusions: An SS self-management app needs to recognize the complexity and overlap of symptoms and the complexities of managing the condition in daily life. Identifying techniques that target several symptoms simultaneously may prevent users from becoming overwhelmed. Including techniques that support assertiveness and communication with others about the condition, its symptoms, and users' limitations may support users in their interactions with others and improve engagement in symptom management strategies. For digital health aids (such as self-management apps) to provide meaningful support, they should be designed according to human needs such as competence, autonomy, and relatedness. However, the complexities among the 3 Self-Determination Theory constructs should be carefully considered, as they present both design difficulties and opportunities.

Introduction

Background

The need to improve the accessibility and quality of care for those with long-term conditions (LTCs) is an international priority [1]. In England alone, LTCs affect 15 million people [2] and account for 70% of health care spending [3]. Rheumatic diseases are LTCs with a particularly high prevalence in the United Kingdom and worldwide, having been estimated to affect up to one-fourth of Europeans [4,5] and a similar proportion of the population in the global south [6]. Sjögren's syndrome (SS) is thought to be the second most common autoimmune rheumatic disease [7] and is associated with poor quality of life [8] and high disease burden [9].

SS is a heterogeneous LTC, with a constellation of unpredictable and diverse symptoms [10,11]. A key characteristic of SS is mucosal dryness due to the destruction of exocrine (moisture-producing) glands by the body's immune system, which particularly affects the eyes, mouth, and vagina [12]. In addition to dryness, common extraglandular features include persistent fatigue [13], chronic pain [14], sleep disturbances [15], and anxiety and depression [16]. People with SS report experiencing these symptoms as being interconnected, with the exacerbation of one symptom impacting others [17-19].

Similar to many other autoimmune diseases, SS does not have a cure [20]. Therefore, intervention efforts have focused on reducing the severity of symptoms; for instance, topical treatments are used for managing dryness [21]. Drug treatments for the systemic management of SS, such as hydroxychloroquine and rituximab, have had disappointing results in clinical trials [22,23]. Behavioral interventions that aim to improve the quality of life are a promising alternative; however, few interventions have been developed, and evaluations of their impact have been of low quality [21,24]. A recent stakeholder engagement study found that support for self-managing symptoms was a key priority for people with SS [25]. The term self-management has been defined as "the individual's ability to manage the symptoms, treatment, physical and psychosocial consequences and lifestyle changes inherent in living with a chronic condition" [26,27]. To support the knowledge, behaviors, and attitudes required, self-management interventions should deliver a range of educational, behavioral, and cognitive techniques [28]. In SS, a targeted "complex" intervention is required, which delivers multiple techniques and targets multiple SS symptoms [29]. Our previous body of work with patients with SS found that they require different levels of support. Some require more complex individual support, but most people require lower levels of support with access to written information and digital self-management tools [29], which could be provided in the form of a website or smartphone app.

Apps as a Support for Self-Management

SS shares multiple symptom and self-management similarities with other LTCs [30], including but not limited to neurological and autoimmune conditions such as rheumatoid arthritis, myalgic encephalomyelitis, and multiple sclerosis. Smartphone apps are a promising approach to support self-management of these LTCs [31,32] and other conditions such as type 2 diabetes [33], asthma [34], and hypertension [35]. Their increasing availability and functionalities enable complex intervention techniques to be delivered in the context of users' daily lives when they are designed with consideration of users' routines and choices [36]. User-centered design studies of LTCs have produced various app features and content [37] to support, for example, user education and cognitive strategies. However, app effectiveness can be limited by very low levels of user engagement [38,39]. Therefore, intervention developers must design apps that are more engaging and carefully consider how such engagement will ultimately lead to long-term behavior change [40]. For example, beyond simply providing information about how to perform techniques, apps can be designed to promote a sense of autonomy and motivation to engage in self-management behaviors over time [41,42].

To increase user engagement, apps should be user centered and person centered [43], that is, designed to fit within individuals' current lives and daily activities [44]. People are more likely to use a new intervention if it can be incorporated into their existing habits, routines, and contexts [45,46]. Therefore, self-management interventions should account for and actively support how people manage their conditions currently [31,47]. Thus, to develop a useful, effective, and engaging app-based intervention that supports those with SS, there is a need to first understand their current self-management opportunities and challenges. To date, limited studies have only been conducted to understand the lived experience of symptoms [17,19,48] and have not explored the self-management of multiple diverse symptoms.

To gain an understanding of individuals' self-management contexts, co-design and user-centered methods are useful [49]. These can involve practical design activities that elicit conversations regarding a topic of interest (such as self-management) to inform the development of a design, product, or intervention and have been used to develop digital health interventions [50,51]. Then, to understand how users in these contexts might best be supported in changing their self-management behavior, co-design findings can be interpreted using theories of motivation and behavior change [41].

Self-Determination Theory (SDT) [52] is one motivational theory widely used in interventions promoting health behavior change [53,54], including those for self-managing chronic illnesses [55,56]. SDT proposes that the constructs of competence, autonomy, and relatedness are required for individuals to be internally motivated to perform behaviors and sustain these changes over time. Situating qualitative findings

within theoretical constructs facilitates the development of apps that are based on theory [42,57]. While intervention developers use SDT to inform their interventions, many do not explicitly link the theoretical constructs directly to their individual components, and we aimed to bridge this gap. To the best of our knowledge, there are no evidence-based, theory-driven, self-management apps for SS.

Study Aims

We aimed to use an SDT framework to explore self-management challenges and approaches used by people with SS and to produce a set of design and therapeutic recommendations for a supportive and engaging app to aid self-management.

Methods

The methods and subsequent results have been reported according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines (Multimedia Appendix 1 [58]).

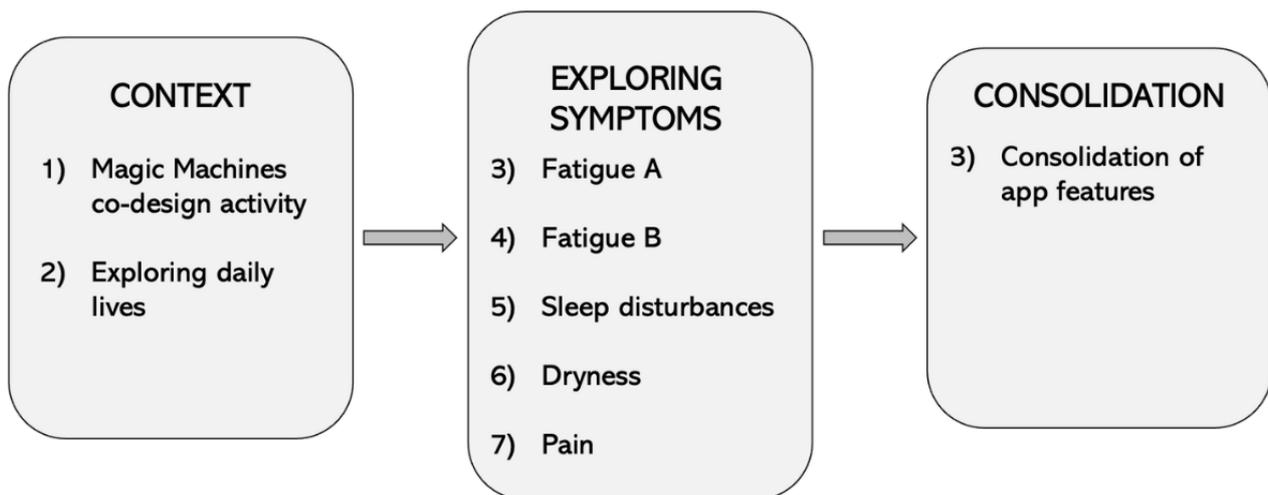

Study Design

A consecutive series of 8 workshops with people living with SS was conducted over 7 months, each involving design activities and focused discussions (Figure 1). The first 2 workshops were open ended to broadly understand participants'

contexts (ie, key self-management challenges and overall self-management routines) and enable participants to become familiar with each other and to feel comfortable while discussing potentially sensitive and personal topics. We decided in advance to include a series of workshops, with each workshop dedicated to in-depth understanding of the self-management activities, challenges, and opportunities for each symptom. However, the order of symptom workshops and their exact discussion topics and activities were not predetermined; their sequential nature enabled us to iteratively design topics based on the findings from the previous session. For example, a clear theme emerged regarding symptom interrelatedness, so subsequent workshops included discussions about how participants managed interrelations among their symptoms. Furthermore, fatigue was a priority for all workshop participants (14/14, 100%), and therefore, 2 workshops were dedicated to this symptom.

Participants were given the option to attend ≥ 1 workshops. Several workshops were repeated to suit participants' availability. To enable those who could not access any workshops due to other commitments and to include the experiences of younger people living with SS, 3 one-off semistructured interviews were conducted. These focused on the key self-management practices and challenges experienced by the respective participant.

Figure 1. The procedural flow and topics of the 8 design workshops.

Ethical Considerations

This qualitative study received ethics approval from Northumbria University ethics committee (reference 11130). Informed consent was obtained before data collection, and travel costs were reimbursed.

Recruitment

Workshop participants were purposively recruited from a regional UK SS support group (Northeast Sjögren's Syndrome Association). Advertisements were distributed via their member mailing list and Facebook page, and the research team presented the project at a support group meeting. The invitation was open to those diagnosed with SS by a physician, and potential participants were invited to attend as many workshops as they liked. Interested participants who were unable to attend due to

their location or life commitments were invited to attend a video web-based interview. Additional participants were recruited via social media (a single tweet on Twitter [subsequently rebranded as X]) and invited to participate in the interviews only.

Data Collection Activities

Overview

Workshops were conducted at Northumbria University, lasted approximately 90 minutes, and included a 10-minute comfort break. The interviews lasted 30 to 60 minutes and were conducted via telephone or videoconferencing software. Workshops were facilitated by 3 authors (CM, MC, and KH)—all were female postdoctoral (PhD) researchers trained in qualitative research methods and experienced in conducting qualitative research interviews and focus groups; one of them

was also an occupational therapist (KH) with experience in SS symptom management. Several workshop participants (4/14, 29%) had attended clinics (conducted by KH), and 14% (2/14) had participated in previous studies (conducted by KH and VD). All participants (17/17, 100%) were briefed about the aims of the study. All workshops and interviews were audio recorded, and facilitators took field notes. In the following sections, we have outlined the focus of each workshop. The individual workshop topic guides are presented in [Multimedia Appendix 2](#) [59-62].

Workshop 1: Magic Machines Co-Design Activity

This workshop introduced the series of workshops, included discussion about some key self-management issues experienced by participants, and involved a Magic Machines [54,59] craft activity where participants created some imaginative design solutions for another workshop participant. The Magic Machines activity aimed to elicit a broad range of knowledge about participants' personal and technological needs through discussions about everyday problems related to their condition and potential solutions. Participants were asked to create an object, which addressed their partner's daily challenge, using household objects and craft items. Data capture was focused on the conversations between participants about their "problem" while making their objects (a potential "solution") and when describing their object to the main group at the end of the session.

Workshop 2: Exploring Daily Lives

The second workshop explored individuals' "daily lives" and the self-management of symptoms. The discussion about daily lives invited participants to discuss their "typical day" in managing SS (ie, their habits and routines), how SS self-management was incorporated into their routines, and any related challenges that they experienced.

Workshops 3 to 7: Exploring Symptoms

These workshops explored the self-management of specific symptoms and their interrelationships through group discussions and invited participants to engage in basic sketching to articulate their self-management experiences and challenges. We preselected the symptoms for discussion based on our previous study where patients identified them as being important and impacting their daily activities [25].

Workshop 8: Consolidation

Sketching was used to explore how an app might be structured to support symptom interconnectedness and complexity. This design activity also elicited discussion about user experience and usability issues. All participants (5/5, 100%) attending this workshop engaged in sketching, but if time was insufficient, they were encouraged to further develop their ideas by articulating them verbally.

Interviews

Following the workshops, 3 semistructured, web-based interviews were conducted by CM. The interviews followed a schedule of open-ended questions to allow for flexibility ([Multimedia Appendix 3](#)).

Data Analysis

Audio data were transcribed verbatim, pseudonymized, and combined into a corpus for analysis using NVivo (version 12; QSR International). Analysis was conducted in 2 phases using a hybrid approach, incorporating both inductive and deductive methodologies, to harness the advantages of both methods [63]. First, an inductive thematic analysis approach [64] was used, where 2 researchers (CM and MC) independently coded the data, generating an initial set of codes related to participants' self-management perceptions and experiences. Then, these codes were applied and refined through the arrival of each new transcript, and independent coding was subsequently conducted by CM. Discussions during regular research team meetings (with CM, MC, and KH) related to the codes and their connections, importance, and relevance were conducted to group codes into themes.

Then, these inductive themes were mapped to the 3 SDT [65] constructs of competency (the sense of capability to perform activities and tasks), autonomy (experience of having control and choice over one's actions and decisions), and relatedness (feeling of connection and belonging and meaningful interaction with others) by CM. SDT was chosen over other motivational theories because it emphasizes social context as a key factor in helping or hindering motivation, which matched a prominent theme in our inductive thematic analysis of social relations, along with other major themes we found related to empowerment, autonomy, and capability (or "competency" in SDT). The theory is also highly translational, enabling findings to inform intervention design [66]. Regular research team meetings were conducted to review and reach consensus regarding the categorization of themes based on the SDT constructs. Opportunities to support participants' challenges associated with these themes through an app were also identified through discussions. Methodological rigor and credibility of findings were pursued through development of a codebook, maintenance of ongoing reflexivity, peer debriefings, and data triangulation (from interviews, focus groups, and observations during workshop activities).

Results

Participants

In total, 17 people with SS participated in the workshops and interviews: 14 (82%) of the 17 participated in the workshops (13/14, 93% women and 1/14, 7% men) and 3 (18%) of the 17 participated in the web-based interviews (3/3, 100% women). Participants' ages ranged from 33 to 76 (mean 56.5, SD 13.95) years, and 82% (14/17) of them had a diagnosis of primary SS. The remaining 18% (3/17) of the participants had a diagnosis of secondary SS. The mean number of years since diagnosis was 7.5 (SD 7.88) years. Regarding employment status, of the 17 participants, 8 (47%) were retired, 6 (35%) were working full time, 1 (6%) was in part-time employment, and 2 (12%) were not working currently. All workshop participants (14/14, 100%) had links to a local SS support group in the north of England. Of the 3 interviewees, 1 (33%) was part of the same support group, and the remaining 2 (67%) were from Spain and Canada, respectively (both were aged <35 years). Workshop

group numbers ranged from 2 to 7 participants and 2 to 3 facilitators in each session. Some participants attended some sessions and not others, whereas a “core” group of 5 participants attended most sessions. One participant (1/14, 7%) attended only the first workshop; others attended at least 2 sessions.

Overview

Participants engaged in a wide range of self-management behaviors, including using prescribed and over-the-counter medications and treatments (ie, applying eye drops and gels; bathing and massaging the eyes; using humidifiers, skin creams, and vaginal lubricants; following mouth care routines; using pain medication; and using hot and cold compresses). They also used cognitive and behavioral techniques including activity pacing, goal setting, general exercise, relaxation, mindfulness, distraction, napping, sleep management and wind-down routines, and social support. Participants used various tools to support and facilitate the learning, use, and practice of these techniques, including books (eg, about managing fatigue), diaries (paper based and digital), websites and forums (eg, National Health Service or SS associations as both knowledge resources and social support), apps on smartphones and tablets (such as for yoga, breathing exercises, and mindfulness), wearables (to track physical activity), and other devices (eg, for relaxing music, “mindless” television, or distracting podcasts and comedy). Not all participants owned or used smartphones. Tools were used in addition to visiting friends and holistic wellness centers (eg, spas and mindfulness classes) and learning self-care techniques directly from health care professionals (eg, when to apply eye drops and more complex techniques such as activity pacing and graded exercise).

In the following sections, we have described the challenges that participants faced in managing their condition and their psychosocial needs in terms of competency, autonomy, and relatedness.

Competency

Participants varied in the extent to which they felt competent and successful in self-managing their SS, and this was related to how well they had established a self-care routine. One participant had a very “strict regime,” which they felt was required to maintain their level of functioning. While hearing about such self-management strategies from others, Jim reflected about his competencies:

I've still got quite a lot to learn...although it has been a few years now, I think I still haven't got a good routine...I listen to your explanation [of another participant's routine] and I think, why can't I get myself like that? I'm supposed to be Mr Organised. I am known as that in my life. My working life and my own home life. Yet with this, I have not gotten organised yet. [Jim]

Regardless of whether participants had routines or described habitual self-management behaviors, their sense of competency in self-managing SS was still impeded by the complex nature of their symptoms. Isolating and targeting individual symptoms was not only perceived to be difficult to perform (“You can't separate the different symptoms” [Jim]) but were also

sometimes unhelpful, as it did not account for their accumulative negative impact:

It is the overall effect to me. That three [symptoms] I can cope with and then the next day one raises its head and floors me...That straw that broke the camel's back effect, you know. [Patricia]

Several participants believed that they could better manage their symptoms through self-management techniques capable of improving multiple symptoms simultaneously. Some had discovered these types of techniques accidentally. For example, participants recounted noticing, with surprise, that eye drops had helped not only their dryness but also mental and physical fatigue. Other participants purposefully sought and regularly used techniques that targeted multiple symptoms simultaneously. Mindfulness and relaxation techniques provided a sense of control and the ability to “keep a cap on” multiple symptoms before they became very severe. Others agreed that seeking these techniques was worthwhile if they resulted in minor improvements across multiple symptoms. Despite valuing self-management techniques that targeted multiple symptoms, most did not feel confident or knowledgeable about which techniques were beneficial.

Another challenge to participants' sense of competency is how SS symptoms are not static but change over time. Participants described instances where individual symptoms would rapidly fluctuate in severity:

[They] come and go...one day you might have a headache, the next day you don't. [Jim]

Participants also explained experiencing longer periods where multiple symptoms were severe (described using phrases such as a “flare,” “phase,” or “wave”) or individual symptoms persisted (such as “a dry patch”). While, sometimes, the onset of symptoms appeared “gradually,” at other times, they changed rapidly, leaving participants feeling unprepared (“a phase hits you”). Fatigue and pain were felt to be particularly volatile and could become severe with no warning and “like somebody just switched a switch” (Penny).

Participants varied in how they managed such changing symptoms. Many attended to symptoms as they arose or increased in severity on a moment-to-moment basis (ie, an adaptive or reactive approach). However, this often meant devising complex and intricate strategies and sequences to manage the new combination of symptoms experienced in that moment. For example, sleep disturbances that might be attributed to pain, dryness, or anxiety required participants to change their approach to getting back to sleep accordingly (“depending on how I am” [Penny] or “what problem I am having” [Jim]). Other participants seemed to disregard the changing combination of symptoms and addressed symptoms “one at a time” based on whether they felt successfully managed. For example, Julie noted the following:

I tend to find like I feel like my feet are sorted, so I am now sorting my eyes, so I'm kind of going through this list.

Addressing symptoms required constant adjustments for participants. Their variable nature meant that just at the point

that the individual starts to feel in control of one symptom, a flare of another may occur.

A final layer of complexity impacting participant competency was how symptoms often change due to environmental factors. For example, dryness was exacerbated by air conditioning, bright lighting, and other people's aftershaves and perfumes, whereas navigating new and busy places could exacerbate mental fatigue. The unpredictable nature of environments outside the home made self-managing symptoms more challenging. While home was characterized as "familiar" and "unchanging," participants felt that they needed to continuously estimate the potential impact of environments on their symptoms and plan accordingly:

You have to be very wary of where you're going...you've got to be careful. I will not walk through [the shopping mall] in the perfumery because there is always somebody going to...pick up a bottle of perfume and [spray]...I go, oh my eyes! [Geraldine]

This planning itself was exhausting to several participants, and it also meant that they lacked spontaneity in their lives. Participants also felt that symptoms were easier to manage at home because they could easily perform physical relaxation and self-care techniques when required, particularly during a flare. During such times Sarah remarked as follows:

I just don't want to leave the house, I don't want to do anything. I just want to go and have like 2-3 baths per day.

In contrast, when symptoms left them debilitated outside the house, participants had to adopt different self-management techniques such as soothing self-talk or be "rescued" by a taxi or friend. Overall, being outside the home meant that participants were less in control of their environments; had to continuously plan and predict how the environment might impact their symptoms, which was mentally and physically tiring; and had to use different techniques to suit different environments.

Autonomy

Our analysis identified many examples of participants feeling that they had autonomy in the self-management of their condition; however, sometimes, the same factors that promoted autonomy also reduced confidence and competence. Participants believed that the availability of various techniques meant that they had options in their self-management; there were multiple "different ways" they could try to improve symptoms. The plurality of techniques appeared to provide reassurance that at least one would be likely to be effective:

I have six choices...I don't beat myself up when it doesn't work because I've already got something else in mind. [Patricia]

This plurality and optimism could provide a strong drive to continue in their self-management activities.

Participants varied in how they kept track of different available techniques. One participant had self-help books at various locations in their home. Another participant explained that they had collated several techniques to create their own book:

I wrote myself a little book...[of] top tips...I just wrote maybe two dozen messages across the book at random, things that might give me a clue. [Debra]

Other participants used an experimental approach:

It's about learning...through trial and error...you'll notice a pattern...you don't know until you've done it for a few months. [Michelle]

These were similarly characterized by the desire to try different techniques and to keep track of their effectiveness:

With time and experience you begin to realise what works and what doesn't. [Penny]

It was acknowledged that this required continuous effort and perseverance.

Having personal choice to decide which techniques to try, as opposed to being directed by a health care professional, provided some participants with a sense of control. Debra likened creating her book of techniques to developing a tailored smartphone app:

It is basically my own app that I've written for myself...I didn't feel like being ordered around by anybody else...I don't necessarily follow it. If it's inside my book, I think, well alright, maybe I'll try something else...I've still got some kind of control over things. [Debra]

Therefore, developing this herself meant that she did not feel obligated to try any 1 technique. Although participants appreciated having the autonomy to choose techniques in a personalized manner, the credibility of these techniques was also very important to them. Perceived credibility seemed to give them confidence to go ahead and try them. Some participants indicated that they understood the distinction between evidence-based information and hearsay:

I am pretty much someone who will try anything once if there's some evidence to support its effectiveness...Some people suggest real outlandish things, like you hear it and you're like, "okay!" I mean, I'm glad that it works for you, but I'm not really sold on trying that just yet. [Ellie]

Participants felt that information about their condition or how to manage symptoms should be credible. For example, Jim explained that simply being presented with multiple self-management techniques and options, without a rationale for why they might be helpful, would not suit him. Others stated that knowing information sources was "useful...[for] controlling symptoms and trying to minimise [them]" (Edith). Information from websites such as the UK National Health Service or regional and national SS organizations was deemed trustworthy.

Although participants respected expert advice and implemented it in their self-management, expert authority was often only 1 element in an autonomous process of symptom management decision-making. For instance, when faced with a conflict between their preferred routines and expert advice, participants trusted their own expertise and experience. Jim outlined how he fell asleep with the help of music or old comedy shows and that he would simply "ignore" any potential prompts about

adjusting his bedtime routine if it meant removing his music from the bed (as may be advised as part of a sleep intervention).

For some participants, smartphones and associated apps appeared to contribute to feelings of autonomy regarding their self-management of SS. Those who used a smartphone reported using basic note apps to track symptoms or calendars built into the operating system to track feelings of fatigue. Experienced smartphone users described how their ubiquitous nature enabled quick access to information and could give them access to techniques whenever and wherever needed, regardless of their location. In sessions where feedback was given about potential app designs, participants expressed the value they would see in new apps that brought various techniques together, provided reminders to apply eye drops, and helped track symptoms in a simpler manner. For instance, Julie suggested that “a tracker or a journal...or something like that on the app would be helpful” as this could help her manage her forgetfulness, which she referred to as “brain fog.”

However, while smartphones could enable autonomy, they also posed challenges that could impact the users’ SS symptoms. It was also noted that looking at the screen of a computer or smartphone for a very long time could exacerbate eye dryness:

It's okay [when it's] short, but you can't spend a long time looking at the screen, because your eyes are just too sore. [Mel]

To overcome this, participants used their smartphones differently. Some described deliberately limiting the amount of time they used them in 1 session, and others described changing their device settings to increase the font size or darken the screens. In addition, participants mentioned improving on-screen accessibility to reduce their eye strain and listening to audio instead of reading text. Patricia, noted that when “I am having my brain fog” the complexity of most apps “would blow my mind.” Among participants, there was a sense that smartphone use was closely related to experiences of mental fatigue from their SS.

Overall, participants valued the diversity of SS self-management techniques that are available and experienced this as enhancing autonomy. Smartphones and both generic and SS-specific apps were viewed as an important part of this diversity and could provide in situ tailored support. However, the apparent abundance of techniques and availability of smartphones also posed a challenge to autonomy. Patricia recounted that soon after being diagnosed with SS, she was overwhelmed by the need to learn about multiple symptoms and techniques from many sources. However, for her, this felt similar to being “shot at” from multiple angles. Sometimes, the factors that enable autonomy can also constrain it.

Relatedness

Relatedness refers to the manner in which participants operated in their social worlds and how their practices of managing SS were related to it. Participants explained that SS profoundly impacted their familial interactions, friendships, and other forms of social contact. Participants enjoyed social activities and cherished positive relationships as a source of social support. Socializing and participating in activities with others provided

a positive “distraction” from their symptoms. However, self-management tasks could impact their ability to socialize and interrupt the flow of conversations:

When in company if you are out and about and talking to people...You have to keep popping off to go and put eyedrops in, in the loo. [Edith]

Furthermore, engaging in certain social activities, such as going to the cinema with friends, required participants to perform additional self-care, for example, applying eye drops more frequently, which could irritate the skin around the eyes. Geraldine explained that although she enjoyed going to live theatre performances, she was now reluctant to go based on previously being “crucified” by a smoke machine.

Pacing was a helpful technique to manage fatigue, but it was not always received well by others in social situations and workplaces. Patricia recounted that she had been regarded as “selfish” by family and friends for cancelling plans while trying to manage her energy and fatigue levels. She also recognized that having to “book” people into her diary well in advance to support her planning and pacing efforts “frightens some people off.” Edith recalled that the need to take more breaks meant that she had to decide to leave her walking group as she was no longer able to keep up with her friends. In turn, this negatively impacted her feeling of belonging.

Communication was key while managing illness demands and relationships. Some participants created their own SS information sheets to give to friends and health care professionals. Creating opportunities to explain difficulties was conducive to receiving valuable social support. Penny’s husband had delegated several household tasks to her, which were conflicting with her pacing technique. Penny explained that after discussing the issue with him, he subsequently understood the need to balance activities and that they were able to do this together. Ellie noted the following:

I do think that it is helpful to have people that you can talk to about Sjögren's. I mean I have a very close relationship with my family, and I have close friends who I do feel like I can confide in, and that is really helpful for me. [Ellie]

The freedom and ability to be open and honest about their SS symptoms with trustworthy family members and friends were central to well-being and helped with symptom self-management. However, despite all efforts to communicate effectively, many participants believed that, often, family, friends, and even health care professionals did not fully understand SS. They felt frustrated that symptoms were dismissed, normalized, or incorrectly attributed to other issues such as “getting old” or menopause. Dealing with invisible, ever-changing symptoms was difficult. Multiple general practitioner visits with complaints about seemingly benign symptoms such as fatigue and thirst were sometimes received with skepticism, and the transient nature of these symptoms made the situation worse:

Then you're fine and you think, “they'll think I am putting it on.” [Geraldine]

Any respite from symptoms made some participants worry that those around them would not believe them the rest of the time. Carol knew that relative to other conditions that may have 1 visible “major” symptom, her multiple symptoms were unlikely to garner support and understanding because of “Sjögren’s [and] all the little things that it has” (Carol). Some participants had stopped attempting to explain their symptoms to family and friends, saying that some symptoms were “very difficult for you to articulate...to somebody who doesn’t feel it” (Joan). This was particularly detrimental to relationships with health care professionals. When health care professionals seemed uncompassionate about their symptoms, some participants talked about “shutting down” and making a choice to no longer discuss their SS in consultations. This had negative consequences on participants who ended up feeling rejected and disengaged, and there was a perception that, sometimes, health care practitioners were not even aware of this relational and motivational shift.

When participants felt disbelieved, it led to experiences of self-doubt. Ellie said she was “bounced around like 4-5 practitioners” to the point where she questioned her illness “almost as if it is in your head.” Carol resorted to maintaining an activity diary, in part to monitor her fatigue and to preserve her sanity. For her, the diary data provided a sense of external objectivity and an opportunity to feel validated when being questioned by other people:

By doing the [diary] you think, yes...I've got a problem and that graph tells me...it is a physical thing, it's not in my mind. [Carol]

Being diagnosed with SS was a lonely experience for some participants due to the challenges of family, friends, colleagues, and health professionals not relating to participants’ symptoms or condition. Social isolation was particularly pronounced for a younger person with SS:

I don't know anyone else who has it. So, it is kind of isolating...I also had a hard time finding people who are...my age. So, I mean, I would definitely be interested in meeting younger women who are working, who are finding strategies. [Ellie]

Overall, connecting with others with SS was important, and participants sought opportunities to meet others with SS, learn, and find the validation and understanding they did not receive from others without SS. Some joined support groups and attended scientific conferences to expand their social circle with other people with SS.

However, not all social contact with others with SS was deemed helpful:

Some of the interactions I had honestly more scared me than helped me because it was people who were really in the throes of severe illness and some who weren't coping well, and it was sort of anxiety-provoking. [Ellie]

Therefore, support from others with SS was generally more welcome when it was helpful and positive, as interactions with those who were struggling to cope could have a negative impact on participants.

Within the construct of relatedness, even positive self-management was found to impact social activity, but having highly supportive friends and family could mitigate this to some extent. Describing and explaining the various, ever-changing symptoms to colleagues, friends, and health professionals who did not fully understand the condition or symptoms could be particularly challenging, but external resources such as using diary data could be a helpful tool to aid communication.

Discussion

Principal Findings

We sought to understand the current self-management approaches used by people with SS to inform the therapeutic ingredients and design recommendations for a self-management smartphone intervention. To date, most studies of lived experience with SS have focused on how specific symptoms are experienced [17,18,48]. To the best of our knowledge, no studies have explored how people with SS perform the day-to-day work of managing their condition and navigating challenges as they do so. This is an important consideration when designing interventions, as those that draw upon users’ expertise are more likely to be used [38]. Therefore, we analyzed qualitative data collated through a series of workshops and interviews with people with SS inductively before mapping the themes to the 3 constructs of SDT (competency, autonomy, and relatedness) [52]. This theory was used because it can help identify the psychosocial and practical requirements to support autonomous motivation to adopt and sustain healthy behaviors and to improve well-being in a population [52,67]. Our findings were consistent with what Cartner [68] first described in her qualitative study with participants with SS: the *labor* of living with SS. For her and our participants, competency was an ongoing effort, never a completed achievement. The complex, multisymptomatic, volatile, and unpredictable nature of the condition meant that their hard-earned expertise was being constantly challenged. Having to adapt to an ever-changing and unpredictable challenge evokes the concept of stress, but more specifically, it is captured by the notion of *allostasis*: the work that needs to be performed to find stability within a situation that is constantly changing. When allostasis is frequent or continuous, more work needs to be performed, and our emotional, cognitive, and biological resources can become dysregulated. This is known as *allostatic load*—the psychophysiological wear and tear that occurs to a system that is constantly having to adapt—which has clear links to anxiety, depression, morbidity, and mortality [69].

The labor of the participants and its costs were also evident in the SDT domain of autonomy. Often, there was a degree of forced autonomy, with participants having to perform the epistemic labor of determining how to manage their condition for themselves. This involved ongoing research and even compiling their own resources. Discernment and discrimination were required to determine what advice to trust and follow and how to balance that advice against their own experience. Although this process was enabling, it was also potentially disabling as the process of gathering and compiling information worsened some SS symptoms.

Finally, in the realm of relationships, managing SS requires significant social labor. Often, participants were required to manage the expectations, lack of understanding, skepticism, and disbelief of others, including health professionals, and these efforts were often only partially successful, leading to self-doubt, isolation, and lack of adequate care and support for their illness. This is not dissimilar to the experiences others face with other fatiguing LTCs such as stroke, fibromyalgia, multiple sclerosis, and ankylosing spondylitis [70].

Design Recommendations

[Multimedia Appendix 4](#) [52] summarizes our key findings, which have been mapped to the 3 constructs of SDT, with identified therapeutic approaches and design solutions for each. The findings within these SDT domains were identified as targets for intervention by the participants. In the following sections, we have reviewed these domains and suggested what interventions might help and how the interventions could be incorporated into an app to support self-management.

A key finding within the competency domain was that SS was multisymptomatic, volatile, and unpredictable. Participants were keen for interventions that would impact >1 symptom at a time. A previous study that investigated patient strategies for self-management of inflammatory bowel disease had similar findings [71]. Several treatment approaches and their components discussed during the workshops could potentially address several symptoms simultaneously. For example, activity and sleep management strategies such as pacing and reflective activity diaries have been used to support self-management of pain, sleep disturbances, and fatigue [72-76], and previous studies that evaluated interventions targeting several symptoms have shown promising results. Therefore, we suggest that when designing complex interventions for LTCs, intervention developers should map the potential, identified intervention content to behaviors and symptoms and select techniques that target >1 symptom where possible, thereby placing a smaller demand on the user. While this may not always be possible, streamlining the intervention content where practicable is likely to decrease the possibility of becoming overwhelmed and thereby supports user competency.

The key challenge in the autonomy domain was the amount of work required by participants to determine how to manage their condition on their own. As with many other LTCs, a large part of the “burden of treatment” is shouldered by the person with the condition [77]. Our findings broadly indicate that technology-enabled symptom management could help with this work of illness management. Participants liked the idea of a smartphone app to support self-management. However, merely operationalizing technology is not sufficient to promote and support self-management. Gldenpfennig et al [78] found that poor design and well-meaning paternalism, for example, through automated support that takes active choice away from the user, may compromise autonomy and proactive self-management. Furthermore, intervention designers should aim to strike a more careful balance between the input of experts by experience and those of professional experts [25,78]. In our study, we found that people with SS managed their symptoms using different approaches but that all of them had arrived at their own set of

strategies and management regimes through experience, research, and trial and error. Acknowledging the individuality of self-management and the necessity to experiment with different approaches would be a key part of any intervention. Having a repository of strategies in 1 centralized app, which would also allow them to add their own strategies, would seem to be a potentially useful resource. This aligns with previous studies of apps that provide resources while allowing customization and thus may support a user’s sense of autonomy [79-82] and move away from a top-down paternalistic or prescriptive approach to LTC management [83,84]. An app for SS would need to combine recognition of the labor of self-management while helping to support it in a manner that honors the user’s autonomy and existing wisdom, providing the ability to choose from a range of therapeutic content and to determine the order in which they interact with it.

The most difficult and often fruitless area of labor was observed within the relatedness domain. Participants were required to manage others’ expectations, lack of understanding, skepticism, and disbelief, often leading to a smaller social world, isolation, and difficulties in accessing help from health professionals. Again, any intervention needs to begin by acknowledging this labor and the emotional and social costs of having a poorly understood and invisible illness. Our findings also showed that there was often a tension between illness management and maintaining relationships. For example, it could become difficult to implement strategies such as pacing when others were involved, particularly when the person with SS had not fully disclosed their symptoms or condition to the people whom their self-management strategy may affect. Therefore, saying “no” could also be hard for participants, particularly when it was perceived that others would not understand. Other participants had found a solution by working on their means of communicating their difficulties with those around them. Winger et al [85] have found that greater practice of assertiveness and communication skills was associated with reduced pain interference and psychological distress in people with lung cancer, and assertiveness and communication is also a key component of an effective fatigue management intervention for people with rheumatoid arthritis [60]. Therefore, we recommend including assertiveness and communication strategies within a therapeutic self-management app for SS. When considering the design of the app, we recommend including some text to help the user provide a brief explanation about their condition, its symptoms, and their impact to share with health professionals, colleagues, or people in social settings, as needed. We also recommend designing opportunities to practice assertiveness and communication skills within the app for those who may find it helpful.

In summary, our findings suggest that some of the key areas of concern for participants were potentially addressable through an intervention. A common starting point for any approach should be an acknowledgment of the real costs and the daily hard work of having an unpredictable, volatile, and multisymptomatic LTC. Any therapeutic approach needs to be designed to help with this labor; to acknowledge the social, emotional, and physical costs of having and managing SS; and to appreciate the wisdom that the “end user” of the app or

intervention will have already accumulated. Strategies obtained from Acceptance and Commitment Therapy [86] and Compassion Focused Therapy [87] could be useful as they have been used to target the psychosocial impact of other related health complaints such as chronic pain [88]. Next, specific strategies (eg, pacing and sleep management) that could help target multiple symptoms or single symptoms in sequence would be useful. Finally, support to perform some of the social labor involved in living with SS should be a key component. In [Multimedia Appendix 4](#), we have further specified the areas of intervention and suggested the broad therapeutic approaches that might be useful.

Regarding our use of the SDT framework, while it was useful to structure our thinking about intervention development, we also noted that the constructs of SDT often existed in a state of tension with each other, where successfully fulfilling the requirements of one construct leads to reduced functioning in another. As noted previously, this tension occurred between competence and relatedness, where symptom management conflicted with maintaining social bonds. Similar tension existed between autonomy and competence, where participants struggled to feel competent if presented with several self-management options. The SDT states that all 3 fundamental needs have to be met for internally motivated, self-determined behavior to occur [52], but we tentatively suggest that the theory needs to consider moments when some needs stand in opposition to each other. Making the nature of these tensions explicit to the users of an intervention or app would be a key part of its opening narrative.

Limitations

The extent of transferability of our findings to other LTCs is not yet known. However, studies of other autoimmune conditions have demonstrated the same need to self-manage complexity—people with inflammatory bowel disease reported that symptoms (pain, fatigue, and diarrhea) changed over time and could be interconnected at different times, and they required a highly individualized management strategy to “balance” the illness and attend to dynamic fluctuations in symptoms [71]. Overall, our findings may provide insight into how several other autoimmune conditions are self-managed or could be

self-managed with the use of an app. However, owing to the nature of the complexity we captured in this study, transferability of our findings to other contexts may be limited. The 17 participants in this study included only 1 (6%) man, which may mean that any unique difficulties experienced by men with SS have been missed in our study. However, SS has a female-to-male incidence rate of 16:1 [89], and the gender makeup of our participants is representative of the wider SS population. Another limitation was that we did not formally collate information about smartphone ownership from participants. Such data should be collated in future similar studies. A final limitation is that most of this study was conducted within the United Kingdom, with only 67% (2/3) of the interviewees living outside the United Kingdom. Therefore, we cannot assume that similar findings would be replicated in other geographical contexts.

Future Studies

Future studies should operationalize the findings of this study to construct an intervention protocol that could be implemented via a smartphone app for the management of SS and empirically optimize its content through pilot and feasibility testing. Furthermore, future studies may explore the transferability of our findings to the self-management contexts of other autoimmune and fluctuating conditions. Our target users were those with primary or secondary SS; future studies should consider how user age influences the design requirements in this patient group.

Conclusions

In conclusion, therapeutic and design approaches for SS should be constructed in both bottom-up (ie, based on the self-management challenges that prospective users already experience) and top-down (according to the most effective treatments documented for SS) formats. For people with SS, choosing to involve an app in their self-management has the possibility of being counterproductive—by adding to their experience of fatigue and becoming overwhelmed. Therefore, the design of a self-management app for SS should support the user in performing the physical, cognitive, emotional, and social work of self-management and should be careful not to add to their already high self-management costs.

Acknowledgments

This study was funded by a grant from Versus Arthritis (grant 22026).

We would like to thank the participants for their time and contribution. In addition we would like to express our gratitude to Michelle Harrison and the North East Sjögren's Syndrome Association, Dr Elizabeth Price, Dr Helen Cartner and Julie Norris for their expert opinion and suggestions regarding the study and the app content.

Abstract

Background: In the medical field of obstetrics, communication plays a crucial role, and pregnant women, in particular, can benefit from interventions improving their self-reported communication behavior. Effective communication behavior can be understood as the correct transmission of information without misunderstanding, confusion, or losses. Although effective communication can be trained by patient education, there is limited research testing this systematically with an app-based digital intervention. Thus, little is known about the success of such a digital intervention in the form of a web-app, potential behavioral barriers for engagement, as well as the processes by which such a web-app might improve self-reported communication behavior.

Objective: This study fills this research gap by applying a web-app aiming at improving pregnant women's communication behavior in clinical care. The goals of this study were to (1) uncover the potential risk factors for early dropout from the web-app and (2) investigate the social-cognitive factors that predict self-reported communication behavior after having used the web-app.

Methods: In this study, 1187 pregnant women were recruited. They all started to use a theory-based web-app focusing on intention, planning, self-efficacy, and outcome expectancy to improve communication behavior. Mechanisms of behavior change as a result of exposure to the web-app were explored using stepwise regression and path analysis. Moreover, determinants of dropout were tested using logistic regression.

Results: We found that dropout was associated with younger age ($P=.014$). Mechanisms of behavior change were consistent with the predictions of the health action process approach. The stepwise regression analysis revealed that action planning was the best predictor for successful behavioral change over the course of the app-based digital intervention ($\beta=.331$; $P<.001$). The path analyses proved that self-efficacy beliefs affected the intention to communicate effectively, which in turn, elicited action planning and thereby improved communication behavior ($\beta=.017$; comparative fit index=0.994; Tucker-Lewis index=0.971; root mean square error of approximation=0.055).

Conclusions: Our findings can guide the development and improvement of apps addressing communication behavior in the following ways in obstetric care. First, such tools would enable action planning to improve communication behavior, as action planning is the key predictor of behavior change. Second, younger women need more attention to keep them from dropping out. However, future research should build upon the gained insights by conducting similar internet interventions in related fields of clinical care. The focus should be on processes of behavior change and strategies to minimize dropout rates, as well as replicating the findings with patient safety measures.

Introduction

Background

In the dynamic landscape of medical internet research, the pursuit of effective interventions and preventive health programs demands a comprehensive understanding of diverse populations, including pregnant women and their unique needs. This paper unveils the outcomes of formative research and preliminary results within the realm of medical and preventive health, exploring an innovation and technology in terms of a digital intervention, that is, apps aiming at improving communication behavior. Formative research, characterized by its emphasis on gathering insights from the intended beneficiaries, emerges as a fundamental tool for tailoring interventions to meet the unique requirements of diverse communities [1]. By demonstrating the integral role of formative research in the early stages of program development, we aim to provide a compelling case for its incorporation in the toolkit of researchers and experts working in the field of medical internet research. In this paper, we outline the potential of using digital tools like apps for improving communication behavior for patient safety and the risks involved with regard to dropouts in app-based interventions. Lastly, we outline a behavior change theory to model communication behavior, which may help to map out the health-related behavior more systematically and which was used for our research investigating communication behavior and app usage.

Patient Safety in Health Care

Patient safety is defined as the absence of harm that could have been prevented in patients. For achieving patient safety, health care should be delivered in an optimal manner, trust should be built among all involved individuals, and misunderstanding, information loss, or error occurrence should be prevented [2]. Thus, patient safety requires effective communication behaviors among health care professionals, patients, their partners, or accompanying persons [2]. In particular, in obstetric care, this holds true [2,3] because women in labor have to express their needs and wishes even in the face of stress and barriers to ensure their active role in the obstetric process. Communication behavior can be measured and taught [3-5] and is a reliable approach for improving patient safety [6,7]. Communication behavior involves multiple individuals, including patients, health care workers, and partners [8-13]. This encompasses not only the importance of perceiving a supportive environment that guarantees an open exchange of concerns and potential solutions but also the individual's competency to communicate safely. Such competency consists of the self-reported communication skills that are based on Rider and Keefer's [14] competencies and are impacted by determinants of the communication behavior, that is, self-efficacy, intention formation, and planning [15-19].

Communication Behavior

Communication is defined as a process involving the exchange of cognitions and emotions through verbal and nonverbal actions [20,21]. In this work, we define patients' communication similarly to communication in health care workers to keep definitions for both groups aligned. Previous work [8,10] performed over the scope of this project has defined communication in line with Rider and Keefer's definition [14]. They describe a set of skills including the creation and sustainability of a therapeutic relationship, use of effective listening, prompt and effective responding, and effective communication [14]. Effective communication is the correct transmission of information without misunderstanding, confusion, or losses.

Although effective communication has been shown to be of importance in preventing errors in medical care as well as in patient-provider relationships [6,22-24], only few studies have investigated effective communication behavior among those receiving obstetric care. Moreover, there is limited evidence for innovative tools aiming at increasing effective communication among pregnant women and their support networks [8,11,25]. Previous research has mainly investigated face-to-face interventions in clinical care or hospital settings [26,27]. Although traditional face-to-face interventions demonstrate efficacy, they tend to show several disadvantages concerning feasibility, such as higher financial constraints, limited utilization due to mobility constraints, or scheduling and time issues [28-31]. These constraints of traditional face-to-face interventions also call for cost-effective, convenient, instantly available, and scalable alternative solutions. One of these alternatives, successfully implemented across multiple therapeutic areas, including the promotion of health behavior change, is support via the internet, digital interventions, and apps in the medical field [32-35].

Digital Interventions and Apps

Digital interventions and apps (also called as medical internet support or web-based communication training) have shown several advantages over traditional face-to-face interventions, such as increased ease of accessibility and personalized interactions with real-time feedback. Furthermore, they offer the opportunity for scalability to larger populations, including individuals who live in remote areas. Moreover, such digital interventions can be relatively cost-effective compared to traditional formats [36,37]. Although there is clear general evidence regarding digital interventions, there is scarcity of research on those targeting to foster effective communication.

The same holds true regarding the applicability and integrability of traditional health behavior change theories such as the health action process approach (HAPA) to explain health behavior changes in digital interventions (ie, smartphone apps). Indeed, literature shows how interventions supporting motivational and volitional processes prove effective [8,9,38]. However, the

HAPA model has been rarely applied to interventions targeting effective communication [8,9], and it is hardly ever used to explain communication behavior in the context of digital interventions or their dropout of pregnant women. Therefore, we review dropout in more detail.

Factors Associated With App Usage and Dropout From Digital Interventions

Early dropout from digital interventions is a key problem [39], as the intervention use is discontinued. This needs more attention because if users drop out, which might occur as often as 1 in 2 cases [40], efficacy is limited, and the reach and generalizability of the obtained results are diminished [39]. However, little is known about the factors associated with dropout [39]. Accordingly, more research investigating and identifying such factors is needed, especially in the context of communication behavior and giving birth.

Looking at the general literature on the potential risk factors for early dropout in digital interventions, the following sociodemographic and behavior change factors were identified: age, education, and social support [41,42]. Although there is no previous study on dropout from digital interventions addressing effective communication of pregnant women, evidence from other areas with digital interventions exist. For example, Wu and colleagues [43] investigated dropout in a blended care cognitive behavioral intervention. They highlighted that a higher dropout rate was associated specifically with female gender, poorer financial status, and the absence of a college degree. Additionally, Gao et al [44] found that younger patients and those who were less educated were more likely to drop out from digital intervention studies. Other factors associated with early dropout were marital status (higher probability of divorced individuals to drop out) and ethnicity [45]. Besides the sociodemographic factors, according to Davis and Addis [46], psychological determinants should also be considered while examining dropouts from digital health interventions. According to [47,48], users with low intention to change their behavior have been found to drop out more often from digital interventions. A study by Schroé and colleagues [49] further investigated why users discontinued the use of digital health interventions. Their results highlighted that whereas sociodemographic factors were predictive of early dropout, psychological determinants such as action planning and self-monitoring were associated with completion of digital interventions [49]. This is in line with other research highlighting that self-monitoring [50] and higher intrinsic motivation were associated with lower attrition rates [51]. A theory that could bring the different factors together to enable systematic research is the aforementioned HAPA model, which is described in more detail below.

HAPA Model to Understand and Improve Behavior Change

Self-reported communication behavior constitutes a preventive health behavior [25] and may be fostered by the same factors and processes that health psychology literature has repeatedly showcased [52-54]. HAPA proved to be a useful theory [11] essentially since it considers the interplay of resources, barriers, as well as the well-known behavior intention gap [54,55]. The

HAPA model is divided into 2 distinct phases: (1) the motivational phase in which individuals consider their competencies' determinants such as self-efficacy, expectations about behavioral outcomes (outcome expectancies) and formulate a behavioral intention (eg, to communicate in the birthing context), and (2) the volitional phase, wherein pregnant women develop and enact behavioral plans in order to bring the intentions to behavioral actions. This whole process is shaped by social-cognitive barriers and facilitators that may originate externally or stem from women's personal belief, which is also called self-efficacy [54,56]. According to the HAPA model, individuals need to first form an intention, which is based on outcome expectancies and self-efficacy, before acting accordingly. Hence, the pathway of intention on the actual behavior is mediated by action planning [8,11,57]—with action planning being more proximal to behavior, and intention, outcome expectancies, and self-efficacy being more distal to behavior.

In order to improve communication behavior, interventions must be tailored to social-cognitive barriers and facilitators of the target population. Previous evidence has demonstrated that classical face-to-face interventions based on motivational and volitional theories such as HAPA are effective in improving self-reported communication [8,9,38]. It should be noted that most of these findings stem from interventions that were solely offered to health care workers [25], but more attention needs to be paid to patient education. This is the basis of our study with pregnant women randomized into an intervention group or a waitlist control group.

Goal of This Study

As previously outlined, there is a need for further studies to investigate effective communication behaviors of pregnant women within the context of a digital intervention. The goals of our study were 2-fold. First, we aimed to uncover the potential risk factors for early dropout from a digital intervention. Second, we aimed to investigate the social-cognitive factors that would predict the self-reported communication behavior after having used the digital intervention. Thus, the hypotheses are as follows:

1. Hypothesis 1: Sociodemographic factors play a larger role in predicting dropout during a digital intervention relative to behavior change variables.
2. Hypothesis 2: The social-cognitive factors outlined by HAPA (self-efficacy, outcome expectancy, and action planning) predict self-reported communication behavior in pregnant women over the course of the app-based intervention.
3. Hypothesis 3: More distal HAPA variables (intention, outcome expectancies, and self-efficacy) indirectly relate with self-reported communication behavior mediated by action planning.

Methods

TeamBaby Project

This study stems from a larger project named TeamBaby, which was tasked with developing interventions to improve

communication behavior between those who receive and provide obstetric care. One of the interventions was a digital intervention, that is, an app (actually, a web-app). Data collected from the TeamBaby web-app were used to investigate our hypotheses. The TeamBaby project was funded by the German Innovation Fund (project 01VSF18023) of the Gemeinsamer Bundesausschuss and preregistered (ClinicalTrials.gov identifier: NCT03855735) on February 27, 2019.

Recruitment and Procedures

Ethics Approval

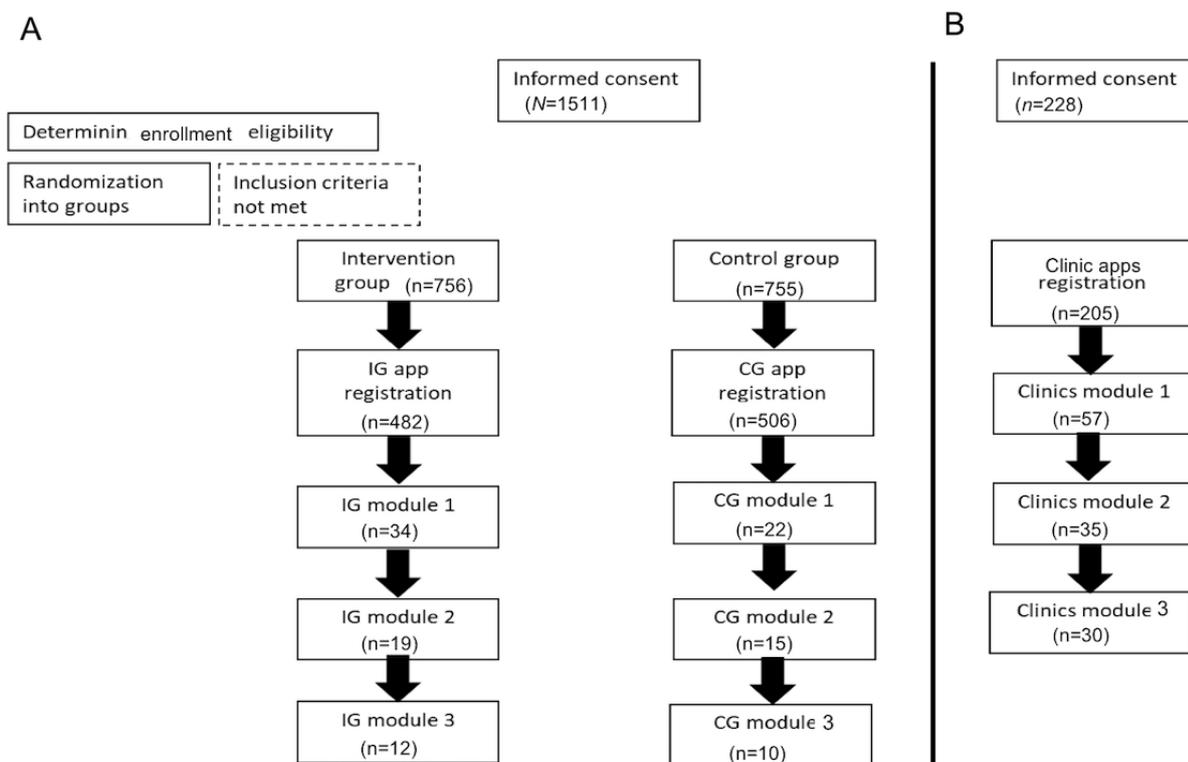

Ethics approval for data collection in the maternity clinics was granted by the ethics committee for human research of the University Hospital Ulm (114/19) and the ethics committee for medical research of the University Hospital Frankfurt am Main (19-292). Informed consent was provided in the registration

process, and all data were anonymized by providing users with a random ID that could not be linked to user emails or personal IDs. No compensation was provided for participation in this study.

Participants

Participants were recruited into this study, as outlined in Figure 1. Participants represented a pragmatic sample. Sample calculations were performed prior to data collection for an assumed dropout of 20%. We estimated that 176 or more individuals would be needed to recruit [9]. All recruited women were able to register to use the TeamBaby web-app if they were residing in Germany, either during the time of our study (if randomized into the intervention group) or 2 weeks later (if randomized into the waitlist-control arm), that is, pregnant women and their support persons.

Figure 1. Flowchart of the study participants. (A) Study participants using the app as intervention group versus being randomized to the control group and using the app only 2 weeks later. (B) Study flow for the clinic's intervention group. CG: control group; IG: intervention group.

Pregnant women were recruited through 1 of the 2 recruitment channels (Figure 1): (1) those who sought treatment during pregnancy in project-affiliated clinics or (2) those who were currently pregnant and based anywhere in Germany. With respect to the former group, project members worked together with obstetricians to recruit patients. The Germany-wide recruitment utilized social media and targeted advertising to promote this study. In addition, flyers were placed in health care clinics and pharmacies across the country. Women were eligible to participate if they were currently pregnant, had sufficient knowledge of German, and were at least 18 years old.

Participants were recruited into this study upon completing a web-based questionnaire. Women recruited in the clinics were invited to register with the web-app. Women from the

Germany-wide recruitment were randomized into either a treatment group or waitlist-control group. The treatment group was presented with a link to use the web-app directly. The waitlist-control arm was provided with a link to the web-app 2 weeks later. All users of the web-app were presented with a series of questions at regular timepoints to determine whether there were changes in HAPA variables and communication behavior as users progressed through the 3 modules of the web-app. Participants who completed less than 2 modules were considered as early dropouts.

Intervention Content

The TeamBaby web-app provided guidance on how to work effectively with health care workers. The web-app consisted of 10 lessons, wrapped in 3 modules, which were developed and

structured based on the processes of behavior change as set out by the HAPA model. The first set of lessons was designed to increase the outcome expectations of effective communication behavior and create an intention to adopt self-reported communication practices. The subsequent lessons were designed to increase the belief or trust in oneself to employ effective communication and enable users to make tangible plans for implementing self-reported communication behavior. More detailed information about the modules and the content can be found in [Multimedia Appendix 1](#).

Measures

Participants were asked to complete questions relating to communication behavior and HAPA variables at 4 timepoints: before starting the first module and after completing each subsequent module. The assessment of self-reported communication behavior was based on Rider and Keefer's competencies [14] and adapted to address pregnant women's behavior in previous publications [12]. As the aim of the research was to understand the underlying social-cognitive processes of communication, the items were developed to capture self-reported communication behavior. [Table 1](#) presents the items [14,58,59] used to evaluate each variable.

Table 1. Measured health action process approach and self-reported communication variables.

Variables	Item example	Range ^a
Communication behavior (7 items) [14]	During pregnancy, I always have communicated my needs clearly.	1-6
Outcome expectancy (single item) [58]	If I communicate well with doctors and midwives, my preferences can be considered during childbirth.	1-6
Intention (single item) [59]	I intend to always make sure that I communicate effectively with the doctors and midwives.	1-6
Self-efficacy (single item) [59]	I am sure I can communicate well even when I am tired or exhausted.	1-6
Action planning (single item) [58]	I have planned precisely how to communicate well while giving birth.	1-6

^aRange of 1-6 spans from "does not apply at all" to "does apply fully."

Sociodemographic Data

In addition to behavior change measures, demographic information was collected. Participants reported their age, marital status, highest level of education, and nationality.

Aggregated Variables

Participant communication scores were combined into a single item for each individual by taking the average across the different communication behaviors. This was expressed as overall communication. The implicit assumption here is that more effective communication within the described obstetric setting should facilitate a safer birth.

Statistical Analysis

All analyses were conducted using the R [60] and RStudio [61] software. Significance was determined at the 5% level. The aim was to determine what variables would predict early dropout from the web-app. Early dropout was expressed as a binary variable: participants were marked as dropping out early if less than 2 modules were completed. For example, participants who completed 2 or 3 modules were marked as 0 (ie, not dropped out early), while participants who completed only 1 module or none were marked as 1 (ie, dropped out early).

To investigate hypothesis 1, a general logistic regression model using the glm function was built to identify whether HAPA variables, age, marital status, education, and recruitment channel predicted dropout. Recruitment channel was a categorical variable that reflected entry into the app. Participants entered the app either directly through clinical recruitment or in the Germany-wide recruitment after randomization into the intervention group or after the waiting time when being randomized into the waitlist control arm. In the logistic regression model, the clinical recruitment group was the reference group to which the other recruitment channels were compared to.

A hierarchical regression was performed to investigate hypothesis 2, using the "lm" function available in Base R; HAPA variables were sequentially added to build a final model that predicts post web-app communication. [Table 2](#) outlines how the predictor and outcome variables were operationalized in the model. Following the construction of a model to explain changes in post web-app communication, possible processes for behavior change were proposed. To investigate hypothesis 3, a structural equation model using the lavaan package [62] was built to identify how HAPA variables related to one another and in turn contributed to changes in post web-app communication.

Table 2. Overview of the operationalization of social-cognitive predictors and communication behavior.

Type	Variable	Operationalization	Example
Outcome	<ul style="list-style-type: none"> Post web-app communication, expressed as C_t 	Respondent's most recent overall communication score after having completed at least 1 module of the web-app. Only individuals who completed at least 1 module were included in the analyses to ensure the data captured those that used the web-app.	If an individual had communication scores after modules 1, 2, and 3, only the response after module 3 was used.
Predictor	<ul style="list-style-type: none"> Outcome expectancy at the preceding timepoint, expressed as OE_{t-1} Intention at the preceding timepoint, expressed as $Intention_{t-1}$ Self-efficacy at the preceding timepoint, expressed as SE_{t-1} Action planning at the preceding timepoint, expressed as AP_{t-1} 	A respondent's HAPA ^a variable score at the timepoint preceding the last available communication score	If an individual had a communication score after module 3, their HAPA variable scores after module 2 were used for the predictor variables.

^aHAPA: health action process approach.

[Multimedia Appendix 2](#) outlines the intercorrelation between all used social-cognitive HAPA determinants as well as self-reported communication behavior over the course of the app-based intervention. Since the abovementioned analysis includes as many timepoints as possible, all variables at the different timepoints were included.

Results

Study Participants

Overall, 1187 women were recruited into this study, of which 988 were from the Germany-wide recruitment ([Figure 1A](#)). Of

those in the Germany-wide sample, 506 were randomized into the waitlist control arm (control group app registration), and 482 were randomized into the intervention arm (intervention group app registration). In the clinics, 199 pregnant women were recruited (after the registration of 205 women with the app). The majority of the participants were aged 30-39 years ($n=881$), had a higher education status ($n=763$), and were married ($n=759$).

Descriptive Statistics

Sociodemographic data are depicted in detail in [Table 3](#) below.

Predicting Dropout

Of the 1187 pregnant women who were recruited and started using the web-app, 1124 dropped out of the intervention, as indicated by completion of less than 2 modules. A general logistic model was estimated to investigate hypothesis 1 and to determine whether social-cognitive HAPA variables and communication behavior as well as sociodemographic characteristics might predict early dropout (completing less than

2 modules). Thereby, the predictive capacity of 4 HAPA variables and behavior along with age, education, and marital status was tested: intention, outcome expectancy, self-efficacy, and action planning, as well as sex, education, and marital status. As [Table 4](#) highlights, only age was a significant predictor of early dropout. In other words, younger pregnant women were more likely to drop out from the digital intervention at an earlier stage. Accordingly, hypothesis 1 can be empirically supported.

Table 4. Parameter table of the generalized linear model predicting early dropout from health action process approach variables and sociodemographic characteristics.

Variable	Estimate (SE)	<i>t</i> test (<i>df</i>) ^a	<i>P</i> value
Outcome expectancy _{tt1} ^b	.005 (.164)	0.034 (418)	.97

Predictors of Self-Reported Communication Behavior

Hypothesis 2 tests whether socio-demographic variables and social-cognitive HAPA variables (self-efficacy, outcome expectancy, and action planning) would predict self-reported communication behavior in pregnant women over the course of the app-based intervention (see Table 5 for details). In the first series of models, each sociodemographic variable was added in a stepwise fashion to predict communication behavior. Adding age ($F_{1,93}=1.16$; $P=.28$), education ($F_{1,92}=0.12$; $P=.66$), and family status ($F_{1,91}=0.39$; $P=.54$) did not significantly improve the prediction of communication behavior scores. In the subsequent models, HAPA variables were added (Table 5),

and intention was added. Upon inclusion, most HAPA variables improved the model fit. For the motivational phase of the HAPA model, outcome expectancy ($F_{1,90}=4.88$; $P=.03$) and intention ($F_{1,98}=8.65$; $P=.004$) improved the model fit, while task self-efficacy ($F_{1,88}=2.11$; $P=.15$) did not improve the model fit. For the volitional phase, action planning ($F_{1,87}=17.74$; $P<.001$) improved the prediction of communication scores.

After including all the variables of HAPA along with sociodemographic variables into the model (for model comparisons, see Table 5), only action planning ($\beta=.331$; $P<.001$) significantly predicted communication behavior (Table 6 for further parameter estimates). Accordingly, hypothesis 2 could be partially empirically supported.

Table 5. Hierarchical regression model comparison of sociodemographic and social-cognitive health action process approach variables predicting communication behavior.

Model name	Comparison model	Predictors	<i>F</i> test (<i>df</i>)	<i>P</i> value
Age	Null	Age	2.165 (1, 92)	.15
Education status	Age	Age + education	0.045 (1, 91)	.83

Mediation Model

To test hypothesis 3 and thus whether distal HAPA variables (intention, outcome expectancies, self-efficacy) are mediated through planning, a path model was facilitated (Figure 2 and Table 7). Indeed, a sequential mediation emerged from self-efficacy to intention to action planning to self-reported communication behavior. This likewise entailed the indirect

mediation from intention via action planning to self-reported communication behavior. Conversely, no serial mediation was found from outcome expectancies to intention via action planning to self-reported communication behavior. Accordingly, hypothesis 3 could only be empirically supported regarding 2 of the 3 distal HAPA variables, namely, self-efficacy and intention.

Figure 2. Regression model of social-cognitive health action process approach variables and safe communication behavior across all groups. Taken together, communication behavior is significantly predicted by action planning, and action planning mediates the impact of self-efficacy and intention on self-reported communication behavior with $\beta=.017$ (comparative fit index=0.994; Tucker-Lewis index=0.971; root mean square error of approximation=0.055). AP: action planning; COM: safe communication behavior; INT: intention; SE: self-efficacy; t: reflects a relative timepoint.

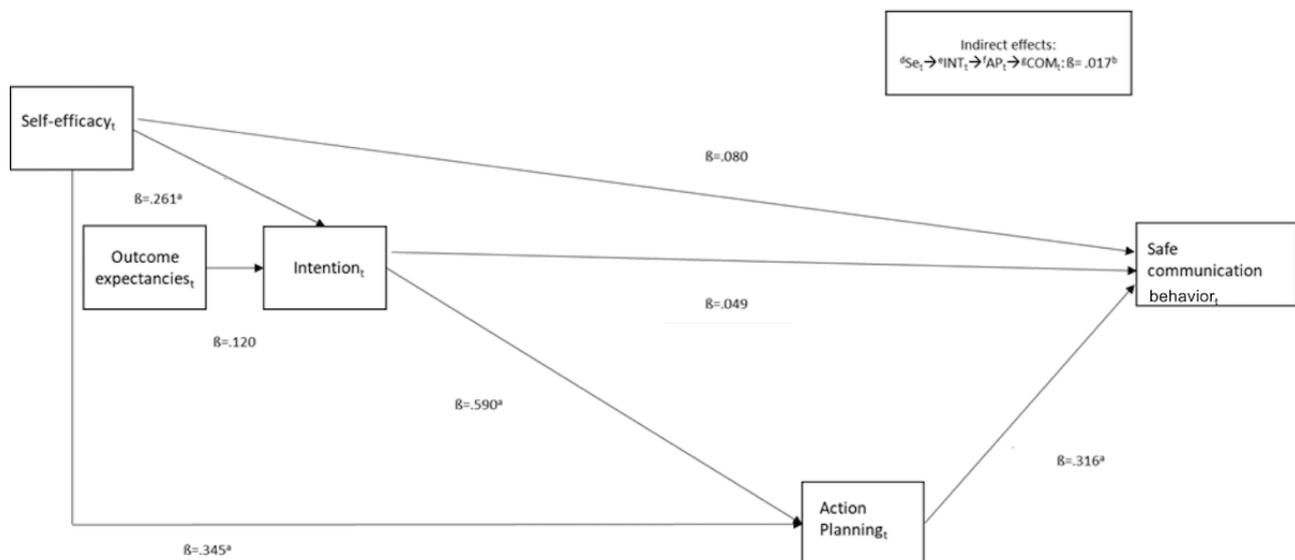

Table 7. Results of the path model depicted in Figure 2.

Predictor variable	Outcome variable	Estimate (95% CI)	SE	P value
Self-efficacy	Intention	.353 ^a (.152 to .555)	.103	.001
Outcome expectancy	Intention	.105 (-.108 to .318)	.109	.33
Intention	Action planning	.408 ^a (.242 to .574)	.085	<.001

Discussion

Principal Findings

In this study, we investigated the determinants of dropout from an app-based intervention for pregnant women and the mechanisms of adopting self-reported communication behavior. Regarding both aspects, variables from HAPA were measured and evaluated with respect to their predictive capability. Consistent with hypothesis 1, dropout analyses found that only age was predictive, and none of the HAPA variables played a role. Communication behavior was only predicted significantly by one of the HAPA variables, namely, action planning. A serial mediation emerged from intention to self-reported communication behavior via action planning. In detail, communication behavior was significantly predicted by action planning, and action planning mediated the impact of self-efficacy and intention on self-reported communication behavior. These findings match previous findings that identified age as a predictor of dropout from digital interventions [41,42]. However, in contrast to the aforementioned studies, no other sociodemographic predictors emerged. Moreover, this study deviates from previous dropout investigations, as no HAPA variables predicted early dropout. This might be a result of differences in the target group or context of the digital tool between studies; predictors of dropout from digital interventions might depend on aspects of specific intervention types and could vary based on the timepoint of dropout, as revealed in a previous research [63]. Regarding the latter, it should be noted that our study only investigated early dropout.

With respect to mechanisms of adopting self-reported communication behavior, the results were in line with hypotheses 2 and 3: the data demonstrated that HAPA variables predicted the self-reported communication behavior. Whether this is a result of the behavior change context (ie, the app) still needs to be determined. However, the findings are in line with previous evidence that HAPA assumptions match the data and accordingly are able to explain the changes in self-reported communication behavior [8,10].

Our findings of early dropout from the app-based intervention are partially in line with those of other studies, in which younger participants were more likely to drop out from digital interventions [42,64-66]. The relationship between age and

dropout could be a result of higher perceived need among older women, that is, older women, through more life experiences and previous pregnancies, may realize a greater need for communication interventions and in turn adhere to the app.

Behavior change variables did not predict dropout from the app-based intervention. This is in contrast to the results of previous studies that have shown that behavior change variables are associated with dropout [63]. Among others, this study shows outcome expectancies as a crucial predictor of retention in digital interventions and likewise concludes that the perception of unmet needs and expectations might be a determinant of dropout [63]. In the context of self-reported communication behavior, expectant mothers' outcome expectancies focused on safe child delivery instead of self-reported communication behavior and the accommodation of individual preferences as the item wording suggests. An alternative explanation would be that the relationship between behavior change variables and dropout is context-specific, as a previous study implicates [63]. In any case, our study shows the determinants of dropout from an app-based intervention. This is an important insight for patient safety interventions in obstetrics because it can be used by future tools to prevent early dropout and maximize the amount of support that pregnant women receive. However, future research should further investigate the contextual variability of predictors of early dropout in digital intervention studies. This is particularly important because app-based interventions generally show high dropout rates [67-70].

Previous studies [8,11] have shown that social-cognitive variables are associated with pregnant women's safe communication behavior in general. Our study demonstrates that some of these associations also drive change in self-reported communication behavior during a digital intervention. This is of importance for theoretical understanding and practitioners; it shows how apps might elicit and affect changes in self-reported communication behavior, highlighting pathways which future interventions can focus on and improve its effectiveness. This might be useful for designing future apps in the specific field of pregnancy and giving birth.

It is striking that not all associations in HAPA emerged as theorized. First, it became apparent that action planning was the single best predictor of change in self-reported communication behavior. Although the predictive capacity of

action planning is expected from its association with behavior within the HAPA model, it was not hypothesized that action planning would emerge as the sole predictor of behavior change. The reason could be pregnant women participating in the app were taught to think of how and when they might communicate effectively, that is, making concrete action plans, which worked well in the app, while other variables were not addressed as effectively. In addition, action planning was targeted in the last lesson of the app, which might have resulted in stronger effects due to a shorter time lag and recency effect.

Relating to the process by which pregnant women improve their communication behavior in clinical care, it is likewise striking why only 2 of the indirect effects specified in the HAPA framework emerged. First, there was an indirect effect of self-efficacy on self-reported communication behavior via intention and subsequently via action planning. Second, self-efficacy also directly impacted action planning and thereby indirectly impacted self-reported communication behavior. Notably, the same predictive capacity in explaining self-reported communication behavior in this study replicated findings from a cross-sectional research [8,11]. Indeed, the HAPA model seems to be applicable for predicting several kinds of behavior change in digitally supported interventions like the app used in this study and has shown similar findings overall [71-73].

In a previous randomized trial in patients with insomnia, both action planning and coping planning in the HAPA model were shown to be effective mediators in improving sleep hygiene [71]. In another randomized trial testing a digital tool to promote active lifestyles in patients with type 2 diabetes, the intervention group showed a significant intervention effect for action planning, whereas the control group exhibited a significant effect for coping planning and self-efficacy [72]. Lastly, in an earlier study primarily focusing on reducing salt intake to prevent high blood pressure, both intention and outcome expectancies as well as risk perception were found to be improved by the digital intervention [73].

In the future, digital and nondigital face-to-face interventions should be compared, especially when aiming to improve self-reported communication behavior in obstetrics and preventing dropout [10]. Different app modes showed various degrees of effectiveness in a study on depression [74]. A meta-analytic review [74] showed that apps in combination with personal contact with a therapist are more effective than self-help apps. However, no differences were found between smartphone-based apps and computer- and internet-based interventions. Similarly, there seems to be no difference between human-guided digital interventions and face-to-face psychotherapy [74]. In other areas of research, gamifications in apps have proven to be beneficial [68]. Among other findings, feedback, leaderboards (participants can compare their own progress with that of others), and storytelling (context within the app to create an alternate reality and guide the user) have been shown to be advantageous for digital interventions [68-70]. Those findings provide some guidance for future teams aiming at developing apps and internet interventions in this field.

Findings from this body of research set the stage for iterating on existing apps in clinical care and for developing new apps.

However, it seems questionable, what kind of intervention might be sufficient or helpful for those participants at risk for dropping out. On the one hand, flexible digital tools, which allow an automatic dynamic change of modules and learning intensity, might be helpful. On the other hand, an overload of information or special attention to these participants might make them even more prone to drop out. To conclude, future research should further uncover the reasons for dropout of such participants, so that optimal strategies for prevention can be devised.

Given that younger patients are at increased risk of discontinuing the digital intervention at an early stage, it is crucial to make the underlying behavior visible and targetable. We made the first attempt to explain this phenomenon. In the literature, the possibility of using behavior change theories to predict dropout behavior has been demonstrated [63]. Future research should be conducted using different intervention modes as well as different digital incentives (eg, optimal level of gamification, possibility to exchange with other users vs personal contact with midwives, doctors, or other birthing professionals, or more intensive self-help vs person-guided self-help).

Limitations and Suggestions for Future Research

This study, as a formative research and with preliminary results, has certain limitations with regard to the conclusions drawn from the results. First, there is a possibility that confounding external factors could have been at play during the course of the internet intervention, such as physiological or mental health risk factors. Second, bias and self-selection might have confounded the web-app data in the sense that only certain women volunteered to participate and continue the app-based intervention. Future internet intervention studies should try to recruit a more diverse sample and find concrete reasons for them completing the app or dropping out. It seems possible that both flexible feasibility questions in the context of the app as well as effectiveness ratings and satisfaction ratings could provide more information about usage behavior.

For the time frame between intervention start and the last timepoint, we have conducted a test of factors predicting dropout, from which we concluded that only younger age at intervention start predicted early dropout. However, factors associated with the selection to participate in the intervention could not be uncovered in our presented design. Future research should target a wider age range of pregnant women to gain further insight between age groups and dropout via subgroup analyses. With a larger sample, it also seems possible to examine the age categories and dropout behavior in more detail.

As mentioned previously, our data do not allow conclusions regarding the motivations of dropout and study retainment—a topic that future studies should investigate further. Relatedly, it would have been important to have more finely spaced time intervals for measurement points, which could add valuable information on the interplay of the processes underlying behavioral change and the topics of the particular lessons that were covered. Additionally, it should be acknowledged that the scales used to measure the social-cognitive variables of HAPA were not previously validated in German language based on evaluating the communication behavior. Hence, the

measurement qualities of the scales in the German population might be limited.

The main contribution of this study can be seen in that it is the first attempt of employing a digitally enhanced internet intervention aiming at fostering self-reported communication behavior within a clinical sample in the context of obstetric care. This has innovation potential, as it shows that technology in terms of a digital intervention, that is, apps aiming at improving communication behavior can make a difference. Therefore, this study sheds light on the mechanisms underlying self-reported communication behavior and its improvement while also investigating the potential predictors of dropout in an app-based intervention. This contribution yields both practical

and theoretical implications. On a theoretical note, our study contributes to a deeper understanding of the genesis of self-reported communication behavior, thereby highlighting various points of the psychological processes that future interventions could address, such as action planning and self-efficacy. Likewise, practical implications arise as our study presents an initial framework for improving effective communication via the app in a clinical sample and explores how to maximize its effectiveness by retaining participants at risk of early dropout. The variables of the HAPA model can function as a toolkit, with a particular focus on action planning, self-efficacy beliefs, intention to communicate effectively, and app users' age.

Acknowledgments

We thank Katharina Schiffer for proofreading the manuscript regarding referencing style and language. We are thankful and appreciative of the help from Dr Marina Schmiedhofer, Christina Derksen (PhD), Prof Dr Frank Louwen, Prof Dr Frank Reister, Johanna Dietl, Freya Häußler, and Sandra Riedmüller in the data collection. This study was funded by the German Innovation Fund (project 01VSF18023) of the Federal Joint Committee (Gemeinsamer Bundesausschuss) as part of a third-party project funding.

Data Availability

The data that support the findings of this study are available on request from the corresponding author SL. The data are not allowed to be made publicly available due to privacy and data security reasons of the research participants.

Authors' Contributions

LK, VA-K, and SL were involved in data collection and monitoring as well as in the conceptual aspects of this study. LK analyzed and described the data statistically and wrote all parts of this paper. SL advised on the methodology and structure. FMK, VA-K, and NTH gave advice on the rationale and structure of this paper. All coauthors approved the final version and contributed to the preparation as well as revision of the final paper.

Abstract

Background: As consent for data sharing evolves with the digital age, plain-text consent is not the only format in which information can be presented. However, designing a good consent form is highly challenging. The addition of graphics, video, and other mediums to use can vary widely in effectiveness; and improper use can be detrimental to users.

Objective: This study aims to explore the expectations and experiences of adults toward consent given in infographic, video, text, newsletter, and comic forms in a health data sharing scenario to better understand the appropriateness of different mediums and identify elements of each medium that most affect engagement with the content.

Methods: We designed mock consent forms in infographic, video, text, newsletter, and comic versions. Semistructured interviews were conducted with adults who were interviewed about their expectations for consent and were then shown each consent medium and asked about engaging elements across mediums, preferences for consent mediums, and the value of document quality criteria. We transcribed and qualitatively co-coded to identify themes and perform analyses.

Results: We interviewed 24 users and identified different thematic archetypes based on participant goals, such as the Trust Seeker, who considered their own understanding and trust in organizations when making decisions. The infographic was ranked first for enhancing understanding, prioritizing information, and maintaining the proper audience fit for serious consent in health data sharing scenarios. In addition, specific elements such as structure, step-by-step organization, and readability were preferred engaging elements.

Conclusions: We identified archetypes to better understand user needs and elements that can be targeted to enhance user engagement with consent forms; this can help inform the design of more effective consent in the future. Overall, preferences for mediums are highly contextual, and more research should be done.

consent; transparency; data governance; visualization; health data sharing

Introduction

Overview

Consent is a cornerstone of ethical research, allowing people to be informed about the risks and benefits of research and

demonstrate their autonomy. Consent has been discussed since the Nuremberg trials and takes on a pivotal role throughout European Union (EU) regulations for data protection, such as the General Data Protection Regulation (GDPR), but there are still challenges as bioethical consent and data protection consent

collide. Digital decision-making about one's own data can be influenced or misled through interface design choices (ie, through so-called dark patterns [1-8]), while the consent experience of most European users corresponds to nagging cookie consent requests with profiling and advertisements that induce consent fatigue while trying to access a needed service [8]. Decades of research in the biomedical domain show that study participants' consent can rarely be deemed actually informed [9], often due to the complexity of language [10] and lack of health literacy [11], as well as the lack of data literacy of the individuals [12].

Engaging individuals in a user-friendly consent experience is thus fundamental to enabling them to meaningfully and freely make decisions with a sense of satisfaction [10] and agency. Improving the readability and comprehensibility of consent notices is one aspect of this, but research is also being done to explore visual communication techniques. Current research often focuses on the effect of multimedia on understanding [11,12], which can have a varied effect based on different studies. Multimedia also spans many formats, and most studies reviewed for their effect on understanding compared 2-3 different formats [12]. The Article 29 Working Party also refers to visual design means, such as "cartoons, infographics, flowcharts," to enhance the comprehensibility of information, and specifically to "comics/cartoons, pictograms, animations" [13]. However, they do not offer further guidance about what mediums to use and for what purpose (eg, how one might prioritize skimming, while another might be better for complex information). Therefore, we experimented with 5 different mediums of consent in this study, building on studies researching the use of a comic [14,15], video [16], infographic, and illustrated text [17], with plain text as a control [18].

In this paper, we substantially built on our previous work [19] by analyzing more mediums beyond the comic and infographic and specific engaging elements. The study presented a fictional scenario with a data trustee who would assist organizations (eg, research institutions, hospitals, etc) in finding suitable participants for clinical trials in a privacy-friendly manner. Participants were given a scenario where they were individuals who may benefit from a clinical trial organized by a hospital, so the data intermediary requested their consent to share their contact information with the hospital.

The objective of this study was to better profile user expectations and their attitudes toward different consent mediums, which included infographic, video, text, newsletter, and comic versions. We specifically analyzed how different elements of consent mediums (eg, narrative, color, and audio) affected participant engagement to survey the different affordances of each medium. Each medium has its own strengths and weaknesses in representing various kinds of information and can achieve various informational goals (eg, the video is low effort but can be skimmed, while the text can be skimmed but boring) [20]. As we intended to understand whether there are benefits to using one medium over another and why participants would prefer different mediums, we compared multiple mediums in this study based on semistructured interviews and dived into participant motivations, expectations, and experiences.

The results hinted at diverse goals among participants. We also identified the elements of document design that make the information concise, structured, and appropriate for the audience. We also found a large influence of context (eg, cookie consent or consent with different trusted institutions) on participant perceptions and expectations. Thus, we offer recommendations on how to better design consent documents to address different general participant profiles using layering and to engage the audience more effectively with a suitable medium. This has a pivotal role in the digital health data sharing space to give more effective transparency to participants who are deciding whether to share sensitive data. Our results can be leveraged by designers of digital consent experiences for more efficient multimedia use.

Background

Consent and Transparency

The European data strategy [21,22] aims to create a single market for data to allow for the free flow of data to benefit businesses, research, and public administrations within the EU. It is built on the GDPR, which aims to give users more control over their personal data.

Informed consent (IC) is a legal requirement specified in the GDPR as "freely given, specific, informed and unambiguous" (article 4(11)); easily withdrawn (article 7(3)); presented in an intelligible and easily accessible form using clear and plain language (article 7(2)); explicitly given for biomedical and genome data categorized as sensitive data (article 9); transparent in terms of completeness, comprehensibility, and accessibility of the information disclosures (articles 12, 13, and 14); and compliant with the principles of data protection by design and by default (article 25) [23]. IC requires user-centric design elements in consent to help achieve the general principle of transparency, which encompasses the "quality, accessibility, and comprehensibility of the information" [14]. The GDPR also contains obligations for "transparency by design" wherein privacy and consent notices should be purposefully designed to adequately inform the intended audience [24]. In addition, the GDPR also refers to other visual design methods like comics, videos, and infographics.

However, most existing informed decision-making solutions fail to reconcile theoretical demands with actual transparency. Conventional data privacy communication is characterized by lengthy, off-putting walls of complex jargon that impact the readability, comprehensibility, navigability, and memorability of information [20]. In addition, it is often standard, vague, or boilerplate instead of customized to the different needs and abilities of the intended audiences [25] and the type of data and processing activity. Reaching beyond plain language, in the last few years, there has been a renewed attention (and quite some experimentation) toward legal document design criteria [26] that more holistically relate to the language, writer-reader relationship, information design, and content.

Profiling User Needs Using Archetypes

Human-computer interaction research has used the persona technique (wherein imaginary users are assigned different profiles or personas with different goals and personalities based

on demographic data) to better understand different users and needs and design suitable solutions [27]. However, it is a lengthy process that is often used for designing IT systems, not the consent processes. User need assessments have been conducted in relation to different demographics in health studies, but rather than focusing on the IC aspect, they focus on the health symptoms and how to address specific health-related needs [18,28,29]. Beyond health-related needs, we are interested more broadly in how the general adult population would interact with consent process to share information for downstream health reasons and what elements would be engaging when making informed decisions. This aspect has not been studied, to the best of our knowledge, but would be important for understanding how to strategically create effective information disclosures. Thus, we wanted to create archetypes, which capture general profiles, instead of personas, which are representations of imaginary individuals with specific population characteristics.

Multimedia Tools and Engagement With Digital Consent

The digitalization of data collection and use authorization allows for multimedia tools to be used during the consent process, which can have a positive outcome for participants. Overall, a systematic review of multimedia consent with videos, interactive programs, so on for surgical procedures found increased patient satisfaction for usability and informational availability [30]. However, for clinical trial consent, videos did not improve understanding [31]. Diving into the reasons that multimedia consent may be preferred to conventional text, one study compared animated videos, slideshows with voice-overs, comics, and text consent for medical practices and found that a dual-channel approach combining audio with visuals helped participant understanding [31]. This study supported older research showing that repetition of information using different multimedia means increases retention [32]. However, the specific elements of videos, comics, and text that contributed to effective communication in more general health consent were not studied—a gap that we intend to bridge with our work.

Textbox 1. Research questions.

1. What kind of goal-oriented archetypes can be created to better understand participant needs for consent?
2. Across the 5 analyzed mediums (ie, infographic, video, text, newsletter, and comic forms), what were the participant rankings of different engaging elements?
3. After exposure to the consent mediums, we asked the following questions:
 - a. What were the participants' rankings of consent mediums?
 - b. What elements reportedly influence their preference for mediums?
 - c. What document quality criteria concerning language, design, content, and relationship with the reader did participants value?

Methods

Overview

AS carried out 24 semistructured interviews in September 2021 in Germany (Figure 1). We created an interview guideline

Even in other domains, studies strive to understand how to achieve effective communication of complex information by analyzing participant engagement, understanding, and recall of the information [33]. In the study by Wang et al [33], engagement refers to the time spent and fun experienced reading a form; and infographics, illustrated text, and data comics of complex economic data were tested. They found that students from different countries (aged from 18 to 35 years) preferred data comics, as they enable the greatest understanding, engagement, and enjoyment of all mediums, while the infographic performed best in esthetics and exploration, and the illustrated text performed the worst. As similar studies had not been performed on consent forms in a health scenario, we sought to study engagement as a factor of effective communication, as it might help understand what gains and retains attention within a complex digital attention economy.

Traditionally, engagement studies in biomedical consent refer to patient engagement with the research or biomedical process. Such engagement refers to participants interacting with the results of a study, updating information, or changing consent [34-36]. However, we are interested in participant motivations to consume the information in a consent form and give their initial and continued attention to a conventionally tedious process while competing in an attention economy [37,38]. Can consent forms be interesting and attention-grabbing?

Research Questions

The previous section has gathered evidence about the interplay between GDPR transparency requirements in data protection, the use of archetypes, and multimedia tools to enhance the experience. However, we lack an understanding of user needs, the impacts of different mediums on the user experience, and user engagement. The research questions that this study sought to answer are shown in [Textbox 1](#).

([Multimedia Appendix 1](#)), which was validated with 3 potential participants to ensure clarity, comprehensibility, and precision of the questions.

Figure 1. A time line of key activities and elaboration of results.

Recruitment

We searched for 24 participants by word of mouth. The demographic included adults from a cross-section of the German adult population by age, sex, and education level (Table 1).

Table 1. Participant demographics (N=24).

Characteristics	Participants, n (%)
Age range (y)	
18-30	8 (33)
31-55	8 (33)
56-90	8 (33)
Sex	
Male	12 (50)
Female	12 (50)
Highest degree	
School leaving or apprenticeship	12 (50)
College or university	12 (50)

The sample size and participant characteristics were based on a systemic review of unbiased citizens’ juries for health policies [39]. Within the age ranges, there was an equal distribution of men and women with the highest degree obtained. All participants were native German speakers and lived in Germany, and the interviews took an average of 60 to 75 minutes.

Study Material

AS created an example plain text document that asked for consent for the transfer of personal data from an intermediation service to another organization, a hospital. On the basis of the plain text, XD designed 4 additional variations in different mediums: an infographic, a comic, a newsletter, and a video. These 4 variations only included the subsection “What happens if you agree?” of the consent form. All 5 consent forms (ie, plain text, infographic, comic, newsletter, and video forms) differed in design, but the core consent text was the same across all mediums. XD followed best practices for information transparency, designed documents for each medium with different subsets of engaging elements, and adapted them for the mediums (ie, additional ellipses between comic text) for the

purposes of the study, consulting coauthors during design. (a) The video (Multimedia Appendix 2) was created to test the use of color, audio, and animations and illustrate the text using free resources on Biteable website (eg, “a doctor will call you” conveyed as an animation of a waving physician). The audio was provided by AS (a native German speaker) out of convenience. (b) The infographic (Figure 2) was designed with a step-by-step format and color from a health template on Canva (Canva Pty Ltd), with icons describing the text (eg, scheduling an appointment had a calendar icon; Multimedia Appendix 3). (c) The comic (Figure 3) used a story element and color and was designed in Figma with input from all authors, and it used simple figures to expedite the creation of the comics. The drawings sought to describe the text as literally as possible (eg, “you will be contacted” depicts a ringing phone; Multimedia Appendix 4). (d) The newsletter (Figure 4) used open format and color and was created in Figma (Figma, Inc; a popular website for user interface or user experience design) based on an existing newsletter template’s structure. The newsletter was thought to be a more familiar medium with more graphics than text (eg, newsletters sent via email; Multimedia Appendix 5).

Figure 2. A translated section of the infographic study material designed with a step-by-step format, color, and structured sections.

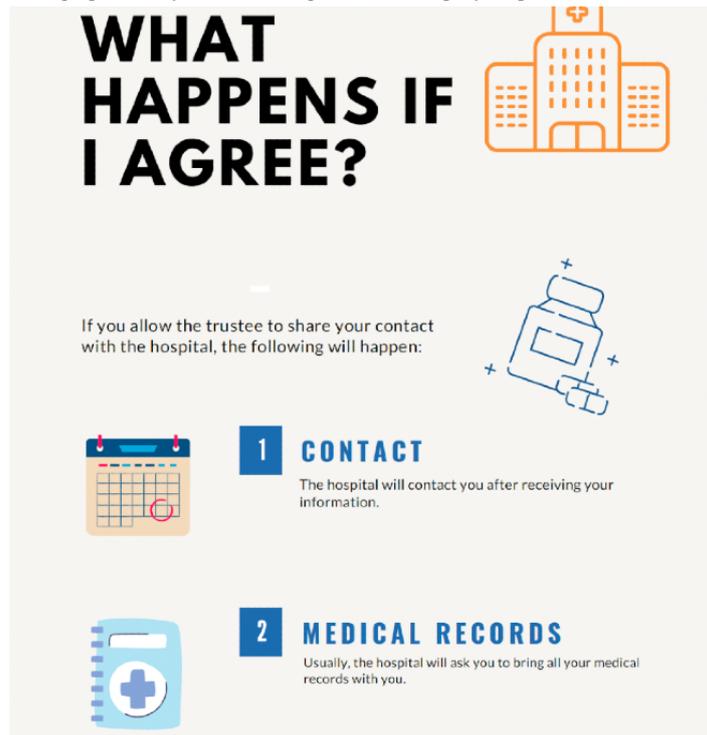

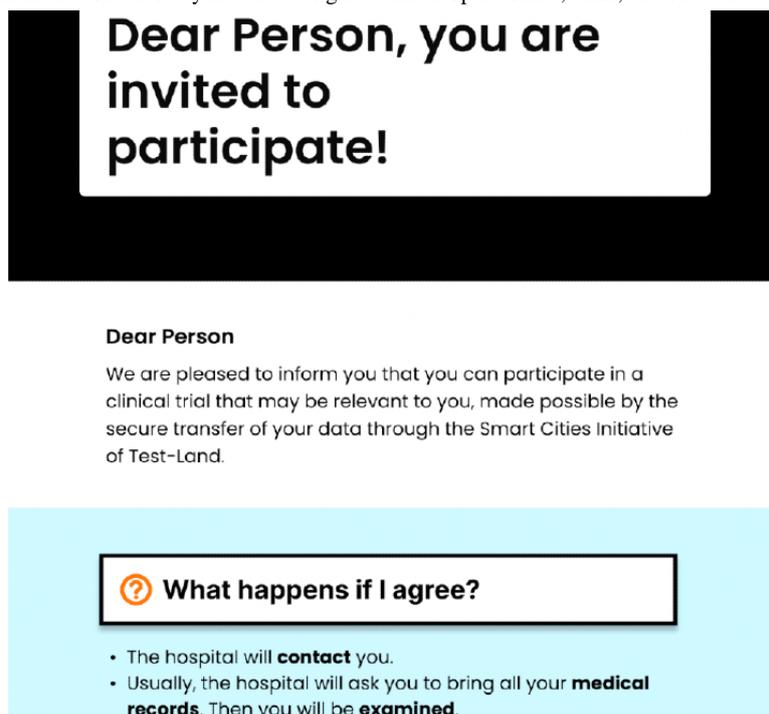

Figure 3. A translated section of the comic study material designed with a story and color.

Figure 4. A translated section of the newsletter study material designed with an open format, color, and structured sections.

Study Design

All interviews took place via a web conferencing system. No recordings were taken, and a summary transcription was written after each question and finalized after each interview. This method was chosen to respect participant anonymity and COVID-19 protocols.

The interviewer invited participants to imagine that they were contacted by a data intermediary to obtain their consent to share their name, email, and allergy information with a hospital that wanted to carry out a clinical trial for lactose allergies. A verbal explanation was given along with the full plain text version of the consent form, and participants could ask questions at any time.

To answer RQ1, participants were asked about their previous experience with consent forms and desires regarding consent.

To address RQ2, after participants were shown all mediums of consent, they were asked to rank 8 design elements of a consent form: the use of colors, audio, animated elements, readability of text (eg, if it is not too technical or complicated), story element (eg, using examples and people in the forms), structured sections, step-by-step elements (eg, having an order to the information with text or visuals), and an open format (eg, being able to skip around to sections) from the most to the least engaging with an option for “other.”

To answer RQ3, we showed them a subsection of the full consent form, “What happens if I agree?” in different mediums (ie, comic, infographic, plain text, newsletter, and video versions) in a random order per participant. Participants were asked to rank the different forms according to their preferences and clarify why.

Data Analysis

The interviews were documented in German, and anonymized answers were translated into English via DeepL (DeepL SE) and proofread by AS to ensure the translations’ adherence to the original meaning and to collaboratively analyze them with XD, AR, and MB (all non-German). Translation verification continued throughout the qualitative coding process in various sessions from November 2021 to April 2022 with the multidisciplinary team. To code the interview, the software MAXQDA (VERBI GmbH) was used. The expertise of the coding team spanned data protection law, usable privacy, bioethics, bioinformatics, and legal design.

To code the interviews, we inductively and iteratively established a codebook over three 2-hour sessions ([Multimedia Appendix 6](#)). The codebook combines a bottom-up approach through analysis of the data (eg, the concept of trust stemming from participant answers) with a top-down approach derived from the criteria for good documents given by Waller [26] ([Table 2](#)) to answer RQ3 (c).

Table 2. Document quality criteria elaborated by Waller [26].

Criteria	Description
Language	
Directness	Using direct language to make it clear who is acting
Plain words	The extent to which the vocabulary is easily understood
Grammar	Conformity with good standard English practices
Readability	Ease with which the reader can follow arguments
Design	
Legibility	Use of legible fonts and text layout
Graphic elements	Use of tables, bullet lists, graphs, charts, icons, etc
Structure	Quality of document organization for function
Impression	Attractiveness and approachability, overall appearance
Relationship	
Who from	Is it clear who is communicating?
Contact	Whether there are clear contacts or means of contact
Audience fit	Appropriateness to the knowledge and skills of users
Tone	Matching the style and language of the context
Content	
Relevance	How relevant is the content to the recipient?
Subject	If it is clear what the communication is about
Action	Clarity about what action is required of the user
Alignment	Compliance with the organization's intended aims and values

Participant consent expectations have been organized into archetypes depending on the salience of reported goals and relevant features. A matrix was created with the participant number, expected features, expected goals, and expected behaviors to help group similar profiles.

Ethical Considerations

The study design has been authorized by the Research Ethics Committee of the University of Luxembourg (ERP 21-038 LeAds), and best practices were followed. We chose a summary transcription to enable easier anonymization of the interview. Once manually anonymized, transcripts were securely shared

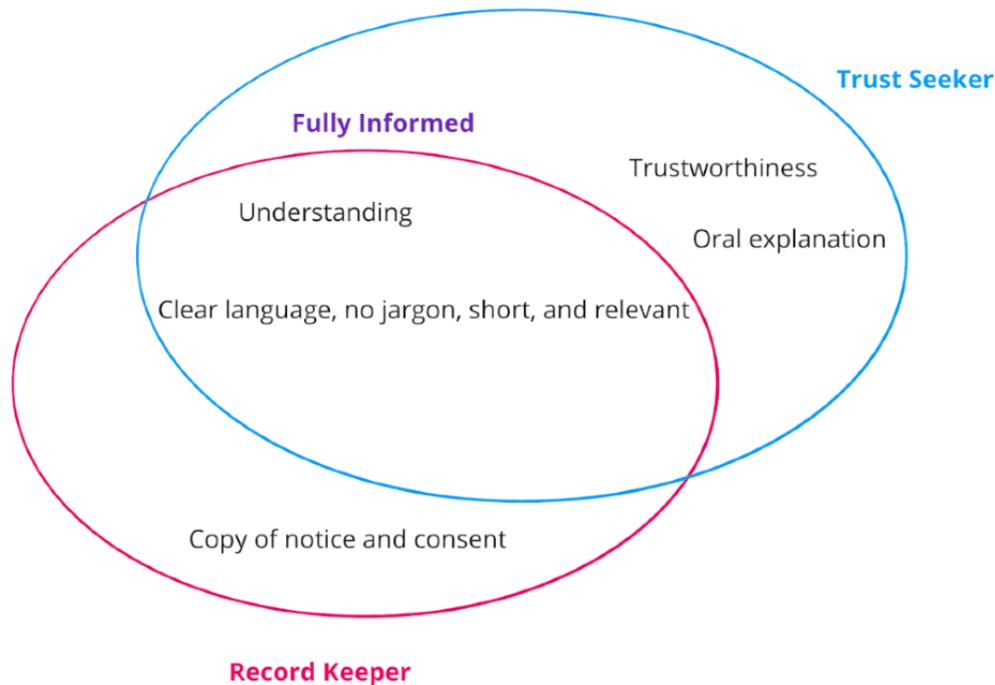

with the authors from the other organization. The interviewees were compensated €30 for their time.

Results

User Desires via Archetypes

The interview findings from the questions, which explore participant expectations, desires, and needs, have been organized into 3 goal-oriented archetypes: the Fully Informed, the Record Keeper, and the Trust Seeker. Not all participants reported specific goals, while some participants reported multiple goals. Thus, the archetypes are based on grouping similar features (Figure 5).

Figure 5. Venn diagram describing the core goals of different consent archetypes.

The Fully Informed archetype wanted relevant and fitting information to understand what they were consenting to. This aligns with the most common goal explicitly reported by participants (14/24, 58%):

[A]s an affected person, I would like to see a few examples to get a better understanding of what may be done with my data. [P1]

The information must also be appropriate for them as an audience:

A simple explanation that everyone understands would be my preference. [P12]

The Record Keeper sought understanding while specifically wanting to remember what they had agreed to (3/24, 13%) or to have a copy for their records (4/24, 17%). For example, participant 13 had a clear idea of the elements they wanted to understand and retain a clear memory of:

It needs to be clear to me what the consent is for, who it is from, and exactly what data is being processed for what purpose. [P13]

In addition, participant 4 stated the following:

It doesn't matter to me if it is paper or digital. The main thing is that I receive a copy of the text to which I have consented. [P4]

The Trust Seeker also sought understanding but was cautious toward the system or desired a trustworthy system (6/24, 25%):

I must have the impression that the data trustee is a reliable company or that there is an expertise that proves that I can trust this data trustee. [P3]

[I would rather avoid] to invest time and read through stuff...[and be able to trust] since I've already given my data...that my data will just be handled well. [P7]

When considered together, the archetypes lie on a spectrum where the Fully Informed archetype relies more on individual responsibility and capacity to make informed decisions, while the Trust Seeker also considers the context of organizational reputation and trust in making their decisions. In addition, the Record Keeper could be seen as an individual who wants to manage their consent decision over time, while those who do not want to review or revise their consent accept a one-time decision without records.

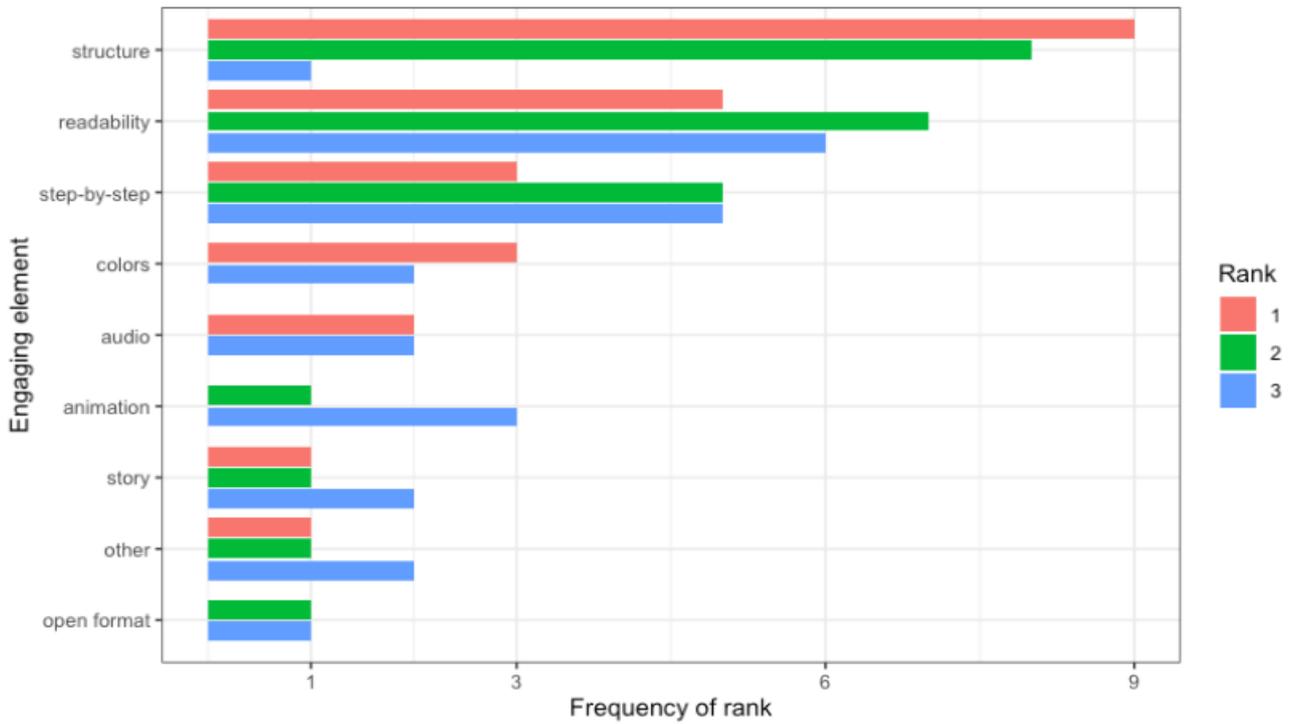

In addition to finding patterns based on common goals, some individuals stood out for their unique consent desires, including using more technical jargon (2/24, 8%). The use of jargon seemed to enable the process more time saving for some participants:

If I had to choose between short technical language and simple but longer language that is easy for everyone to understand, I would choose the short technical language. [P15]

Top Engaging Elements

To better understand RQ2, about how different elements across mediums were perceived by participants, they were asked to rank the listed elements after experiencing all mediums. The most frequent element ranked first was structure, followed by readability, colors, step-by-step elements (tied with "colors"), audio, story, and others (also tied with "story"; Figure 6). The top element at rank 2 was also structure, and the top element at rank 3 was readability. When the option "others" was chosen, not all participants elaborated on what "other" element they referred to, but when they did, personal engagement (4/24, 17%) was most commonly cited. In ranks 2 and 3, structure, readability, and step-by-step were also frequently cited engaging elements.

Figure 6. The frequency of each engaging element ranked from 1 to 3 by participants.

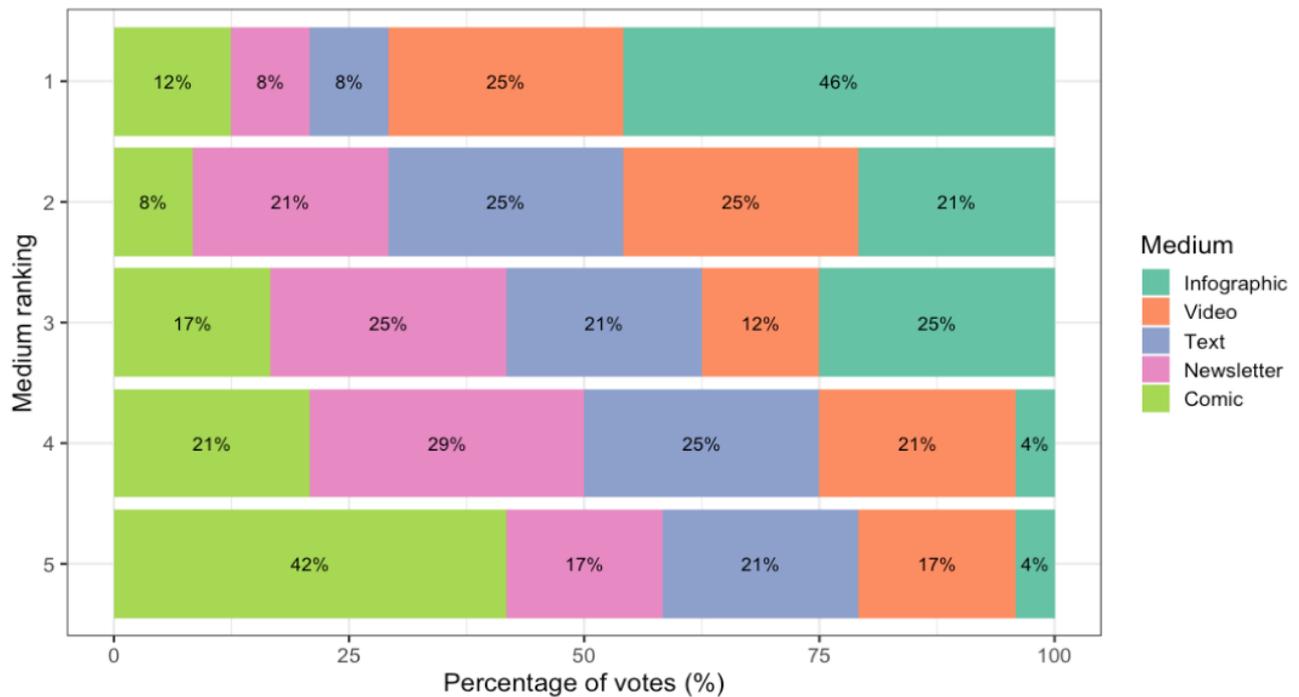

Preferred Mediums and Document Criteria

Overview

To answer RQ3, we report the results about participants’ ranking for their preferred consent form after being shown each medium

in Figure 7. The infographic was the overall winner and the comic the overall loser, while the video, text, and newsletter had varying trends (eg, the text was uniformly distributed across ranks 2 to 5, while the video was most often ranked 1, 2, or 4). Interestingly, no medium had consensus across the 24 participants.

Figure 7. Participant ranking of mediums (where 1 corresponds to the first choice and 5 to the last choice) by percentage of votes.

In the following sections, each medium is discussed based on (1) the top 3 factors that influenced the ranking and (2) the top 3 positive or negative document criteria adapted from good document criteria by Waller [26] (Table 1). A participant could

share multiple influencing factors or document criteria. We instead looked at the number of unique coded segments within their answer. Participants could share as few (though they were prompted to try to give at least 1) or as many factors as they

desired. The coded segments for influencing factors, such as the element of time, could be positive (time-saving) or negative (time-wasting). This was to help us identify the categories that were most important to participants. Then, we contextualize the

data and report whether important factors were positive or negative and their respective coded segments volume in the detailed section. Finally, Table 3 offers a summary of rank, top influencing factors, and document criteria per medium.

Table 3. Overview of the top 3 influencing factors and document criteria per medium with overall participant ranking.

	Medium				
	Infographic (rank 1)	Video (rank 2)	Text (rank 3)	Newsletter (rank 4)	Comic (rank 5)
Influencing factors					
Positive element	Understanding, time, and interest	Understanding and effort	Understanding and time-saving	Prioritization and understanding	Understanding and interest
Negative element	N/A ^a	N/A	Boring	Association with advertisements	Inappropriate fit for the context
Mixed	N/A	Time-saving and time-wasting	N/A	N/A	N/A
Document criteria					
Positive element	Numbered lists, icons, bold headings, and graphic elements	Audio, step-by-step elements, and interplay of text and graphics	Structured layout	Bolded key text, sections, and open format for skimming	Text and graphics
Negative element	Extraneous or leading icons	N/A	Lacked highlighting	Advertisement impression	Tone and audience fit

^aN/A: not applicable.

Infographic Medium

The infographic was strongly preferred, with one-third of the participants (15/49, 31%) citing understanding as a positive influencing factor, while time and interest were in a close second. Elements such as numbered bullet points, bold headings, and icons were referenced:

With the bullets, you know right away what each is about in the text written underneath. In general, this is easy to grasp... [P3]

The top 3 influencing factors were overall positive, in contrast to the other mediums.

Most positive document criteria concern design criteria such as step-by-step elements, icons, bold headings, bullet points, and color. There were much fewer negatively received elements, which were also related to the design criteria: the overuse of color and icons and the large size of the infographic. Participants had specific reactions to different icons, such as the hospital or medical professionals at the top and bottom that did not support any text or specific icons that might seem manipulative:

[W]ith the consent form, the “thumbs up” graphic makes it look like I’m being preempted from making a decision. [P14]

Video Medium

Approximately one-third of the participants (14/44, 32%) reported that it influenced their understanding, followed by time and effort. Understanding was largely positive, partially due to the format that they’re “forced to watch it from beginning to end, so that you perceive the whole content” (P15).

On the other hand, time was slightly more positive than negative because while most participants felt that compared to reading, the video saved time, some felt it was inefficient compared to their reading speed, or they wanted to review material but felt rewinding would be time-wasting. Saving effort was wholly positive, with participants saying that it was more accessible, entertaining, or less attention draining while still being understanding. One minor interesting influencing factor unique to the video was a perceived feeling of trust from the audio, with 2 participants mentioning that a human voice engendered confidence in the process.

More than half of the positive feedback about the video mentioned the audio element, followed by the sequential nature and use of animation and images. Less than one-fourth of the participants (12/54, 22%) liked the content, which included the interplay between text and graphics and the story element:

What I like about the video is that...you see movements that show what you hear at the same time via audio. [P3]

There were about half as many negative elements as positive ones, and most were due to the video pacing. Some wanted it faster, while others wanted it slower. Interestingly, 1 participant noted the following:

I have the feeling that with a video like this, people are rather uncritical of the content of the consent form. One is rather tempted to agree to something. If, for example, a button appeared after the video that allowed me to consent, I would probably consent. [P17]

Text Medium

Approximately one-third of the participants (12/42, 29%) indicated that interest and understanding were most influenced by the text. Interest was a complex influencing factor that was slightly more negative. Those stating that it negatively influenced attention felt that the text medium was boring or lacked interest compared to other mediums. The participants who viewed it positively said that the text had a simple, clean layout allowing for quick skimming, and those who felt it was neutral felt like participant 21:

This is the format that I know and have simply accepted by now. [P21]

The understanding was generally a positive influencing factor, with many saying that it was clear, concise, and short; however, some felt that it was difficult to skim or that the text was confusing or dry. Some participants also felt that it saved time by being short and concise.

The most cited positive document elements of the text were the use of clear sections, headlines, and bullet points. The positive elements were twice as common as the negative elements; the majority of both positive and negative elements also stemmed from design. Participants wanted more highlighting of key facts via colored, bold, italicized, or underlined words. Less than one-third of the participants (5/18, 28%) also cited the negative impression the document gave them:

[I]t is still a bit boring and trivial, so you might not read it properly if you get it as a letter home, for example. [P5]

Newsletter Medium

More than a quarter of participants (6/22, 27%) mentioned prioritization as an influencing factor, less than a quarter (5/22, 23%) mentioned understanding, and 18% (4/22) mentioned interest. Prioritization and understanding were positive influencing factors, with participants saying that the bold words and ability to skip sections allowed them to roughly understand the contents because the bold text highlighted the important information in sentences. However, the interest factor was equally mixed, with the positive influence surrounding the bolded text and headers, while the negative influence was mainly attributed to the association with advertising spam. More than half of the participants (13/24, 54%) agreed with participant 1, who stated the following:

It looks like advertising, by the structure and the "headline," which is repetitive. [P1]

Although it had positive influencing factors, the negative interest likely had a large impact on the lower ranking of this form, as participant 5 said the following:

[I]t looks like advertising and I don't like that.... I am rather annoyed by it. The bold as highlighting and the textual design I find good. [P5]

The newsletter's positive elements were largely regarding the design and use of structure, headings, bold text, sectioning, and the open format for skimming. The negative elements also similarly mentioned the design criteria because it looked like advertising based on prior experiences. The use of color was

also disliked because the black header was too strong and off-putting.

Comic Medium

The main influencing factor was understanding, with one-third of the participants (7/24, 29%) mentioning it both positively and negatively. A slight majority (4/7, 57%) cited a positive influence on understandability. Interest was generally a positive influencing factor because the medium was novel. Less than one-fourth of coded segments showed that the comic had an overall negative influence on skimming, as the narrative-driven step-by-step format made it difficult to prioritize, reread for specific elements, or gain a quick overview. In addition, many participants disliked the comic medium as a whole, even if they could find some helpful design elements:

I found the comic a bit inappropriate for the topic...the message is better visualized by the little pictures, which may be better remembered but I don't like it. [P20]

Almost half of the positive feedback for the comic stemmed from the support of text with graphics, narrative elements, and illustrations. A third felt that the tone and audience fit suited them. However, negative impressions were almost double the positive ones because audience fit and tone were unsatisfactory for more than half of the participants (14/24, 58%):

I'm out of the age where I still like comics.... I don't feel like I'm being taken seriously as a customer with a consent form like this. [P16]

Participants suggested that children or older adults might be a better audience fit. Other negative feedback arose from the impression and graphic elements concerning the execution of illustrations, legibility, and lack of structure.

Discussion

Principal Findings

Qualitative analysis of participant desires for health consent revealed 3 archetypes: the Fully Informed, the Record Keeper, and the Trust Seeker. All participants wanted a high level of understanding before the consent decision, with some valuing additional elements such as obtaining copies of their decisions for their records and the trustworthiness of institutions like hospitals. The participants greatly stressed the need for short, concise, and direct consent forms that should not be longer than a page. Our results support the results of other authors, who have found that participants want to skim consent forms because consent documents are all the same, they want to save time, or they trust the ethical review of the related study [40]. In other words, individuals often engage in a form of strategic reading [26] instead of relying on attentive reading. This is why consent should contain elements that allow the visual prioritization of certain content over others, like headings, bullet points, and highlights (ie, "surface-level cues") [26] that allow individuals to skim the document effectively and discern the most important information at first sight.

On the basis of the ranking of engaging elements, the participants preferred step-by-step documents (eg, linearly

numbered lists with clear headings) instead of open or story-based formats. Structure, readability, and step-by-step elements were the top 3 engaging elements and could be easily integrated into most mediums. While our study only designed the infographic using 4 of the top engaging elements (ie, structure, readability, color, and step-by-step element), other mediums like text could also use color and step-by-step elements instead of the open-format element. However, the tone and audience fit of mediums greatly influenced participant rankings, even if some mediums enhanced understanding or visual interest (eg, comics and newsletters). The negative connotations of the newsletter with marketing and comics with childishness contributed to their low rankings, while text was seen as routine and acceptable, if boring. Instead of prioritizing one medium over another, there could be a greater focus on including the most important engaging elements within mediums (eg, adding step-by-step elements in all possible mediums).

Implications for Practice

First, the creation of data-informed archetypes can be used for better understanding, and therefore accommodating, the diverse needs of a population. To leverage information describing the use of one's own personal data as a self-determination instrument, individuals can receive contextualized information and concrete examples that are relevant to their specific needs (eg, the Fully Informed and Trust Seeker archetypes), rather than one-size-fits-all terms. Archetypes also support general audience tailoring for different goals. Different approaches to consent notices may reflect strategies to cope with the 2-fold reality stemming from the fact that the risks of consent decisions are individual, while the data sharing and processing are networked across the individual, responsible institutions, and beyond [41]. For example, the Fully Informed archetype may be more concerned with individual responsibility and the personal data processing, while the Trust Seeker wants information about the organizations involved and their security and privacy measures. Using archetypes to base user profiles could also be a way to customize their experience in meaningful macrocategories without needing to customize every possibility for individual preferences. However, more research is needed to balance the actual benefit of tailoring information to different learning styles [42] against the increased costs of its creation and implementation.

Second, different mediums can be targeted based on needed affordances (Table 3) and layered to reinforce the understanding of complex information, for example, through a multifold presentation of the same content through text, video, and infographics. Official guidance about transparency requirements' implementation [15] portrays layering techniques as an appropriate means to achieve the requirement of full disclosure while allowing for prioritization and brevity. For example, summaries containing an overview of the main clauses can accompany the more comprehensive version and can be more easily browsed while consenting, with short videos and privacy icons constituting the first layer of a written notice [20]. Distributing information on separate mediums can additionally contribute to presenting the relevant information at an appropriate time. For instance, the first layer with essential information can be displayed at the moment of the consent

decision, while detailed information can always remain accessible on request [43]. However, as more guidelines for multimedia consent design arise [14,20], testing and co-designing with the intended audience is key; otherwise, a medium with a negative audience fit for certain contexts may be less effective than plain text consent (eg, the unsuitable comic medium for German adults). This can be important to test for among the intended audience, especially as comics have been a case study for cultural stigmas [44]. While they have been suitable for Indigenous populations [15], some researchers are pushing for more serious comics (similar to serious games for education) [45] and the comic co-design process itself as a research practice [46].

In terms of implementation, layering has been integrated with dynamic consent platforms. Dynamic consent was built to leverage the benefits of digital communication for health research by using digital platforms to connect people and researchers and allow participants to view, update, and change their data sharing permissions dynamically. Australia's CTRL [36], a dynamic consent platform based on open-source code, incorporates multimedia (video, illustrated text, and infographics); personalization options; and informational layering techniques. Building upon this, the layering could incorporate archetypes of general profiles to be tailored for different goals. Users of different ages may prefer different mediums, such as comics for younger audiences and videos for older audiences; similarly, users with domain expertise could choose content explained with jargon.

Finally, although we did not explicitly ask about undue influence of design elements on consent decisions and trust implications, participants clearly connected the 2, and more research is needed to better understand the deep connection. The infographic had a few complaints about specific graphics, with participant 14 saying that showing a "thumbs-up" icon was perceived as a manipulative way to preempt one from making an informed decision. Similarly, participant 17 stated that participants might believe anything shown in a video and be inclined to give consent. While guidance on ethical nudging design [47-49], as well as research on dark patterns that are to be avoided [7,8], can help shed light on such thorny issues—the issue should be more deeply studied. Considering how often human beings take decisions that are not completely rational [50,51], adding elements such as icons, color, or audio may increase the potential for manipulation of choice.

Limitations

Although we strove to obtain balanced age, education, and sex representation in our sample, they cannot be fully representative of the population. More research should be done on populations other than German adults with a larger sample size. It should also be replicated in the specific consent context of interest, as our study focused on consent to share personal data for further contact; replicating the study for clinical trial consent is important, as it may offer new archetypes, rankings, and contextual concerns. More research should also be done to study how to refine and apply archetypes in practice, as it can be insufficient or biased without continued user, expert, or patient input. Our methods only concern self-reported opinions, so there

may be a discrepancy between reported preferences and observed behaviors. The study materials may have influenced rankings and preferences, as they were generated by XD, who is not a professional designer. Therefore, certain choices (eg, the simple comic style) could have influenced participants' attitudes, making it difficult to determine the exact stimulus based on self-reported answers. While out of scope of this work, future studies can research how specific design elements or stereotypes impact rankings, for example, showing a comic with stick figures or realistic figures to German adults to better understand how to design the specific element. Before implementing consent mediums in line with applicable constraints, relevant expertise should be included in the design and evaluation of each medium.

Conclusions

To better understand the diversity of participant preferences, opinions, and emotions for IC in a health care scenario and the relevance of specific document criteria for engagement with

various mediums (ie, infographic, video, text, newsletter, and comic), this study interviewed 24 individuals. The results not only have informed the generation of archetypes based on desired document features and goals but can also help create standardized consent documents that use layering to help address varying needs identified via archetypes. We also proposed recommendations for designing multimedia consent forms with a structure that promotes prioritization, such as headers, bullet points, and bold type within a contextually appropriate medium, such as an infographic or a video, so that the forms are seen by our participants as more attention-grabbing and serious than comics. It would be important to replicate this study setting in other countries, and the results could lead to contextually designed consents that align with the GDPR and other EU regulations. The findings reported here are meant to encourage further research to determine how to better involve individuals in designing useful, engaging consent forms to facilitate informed decisions concerning data sharing.

Abstract

Background: More than one-third of older adults (aged ≥ 65 y) experience falls every year. The prevalent modifiable risk factors for falling are malnutrition and physical inactivity, among others. The involvement of older adults in the prevention of falls can decrease injuries, hospitalizations, and dependency on health care professionals. In this regard, eHealth can support older adults' self-management through more physical activity and adequate food intake. eHealth must be tailored to older adults' needs and preferences so that they can reap its full benefits. Therefore, it is necessary to gain insight into the knowledge, skills, and mindset of older adults living at home who are at risk of falls regarding eHealth.

Objective: This qualitative study aims to explore older adults' use of everyday digital services and technology and how they acquire knowledge about and manage their nutritional intake and physical activity in relation to their health.

Methods: Semistructured interviews were conducted with 15 older adults (n=9, 60% women; n=6, 40% men; age range 71-87 y) who had all experienced falls or were at risk of falling. These individuals were recruited from a geriatric outpatient clinic. The interviews were analyzed using deductive content analysis based on a modification of the Readiness and Enablement Index for Health Technology framework.

Results: The qualitative data showed that the informants' social networks had a positive impact on their self-management, use of technology, and mindset toward nutritional intake and physical activity. Although the informants generally lived active lives, they all lacked knowledge about how their food intake influenced their physical health, including their risk of falling. Another finding was the large diversity in the use of technology among the informants, which was related to their mindset toward technology.

Conclusions: Older adults can use technology for everyday purposes, but some need additional introduction and support to be able to use it for managing their health. They also need to learn about the importance of proper nutritional intake and physical activity in preventing falls. Older adults need a more personalized introduction to technology, nutrition, and physical activity in their contact with health professionals.

Introduction

Background

Among older adults, falls are common occurrences, with one-third of the population aged ≥ 65 years experiencing falls every year [1]. Falls are among the major causes of mortality and morbidity in older adults [2,3], and they contribute to social and economic costs as well as create a dependency on health care professionals [4]. A reduction in the incidence of falls would increase older adults' quality of life [5], relieve the pressure on health care professionals by reducing hospitalizations [6], and reduce health care system costs [4].

Malnutrition and physical inactivity are well-known modifiable behavioral risk factors for falls in older adults [7-9]. Older adults who are malnourished have a 45% higher risk of falling at least once [7]. Increased daily activity and moderate strength and intensity training 3 times a week can reduce the risk of falling by 30% [8]. Therefore, behavior change regarding nutritional intake and physical activity is important to prevent falls, which is also recommended in international clinical guidelines [8,10]. Behavior change in individuals is influenced by their self-management abilities [11,12].

eHealth, defined as "an emerging field at the intersection of medical informatics, public health, and business, referring to health services and information delivered or enhanced through the Internet and related technologies" [13], is often considered an effective tool for supporting self-management [14]. It may serve as an important "copilot" for older adults to increase their awareness of their nutritional needs and motivate them to engage in higher levels of physical activity [15-17]. To ensure that older adults adopt eHealth and find it useful, their level of knowledge, skills, and experience with eHealth must be addressed when they are introduced to it [18,19]. This includes the level of digital health literacy because it is a determinant considered important for technology adoption [20] and self-management [14].

Another important factor is the existence of social support from relatives and friends to successfully find and understand health information [21,22]. Support and encouragement from health care professionals are also essential for the sustainable adoption of health information and eHealth [22,23].

Older adults' perceptions and mindset may affect their engagement with health initiatives [24,25]. We have previously shown that older adults' perceptions and mindset affect their use of technology [6] and self-management [26]. Among older hospitalized patients, we found that a lack of awareness regarding meeting their nutritional needs was related to limited knowledge of their nutritional requirements and the impacts of food intake on their physical function [26]. Consequently, many older adults may not eat adequately [26].

The use of eHealth, the existence of social relations, and the capability to manage one's own condition, as well as perceptions

and mindset, are all intermingled factors and important to include to obtain a well-functioning sociotechnical ecosystem that enables healthy behavior. In this study, we explore these aspects in the context of nutritional intake and physical activity in older adults living at home who are at risk of falling.

Objectives

The aim of this study is to explore older adults' use of everyday digital services and technology and how they acquire knowledge about, and manage, their nutritional intake and physical activity in relation to their health. These data may help differentiate among users and address specific gaps in relation to knowledge, skills, and mindset. The findings will provide insight into whether eHealth may be a feasible approach to enable and engage older adults living at home who are at risk of falling.

Methods

Overview

This is an explorative qualitative study based on semistructured interviews, which were analyzed using content analysis with a deductive approach. The study is part of a larger research program exploring how, through the use of eHealth, we can optimize older adults' self-management regarding nutritional intake and physical activity to prevent functional decline and reduce the risk of falling. An intervention outlining how health care professionals can assist and support older adults in self-management through the use of eHealth will be designed, developed, and tested. The findings of the study reported in this paper will inform the design of the intervention.

Participants and Setting

All informants were recruited through convenience sampling from a geriatric outpatient clinic in a university hospital in the capital region of Denmark. An exercise physiologist employed at the clinic obtained informed consent, allowing the first authors (JK, EM, and MSR) to contact and inform the informants before their inclusion in the study. The inclusion criteria were age ≥ 65 years, good comprehension of the Danish language, and being at risk of falling. The exclusion criterion was the inability to provide informed consent because of cognitive impairment. Before being interviewed, 16 informants were contacted by telephone by one of the first authors to inform them about the study and arrange the interviews. Of these 16 informants, 1 (6%) retracted their earlier decision to participate after the telephone call. Of the 15 informants, 12 (80%) were interviewed in February and March 2022; the remaining 3 (20%; all male informants to ensure information power by gaining varied experiences from both sexes [27]) were interviewed in February and March 2023 [27].

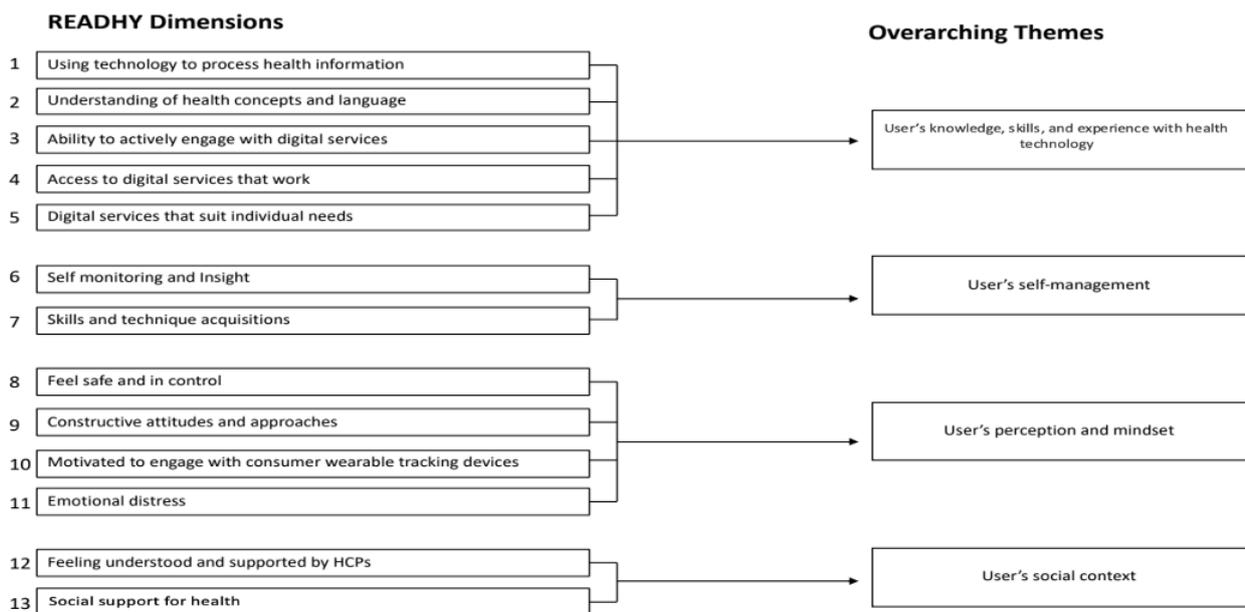

Theoretical Framework

This study is based on a sociotechnical perspective, meaning that technologies are seen as actors that interact with the users

in specific contexts instead of being passive tools [28]. To explore our informants' ability to engage with eHealth, we used the Readiness and Enablement Index for Health Technology (READYH) as the theoretical framework for the interview guide and analysis [22]. The framework can be used to describe individuals' readiness for, and enablement by, eHealth. It consists of 13 dimensions within 3 main themes: self-management, social support, and digital health literacy [18]. In this study, we applied the modified READYH framework

proposed by M Blaauwhof (personal communication, November 2020). The 13 dimensions were aggregated into the following four main categories: (1) the user's knowledge, skills, and experience with eHealth; (2) the user's self-management; (3) the user's perception and mindset; and (4) the user's social context (Figure 1; M Blaauwhof, personal communication, November 2020). The main categories were used to understand how eHealth could be applied to support older adults' health behaviors regarding nutritional intake and physical activity.

Figure 1. Aggregated themes. HCP: health care professional; READYH: Readiness and Enablement Index for Health Technology.

Data Collection

Data were collected from 15 semistructured interviews using an interview guide (Multimedia Appendix 1) with open-ended questions about nutritional intake and physical activity, self-management, social context, and the use of technology. All interviews were conducted by the first authors and took place in the informants' homes. A minimum of 2 of the 3 first authors were present during the interviews. Of the 15 informants, 4 (27%) had spouses present during the interviews. The interviews lasted from 23 to 60 minutes, with an average of 42 (SD 12) minutes.

Data Analysis

The interviews were recorded using Microsoft Teams, transcribed by the first authors, and analyzed using deductive content analysis [29] based on the 4 categories from the modified READYH framework. The codes for the deductive content analysis were identified by the first authors by dividing the 4 categories from the modified READYH framework into subcategories and afterward into codes. The first authors coded the interviews using the data management software program NVivo (version 14; Lumivero). The codes were revised by the first authors and the second author (LK) to ensure reliability and to provide the option of adding newly identified codes when appropriate. The codebook consisted of 25 unique codes with a matching description (Multimedia Appendix 2). First authors JK, EM, and MSR have BSc degrees in health informatics and

have experience in using qualitative and quantitative methods during their studies. JK, EM, and MSR were supervised by LK and RT, who have experience in using qualitative methods. ChatGPT (GPT-3.5; OpenAI) and Grammarly (Grammarly Inc), which offers artificial intelligence-powered writing assistance, were used to support the translation of selected anonymous quotes, the interview guide, and the codebook to improve readability and language.

Ethical Considerations

Verbal and written information about the study was provided to all informants, and written consent was obtained from all of them. The study was conducted in accordance with the Helsinki Declaration. According to Danish regulations, health science questionnaire surveys and interview studies that do not involve human biological material (section 14(2) of the Danish Act on Committees) do not require reporting to, or approval from, the Danish National Centre for Ethics [30]. All data are stored in accordance with Danish legislation (General Data Protection Regulation). The informants were not reimbursed for their participation.

Results

Informant Characteristics

A total of 15 informants (n=9, 60% women; n=6, 40% men) were included. Their mean age was 80 (range 71-87, SD 5.3) years. Of the 15 informants, 12 (80%) had experienced falls

within the last year, and 3 (20%) had experienced balance issues and dizziness. Other characteristics of the informants are

summarized in [Table 1](#), including sex, age, cohabitating status, and highest educational level attained.

Table 1. Informants' characteristics.

ID	Sex	Age (y)	Living alone or cohabiting	Highest level of education attained ^a
#1	Female	81	Cohabiting	Medium
#2	Male	72	Cohabiting	Short
#3	Female	85	Living alone	Medium
#4	Female	80	Living alone	Medium
#5	Female	86	Living alone	Short
#6	Female	80	Cohabiting	Short
#7	Male	83	Cohabiting	Medium
#8	Female	87	Cohabiting	Comprehensive school
#9	Female	79	Living alone	Medium
#10	Female	71	Living alone	Medium
#11	Female	87	Living alone	Short
#12	Male	84	Living alone	Medium
#13	Male	74	Cohabiting	Long
#14	Male	75	Cohabiting	Short
#15	Male	80	Cohabiting	Short

^aThe education variable is aggregated from the 8 levels of the International Standard Classification of Education 2011 [31] and classified into 4 categories as follows: comprehensive school (typically up to lower secondary education), short education (including upper secondary and some postsecondary programs), medium education (encompassing bachelor's and master's degrees), and long education (referring to doctoral studies).

The findings are presented in four categories: (1) the user's knowledge, skills, and experience with eHealth; (2) the user's self-management; (3) the user's social context; and (4) the user's perception and mindset.

The User's Knowledge, Skills, and Experience With eHealth

There was a large diversity in how experienced the informants were with technology and how often they used it in their everyday lives. The informants were divided into three groups based on their knowledge, skills, and experience with technology: (1) those who used technology daily (experienced informants); (2) those who used technology to some extent (partially experienced); and (3) those who had limited use of, and skills with, technology (inexperienced informants). More than half of the informants (8/15, 53%) were experienced users of technology, and 5 (83%) of the 6 male informants were experienced users of technology. The experienced informants were frequent internet searchers and daily social media users. The partially experienced informants only used technology for necessary purposes, such as checking email. Finally, the inexperienced informants had, to some extent, given up on technology either because they had no interest in using it or because they found it too difficult to use; these were also the oldest of the informants.

The experienced informants were aware of the fluctuating credibility of web pages on the internet:

It must be kind of random what you can do, what you find, and how you're loaded with the information

you're seeking. So, you can risk finding something, I wouldn't say a lie, but something that might not be what you were searching for. [Informant #2, male, aged 72 years]

All informants had mobile phones, and most of them (14/15, 93%) also had computers. The informants, usually the experienced ones, had smartphones (11/15, 73%), while some had nonsmartphones (4/15, 27%). The evolution of technology was unwelcome to some of the informants, and they were more comfortable using familiar technologies:

I don't have a modern cell phone, nor do I want one. I have this old Nokia, and it can send a text [message] and tell me what time it is; I can forward my landline calls to it whenever I'm out for a walk, so I just have it with me in my pocket. [Informant #3, female, aged 85 years]

It's [the cell phone] just this one you can call from. It [the cell phone] can only do what I need it to do. [Informant #11, female, aged 87 years]

Several informants used health technologies, such as pedometers, click-ons for hearing aids, and health information web pages. Experienced users were the ones who used technology to search for health information, but only a few used the Danish national health portal:

It was not long ago that I was on it [the Danish National health portal] to see all my diseases and look at my test results. [Informant #7, male, aged 83 years]

The User's Self-Management

The data indicate that the informants in general were interested in taking care of their health, and several were making efforts to do so, including being physically active, but seemingly they paid limited attention to their nutritional intake. One informant expressed how important it was for her to be physically active for fear of losing the ability to move around freely one day. The same informant mentioned that she does not pay much attention to what she eats, arguing that she feels good now, so what she is eating must be fine:

Can you tell me about how you try to take care of your health? [Interviewer]

Well, first and foremost, I do that by being physically active. And I'm so scared actually, it's something I'm afraid of, that one day I won't be able to move anymore. [Informant #11, female, aged 87 years]

Do you ever think about what you should eat in relation to your health? [Interviewer]

Not so much. I must admit.... I tell myself that I feel so good and I can still do so much, so what I eat cannot be completely wrong. [Informant #11, female, aged 87 years]

Many of the informants understood and adhered to the health information they received from the internet, their relatives, health care professionals, and other sources of information, whereas only a few informants searched for health-related information themselves. Those who searched for health information typically used the internet or consulted their friends and relatives. Seemingly, the informants living with chronic conditions were more aware of seeking and appraising health information to minimize the impact of their conditions:

And we [friend] talked a lot about what she did... Well, but she recommended the anti-inflammatory diet, and so I did that for a longer period. [Informant #4, female, aged 80 years]

And specifically with Parkinson's, you stiffen up, so it's especially good to stay active. [Informant #9, female, aged 79 years]

Regarding nutrition, it also seemed that primarily those informants with diet-related conditions either sought or received information from health care professionals. Some mentioned receiving and adhering to nutritional advice from their general practitioners to better manage their conditions, such as high cholesterol, imbalanced salt concentration, and celiac disease.

Several informants set health-related goals for themselves to stay physically active in their everyday lives, such as taking daily walks, achieving a certain number of steps, and losing weight. In addition, they focused on maintaining mental well-being. Two of the informants, whose goals were taking daily walks and achieving 10,000 steps a day, expressed how they used pedometers to track their progress:

We walked, well, over 10,000 steps per day. [Informant #1, female, aged 81 years]

Some of the female informants had goals related to losing weight or avoiding weight gain. Several had tried various weight

reduction diets that they had heard about from relatives or the media, including commercial television programs. Diets included the ketogenic diet and intermittent fasting. In general, all informants who had health-related goals focused on achieving these goals. Some also expressed how their goal of having positive attitudes toward physical activity helped them become more physically active in their everyday lives:

Then I have a good [motivational] phrase: I always tell myself that what I could do yesterday, I can also do today. [Informant #11, female, aged 87 years]

The User's Social Context

In general, the informants' relatives, particularly their children and grandchildren, were involved in, and supported them in, managing their health in terms of their nutritional intake and physical activity. Relatives inquired about the informants' health and took the initiative to help them improve it. These initiatives were often in the form of encouragement and incentives to be physically active, such as walking or using workout equipment or exercise bikes:

[T]hen my daughter and my son-in-law came by last Sunday and asked whether I wanted to go for a walk, and so, of course, I went with them. That happens sometimes. [Informant #3, female, aged 85 years]

ago that I can use at home. [Informant #12, male, aged 84 years]

The informants expressed that their relatives also played a role in shaping their eating habits, such as by introducing them to new diets or suggesting nutritional changes. However, only a few informants expressed involvement from their relatives regarding nutritional intake (compared to involvement in their physical activities):

[My son and daughter-in-law] have switched to a vegetarian diet 3 times a week, and we are also on board with that. [Informant #2, male, aged 72 years]

Friends were also important sources of support. For the informants, talking with friends about their disease was a way to feel supported by discussing and sharing their experiences with peers, whereas relatives were the most important sources of support when it came to encouragement and incentives to improve their health:

[W]e ache and wonder how much one can actually become afflicted, as it gradually hits you. So, naturally, we discuss it a bit [with friends]. [Informant #9, female, aged 79 years]

Relatives, particularly the informants' children, were also perceived as important sources of support for technology use. They helped with the installation of new technologies and with other technical difficulties, such as pressing the wrong buttons or understanding how to use new apps:

[A]nd then maybe I've got a hold of something, and without knowing what it is, I fiddle and press various buttons, you know. And then it's good that I have him [his son]. [Informant #2, male, aged 72 years]

Only one informant had neither a child nor a spouse, and she experienced less social support than the other informants. This informant had no interest in physical activity, did not receive incentives from others to improve her health, and did not talk to friends about health-related topics to avoid burdening them:

It's not that I don't have good friends. But now, for instance, I have a very good friend who has been sick, with ataxia, and I don't want to burden her with that, you know. Because she's very sick already, so I don't want her to worry about me. [Informant #10, female, aged 71 years]

If the informant had problems with technology, she sought help professionally, not from friends:

I have had some issues with my mail because YouSee and TDC [telecommunication providers] had some spam filters that hid all of my emails. I couldn't enter my email then...then they wrote to me and told me how to fix it. [Informant #10, female, aged 71 years]

Most of the informants had positive experiences with support from health care professionals from the geriatric outpatient clinic. They felt supported by the exercise programs provided by physiotherapists from the clinic. In many cases, the positive experiences of support were related to being provided with individualized physical exercises and advice relating to their health conditions:

And she [the physiotherapist] has shown me some exercises to help with my balance, among other things. And I've gotten one of those round cushions that are soft, you know, so I can stand and maintain my balance. [Informant #11, female, aged 87 years]

However, a few informants felt less supported because they had to perform a large part of the physical exercises on their own at home, and they lacked detailed instructions for these exercises:

Sometimes, I feel like I need an instructor. [Informant #2, male, aged 72 years]

It [exercise instructions on paper] doesn't say; there are no measurements for the width of the board or how long you need to walk and how much you can deviate. I think it's very unspecific. [Informant #7, male, aged 83 years]

Most of the informants listened to, and followed, the advice provided by the health care professionals from the geriatric outpatient clinic regarding their health and how to minimize the risk of falling. The advice included drinking enough fluid during the day and using training equipment at home correctly. Despite the informants' history of being at risk of falls, they generally did not report receiving information or advice from health care professionals regarding nutrition to maintain their physical function and thus minimize their risks of falling.

The User's Perception and Mindset

The informants' physical activities varied and could be classified into three groups: (1) structured physical activities, (2) incidental physical activities, and (3) inactive. Approximately half (7/15, 47%) belonged to the group that engaged in structured physical

activities, such as daily physical exercises or weekly planned exercises with peers [32,33]. One-third (5/15, 33%) belonged to the group that engaged in incidental physical activities, such as house cleaning, short walks, and gardening [33,34]. Only a few (3/15, 20%) belonged to the inactive group of informants, who only did what was necessary because they seemingly had little interest in physical activities.

The informants' motivation for being physically active stemmed from the desire to remain physically mobile and avoid relying on others, as well as the opportunity for social interactions. Several informants found it enjoyable to participate in various structured physical activities together with their peers, such as going on excursions or joining training groups, rather than performing exercises alone:

And I'm so afraid; it's actually one of the things I'm most afraid of, that one day, I can't move, walk, or take care of myself anymore. [Informant #11, female, aged 87 years]

And then I made a club down here, where we meet every Wednesday. And there [in the club], you're motivated to engage in a lot of events through songs, or someone comes and gives lectures. We'd go for a walk in the forest, or take trips on a bus, where we have lunch, or take some trips in which we'd have lunch out. All such events. [Informant #8, female, aged 87 years]

A few informants from the structured physical activities group described how they did not perceive themselves as physically active. Some even expressed that they were lazy:

I must say that I'm living with the effects of my broken shoulder. And I'm completely lazy. [Informant #4, female, aged 80 years]

The informants from the incidental physical activities group were familiar with how performing daily physical activities improved their health, but despite this knowledge, their motivation to perform physical activities was limited. However, there was a tendency for social interactions to be motivating factors for the informants belonging to this group:

Yes, and I can say that I don't think I'm fulfilling my responsibility [performing exercises] if I have to do it alone. I'm probably better at doing it with others. [Informant #8, female, aged 87 years]

For the inactive informants, a primary reason for not exercising was the difficulty in finding personal meaning and purpose in physical activities. For some of these informants, the potential opportunity to engage in social interactions did not increase their motivation to be physically active:

I've always hated going on walks without a purpose. I've never played sports. [Informant #12, male, aged 84 years]

Well, I don't like to do anything when there are a lot of people around, and when I need to stand there and do one thing after another. [Informant #6, female, aged 80 years]

Some informants who were physically impaired because of health-related conditions found it difficult to be physically active. These informants were also either in the inactive or incidental physical activity group:

Then, I'll take a walk in the forest. I haven't done that very much lately, perhaps because I've had an operation on my knee. I'm not particularly fond of it, but right now, I can't go on my long walks. [Informant #3, female, aged 85 years]

By contrast, the informants from the structured physical activities group had more knowledge about, and were more attentive to, staying active during and after an illness or injury.

Regarding the informants' perception and mindset toward their food intake, many expressed uncertainty about whether there were particular foods that would benefit their health. However, the majority expressed that they should consume more vegetables, and some also expressed that they strived to do so. Vitamins, both as supplements and in food, were highlighted as important for staying healthy. One informant expressed that protein intake was beneficial for weight loss. No informant mentioned the importance of protein intake for maintaining muscle strength and thus preventing falls. Several informants expressed acceptance regarding not necessarily adhering to recommendations for healthy eating (generally referred to as the intake of vegetables and foods low in fat and sugar) because most of them were under the impression that they ate according to their nutritional needs:

I actually think I eat as I should. [Informant #3, female, aged 85 years]

Despite the informants' narratives revealing their perception of the concept of healthy food, it was evident that their food intake was largely guided by their preferences for the foods they liked. Some informants revealed positive attitudes toward allowing their preferences for tasty food to guide their intake:

I think about having some vegetables because it's supposed to be good for the stomach. But otherwise, I don't really think about whether it's healthy or not. I think all food is healthy if you feel like it. Unless you overdo it, of course. [Informant #7, male, aged 83 years]

Advanced age was also mentioned as a justification for not making any changes to their eating behavior just to adhere to the consumption of "healthy food":

I suppose now that I've gotten so old, so... [Informant #6, female, aged 80 years]

In general, the informants had a limited focus on their nutritional intake and on fulfilling their dietary needs. However, some female informants were more likely to report avoiding fatty food to avoid weight gain:

No, I don't eat fatty food, I don't eat butter on bread...It's a waste of calories because you don't need it; there's liver pâté. [Informant #10, female, aged 71 years]

Several informants perceived technology as a necessity in their daily lives; however, some expressed that they thought technology had too much of an impact on their lives:

And the worst part of it is this damn computer. It starts in the morning during breakfast when I open it up, and then I'll check my email, then Ekstra Bladet [a Danish news magazine], and then Facebook, and only then am I ready for the day. [Informant #14, male, aged 75 years]

Many of the informants had positive attitudes toward using a mobile phone because it made it easier for them to reach others and stay in contact with them. The experienced users preferred using computers or iPads because of their large screens, which made them easier to use:

Well, now if I should look at it [exercises on the computer] right, then I don't have to deal with the small font. It's nice with a big screen. [Informant #1, female, aged 81 years]

Some informants expressed negative attitudes toward technology because they felt that it hindered personal communication and was challenging to manage. Several informants mentioned that negative experiences mainly occurred when the technology changed or did not work. These challenges were demotivating for the informants because it required time to resolve the problems and caused great frustration:

I think that, at least for us, there are too many times when it [the technology] doesn't work...and it takes too long. [Informant #8, female, aged 87 years]

Discussion

Principal Findings

We explored older adults' use of everyday digital services and technology and how they acquire knowledge about, and manage, their nutritional intake and physical activity in relation to their health. A main finding in this study was the great diversity in the informants' experiences, mindset, and use of technology: some perceived technology as a necessity in their daily lives, whereas others viewed it as a source of frustration. Feelings of frustration were more prevalent among the oldest informants. Another main finding was that, although the informants were at risk of falls and had been referred to a geriatric outpatient clinic for the assessment and management of their fall risk, they possessed limited focus on, and knowledge about, nutritional needs to promote or maintain good physical function and thereby decrease their risk of falling. An important finding was the positive impact of the social network of relatives and health care professionals on the informants' use of technology and motivation for the self-management of nutritional intake and physical activity. There seemed to be a relationship between the informants' levels of physical activity and having a positive mindset, whereby the most active informants seemed to be more aware of the benefits of staying active and thinking positive. By contrast, there was limited focus on the importance of their food intake, which seemed to be related to the informants' limited knowledge about this topic and not to a lack of motivation to look after their health and well-being.

Comparison With Other Work

The great diversity in the informants' experiences and use of technology, with inexperienced informants belonging to the older age group, is also described in previous studies [6,35,36]. Rossen et al [35] examined readiness for technology and showed that the older age group had the lowest readiness for technology. However, the findings of Goyal et al [37] indicated that older adults may have greater adherence than younger adults once they adopt technology. This suggests that it is important to provide older adults with sufficient support to help them adopt technology. Although most of the informants (14/15, 93%) used technology, only a few (6/15, 40%) used it for health-related purposes. It was mainly the informants with chronic diseases (6/15, 40%) who searched for information on treatment and medication and generally focused on information that could minimize the impact of their chronic diseases. This is in alignment with 2 other studies and a recent review [6,23,38], which found that when older adults seek health-related information, it is often related to information about specific diseases, treatments, and medicines. Interestingly, those informants who used eHealth to find health-related information (6/15, 40%) mainly searched for information about their chronic diseases but did not search for information about how to prevent falls. This signifies that they do not consider information about preventive measures in relation to falls as being health related.

To understand individuals' motivation and ability for self-management, it is important to gain insight into their perception and mindset because these affect their motivation to engage in a specific behavior [39,40]. Our finding that older adults generally have positive attitudes toward technology is supported by the results of other studies [6,41]. The main reason for not using technology was frustration with technological challenges and because it hindered personal communication. This aligns with the results in the review by Wilson et al [19], who found that barriers to using eHealth included dislike of the technology and problems with functionality. Perceiving technological challenges may affect individuals' perception of ease of use, which is an important determinant for the intention to use technology [42]. Therefore, these potential barriers need to be addressed in future interventions. Furthermore, Wilson et al [19] found that a lack of knowledge and experience with using technology hindered use, whereas a belief in its benefits facilitated use. These findings are consistent with those of Terp et al [6], who found that the perception of technology as being useful facilitated its use among older hospitalized patients and that nonuse was mainly due to a lack of knowledge about the derived benefits from the technology. These findings suggest a need to provide older adults with knowledge about the advantages of using eHealth.

We found that the informants who were physically active (structured and incidental physical activities groups) were motivated to perform physical activities because they experienced these as being fun, they enjoyed the social element, they had been active throughout their lives, and they wished to remain physically mobile and avoid relying on others. These motivational factors for physical activity have also been described in other studies [43,44]. The reviews by Sandlund et al [43] and Bunn et al [44] found that important facilitators for

commencing fall exercise programs were previous exercise habits, social support and interaction, the ability to remain independent, and the fun element. For the inactive informants, a primary reason for not exercising was the difficulty in finding personal meaning and purpose in physical activities. These findings also align with those of Sandlund et al [43] and Bunn et al [44], who found that the barriers to commencing fall exercise programs were lack of support and interest, concerns about the exercises, and unawareness of the benefits.

Our findings indicate that older adults, despite being at risk of falling, may have a limited focus on eating adequately to maintain or improve their physical health. Among several of the informants, the behavior and mindset toward food intake were focused on society's notion of an ideal slim body, which corresponds to the findings of previous studies [26,45]. Our findings suggest that this may not be due to a lack of motivation but merely due to limited knowledge; the majority were motivated and focused on maintaining their health because of their fear of losing physical function. Despite the importance of adequate nutrition, previous studies have reported limited nutritional knowledge among older adults [45,46]. Our findings indicate that older adults are more likely to receive, rather than actively seek, health-related information, a result also supported by our previous study among Danish hospitalized patients [26]. Therefore, health care professionals play an important role in providing older adults with relevant information, including information on their nutritional needs and the risk of falling. Our data revealed that older adults, in general, trusted health care professionals and adhered to the advice they provided. Our findings indicate potential benefits in ensuring that older adults receive relevant information and advice in future fall prevention interventions.

Social support from family, especially from their adult children, had a positive impact on the informants' technology use, self-management, and mindset concerning physical activity and nutritional intake. This positive influence on older adults' technology use was reported in a review by Levin-Zamir and Bertschi [21], who found that social support is paramount for many older adults in executing tasks related to health information from media sources. This finding is also corroborated by Takemoto et al [41], who found that human support increases accountability and enhances the use of technological devices. The positive impact of support from the family on the informants' mindset for nutritional intake and physical activity was also established in other studies [2,26,47]. Spiteri et al [47] reported that family support was one of the key motivators for physical activity among older adults, and Terp et al [26] found that relatives were an important resource for older adults' food intake. The positive impact of social support on older adults' self-management is also corroborated by Schnock et al [2], who found that being married or living with someone had a positive impact on engagement in fall prevention interventions and self-management among older adults. Although almost half of our informants (7/15, 47%) lived alone, our data showed that most of them (6/7, 86%) experienced social support. This is contradictory to the findings of another study [48] in which older adults who lived alone experienced less social support. Overall, in our study, relatives

were seen to have a higher impact on the informants' levels of physical activity than on their nutritional intake. This may be explained by a lack of knowledge among the relatives about the nutritional needs of older adults. In future fall prevention interventions, it is important that information about nutrition and its impact on physical function and the prevention of falls is also provided to relatives.

Several findings of this study correspond to those in our previous study, which we conducted among older hospitalized patients [6,26]. The population in the study reported in this paper differs because all informants were at risk of falling and underwent evaluation and treatment in a geriatric outpatient clinic. International guidelines [10] recommend fall prevention interventions that enhance health behavior to reduce the risk factors for falls, such as inadequate nutrition and a lack of physical activity. The informants were recruited from the outpatient clinic and had received information and training from the clinic before the interviews. We therefore expect that they were provided with information on risk factors and advice regarding optimal nutritional intake and physical activity. However, we cannot conclude from this study whether the informants had been offered such interventions. This study provides important knowledge from the perspective of older adults about their needs in terms of developing an eHealth-based intervention aimed at supporting and motivating better health behavior, thus preventing functional decline and its consequences, such as falls.

Strengths and Limitations

A strength of this study was the use of READHY as a theoretical framework because it provided a conceptual understanding of relevant aspects of individuals' readiness to engage with

eHealth, such as digital health literacy, social support, and the capability to manage their own condition. The use of a modified version of the READHY framework with the addition of a fourth theme (perception and mindset) is better suited for a qualitative analysis process. Another strength is that the informants live in a country that is among the most digitalized in the world [49]. The use of digital services and technology is therefore common in the general population, and a lack of resources or difficulties in accessing the internet and eHealth are usually not barriers, as our data also indicate. Thus, as the lack of access to digital technology is not a barrier among this group of informants, it enabled us to explore how the informants acquire knowledge about their nutritional intake and physical activity in relation to their health. However, the transferability of the study is worth considering, given that the majority of the informants (11/15, 73%) lived in the same geographic area of Denmark (Nordsjælland). In future studies, the inclusion of informants from other geographic areas can help achieve greater heterogeneity.

Conclusions

This study demonstrates the potential of eHealth to support self-management in older adults, as most of them already use digital technology in their everyday lives. Older adults' age, social context, and mindset should be considered when implementing and supporting eHealth. They must be provided with knowledge about the benefits of using eHealth to improve their motivation to use it for the self-management of their nutritional intake and physical activity. Furthermore, health professionals must be aware of the need to educate older adults about the impact of nutritional intake and physical activity in fall prevention, particularly for those who lack social support.

Acknowledgments

The authors would like to thank the informants who participated in this study. The authors also thank exercise physiologist Pernille Hansen from the geriatric outpatient clinic, Herlev-Gentofte Hospital for the assistance in recruiting informants, and Marijke Blaauwhof for sharing her master's thesis work with us and allowing us to use her modified model of the Readiness and Enablement Index for Health Technology framework. The authors used the ChatGPT (GPT-3.5; OpenAI) [50] and Grammarly (Grammarly Inc), which offers artificial intelligence-powered writing assistance, to support the translation of selected anonymous quotes, the interview guide, and the codebook to improve readability and language.

Abstract

Background: Although the effects of digital health are receiving wide scientific attention, very little is known about the characteristics of digitally engaged people experiencing homelessness, especially in Central and Eastern Europe. Our previous research revealed a considerable level of internet use in the homeless population of Budapest, Hungary, for general purposes (350/662, 52.9%) and medical purposes (229/664, 34.6%). Moreover, a digitally engaged subgroup was identified (129/662, 19.5%).

Objective: The aim of this exploratory study was to map out the resources, attitudes, and behaviors of digitally engaged homeless individuals in relation to digital technology to set the basis for potential health policy interventions, which will enable better access to health services through strengthening of the digital components of the existing health care system.

Methods: Between August 18, 2022, and October 27, 2022, a total of 12 in-depth semistructured interviews were conducted in 4 homeless shelters in Budapest, Hungary. Upon analysis by 3 independent evaluators, 2 interviews were excluded. The interviewees were chosen based on purposive sampling with predefined inclusion criteria. Thematic analysis of the transcripts was conducted.

Results: In the thematic analysis, 4 main themes (attitude, access, usage patterns, and solutions for usage problems) emerged. Health-related technology use mostly appeared in health information-seeking behavior. Online search for prescribed medications (5 interviews), active ingredients of medications (4 interviews), medicinal herbs believed to replace certain pills (2 interviews) or foods, and natural materials (1 interview) were mentioned. Moreover, mobile health app use (3 interviews) was reported. The intention to circumvent or check on mainstream health care solutions was mainly associated with previous negative experiences in the health care system. Several gaps in the daily use of technology were identified by the interviewees; however, more than half of the interviewees (6/10) turned out to be contact points for their peers for digital problem-solving or basic digital literacy skill enhancement in the homeless shelters. Furthermore, a lack of institutional support or special programs targeting senior clients was noted.

Conclusions: Digitally engaged homeless individuals might become mediators between their peers and comprehensive digital health programs. They have the trust of their peers, can recognize and harness the benefits of digital technology, and are able to provide meaningful help in technology- and usage-related issues through experience. Digital health services have great promise in community shelters for managing and preventing health issues, and digitally engaged individuals might be important for the success of such services.

Introduction

The Digital Health Paradox

By the end of 2022, the number of mobile service subscribers climbed to over 5.4 billion people globally, including 4.4 billion people who also used mobile internet, and the usage gap has narrowed markedly in the last 5 years (from 50% in 2017 to 41% in 2022 on average) [1]. As of October 2023, around 5.3 billion people use the internet worldwide, which is equivalent to 65.7% of the total population of the world, and in the last year, 189 million new members joined the global community of internet users [2]. These are unprecedented numbers. Digitization, especially the adoption of digital health technologies at scale, has been boosted by the COVID pandemic since 2020, promising access to health care systems and beneficial health outcomes.

However, there is a growing body of evidence indicating that greater reliance on digital tools has the potential to widen the gap between those who have digital skills and access to digital tools and those who do not, thereby increasing already existing health inequalities [3]. Although digital solutions might be designed following guidelines, such as the World Health Organization (WHO) Global Strategy on Digital Health 2020-2025, which states that “digital health should be an integral part of health priorities and benefit people in a way that is ethical, safe, secure, reliable, equitable, and sustainable,” certain groups are unintentionally left out of the digitization boom [4]. Paradoxically, these groups often represent patients with complex psychosocial needs, specific sociodemographic characteristics, and multiple chronic conditions, and they would benefit the most from the use of digital health technologies [5-8]. van Kessel et al [6] have referred to this as the digital health paradox.

Vulnerable Groups, Homelessness, and Health Disparities

The abovementioned groups might represent vulnerable populations that are already experiencing negative health outcomes due to their detrimental social determinants of health. This has been defined by the WHO as “the forces and systems shaping the collective conditions in which people are born, grow, work, live, and age, as well as the conditions of their daily lives” [9], and they are shaped by the distributions of money, power, and other resources [10]. Emerging research shows that there is a strong relationship between socioeconomic factors, geography, demographics, and health, with poverty, housing problems, food insecurity, abuse, gender, and ethnicity creating chronic stress, which can leave the human organism with maladaptive mechanisms that result in damage to the body’s functioning systems [11,12]. These have been linked to hypertension, premature aging, cardiovascular disease, type 2 diabetes, stroke, cancer, pulmonary disease, kidney disease, and many other health problems [10,13].

In the case of people experiencing homelessness, a complex set of social determinants of health are at play, which amplify each other’s impacts and leave this vulnerable group at the extreme low end of health outcomes, health care access, and health literacy. According to previous research, living without adequate housing options is associated with significantly higher rates of bacterial and viral infections, diabetes, hypertension, cardiovascular disease, mental health issues, and problematic substance use compared to populations with adequate housing options [14-16]. The COVID-19 pandemic has also increased the vulnerabilities and health risks of people experiencing homelessness [17].

Life expectancy data for people experiencing homelessness compared to the general population also support these findings. In a systematic review, Aldridge et al [18] found that socially excluded populations have an 8 times higher mortality rate for men and 12 times higher rate for women than the average population. In Western high-income countries, studies have shown that homelessness is an independent risk factor for mortality, and life expectancy varies between 50 and 65 years on average [19].

When considering health care access, homeless populations frequently experience structural barriers to obtain health care, including lack of health insurance in countries without universal health insurance, as well as competing interests in health care settings to their disadvantage alongside their own financial difficulties and competing priorities, which might lead them to secure food and accommodation before health care [17,20]. Research has also shown mistrust of health care systems and experiences of discrimination in care settings. Poorer health literacy measured among people experiencing homelessness compared to the general population might also lead to a poor self-rated health status and less adherence to medical recommendations and prescription medicines [21].

Digital Health and People Experiencing Homelessness

Previous research has shown that people with lower socioeconomic status are slower to adopt new technology, and the rates of smartphone and internet use among people experiencing homelessness were lower than the rates among those with similarly low socioeconomic status but more stable housing [22]. VonHoltz et al [23] found that while experiencing homelessness, study participants showed a 68% reduction in their likelihood to access the internet compared to when they were housed. However, in terms of preferences, it was found that low-income populations, including people experiencing homelessness, rely on smartphones rather than computers for internet access owing to cost considerations, portability, and storage issues [24]. Populations at risk for limited health literacy, as indicated in the case of the homeless populations above, are also at risk for having challenges with digital technology [25].

Previous research has mentioned that it would be beneficial to equip people experiencing homelessness with the necessary tools to get them involved in digital health ecosystems as the costs of inclusion are significantly lower than the costs of

treatment of health conditions, and the overall benefits show significance and persistence [3].

Digital Health and Homelessness: Research in Hungary

While the associations between people experiencing homelessness and their health status are well researched, especially in English-speaking countries, such as Canada, the United Kingdom, and the United States, a lot less is known about the access of people experiencing homelessness to digital health tools, their digital health literacy, their attitudes toward digital technologies, or their overall characteristics in different local settings, such as Hungary, and about the specific groups existing within homeless populations [26,27].

For these reasons, the Digital Health Research Group at Semmelweis University and the Hungarian Charity Service of the Order of Malta (HCSOM) have undertaken an overarching research agenda aiming to uncover the relations between digital health and homeless populations in Hungary. Digital health technologies are defined as “technologies which use computing platforms, connectivity, software, and sensors for health care and related uses” [5]. Previous research has mapped out the attitudes of people experiencing homelessness in Budapest, Hungary, toward telecare services, with the main finding that trust in the general health care system is the central issue when it comes to the decision of homeless populations about whether they have trust in telecare services as well [28]. This study served as a starting point for a pilot project assessing the viability of a telecare system for homeless populations [29].

Access to digital tools and digital health literacy were measured in another survey ($n=662$), where the results demonstrated that a significant proportion of people experiencing homelessness in Budapest, Hungary, were using the internet (52.9%), while the proportion was 81.3% in a representative sample of the Hungarian population that was used as a reference group [30]. Moreover, 69.6% of people experiencing homelessness reported mobile phone ownership, with 39.9% adding that their phone had a smartphone function and 34.6% mentioning that they have already used the internet for medical purposes [30]. In terms of self-rated digital health literacy, 24.5% rated themselves as experienced or very experienced regarding internet use, while 21.5% self-reported having mediocre experience [30].

Based on these access and skill-related characteristics, we were able to filter out a broadly defined digitally engaged group ($n=129$, 19.5%). This subgroup possessed their own digital tools, had some level of digital health literacy, and was partly using these digital tools for health-related reasons. When we analyzed the group and ran chi-square tests for gender, age, education, frequency of medical visits, prevalence of chronic illnesses, shelter type, and social services, the prevalence of chronic illnesses ($P=.047$) was found to be an associative factor in this subgroup for the likelihood of using the internet frequently for health-related reasons. However, the quantitative survey could not discern more relevant information [30].

Thus, the main aim of this study was to map out the characteristics of this specific subgroup in order to determine (1) for what purposes and (2) how the individuals in this

subgroup are using digital health technologies in the framework of an exploratory qualitative analysis.

Methods

Checklist

Our methodology is based on the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist as well as the methodological framework of Gyórfy et al [31] (Multimedia Appendix 1). For data collection, 12 semistructured interviews were conducted.

Ethics Approval

For all interviews, written informed consent statements were obtained, and ethics approval for the study was issued by the Scientific Research Ethics Committee of the Medical Research Council of Hungary (TUKEB 133/2020 and IV/10927/2020/EKU). In terms of the analytical framework, thematic analysis was chosen.

Recruitment

Purposive sampling was based on the following criteria: (1) presence in the social care system of the Charity Service of the Order of Malta, (2) use of the internet every second week or more frequently, (3) internet access with own smartphone, computer, or tablet or another device with a data contract, a pay-as-you-go facility, or free Wi-Fi, (4) self-rating of an average or more competent internet user, and (5) ever use of the internet for health-related reasons. The sampling criteria of this research and the filtering criteria for the broadly defined digitally engaged subgroup in our previous research matched [30]. However, the previous research involved anonymous data collection, and the present purposive sampling did not use the previous data pool as a starting point. Thus, there may or may not be an overlap between the 2 groups.

Malterud et al [32] theorized that information power can determine the ideal sample size for qualitative studies, with a sample holding more information requiring a lower number of participants. They enlisted the following 5 criteria for analyzing information power: (1) aim of the study, (2) sample specificity, (3) use of an established theory, (4) quality of dialogue, and (5) analysis strategy. In this case, the aim of the study was to assess the specific characteristics of a subgroup of people experiencing homelessness who have a digital skillset and usage pattern (see Multimedia Appendix 2 for the interview guide), thus creating a very specific sample with limited prevalence in the overall population as measured in our previous study [30]. As a result, a smaller sample size was chosen.

In the research process, 12 interviews were conducted, but in the final analysis, 10 interviews were included, which presented all the criteria of the purposive sampling specified above. Two interviews did not contain any reference to digital health usage. At this point, this might seem as a contradiction, but people experiencing homelessness may experience literacy issues, may have somewhat limited understanding due to health issues, and may have a risk of social desirability bias in relation to interview situations, which may result in self-contradictory statements,

opinions, and behaviors, in line with previous methodological findings in relation to this vulnerable population [33].

Data Collection

Interviewees were contacted by social workers or institutional assistants at 4 shelters in the social care system of HCSOM or partner institutions. These shelters either served as a night shelter (n=1) or provided accommodation on a 24/7 basis (n=3) in Budapest, Hungary.

Based on the recommendations of the social workers or institutional assistants, one-on-one semistructured interviews were conducted between August 18 and October 27, 2022.

The interview guide was developed from experiences of the previous research, the specific study aims, and a literature review. The interviews were conducted in Hungarian with a trained interviewer. The interview guide was checked on a smaller sample of the specific subgroup (n=2) and modified based on their initial feedback.

The interview guide was based on the following topics: access to and attitude toward the health care system in general, access to and attitude toward digital tools in general and usage patterns of the internet and digital tools, and access to and attitude toward digital health and usage patterns of the internet and digital tools for health-related reasons (see [Multimedia Appendix 2](#) for the complete interview guide).

Interviews were audio recorded in person, with an average interview length of 30 minutes. All audio-recorded interviews were transcribed verbatim, and each transcript was anonymized and assigned a unique code. The interviewer checked the transcriptions for accuracy. They were not sent back to the interviewees because people experiencing homelessness struggle with literacy challenges and Thomas et al [34] argued that evidence does not support the idea that member checking

increases the credibility or trustworthiness of qualitative data [34].

Analysis

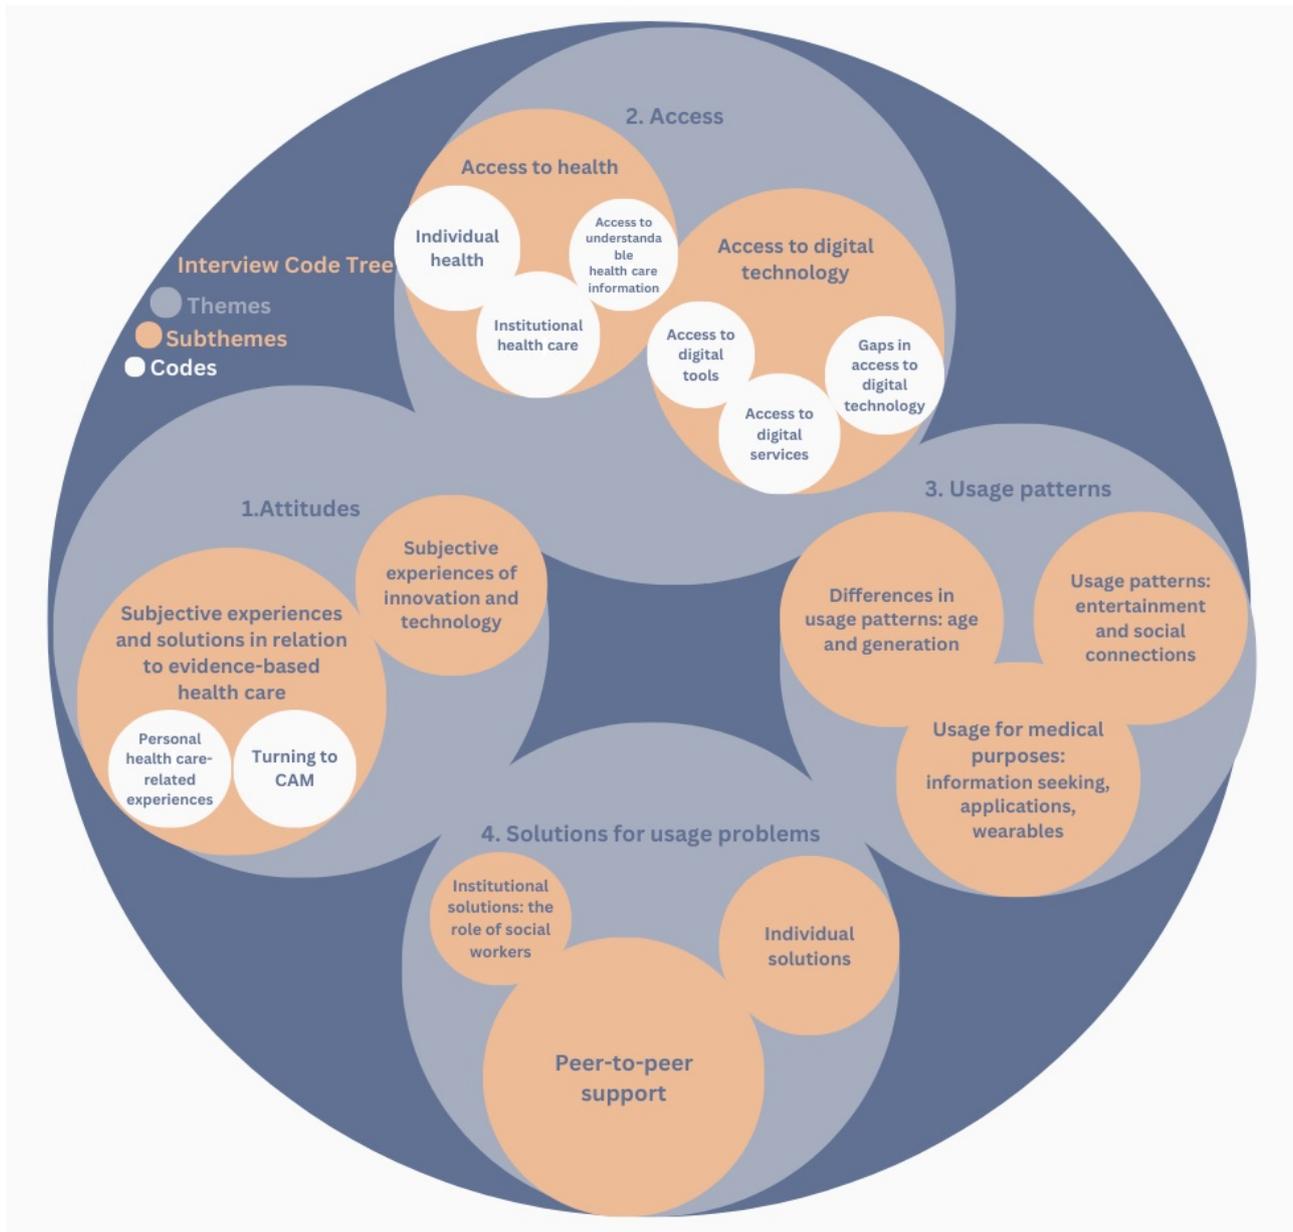

Thematic analysis as described by Braun and Clarke was chosen as an analytical and theoretical framework [35]. In coding, we followed the “theoretical” technique in an essentialist or realist method, driven by the analytic interest to report about the experiences and realities of the study participants in relation to their engagement in a digital health ecosystem. In coding, we followed the deductive technique, that is, we worked with predetermined assumptions and themes, which followed the interview guide; however, clearly characterizable subthemes emerged around the previously identified main themes. Three independent researchers (ZG, SB, and NR) read and analyzed the data and discussed their findings.

A theoretical thematic approach was used to analyze the data and identify patterns of themes based on the checklist elaborated by Braun and Clarke [35]: (1) familiarizing with the content of the data, taking notes, and making ideas for coding based on previous assumptions and following the interview guide, (2) generating initial codes manually, (3) identifying and indexing different codes across the data set manually, (4) creating relationships between the themes and subthemes, (5) defining, mapping, and naming themes, and (6) interpreting the results.

The 3 researchers discussed and developed all themes and subthemes and clarified any discrepancies during the coding. Afterwards, they laid out the final thematic map in mutual agreement. The results are supported by participants’ anonymized quotes. Interview IDs are provided for all quotes. For each interview ID, the letter indicates the first letter of the shelter where the interview was conducted (M, Miklós utca; F, Feszty; B, Budaörs; R, REVIP) and the number indicates the serial number of the interview.

For an overview of the themes, see [Figure 1](#).

Figure 1. Interview code tree. CAM: complementary and alternative medical solutions.

Results

Demographic Characteristics

General demographic characteristics of the sample are presented in [Table 1](#). In terms of gender, 6 male and 4 female participants were interviewed. Older age groups were overrepresented in

the sample: 1 person was <40 years old, 4 people were 40-49 years old, 2 people were 50-59 years old, and 3 people were ≥60 years old. In terms of education, high school (4 people) and vocational school (3 people) were overrepresented, while 1 person had a university education and 2 people completed primary school or below.

Table 1. Demographic composition of the sample.

Characteristic	Value (N=10), n (%)
Gender	
Male	6 (60)
Female	4 (40)
Age (years)	
<40	1 (10)
40-49	4 (40)
50-59	2 (20)
≥60	3 (30)
Education	
Primary school or below	2 (20)
Vocational school	3 (30)
High school	4 (40)
University	1 (10)
Shelter	
HCSOM ^a Temporary Shelter (Feszty)	2 (20)
HCSOM Integrated Shelter (Miklós utca)	4 (40)
Shelter House Foundation's Night Shelter (Budaörs)	2 (20)
REVIP Baptist Integration Center (REVIP)	2 (20)

Theme 1: Attitudes

Subtheme 1: Subjective Experiences and Solutions in Relation to Evidence-Based Health Care

Code 1: Personal Health Care-Related Experiences

Experiences with mainstream health care systems (hospitals, doctors, nurses, pharmacists, other medical personnel, prescription medicines, and pills) were mixed. In a minority of interviews (2/10), positive experiences with regard to access to care, quality of care, and how one was treated by the medical personnel were noted. However, the majority (7/10) reported negative experiences largely due to a negative attitude, stigmatization and mistreatment coming from the medical staff, and inadequacy of care. These signaled an overall negative attitude toward the general health care system.

I'm completely okay to be honest, I experienced that there are differences between the hospitals, I can only say that. [Interview M05]

(...) ...they notice where they have to go and then they have a completely different stance. Also, the emergency medical doctor, who is here, or if the ambulance services come. They behave completely differently. (...) They are condescending. Okay, we'll do it later. Okay, come back later. And another one: do pack your stuff already, we are set to go. So, they (...) are not helpful. [Interview B09]

Code 2: Turning to Complementary and Alternative Medicine

In a minority of interviews (3/10), turning to complementary and alternative medical solutions, medicinal herbs, or Chinese medicine was noted, which was considered as an equivalent alternative of traditional Western medicine. In parallel, in 2 interviews, a negative stance toward drugs and medicines (mentioned within the same textual context) was noted.

These shed light on the fact that interviewees sought out different potential solutions to their medical problems as some of them experienced that health care systems and traditionally produced drugs cannot and have not so far provided them with appropriate solutions. They had taken medicinal herbs or trusted ingredients, which were recommended by a trusted person or were found online.

I am aware of that, I looked up the side effects, the medicines, I will not take what they prescribe. I have already played along for long. I rather drink an herbal tea. [Interview F01]

I can feel if something's off in my body, and then I look up certain things, but to be honest, I always start with medicinal herbs, and not with pills. I go to the pharmacy, and I look up on the internet what is recommended for example for lower abdominal pain or for a story with joints. [Interview M07]

Subtheme 2: Subjective Experiences of Innovation and Technology

Subjective experiences and attitudes toward novelties and technology were mixed. In almost half of the interviews (4/10), openness toward trying new programs and applications appeared, while in 2 interviews, a complete lack of interest was reported.

Attitudes toward the use of digital tools and the internet were also mixed. In part of the interviews, lack of trust and negative experiences were reported, for example, the risk of data misuse (1 interview), risk of making mistakes due to the autocomplete function and the speed of digital tools (1 interview), and inaccuracy of step counting (2 interviews). In another set of 4 interviews, openness toward trying new programs and applications appeared, while in a minority of interviews (2/10), lack of interest in this area was reported.

As I'm homeless at the moment, I don't have enough (money) on my pay as you go facility that I could use the internet unlimited. Where there is free Wi-Fi, I certainly search for things I think of or what I gather from my environment, or from my godchildren. So, I want to keep up with today's world in spite of the fact that I'm now a little bit on the brink of it. [Interview M07]

You can really misuse data. I had that now, as well. Someone tapped into my bank account, abroad. I had to block access to my debit card, and I will have it done at some point. [Interview F01]

As this device (tablet) works so that if my hand starts to shake just a little bit, and it gets close to it, it pulls in. And then, it writes something that I don't want to. So, I don't think that it is so reliable. [Interview R12]

Theme 2: Access

Subtheme 1: Access to Health

Code 1: Individual Health

The majority of interviewees (7/10) self-evaluated their health status as average or worse. Chronic diseases (cardiovascular and heart problems, and type 2 diabetes), cancerous tumors, and lasting harm from injuries were characteristic for the group. In 4 interviews, managed alcohol problems were reported. Drug abuse was not mentioned, and in 2 interviews, aversion to drugs was noted. Diagnosed mental health problems were not mentioned.

Some interviewees regularly took medicines or mentioned that their doctors prescribed them certain types of medications, which they did not take. Some interviewees made decisions in medical matters based on their own opinions and beliefs without any professional evidence.

My troubles look like heart, liver, kidney, arterial obstructions. I had deep vein thrombosis in both legs but I carried that for long. I have a very high tolerance for pain. I usually operated on myself. I froze both of my legs and I cut the ulcer out as deep

as I could. Then I put herbs into the wound. It recovered within 2 weeks. [Interview F01]

Code 2: Institutional Health Care

Interviewees were clients of 4 homeless shelters in Budapest, meaning that they had institutional access to basic health care. Their legal social security status could be provided by social institutions on the grounds of homelessness under Hungarian law. Accessible health care services included primary care (prescription and dispensing of medicines, referral to specialists, and care work), publicly funded specialized outpatient care, inpatient (hospital) care, and rescue in case of emergency.

If I have any problem, the Maltesers (HCSOM) have a doctor's office. And if I can go there on my own feet, then I go there. If you can't, then you will be transported to the hospital by default. There are decent people who help or call an ambulance. In the doctor's office, they refer you to any specialist, no matter whether it's dermatology or cardiology. Thus, they can get you to any kind of specialist. [Interview F03]

Code 3: Access to Understandable Health Care Information

In at least one interview, a lack of access to understandable health care information was reported, and several interviewees pointed out that they were seeking out medications and ingredients online with the help of digital tools in order to understand what impacts those materials had on their body. The need for understanding health-related information was noted in at least half of the interviews in certain forms, for example, they looked up prescription medicines (5 interviews) and their ingredients (4 interviews) online, and in at least one case, they did that for their family members as well.

(...) most of the time, physicians use such Latin words in general, as lawyers do. Make it simple! No one is that much overeducated to know these. For example, laboratory tests. They should include what does this mean, sodium was X. There are some apps where you can look that up. [Interview F01]

Subtheme 2: Access to Digital Technology

Code 1: Access to Digital Tools

An overwhelming majority of interviewees (7/10) used smartphones. Notebook use was reported in 1 case, and tablet use was reported in further 2 cases. One interviewee reported power bank use to charge the device.

In a minority of interviews (2/10), it was reported that in times of need, phones, tablets, and computers were sold; thus, these were not permanently accessible tools.

In this living situation, people get such digital devices much easier off their hands, if they are not in such a whacking need of them, simply to be able to make money out of it. [Interview F04]

Code 2: Access to Digital Services

In homeless shelters, interviewees had access to the computers in possession of the shelters, and through those devices, they

could get access to the internet. In certain shelters, free Wi-Fi and the option to charge their phones were available.

The majority (6/10) used free Wi-Fi inside and outside of the shelters and looked actively for options of free Wi-Fi. They could afford subscription (3 interviews) or pay-as-you-go facilities (5 interviews) less frequently. In some cases, the interviewees reported that they visited cafes in order to be able to charge their phones or use the internet (3 interviews).

(...) the Wi-Fi is so strong that you don't have to go in and consume something, or if you go in and drink a cup of coffee or water, you get the Wi-Fi password, then sit in front of it on a bench, and it has such a strong signal that you can use it there as well, until it is open. [Interview M07]

Code 3: Gaps in Access to Digital Technology

The interviewees reported both tool supply and network coverage as existing problems. Several interviewees mentioned the need for securing a device (smartphone) or asked about whether there was potential for decreasing the price of subscriptions and pay-as-you-go facilities. The presence of smart benches in public spaces was mentioned in 1 interview, and free Wi-Fi on trams and busses in Budapest was mentioned in another interview.

The computer park and Wi-Fi network coverage in the shelters were not mentioned as problems in the majority of interviews (7/10), and the idea of having more connectors in the building to allow easier charging surfaced in 1 interview.

Some support would be great so that a basic device could be ensured for them. And a separate health network, which is for free. For people who are ill. As there are these crisis helplines and these have green numbers. [Interview F01]

... prices could be reduced (...) and for example such benches could be installed where phones can also be charged. And then you could use the Wi-Fi there. [Interview F03]

It's very difficult, I would say there could be more charging stations. The bigger shopping malls are covered, that's fine, but what if you suddenly notice your phone is dead and you cannot go into any such places, or you are far (from the charging station), and a homeless cannot buy a ticket... How do you go there? [Interview M05]

I would tell you the truth... I'm sure it would be feasible to have free Wi-Fi on busses and low-floor trams. So here, we have Wi-Fi, since this is a shelter but when we go 20 meters further, there isn't any, the network disconnects. [Interview M05]

Theme 3: Usage Patterns

Subtheme 1: Differences in Usage Patterns: Age and Generations

Every interviewee used the internet at a measurable frequency on their own device. The age of the participants ranged from 35 to 69 years. The interviewer did not explicitly ask about

usage characteristics by age, and the topic came up spontaneously in the case of 6 interviewees when talking about attitudes toward novelties.

In several cases, the interviewees mentioned generational differences in usage, characterizing the older generation as less involved in the digital world and less interested in novelties, while younger people were considered to be already born with digital devices, and their usage seemed to be self-evident. In 1 interview, it appeared that if there was individual motivation, then age would not pose a hindrance with regard to usage.

This is a fundamental thing, really, but many don't know, especially the older generation. (...) So, I'm quite digital, but I'm only 40 years old for that matter. We grew up on these devices more or less already. [Interview F03]

(...) I think this is age-dependent, thus generation-dependent. The elderly are okay with their basic phones. When it rings, they pick it up, then put it down. My generation already needs it more, we use it more often and the younger even more, they don't even put it down. [Interview M05]

Subtheme 2: Usage Patterns: Entertainment and Social Connections

Interviewees mainly used the internet for entertainment and maintaining their social relationships. Watching movies, listening to music, reading e-books, and playing phone-based games were also reported. Seven interviews mentioned Facebook and 1 interview also mentioned X (or formally Twitter) as frequently used social media sites. A minority of interviews mentioned information gathering through Wikipedia (1 interview), reading news (1 interview), and online banking (1 interview) as use cases.

I watch movies, and look up e-books, in a topic that I'm interested in. Mostly self-healing, quantum healing and such banalities. [Interview F01]

I had a smartphone, so not only the music, YouTube, Facebook page is important to me, but also Wikipedia, where I can look up everything, or for example, I read a lot about various things, and the disease that I had. This is very important to me. [Interview M05]

Interesting that I also keep in touch with my physician via e-mail. I had for example a CT scan, and then everything worked entirely online. I received my appointment and also the findings online. I also consider this a very positive thing, so that it is also in the cloud, and they can see it, the whole thing is much easier... I just give them my social security card (TAJ-card), and then I tell them what prescribed medication I want to have. So, I consider this absolutely positive. [Interview M05]

Subtheme 3: Usage for Medical Purposes: Information Seeking, Applications, and Wearables

In several interviews, information seeking for medical purposes was reported. For example, interviewees looked up prescribed medications (5 interviews), active ingredients of medications

(4 interviews), medicinal herbs believed to replace certain pills (2 interviews) or foods, and natural materials (1 interview). One interviewee mentioned purchasing a product believed to have medicinal value online on the basis of a Facebook advertisement.

One interviewee in their 30s communicated with the doctor about health problems via email, provided information about their illness and the prescribed medicines online, and used a health app and a step counter. These tools (health app and step counter) were also mentioned by 2 other interviewees, but one of them stopped using the step counting option as they believed it was inaccurate.

I look up the active ingredient of a pill, for example when before chemotherapy certain medicines were prescribed for me, and I looked up what kind of active ingredients they have, what side effects could they have, because a package leaflet is one thing and a real person who already had this experience and took the medicine, and what is their opinion, is another thing. [Interview M05]

I already had this step counting thing, this daily fitness thing. And I remember I had a heart rate monitor in my old Samsung S5, and now I really miss that my current phone doesn't have that anymore. (...) I also use a menstruation tracking app. [Interview M05]

I usually look up online for my partner what kind of cremes and medicines there are ... if they are interested what kind of ingredients the pill has, and due to his blood pressure. [Interview M06]

Theme 4: Solutions for Usage Problems

Subtheme 1: Individual Solutions

We included interviewees in this study who previously stated that they frequently used digital tools and self-evaluated their skills as at least average. The majority of interviewees (8/10) themselves did not mention usage problems, and when they had problems, 1 interviewee asked their family members for help but added that they preferred to solve their problems on their own.

Subtheme 2: Peer-to-Peer Support

It was frequently (6 interviews) reported that the interviewees offered their help to other clients who lived with them in the same shelter if they had trouble around the usage of digital tools or the internet. They solved usage-related problems for their peers, such as registration of SIM cards, activation of pay-as-you-go facilities, antivirus actions for devices, problems around online programs like Facebook and Messenger, and questions around online purchases. These user troubles represented basic problems, and the majority of interviewees (8/10) had the knowledge and skills to solve them.

Last time they wanted to buy something online, and they asked my help in that. (...) Now one of the guys from the shelter came up to me how to activate the SIM card. And then I activated it for them. Such issues are always in need. [Interview F04]

There were some who asked me how to log in, how to register with an email address, how can they make a Facebook profile. Then I helped first to make an email account and then to register with that. (...) I was happy that I could help and they accepted it gladly. And then I saw that they were using it very well, they were glued onto their screens and were happy about it. [Interview M05]

Usually Facebook, Messenger, or when they cannot download a game. And there is an antivirus program on every smartphone with a broom icon but they don't know what that is. So, I tell them, pick it up and swipe with it. Clean it. And then they look at me confused. Okay, give it to me. So, then I do it, and they look. Wow, then they say, it went down to zero. Yeah, and then I say that's the point, not to have anything on it. So there are always things like this. [Interview B09]

Subtheme 3: Institutional Solution: Role of Social Workers

Interviewees did not report institutional solutions aiming at the development of digital skills. In 1 interview, a social worker was mentioned who provided the client with basic information on tablet use. In this case, it was the individual initiative of the social worker and not an element built into the given institution's services.

(...) then the social worker came up to me, and taught me the basics, and then they said that I should now keep pressing the buttons around nicely, and then I'll figure everything out by myself. [Interview R12]

Discussion

Digital Technology and People Experiencing Homelessness

Digital technologies show a general potential for improving patient outcomes. For example, Bruce et al [36] showed that both clinical and patient-centered care outcomes were significantly better with the use of mobile health technology among 2059 orthopedic patients. However, according to a systematic catalog on digital health systematic and scoping reviews, there is less specific evidence on equitable health care (16.7%) [37].

In relation to the homeless population and digital technology, Heaslip et al [26] identified in their systemic review that mobile technology has a measurable health impact on the homeless population directly and indirectly. As an indirect impact, maintaining relations with relatives and friends as well as the outside world through entertainment, movies, and music strengthened their social connectedness and elevated their self-esteem, which in turn can have a positive impact on their personal health [38]. For the direct health impact of digital technology, they found limited evidence, with the main areas being reminders for repeat prescriptions or health care appointments. However, Heaslip et al [26] mentioned that the homeless population appears to consider that digital technology has potential health benefits, mostly in terms of online health information support and appointment reminders.

Our results partly strengthen these findings. The interviewees in our digitally engaged homeless subgroup used their digital tools primarily for entertainment purposes and to maintain their personal relationships. In terms of health care, they used their devices as new channels to reach solutions for their health problems outside the conventional health care system and to search for health-related information. However, most interestingly and most importantly, the majority of interviewees (6/10) shared that this subgroup is supporting their peers in taking up digital skills and is helping them solve their usage- and device-related problems, and this behavior has a lot of untapped potential for widening digital health usage in the homeless population.

Health Care Needs and Personal Experiences

As indicated by the demographic characteristics, older and predominantly male interviewees shared their experiences. Consistent with the results from our previous studies [28-30], the majority of interviewees (6/10) reported multimorbidities [39,40] and having chronic diseases, such as cardiovascular diseases [41], type 2 diabetes, cancer, and permanent injuries. Older age (≥ 50 years) was associated with worse physical health in the homeless population, which was noted in the interviews, as the self-reported health status was regarded as average or worse [19].

In our small sample, there was no mention of mental health problems other than addictions. Previous research found that the ratio of serious mental disorders among people experiencing homelessness in Hungary was very high [42], which is in line with findings from Western countries [43]. Underdiagnosis and undertreatment of mental health problems caused by stigmatization and underperformance of the Hungarian care system might be prevalent among our interviewees as well [44]. Moreover, in line with previous studies, which estimated the prevalence of alcohol abuse at 8.5%-58.1% [45], treated alcohol problems were noted in 4 interviews; however, illicit drug use or treated drug abuse problems were not mentioned. A systematic review found that alcohol abuse is more prevalent in mainland Europe [43].

Issues of Access to Health Care and Digital Tools

Access to primary care is resolved via the care settings of the Health Center of the HCSOM, which includes prescribing drugs, providing basic care services, and referring clients to specialists. In line with previous studies [17,20], the experiences of interviewees with accessing health care were mixed.

When looking at access to digital tools and digital services, in line with previous research, the majority of interviewees (7/10) had smartphones, which are more accessible to people with a low socioeconomic status [24]. The partial accessibility of digital devices and their use as assets in times of need as described in a minority of interviews (2/10) have been mentioned by Heaslip et al [26]. As a need, device supply was primarily mentioned by the participants, and this is in line with our previous study where 21.4% of respondents mentioned lack of a smartphone as the main barrier for not using the internet and 24.1% mentioned that availability of an appropriate device would help them use the internet more [30].

Digital services, such as computers of the shelters, were available to the participants, and in some shelters, free Wi-Fi or charging was also provided. The majority of participants (6/10) looked for free Wi-Fi options outside the shelters as well. One interviewee mentioned the lack of free Wi-Fi on public transport services and the lack of installation of smart banks in Budapest as barriers to usage. Such infrastructural problems were mentioned as causes of nonusage by 7.6% of respondents in our previous study [30]. On the other hand, several interviewees mentioned using the paid services of cafes to charge their phones or use Wi-Fi.

Several interviewees also mentioned the need for a potential decrease in internet service prices or device prices, which is in line with the finding of our previous study where 18.4% of participants said that better access to free Wi-Fi, pay-as-you-go facilities, or data contracts would help them use the internet more [30].

Problems Around Trust

Some interviewees mentioned the feeling of being unwelcome in conventional health care settings, which is in line with previous research [41]. Some of them mentioned difficulties in getting appropriate treatment and a negative attitude from health care personnel, which might negatively influence their desire to seek health care in the future and their overall trust in the health care system, and this might explain their turn away from mainstream health care solutions.

These aspects might include a negative impact on medication adherence and an overall mistrust in mainstream medical solutions, such as taking antibiotics and chronic disease drugs, with a turn to alternative solutions. From the interviews, it was found that managing treatment themselves instead of relying on medical personnel based on their own beliefs without medical evidence was a solution. Moreover, turning to alternative and complementary medical solutions, such as homeopathy, herbal medicine, and Chinese medicine, was a way to express mistrust in conventional care settings, and digital solutions can open up a channel outside of the conventional health care system to reach such alternative solutions.

Mistrust and negative attitudes toward the health care system coupled with the need for understanding health-related language, prescription drugs, and active ingredients were associated with the main health-related use of digital tools and services in the majority of interviewees (8/10).

Age as a Predictor for Usage and Openness

When asked about usage patterns, several interviewees spontaneously shared their views on how age differences matter in usage prevalence, outlining that older generations might be less involved and less interested in novel technologies. Several studies, including our previous quantitative research, support that age is a key sociodemographic variable that has an impact on use [29,30,46,47]. Our quantitative data showed that in access to technology, age did not seem to be a key factor; however, it might be considered as a significant factor when self-evaluating competence in digital literacy skills. This appeared in at least one of the interviews, with the respondent explaining less elevated technological skills with age.

At least three interviews indicated that age was associated with openness toward or willingness to try new technologies, which might be in line with the findings of a representative questionnaire survey (n=1500) on digital health-related knowledge, attitudes, and needs [46]. This survey was completed in 2021 and found that a quarter (26.5%) of individuals aged 65-74 years and a third (31.9%) of individuals aged older than 75 years would not like to try digital technologies in the coming years [46].

Lack of Systematic Support Results in Peer Support for Skill-Related Problems

While interviewees recognized some support from shelters in solving infrastructural and service-related technology issues, there was a perceivable lack of systematic solutions when it came to usage-related problems and digital literacy issues. Only 1 interviewee mentioned that a social worker helped them set up their tablet and navigate through basic usage scenarios.

As we selected interviewees based on at least average self-reported digital health literacy skills and aptitude toward digital technology, with some demonstrating previous educational or professional background in IT services, their less digitally skilled peers turned to them for help.

The majority of interviewees (6/10) provided unintentional peer support in relation to technology usage issues, solved technology-related problems, and provided guidance for future scenarios. Peer support, also in this context, is defined in the literature as a process whereby individuals with lived experiences of a particular phenomenon provide support to others by explicitly drawing on their personal experiences [48]. Intentional peer support works as a formalized framework of this process that is fostered and developed by institutions, while unintentional peer support remains under the radar of institutions. The literature recognizes the potential of peer support and peer support workers, who have the necessary training and provide intentional support to their homeless peers by sharing their lived experiences in different areas of life, and members of this digitally engaged subgroup might show potential for offering peer support in digital upskilling [48,49]. Moreover, anyone considering a comprehensive digital health program for homeless groups in Hungary that concentrates on offering solutions to infrastructure and skill-related problems should take into account the untapped potential of members of digitally engaged subgroups. These individuals, through their elevated trust levels among peers, might provide better outcomes in digital upskilling than official and institutionalized digital health literacy programs. A systematic review found that empowerment and self-esteem in the homeless population increased when working with homeless peers as mentors and educators, and that peer support in general facilitates acceptance of illness and recovery and increases efficacy, social skills, and coping [50].

Strengths

Through the qualitative analytical framework, the characteristics of a unique subgroup of digitally engaged people experiencing homelessness could be explored in a less studied area of digital

health for equitable health care, where systematic mapping of review studies showed notable gaps in evidence [37].

The study aimed to enrich the still relatively small body of research concerning the characteristics, including the digital health-related characteristics, of the homeless population in Central and Eastern Europe. In North America and Western Europe, where the majority of studies involving the homeless population are conducted, the demographic composition of such populations as well as the health care system may differ significantly from Hungarian experiences, with different problems and solutions at individual and systemic levels.

Limitations

Our study has certain limitations. As a qualitative study using in-depth semistructured interviews, the sample size was small, and this should be taken into account when drawing inferences. The study participants represented the urban homeless population from Budapest, Hungary, where socioeconomic conditions might differ from those in the countryside. The recruited homeless people had a living connection to the social infrastructure; therefore, rough sleepers and other people who were not connected to any social initiatives were not represented. The research team exclusively relied on self-reporting of digital tool access and use, and did not attempt in any way to verify these reports (eg, via phone bills, direct observation, and other methods).

In relation to people experiencing homelessness, there is an increased risk of social desirability bias when conducting interviews, meaning that respondents tend to modify their responses in the presence of an interviewer perceived to be in a different socioeconomic and overall social situation than their own [51].

Conclusions

People experiencing homelessness can face many barriers when accessing digital technologies, including lack of appropriate devices, lack of operating infrastructure (eg, free Wi-Fi hotspots), some blind spots regarding digital skills, and a general lack of interest due to the prioritization of other basic life-supporting drives. However, in spite of all these barriers, our previous research identified a digitally engaged homeless subgroup in Budapest, Hungary, whose behaviors, usage, and access patterns were mapped in this study [30].

We found that the majority of participants (7/10) possessed a smartphone and used the often scarce pool of free Wi-Fi and the infrastructural capabilities of the shelters. Based on their articulated needs, various policy recommendations might be formulated for telephone companies and government agencies or support services. Telephone companies may consider subsidy programs to support mobile ownership and data services for this vulnerable population, as well as specific discount packages and more publicly available recharge options, as these would greatly support this group that is often in crisis and need. Government agencies may consider strengthening the infrastructural background of shelters and making free Wi-Fi accessibility an option in more public places, such as busses and piazza places, which could greatly reduce the access issues of this population. Institutional aid for accessing services and

digital tools may also offer a viable option for people experiencing homelessness. A higher digital accessibility of an institution in terms of both infrastructure and digital literacy is associated with a greater likelihood of an increase in the number of digitally engaged people experiencing homelessness.

In terms of usage patterns, digitally engaged people experiencing homelessness use digital tools as an alternative information point beyond mainstream health care channels, which gives them access to check information originating from mainstream health care personnel and to seek out complementary and alternative medical solutions. These might be related to low trust in mainstream health care solutions, which might be enhanced through appropriately tailored comprehensive digital health programs. These programs could include awareness raising programs on trusted online health information sources, digital literacy and health literacy enhancing programs, and other programs to enhance their general trust in evidence-based health and the health care system.

Our most important finding is that digitally engaged homeless individuals have an aptitude for technology, and they are ready

and eager to share their knowledge with their peers. This could elevate them to the role of a mediator between their peers and any potential comprehensive digital health program. Digitally engaged individuals have the trust of their peers, recognize the benefits of digital technology, and are able to provide meaningful help in technology- and usage-related issues. Thus, with appropriate training, they might become tutors for upskilling people experiencing homelessness, building a bridge between their peers and digital technologies as well as digital health ecosystems. These well-informed technologically able peers might also help enhance trust in the general health care system if their peer-to-peer support could be steered toward peer-to-peer recommendations of trusted health information sources via a specific institutional program.

Overall, our previous research showed that digital health services have great promise in community shelters for managing and preventing health issues [29,30], and this study found that digitally engaged individuals might be important for the success of such services.

Abstract

Background: Given the physical health disparities associated with mental illness, targeted lifestyle interventions are required to reduce the risk of cardiometabolic disease. Integrating physical health early in mental health treatment among young people is essential for preventing physical comorbidities, reducing health disparities, managing medication side effects, and improving overall health outcomes. Digital technology is increasingly used to promote fitness, lifestyle, and physical health among the general population. However, using these interventions to promote physical health within mental health care requires a nuanced understanding of the factors that affect their adoption and implementation.

Objective: Using a qualitative design, we explored the attitudes of mental health care professionals (MHCPs) toward digital technologies for physical health with the goal of illuminating the opportunities, development, and implementation of the effective use of digital tools for promoting healthier lifestyles in mental health care.

Methods: Semistructured interviews were conducted with MHCPs (N=13) using reflexive thematic analysis to explore their experiences and perspectives on using digital health to promote physical health in youth mental health care settings.

Results: Three overarching themes from the qualitative analysis are reported: (1) motivation will affect implementation, (2) patients' readiness and capability, and (3) reallocation of staff roles and responsibilities. The subthemes within, and supporting quotes, are described.

Conclusions: The use of digital means presents many opportunities for improving the provision of physical health interventions in mental health care settings. However, given the limited experience of many MHCPs with these technologies, formal training and additional support may improve the likelihood of implementation. Factors such as patient symptomatology, safety, and access to technology, as well as the readiness, acceptability, and capability of both MHCPs and patients to engage with digital tools, must also be considered. In addition, the potential benefits of data integration must be carefully weighed against the associated risks.

Introduction

Background

People with “severe mental illness” (SMI), such as schizophrenia, bipolar disorder, and associated psychotic or mood disorders, experience poorer physical health outcomes, which negatively affects their well-being across the life course and reduces life expectancy by up to approximately 15 years [1-3]. To reduce health disparities, it is crucial to adopt a preventative approach and intervene early. Adolescence or young adulthood presents a key opportunity as this is when most enduring mental health conditions are first diagnosed [4]. Young people with SMI and those at risk of SMI exhibit signs of poor cardiometabolic health and are more likely to engage in behaviors that are detrimental to their physical health; yet, much of this risk is modifiable [4,5].

Mental health care professionals (MHCPs) play a crucial role in supporting the mental and physical health needs of people with psychosis. However, MHCPs face significant barriers to delivering physical health interventions in practice [6]. This includes inadequate time and training in delivering evidence-based physical health interventions, difficulty reaching people in rural or remote areas, financial implications of delivering face-to-face interventions (particularly one-to-one), and limited National Health Service (NHS) resources for implementation [6].

Given these barriers and the increasing demand on the NHS, there is a growing focus on digital lifestyle interventions (DLIs), for example, using smartphones and websites to provide low-cost, scalable, and flexible interventions to promote healthier lifestyles [6,7]. The delivery of DLIs will require behavior changes among MHCPs. One model that can explain behavior change is the Capability, Opportunity, and Motivation–Behavior (COM-B) model [8]. According to this model, MHCP capability and opportunity to perform the behavior will influence their motivation to use DLIs and impact their delivery of DLIs in mental health care (MHC) settings. Capability refers to whether a person has the psychological (knowledge) or physical (skills) capability to perform the behavior. Alongside capability, an individual must have the opportunity to perform the behavior, and this refers to both physical (this includes the environment where the behavior will be performed and resources such as money and time) and social (the behavior of others) opportunity. Both reflective (reflective processes such as beliefs, goals, and values) and automatic (habitual and emotional responses) motivation also influence our behavior. The COM-B model can be used to inform future interventions [8].

Previous research suggests that MHCPs see the benefits of physical activity interventions [9]. However, MHCPs report barriers to implementation such as concerns about patient motivation and safety and logistical concerns on behalf of the patient, such as having equipment, clothes, and space. MHCPs have also reported personal barriers such as low confidence and capability to deliver interventions, lack of time and resources, and the belief that MHC should be a priority [10].

It is likely that MHCP attitudes toward and perceived barriers to using DLIs in MHC settings will vary from those for in-person interventions. According to actor-network theory, technology is not simply a tool or passive instrument that humans use to accomplish their goals [11]. Instead, technology can shape human behavior by creating new opportunities, alleviating constraints, and providing affordances that shape the way in which people think, communicate, and interact. Previous research has found that MHCPs believe that digital tools that support patient self-management would change their own roles and responsibilities [12]. Numerous studies have shown that, while MHCPs see the potential benefits, they are concerned about issues of liability, harm to patients, and lack of training regarding using DLIs [12-14]. As the MHCP role primarily focuses on treating mental health difficulties [15], it is important to explore and compare MHCP beliefs about using digital health for managing symptoms versus delivering lifestyle interventions.

Objectives

Therefore, this study aimed to explore MHCP perspectives, including barriers to and facilitators of using DLIs in MHC settings, with a particular focus on young people. These insights will provide key considerations for the implementation and use of DLIs in MHC settings.

Methods

Study Design

A mixed methods design was used, including a web-based survey and qualitative interviews, to examine the attitudes of MHCPs toward digital health in young people’s MHC. An overview of the aligned findings of the combined survey and interview components of the project has been presented elsewhere [15]. While the previous mixed methods analysis provides a foundation for the research presented in this paper, this paper focuses on presenting the results of an in-depth qualitative examination of all the interview data, presenting the subjective experiences and perspectives of MHCPs regarding digital technology. Using a reflexive thematic analysis, we offered a more comprehensive understanding of subjective factors affecting the barriers and implementation of DLIs in clinical practice beyond the scope of the previous descriptive results to present useful recommendations for facilitating uptake of novel technology in health care settings.

The inclusion criteria were NHS MHCPs (1) working with young adults aged 16 to 35 years with mental illness, including specialist mental health services or in the context of broader primary care, and (2) working with young adults with mental illness for at least 6 months. The exclusion criteria were MHCPs working primarily with eating disorders due to differing treatment needs on nutrition and exercise [16-18]. The COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist was used to ensure a comprehensive and explicit report of the interview process (Multimedia Appendix 1).

Participants

All 13 participants were MHCPs working within NHS services with young adults aged 16 to 35 years, including specialist

mental health services. Purposive sampling was used to recruit potential participants of a variety of occupational backgrounds and years of experience. Participants were recruited through emailed flyers. While interview participants were not reimbursed or rewarded for taking part in the interview, survey respondents were offered the choice to enter a prize draw to win a £50 (US \$62.62) voucher. It was made clear to participants that completing the interview did not increase their chances of winning.

Data Collection

Overview

Semistructured interviews were conducted remotely using Microsoft Teams (Microsoft Corp) and audio recorded with participant consent. The interviews lasted 26 to 79 minutes and followed a topic guide ([Multimedia Appendix 2](#)) developed with input from our Patient and Public Involvement group and research team. In total, 2 researchers (CS and JF) conducted the interviews, which consisted of questions about participants' experience using digital health, the potential use of mobile health and DLIs in MHC, barriers to integration and use, and ways to boost engagement. Interview guides were flexible, using prompts and open questions to encourage participants to talk in depth about their experiences. All interviews were recorded and transcribed verbatim. Participants were assigned pseudonyms to maintain anonymity.

Data Analysis

Interviews were analyzed using a reflexive thematic approach [19-21]. Reflexive thematic analysis involves the researcher reflecting on how their experiences, personal assumptions, and background shape their analysis and interpretation of the data [20]. An inductively orientated experiential approach underpinned by critical realism was used [20]. This means that our themes were generated from the interviewees' direct experiences and observations while also recognizing that their understanding of reality is shaped by social and cultural factors. Critical realism was used as it allows the researcher to analyze participants' experiences while allowing the analysis to be informed by theory. The COM-B model of behavior change [21], which proposes that behavior is defined by our capability, opportunity, and motivation, was used as a theoretical underpinning and a prespecified area of interest. The model was used to identify potential barriers to the implementation of DLIs for young people with mental health conditions and any potential solutions to overcome these barriers.

Thematic analysis is a systematic approach whereby patterns and common themes are identified to describe a data set and understand a phenomenon [19,20]. The 6-phase guidelines by Clarke and Braun [20] were used to guide the analysis. These phases are recursive: (1) transcripts were read and reread so that the researcher (CS) could become familiar with the data, (2) systemic line-by-line coding was conducted to identify common features in the data, (3) codes were reviewed to determine themes, (4) themes were reviewed by 3 researchers (JF, CS, and LH) for homogeneity and heterogeneity to ensure that they were distinctive and coherent, (5) themes were defined and names were generated, and (6) findings were reported.

A primarily inductive approach was adopted with the interviews, but a deductive approach was taken when examining the barriers and facilitators informed by the COM-B model (based on previous research). Interview extracts related to barriers to and facilitators of implementing DLIs were mapped to the components of the COM-B model, whereas an inductive approach was taken for the remaining data. At the time of analysis, the researcher was not familiar with the current literature on digital health and in particular in the context of mental health, allowing them to analyze the data without preconceived themes or experiences.

To reduce the risk of bias, all researchers were involved in the analysis through regular meetings to discuss codes and themes. Themes and subthemes were generated and finalized using the NVivo software (version 12; QSR International) and MindView (version 7.0; Matchware). The team discussed the themes until consensus was reached within the team. During manuscript writing, subthemes with overlap were combined to avoid repetition. The final theme structure presented in the manuscript was reviewed and agreed upon by all coauthors.

Reflexivity

The two researchers who conducted the interviews (JF and CS) do not work in the NHS and made this clear to interviewees who were NHS employees. Both researchers have experience interviewing people on a variety of sensitive topics (self-harm, cancer [CS], and mental health [JF and CS]). All authors have an interest in digital health and promoting physical health in MHC settings. First author CS personally uses digital health apps. These views and experiences may have influenced our analysis; therefore, author CS kept a reflexive journal throughout the study. The author routinely reflected in the journal during data collection and analysis to reduce the possibility of their personal experiences and beliefs biasing their interpretations. A potential influencing factor in the interviews could be attributed to age. Some of the interviewees remarked that they did not have the same familiarity with apps as the interviewer (CS); this assumption could have influenced the views and opinions that participants expressed to this author.

Due to the COVID-19 pandemic, the interviews were conducted remotely using Microsoft Teams. Most participants joined the interviews from their own homes, providing a private setting that potentially fostered comfort and openness. However, working from home could have affected their work mindset and introduced distractions, such as pets, deliveries, or background noises. During an interview held in a private room at an interviewee's workplace, a team member interrupted the participant. While this interruption may have had an impact, it did not seem to alter their perceived barriers, and they continued discussing barriers, including those related to NHS staff, possibly influenced by their senior role. The remote format of Microsoft Teams interviews might have resulted in the interviewer missing out on subtle body language and facial responses, especially in the case of one participant who opted to keep their camera off. Nonetheless, Microsoft Teams provided flexibility, enabling participants to join at their preferred times.

Patient and Public Involvement

The overall study protocol had patient and carer involvement to ensure that all materials were appropriate and the content discussed about patients was appropriate and meaningful. The topic guide was developed using lived experience input. RC is a research fellow at a research unit embedded within clinical services at the Greater Manchester Mental Health NHS Foundation Trust (JUICE Youth Mental Health Research Unit). JUICE consists of academics as well as current practicing clinicians such as ward managers, lead psychiatrists, therapists, physiotherapists, dietitians, occupational therapists, experts by experience, and carers. A weekly consultation is held on the Child and Adolescent Mental Health Services inpatient units, where the topic guide was discussed.

Ethical Considerations

Ethics approval was granted by the University of Manchester Research Ethics Committee (2020-10603-17104) and the Health Research Authority (288734). Participants were briefed on the purpose of the study, and written informed consent was obtained.

Results

Participant Characteristics

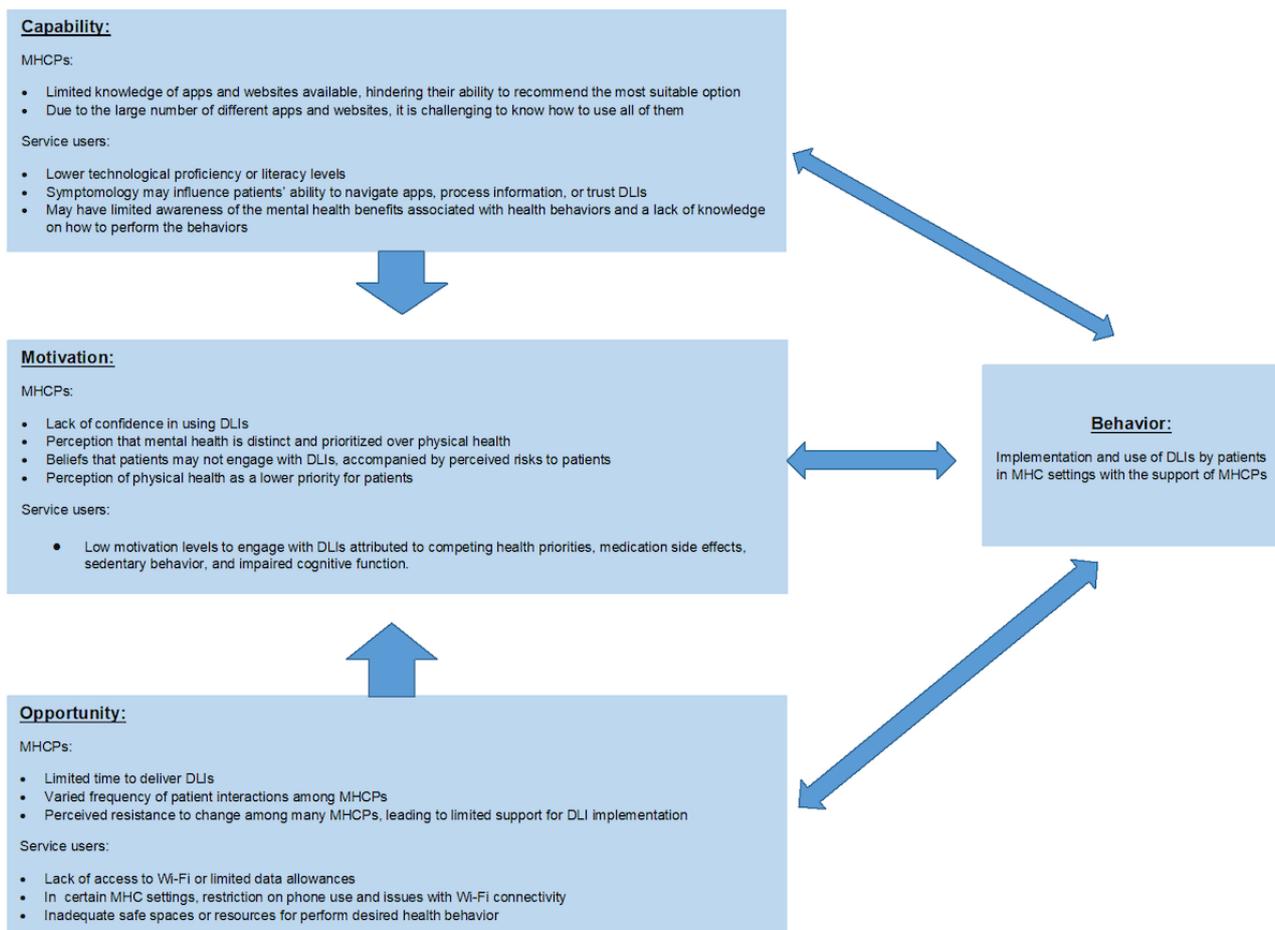

A total of 13 MHCPs were recruited from various MHC settings and roles, including MHC and research nurses (n=4, 31%), trainee psychiatrists (n=2, 15%), support workers (n=2, 15%), occupational therapists (n=1, 8%), physical health support workers (n=1, 8%), service managers (n=1, 8%), operational leads (n=1, 8%), and trainee advanced practitioners (n=1, 8%). Of the participants, 85% (11/13) were female, and 100% (13/13) were White British, with experience varying from at least 6 months to 20 years working in MHC service.

Analysis

Overview

Three main themes were identified: (1) motivation will affect implementation, (2) patients' readiness and capability, and (3) reallocation of staff roles and responsibilities. The themes and subthemes are described in [Multimedia Appendix 3](#). [Figure 1](#) presents how our findings also fit with the domains of the COM-B model [8].

Figure 1. Barriers to implementation of DLIs in MHC using the COM-B model_v2. COM-B: Capability, Opportunity, and Motivation–Behavior; DLI: digital lifestyle intervention; MHC: mental health care; MHCP: mental health care professional.

Theme 1: Motivation Will Affect Implementation

Overview

MHCP and patient motivation was perceived as the largest potential barrier to implementing DLIs in MHC settings. All interviewees felt that it would be important to emphasize the value and benefit of DLIs to patients, whereas acknowledging their potential risk is crucial for implementing DLIs in MHC settings:

I think some of them [MHCP], don't necessarily promote the apps, erm, because of the motivation...it can be quite problematic getting them [patients] to engage. [INT5]

Subtheme 1: Individuals Are Motivated but Others Are Resistant

Most participants had a positive personal view of using digital health in MHC, in particular for young adults. However, some interviewees said that, although they were personally motivated to introduce and implement DLIs in the context of MHC delivery, their colleagues were reluctant to change, which posed a barrier to rolling out DLIs. MHCPs who are unaware of the benefits of DLIs or, for example, who are accustomed to established ways of working, were perceived by interviewees to be more resistant to adopting new practices:

...lots of people don't like change do they, and I think whenever you try and do anything new they'll be somebody that, will have something to say about it. I can't think of any specific kind of negative view of it, other than that, that just, traditional view that, oh it won't work, they won't use it. [INT10]

Furthermore, several participants expressed concerns about time constraints and competing priorities faced by MHCPs. With an already demanding workload, interviewees said that MHCPs tend to prioritize mental health-focused care over physical health approaches or interventions. Interestingly, most people felt that their role was not best suited to the introduction of DLIs due to limited interactions with patients compared to their care coordinators despite being supportive of DLIs and their benefit more generally:

...it's [digital interventions] probably one of those things it's quite a good idea for the whole team to have an awareness of, but maybe, erm, you know, particularly care coordinators who are having the most contact with service users. [INT9]

Subtheme 2: Patients Have Other Priorities

Interviewees perceived low motivation among young adults as a common barrier to engaging with DLIs. Low motivation was often attributed to medication side effects, sedentary behavior, and impaired cognitive function. Many interviewees perceived physical health to be a low priority for patients and that patients' main priority during their involvement with an MHC team was their mental health:

I think it depends on where they're at within their illness and how engaged they are with treatment and especially during those initial phases, it can be quite

problematic, erm, and getting them to...engage. [INT5]

Some interviewees felt that it was important to highlight the link between patients' physical and mental health and how changes to behavior could lead to changes in medication or treatment as well as improving physical and mental health:

Well talk about how, erm, maybe weight changes affect their mental health, how their medication has, the amount of medication that they've had has changed, how their, erm, you know, their diabetes diagnosis was reversed because they engaged in exercise and speak to them about what significance it would be to them, it's not about a size 8 jeans, it's about, I don't need to take as much Clozapine, and plus if I don't take as much Clozapine at night, then in a morning I'm not as knackered. [INT5]

Interviewees also felt that the service setting might influence the uptake of DLIs. For example, young adults in inpatient settings may be hesitant to change due to the various restrictions in place, such as limiting takeaways or access to unhealthier food. DLIs that provided young adults with something such as promoting physical activity in inpatient settings were viewed as acceptable by interviewees. However, DLIs viewed as restrictive, such as those concerning diet or smoking, were assumed as not being well received by patients:

...inpatient mental health unit, erm, you've had so many bits of your identity taken away from you, in terms of like being able to access outside, and, I think, when you do try and have those conversations about, you know, well try and eat a bit healthier, it's gotten very angry really quickly because there's been so much of their liberties taken away, the fact that we try and take away the little things that they do enjoy like, staying in bed, erm, eating junk food, smoking, it, it, yeah, it can be quite a difficult subject. [INT11]

Therefore, these preassumptions regarding what types of DLIs young adults are resistant to may reduce MHCP enthusiasm for undertaking the actions required to implement specific DLIs in inpatient settings. One MHC service that several MHCPs felt could work well to integrate DLIs in was early intervention services:

I think the young, younger people are more likely to use apps and You know when people first present to services, such as early intervention team. Uh, I think that would work very, very well. [INT1]

Subtheme 3: DLIs Need to Be Intuitive and Engaging

To overcome the perceived low motivation of patients to engage with DLIs, MHCPs felt that DLIs need to capture patients' attention and be engaging, which involved being visually appealing, interactive, and user-friendly, particularly due to the patients' age. Gamification, linking changes in behavior to patient-valued outcomes, and intuitive interfaces were perceived as being important in promoting engagement. Simple designs and usability were considered key, ensuring that both MHCPs and patients can navigate through the intervention:

...if you're focussing on young people, I think, I don't really see many barriers, if it's free, and, you know it's easy to use, I think it's just, it'd just be about that initial engagement, that initial kind of, them trying and it being good enough to keep them, er, interested. [INT10]

...anything that's simple, straightforward and just easy to use would be probably the best starting point for now, for us [Mental Health are professionals]. [INT12]

I've never used gamified apps to be honest up, but yeah, it sounds great, It will make the younger people engage. [INT2]

Several MHCPs shared the perspective that involving young adults with a wide spectrum of mental health conditions and literacy skills in the app design process is crucial to ensure both intuitiveness and engagement for patients:

...the important thing would be that if you were gonna design an app to, to genuinely have young people with a variety of mental health conditions, neurodevelopmental disorders, etc, all having input on what it looks like, how it works and how you engage with it. [INT13]

Theme 2: Need to Consider Patients' Readiness and Capability to Use Digital Health

Subtheme 1: Patient Safety

A prominent theme was the need for patient benefit from digital health to outweigh potential risks or harm. Interviewees expressed the need to consider each patient and when was best to introduce DLIs. Initially, interviewees focused on what MHC settings would be the most suitable to introduce DLIs, with mixed views on the appropriateness of implementing DLIs in inpatient settings. On further reflection, the severity of the patients' symptoms rather than the MHC setting was considered most important when deciding on an appropriate time to introduce patients to DLIs:

...people with schizophrenia aren't unwell constantly, so you would use it and if they started to become paranoid or unwell, that's probably when you'd be able to just say, let's just remove it. [INT12]

Concerns for patient safety were raised if DLIs required the young person to self-monitor physical activity or health data. For example, there were concerns that patients might misunderstand and assume that their MHC team was also monitoring their data, potentially leading them to not inform their MHC team of important changes. Alternatively, if health data were integrated and monitored by their MHC team, there were concerns that important data such as irregular heartbeat or reduced smoking while on clozapine could be missed, which could lead to harm:

I'm just thinking about difficulty I'd, I'd, feel terrible. If I had somebody on my caseload as a care coordinator and this information was there and I didn't pick up on it and I didn't notice that and then something happened, it's. Then there's a kind of risk

factor there of Case negligence, maybe potentially, and who's going to be overseeing that. [INT1]

Interviewees were also concerned that DLIs could worsen young adults' mental health symptoms, including paranoia, particularly for those who used phones or wearable devices. MHCPs articulated concerns that the tracking of patients' location and behavior via these wearable devices and phones could intensify patients' anxieties regarding perceived surveillance:

Consideration for people who could be psychotic, paranoid, suspicious, you know, and whether that might increase some of their Symptomatology, illusions or paranoia. You know if they were wearing a watch. For instance, knowing that I had access to that information. [INT1]

MHCPs expressed concerns about potential risks that DLIs could pose regarding social interactions for young adults with psychosis. They were worried about inaccurate or harmful advice, exploitation, or negative interactions. Therefore, ensuring monitoring and moderation of social interactions within DLIs was necessary. However, interviewees also recognized the benefits of social support in boosting engagement:

...you would need some level of moderation in that community, 'cos you don't want unhelpful comments and views and, and unfortunately with online systems you get a lot of that. erm, because people are anonymous...there could be like a positive element of that and it could increase engagement. [INT13]

Subtheme 2: Patients' Capability and Opportunity to Use Digital Technology

Digital health was perceived to be acceptable in MHC, especially among younger patients who were likely to have higher smartphone use. However, symptoms (eg, paranoia), reduced cognitive abilities (partly due to medication), and limited technological skills were seen as barriers to patients using digital technology:

A lot of the younger people are, erm [have technical skills], but, but also even, even the younger people when they're unwell, they have information processing problems. [INT6]

Some MHCPs commented that paranoia may also hinder engagement. To address this, collecting minimal personal data through apps or websites was recommended:

I think just, the simpler the better maybe, you know, not having to gather as, as much information, just going off, you know, erm, individuals who, who can paranoid or, or the barriers, I think it, just something that's simple, that's easy, you know, you're not having to put a lot of data in. [INT7]

Access was a potential barrier as some patients may lack access to phones, data, or apps, especially during periods of psychosis or as inpatients due to restrictions or poor Wi-Fi connections. Interviewees suggested that data-free apps that synchronize to Wi-Fi or apps with lower data requirements might overcome this barrier. To reduce the digital divide, interviewees said that services (ie, the NHS) should provide smartphones, pay for

subscription costs or data network charges, or provide wearables to ensure that recommended DLIs can be accessed fairly:

If something's gonna be effective and there's evidence base into it, I don't think that people should [pay], if it's about health and it's actually gonna reduce our costs in the long term, then it should be free. [INT13]

Theme 3: Integrating Digital Health Will Require the Reallocation of Staff Roles and Responsibilities

Subtheme 1: Technology Changes Our Roles and Responsibilities

Despite attitudes being largely positive, there were differences in interviewees' perspectives on the impact that implementing DLIs into routine care would have on MHCP workload. Some interviewees who felt that their role should mainly focus on the mental health needs of a patient believed that DLIs would increase their workload. They suggested that the care coordinator (case manager) role would be best placed to implement DLIs as they have more patient contact and involvement and, therefore, have the time and a preexisting relationship:

...particularly care coordinators who are having the most contact with service users. [INT9]

In contrast, interviewees in senior or physical health-focused professions viewed digital health as a way to reduce staff workload and enable frequent physical health monitoring (eg, remote blood pressure monitoring), resulting in better patient care; these interviewees believed that it was everyone's role and responsibility to implement DLIs in MHC:

...anything that's from that, the core components of the physical health check that they can input, would save everybody a lot of time and, erm, effort and money and it would also make it much more up to date. [INT10]

Interviewees expressed concerns that the use of DLIs in MHC could affect their interactions with patients. Some interviewees believed that building a strong relationship with patients was crucial and DLIs entail a loss of face-to-face nuances, resulting in difficulties detecting physical symptoms, which in turn would be detrimental to patients' mental health. While some interviewees felt that DLIs may lead to people "becoming more isolated" (INT3), others felt that they would improve access to services for patients, particularly those with social anxieties and those who, due to their younger age, are more comfortable interacting digitally:

...with our cohort who might socially find things challenging and difficult actually a screen is quite familiar to them, so they will often prefer that. [INT8]

Subtheme 2: MHCPs Will Need to Acquire Additional Skills

Interviewees said that staff involvement was crucial for successful implementation of DLIs in MHC settings. However, interviewees recognized that not all staff members have the necessary skills or knowledge to do this. Tailored training, including interactive sessions and MHCPs using the apps themselves, was recommended to enhance confidence,

motivation, and psychological capability to use and recommend digital technology in clinical settings:

There's always room for training I find that interesting to go through it and if I was clinician, finding out what apps there are out there, how we can use them, how we can recommend. [INT1]

One interviewee also felt that digital health education could be provided in health care degrees such as nursing and occupational therapy. Several MHCPs lacked awareness of available apps or websites. To address this, interviewees suggested that the NHS could provide a list of approved apps, improving trust and credibility while improving their knowledge and reducing guilt or personal blame in case of adverse events. Opinions differed on recommending apps without previous experience. Some expressed concerns about patient safety when recommending potentially ineffective or harmful apps, such as exercise apps that result in injury, whereas others felt comfortable if the apps were available to the general population:

...some people, if it's not NHS approved, might be a bit more nervous. I think that's a thing with the YouTube videos as well, like if it's just a person who's put together a, an exercise for somebody to follow, and it's not to do with the NHS, I think it does make people a bit more nervous about engaging people in that, but I personally have done, if, if I feel confident. [INT11]

Subtheme 3: Who Is Responsible for Managing the Risk?

A concern regarding the implementation of DLIs was the issue of responsibility. All interviewees questioned who would be responsible if patients experienced negative outcomes as a result of using digital technology in the context of their health care. A particular concern was related to data monitoring, such as what data MHCPs should have access to and who should monitor them (patients or MHCPs). Interviewees expressed concerns about who was responsible for the oversight of digital data collection, especially if fluctuations in health or changes in behavior were missed. Interviewees wondered about their potential liability and described the guilt that they would feel if important changes in mental or physical health were missed. Some MHCPs strongly believed that data should never be integrated into NHS systems but patients could share and discuss their health with MHCPs if desired, empowering patients to take responsibility of their health:

I was thinking about the patient doing it for themselves rather than anybody having anybody sitting behind the scenes monitoring it. [INT2]

On the other hand, some interviewees who routinely collected physical health data felt that, if DLIs collected data without MHCPs acknowledging or providing feedback in response, this could demotivate younger patients to use apps that track or record behavior:

I think for this kind of age group and even older, you need that, well done, you're doing well there, and not, relentless, I think having a barrier would be if there wasn't any kind of short-term goals that you could say, right we're making progress here, we're

doing well, or this is what you need to work on. [INT8]

...like the feedback, you know, 'cos a lot of the young people that, that we work with on the wards, they really, are seeking time with people and if you can provide that time that's quite focused on something and provide lots of positive reinforcement if something's gone really well, I think it might motivate people to, to get sustained use from an app like that, you probably need somebody who's on your side and really supporting you to use it well. [INT11]

In addition, interviewees believed that young adults with mental health conditions may need support and advice from MHCPs in cases in which they implemented minor changes but did not observe any discernible outcomes, for example, if they made changes to their diet but did not lose weight. To overcome the burden of data monitoring and potential liability, one interviewee suggested implementing automated systems that notify clinicians of changes in heart rate, smoking behavior, and so on:

I prefer the idea of, I think it's a fantastic idea for them [young adult service users] to go away and when they come back and you say, your weight, you've been putting weight on, let's have a look on your app what you actually have been eating, so you can have those sort of discussions with them. [INT6]

Discussion

Principal Findings

The aim of this study was to explore MHCP perspectives, including barriers to and facilitators of using DLIs to support young people with mental illness. To our knowledge, this is the first study to explore MHCP views on using and integrating digital health in MHC for young people. Overall, MHCPs felt that digital health care is acceptable when delivered alongside face-to-face care and has the potential to enhance the current care that patients receive. However, they also identified barriers to implementation, including staff and patient motivation and capability to deliver or use DLIs, concerns regarding patient safety, the digital divide, and the privacy of data.

Relevance to Previous Research and Existing Theory

Overview

Similar to previous research on lifestyle interventions [9,10,22], MHCPs expressed concerns with patient motivation and safety as well as time constraints and staff motivations and capability to deliver interventions. Notably, there were differences in concerns about resource availability as, while there were concerns about insufficient phone data interfering with DLIs, a lack of other resources (such as home exercise equipment, healthy eating ingredients, or staffing and clothing [9,22]) was not commonly raised as an issue in this study. The remote nature of DLIs raised concerns about missing important data, and key considerations for implementation included ensuring the credibility and trustworthiness of the apps or websites used in DLIs, prioritizing patient safety, and effective data monitoring.

In some cases, MHCPs may differentiate between the promotion of physical health and their core responsibilities. A decreased enthusiasm among MHCPs for addressing physical well-being may be tied to factors such as apprehension toward assuming personal responsibility and diminished patient motivation [10].

Our findings were in line with actor-network theory [11]—MHCPs did not perceive the implementation of DLIs as an additional resource to use. Instead, they felt that the implementation of DLIs would change their roles, bring new risks to patients, and affect rapport. However, a recent study exploring the views of patients with SMI on digital health found that they also believed that such technologies could change the relationship with MHCPs but in a positive way by empowering them to manage their health and providing a source of help other than their health care providers [18,23]. They also valued the ability to self-monitor and share their progress or behavior with their MHCPs to obtain additional support or positive feedback [23]. These results are also in line with those of broader digital health implementation studies suggesting a need for support for patients and clinicians as well as systems-related issues such as regulation, workflow, and safety [24]. Our findings also fit with the domains of the COM-B model [8] (Figure 1). Barriers identified from the interviews related to capability, opportunity, and motivation, along with potential solutions to overcome these barriers generated by the researchers, are presented in Table 1. The potential solutions were then mapped to potential intervention functions (broad categories to change behavior), and these potential barriers and solutions are discussed in more detail in the following sections.

Table 1. Potential problems and solutions for the implementation of digital lifestyle interventions (DLIs) in mental health care settings.

Domain and problem	Solution	Intervention function
Capability		
Patients may have poorer digital literacy and skills to use technology or phones (perceived as less of an issue for younger populations)	Instructions on how to effectively use phones and apps	Education
Symptoms that may limit patients' cognitive ability to use digital technology (eg, side effects of medication)	Introduce DLIs only when patients have the mental capacity to consent	Restriction
MHCPs ^a do not know which apps are available and effective and how to use them	Training on how to find and use apps and knowledge sharing within clinical teams	Training or education
Opportunity		
Patients not having access to phones, internet, or data	Provision of phones, payment for data and wearables, and use of apps that are usable offline and resynchronize or update once connected to Wi-Fi or data	Enablement or environmental restructuring
Cost of wearables, data, and app subscriptions	Provision of wearables, NHS ^b covering the cost of app subscriptions, and having an iPad or device that can be used by an entire inpatient ward or service	Enablement or environmental restructuring
Restrictions (eg, no phones and no space) and restricted use or functionality when in inpatient units	Having a shared device on the ward or having supervised access to use the app and being shown how to use it before discharge	Service provision
MHCPs do not have the time to deliver interventions	Peer coaches or digital navigators to help patients install apps and deal with issues	Environmental restructuring
Integrating health data to ensure patient safety	Automated notifications if there are high risks or behavior changes that need to be addressed (ie, changes in smoking on clozapine)	Enablement
Secure storage of data	Improvement in the current technology infrastructure of the NHS to allow app data to be securely stored on the system	Enablement
Motivation		
Patients having low motivation	To boost motivation, use rewards, games, self-monitoring of behaviors or health outcomes, and provision of feedback	Incentives
MHCPs lack confidence with digital technology	Training and education and having regular drop-in clinics to problem solve any issues	Training
MHCPs' competing priorities (focus on treating mental health)	When implementing DLIs, services will need to consider which MHCP roles would be best to implement this and could use individual or service-based targets regarding delivering DLIs	Incentives or coercion
MHCP believes that patients do not want to change behavior	Involve patients in the integration of DLIs; this will demonstrate that patients are willing to use DLIs	Persuasion
MHCPs do not see the benefit of digital interventions	Educating MHCPs on the benefit of treating physical and mental health together and how digital health can play a role in this	Education

^aMHCP: mental health care professional.

^bNHS: National Health Service.

Capability

MHCPs voiced uncertainties about their own confidence and ability to effectively deliver DLIs. According to our previous work, MHCPs have limited opportunities to use DLIs in their current role [15], and this is consistent with current literature [13,25]. This may have led MHCPs to perceive a lack of psychological capability (knowledge) to recommend and use apps. Therefore, appropriate training is required, such as interactive training sessions that allow MHCPs to trial various apps and websites, thereby boosting their self-efficacy (the

belief in their ability to perform the behavior) and motivation [26]. Alternatively, some MHCPs suggested that participating in DLIs themselves could enhance their motivation. This notion is supported by recent research demonstrating that MHCPs who actively participated in exercise were more inclined to encourage its adoption among inpatients [10].

A lack of knowledge of apps available was perceived as a barrier. MHCPs felt that receiving a list of approved apps to recommend would reinforce the credibility and trustworthiness of the apps, remove personal liability, and improve their

knowledge about what is available. Interestingly, very few MHCPs were aware of organizations such as the Organisation for the Review of Care and Health Apps or SilverCloud, which provide a list of NHS-approved apps. Awareness of approved and endorsed apps could reduce the burden on MHCPs in selecting appropriate apps for patients. For example, the MINDapps database allows users to search for mental health apps using specific criteria and provides a description, a rating, and reviews of each app.

MHCPs emphasized the need for considering the clinical presentation of young adults with a mental health condition before the initiation of DLIs and continuously monitoring it should any clinical deterioration occur. They stressed the importance of evaluating symptom severity and diagnosis, with particular care taken for individuals with eating disorders (when recommending diet or physical activity interventions). The focus was on prioritizing patient safety and avoiding potential harm while acknowledging that symptom severity influences patient engagement and motivation regarding physical health interventions. In addition, patients may have limited technology skills or literacy and may need additional support or training on how to use apps [27]. Promisingly, previous research [28,29] has shown that individuals who are less familiar with DLIs can use them after minimal training or with support from peer coaches. Incorporating peer coaches to train and support patients could help lighten the workload burden on MHCPs and contribute to reducing the digital divide [30].

Opportunity

Competing interests and limited time, limited patient contact, and inadequate technology infrastructure in the NHS were perceived as barriers to implementing DLIs in MHC settings for MHCPs. This was in line with a recent study that found that MHC settings lacked effective integration of digital technologies [31]. The study also found significant differences among MHCPs regarding whether it falls under their role to implement digital MHC [31]. Therefore, ensuring successful integration of DLIs in MHC requires a thoughtful evaluation of their alignment with existing services, restrictions in inpatient settings, the optimal MHCP role or roles to deliver DLIs, and ways to minimize unnecessary burden on MHCPs.

One solution alongside improvements in technology infrastructure is new MHCP roles dedicated to implementing DLIs and monitoring patient data in MHC settings via the digital navigator pathway [30]. In addition to alleviating burdens, digital navigators could provide feedback to patients on their data. Berry et al [32] discovered that patients expressed a keen interest in engaging with MHCPs to review digitally collected outcome data related to their mental health. This notion was mirrored in this study, with MHCPs emphasizing the need for feedback on health data to gain deeper insights into causal links between behavior and health or to underscore the effectiveness of subtle changes that might take time to be realized more broadly. Although concerns were expressed about collecting and monitoring health data, there are several benefits to using near-real-time data—they can improve the quality of care received, detect health deterioration earlier, and reduce staff demands through more efficient monitoring [33-35].

In contrast with other research exploring MHCPs' views on digital health for the self-management of severe mental health conditions [32], we found that access to phones was not perceived as a barrier, likely due to the young age of the patient population (18-35 years) and increase in mobile phone ownership in the last decade [36]. However, limited data and app subscriptions were perceived as significant barriers. Staff felt that the NHS should provide phones and wearables and cover the cost of app subscriptions and data allowance. If the NHS is to cover app subscriptions and data allowance, the cost-effectiveness of DLIs needs to be considered to reduce the digital divide [30,37,38].

Motivation

In line with previous research, staff were reluctant to promote physical health [10,39,40] because it was perceived as not part of their role. MHCPs also lacked confidence in delivering DLIs and perceived that young people with mental illness have other priorities than their physical health and that risk of harm to patients may outweigh potential benefit. This perceived distinction between physical and mental health needs to be addressed through wider changes in education or service provision to highlight the need to take a holistic approach and treat mental and physical health concurrently [10]. Staff were particularly reluctant to implement DLIs for young people in inpatient settings, where the environment may be more unpredictable and access to technologies may be restricted in some cases. Furthermore, MHCPs felt that young people may be difficult to engage in this environment due to feeling out of control and to restrictions on movement [41]. However, introducing DLIs may provide patients with the autonomy to look after their own physical health when they feel out of control [42] as well as the potential therapeutic effects from physical activity [43]. To address MHCPs' concerns regarding professional liability and patient safety, clear guidelines and frameworks will need to be in place. MHCPs also stressed the significance of engaging both MHCPs and patients in the development and implementation of DLIs in MHC, believing that this collaborative approach can enhance overall buy-in from MHCPs and patients alike.

Strengths and Limitations

A strength of this research is the potential real-world impact on patient care by providing a rich understanding of MHCP experiences and clinical recommendations to implement digital health in MHC settings. Our sample comprised primarily White British and female individuals; this means that the findings may not be transferable across cultures, gender, and ethnicities. As with all qualitative research, this study was shaped by the researchers' personal experiences and views stemming from their own use of digital health and views on DLIs. A reflexive approach among the research team reflecting on the researchers' personal experiences, assumptions, and perspectives was used throughout the research process.

Recommendations for Implementation

We make 5 recommendations based on our findings. First, clear guidelines for recommending apps, handling data, and monitoring safety are needed. These guidelines should be

developed with stakeholders, patients, and MHCPs to ensure that their concerns and needs are addressed. Second, DLIs should be coproduced, to some extent, with their intended end users to ensure that they are appropriate, engaging, and user-friendly and with those who will be delivering the DLIs to ensure that MHCPs have the skills and these steps may lead to better engagement. While coproduction of DLIs could involve full cocreation of bespoke technologies, this may not always be required, and instead, coproducing the way in which an existing technology is implemented in MHC and provided to patients could be sufficient. Third, to boost MHCPs' psychological capability and skills in using digital technology, training should be provided. This training could be provided by colleagues who were involved in implementing DLIs to gain clinician buy-in or as part of their professional training, which could lead to increased adoption, better implementation, and improved outcomes for patients. Alternatively, the delivery of this training by patients could help dispel certain preconceived notions, such as the belief that service users may be unable or unwilling to effectively use apps. Fourth, MHCPs need to be made aware of evidence-based digital resources available to them. Finally, a patient-centered approach should be used when implementing DLIs that considers patients' current symptomatology, particularly regarding paranoia, and clear criteria should be set to reduce any potential risk.

Future Research

Areas for future consideration toward real-world implementation are (1) the provision of apps, data, or phones to reduce the digital divide; (2) the practical, ethical, and security issues regarding the collection and monitoring of health data; and (3) which MHCP role would be best to implement DLIs or whether a new role is required. First, bridging the digital divide is crucial, and we need to ensure equal opportunities for those with mental health conditions to engage with DLIs. Therefore, future work needs to determine the preventative cost and impact of providing DLIs in MHC settings, focusing on patients' safety, efficacy,

the quality of care received, and the impact on patients' physical health and their use of other health services. Second, it is important to determine the parameters for data collection. This includes working to determine the optimal type and frequency of health or behavior data and how this can be applicable beyond research purposes and actually become clinically useful for improving patient outcomes. In addition, there is a need to address the ethical considerations surrounding data access in clinical settings, ensuring that patients are able to provide informed consent and outlining what happens when patients lose the capacity to provide informed consent. Finally, further efforts are required to establish whether MHCPs can adequately deliver DLIs in their current roles or whether the development of a new role is necessary to maximize the effectiveness of DLIs in MHC settings. In summary, future research is required to examine the sustainability and cost-effectiveness of the implementation of DLIs, the optimal times and means for introducing DLIs to patients, and how this can be tailored to suit the individual needs of people diagnosed with a mental health condition.

Conclusions

Implementing lifestyle interventions for individuals with SMI is imperative, and the incorporation of DLIs may overcome some of the barriers faced by in-person interventions. Alongside this, implementation during the early intervention period could present a pivotal opportunity for timely approaches to preventing physical comorbidities from arising. The findings from this study suggest that, while digital health has the potential to enhance MHC and the quality of care that patients receive, there are important concerns that MHCPs hold that need to be addressed when considering implementation. Efforts are required to work with patients, MHCPs, and other stakeholders to identify appropriate content and delivery of DLIs, along with the types and content of training required to facilitate their implementation in routine clinical practice.

Acknowledgments

The authors would like to thank all the mental health care professionals who participated and helped recruit participants for this study. This study was funded by the University of Manchester Presidential Fellowship (P123958) and a UK Research and Innovation Future Leaders Fellowship (MR/T021780/1). SB is funded by a research professorship (NIHR300794).

Data Availability

Data sharing is not applicable to this paper as no data sets were generated or analyzed during this study.

Authors' Contributions

JF, RC, JS, and SB developed the study design. JF supervised the study. CS and JF collated and analyzed the data. CS, LH, and JF discussed the themes. CS and JF wrote the manuscript. JF, SB, LH, RC, and JS provided substantial input throughout the development and writing of the manuscript.

Conflicts of Interest

JF has received honoraria and consultancy fees from Atheneum, Informa, Gillian Kenny Associates, Big Health, Nutritional Medicine Institute, ParachuteBH, Richmond Foundation, and Nirakara independent of this work. SB is the director and a shareholder of CareLoop Health Ltd, a spinout from the University of Manchester to develop and market digital solutions for remote monitoring using smartphones for mental health conditions (currently, schizophrenia and postnatal depression). JT is the editor of JMIR

Mental Health and is on the scientific board of Precision Mental Wellness; however, this is unrelated to this work. The remaining authors (CS, RC, and LH) declare no other conflicts of interest.

Abstract

Chatbots are increasingly being applied in the context of health care, providing access to services when there are constraints on human resources. Simple, rule-based chatbots are suited to high-volume, repetitive tasks and can therefore be used effectively in providing users with important health information. In this Viewpoint paper, we report on the implementation of a chatbot service called Ask Anxia as part of a wider provision of information and support services offered by the UK national charity, Anxiety UK. We reflect on the changes made to the chatbot over the course of approximately 18 months as the Anxiety UK team monitored its performance and responded to recurrent themes in user queries by developing further information and services. We demonstrate how corpus linguistics can contribute to the evaluation of user queries and the optimization of responses. On the basis of these observations of how Anxiety UK has developed its own chatbot service, we offer recommendations for organizations looking to add automated conversational interfaces to their services.

KEYWORDS

chatbots; anxiety disorders; corpus linguistics; conversational agents; web-based care

Introduction

In the context of developing technologies, many businesses and services are turning to automated systems to provide users with information and accessible customer service. Among such tools, we find natural language processing systems, such as chatbots, that act as conversational interfaces, typically in lieu of interactions with human professionals. In health care, chatbots have a meaningful role to play, alongside other provisions, in increasing access to services, particularly in instances where there are restrictions in accessing face-to-face services [1,2]. Medical chatbots are already being used to provide and elicit information, create patient records, and discuss the results of clinical tests [3]. Furthermore, as Amiri and Karahanna [4] argue, health chatbots were shown to be particularly valuable in periods of quarantine as a response to the COVID-19 pandemic, in that “[t]heir scalability, wide accessibility, fast

information dissemination, and substitution for in-person contact provide the functionality required to address the capacity expansion, social distancing requirements, and quick accurate information transmission needs of the public health response.” Ultimately, chatbot tools and similar automated systems can make an important contribution to the provision of health information and support in the context of time and resource restraints.

There is a wide range of capabilities demonstrated in the deployment of conversational interfaces of varying complexity, from rule-based chatbots that produce prewritten responses based on recognizing programmed terms and phrases to embodied conversational agents manifesting as a computer-generated avatar and smart conversational interfaces such as Apple’s Siri or Amazon’s Alexa [1]. Nevertheless, simple conversational agents are increasingly used in executing tasks without the need for human involvement, including

booking appointments, purchasing merchandise, ordering food, and sharing information [5].

Research has shown that users respond positively toward the perceived convenience of medical chatbots, showing appreciation for swift information retrieval as an alternative to delays in scheduling a consultation, queuing in a phone service, or waiting for an email response [3]. There is wide acceptance of automated systems providing general health advice [2]. Furthermore, there are indications that computer services can reduce perceived stigma, in that users are more willing to disclose details about their health concerns to an automated system on the basis that they are regarded to be more trustworthy and nonjudgmental, reducing the potential for embarrassment [6,7]. In the mental health domain, chatbots and other kinds of conversational agents have been shown to assist in the diagnosis and reduction of symptoms among individuals with major depressive disorder, promote adherence, provide cognitive behavioral therapy, and cultivate a stronger therapeutic alliance compared with users' interactions with a clinician [7].

This study details the development and learning from the implementation of a chatbot service through the website of the mental health charity Anxiety UK, the largest national charity in the United Kingdom to offer support for anxiety disorders. The charity has created a chatbot service called Ask Anxia to complement its other support and information services. In this study, we summarize the patterns of queries submitted to the Ask Anxia service after approximately 18 months of its activation using procedures from corpus linguistics, which involves using software tools to compute frequency-based measures of naturally occurring language data [8]. In addition, we review the quality of Ask Anxia's responses based on manual coding. We offer some reflections on the development of the Ask Anxia service as "lessons learned," with the intention that these will be instructive to others seeking to incorporate a conversational agent into their provision of information and support.

Anxiety UK and Ask Anxia

Anxiety UK was established in 1970 and provides a wide range of support services and information for those affected by anxiety, stress, and anxiety-based depression. Anxiety disorders are characterized by excessive worry and fear [9] and are included among the "Common mental disorders" that are recorded as becoming increasingly prevalent in the United

Kingdom [10]. The charity supports individuals from all over the United Kingdom and, in some cases, the rest of the world and has recently led on the development of an informal global alliance of not-for-profit anxiety organizations. Anxiety UK has a strong service delivery arm offering support via their helpline, therapy, peer support groups, and anxiety management courses. Most of, if not all, its volunteers, staff, and trustees have some experience of anxiety disorders. Anxiety UK states through all its communications, including the chatbot service, that it does not provide crisis support and directs those in need of such support to urgent care services such as the National Health Service and the charity, Samaritans.

Anxiety UK introduced an automated chatbot service, Ask Anxia, with the principal aim of offering an out-of-office-hours service to users, helping them to navigate more quickly to information that was already available, for example, through Anxiety UK's web pages. Furthermore, the Anxiety UK team found that a high number of user queries received by phone or email concerned administration issues, and so, providing such information through an automated chatbot was seen as a way to release staff members and helpline volunteers to attend to other responsibilities that demanded more critical and engaged attention, including providing real-time interactional support via the helpline. Anxia is now a registered trademark that includes but is not limited to computer and application software provided by Anxiety UK as part of their mental health services.

Ask Anxia is a simple, pattern-matching chatbot that has been programmed to recognize certain stimuli (specific terms or phrases) and generate a response, which has been composed by the Anxiety UK team. At the time of writing, Ask Anxia had a content bank of 315 unique responses that has been developed and refined since the service has been operational, and the Anxiety UK team continues to monitor these response options based on the range of queries that users submit. An overview of the categories of responses is provided in Table 1, indicating the types of terms that Ask Anxia has been programmed to recognize in user queries.

Ask Anxia was launched in the beginning of July 2021, and we have applied procedures from corpus analysis (discussed in the Developments section) to 56 weeks' worth of anonymized, aggregated user queries submitted to the service (up until the end of July 2022). This amounted to 14,359 queries consisting of 139,286 words.

Table 1. Recurring themes in queries to Ask Anxia and examples of terms used to determine a response.

Theme	Examples of pattern-matched terms
Request for help	help; support; advice; guidance
Looking for information on a specific anxiety type	GAD; health anxiety; OCD; PTSD; emetophobia; phobia
Physical symptoms	headache; chest pain; breathing; appetite; nausea; feel sick; dizzy
Psychological symptoms	intrusive thoughts; negative thinking; overthinking; constant worry
Information on a service	therapy; group; course; class; counselling; CBT; EMDR; resources
How to access a service	membership; cost; referral; book; sign up; join
Wanting to connect	talk; human; chat; agent
How to support others	family; partner; son; daughter; child; colleague
Getting involved with Anxiety UK	volunteering; approved therapist; fundraising; donate; placements
Diagnosis	do I have anxiety; diagnosis; symptoms
Medication	antidepressants; tablets; medication
Coping techniques	can't cope; what can I do; panic; now; thoughts; relax; sleep
Location	in person; areas; UK; Europe; face-to-face; online
Crisis	suicidal; self-harm; die

We recognize that there are important ethical considerations pertaining to the data, given that queries submitted to the Ask Anxia service are highly personal and relate to individuals' well-being. In the privacy notice that is posted on the Anxiety UK website, users are informed that interactions with Ask Anxia are reviewed as part of the procedures for improving the quality of the service and that these may be shared with third parties for the purposes of research. Participants are discouraged from including personal information in their queries, and any such information that appears in the original message has been redacted. To protect the personal experiences of those who have accessed the service, we have provided generic examples, where cited, to demonstrate the interactional dynamics between constructed user queries and Ask Anxia's (authentic) responses. Reported figures for word frequencies are based on original user queries. As part of a more recent update to the service (July 2022), a message encouraging users not to disclose personal information (such as name, address, and place of work) was added to the Ask Anxia header to ensure that this is visible. Furthermore, such information does not inform Ask Anxia's pattern-matching programming, and so, it will only hinder the identification of an appropriate response.

In addition to reporting commonly used terms and phrases, we refer to the quality coding carried out by the Anxiety UK team, which is explained in the next section. Our study, then, offers a critical evaluation of the contribution of the chatbot Ask Anxia to Anxiety UK's wider provision of services and helps us to understand the general patterns of what visitors to the site collectively seek, in terms of information and support. In the next section, we summarize the insights that we have gained through developing Ask Anxia's programming, as the service has evolved over time.

Developments

Overview

In this section, we summarize the developments that have been applied to the Ask Anxia service based on observations of user queries, including where potential misunderstandings in queries asked by users arose. We present these developments as the lessons we have learned through reviewing the various updates that have been applied to the service since its launch, which are likely to be informative to those looking to implement similar tools. The continued monitoring of the service has contributed to its optimization and generated insights into user expectations. The time stamps for user queries indicate that 57.2% (8213/14,359) of the queries were submitted outside of Anxiety UK's office hours (9:30 AM-5:30 PM), demonstrating that the Ask Anxia service is used when other contact services, such as the helpline, are closed. Indeed, one of the earliest modifications to Ask Anxia, in August 2021, was to remove the cap on how many queries it responded to, given its popularity.

Updates Based on Frequent Terms in User Queries

The pattern-matched terms presented in [Table 1](#) were largely informed by the Anxiety UK team's own long-standing experiences of working with people seeking support for their, or a loved one's, experiences of anxiety. Of course, the queries submitted to Ask Anxia provide further indications of what users seek from the service. As such, alongside the Anxiety UK team's expert judgment, procedures from corpus linguistics can be drawn on to help identify topics and terms that are commonly cited by users, which can potentially highlight important areas for extending the existing information provision.

Corpus linguistics refers to a set of procedures for making quantitative and qualitative observations of the patterns of natural language use and can straightforwardly tell us, by way of a wordlist, for example, what the most common terms in our data are and how often they occur. We used the corpus analysis

tool #LancsBox [11] to examine the user queries. Researchers have found, however, that because of how the English language is structured, often the most common words largely remain the same across data sets (typically, *I, the, you, and, it*, etc). Indeed, the 5 most frequent terms occurring in the user queries of the Ask Anxia service, were *I, to, a, and, and hi*. As such, corpus linguists have developed the concept of keyness, enabling us to determine which words appear in our data more frequently, to a statistically significant degree, when compared with a corpus of larger or equal size [8]. A keyness analysis of the queries submitted to Ask Anxia through comparison with a 10

million-word corpus of general English spoken language, the British National Corpus 2014 [12], identified the keywords that are particularly characteristic of the language used by contributors in this context. The statistical measure used in this case was log likelihood, which established a confidence score indicating that the observed differences are not the result of chance. A threshold value of 15.13 was applied, which equates with a *P* value of <.001. The top 20 keywords are shown in Table 2 and ranked according to log likelihood value (not reported).

Table 2. Keywords in user queries to the Ask Anxia service (n=139,286).

Rank	Keyword	Frequency, n (%)
1	anxiety	2461 (1.77)
2	hi	2670 (1.92)
3	help	1588 (1.14)
4	hello	1332 (0.96)
5	yeah	13 (0.01)
6	am	1123 (0.81)
7	anxious	525 (0.4)
8	therapy	451 (0.3)
9	my	2358 (1.69)
10	panic	373 (0.3)
11	support	411 (0.3)
12	im	302 (0.2)
13	membership	310 (0.2)
14	struggling	334 (0.2)
15	i	7805 (5.6)
16	ok	259 (0.2)
17	how	1370 (0.98)
18	oh	47 (0.03)
19	feeling	394 (0.3)
20	can	1606 (1.15)

What is clear from the keywords is the topical focus on *anxiety* and the prevalence of appeals for *help* and *support* on the basis that users are *struggling, feeling anxious*, or experiencing *panic* (attacks), for instance. We can also see that queries are typically written in the first person (*I, my, and im*), take a question form (*how* and *can*), and have a relatively informal style (*hi, yeah, ok, and im*), that is, consistent with the instant messaging-like format through which users interact with Ask Anxia.

The prevalence of the terms *help* and queries about *therapy* and *membership* indicate that the Anxiety UK team had largely anticipated the themes most often captured in user queries, as indicated in Table 1. Nevertheless, the recurrence of particular terms, including at specific moments, has informed the continued refinement of Ask Anxia's responses and the information that is made available through the website. For example, in the week beginning September 13, 2021, keyness analysis showed that there was an increase in references to *fear*

and *needle*, which coincided with booster doses of the COVID-19 vaccine being made available (to certain groups) and vaccines being approved for 12- to 15-year-olds, in anticipation of a new school term. Subsequently, the terms *fear* and *needle* appeared much more frequently in user queries. In response, Anxiety UK produced specific information concerning COVID-19 and related vaccines.

The Anxiety UK team has continued to extend Ask Anxia's response options since it was launched in July 2021. In addition, because of identifying themes arising from user enquires, the team has carried out the following activities:

- created factsheets specifically on perinatal anxiety, peri- and postmenopausal anxiety, and negative thoughts and catastrophizing
- created additional web content such as adding a do-it-yourself self-diagnosis section to the "About Anxiety"

page, extending the list of associated symptoms, explaining additional types of anxiety disorder such as dermatillomania, and adding further detail to the process of becoming a volunteer

- written and posted blogs on the topics of older people and anxiety, high functioning anxiety, highly sensitive people and anxiety, work anxiety, anxiety and appetite, autism and anxiety, anger and irritability with anxiety, returning to work post lockdown, and placements for students
- added entries to the frequently asked questions section relating to costs and arrangements for therapy
- extended member benefits, including researching the provision of fidget toys and fidget jewelry

As the updates have been informed by recurring user queries, we can expect that they will be of value to users generally, and by linking the updated information to Ask Anxia’s responses, a greater number of queries can be addressed automatically, out of hours and without the need for human intervention. Being able to identify trends in information-seeking requests has enabled Anxiety UK to respond operationally and strategically to meet the needs of its beneficiaries.

Quality Coding

Each week, the Anxiety UK team manually coded a sample of Ask Anxia’s responses to monitor quality, which we have labelled Good, Okay, Bad, or Puzzled. On average, the Anxiety UK team would code 155 queries per week (ranging between 0 and 408). Good responses provided the appropriate information based on the query and constituted the response option that the human coder would have selected. The following example shows how Ask Anxia responds to the mention of “social anxiety” and directs users to the appropriate information:

Details about social phobia/social anxiety can be found here [link provided]

Responses coded as Okay were not necessarily the optimal response option but were still topically relevant. For instance, in the case of a user posting a query that indicated that they wanted to talk to someone about dealing with anxiety, a human reader is likely to recognize the importance of talking to *someone*, whereas a response from Ask Anxia, which would subsequently be coded as Okay, might respond to the mention of anxiety as follows:

We provide a wide range of services and information for those dealing with anxiety, stress, or anxiety-based

depression. Check out our homepage as a start here: [link provided] to see our calendar of upcoming events and our latest news.

In this instance, the user is still directed to information that is likely to be useful to them, even if this was not the primary purpose of their query. Where this points to a potential recalibration of the service is that Ask Anxia was already programmed with a response that more directly attends to the question of speaking with a (human) member of the team.

Bad responses appeared when there was misalignment with what the coders, and we, can perceive as the user’s intended meaning, with Ask Anxia generating an irrelevant or inappropriate response when a more pertinent option was available. For example, following a query that mentioned “joining,” that is, membership with Anxiety UK, Ask Anxia generated the following response pertaining to joining a webinar:

You can book on to our next webinar here: [link provided]

Again, reviewing the cause of the misalignment highlights ways in which Ask Anxia can be improved.

Finally, certain responses are generated when a more specific alternative, relating to the topic or passage of interaction, is not available, such as:

Sorry, I am not sure how to answer that, do feel free to use our website search bar which may find the answer for you or contact our team directly; we are open Mon-Fri 09:30-17:30 (excluding bank holiday) and our contact list can be found here: [link provided]

Such responses were coded as Puzzled.

Of the 14,359 queries, 8669 (60.37%) were subject to quality coding, and the distribution of these according to the different quality labels is shown in [Table 3](#).

The quality coding figures provided in [Table 3](#) indicate that Ask Anxia generally performed well, providing a Good response in two-thirds of cases. Furthermore, we can see how this coding was applied weekly, given that the Anxiety UK team made adjustments to Ask Anxia’s response options based on what they observed in their coding. [Figure 1](#) indicates how the queries were coded between October 2021 and December 2022, showing the proportion of Ask Anxia responses that received the codes Good, Okay, Bad, and Puzzled.

Table 3. Number of queries coded according to each quality code (N=14,359).

Code	Queries, n (%)
Good	5801 (66.92)
Okay	911 (10.51)
Bad	1537 (17.73)
Puzzled	420 (4.84)

Figure 1. Quality coding of Ask Anxia responses as a percentage during each week from September 27, 2021, to December 26, 2022.

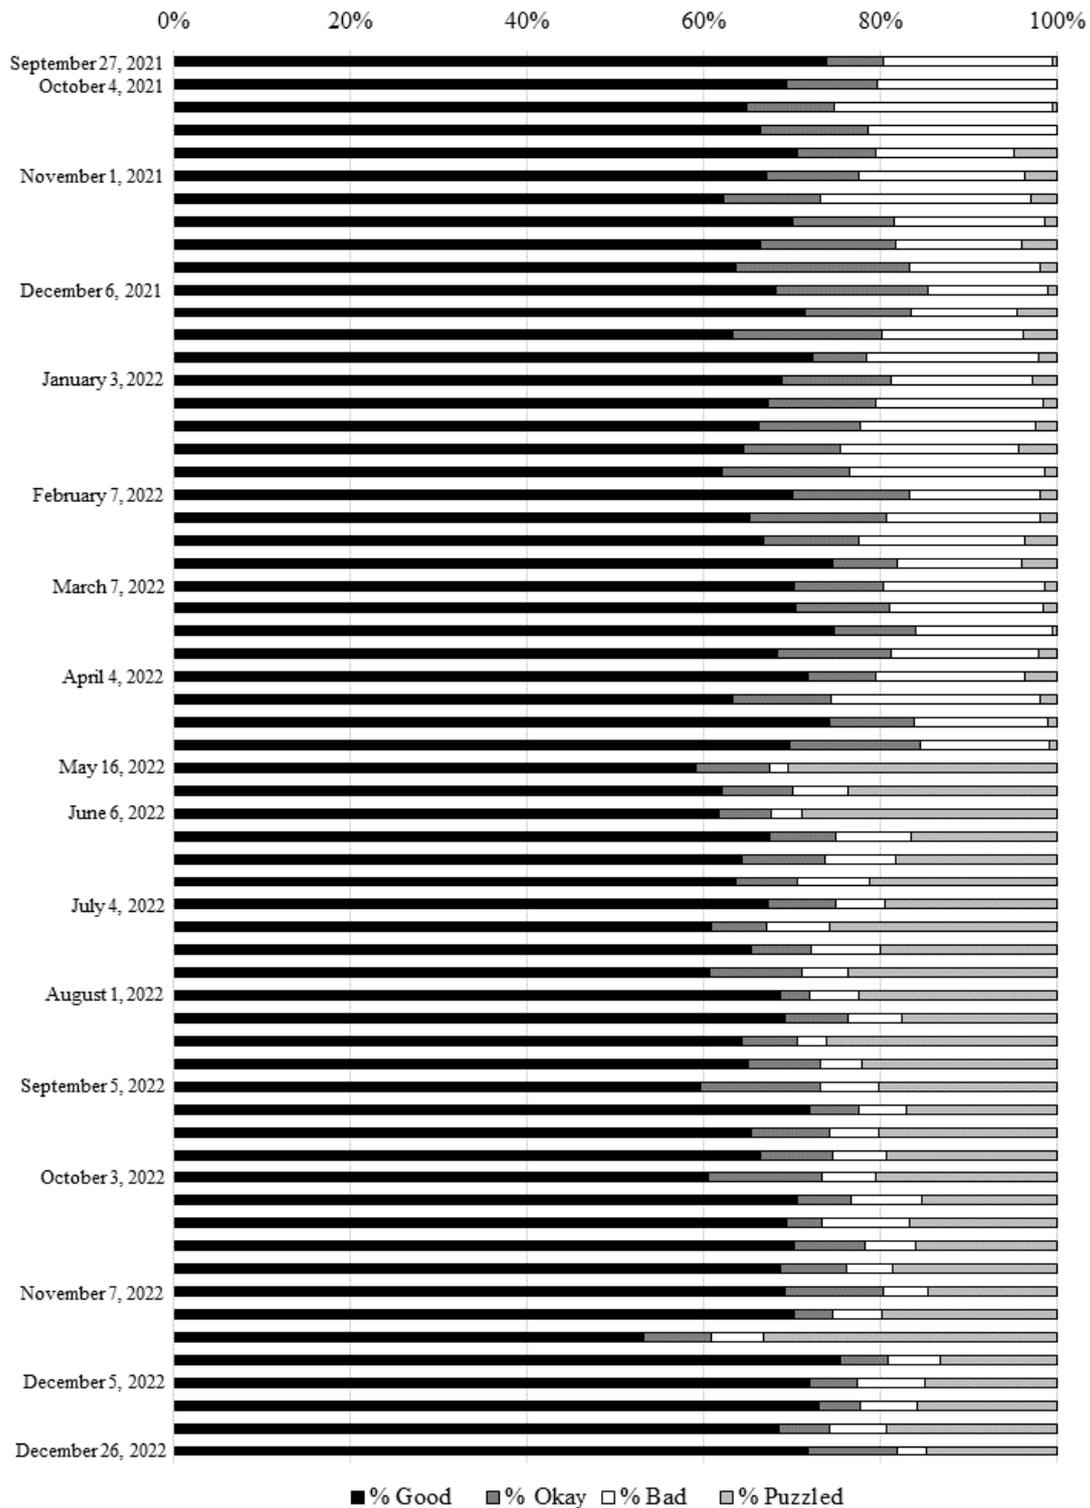

Figure 1 shows that the proportion of responses coded as Good was consistently >60% and that typically, Bad responses accounted for <30%. From May 2022 onward, there is a notable shift toward a smaller proportion of Bad and Okay responses and, instead, a greater number of Puzzled responses. As opposed to any change in the human evaluation of the responses or specific update to the software, this improvement reflects the ongoing work that the Anxiety UK team had been doing to calibrate the responses. This finding indicates that over time,

Ask Anxia is less likely to generate an inappropriate or irrelevant response that could lead to disengagement from the user and more likely to provide a response that facilitates further engagement and opportunities for the user to find the relevant support.

The example of a Puzzled response provided earlier in this section on Quality coding was not initially one of the preprogrammed options but was added shortly after the launch (in September 2021), as the Anxiety UK team recognized a need

to indicate when an optimal response could not be offered. The necessity of a Puzzled response is to be expected, given that the Anxiety UK team is not reasonably going to be able to anticipate the full range of queries users could conceivably submit. Furthermore, in many cases, a Puzzled response is preferable to a Bad response because it encourages the participant to remain engaged and try again. In work analyzing approximately 20,000 conversational exchanges between customers and a task-oriented chatbot for a Taiwanese banking firm, Li et al [13] focused on the problem of “nonprogress” responses, where users abandoned the dialogue. They identified a number of “reformulation” strategies when progress was halted, including rephrasing; adding different words; repeating the same words; and to a lesser extent, removing words [13]. This suggests that prompting the user to reformulate their query or to try an alternative mode of engagement, which the Puzzled response does, is preferable to closing down the exchange. Often, users simplify their reformulated messages [14], which increases the probability for pattern matching and Ask Anxia finding a relevant response.

While a Puzzled response can be the appropriate response, for example, when there is no suitable prewritten response or information provision, monitoring the instances when such a response is elicited highlights areas where Anxiety UK can consider extending the response options or the information and services they provide through their website.

Pattern Matching

In this section, we report some of the modifications made to Ask Anxia designed to attend to features of user queries that can potentially disrupt the pattern-matching mechanism of simple automated chatbot systems. For instance, the Anxiety UK team became aware that the use of certain punctuation affected the ability of the bot to respond correctly to the query and duly updated the program to navigate around such characters.

The simplicity of a pattern-matching procedure is demonstrated when the input (the user query) is not identical to the stimulus the chatbot is programmed to recognize, which can occur with misspellings. In addition to informing us that the term *anxiety* appeared 2461 times in the user queries, the wordlist generated in #LancsBox also indicates that the following (likely) misspellings of “anxiety” occurred: *aniety*, *aniexy*, *aniexy*, *anixety*, *anixity*, *anixety*, *anixity*, *anxiety*, *anxeity*, *anxety*, *anxiatety*, *anxiery*, and *anxiety*.

Recognizing common misspellings of relevant terms can help to minimize the number of cases in which the chatbot cannot identify an appropriate response, and while it may be unfeasible to program the service to recognize all possible variants, the wordlist allows us to identify the most common.

The use of negation can result in false negatives, in cases where users produce the relevant stimulus but deny or distance themselves from the concept in their proposition, for example, “not needle phobia.” In such instances, while a chatbot can be programmed to recognize negation (in terms such as *not*, *isn't*, or *no*), the query does not provide the input to determine what is the impetus of the query, and so recognizing negation would not then help to identify a suitable response. In such cases, the

onus may be on the user to deduce how the inappropriate response has been generated (ie, seeing the pattern matching with their original query) and to try reformulating their message. A more proactive response, on the part of the service provider, would be to program the chatbot to recognize negation and to generate a Puzzled-type response that prompts the user to reformulate their query.

Users’ queries might also include additional pattern-matching terms that do not constitute the primary focus of their message but which nevertheless prompt a response. This was often the case with longer, more complex query formulations in which multiple competing trigger terms appeared. In most cases, one of the terms would elicit a corresponding response, but this might simply be a greeting to a query that happened to begin with the word *hello*. AbuShawar and Atwell [15] compare a “first-word” approach to a “most significant word” approach with respect to programming chatbots; they explain that the “most significant” word is determined according to low frequency, on the basis that a low-frequency word is what distinguishes an utterance and will favor informational content over high-frequency function words, such as *a*, *to*, *in*, etc. This approach increases the probability that the tool is responding to a “topic” word rather than, say, a grammatical word; however, implementation as part of a simple, pattern-matching chatbot would require additional programming. In the case of Ask Anxia, the Anxiety UK team introduced a prompt in August 2022 that advised users to construct their queries in a simple and direct manner, thereby maximizing the potential for Ask Anxia to recognize a relevant term. Such a response can be generated on the basis of the length of the query (ie, character or line count).

Managing Expectations

In the previous section, we have seen that optimizing a chatbot service relies, to some extent, on the understanding of the user that, for example, simple direct queries are likely to produce the best results. As such, there is a degree of familiarity, or “literacy,” that can help to ensure that users find the support and information that is of most benefit to them. Working toward this alignment between user goals and service is also a case of managing expectations, first and foremost in relation to what the Ask Anxia service is and can do.

A series of updates applied to Ask Anxia reflected the increasing explicitness with which the Anxiety UK team described the automated nature of the service. Shortly after its initial launch (July 2021), the team supplemented the initial “Hello” response with the following message:

Hello, I am Anxia the Anxiety UK chat bot. I am here to provide you with advice and information. A brief disclaimer: this is not a crisis service, if you feel you are at risk, please contact 111 or 999. Now, how may I help?

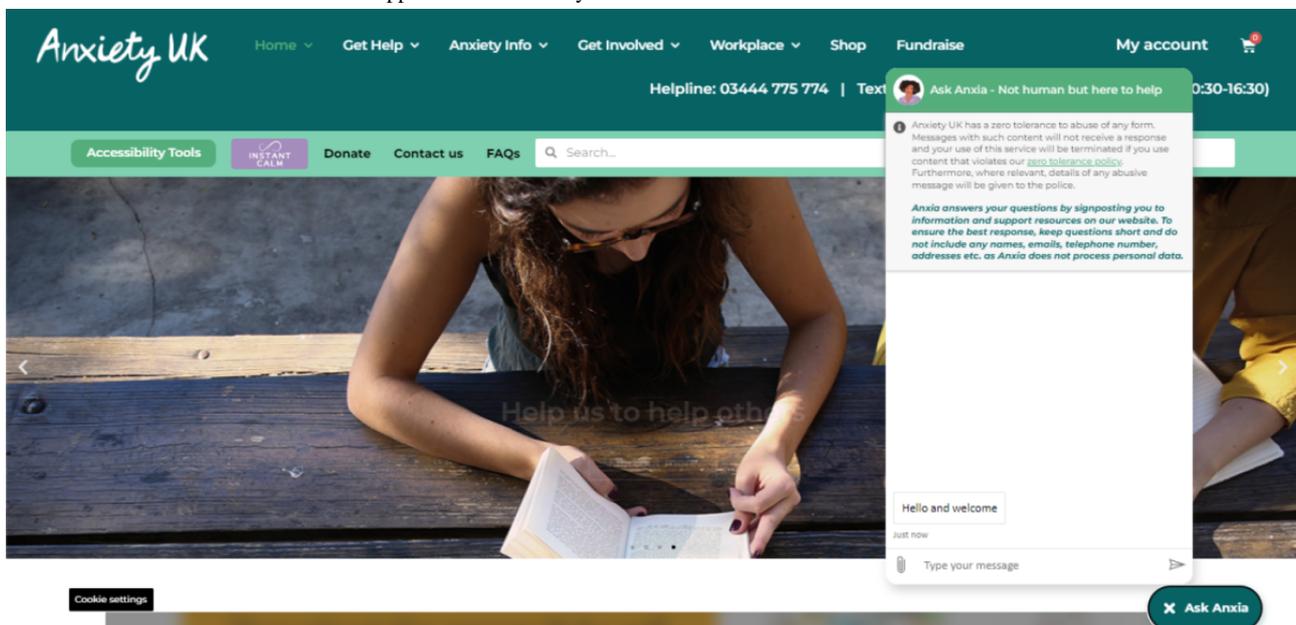

Subsequently, Ask Anxia has been relabeled an “eHelper” (August 2021) to avoid potential stigma associated with “chatbots” [3], then later (February 2022), the introductory prompt was rephrased to read the following: “Ask Anxia—Not human but here to help.” Reviewing user queries, it becomes

apparent why this clarification that the service is not operated by a human was required.

In [Table 2](#), we say that one of the keywords for user queries was *oh*. Heritage [16] asserts that “where *oh* is produced as a response to information of some kind, it functions as a ‘change of state’ token; it registers, or at least enacts the registration of, a change in its producer’s state of knowledge or information.” In other words, the use of *oh* can indicate a degree of surprise or unexpectedness on the part of the recipient. When we refer to the queries, we see that often, this interjection reflected a realization on the part of the user that they were interacting with an automated service. The wordlist for the queries demonstrates the number of references to *bot* (87), *robot* (62), and *chatbot* (3), and we can extend our analysis in *#LancsBox* to determine frequencies of fixed phrases that include these terms, namely, *are you a robot* (21), *is this a bot* (16), *is this a robot* (14), *are you a bot* (12), etc.

On the one hand, this realization indicates a prior belief that the service was operated by a human and thereby might attest to the verisimilitude of the responses. On the other hand, the fact that this realization has come about indicates that such an illusion has been shattered, that is, because of an inappropriate response or perhaps because of repetition of the kind that is associated with pattern-matched chatbots with a limited number of responses [17]. Thus, with the aim of managing expectations and minimizing the potential for interactional trouble, the Anxiety UK team has worked toward more explicit signaling of the automated nature of the service ([Figure 2](#)). With this transparency, users can design their queries appropriately, and Anxiety UK can avoid too many instances where users become disillusioned by the potentially jarring realization that the interaction is not what they had presumed. Furthermore, we have established that some users may be more forthcoming knowing they are interacting with a nonhuman automated service [6].

Figure 2. The Ask Anxia chat window as it appears on the Anxiety UK website.

The Anxiety UK team had initially programmed Ask Anxia with a small number of light-hearted, conversational responses that contributed to a kind of persona, such as “I’m great, thanks for asking!” and “I don’t have an age.” Many of these responses were removed around September 2021 to October 2021, as they were often generated in inappropriate situations and there was a danger that they undermined the serious nature of the user query. Following their survey of motivations for using medical chatbots, Chang et al [3] determined that helping users acquire critical health information should take precedence over whether or not the chatbot appears empathetic or personable. Furthermore, when chatbots appear “humanlike,” this can raise expectations about interactive capabilities, which in turn can negatively impact the interaction when the service’s limitations are exposed [18]. Ultimately, transparency around the service’s purpose and capabilities can help to avoid communicative misalignments and, given the high risk for responses that are designed to appear person like to actually appear flippant, such

responses are arguably best avoided when user disengagement could potentially give rise to detrimental health consequences.

Finally, while Anxiety UK encourages users to be candid in their queries, on the basis that being direct will most likely mean that they can get the appropriate support, another series of developments to the Ask Anxia service has been to communicate a zero-tolerance policy for the use of profanities or abuse. A predefined response expressing this position was introduced in December 2021 and has since been subject to minor edits (also shown in [Figure 2](#)). Whether the use of profane language is motivated by frustration or is a more facetious “test” of the chatbot’s capabilities (and there is evidence in the queries to indicate both), this does not include terms that are likely to be pattern matched to an informational resource. As such, there is no more preferable response for Ask Anxia to provide, other than to restate the zero-tolerance policy for such language, or alternatively, a response that encourages the user to reformulate their query. A summary of the updates described here is provided in [Table 4](#).

Table 4. Summary of updates to the Ask Anxia service.

Date	Action
July 2021	<ul style="list-style-type: none"> Extended welcome message clarifying that the service is operated by a bot as opposed to a human and to advise users that the service is not a crisis service.
August 2021	<ul style="list-style-type: none"> Removed the limit cap on messages.
September 2021	<ul style="list-style-type: none"> Removed a selection of prebuilt answers that were designed to make the bot seem more friendly and human-like but were giving inappropriate responses to sensitive queries. Added a response advising users that the bot did not know how to answer their query (“Sorry I’m not sure how to answer that...”) as an alternative to generating poorly matched responses from the existing content bank.
December 2021	<ul style="list-style-type: none"> Added a “zero-tolerance policy” response due to a minority of users using profanities. Further clarification of this response was enacted through minor amendments in January 2022 and also February 2022.
July 2022	<ul style="list-style-type: none"> Added a response discouraging users from including personal data in their queries.
August 2022	<ul style="list-style-type: none"> Added a response advising users to keep messages brief, on the basis that longer queries gave rise to confusion and poor responses from the chatbot.
October 2022	<ul style="list-style-type: none"> Updated the content bank to recognize regular typing errors related to existing prompt terms.

Future Developments

It is worth highlighting some of the anticipated developments that will be implemented to continue to optimize the Ask Anxia service. These developments primarily orient around connecting users to the appropriate mode of service, for instance, providing the connection to contact a (human) operator when this is recognized in the user query. There are also instances in which a more informed response, beyond the level of detail provided in the preprogrammed replies, is required; in such cases, where the user query seems to rely upon more specific contextual or personal circumstances, Ask Anxia can direct users toward the helpline. The Anxiety UK team continues to refine the Puzzled responses to encourage further engagement from the user, for instance, providing the prompt, “Can you phrase this differently?” Finally, the Anxiety UK team is working on developing a mobile app that has the chatbot functionality embedded within it, thereby providing another arm of support and format to use the Ask Anxia service to reach a wider audience and attend to different user preferences.

Discussion

Organizations implementing pattern-matching chatbots for the purposes of providing information and support will benefit from continuous review of the response options and queries that users submit to their service. Furthermore, an initial set of programmed responses will likely need to be extended, and this will be informed by the nature of the queries that users submit. Our corpus analysis of frequently used terms in user queries to Ask Anxia demonstrated that the initial set of programmed responses was well aligned with the concerns of users but nevertheless helped to highlight areas where additional materials could prove to be useful. The manual quality coding of responses showed that Ask Anxia performs well, offering Good responses at a rate consistently >60%, and this procedure helped to identify areas where responses could be developed to address information gaps or otherwise refined to discern, for example,

queries about needles generally and questions about specific vaccinations.

With respect to lessons learned through the implementation and review of the service, first, we have highlighted the informal nature of user queries, which often included ritualized greetings (*Hi* and *hello*). As such, it is useful to have a chatbot response that simply provides a greeting in kind. However, it is important to note that if a user greeting appears at the beginning of a more elaborate query, a response that attends to the topic of the query would be more appropriate.

Second, we have recommended that when an appropriate response cannot be readily identified, there is value in continuing the exchange, that is, encouraging the user to reformulate their query and thereby create additional input from which the chatbot can match an appropriate response. Researchers have highlighted the dangers of “nonprogress” responses that result in user disengagement [13]. Thus, while service providers are unlikely to be able to anticipate the full range of queries their users will submit, they can at least work to facilitate further engagement and use a preprogrammed, albeit uncertain reply to instruct participants on how best to elicit an acceptable response.

Third, we have seen that it is important to manage users’ expectations about what the tool can provide, which includes being explicit that the service is not provided by a human. Relatedly, responses that presented humanlike qualities proved to be of limited value, potentially raising expectations that the tool could offer humanlike judgments. Simple, pattern-matching chatbots such as Ask Anxia are best suited to “frequently asked questions”-type services, rather than more interactional, relationship-building tasks [17]. The benefit of these less-complex systems is that they are easier to program and implement and so can be adopted by service providers with minimal knowledge of the computational systems involved. It is important, nevertheless, to be cognizant of the limitations of such services. For instance, Ask Anxia does not track conversations over multiple turns but rather treats each post as

a new query; as such, any pertinent information provided at a previous turn is lost, and users may find themselves having to restate the fundamental purpose of their query. Similarly, the quality of Ask Anxia's performance is likely to diminish with longer, more complex queries, as it becomes more difficult to discern a singular, relevant prompt. Subsequently, users will be discouraged from providing contextual information (Figure 2) and are unlikely to receive personalized support in this mode. Simple chatbots, therefore, are arguably best used as part of an array of support options, including those which allow for more nuanced exchanges, for example, with a human provider over the telephone.

Laranjo et al [1] assert, based on a systematic review, that applications of chatbots in health care are in the early stages of development and evaluation. Furthermore, the systems used in health care lag behind those used in domains such as travel information and restaurant selection. As their deployment can have consequences for health outcomes, it is appropriate that such systems are continuously tested and evaluated. Language

analysis is key to understanding both how users express themselves in queries to chatbots and the design of appropriate responses, and so, we advocate for the continued application of procedures such as those of corpus linguistics to support the extended use and performance of chatbots in health care.

Conclusions

The launch of the chatbot Ask Anxia was designed to support Anxiety UK in delivering information and support services to people concerned with anxiety disorders. The number of queries submitted to Ask Anxia, particularly out of hours, attests to the value of the service. In this study, we have demonstrated that procedures from corpus linguistics can help to identify patterns in user queries that reflect their needs and expectations of the service as well as direct us to where potential breakdowns in communication occur. For chatbot services to achieve optimal performance, human oversight is required, particularly during the first 6 to 12 months. Thereafter, less staff intervention is likely to be needed.

Acknowledgments

The authors would like to acknowledge the technical support provided by Roger Kadama in developing the Ask Anxia service. LC and PB were supported by funding from the Economic and Social Research Council (ES/R008906/1). The funding source had no role in the design of this study.

Authors' Contributions

All authors participated in the conceptualization of the paper and reviewed the manuscript. NN, NL, and DS carried out the manual coding of Ask Anxia's responses. LC and PB carried out the corpus analysis of user queries. LC wrote the manuscript with contributions from NN and NL on developments to the Ask Anxia service. NL conceptualized the Ask Anxia service. NN, NL, and DS contributed to the initial development of Ask Anxia and each continues to shape its development.

Conflicts of Interest

NN, NL, and DS are employed by the national charity, Anxiety UK, and were involved in the development of the Ask Anxia chatbot service.

Abstract

Background: The high number of unnecessary alarms in intensive care settings leads to alarm fatigue among staff and threatens patient safety. To develop and implement effective and sustainable solutions for alarm management in intensive care units (ICUs), an understanding of staff interactions with the patient monitoring system and alarm management practices is essential.

Objective: This study investigated the interaction of nurses and physicians with the patient monitoring system, their perceptions of alarm management, and smart alarm management solutions.

Methods: This explorative qualitative study with an ethnographic, multimethods approach was conducted in an ICU of a German university hospital. Using triangulation in data collection, 102 hours of field observations, 12 semistructured interviews with ICU staff members, and the results of a participatory task were analyzed. The data analysis followed an inductive, grounded theory approach.

Results: Nurses and physicians reported interacting with the continuous vital sign monitoring system for most of their work time and tasks. There were no established standards for alarm management; instead, nurses and physicians stated that alarms were addressed through ad hoc reactions, a practice they viewed as problematic. Staff members' perceptions of intelligent alarm management varied, but they highlighted the importance of understandable and traceable suggestions to increase trust and cognitive ease.

Conclusions: Staff members' interactions with the omnipresent patient monitoring system and its alarms are essential parts of ICU workflows and clinical decision-making. Alarm management standards and workflows have been shown to be deficient. Our observations, as well as staff feedback, suggest that changes are warranted. Solutions for alarm management should be designed and implemented with users, workflows, and real-world data at the core.

Introduction

Background

In intensive care units (ICUs), continuous monitoring of multiple vital signs results in a high number of alarms [1] intended to inform staff of critical patient conditions, thus ensuring patient safety [2]. However, a large proportion of alarms do not require medical intervention [3], which, along with the sheer amount of alarms, disturb patient care [4]. In addition, the desensitization of ICU staff to alarms, “alarm fatigue” [5-7], is a threat to patient safety as it causes slower or no reactions to alarms [8,9]. Alarm fatigue is associated with working conditions and individual staff characteristics in deteriorating alarm monitoring performance [10]. Thus, for an improved monitoring performance, an understanding of workflows and the inner setting of a unit conducting vital sign monitoring is essential.

Alarm management standards have been proven effective in reducing unnecessary alarms [11,12]. Individual alarm thresholds, tailored to a patient based on previous monitoring data, alarm logs, and the medical data stored in the patient data management system (PDMS), would further improve alarm management [13,14]. One approach to this is using artificial intelligence (AI) to integrate these data and suggest alarm thresholds for an individual patient or actions to take after an alarm [15,16]. The research project *Intelligent Alarm Optimizer for the Intensive Care Unit* (INALO) follows this approach by creating a data set with semiautomatically annotated data (ie, alarms and the reactions to it) and using machine learning to predict the probability of an alarm to be actionable or nonactionable [17].

Before introducing new procedures or technologies in a complex sociotechnical environment such as an ICU, the characteristics of this setting and the individuals working there should be assessed [18,19], especially focusing on lived everyday work practices [20]. Since many alarm reduction solution approaches known in research have failed because of being too general [5], the interaction of the ICU staff with the patient monitoring system and the practiced alarm management should be investigated.

Objective

This qualitative study aimed:

1. to investigate the sociotechnical system ICU, with regard to the interaction of staff with the patient monitoring system and its alarms and
2. to understand the staff’s perceptions of alarm management and the potential they see in the use of AI in this context.

We aimed to address the following research questions:

1. What is the sociotechnical role of patient monitoring in the work practice of nurses and physicians of the research site?
2. How does the staff, including nurses and physicians, of an ICU of a university hospital interact with the patient monitoring system, especially their interaction with alarms?
3. What is the attitude of physicians and nurses toward intelligent alarm management systems?

Methods

We consulted the Standards for Reporting Qualitative Research for reporting this research [21].

Qualitative Approach and Research Paradigm

This ethnographic study follows an explorative approach with (1) observation-based data collection triangulated with (2) semistructured interviews supported by (3) a self-reported overview of activities mapped out by each participant [22-24]. The research paradigm is postpositivist. We aimed to maintain a holistic, observing perspective while acknowledging that all the collected data and the derived findings are fallible, value laden, and need to be reflected from different researchers’ perspectives [25]. The use of ethnographic methods fulfills the requirements of the postpositivist paradigm; it can create an understanding of social structures and capture the role and interaction with a technical system within those structures, revealing underlying sociotechnical relationships and patterns [26]. In order to build this comprehensive understanding, ethnographic research usually uses other methods in addition to observation [27]. Therefore, in addition to observation, semistructured interviews were conducted, and a participatory task was set for this work.

Researcher Characteristics and Reflexivity

The interdisciplinary research team consisted of a physician with work experience in medical informatics and anesthesiology and a research focus in implementation science and patient monitoring (LM); a psychologist enrolled in the master’s program, *Human Factors*, exploring the interface between humans and technology (MS); a digital clinician scientist with work experience in medical informatics, anesthesiology, and internal medicine and a research focus on patient monitoring and alarm management (ASP); a professor of medical informatics (FB); a professor of inclusive work systems with research focus on ethnographic methods for technology design (FM); and a professor of ergonomics with a focus on human factors research in medical work environments (MF). MS was methodologically trained by FM and conducted the data collection from the etic perspective, that is, from the perspective of a person foreign to the field and the field of activity, supervised closely by FM throughout the field work. LM’s and ASP’s clinical perspectives provided a strong interdisciplinary contextualization of the data and informed the analysis. Throughout all phases of the research, FM, MS, and LM met regularly to discuss and reflect on the data collection process and preliminary findings. None of the research team members had a direct professional relationship with the research field.

Context

The motivation for this research, along with literature evidence of alarm fatigue, was a previous study that we had conducted to identify clinical requirements of future patient monitoring. We found that staff perceived alarm management as insufficient, threatening patient safety and disturbing workflows [28].

Setting

The research field of this study was an ICU of a German university hospital, where up to 21 patients can be treated in nine 2-bed rooms and six 1-bed (isolation) rooms. The devices used in the patient rooms were a continuous monitoring system (Philips IntelliVue) with sensors monitoring multiple vital parameters (eg, electrocardiogram, blood pressure, temperature, oxygen saturation, intracranial pressure, and electroencephalogram); a ventilator (Dräger Evita V800); infusion pumps (Agilia connect by Fresenius Kabi); and, if needed, a temperature management system (Arctic Sun by BD) or a dialyzer (various manufacturers). A table near the patient's bed with a computer enabled the caregivers to call up the PDMS to retrieve patient data and to document examination results. The PDMS used in this setting was COPRA 6 (COPRA System GmbH) [29], while the hospital information system used was i.s.h.med by Cerner [30]. The patient monitoring system installed on the ward included screens at the nurses' workstations directly outside the patient rooms and in the ward pulpit, the conference room, and a medication room. These screens displayed an overview of the vital signs of patients in adjacent rooms or of all patients in the ward.

Intelligent Alarm Optimizer Project

This study was conducted before the implementation and testing of INALO [31]. This project aims to improve alarm management for medical personnel using AI to decrease alarm loads, therefore easing the burden of alarm fatigue. The methodological approach included integrating and annotating data from multiple sources, including the hospital-wide patient monitoring system, the PDMS, and the hospital information system.

Access to the Field and Sampling Strategy

Access to the field was provided by the medical supervisor of this work (ASP) as well as the nursing management of the researched unit. The observations were announced to the entire ward staff by the ward manager via email, and the staff members were provided with the opportunity to address any concerns or queries they might have. A total of 12 observations were conducted by MS, each of which involved shadowing a nurse or physician for the duration of a shift (Table 1), for a total of 102 hours of observational data. The first 2 observations, shadowing both a nurse and a physician, were considered pilot observations. Their purpose was to become familiar with the environment of an ICU, test the methodology of observation and interviewing, and adapt the interview questions. The data from pilot observations were not used for later analysis.

Table 1. Number of observations divided by shift and profession and level of expertise, respectively^a.

Profession and level of experience	Early shift	Late shift	Night shift
Nurse (1.5-30 years of work experience in the ICU ^b)	3	2	1
Resident physician (1-2 years of work experience in the ICU)	2	1	— ^c
Senior physician (7 years of work experience in the ICU)	1	—	—

^aOne participant was shadowed twice.

^bICU: intensive care unit.

^cNot applicable.

The 5 nurses shadowed were suggested by the ward manager and scheduled with MS for different observation days after they had given written consent to participate in the study. Physicians were contacted by MS partly with the help of the medical supervisor or directly in the course of a field observation. In total, 4 physicians agreed to participate in the study.

The aim was to shadow a sample of staff members representative of the whole team, thus covering the greatest possible variety of perspectives in the research. Nurses and physicians of different ages and experience levels in an ICU were shadowed in all possible work shifts (early, late, and night shifts). The number of accompanying nurses and physicians per shift is listed in Table 1, where the experience level of working on an ICU is shown as the duration of work in intensive care.

Ethical Considerations

The study was approved by the ethics committee of the Charité Universitätsmedizin Berlin (EA4/218/20). Field notes and transcripts were anonymized or, if complete anonymization was not possible, pseudonymized. The data are stored on an internal institutional server, encrypted so that only the research team had access to it. Audio recordings were deleted after

transcription. All staff members shadowed and interviewed for this study were informed about the research project and its aims and gave their written consent to participate. There was no compensation given to the staff members who were shadowed or interviewed.

Data Collection Methods and Instruments

Field Observation

The main data collection method in this study was field research in the form of observation. In ethnographic research, the observation part varies by the degree of participation of the researcher in the field [32]. The setting of the field observations and the nonmedical background of the researcher suggest a nonparticipatory observer role (shadowing), in which events are observed in the background without involvement in any work processes. This methodology has been previously used in clinical settings [33-36]. Although the researcher observed the field from the background most of the time, she was also involved in conversations during the shifts by the shadowees. This gave her the opportunity to ask clarifying questions, which was beneficial in gaining insights. The observations were performed from April to October 2021. Breaks of up to 3 months

were taken for interim analysis of the data. This allowed for the readjustment of focus for the remaining observations and the evaluation of inductive thematic saturation [37], ultimately leading to the determination of the number of field observations as 7.

Semistructured Interviews

The interviews serve to explore the nonobservable topics relevant to the research question. They add to the observation method in the sense of methodological triangulation [22]. In particular, reactions to the planned AI-based INALO system and specific inquiries about the handling of the monitoring and

its alarms were assessed. By not including the explicit term *AI* in the interview guide, the goal was to avoid potential biases or preconceived notions associated with the term, allowing for a more neutral and open interview discussion. *AI* was considered a polarized term, evoking personal opinions, as people may have subjective and varied views on the topic [38-40]. Consequently, the interviewees were provided with an explanation of the functionality of the INALO system, leaving out the specification *AI* (refer to question 5 in the interview guide in [Textbox 1](#)). The interview guide was developed through discussions of the research team and informed through the first 2 pilot observations

Textbox 1. Interview guide.

Questions

- Are there certain situations in which the sounding of an alarm is particularly inconvenient for you? Which ones?
- What role does managing alarms and especially their thresholds currently play during your work?
- How do you know it is time to adjust the alarm thresholds of certain parameters?
- When do you take the time to adjust an alarm threshold?
- Imagine a system, in addition to patient monitoring, that controls the alarm thresholds for oxygen saturation, arterial blood pressure and heart rate. If it registers that the current thresholds are no longer suitable for the patient in question, it suggests suitable alarm thresholds. What do you think about such a system?

In total, 7 interviews were performed individually with the 7 shadowed staff members ([Table 1](#)) after the end of a work shift in an open space to minimize outside distractions. The mean length of the interviews was 37:57 (range 56:22-15:05) minutes. We considered data saturation [37] including notes from field observations and interview transcripts. It was achieved after 6 field observations and, correspondingly, 6 interviews, which included early, late, and night shifts as well as nurses, resident, and senior physicians.

Participatory Task

In addition to the observation and the interview, following the triangulation strategy [41], a participatory task was conducted with the study participants. This helped gain insight into the representation of patient monitoring in the daily work routine and workflows of ICU staff members.

In a classic note-and-pen task, participants were asked to draw a pie chart of all the thoughts and tasks they think about during a work shift, with each piece of pie representing a thought, a task, or a task area. The size of the pie pieces was intended to show how the respondent's cognitive resources were divided during a shift. The participants were requested to prioritize the tasks that they had visualized based on their subjective perception. This was done to compare the estimated time allocated to each task in their workday with its perceived importance. The goal was not only to obtain indirect evidence on the importance of monitoring and alarms but also to understand the work routine in general from the respondent's perspective.

Data Collection Instruments and Technologies and Data Processing

Handwritten field notes were prepared following the methods of Emerson et al [42], and the date, location, and content of the

observation were taken and promptly consolidated in MAXQDA (VERBI GmbH) [43] after each observation session. Interviews were recorded and transcribed according to the minimal transcript based on GAT 2 [44] and consolidated in MAXQDA. The participatory task was recorded in order to be able to use follow-up questions about the processing of the task as well as incidental comments for the later analysis.

Data Analysis

For inductive analysis, a grounded theory approach was followed [45]. The consolidated field notes and transcribed interview data from 6 observations were analyzed in MAXQDA 2022 and coded line by line in a first step, deriving thematic codes from the data while trying to neglect any relationship of the codes to the overarching research questions. In a second step, memoing was started to extract meaning from the data and to create and map an initial overview of themes [46]. This overview represented a preliminary code system after 6 observations. After all the gathered data were collected, coded, and tagged with open memos, the result consisted of 1336 coded data sections assigned to 47 parent codes and 70 thematically subordinate codes and tagged with 207 memos. Memos (ie, field notes with headlines) were organized thematically and considered in the context of their associated data sections (eg, interactions with the monitoring systems and alarm management). To ensure this thematic clustering according to the memo headline was rightful, we went back into the raw data (field notes) to evaluate whether the groups of memos with a similar headline could indeed be grouped together based on their raw data points. This helped to reevaluate and refine the derived themes from the memos (eg, integrating memos for more specific details and adding key points from field notes to memos from interviews and vice versa). When analyzing the data collected through the participatory task, the recorded topics

were written down, divided according to occupational group (nurses and physicians), and their occurrence was counted. As a result, an overview of superficial and seemingly less relevant task areas was created. The resulting themes from memos, codes, and topics from the participatory task were summarized and put in writing.

Techniques to Enhance Trustworthiness

Regular research meetings took place, where LM and MS discussed the findings and reflected on them. The code system (Multimedia Appendix 1) and memos were checked by both researchers under the supervision of FM. The combination of a psychologically trained Human Factors graduate student (MS) together with an expert in ethnographic research for work systems design (FM) and a physician with professional experience in an ICU and expertise in qualitative methods and implementation science (LM) was chosen to achieve the best balance of perspectives and topic prioritization. Interdisciplinary approaches are important to leverage the potential of research

on the intersection of human-computer interaction, information systems, and health [47]. In addition, the multimethod study design with triangulation of complex data allowed for an increased credibility and trustworthiness of the results.

Results

Overview

The following 3 topics were identified from the data, following the research questions:

- the perception of the role of monitoring in the ICU
- the management and communication of vital sign limits (*dealing with alarms*)
- wishes and concerns regarding the intelligent alarm management system (eg, INALO)

An overview of nurses' and physicians' perceptions can be found in Table 2.

Table 2. Perceptions of monitoring and alarm management divided by professions.

Categories	Nurses	Physicians
The role of monitoring in the intensive care unit	<ul style="list-style-type: none"> • Use monitors at the bedside • Direct monitoring of vital signs at the screens 	<ul style="list-style-type: none"> • Use monitors in the pulpit • Use nurses as monitoring filter
Dealing with alarms	<ul style="list-style-type: none"> • Subconscious adaptation to alarm patterns • First reaction to alarms • Implement alarm thresholds 	<ul style="list-style-type: none"> • Subconscious adaptation to alarm patterns • Set and adjust alarm thresholds
Intelligent alarm management	<ul style="list-style-type: none"> • Concerned about the system's functionality • Highlighted the importance of understanding the system's operational principles • Concerned about excessive confidence 	<ul style="list-style-type: none"> • Perceived as positive for lowering alarm burden • Perceived as valuable for new patients in the ward or upon returning from leave

The Perception of the Role of Monitoring in the ICU

Continuous monitoring of vital signs is an essential component of intensive care management of critically ill patients and a ubiquitous part of the ICU under study. According to a senior physician, even a short period without monitoring would be "grossly negligent."

The nursing staff primarily used the monitors located directly at the patient's bedside (ie, *direct* monitoring), as well as the overview screens at their workstations outside the patient rooms. During lengthy nursing activities in a room, it was observed that nurses used the monitoring system's function to display other patients' vital sign data on the screen of the bed where they were busy. Due to the larger number of patients under their care, physicians relied on the feedback from the nursing staff in the event of a critical situation (nurses as *monitoring filter*). They also paid closer attention to alarms on the overview monitors at the pulpit, and it was important that alarm thresholds were well set so that potentially life-threatening situations did not go unnoticed for long:

Especially when patients deteriorate, you notice that very often because the alarms are triggered all the time...These alarms...also signal something to us[...], without us seeing the patient directly[...], and if [the thresholds] were always set lower and it simply no

longer alerts me, I'd only notice it when it's really bad or too bad or the catastrophe is there, and I wouldn't want that. [Interview, physician]

When making therapy decisions, physicians considered the target values for specific parameters that had to be adhered to, based on therapy plans. Continuous monitoring of vital signs was crucial for physicians in ensuring that these target values are met.

Although monitoring was used in various areas of activity, it was not considered a central activity in and of itself. In the participatory task, monitoring was not mentioned by anyone. Alarms occurred in 2 of the 5 participatory tasks completed. However, when asked to indicate the role of monitoring in all the tasks written down, interviewees assigned monitoring to most of them (Multimedia Appendix 2).

Dealing With Alarms

The predominant observation regarding the handling of alarms was that they were directly paused or completely ignored, unless it was a red alarm. Often, there was no further reaction or intervention following an alarm.

However, as described in the previous section on monitoring, even an alarm that did not require intervention could provide helpful information about the progress of an individual patient's

condition. Both physicians and nurses showed a reliance on the alarms' feedback to be passively informed of the change in their patients' condition (subconscious adaptation to alarm patterns). In contrast, the alarms interfered with their work:

[...]as you may have noticed, and if this alarm comes up all the time...I actually look at it [the overview monitor] a lot. That disturbs me in my regular workflow. [Interview, physician]

The alarm thresholds of vital parameters were set and adjusted either based on a patient's admission to the ward or return from the operating room or based on evaluations of the thresholds during the course of therapy. In the case of newly admitted patients, the threshold values were determined directly on admission, with the parameters being set according to standard values or having to be determined individually depending on the clinical picture. Nurses, in consultation with physicians, adjusted alarm thresholds according to the patients' condition to avoid unnecessary alarms. The decision to adjust thresholds varied based on the nurse's experience and familiarity with the patient. However, these informal procedures sometimes led to inappropriate thresholds on the next shift, as they were not always updated in the COPRA PDMS [29]:

...I come to the ward, and I don't know the patient. COPRA is binding, what is documented there should be correct and implemented at the bedside. If you're lucky, it says everything about which blood pressure values are desired...You have to ask about all that [if it is not entered correctly] and that's sometimes a bit annoying, until you find out which doctor is responsible for your room, where he is and what his telephone number is. It doesn't have to be like that. [Interview, nurse]

Ideally, the determined threshold values were reevaluated daily in the morning shift. Often this was not the case due to a lack of time. Rather, this reevaluation only happened, if a new test result or diagnosis was found or in the case of disturbing, conspicuous, and unnecessary alarms. The chain of communication regarding the change of alarm thresholds from their determination to their implementation in monitoring ran hierarchically downwards, from senior physicians to assistant physicians to nursing.

If the alarm of a certain parameter would continue despite intervening measures or if no measures had been necessary at all, the alarm thresholds would be adjusted. Physicians and nurses frequently sought each other out for direct and immediate instructions. The official way of issuing instructions was via the COPRA PDMS, but according to staff, this was often too time-consuming, with delays for actual implementation:

And this adjustment [of the thresholds]...doesn't take place so much on this piece of paper, but rather on the patient himself, that I say, ok, we have to change the threshold here[...], then you discuss it next to the device itself with the nursing staff. [Interview, physician]

Staff Perceptions of Intelligent Alarm Management

There were mixed reactions regarding an automated system to improve alarm management on the part of the nursing staff interviewed. Some expressed reservations, while others were open to the system described but said it would have to work well. There were concerns about the functionality of an intelligent system. The importance of understanding how such a system operates was highlighted. Staff members argued that currently a lot of responsibility was being handed over to technology anyway and that it would be more appropriate to be cautious about overconfidence:

I probably rely more on my own experience and won't put it in the hands of a machine that I don't know how it's programmed, what kind of things it reacts to, or what it takes as a basis for the recommendations. That would make a lot of sense for young colleagues who don't have a lot of experience yet, but you end up relying more on your own experience. [Interview, nurse]

The patients, the clinical pictures, and that's all so individual and different that I can't imagine that a machine can [suggest thresholds]. [Interview, nurse]

Second, the statement was made that with clinical experience, one would notice when a threshold should be changed, and therefore, no system would be needed to do so:

I know already by my experience that I must intervene starting from certain values...you observe the patient, you observe the monitor and you already see...that you have to do something. [Interview, nurse]

Thus, staff members saw the added value of an intelligent alarm system for less experienced colleagues and for leasing nurses, as the former would not yet have developed a sense of threshold assessment and the latter would not be familiar with patients. In addition, staff members saw a benefit in the use of the system to ensure regular evaluation and adjustment of alarm thresholds, preventing them from being forgotten.

Physicians reported that any solutions leading to a reduction in alarms would be welcome due to frequent alarms disturbing their concentration during work, especially in the ward pulpit:

[...]If it leads to the fact that the alarms are optimized, then I think it is already a relief, because I get fewer false alarms and thus, I can do the rest of the work more concentrated. So, that would already be an advantage. Certainly, it doesn't take away my cognitive work whether these alarms are, so to speak, suitable or not, I have to do that, but that's also my job. [Interview, physician]

Finally, the advantage of such a system was observed by physicians for patients who were new to the ward and whose condition they did not yet know. The physicians said that it was also helpful to receive threshold suggestions when returning to the ward after a leave of absence, as they also needed to reacquaint themselves with patients.

Discussion

Principal Findings

Patient monitoring is an integral part of the work routine in the ICU. However, standards for working with the system were not implemented in clinical routine in the studied ICU. Alarm management is one of the core interactions with the monitoring system. Most alarms were confirmed without a reaction or intervention. The setting and adjusting of alarm thresholds were performed upon the arrival of a patient in the ICU or over the course of treatment by (senior) physicians and implemented by nursing staff. Perceptions of an intelligent system to suggest alarm thresholds varied: physicians saw potential advantages in a relief of the flood of (nonactionable) alarms by individualized alarm thresholds. In contrast, both nurses and physicians were skeptical about the capability of an automated system to perform the complex task of interpreting alarms and suggesting thresholds, encompassing the integration of different data and information. The importance of knowing how such a system worked internally and how it took decisions was highlighted.

Guidelines for Patient Monitoring and Alarm Management in the ICU

This work highlights the essential role of vital sign monitoring in the daily routines of all health care professionals in the ICU. Yet, to the authors' knowledge, interprofessional, systematic standard, and evidence-based guidelines for patient monitoring in clinical practice remain limited. Alarm management, a fundamental aspect of interacting with monitoring systems, warrants special attention, since alarm overload in ICUs hampers adequate response by personnel [48]. The American Association of Critical Care Nurses published recommendations for clinical alarm management, focusing on personalization of alarms and interprofessional alarm management strategies and highlighting the potential of smart alarms [49,50]. Our research supports the need for a wider clinical implementation of such recommendations, as we saw that a majority of alarms are disregarded or confirmed without any medical response or intervention [51,52].

Take Aways for Future Alarm Management

It is crucial to understand user perspectives when developing intelligent (AI-based) systems for alarm management in intensive care medicine [49]. The following aspects should be considered.

- Skepticism exists among staff members regarding the ability of an intelligent system to integrate diverse data formats and information to effectively interpret alarms and propose suitable thresholds. It might stem from a lack of knowledge and understanding of the internal workflows and decision-making processes of such systems. The potential benefits of integrating intelligent systems to automatically suggest personalized alarm thresholds and alleviate alarm fatigue [16,53] were acknowledged by physicians in our study.
- Standardized workflows for alarm management were not existent, and alarm thresholds and their adaptation were

communicated irregularly and in a variety of ways. Well-defined and clearly communicated standard operating procedures (SOPs) for alarm management could address some of the challenges faced by health care professionals in the ICU [54,55]. Intelligent alarm management solutions should be implemented in clinical environment with well-established alarm management SOPs.

- Alarm management was performed mainly after new test results for the patients were received, a diagnosis was confirmed, or when the alarms were frequent and obviously unnecessary. This indicates that the data used for future alarm management systems based on AI need to mirror highly individual and complex medical conditions. Patients and clinical routines can differ even for various wards in the same clinic.

Extrapolating from these findings, we advise the following for ICU AI projects.

- For a truly effective implementation of AI systems, the ICU staff must be integrated in the design and implementation process, as well as possess adequate AI literacy. Encouraging and providing training to understand and use AI can empower ICU staff to embrace AI technologies confidently.
- As we need standards for alarm management workflows today, standardization is all the more essential in the context of integrating intelligent alarm management (AI-based) technologies. Significant workflow changes could be evoked and need to be considered by ICU leaders and implementation managers.

Limitations

In this study, the research focus lay on a single setting (ICU), which was suggested as a methodological approach by Wilken et al [5], allowing for an in-depth analysis of the contributing factors to an ICU's alarm management and dealing with the patient monitoring system. In addition to the stated benefits of this approach by the authors, it comes with limitations. On the one hand, the focus on a single ICU's cultural peculiarities restricts the transferability of the derived recommendations to other settings. The results and methods may serve, however, as inspiration and study protocol for evaluating an ICU's alarm management. By contrast, following a qualitative research approach, the number of shadowees and the number of shadowing days had to fit in a reasonable time schedule for the research conduction. The unit manager's suggestion of shadowees may have introduced a selection bias, despite being informed about the goal of diverse perspective shadowing. The results presented here are therefore only an excerpt of the reality in the ICU, which must be taken into account when interpreting them.

Conclusions

Our study highlights that interactions with the patient monitoring system and its alarms are a core part of tasks and workflows in the ICU. Alarm management tasks are performed based on ad hoc responses to clinical events; responsibilities are not well defined, and there is no standardized workflow or an SOP. Staff members were not satisfied with the current alarm management,

which emphasizes a need for standard and clinician-centered guidelines in this field. Establishing SOPs for configuring and responding to alarms and considering local patient and workflow characteristics can streamline tasks and enhance the overall efficiency of care delivery. Systems that enable an intelligent alarm management to reduce alarm fatigue among staff members should be designed to make understandable and traceable

suggestions, while health care professionals should be empowered to use them meaningfully through digital health literacy. By establishing these standards and thoughtfully incorporating AI into clinical workflows, health care institutions could enhance patient safety and relieve staff and patients from alarm-induced stress. To explore this effect on outcomes, more research in this field is needed.

Acknowledgments

The authors express their gratitude to the volunteers and the ward staff members. The project *Intelligent Alarm Optimizer for the Intensive Care Unit* (INALO) is funded by the German Federal Ministry of Education and Research under grant 16SV8559. We acknowledge financial support from the Open-Access Publication Fund of Charité Universitätsmedizin Berlin and the German Research Foundation (DFG). We used the generative AI tool, ChatGPT by OpenAI, after the manuscript was written to rephrase single (approximately 12) sentences, to improve readability. The original ChatGPT transcripts can be obtained upon request from the first author (LM).

ASP and ARF received funding by the German Federal Ministry of Education and Research under grant 16SV8559 as part of the project INALO. The authors acknowledge financial support from the Open-Access Publication Fund of Charité Universitätsmedizin Berlin and the German Research Foundation (DFG).

Data Availability

The data sets generated and analyzed during this study are not publicly available because of data privacy; however, they are available from the corresponding author (LM) upon reasonable request.

Authors' Contributions

The study was conceived by ASP, LM, FM, and MS. FM designed the ethnographic study. MS conducted the data acquisition, supported by LM and ASP and under the methodological supervision of FM. Data analysis was performed by MS, LM, and FM. LM, MS, and ARF wrote the manuscript. ASP, FB, and MF supervised all parts of the study. All authors critically reviewed and approved the manuscript.

Conflicts of Interest

ASP and ARF received funding by the German Federal Ministry of Education and Research under grant 16SV8559 as part of the project INALO.

Multimedia Appendix 1

Codes and subcodes derived during data analysis from field notes, interview documentation, and documentation of the participatory task.

[[DOCX File, 31 KB - humanfactors_v11i1e55571_app1.docx](#)]

Multimedia Appendix 2

Indicated activities of a physician and their perceived proportion of the workday adapted from the results of the participatory task performed by a physician shadowee. The tasks with monitoring influence are indicated with the monitor icon.

Abstract

Background: Technology has significantly reshaped the landscape and accessibility of gambling, creating uncharted territory for researchers and policy makers involved in the responsible gambling (RG) agenda. Digital payment solutions (DPS) are the latest addition of technology-based services in gambling and are now prominently used for deposit and win withdrawal. The seamless collaboration between online gambling operators and DPS, however, has raised concerns regarding the potential role of DPS platforms in facilitating harmful behavior.

Objective: Using a focus group session with problem gamblers, this study describes a preliminary investigation of the role of DPS in the online gambling context and its influence on players' gambling habits, financial behavior, choices of gambling environment, and the overall outcome of gambling subjective experiences.

Methods: A total of 6 problem gamblers participated in a one-and-a-half-hour focus group session to discuss how DPSs are integrated into their everyday gambling habits, what motivates them to use DPS, and what shifts they observe in their gambling behavior. Thematic analysis was used to analyze the empirical evidence with a mix of inductive and deductive research approaches as a knowledge claim strategy.

Results: Our initial findings revealed that the influence of DPSs in online gambling is multifaceted where, on the one hand, their ability to integrate with players' existing habits seamlessly underscores the facilitating role they play in potentially maximizing harm. On the other hand, we find preliminary evidence that DPSs can have a direct influence on gambling outcomes in both subtle and pervasive ways—nudging, institutionalizing, constraining, or triggering players' gambling activities. This study also highlights the increasingly interdisciplinary nature of online gambling, and it proposes a preliminary conceptual framework to illustrate the sociotechnical interplay between DPS and gambling habits that ultimately capture the outcome of gambling's subjective experience.

Conclusions: Disguised as a passive payment enabler, the role of DPS has so far received scant attention; however, this exploratory qualitative study demonstrates that given the technological advantage and access to customer financial data, DPS can become a potent platform to enable and at times trigger harmful gambling. In addition, DPS's bird's-eye view of cross-operator gambling behavior can open up an opportunity for researchers and policy makers to explore harm reduction measures that can be implemented at the digital payment level for gambling customers. Finally, more interdisciplinary studies are needed to formulate the sociotechnical nature of online gambling and holistic harm minimization strategy.

KEYWORDS

digital payment solutions; online gambling behavior; sociotechnical; subjective experience; focus group

Introduction

As gambling became a readily available digital commodity, examining and regulating the influence of technology on gambling behavior has emerged as an important agenda for harm reduction research [1]. In the early days of the internet, Shaffer [2] noted that the innate nature of the “new” technology has the potential to become a potent vehicle to introduce certain biases in gambling, resulting in a shift in the subjective experiences of gamblers. Almost 30 years later, and with online gambling becoming commonplace, the extant literature has seemingly reached a consensus that technology-enabled gambling platforms with engaging and persuasive features can facilitate attention bias, impulsive betting, or longer time-on-devices, which can ultimately trigger or maintain addictive behavior [3].

The online gambling landscape has also created a demand for more enabling technologies, such as digital payment solutions (DPSs), for gambling activities. Under the umbrella of a general term known as financial technology, DPSs come in different forms, including digital wallets, payment gateways, or processors that can easily be integrated with online gambling sites or points of sale. Historically, the transfer and funding process of gambling has been perceived as cumbersome practicalities with unacceptable downtime in the eyes of gambling operators [4]. The fast adoption of DPS among the general population in other consumer domains (eg, digital shopping), its convenient account-to-account (direct bank) solution, and merchant-centric flexibility have quickly attracted gambling operators to integrate it into their digital platforms.

DPSs are seen as having a multifaceted advantage for the gambling industry [5]. First, DPS’s fast and seamless deposit and withdrawal solution facilitates longer gambling periods (ie, time-on-device) while solving the problem of downtime [4]. Second, DPS connects multimodal payment options to a one-click account [6]. Depending on local jurisdictions, a user can, for example, connect different payment modes, such as credit or invoice or several bank accounts, to their DPS account, to achieve multiple funding paths. Third, DPSs enable a unison provision of multiple services in one speedy process. For example, gambling operators can use DPS providers to both process payments and conduct Know-Your-Customer responsibilities of authenticating users [7], hence reducing the time and inconveniences associated with starting gambling. With the removal of lengthy registration and authentication processes, options, such as pay-and-play and no-account casinos, are emerging as the new standard of online gambling [8]. Other factors, including general familiarity with DPS in other e-commerce settings in past purchases and trust, can play a role in easy implementation, as well as the adoption of DPS in online gambling [9].

Apart from the technical aspect, DPS providers have benefited from recent policy relaxation of financial regulations, such as open banking [10]. Consequently, digital payment companies

have the advantage of both agility and unprecedented access to financial data to influence consumer behavior (provided users’ consent). The nature of open banking allows more transparency and access to individual payment behavior; however, there is currently no strong incentive for DPS providers with gambling customers to be involved in the effort to promote responsible gambling (RG). Traditional policies and regulatory bodies that govern financial institutions, including DPS providers, mainly focus on ensuring that financial legal requirements are met and that a “well-functioning” marketplace is viable [11]. Financial decisions and well-being are broadly seen as individual responsibilities [12]. In addition, gambling policy making has historically focused on either RG measures implemented at gambling operator sites or consumers’ responsible behavior agendas.

Similar to other technological products, digital payments have been shown to influence subjective gambling experiences, even promoting harmful gambling. For instance, DPS enables an account-based registry in which consumers can connect different sources of funds (eg, multiple bank accounts) into a one-click account, which creates (an illusion of) “uninterrupted availability” of funds. Their fast-deposit mechanism and auto-deposit functionalities can result in lowering the awareness of money spent, leading to prolonged gambling consumption, and dark gambling flow—a state of intense immersion experienced by gamblers leading to a loss of awareness of money and time spent in gambling [13,14]. Previous studies have also theoretically explored DPS in the context of gambling, where payment technologies can be used to augment harm reduction measures [13].

Although the significance of DPS in gambling is beginning to gain attention [5,15-17], we are unaware of any past research that has examined players’ perspective of digital payment in an online gambling setting. In addition, and perhaps due to its interdisciplinary nature, there exists no conceptualization of the mechanism through which technology-enabled payment platforms can shift players’ subjective experiences toward harmful gambling behavior. As the current harm-minimization efforts in online gambling are heavily dependent on understanding, predicting, and promoting healthy gambling behavior, the research field needs to have a holistic understanding of how these tools are integrated into players’ everyday gambling experience and possibly facilitate harmful behavior.

This study aims to supplement the research area by conducting explanatory qualitative research involving first-hand accounts of DPS use among problem gamblers. Exploratory qualitative methods provide a practical approach for laying a strong foundation to further investigate emerging research areas [18]. In addition, qualitative methods, in general, are effective in understanding complex social phenomena of interest and human stories that involve probing participants regarding their experiences with open-ended questions [19]. In this study, the following explorative research questions were examined:

- How are DPSs used in gambling activities among problem gamblers, and what do they think about the influence of DPS on their gambling behavior?
- How can we conceptualize the role of DPS on the outcome of gambling behavior?

Methods

Ethical Considerations

The Swedish Ethics Authority approved this qualitative focus group study (DNR 2022-05843-01). All focus group participants gave informed consent before joining the sessions, and pseudonyms were used to protect their identities during the analysis. Participants were not compensated for their involvement in the study.

Design and Data Collection

The research uses an exploratory qualitative design approach [20]. The approach provides methodological and theoretical flexibility to investigate topical research domains, aiming to identify important concepts and potential conceptual constructs [21,22]. Qualitative exploratory inquiries typically entail gathering primary data using techniques, such as interviews and focus groups, followed by a grounded theory approach analysis, occasionally leveraging on deductive insights from existing literature [23]. In this study, a focus group session serves as the primary data collection method. Following an explanatory research approach, the questions posed during the session were semistructured yet exploratory, providing participants with an opportunity to share their experiences freely.

Current studies on the adverse impacts of gambling indicate that harmful consequences, including financial ones, are prevalent in the problem gambling (PG) community [24]. Our

study participants were selected from this group, allowing us to observe a wide range of harmful gambling behaviors. In addition, the homogeneity of the group has provided an environment where all participants felt comfortable to freely express their past experiences and views. However, it is important to note that individuals who do not have a gambling problem are not necessarily immune to the impact of DPS.

A total of 6 participants with a history of PG were recruited for a focus group interview. The participants were recruited through the Swedish National Association for Gambling Addicts—a national support group for problem gamblers. With the help of the support group administration, a recruitment leaflet was prepared and distributed during support group sessions. The leaflet outlined the goals of the focus group discussion and criteria for participating in the session: (1) experience in online gambling using 1 or more DPS, (2) having played in land-based gambling avenues using nondigital payment methods, and (3) being able to speak English. The participants accepted and returned the consent statement to the support group administration before the focus group session.

Participants were asked to complete brief questionnaires regarding demographics and gambling history before the focus group session started (Multimedia Appendix 1). The most common gambling modality reported was online gambling, including casinos and sports betting, with excitement chasing ranked as the main reason for gambling. The participants' average gambling experience was more than 10 years. All participants were engaged in a biweekly support session. Table 1 provides supplementary profile details; however, following the ethical approval obtained and the sensitive nature of the research, we are only able to provide aggregate information regarding the participants.

10+	3 (50)

Procedure

The focus group discussion was conducted at the premises of the association after one of the support group sessions was completed. The focus group study format enables researchers to collect empirical evidence from multiple sources simultaneously while providing a sense of cohesiveness and a safe environment for participants to share their opinions [25]. In addition, live interaction between participants who share the same background (here, problem gamblers) provided an opportunity for honest and personal story discussions about their struggles and reflection on each other's experiences. The first author (NL) led the focus group discussion, while the second author (JJ) played a supporting role during the meeting, including time management and follow-up questions. Additionally, the second author (JJ) participated as a professional psychologist with experience in gambling therapy to ensure safety in case the group discussions triggered any distressing memories among the participants.

The one-and-a-half-hour session started with an introduction of the aim of the focus group and the procedure. Participants were informed that they had the right to leave the session at any given time, refrain from responding to questions, and provide other relevant practical information. A semistructured set of questions was prepared in advance to conduct the discussion, and this material was used to organize the discussion around DPS's influence on financial behavior, user gambling behavior, time spent on a device, gambling environment, and segment

choices. The focus group protocol can be found in [Multimedia Appendix 2](#).

Analysis of Empirical Evidence

The focus group session was recorded and transcribed verbatim by NL. Thematic content analysis was then applied to analyze the material [26]. The analysis was conducted to develop a "ground-up" understanding of problem gamblers' experience with DPS, which was later used to conceptualize the influence of DPS on the subjective experience of gambling. As such, thematic coding was performed using a grounded theory framework starting with "open coding" or manifest data analysis [27]. The transcribed focus group session was coded using QualCoder 3.2 (MIT-based open-source qualitative data analysis tool), with each participant assigned a pseudonym of P1-P6. The first 2 authors read and reread the empirical material for conversational-level open coding [28]. NL used the first coding, which was later reviewed by JJ for interpretation and coding validity. The manifest analysis followed an inductive approach where efforts were made to code block the material based on "first order value data," which is what is obviously observable in the transcription [29]. With iterative coding and merging of codes at hand, a further validity review of codes was performed by JJ.

After organizing the merged codes into meaningful subthemes, potential themes emerged to categorize the subthemes. At the stage of building subthemes and themes, a deductive research approach was comparatively used as a lens to supplement theme

building using existing relevant theoretical concepts in gambling and sociotechnical research, such as socio-materiality, imbrication, and reciprocal interaction theoretical frameworks [30-32]. The final themes and subthemes were then discussed by all 3 authors (NL, JJ, and PL) with the original text of transcription used as a confirmation of concept summary and naming before the final reporting.

Results

Overview

Three main themes emerged from the explorative analysis: (1) existing addictive needs dictate DPS's "placement" in gambling, (2) DPS changes gambling subjective experience, and (3) problem gamblers' perspectives on DPS. The first theme focuses on players' way of integrating DPS into their gambling activities, covering three subthemes, each developing players'

appropriation of DPS into their gambling context to (1) workaround RG measures, (2) fit into gambling habit, and (3) shorter time to start and get a reward. With four subthemes, the second theme sheds light on DPS's influence on gambling habits in the form of (1) subtle nudge on behavior, (2) opens up new gambling habits, (3) introduce bias, and (4) facilitate intangible qualities, such as trust to sanction different forms of illegal gambling.

Additionally, we find three subthemes with a nature of reflective content summarized in the third theme where problem gamblers react to DPS: (1) DPS is not for us, (2) pessimistic about RG tools in DPS, and (3) recommendations and opinions where the DPS role is conceived as having a minimal role in harmful gambling. [Table 2](#) presents the analysis summary, and a more detailed theme development process can be found in [Multimedia Appendix 3](#).

Table 2. Summary of themes and subthemes.

Main themes and subthemes	Summary of subthemes
Existing addictive needs dictate DPS's^a "placement" in gambling	
Workaround RG ^b measures	<ul style="list-style-type: none"> DPS can be used to bypass RG tools. It can also enable players to maximize gambling "perks."
Fit into gambling habit	<ul style="list-style-type: none"> DPS fits into a habit of a gentle start of the day with gambling. Gambling habits direct both the choices and ways of DPS use.
Shorter time to start and get a reward	<ul style="list-style-type: none"> DPS is used to make the "chores" of depositing "invisible." DPS's speedy withdrawal function is seen as a reward not just in terms of earning a prize but also for continuing to play.
DPS changes gambling subjective experience	
Subtle nudge toward harmful behavior	<ul style="list-style-type: none"> DPS can potentially facilitate dark flow in gambling. Subtle nudging toward longer "time on device" and harmful games, such as casinos.
Opens up new subjective experience	<ul style="list-style-type: none"> DPS enables one to develop new habits and ways of being a gambler. Rewards do not feel like wins anymore as they just represent numbers.
Introduces bias	<ul style="list-style-type: none"> DPS can introduce multiple biases, such as the illusion of control or the availability of unlimited funds. DPS can create a desensitizing feeling toward the value of money and gambling losses.
Facilitate intangible attributes	<ul style="list-style-type: none"> DPS can facilitate confirmation bias and increase trust in unregulated gambling sites.
Problem gamblers' perspectives on DPS	
DPS is not for "us"	<ul style="list-style-type: none"> The integration of DPS into the gambling context needs scrutiny. The payment tool is used in gambling with an advantage for the industry in mind.
Pessimistic about RG tool in DPS	<ul style="list-style-type: none"> The effect of DPS on gambling behavior is minimal. Integrating "passive" RG tools, such as red warning with DPS, will not help problem gamblers.
Recommendations	<ul style="list-style-type: none"> Wins withdraw-focused RG measures in DPS can be more effective. DPS should be banned from operating in unregulated gambling sites.

^aDPS: digital payment solution.

^bRG: responsible gambling.

Existing Addictive Needs Dictate DPS Placement in Gambling

Workaround RG Measures

The participants noted that DPS provides opportunities to engage in gambling behaviors that would not be easily possible otherwise. In some instances, for example, participants reported that access to gambling was intact even though their names were included in the Swedish national self-exclusion registry because DPS enabled them to access unlicensed gambling operators. One participant described the use of DPS as a “negotiating system,” effectively offsetting the goal of RG tools implemented nationwide:

The bigger factor for players to go play on unlicensed (sites) is payment solutions. They (players) are in Spelpaus (self-exclusion registry). Therefore, they negotiate the ban with (a) payment solution in Sweden. [Participant 1]

In other instances, some participants describe using DPS to circumvent specific RG features aimed at preventing harmful gambling, such as bonus offers and free spins on online casinos. Consequently, most participants recognized how DPS can constitute a ready-to-hand tool to overcome the “challenges” they face in satisfying gambling cravings and maximizing rewards.

Swedish casino is super easy, but I get (a) bonus in the unlicensed sites. Sometime(s) also find it cheaper to deposit in the unlicensed ones. I used the payment solution to do that. They (unlicensed sites) also offer free spins. [Participant 4]

Fit Into Existing Gambling Habits

We also found players to appropriate DSP in line with their usual gambling habits. As they became comfortable with different payment solutions, they picked “favorites” that seamlessly fit into their gambling style. For example, 1 participant noted that his choice of a specific DPS—a popular Swedish mobile payment system—allowed him to start the day the way he “wanted it”:

I always start with the Swish [a mobile payment solution] on casinos, and when I reach my limits, I move on to the ones that I have my card saved and so on. For me, the easiest one to start the day with and then just push it forward. [Participant 4]

Furthermore, the participant also mentioned that his choice of DPS has enabled him to make a smooth transition to other casino games after a win without worrying about lengthy fund transfer processes.

I want to change casino(s) because I've been lucky for a while and then I need to try the other sixteen so just moving around the money. Swish is the best one because if you played with the Swish, you could have the money quite quick(ly) back and move it forward. [Participant 4]

The same sentiment was shared by other participants: different payment solutions were seen to satisfy different purposes and hence apt for different gambling routines.

Shorter Time to Start and Get a Reward

The most prominent reason for integrating DPS noted among all participants was related to the speed and “invisibility” a DPS affords in transferring funds during both deposit and win withdrawal. Most participants noted that they always wanted to quickly start gambling and perceived the process of depositing funds as a cumbersome chore to deal with before the fun started. DPSs that are already integrated with operators and commonly used among the players for other purposes were considered the best to make depositing “task invisible.” One participant noted that he chose a payment solution that makes betting and deposit almost synonymous:

When I'm thinking about payment solutions, for me I never used a solution where you had to make an account on one and then deposit. Everything should be direct. I never used the systems that were not directly connected to the account. Because it was too much of a hassle and then I had to see the money two times I would say (laugh). Yeah, but yeah, I had to see the money going in one then going away to another account. I didn't want that. [Participant 5]

Participants saw a speedy win withdrawal not just as receiving a prize but mainly as a resource to continue gambling. As such, win withdrawals may stay in the DPS account for fast redepositing. In addition, the need for speedy withdrawal seemed to correlate with the progressive worsening of PG.

The withdrawal time is important, especially when you need the money. When I started gambling, it was OK for me to wait for a couple of days. But when I got more and more addicted and intense, it became very important for me then. I remember I used to select Poker sites on stuff like how they looked; but that all went away once I got addicted, and payment solution and withdrawal time became important factors for me. [Participant 1]

DPS Changes Gambling Subjective Experiences

Subtle Nudges Toward Harmful Behavior

Most participants noted that DPS seamlessly fit into, and contributed to, the development of an uninterrupted “fictional world of gambling,” potentially affecting one’s financial well-being. Recounting such an experience, one participant described a dark flow of gambling where even getting a payday loan amid intense gambling activity was perceived as winning a jackpot:

You keep swishing; it is a fantasy world. When you are out, you (use) SMS loan money, it takes only 5 minutes. It's as if you got a jackpot in (a) casino. It is the same feeling. It is a success as if you gamble and win. [Participant 5]

In the same vein, DPS has been shown to subtly facilitate longer time-on-device by enabling operators’ actions, such as a

suggestion to refill deposit accounts via a DPS one-click link and a sign-off. At times, refill amounts were suggested.

When money is almost gone, not completely gone almost gone always pops up “OK do you want to refill” ... that’s bad because then it’s like a quick link ... When you’re in a game and then it’s just OK, it feels quick and it’s like one press. That’s really stupid. [Participant 3]

As noted in the first theme in passing, the speedy solution among payment methods was revealed to subtly nudge players toward harmful types of games. In many instances, participants were heard associating DPS with casino games where at times, the payment method is used as a reason for choosing gaming platforms.

You always choose those casinos that are easy to deposit. I used quick casinos to put small amounts of money many times ... I use the easiest, Swish, to deposit. [Participant 4]

Open Up New Subjective Experience

In addition to subtle behavioral nudging, DPS can enable a new subjective experience of gambling behavior. Some participants reported that they developed new habits, such as gambling at workplaces or playing while driving as the adoption of DPS became widespread.

I started to play a lot more at (the) workplace when Swish came into (the) picture, and it was so easy. I have what you call blue-collar work that I must work (with) my hands, but I’ve seen when it was so easy you managed to work and play. [Participant 6]

After 6 hours I could drive 300 km, and I use the easiest one; Swish to put the deposit while driving. One time I was about (to) crash: I panicked. [Participant 4]

Introduces Bias

We also found some evidence of DPS’s nature in introducing multiple biases in gambling activities due to its technological makeup. In line with past research, the most obvious observation was the effect of digitalization on diminishing the value of money [33]. Some participants have also discussed how DPS enables them to connect different sources of funds (eg, different bank accounts, cards, or at times, invoices) into 1 DPS account to select deposit sources as they see fit. In addition to increasing money spent on gambling, such a setting created the illusion of unlimited funds during gambling activities.

They’re very easy because when I played, I had a few cards here which are used and they just picked up one of them, and (that) is OK. [Participant 4]

You lose all the picture and it’s just a figure. You have money then out of money and done. [Participant 5]

DPS was also shown to preface the illusion of control by enabling both a “controlled” amount of spending and frictionless payment. One participant noted that since his choice of DPS asks him to sign off each deposit amount, it felt like it was controlled spending. However, since the flow of signing off

was frictionless and almost invisible, in practice, it was not so controlled.

For me, I used quick casinos to put in small amounts of money many times to not feel bad and lie to myself. I put 500 SEK again and again, but how many times? (laugh). [Participant 4]

Facilitate Intangible Attributes

Finally, participants were heard discussing how DPS can influence their choice of games, gambling segments, and environment (ie, licensed vs unlicensed operators) by creating confidence and trust in the site where they are being integrated. The trust relegating effect was stronger for DPS, which is also used daily for other digital purchases.

It mattered to me if I knew the payment solution to play in the unlicensed sites, and it is a factor in selecting unlicensed sites. [Participant 2]

Problem Gamblers’ Perspectives on DPS

DPS Is Not for Us

The majority agreed that DPSs have negatively influenced their gambling behavior. There was a general sentiment that DPS are being swiftly integrated into gambling platforms without sufficient regard for the challenges they present to problem gamblers.

I think it’s scary that the Swish doesn’t have some red button. No one asks you if you do it again and again. [Participant 4]

Yeah, or at least red flags ... The system wasn’t designed for us. It was designed for the general population. [Participant 1]

Another reaction from the participants emphasizes that the DPS industry is taking advantage of the transition to a cashless society, which in general, gives an advantage to the financial industry.

Pessimistic About RG Tools in DPS

Some participants expressed pessimism about whether DPS-specific RG tools would even have helped them. More specifically, RG measures that are more reactive to players’ behavior, such as warnings or even bans based on gambling behavior, would not have helped. They noted that as long as the resource exists to spend on gambling, such measures can easily be evaded.

For me, the payment solution didn’t (matter), I mean, I would have gambled. It doesn’t matter if it took five minutes or ten, I would still have done it ... For the people who do it on a smaller scale then maybe it’s a little bit different. For me, it didn’t matter. If I just can get money in and out; that is the way, it is. [Participant 5]

I’m just thinking that a limit or ban can be good in some ways in Fintech, but I also think that for me I wouldn’t stop there if there was a red button or something like that it wouldn’t have helped me. [Participant 6]

Recommendations

Toward the end of the session, participants made a few proposals on how to make DPS a more RG-oriented product. This included measures concerning withdrawals, including making it harder to withdraw, removing cancel withdrawal options, and rethinking the design of win redepositing options. Other proposals include flagging deposit intensity as opposed to amount and the banning of DPS at unlicensed gambling operators.

It is easier to deposit than to withdraw your money, but it should be the other way around ... I will make it harder for withdrawal. [Participant 3]

So, the amount might not be a good sign, but how many times I did (deposit) should be the sign for them to signal ... no one asks you if you do it again and again. [Participant 4]

Discussion

General Findings

Our preliminary findings revealed DPS's ability to seamlessly integrate into existing habits and enhance players' ability to achieve their goals. We also found evidence that the harmful influence of DPS can, at times, originate from its technological makeup. Consequently, changes in subjective experiences that emerged in the use of DPS were multifaceted. First, existing gambling routines, sensemaking of DPS features, and variation of individual habits and behaviors influence how and to what extent DPS affects gambling behavior. This aligns with existing literature that shows how various users interpret and use DPS features in diverse ways. Some problem gamblers, for example, were shown to perceive DPS's budget tools as a means to address their gambling issues while players who identify themselves as healthy gamblers considered such features as merely a "safety net" [5] or found them restrictive and unnecessary [17].

Second, our findings indicate that the nature of DPS can influence players' gambling behaviors in a variety of ways. For instance, participants felt that they were in control of their spending since they authorized the deposit "button" at all times, while the frictionless payment flow diminished the money spent. As such, the inherent flexibility and "invisibility" of DPS in players' gambling experiences enabled the mediation of conflicting values and facilitated impulsive deposits over rational decision-making. In another respect, we observed a more pervasive nature of DPS where it can trigger new gambling behaviors. For instance, participants reported gambling more often in situations that they would not typically gamble in (eg, workplace or driving), while others noted that they developed trust in illegal operator sites because of their familiarity with the DPS used by those operators.

Finally, participants' discussion on their general perception of DPS surfaced different perspectives that span from an unfavorable view of DPS to an agnostic attitude to recommendations on how to make payment solutions better. The findings underline players' keen awareness of digital payment pitfalls in their gambling behavior and disappointment

in the lack of RG effort in the area. In what follows, some theoretical and practical implications of this study are outlined.

Theoretical Implications

This study highlights the need for interdisciplinary research to conceptualize the role of DPS in gambling activities. On the one hand, the evidence of how existing gambling behavior influences players' way of integrating DPS for gambling is in line with research that underscores the "social imperative on the technical"—the argument that technological features or their use are dependent on, and a product of human choices [34]. Typically, characterized as a sociocentric framing, users and their existing habits influence how technology is used, hence the outcome of subjective experience [35]. From this perspective, DPS can be seen as a tool to enhance one's ability to work around, augment, or enable existing habits in gambling activities.

On the other hand, the findings that emphasize DPS's both subtle and pervasive influence in determining the outcome of gambling, underscore a techno-centric perspective where technology has a more "deterministic" demeanor and direct effect on subjective experience. From this contrasting perspective, a more dominating role can be manifested where DPS can constrain, institutionalize, or directly shape players' gambling activities. In addition to being visibly deterministic, technology can have an "imposter" nature by presenting itself as a response to human needs while subtly nudging players toward harmful experiences [36]. With so-called user-centric design, for instance, gambling technologies have been shown to trigger greater betting intention, an illusion of control, and attention bias [3,37]. In both the "subtle and pervasive" nature of technology influence, our analysis has shown that DPS can facilitate gambling dark flow, longer time-on-device, access to unsafe gambling environments, diminish the value of spending, and nudge toward harmful games, such as casinos. Finally, the innate nature of technology, such as its transparency, is associated with lessening the pain of paying, resulting in impulsive consumption [33].

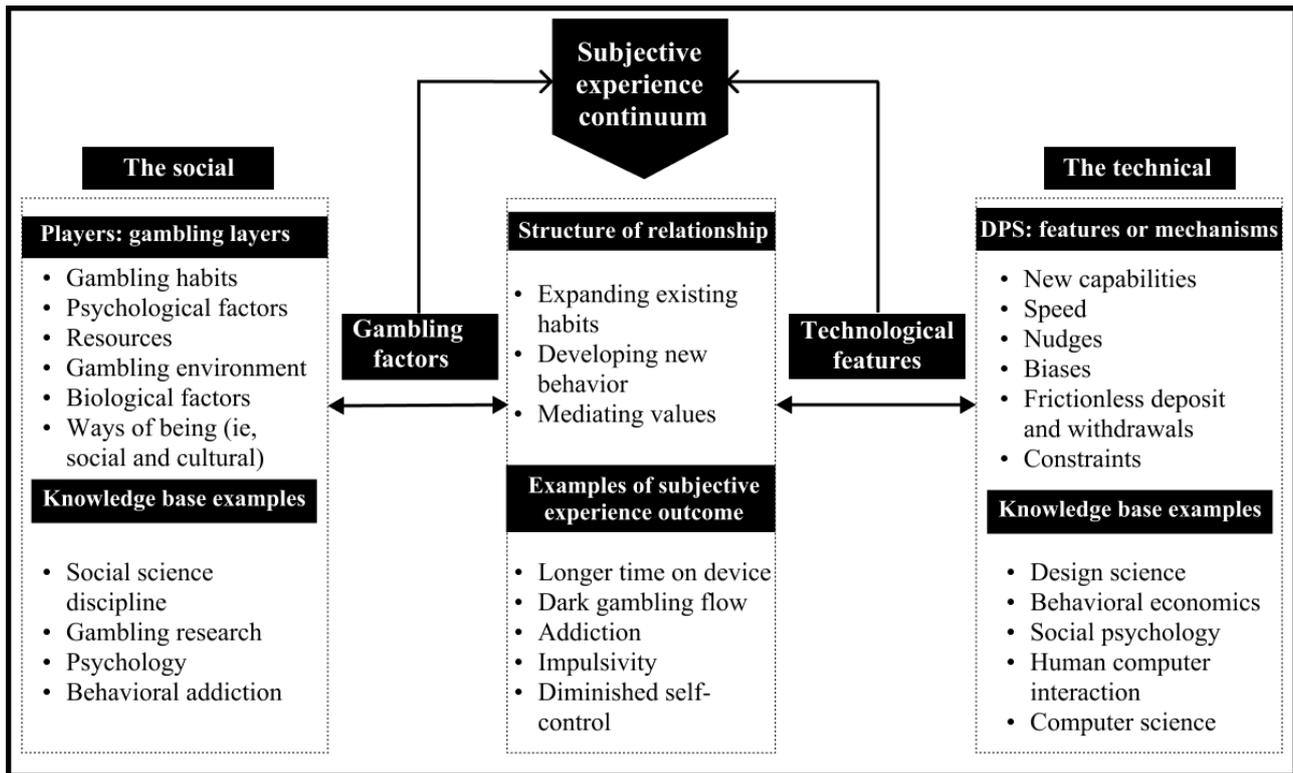

As such, conceptualizing the influence of DPS on gambling behavior constitutes a confluence of multifactorial structures. Put another way, capturing the interplay between the socio and technical aspects, symbolized by the hyphen that connects the 'socio-technical' term, is imperative to conceptualize the role of DPS in gambling activities [38]. The societal context on the left side of the hyphen encompasses cultural factors, sociodemographics, psychology, and broader societal influences, all of which shape habits and behaviors [39]. Representing the technical, the right side of the hyphen encompasses DPS's technological features and mechanisms that facilitate players in achieving their goals or directly enable new capabilities and forms of gambling activities. A preliminary conceptual framework illustrating the interaction between the social and technical aspects within the context of DPS is depicted in Figure 1. DPS-related changes in gambling subjective experiences (eg, addiction) can be seen as an outcome of various factors from the social and the technical. In terms of their scale of influence, these factors are not equally distributed and vary based on

contexts, such as individuals and time (eg, severity of gambling addiction).

As players integrate DPS into their gambling activities in the context of existing habits, their subjective experience can shift toward harmful gambling based on what the technology affords them to achieve. In addition, the framework suggested that layers of contextual factors that can affect an individual’s use of DPS in gambling are best developed in social disciplines, such as gambling research, psychology, and behavioral addiction

[39]. DPS can also directly influence gambling experience outcomes in the form of technological features using mechanisms, such as nudging, pervasive enframing, and constraining options. These features can introduce harm to gambling activities in the form of speed and biases or enable new ways of harmful gambling, which in turn can be translated to longer time-on-device, excessive spending, or dark flow of gambling. The development of these features and mechanisms can be both technical and psychological; hence, they apply design and behavioral science principles.

Figure 1. Preliminary conceptual framework to examine the influence of DPS in gambling subjective experience. DPS: digital payment solution.

Practical Implications

Historically, intervention measures, policies, and RG tools predominantly focus on gambling operators since they are responsible for how the gambling product is ultimately presented to the customer. However, the findings from this study illustrate that DPS can play an active role in facilitating harmful gambling experiences. Account-level protection, such as a “universal” budget limit and single customer view options with high spending and gambling intensity data sharing, are some of the opportunities that exist for policy-anchored implementations. In addition, it is important to detect and disable technology-enabled workarounds, such as gambling on unlicensed sites to rein in DPS’s offsetting nature of RG efforts. In line with policies, effective design interventions can also be used to compensate for “harmful” affordances. For instance, as noted by the participants, intentional delays in win withdrawal and monthly gambling spending reports across operators are within reach for any financial institution given their data set.

Finally, there have been calls for a more comprehensive and cross-sectoral approach, incorporating measures, such as data interoperability among industry stakeholders and integrating

public health perspectives [40,41]. With appropriate regulations, DPS with gambling customers can play a pivotal role in data-sharing efforts that enable an overview of a customer’s gambling activities across different operators. In addition, public health preventive measures, such as affordability testing, which takes into account both financial state and gambling behavior, can be implemented in DPS platforms as a deterrent against unaffordable gambling [42]. These preventive measures also serve as a “safety net” for nonproblem gamblers, thereby facilitating the implementation of a population-oriented harm minimization strategy [5].

Limitations and Future Research

Given the exploratory nature of this study, several limitations have been identified, highlighting both the necessity for further investigation and new research opportunities. First, due to its limited size of empirical evidence, there is a need for more studies with a larger number of participants for the generalizability of this study’s results. Second, we decided to select problem gamblers as focus group participants, as financial decision-related gambling harm is more visible among high-intensity gambling user groups. However, the associations made between gambling behaviors and DPS can benefit from

future diverse groups of gambling participants. Furthermore, there were no notable demographic-based differences observed in the use of DPSs, possibly due to the group's uniformity in terms of payment methods used, types of gambling, or the regular attendance of participants in biweekly gambling support sessions. We also want to stress that the proposed conceptual framework presented here should be seen as a preliminary effort to start the conversation of how DPS, in its capacity as a technological product, can potentially facilitate harmful behavior. Using the corresponding knowledge base noted on either side of the hyphen, future research can identify and conceptualize key sociotechnical elements and their mode of interaction in shaping players' behavior.

Finally, technological products can be intentionally designed to mediate certain values—positive interventions or self-interest goals—that can shift subjective experiences for better or worse [43]. As such, more research is needed on the design aspect of technology that has a target audience in gambling. Due to space limitations and the scope of this paper, we will not go further into the design research field. However, the concepts of user-centered design, design for appropriation, persuasive system design methods, and overall intentional design research need to be part of future research to examine technological antecedents and their influence on gambling behavior [44-48].

Conclusions

Given that online gambling will continue to optimize its edge with the support of technological products, new challenges are emerging for researchers and policy makers in the effort to

reduce gambling harm. This study focused on problem gamblers' first-hand experience of DPS to examine its role in the overall setup of online gambling activities. Our preliminary findings suggest that seamless collaboration between operators and DPSs can create a potential environment conducive to facilitating harmful gambling behavior. Given their central place in gambling activities, however, DPS providers are also in a unique position to implement umbrella-like harm reduction measures, such as limit settings applicable across gambling sites. As such, there exist avenues for policy makers to onboard DPS to positively contribute to the effort of the RG agenda, as they have a bird's-eye view of gamblers across different operators.

Finally, as digital payment providers continue to attune their products to gambling merchants using "user-centric" design and consumer behavior data, the field needs to examine DPS's platform-like role in transforming players' subjective experiences in online gambling. This study highlights possible interdisciplinary avenues, such as sociotechnical-oriented research, to fully grasp the role of technological products in general and DPS in particular in gambling behavior. The preliminary framework demonstrates the interplay between the sociotechnical components—from privileging the social while acknowledging the technical to giving equal agency for both sides of the hyphen to tech-dominated social experiences. More research is needed to further delineate the structure of the relationship between enabling technological products and the characteristics of gamblers that will ultimately influence the outcome of gambling.

Acknowledgments

The authors would like to thank their focus group participants for sharing their stories and willingness to spend time with us. This study was funded by a grant from the Independent Research Council (forskningsråd) of Svenska Spel in Sweden (fund ID FO2022-0004).

Data Availability

The data sets generated and analyzed during this study are not publicly available due to the sensitivity of the data and per ethical approval guidelines.

Conflicts of Interest

NL has received funding from the independent research council of Svenska Spel and is currently employed by Karolinska Institute. He has not received any direct reimbursement from the gambling industry, nor holds any shares. JJ is an employee at Sustainable Interaction, a private company working with responsible gambling and online training with the gambling industry, reports past and ongoing industry-academia collaborations with several gambling providers, yet has no personal financial ties to the industry. PL is employed by the public-operated addiction clinic in Stockholm and has past and ongoing industry-academia collaborations (with full academic freedom) with several gambling operators, including project-specific financing, albeit not on the topic of the manuscript in question. PL has no personal financial ties to the gambling industry (including no honoraria) nor any other ties.

Abstract

Background: Digital adherence technologies (DATs) are being studied to determine their potential to support tuberculosis (TB) treatment and address the shortcomings of directly observed therapy. Previous research has shown inconclusive results on whether DATs can enhance medication adherence among persons with TB.

Objective: This study aims to understand the acceptability of DATs, namely, medication labels and smart pillboxes, among persons with TB, health care workers (HCWs), and key informants (KIs) in the Philippines. The objective is to gain valuable insights that can inform the design and implementation of DATs in the Southeast Asian region, which meet the needs and preferences of end users.

Methods: Persons with TB, HCWs, and KIs were recruited from intervention facilities to participate in in-depth interviews conducted between March 2022 and January 2023. These interviews were transcribed and translated into English. A thematic analysis was carried out using NVivo software (Lumivero) to identify and analyze themes. Themes were then structured within a modified social-ecological model.

Results: A total of 25 persons with drug-sensitive TB and 20 HCWs or KIs were interviewed. Both groups emphasized that users' technology literacy level, financial conditions, and motivation to be cured determined how they interacted with the DAT. They also acknowledged that DATs helped foster their relationship with HCWs and enabled efficient treatment support. Concerning technology, persons with TB found DATs easy to use and able to reduce clinic visits. HCWs mentioned that DATs added to their workload but also allowed them to support users who missed doses. However, both groups experienced technical challenges with DATs. Regarding program implementation, users appreciated the clear explanations and demonstrations provided by HCWs. Yet, some users reported inconsistencies between DAT settings and the information provided. HCWs stressed the importance of comprehensive training and sufficient resources for effective program implementation in the future. At the community level, both groups noted that DATs and program design protected users' privacy and reduced the risk of stigma. Finally, users and HCWs shared various contextual factors that influenced their experience with DAT, including infrastructure challenges and the impact of the COVID-19 pandemic.

Conclusions: In the Philippines, persons with TB and HCWs showed a high level of acceptance and satisfaction with the impact of DAT and program design. They expressed a desire for the continuation of DATs. The challenges encountered underscore the need for ongoing technological development to minimize malfunctions, enhance the capacity of health facilities, and improve infrastructure. DATs have demonstrated their ability to strengthen user-HCW relationships and protect users from stigmatization. Additional efforts are required to scale up the DAT program in the Philippines.

Introduction

Endorsed by the World Health Organization (WHO), directly observed therapy (DOT) is part of tuberculosis (TB) programs worldwide at varying degrees of implementation. Despite its widespread implementation, shortcomings in the DOT approach have emerged. Frequent health facility visits disrupt patients' daily routines, increase financial burdens, and impact patient autonomy [1,2]. Hence, alternative treatment support strategies such as digital adherence technologies (DATs) are being evaluated to determine their effectiveness in supporting TB treatment and addressing the limitations of DOT [3-5]. These technologies leverage mobile phones, computers, web-based platforms, and smart pillboxes to collect real-time data on patient treatment adherence.

Studies conducted in Kenya, Vietnam, Peru, and China have shown that DATs have the potential to improve medication adherence among persons with TB [4,6-9]. By empowering persons with TB to take a more active role in managing their health conditions alongside health care providers, these technologies have the potential to reduce the financial burden and disruption associated with DOT and promote autonomy [10]. Additionally, DATs allow health care workers (HCWs) to identify individuals who may require additional support during their treatment [11]. Studies conducted elsewhere have yielded inconsistent evidence regarding the impact of DATs on improving adherence outcomes compared to the standard of care, which includes DOT [4,12-17].

The multicountry Adherence Support Coalition to End TB (ASCENT) project was initiated to add to the evidence base around DATs [18]. This multidisciplinary project compared the impact of DATs against the standard of care in terms of treatment outcomes and sought to determine the feasibility and acceptability of DATs for TB treatment support. Understanding the acceptability of DATs among persons with TB and HCWs implementing DATs are key to determining the technology's long-term impact and viability. According to Sekhon et al [19], the acceptability of a health care intervention is determined by the "people delivering or receiving a health care intervention consider it to be appropriate, based on anticipated or experienced cognitive and emotional responses to the intervention." Currently, there is limited research examining the acceptability of DATs among persons with TB and HCWs in the Southeast Asian region; further research is needed to determine their long-term impacts and viability [20-22].

Drawing on in-depth interviews conducted as part of the ASCENT study in the Philippines, this paper describes the perceptions and experiences of persons with TB, HCWs, and key informants (KIs) regarding DATs. It seeks to address the evidence gap around the acceptability of DATs and ultimately seeks to garner insights to design and implement DATs in the Southeast Asian region that are responsive to the needs and preferences of the end users.

Methods

Study Setting

This study is part of the ASCENT: 4-country evaluation of DATs for TB treatment, aimed at evaluating the effectiveness of DATs across 4 countries [18]. The DAT intervention included the provision of medication labels or smart pillboxes ([Multimedia Appendix 1](#)), a digital adherence platform, and differentiated care among adults with drug-sensitive tuberculosis (DS-TB) in the Philippines, South Africa, Tanzania, and Ukraine.

According to the WHO [23], the total TB incidence rate in the Philippines was 638 per 100,000 population in 2022. In the 2000s, directly observed treatment short-course achieved full coverage in the Philippines, being available in public and private health care facilities [24]. As per the National Tuberculosis Control Program (NTP) Manual of Procedures 6th edition of the Philippines [25], DOT can be administered within a health care facility on a daily basis by an HCW or outside the facility by a trained treatment supporter, typically receiving a 1-week supply of medication. The treatment approach is determined jointly by the persons with TB and the health care provider.

In the Philippines, the ASCENT study used a cluster randomized trial, using health facilities as the unit of randomization. In total, 64 health facilities from the Bulacan and Pampanga provinces in Region III of the Philippines were included. Of the 32 facilities in the intervention arm, 16 used medication labels, while the remaining ones implemented smart pillboxes. Adults (18 years or older) starting the DS-TB regimen were invited to enroll. In medication label facilities, DAT was offered to consenting persons with TB who had access to a mobile phone, either their own or that of their treatment companion. Persons with TB who did not have access to or had difficulties using mobile phones were offered a smart pillbox while supplies lasted in that facility. In smart pillbox facilities, consenting persons with TB were offered a smart pillbox. Individuals younger than

18 years and with drug-resistant TB were excluded from the study according to the study protocol [18].

The overarching digital adherence platform was used to track adherence information for both DATs. Medication label users were asked to take their daily medication and then log their intake by sending an SMS text message using the toll-free number on the medication blister packs. Some telecom operators in the Philippines require a positive credit balance (Php 1.00 or approximately US \$0.02) to send free SMS text messages. Smart pillbox users received a pillbox to store their medication. When the user opens the box to take their medication, the box's sensor sends a notification to the platform registering the medication intake. In cases of an unstable network connection, the box records the opening and transmits the timestamped data once the network is available again. If a user fails to send a code or open the box before 4 PM, the system triggers a reminder message sent to the user's phone to prompt the patient to take and log their daily dose. If no dose is subsequently logged before midnight, the system triggers a notification message sent to the user at 8 AM the following morning, alerting them of their missed logged dose and reminding them to complete the current day's intake.

The digital adherence platform allows HCWs to remotely view users' treatment adherence. Each person with TB is linked to an adherence calendar, visualized by 1 colored box per day. Individuals who have logged their dose by opening their smart pillbox or sending a message will have that day marked in green on the platform, whereas those who have missed a dose will have it marked in red. If a person with TB missed 1 daily dose, the HCW was expected to make a follow-up call to provide support. If a person with TB missed doses for 2 consecutive days, community-level HCWs were expected to visit the user. Persons with TB were only required to visit the facility to refill their medication or seek medication advice. HCWs were expected to check the system daily, wherein they viewed the adherence calendars and accessed Task Lists—consolidated lists per support action (eg, call and home visit) indicating which persons with TB required follow-up support. This full pathway of support escalation, or differentiated care, was determined together by in-country health system stakeholders, implementers, and patient advocacy groups.

User adherence records were captured by the adherence platform and then transferred to the local Department of Health (DoH) Integrated Tuberculosis Information System. Prior to the implementation, training was provided to all HCWs from the 32 intervention facilities involved in the project on platform use, patient orientation, knowledge about DATs, and treatment counseling.

Participant Recruitment and Data Collection

We used semistructured, in-depth interview methods. DAT users (medication label and smart pillbox), HCWs, and KIs were purposively recruited from up to 10 ASCENT DAT facilities in the Philippines. HCWs and KIs were selected based on their role and level of involvement in the project. Interviews were conducted in enclosed meeting rooms within the facilities, and before the interviews, all participants provided informed

consent for the interview and it being recorded. Data collection took place between March 2022 and January 2023.

For user interviews, we aimed to recruit a minimum of 20 participants, comprising 10 male and 10 female participants, who were currently undergoing TB treatment in DAT facilities (offering either DAT). Users were selected based on either demonstrating documented good adherence, receiving differentiated care, or having chosen not to use DAT. Furthermore, we sought to purposively recruit a minimum of 20 DAT HCWs and KIs from the DoH or the NTP of the Philippines.

Data Collection

The interviews were conducted by 1 researcher and 2 research assistants from the ASCENT Philippines team. These individuals received training in qualitative research methodologies prior to data collection. An open-ended interview guide was used to facilitate the interview with persons with TB. The guide covered topics, such as users' experiences with using DATs, including unintentional disclosure, factors that facilitated adherence or nonadherence to the treatment, and cultural or other barriers that deterred them from using DATs. Due to COVID-19 restrictions in the Philippines, interviews were conducted via phone calls. Due to language barriers and age considerations, some interviews were conducted in the presence of the user's treatment companion. The duration of the interviews ranged from 30 to 50 minutes. The same research team used a separate interview guide developed for HCWs and KIs. They were queried about their perceptions and the feasibility of implementing DATs in the Philippines. The duration of these interviews ranged from 40 to 60 minutes. Interviews were conducted in either Filipino or English, depending on the participants' preference, and were audio recorded.

Data Processing and Analysis

The recorded interviews were transcribed verbatim in the local language and subsequently translated into English. To ensure accuracy and quality, an independent staff member translated the English transcript back into Filipino for cross-checking. This process helped validate the quality of the translation and ensure that the original meaning was preserved.

Thematic analysis was conducted to identify and analyze themes emerging from interviews, capturing the richness of the data while remaining independent of existing theory [26]. Using critical realism, this analysis describes participants' experiences with DAT and their interpretation of those experiences in relation to the local context [27].

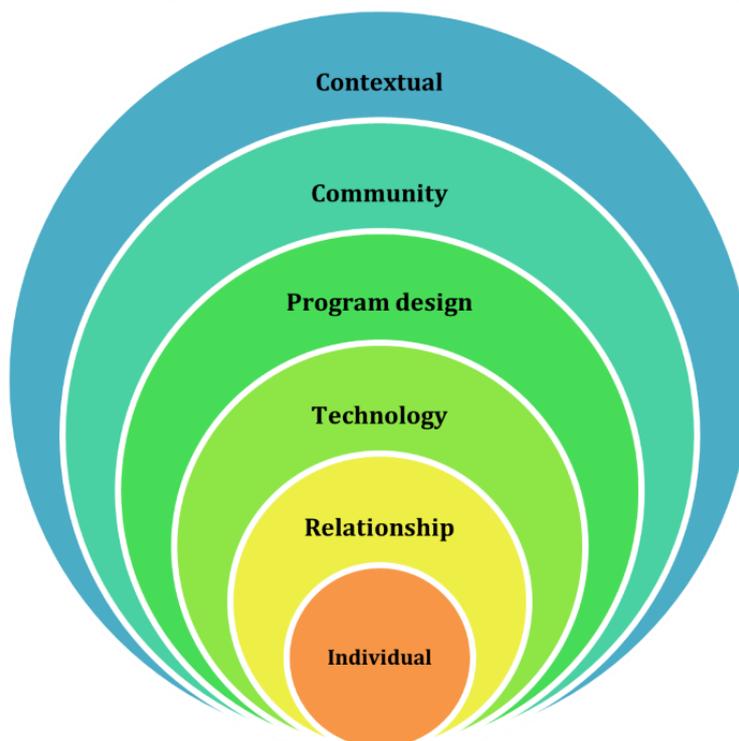

A total of 2 coders, CLL and BGT, based in the Netherlands, independently coded the transcripts using NVivo software (Lumivero). Regular meetings were held between the coders and other coinvestigators to discuss the coding process and identify emerging themes. Following the establishment of the initial codebook, the coders collaborated with the interviewers from the Philippines to gain a deeper understanding of the interview process, project implementation, and the contextual factors specific to the country. This collaboration aimed to further refine the codebook.

The coding process was conducted separately, categorizing the type of DAT used by persons with TB or overseen by HCWs. After refining the individual codebook for each DAT, a decision was made to consolidate the analysis of the 2 DATs featured in this study. This decision was supported by the observation of overlapping factors influencing persons with TB and HCWs in their use of the 2 DATs.

Following the coding process, the social-ecological model has been modified to present the identified themes into 6 levels (Figure 1). The individual level considers personal factors (eg,

age, education, and income) that influence DAT interaction [28,29]. The relationship level focuses on social ties impacting DAT engagement [29]. The technology level explains how the function of DATs impacts user use. Program design levels relate to how the implementation process influences DAT use. The community level encompasses aspects of social culture, norms, and stigma, explaining how these factors guide interactions involving DATs [30]. Finally, the contextual level considers country-specific conditions (eg, infrastructure and policy) affecting DAT implementation.

Figure 1. The modified socioecological model (adapted from the findings of Sazzad et al [28] and McLeroy et al [29]).

Ethical Considerations

The main study has been approved by the WHO Ethical Review Committee (0003296), the Single Joint Research Ethics Board (the Ethics Committee for the Philippines), and the London School of Hygiene & Tropical Medicine Ethics Committee, United Kingdom. Written informed consent was obtained from all participants prior to their interviews. All interview transcripts were deidentified to preserve the privacy of the participants.

Results

Characteristics of Participants

Interviews were conducted with 25 persons with DS-TB (12 male and 13 female participants; ages ranged from 22 to 86 years; 14 bacteriologically confirmed TB and 11 were clinically diagnosed) from DAT implementation facilities. Overall, 19 persons used medication labels, and 6 used smart pillboxes.

Notably, 2 users who chose not to use DAT were invited to participate in the interview but did not provide consent. As a result, this study included only individuals who used DATs in their treatment.

A total of 20 HCWs and KIs (5 male and 15 female participants) were interviewed. In total, 10 HCWs worked in a medication label facility and 10 in a smart pillbox facility. In terms of professions, 13 of the participants were nurses in health care facilities, 3 were NTP medical coordinators, 2 were midwives, 1 was a medical technologist, and 1 was a data encoder. Due to a shortage of HCWs, midwives were assisting with TB treatment; thus, they were included in this study. The 3 KIs included an NTP medical coordinator, an NTP city health officer from Bulacan, and an NTP municipal health officer from Pampanga. In terms of the geographical distribution of HCWs, 11 were from Bulacan, 8 were from Pampanga, and 1 was from Region III province office (Table 1).

DAT User and HCW Perceptions and Experiences

Individual Level

At the individual level, users' technology literacy, financial conditions, and motivation to be cured influenced their

interactions with the DAT. Prior to implementation, HCWs expressed concerns about the potential technological complexity of DAT, which could pose usability and adaptability challenges for users.

... it seems like it's easier for the patient to have face-to-face interaction with the HCW. [Nurse, female]

Users with low technology literacy and older people encountered difficulties in sending the code using the mobile phone. Without the assistance of family members or treatment companions, older people struggled to comprehend the instructions for using DAT. HCWs also found it challenging to explain the system to individuals with limited technology literacy.

Interviewer: When Grandma just started taking medicine, did the nurse teach her as well?

Participant: No, just me because she wouldn't be able to understand the instructions. [Treatment companion of a medication label user, age ≥60 years, female]

So, the challenge when we introduce it to the elderly, they feel like they can't understand, and it's hard to use. Then they refuse. [Nurse, female]

HCWs observed that many potential DAT users lacked access to a phone or had insufficient credit on their SIM cards, causing fewer individuals to use the medication label. Some HCWs working in the medication label facility mentioned that if the facility ran out of pillboxes, eligible users for joining the DAT program would be excluded from the intervention.

That's when we have a problem when the patient doesn't have a cell phone and then they don't have a support system, so we give them a pillbox. [Nurse, female]

Despite the above personal circumstances, many users showed a strong intrinsic motivation to be cured, which drove them to embrace the DAT and remain committed to their treatment. Some users even used supplementary methods, such as paper calendars and phone alarms, to stay on track with their treatment.

It was his willingness to get better. That was his main motivation to continue taking the medications given by the nurse or the doctor. [Treatment companion of a medication label user, age ≥60 years, male]

Relationship Level

Interpersonal relationships shaped how users interacted with DATs, potentially facilitating their use and potentially being transformed by DATs. Many users disclosed their use of DAT to their family members but did not share this information further. This is because, during their initial facility visit, persons with TB in the Philippines are required to bring along a family member as their treatment companion. Multiple participants mentioned that their family members or treatment companions reminded them to take their medication.

Yes, because aside from me, I was also being reminded by my husband. [Smart pillbox user, age 50-59 years, female]

Users and HCWs both acknowledged that using the DAT helped foster trust between them. It enabled efficient and less intrusive treatment support.

there is another monitor on their end where they could see if you took your medicine or not. Doesn't it make

you happy and proud to have something like that? [Medication label user, age 30-39 years, female]

Yes, it will help me because there are patients who are compliant and we do not supervise them that much. We have built trust with each other. [Nurse, female]

I can say that I have become closer to the patients but it really depends on the person. They know that I am checking their adherence, so they can approach me with more ease. [Nurse, female]

Technology Level

At the technology level, both groups experienced positive effects and technical challenges of the DAT that affected TB care. Among the positive effects, many DAT users reported that it reduced the burden of treatment by decreasing the frequency of clinic visits and the associated transportation costs. They described how this allowed them to maintain their regular lives while adhering to their treatment. In contrast to traditional DOT, HCWs agreed DAT can reduce user burdens and increase autonomy considerably.

... if we go to the centre daily, the fare back and forth will cost us 200 pesos ... it's difficult if I must go there daily because I can't work and do anything. [Medication label user, age 18-29 years, male]

You have to think economically. If the house is far away, the concern is not just the relationship of having a face-to-face talk, but economically it would burden the client. [NTP medical coordinator, female]

Moreover, users found DATs easy to use, describing the experience as trouble-free. They appreciated the specific features of each DAT that helped them stay on their treatment. Medication label users valued the SMS text message reminders, while pillbox users relied on the alarms. One user mentioned that simply seeing the smart pillbox at home served as a reminder to take medication.

I work the night shift, and sometimes the morning shift, sometimes I don't know the time anymore ... it reminds me that I need to take my medications. [Medication label user, age 30-39 years, female]

... it's good because every time I forget to take medications ... it has an alarm that rings at a quarter to 8 in the morning. So, this pillbox reminds me to take my medications. [Smart pillbox user, age 30-39 years, male]

Prior to the implementation, HCWs were concerned that DAT would increase their workload, but once the program was in place, some of them changed their perspective. They reported that DATs added to their tasks but also allowed them to view users' adherence and helped them adhere to treatment. This enabled HCWs to provide differentiated care to those who missed doses.

At first, I thought it was extra work because you have a lot [of forms] to fill out and with the number of patients we have, a few minutes for each TB patient ... [Midwife, female]

I'm able to know immediately with the use of the apps from Everwell who missed their intake, and I would call right after. [Nurse, male]

However, both DATs and the adherence platform experienced glitches. Medication label users sometimes received reminders after sending the code or did not receive SMS text message reminders at all. Although a small number of users expressed worry, most users disregarded incorrect reminders, confident that they had taken their medication.

A bit dissatisfied because then I get confused. Of course, at my age, I can be forgetful, but I know in myself that I have taken my medications. When they send that type of text, it makes me think again. [Medication label user, age 40-49 years, female]

Pillbox users and HCWs reported pillbox alarm malfunction, and the adherence platform also failed to show user adherence records correctly.

Interviewer: Was there a time when you were not sure what would happen to the pillbox while you were using it?

Participant: Yes, because sometimes it suddenly makes a sound, but sometimes we've already taken the medicine but it still makes a sound. [Smart pillbox user, age 50-59 years, female]

When the pillbox is opened, sometimes they don't even turn green. [Midwife, female]

In response to the technical challenge, HCWs highlighted the importance of improving the adherence platform by solving the existing glitches and integrating it with the local digital health information system.

Maybe what we mentioned is to integrate the KNCV program with ITIS so that there is less workload for HCWs so that they don't have to work twice. [Nurse, female]

Program Design Level

Similarly, users and HCWs shared their positive and negative experiences regarding the program implementation, which had direct implications on the effectiveness and user perception of the intervention. Users generally appreciated the clear explanations and demonstrations provided during their initial DAT consultations with HCWs. HCWs remain supportive throughout the treatment was one of the reasons why users adhered to using DATs and following the treatment.

they will find out what your concern is ... The people are kind. You won't feel that you are treated like someone who's sick. You will not feel discriminated that you are sick, that you have TB. They are accommodating ... Ahhh caring. [Medication label user, age 40-49 years, male]

Nevertheless, some users reported that the DAT setting did not align with what HCWs had initially informed them during the introduction session, causing confusion. Additionally, individuals working in environments where cell phones were prohibited faced challenges with the use of DAT.

I'm just wondering, the medications are reminded to be taken at 12 midnight in the text message. But the instructions given to me before at the centre are in the morning. [Medication label user, age 30-39 years, female]

Cellphones are prohibited in our factory ... Yes, so I get to text during trips. [Medication label user, age 18-29 years, male]

Regarding HCWs' experience, they acknowledged the value of DAT training in understanding its purpose and operation to alleviate misconceptions and misconceived notions of DAT complexity. However, some HCWs expressed concerns about sporadic or insufficient training opportunities, and others mentioned a lack of follow-up or refresher training. In some instances, HCWs were tasked with implementing DAT without adequate training. Hence, HCWs require comprehensive training and adequate resources to effectively implement the program in the future.

I wish there would be another training so that I can really know the program. I was just able to do that by fiddling with my cellphone. [Nurse, male]

When she gave it to me, I was not yet trained. There was only one time that she told me to train but that time I couldn't train either because I was alone. [Midwife, female]

HCWs also indicated that there was a shortage of pillboxes in their facilities, leading to the exclusion of persons with TB from the DAT program when they could not use medication labels for whatever reasons.

So, there are times when we can't enrol the patient to DAT because we don't have any pillbox available anymore. [Nurse, female]

In summary, users and HCWs were satisfied with the result, and they expressed a strong desire for the continuation and expansion of the DAT program in the future.

I wish they continue to give me medicine and always remind me. [Medication label user, age 18-29 years, male]

I hope this DAT can used by TB patients all over the Philippines because I think it is really useful. [Nurse, female]

Community Level

Many users highlighted that TB stigma remained an important issue within their communities. They expressed concerns about discrimination and stigmatization, which often deterred them from disclosing their use of the DAT to persons outside their immediate family.

I told ma'am that there are a lot of gossip mongers here and they might ask why the centre is bringing medicines to me, right? [Smart pillbox user, age 40-49 years, male]

Not anymore, but of course there is discrimination, isn't there? People are not that open about it yet, like,

“Oh my gosh, [she has] TB.” [Medication label user, age 30-39 years, female]

Nonetheless, both groups stated that DATs and the program design helped mitigate the risk of unintentionally disclosing users' health conditions through daily visits to TB clinics. Users viewed DAT as a way to protect their privacy and reduce the chances of experiencing stigma. As one medication label user expressed:

Because you stick to texting ... You will not be ashamed to go out as if the stigma you are talking about is already gone ... They don't know you're sick ... so you are not immersed in such an issue ... then your treatment is monitored so you come out of the treatment episode quietly. [Sleeve label user, age 40-49 years, male]

If there is someone that you know saw you at a TB facility, the perception is you have TB, and they will avoid you. So, by means of texting, and having their medicines daily, their neighbors don't have to know that they are having checkups with DOTs. [Nurse, female]

In this context, stigma not only acts as a factor for users to keep their health condition undisclosed but also serves as an incentive for them to use DAT to avoid revealing their health condition through HCW visits or daily visits to the facilities.

Contextual Level

Users and HCWs also shared various contextual factors that influenced their experience with DAT. Medication label users encountered challenges related to the availability of mobile network signals and power in their areas. Users were not able to charge their phones when there was a power outage in the area. These issues prevented them from instantly sending SMS text messages as required. Some service providers in the Philippines also required users to have a positive balance on their SIM to send the code. When users depleted their credit, they were unable to send the code, which then led to receiving reminder SMS text messages from the adherence platform.

It's just really difficult, for example, when the signal is affected ... What happens is when there is no electricity ... you can't feedback. [Medication label user, age 40-49 years, male]

Interviewer: But you mentioned that there were issues with the network sim card?

Participant: Because I am unable to chat when I don't have load. That is why I load up whatever amount. [Medication label user, age 18-29 years, male]

For HCWs, the challenges posed by the COVID-19 pandemic added to their workload, which, in turn, affected the implementation of the program. Some HCWs were diverted to COVID-19-related tasks, limiting their ability to handle DAT-related tasks.

However, because of COVID-19, there were many cases. My job then was to swab patients, so I wasn't able to visit the RHU and handle DAT-related tasks. [Medical Technologist, female]

HCWs recognized the need for additional resources to address these challenges effectively. They emphasized the importance of improving the network infrastructure to ensure reliable communication for DAT users. Additionally, they called for dedicated staff members to manage and support the DAT program.

I think the system improvement with the network because some clients are complaining that they cannot send a message and they didn't receive a reply. [Nurse, female]

There should be staff handling this program ... I have many programs under me. So really there should be staff who will handle that specific program, correct? [Nurse, female]

Discussion

Findings

This study illustrates the perceptions and experiences of persons with TB, HCWs, and KIs regarding the use of DATs. By analyzing their responses, we can assess the acceptability of DAT as described by Sekhon et al [19]. As previously highlighted, user and HWC use of the 2 DATs are influenced by overlapping factors. Our analysis also observes DAT-specific strengths and weaknesses, which will be illustrated using a modified social-ecological framework.

At the individual level, the results highlight the critical role of user motivation in achieving successful treatment outcomes. Users demonstrated their commitment to treatment through various means, not solely relying on DAT, HCWs, or family support. This observation aligns with prior research conducted in Pakistan [31]. HCWs noted that DATs assisted users adhere to treatment and fostered a sense of accountability for timely medication intake. This finding is consistent with similar results from Uganda and a meta-analysis [12,22]. However, users with lower technology literacy and financial constraints faced more challenges in using the medication label, potentially leading to exclusion from the program if a smart pillbox was unavailable in the facility. Within this group, acceptability appears to be slightly lower. Increasing the supply of smart pillboxes in the future might assure more users can benefit from the program.

Regarding relationships, DAT significantly alters the user-HCW relationships, even in the context of limited in-person interaction when compared to traditional DOT. Through DAT, persons with TB felt supported by knowing that HCWs were supporting them remotely, even when care delivery had been substantially impacted by COVID-19 restrictions. This finding aligns with similar research conducted in Africa, South Asia, and Southeast Asia contexts [4,12,20,21,32,33]. Technological advancements enabled users and HCWs in the Philippines to stay connected via mobile communication apps such as WhatsApp and Facebook. These communication channels contributed to the enhancement of their relationship, requiring minimal effort on both sides. In this aspect, both groups exhibited a high level of acceptability.

At the technology level, users and HCWs showed high levels of acceptability toward DATs due to their ease of use, assistance

in maintaining treatment adherence, and reduced treatment burden. HCWs valued the adherence platform for its ability to assist them in providing adherence support despite the additional workload it entails. However, the interviews revealed that medication label users faced more challenges stemming from external factors such as network issues, power supply, user technology literacy, phone ownership, and SIM card credit. Similar challenges were observed in previous research [20,22]. The smart pillbox on the other hand also encountered alarm malfunction issues. Research in Vietnam and India [13,21] showed that users consider pillbox alarms too loud and inconvenient for travel and might attract unnecessary attention when they visit the clinic to refill their medications. Yet, users from the Philippines did not express these concerns. In addition, the adherence platform sometimes failed to show correct user adherence records. Despite both groups expressing worries when the technology failed and stressing that these glitches need to be addressed, they wanted the DAT program to continue in the future, which shows they have a high degree of acceptance in this domain.

At the community level, TB stigma remained a significant concern causing hesitancy among persons with TB to seek help. The 2 groups stressed how DATs and its operating model in the Philippines effectively protected user privacy, reducing the risk of stigmatization. In contrast to certain other countries, users in this context reported no worries about stigma within their families, given the mandatory requirement for them to be accompanied by a family member or treatment companion during their initial consultation. However, they remained concerned regarding potential stigma at the community and societal level. Users refrained from sharing their use of DAT beyond their immediate family and fearing stigmatization if observed visiting a TB clinic. Research conducted in Ethiopia, Thailand, South Africa, and Zambia found that persons with TB do not want to be seen at TB clinics because of perceived stigmatization [34-37]. As previously outlined, in the Philippines, DATs substantially reduce the frequency of facility visits, from daily to every 2 to 4 weeks, depending on the user's circumstances, HCW arrangements, and local COVID-19 restrictions of the time. In some instances, community HCWs deliver medication to the person with TB if one lives in remote areas or without a means of transportation. During COVID-19, some local health care facilities also deliver medication to users because of the government's "no contact policy." The DAT operating model in the Philippines decreases the frequency of clinic visits, protects users from unintended disclosure, and thus reduces their perceived stigma.

Despite COVID-19 restrictions limiting home visits, users were motivated to adhere to their treatment to avoid being visited by HCWs, which might expose their condition within their community. This could explain why the interview participants demonstrated a high level of acceptance toward DAT, as it can protect them from stigmatization.

Program implementation is closely intertwined with contextual factors. The outbreak of COVID-19 significantly influenced DAT implementation in the Philippines, leading the government to enforce policies aimed at containing the virus's spread. The pandemic further strained the already burdened health care

system in the Philippines. HCWs stationed at research facilities were required to conduct COVID-19 testing and vaccination, diverting their attention and resources from providing differentiated care. This further amplified the workload of HCWs who were enrolling DAT users and managing 2 parallel health information systems without additional staff. Despite these challenges, they acknowledged that DAT enabled real-time monitoring and facilitated prompt follow-up with nonadherent users, ultimately enhancing their efficiency. The consensus among both groups underscored DAT's capacity to function in regions facing health emergencies and operating in stressed health care systems.

The issue of training remained a persistent concern for HCWs involved with DAT across various settings. Previous research carried out in India revealed that HCWs emphasized the necessity for more DAT training due to the frequent turnover of staff [21]. The phenomenon was also reported by the ASCENT Philippines team. The impact of COVID-19 further heightened matters, with newly recruited HCWs being focused on enrolling persons with TB without sufficient training. This issue is rooted within the health care system, and simply increasing the frequency of DAT training may not fully address the underlying problem. These observations emphasize that the acceptability of DAT is heavily reliant on the local health care system. Expanding the DAT program effectively requires addressing systemic health care issues. Failure to do so may compromise the program's impact and effectiveness.

Limitations

This study has successfully captured the perspectives and experiences of persons with TB, HCWs, and KIs in the Philippines who engaged with DATs. It is the first DAT acceptability research conducted in the Southeast Asian context and provides insights on how to improve DAT adoption in the Philippines from a bottom-up approach. However, this study only included individuals who used DATs in their treatment because some persons with TB who demonstrated low levels of treatment adherence or opted out of using DAT declined participation in this research. It was not possible, therefore, to examine the reasons underlying the low levels of adherence or why persons opted out of DATs. Their experiences and perceptions are extremely important for DoH and NTP to formulate a better DAT implementation. Hence, further research is needed to study users who opted out of DATs. This study included only 6 smart pillbox users, so we might risk underreporting issues encountered by smart pillbox users during the treatment.

Conclusions

In conclusion, this study reveals the experiences, perceptions, and challenges encountered by persons with TB, HCWs, and KIs during the research period. Both groups demonstrated a high level of acceptance and satisfaction toward the positive impact brought by DAT. The challenges encountered underscore the need for ongoing technological development to minimize malfunctions and improve local adoption. The majority of interviewees expressed a desire for the scaling up of DATs in the Philippines.

To achieve this, enhancing the capacity of health facilities through increased staffing, particularly with personnel dedicated to enrollment and user support, is crucial. Regular training can contribute to manageable user monitoring. External factors, such as network availability, SIM card credit, and power supply, need to be fixed to ensure smooth DAT implementation, especially for the medication label, in the future.

Finally, integrating the parallel digital health systems is essential to alleviate the health care workload. Beyond the potential to improve treatment outcomes and reduce loss to follow-up, DAT

has demonstrated its ability to enhance user-HCW relationships and prevent unwanted TB treatment disclosure or even stigmatization. Additional efforts are required to enhance the user experience for both persons with TB and HCWs, with the aim of expanding the program to other regions in the Philippines. Although the experiences gained in the Philippines can serve as a reference for other countries in the region considering implementing DAT in the future, it is crucial to recognize that DAT programs need to be tailored to fit within the local health systems and context of each specific region.

Acknowledgments

This research and the main Adherence Support Coalition to End TB project were primarily supported by grants from Unitaid. The funding organization had no role in the study design, data collection, data analysis, data interpretation, or manuscript writing.

Conflicts of Interest

The authors of this study received funding to implement the digital adherence technology (DAT) program in the Philippines as part of the Adherence Support Coalition to End TB project led by KNCV. The Adherence Support Coalition to End TB project aims to establish the evidence base for DATs and oversees their implementation across Tanzania, Ethiopia, and the Philippines. In addition, KNCV receives funding to facilitate the Global DAT Task Force secretariat and by extension to provide technical assistance to countries planning or implementing DAT.

Multimedia Appendix 1

Information on the medication label and smart pillbox.

Abstract

Background: In many parts of the world, men who have sex with men and transgender individuals face criminalization and discrimination. As a result, they are less likely to seek medical help, despite experiencing higher rates of HIV/AIDS, mental health issues, and other health problems. Reaching key populations (KPs) with essential testing, care, and treatment services can be challenging, as they often have a higher likelihood of contracting and spreading the virus. They have limited access to antiretroviral (ARV) therapy (ART) services, which means that KPs may continue to serve as reservoirs for new HIV infections if they do not receive effective HIV programming. This ongoing issue complicates efforts to control the epidemic. Therefore, modeling a digital health system to track ARV medication access and use is crucial. This paper advocates for the use of digital interventions to manage the health of KPs in underserved regions, using Nigeria as a case study.

Objective: This study aims to assess digital health interventions for monitoring medication and consultations among transgender people in underserved communities. It also sought to determine whether a system exists that could support ART adherence in Nigeria. Additionally, the study evaluated design strategies to address privacy and confidentiality concerns, aiming to reduce nonadherence to ARV medications among KPs in Nigeria.

Methods: A qualitative approach was adopted for this research, involving a thematic analysis of information collected from interviews with clinicians and other health practitioners who work directly with these communities, as well as from an interactive (virtual) workshop.

Results: The findings from the thematic analysis indicate a need to increase attendance at ART therapy sessions through the implementation of an intensive care web app. Unlike previous solutions, this study highlights the importance of incorporating a reminder feature that integrates with an in-app telemedicine consultancy platform. This platform would facilitate discussions about client challenges, such as adverse drug effects, counseling sessions with clinical psychologists, and the impact of identity discrimination on mental health. Other data-driven health needs identified in the study are unique drug request nodes, client-led viral load calculators, remote requests, and drug delivery features within the web app. Participants also emphasized the importance of monitoring medication compliance and incorporating user feedback mechanisms, such as ratings and encouragement symbols (eg, stars, checkmarks), to motivate adherence.

Conclusions: The study concludes that technology-driven solutions could enhance ART adherence and reduce HIV transmission among transgender people. It also recommends that local governments and international organizations collaborate and invest in health management services that prioritize health needs over identity.

Introduction

Background

The HIV infection rate in Nigeria is the third highest in the world [1]. As of 2018, 1.9 million people in Nigeria were living with HIV/AIDS, according to the 2019 Nigeria National HIV/AIDS Indicator and Impact Survey [2]. HIV and AIDS are much more prevalent among incarcerated individuals, high-risk drug users, sex workers, transgender people, men who have sex with men (MSM), and people who inject drugs. Studies by the United Nations Office on Drugs and Crime found that 9% of people who inject drugs [3] and 2.8% of incarcerated individuals in Nigeria are living with HIV/AIDS [1]. These rates are significantly higher than the estimated 1.4% prevalence in the general population [1].

HIV/AIDS is undoubtedly a challenging condition, as it requires lifelong therapy and may lead to the emergence of new HIV-associated complications, as noted by Deeks et al [4]. Although combination antiretroviral (ARV) therapy (ART) can improve the health of patients infected with HIV, barriers to effective ARV treatment can negatively affect outcomes for those living with the disease [5]. HIV/AIDS is a highly stigmatized condition, and individuals with HIV/AIDS are more likely to be diagnosed with other health issues, such as poor mental health, psychiatric disorders, and substance use disorders. These additional, negatively perceived conditions can increase stigma and hinder adherence to care [6,7]. Therefore, it is crucial to explore the benefits of digital health interventions for monitoring medication and consultations among people living with HIV/AIDS.

It is crucial to provide key populations (KPs) with necessary testing, care, and treatment services, as they are at higher risk of contracting and spreading the virus. Unfortunately, these groups often have limited access to ART services. Without proper HIV programming, KPs may continue to serve as a reservoir for new infections, hindering efforts to contain the pandemic [8]. There is a need to expand knowledge on the use of digital health innovations in ART delivery. However, there is a lack of understanding regarding the ethical creation and use of these digital health solutions [9]. This study aims to cocreate a digital health solution to track ARV drug access among transgender people in underserved communities. It also seeks to determine if a system exists that can be utilized to support ARV adherence in Nigeria. The study also explored design strategies to address privacy and confidentiality concerns among KPs, aiming to reduce nonadherence to ARV medications in Nigeria.

This paper advocates for the role of digital interventions in managing the health of KPs in underserved regions, using Nigeria as a case study. The study makes several innovative contributions: first, it documents for the first time in the literature the challenges faced by health care professionals working with KPs in Nigeria; second, it introduces a trigger question on the role of digital health interventions through an

interactive management (IM) approach; and third, it outlines the cocreation process with users in developing a digital solution, presenting this as an agenda for future research. The “Literature Review” section reviews the literature on ART and digital interventions, followed by the “Methods” section, which outlines the research approach and methods used in this study. The key findings (the “Results” section) and discussions (the “Discussion” section) are then presented, followed by vital recommendations and an agenda for future research in the “Conclusions” section.

Literature Review

ART has transformed HIV infection from a fatal illness into a manageable chronic condition [10]. ART can also reduce viral load (ie, levels of HIV RNA) and the risk of secondary transmission, establishing a new preventive paradigm where effective scaling of therapy could contribute to the end of AIDS [11]. Iyun [12] found that the majority of the 35 million individuals testing positive for HIV live in resource-limited settings. In 2016, an estimated 17 million of them were receiving ART, up from 1.3 million in 2006. Goals for 2020 projected treatment for an additional 20 million patients [13]. Although this expansion of ART is one of the greatest public health achievements of our time, significant challenges remain. Patients require near-perfect adherence of at least 95% to maintain undetectable viral loads and support immune system activity, making adherence to ART a considerable challenge.

In Nigeria, HIV prevalence rates among lesbian, gay, bisexual, transgender, queer, and intersex (LGBTQI) communities and MSM are up to 19 times higher than those in other populations [14]. Analyzing these groups is particularly challenging due to the limited number of studies and the insufficient funding allocated to this community. In a study by Liu et al [15], only 45% of MSM reported good adherence to ART. Low adherence rates are attributed to various issues, including HIV stigma, social exclusion, limited access to health care programs, fear of seeking care or being denied it, depression, and insufficient information about drug interactions between hormonal therapy and ART [16]. A recent meta-analysis [17] revealed that only 77% of sub-Saharan Africans on ARV medications adhered to the recommended dosage schedule. Overall, there is limited information available on the adherence levels achieved by medical facilities providing regular ART services.

Individuals who use ARV medication erratically may experience side effects, minimal benefits, and fewer treatment options in the future. It is crucial that every patient understands this before starting treatment. If a patient discontinues ART entirely, they will quickly lose any gains in immunity due to the continued spread of the virus and destruction of CD4+ cells [18]. It is essential to emphasize to patients that ART is a lifelong commitment. Effective patient education and adherence assessments require significant time and effort, but this investment is worthwhile. Clinical negligence occurs when a prescription is provided only at the initial visit without adequate

adherence counseling, a practice that unfortunately remains common [19].

Transportation issues, such as difficulties reaching the nearest medical facility, combined with fears of job loss from taking time off work, have made consistent adherence to ART challenging [20-23]. Additionally, several interview-based studies have identified patients' attitudes toward ART as a factor contributing to the rejection of HIV/AIDS antiretroviral therapy (HAART) [24,25]. People with HIV/AIDS have expressed various concerns about HAART, including worries about side effects, the need for strict adherence, inconvenience and practical issues related to the regimen, mistrust of conventional medications, fears of long-term organ damage, and the belief that treatment is unnecessary in the absence of symptoms. Additionally, concerns about the impact of HAART on self-identity and the potential for treatment to reveal their HIV status contribute to these negative opinions [26,27]. These concerns highlight the need to explore digital health solutions.

The potential of digital interventions in ART has yet to be fully realized, partly because it is challenging to build a comprehensive body of knowledge to guide decisions about digital health solutions. Information and communications technology is utilized in digital health interventions to improve health outcomes [28]. Digital innovations can be categorized into noninternet technologies (eg, SMS text messages and phone calls) and internet-based technologies (eg, social media, mobile apps, and websites) [29]. Internet-based digital interventions allow users to publish content and share information on sensitive topics at any time and from any location, potentially minimizing the risk of unintended disclosure of private behaviors. The recent globalization of instant messaging platforms has laid the foundation for internet-based digital interventions. For example, a widely used instant messaging service, which includes nonsmartphone options, has 2 billion monthly active users across 180 countries [30]. SMS text messages and real-time medication monitoring through such platforms have been promoted to enhance ART adherence [31-34].

Correspondingly, the World Health Organization (WHO) and other agencies have recommended using digital technologies to deliver adherence interventions [35]. The rapid advancement of the technological landscape requires the continuous evolution and updating of digital interventions to improve adherence to ARV medications. These digital technologies can promote healthy behaviors; enhance treatment outcomes for chronic conditions such as diabetes, heart disease, and mental health issues; and provide remote access to effective treatments (eg, computerized cognitive behavioral therapy for patients with HIV) [36]. Digital interventions are often complex, involving multiple components and goals. These can include empowering users to learn more about their health, share experiences with others in similar situations, change perceptions and beliefs about health, evaluate and track health states or behaviors, adjust medication, identify health priorities, make informed treatment decisions, and enhance communication between patients and providers.

However, there have been reports of negative effects associated with digital health interventions. Research conducted in some

parts of Africa revealed concerns about unintended HIV disclosure [37-40], while others anticipated stigma from SMS text message content that included terms such as "medication" and "HIV" [41,42]. Systematic evaluations [43,44] have also found that low-resource environments, poor internet connectivity, and the high cost of smartphones and their maintenance have contributed to the failure of digital health interventions. Logistics issues, such as frequent sharing of mobile phones among family members, intermittent electricity availability, and mobile phone malfunctions, were also highlighted [45]. These factors can complicate the adoption of digital innovations by clinic personnel and end users [46]. Given the recognized implementation challenges associated with digital innovations, further research is needed to identify and address barriers that may limit the acceptance of these interventions in practical settings.

Methods

Research Design

A qualitative approach was adopted for the research, utilizing thematic analysis of data collected from an IM workshop and an interview session. This approach was chosen because it facilitates in-depth probing and questioning of participants based on their responses, allowing both participants and researchers to explore underlying reasons and sentiments. The study aims to understand the perspectives of health professionals on how digital health care interventions can best enhance the monitoring of ARV medications among KPs. Interaction among focus group participants can often yield more insights than one-on-one interviews. Therefore, relevant data are collected through an IM workshop and a follow-up interview.

Ethics Approval

This study was approved by Bournemouth University (approval number 44608). The authors understand that their data may be used in an anonymized form by research teams to support other ethically approved research projects in the future, including future publications, reports, or presentations.

Population and Sample

Health care practitioners participating in the study included doctors, pharmacists, nurses, and clinical psychologists from Lagos State, Nigeria. Two sampling techniques were used: purposeful and convenience sampling. The purposeful sampling technique was used to select health care professionals working within the KP community. The convenience sampling technique was then used to select 1 doctor, 1 nurse, 1 pharmacist, and 1 clinical psychologist, with additional participants being social workers who work with the KP. The 2 sampling techniques were chosen because they help identify participants who are well-suited for the study [47,48]. Because of the extensive ethical clearance required, the study could not include all relevant participants. The Initiative for Equal Rights (TIERs) was selected as the venue for the IM workshop, while the interview was conducted via Zoom (Zoom Video Communications/Qumu Corporation) after securing participant agreements for both the workshop and interview. The study

sample consisted of 13 participants in total, with all participating in the IM workshop and 7 participating in the interview.

Instrument

Initially, an open-ended survey was planned, accompanied by an interview guide with 5 questions aligned with the study’s objectives. Instructions were provided on how to respond to the questions and an explanation was given about the features of digital health care interventions for monitoring ARV medications among KPs. This was done to ensure participants had a clear understanding of the study and how to provide their responses. The interview questions are crucial for gathering information on factors pertinent to the study’s objectives.

The Procedure of Administration

A formal agreement was established with each contact person to schedule an interview following the IM workshop, conducted as a focused group discussion. The interviews lasted between 20 and 30 minutes, with responses recorded for transcription. Participants provided informed consent by signing agreement forms after carefully reviewing the participant information page, which included all relevant details about the project, as required by ethical standards. During the interview, 5 questions were posed, and 7 participants actively responded. Their answers were recorded, transcribed by a researcher (FFA), and reported accordingly.

Trustworthiness

Trustworthiness is a critical consideration in research as it allows researchers to demonstrate the value of findings beyond typical qualitative research parameters [47]. In this study, trustworthiness is aimed at reinforcing the significance of the findings. To achieve this, a pilot study was conducted to assess the reliability of the data. Additionally, an interview was conducted with 1 pharmacist and 1 doctor, and their responses were transcribed and returned to them for verification to ensure the accuracy of the content.

Interactive Management Session

Group work on complex issues is facilitated using computer assistance through IM [49]. IM can be viewed as a structured focus group method applied across various research fields, including cybersecurity. It uses human factor approaches [50] and requirements engineering [51] to support consensus decision-making through idea generation, structuring, and design. Typically, an IM session involves 8-12 participants who are knowledgeable about the topic and represent diverse viewpoints. The group usually convenes for 3-5 days, with follow-up sessions often occurring as needed. Before the working sessions, a detailed work plan is developed through collaboration between the workshop planner and an organizational representative. Participants are supported in generating, clarifying, and structuring concepts using well-established and effective approaches. The flowchart for conducting a successful IM session, as adopted for this research, is presented in Figure 1.

Figure 1. Interactive management flowchart.

The Planning Phase

Overview

The first and most crucial step in this phase is to understand the current situation. This involves defining the state, identifying the key actors, and drafting scope and context statements. These techniques help participants explore who is affected, what issues arise, and how they are impacted. By clearly defining the problem, participants can identify key questions that, when answered, could significantly expedite the development of effective solutions [49].

The Workshop Phase

Next is the workshop phase, where participants convene to address planning-related concerns and implement consensus decisions. The session focuses on 3 key concepts: context, content, and process [49]. The facilitator begins by guiding the discussions and providing context from the planning phase. The group then contextualizes the information through discussion and idea sharing. The facilitator manages the workshop flow to ensure discussions remain focused and participants make efficient use of their time.

Idea Writing

Nominal group technique and interpretive structural modeling are the techniques covered in the IM workshop. Participants start by responding to a trigger question through idea writing. After exchanging written ideas with others, additional ideas are integrated. The compiled information is then categorized and presented to the group. Following this, the nominal group technique is applied, where participants generate further ideas based on the enhanced understanding of the issue gained from the initial idea writing. Additionally, the workshop facilitates the editing and clarification of problem statements. Participants assign priority ratings to each idea. The final stage of the workshop aims to convert idea statements into objectives, which are then used to construct an interpretive structural model to reveal connections between different aspects of the issue [52].

The Follow-Up Phase

This stage marks the beginning of the solution implementation planning while putting the workshop’s goals into practice. If it is discovered during this phase that the problem was misunderstood or if new issues have emerged that were not previously considered, a new planning phase would be initiated [49].

Thematic Analysis

A thematic analysis was conducted on the core questions asked during interviews with key stakeholders working with KPs. The data were collected between July 2022 and August 2022. The process and core issues identified from the thematic analysis are presented in Figure 2 and are derived from the interview questions listed in Table 1.

Figure 2. Thematic map capturing the core themes from the qualitative analysis. ARV: antiretroviral.

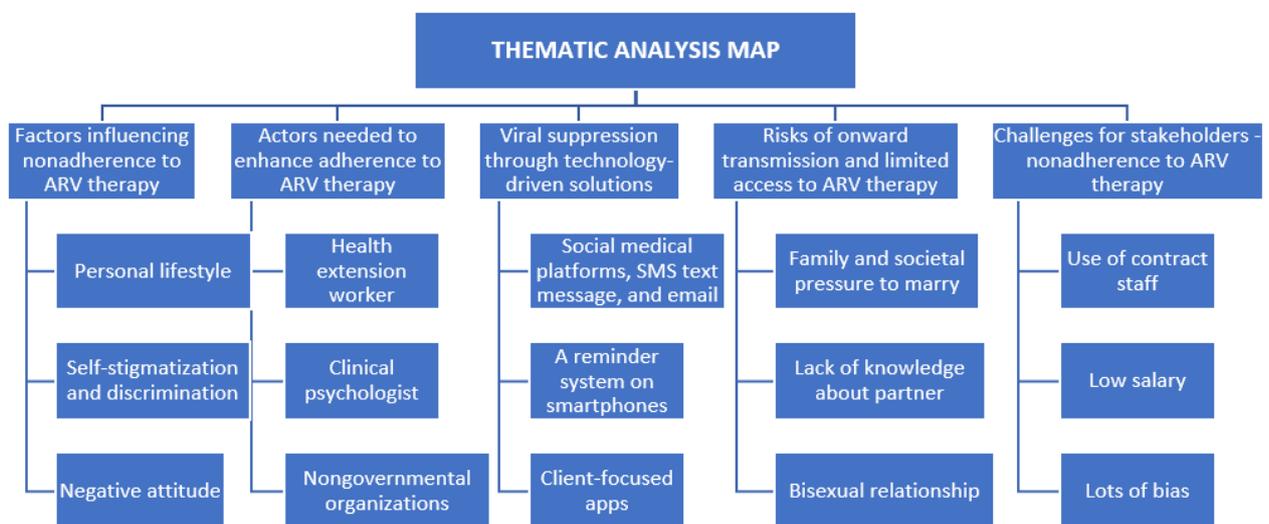

Table 1. Interview questions and codes for creating themes from interview responses.

Question number	Interview questions	Codes for creating themes from interview responses
1	What are the key factors influencing nonadherence to ARV ^a therapy among key populations?	Self-stigmatization, condition of health status, poverty, lack of sensitization and information, poor attitude, personal lifestyle, substance abuse, state of hopelessness, denial of diagnosis, cultural disposition, psychological distress, migration, logistics and financial constraint, privacy and confidentiality, the proximity of medical care facility, religious belief, hostile environment, drug side effect.
2	What category of actors do you consider relevant in the suppression of nonadherence to ARV therapy among key populations through technology-driven solutions?	International organizations, national organizations, NGOs ^b , health practitioners, religious organizations/leaders, and health extension workers are the key actors that are relevant in the suppression of nonadherence to ARV therapy.
3	How can we maintain viral suppression through technology-driven solutions among key populations?	Social media, SMS text messages, email, Google Maps, a reminder system on smartphones, embedded app software powered with AI ^c , client-focused apps, mobile apps, and interactive-driven systems are identified by the participants as a way of maintaining the viral suppression.
4	How do you consider the high risk of onward transmission and limited access to ARV therapy?	Key populations are not ready to share their problems with anyone, and at the same time, they engage in unprotected sex. The key populations also lack sufficient information to help prevent the spread of the virus, as well as awareness campaigns from key actors to address nonadherence to ARV therapy. Additionally, there is a lack of knowledge about one's partner, societal and family pressure to marry at all costs, and self-denial of a diagnosis.
5	What are the challenges associated with working with the key stakeholders in the suppression of non-adherence to ARV therapy?	The workers working with the NGOs are contract staff; therefore, their salaries are not encouraging. Lack of collaboration between and among stakeholders as well as a lack of passion to work and lots of bias.

^aARV: antiretroviral.

^bNGO: nongovernmental organization.

^cAI: artificial intelligence.

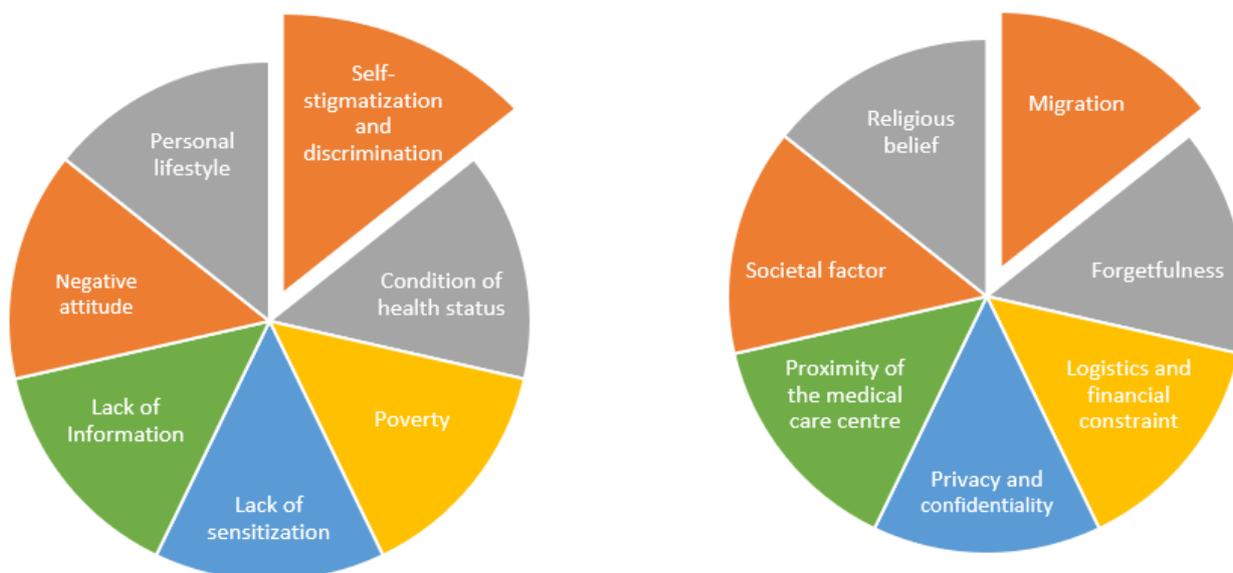

Results

Factors Influencing Nonadherence to ART

The participants were asked about the key factors likely to influence nonadherence to ART among KPs. The findings revealed that factors such as self-stigmatization, health status, poverty, lack of sensitization and information, poor attitude, personal lifestyle, substance abuse, hopelessness, denial of diagnosis, cultural disposition, psychological distress, migration,

logistical and financial constraints, privacy and confidentiality concerns, proximity to medical care facilities, religious beliefs, hostile environments, and drug side effects all contribute to nonadherence to ART. Participants provided various justifications for the factors influencing nonadherence to ART. However, self-stigmatization and discrimination, economic status, attitude, religious beliefs, and proximity to medical care facilities were ranked as the most significant factors, as shown in [Figure 3](#).

Figure 3. Thematic description of key factors influencing non-adherence to antiretroviral therapy.

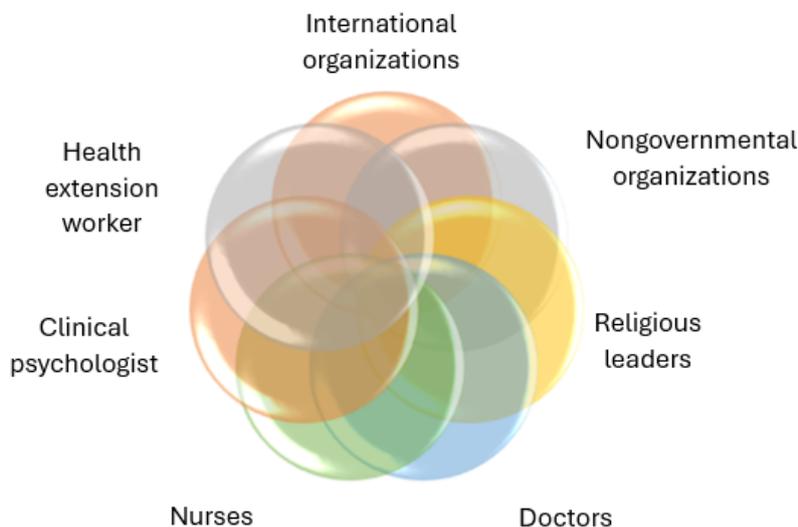

Actors Needed to Enhance Adherence to ART

Participants were asked to identify and categorize the key actors relevant to addressing nonadherence to ART among KPs. The findings indicated that international organizations, national organizations, nongovernmental organizations (NGOs), health practitioners, religious organizations/leaders, and health

extension workers are crucial actors. Their categorization and ranking are as follows: NGOs, international organizations, national organizations, doctors, nurses, clinical psychologists, and religious organizations. This is illustrated in Figure 4, highlighting the significant influence of international organizations in financing health care interventions for KPs in Nigeria.

Figure 4. Thematic description of actors needed to enhance adherence to antiretroviral therapy.

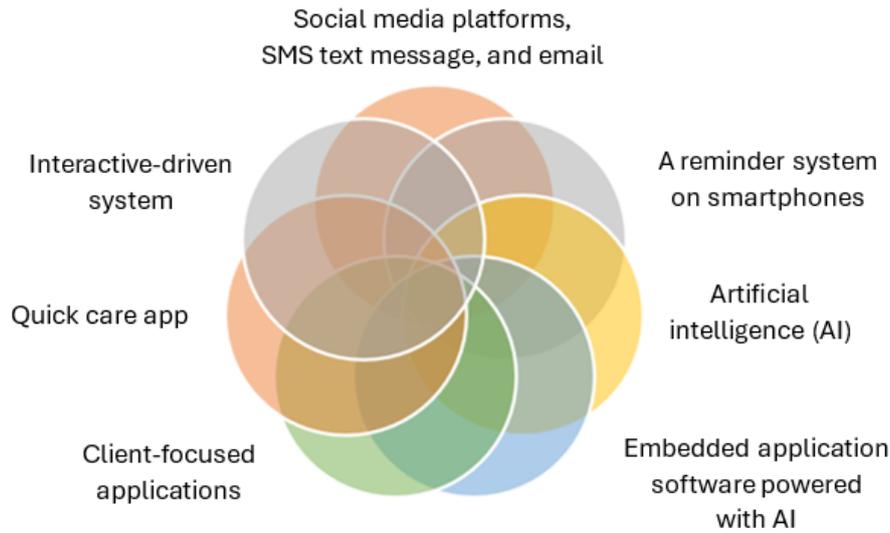

Maintaining Viral Suppression Through Technology-Driven Solutions

Participants were asked to suggest technological solutions for maintaining viral suppression among KPs. The results revealed

that social media, SMS text messages, email, Google Maps, smartphone reminder systems, artificial intelligence-powered app software, client-focused apps, mobile apps, and interactive systems were identified as effective methods for maintaining viral suppression, as shown in Figure 5.

Figure 5. Thematic description of maintaining viral suppression through technology-driven solutions.

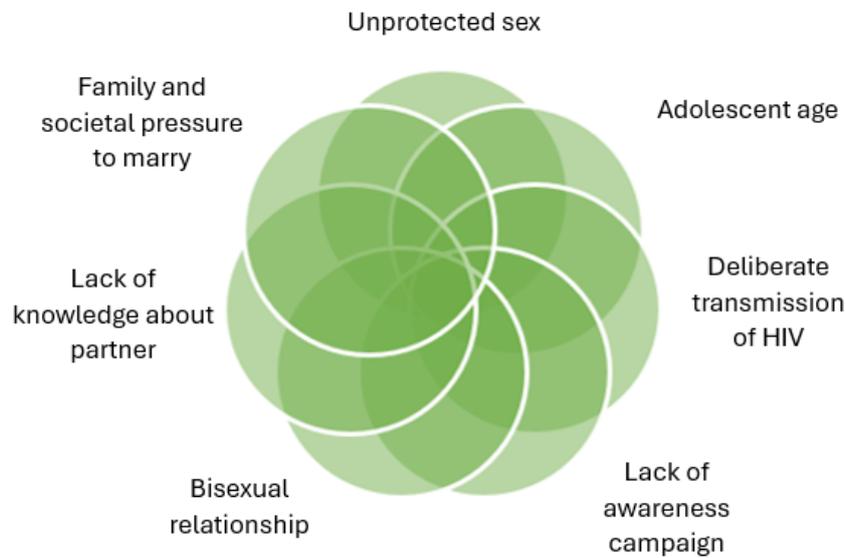

Risks of Onward Transmission and Limited Access to ART

Participants were asked about factors contributing to the high risk of onward transmission and limited access to ART. The findings indicated that many KPs are unwilling to share their

issues, engage in unprotected sex, lack information to prevent virus spread, experience insufficient awareness campaigns, engage in bisexual relationships, have limited knowledge about partners, face family and societal pressure to marry, and self-deny their diagnosis, as presented in Figure 6.

Figure 6. Thematic description of risks of onward transmission and limited access to antiretroviral therapy.

Challenges With Stakeholders in the Suppression of Nonadherence to ART

Participants were asked to identify challenges in working with stakeholders to address nonadherence to ART. Findings,

presented in Figure 7, highlight issues such as contract staff with inadequate salaries, lack of collaboration among stakeholders, lack of passion for the work, and prevalent biases.

Figure 7. Thematic description of challenges with stakeholders.

Results of the IM Workshop Session

The IM workshop (virtual) was facilitated by one of the authors (FFA) and took place in a conference room at Bournemouth University for the attendees' convenience. A total of 8 participants were selected based on the following criteria: they must be a member of the social care community, volunteer within the LGBTQ community in Lagos, and have expertise in HIV/AIDS care provision. The exclusion criteria for the workshop included health care workers not involved in ARV medication provision and care. Of the 8 participants, 7 participated in the Zoom session. To facilitate idea writing, a trigger question was provided for participants to record their responses and exchange them. As a result of time constraints imposed by participants' schedules, the phase of sharing ideas aloud began immediately. A computer paired with a projector was used to record and display the ideas.

The following are the trigger queries:

- What digital intervention can be used to improve ARV medication delivery and usage?
- How can we enhance viral suppression through technology-driven solutions?

Tables 2-5 present the ideas and responses generated from the trigger questions. These ideas were categorized as shown in Table 2, which outlines the different categories of responses. Table 3 highlights the significant concern for health care professionals regarding the development of a drug interaction monitoring system, as this was a major point of discussion among doctors, clinical psychologists, social workers, and other health care professionals working with KPs. The categories are ranked based on the number of ideas in each category. The IM session also identified the development of a web app, ideally named a KP Intensive Care App, and a medication use tracking system as crucial digital solutions or digital health care interventions.

Table 2. Results of idea generation.

Number	Idea
1	Development of the KP ^a Intensive Care App that would enable easy access to and delivery of ARV ^b medication.
2	A reminder feature to notify the client to take medication at scheduled times, and to remind them of upcoming appointments and drug pickups.
3	In-app telemedicine consultation to address client challenges, such as drug side effects and counseling needs.
4	Request for medication and viral load tests remotely, with delivery arranged through the app.
5	Pop-up messages to notify clients about potential drug interactions.
6	Avatar-guided animation videos demonstrating how to use medications, collect samples for viral load testing, and present samples within the app.
7	Section for booking appointments, including next drug pickup and doctor visits.
8	Monitor medication compliance and provide feedback for encouragement, such as stars or okay signs.
9	A feature that displays up-to-date tracking data, such as consultation records and viral load results, for both backend management and client benefits.
10	Development of a KP-friendly app, similar to a chatbot, to remind clients about medication schedules and clinic appointments.
11	Manufacturing medications or injectables with less frequent dosing to reduce pill burden.
12	Using dried blood spot collection for viral load testing can encourage clients, especially those with trypanophobia, to undergo viral load testing and adhere to their testing schedule.

^aKP: key population.

^bARV: antiretroviral.

Table 3. Categorization of ideas.

Category	Ideas ^a	Ranking
KP ^b Intensive Care App	1, 3, 10	2
Viral load collection system	4, 9	3
Medication use tracking device	2, 6, 8	2
Drug interaction monitoring system	5, 7, 11, 12	1

^aRefers to the categorization of results of idea generation in [Table 2](#).

^bKP: key population.

Additionally, the nominal group technique was used to enable participants to prioritize the top 5 issues from the generated ideas, as shown in [Table 4](#). Participants ranked each idea from 1 (most important) to 5 (least important). The results indicate that the development of a KP Intensive Care App, which facilitates easy access to ARV medication, provides a digital

platform for monitoring medication compliance, and offers motivational feedback (such as stars or okay signs), is considered the most important. Moreover, within the web app, features such as reminders for drug use and appointments, management of drug requests, calculation of viral load, and remote ordering and delivery were also ranked as significant.

Table 4. Participant's ranking of ideas.

Idea	Participant 1	Participant 2	Participant 3	Participant 4	Participant 5	Total score
1	1	3	1	5	1	11
2	— ^a	5	2	1	2	10
3	3	—	—	—	—	3
4	—	1	—	—	—	1
5	—	—	—	5	—	5
6	4	—	3	—	2	9
7	—	4	5	—	5	14
8	1	—	1	—	—	2
9	—	2	—	—	—	2
10	—	—	—	4	—	4
11	2	5	—	—	3	10
12	—	3	—	5	—	8

^aNot available.

According to [Table 4](#), ideas 7, 1, 2, 11, and 6 are ranked as the top 5 based on the total score.

[Table 5](#) displays the objective statements derived from the idea statements during the workshop. These objective statements

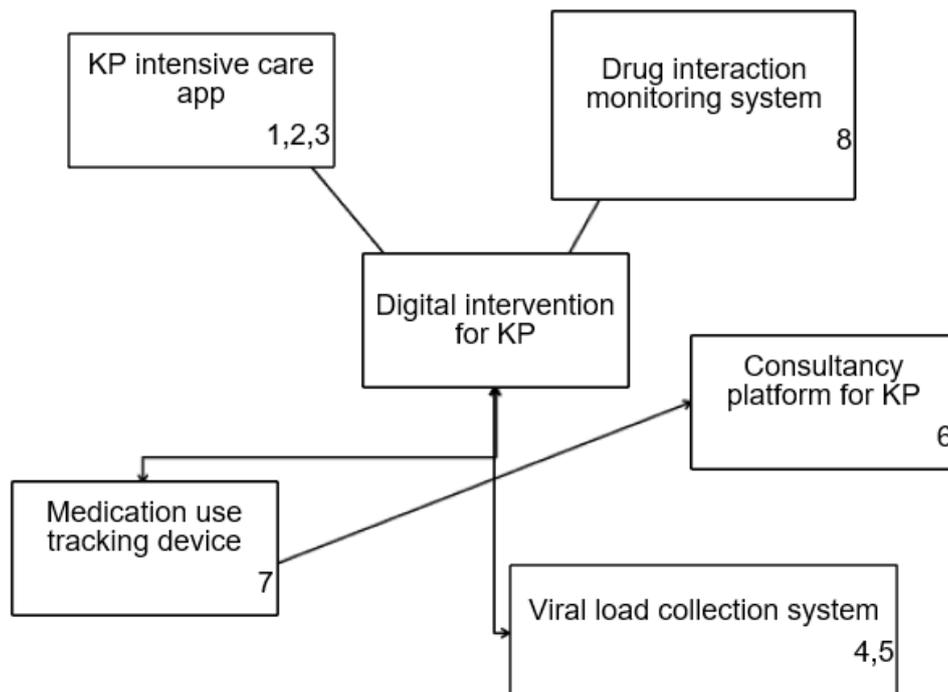

were used to construct an interpretive structural model, as illustrated in [Figure 8](#). The figure shows the grouping of similar objective statements, with numbers assigned to each box to reflect their categorization.

Table 5. Objective statements.

Number	Objective statements
1	Develop a KP ^a -focused intensive care app that provides easy access to and delivery of ARV ^b medication.
2	Include unique reminder features to notify clients to take their medication at scheduled times, as well as to remind them of appointments and drug pickups.
3	Develop an in-app telemedicine consultancy platform for clinical psychologists to conduct private sessions with KPs.
4	Incorporate a drug request framework that depends on the accurate calculation of viral load from the app.
5	Provide pop-up messages to alert clients about potential drug interactions.
6	Include avatar-guided demonstrations and animation videos on how to use medications.
7	Establish a partnership with HIV/AIDS medication manufacturers to explore options for less frequent usage or dosage of medicines.
8	Develop a systematic and noninvasive data collection approach to encourage clients to participate in testing and adhere to their treatment regimen.

^aKP: key population.

^bARV: antiretroviral.

Discussion

Summary

The study focused on utilizing digital health care interventions for the consultation and monitoring of ARV medication among transgender individuals in underserved regions. To achieve the study's objectives, the following topics were investigated: factors influencing nonadherence to ART; key actors needed to improve adherence; methods to sustain viral suppression through technology-driven solutions; reasons for the high risk of onward transmission and limited access to ART; and challenges associated with collaborating with stakeholders to address nonadherence to viral treatment.

Principal Findings

Indeed, the study's findings revealed that several factors influence nonadherence to ART among MSM. These factors include self-stigmatization, health status, poverty, lack of awareness and information, poor attitude, denial of diagnosis, cultural disposition, psychological distress, migration, logistical and financial constraints, issues of privacy and confidentiality, proximity to medical facilities, and drug side effects. Indeed, these results align with a previously conducted study [15], which indicated that ART adherence was below average among MSM at risk for HIV infection in the United States. Several factors contribute to these low adherence rates, including HIV stigma, social exclusion, difficulties accessing health care programs, anxiety about seeking and potentially being denied care,

depression, and a lack of knowledge about the interactions between hormonal therapy and various medications.

The findings also identified key players crucial for addressing nonadherence to ART, including international organizations, national organizations, NGOs, health professionals, religious leaders, and health extension workers. This outcome is supported by recent research conducted in South Africa, which concluded that a shortage of health professionals at medical centers is a significant barrier to adherence. This suggests that medical staff are essential actors in efforts to reduce nonadherence to ART [53]. Furthermore, this study aligns with the perspective of Murungi et al [54], who argued that religious leaders play a crucial role in HIV/AIDS prevention and ART adherence [55].

In addition, our study revealed how viral suppression can be maintained through technology-driven solutions for KPs. Participants identified several tools, including social media, SMS text messages, email, Google Maps, reminder systems on smartphones, artificial intelligence-powered embedded apps, client-focused apps, mobile apps, and interactive systems, as effective means for sustaining viral suppression among these groups. This aligns with Phan et al [56], who demonstrated the potential benefits of digital interventions in promoting adherence to health solutions among people living with HIV/AIDS.

Furthermore, our data revealed that many key demographics are unwilling to disclose their challenges while continuing to engage in unprotected sex. KPs also face a lack of information to help combat virus transmission, as well as insufficient awareness campaigns, bisexual relationships, inadequate knowledge about partners, family and societal pressure to marry at all costs, and self-denial of diagnosis. Several studies corroborate this finding. For instance, Cherutich et al [57] identified a lack of HIV status knowledge as a significant barrier to HIV prevention, care, and treatment activities. In Kenya, high rates of undiagnosed HIV infection are prevalent among gay, bisexual, and other MSM, as well as transgender women [58]. The African Union Commission [59] has demonstrated that high rates of child marriage often coincide with high rates of HIV infection in many countries. Acceptance of HIV status is critical for the effectiveness of HIV tests and related activities, whereas self-denial following a positive diagnosis can hinder adherence [60].

Our findings also identified several significant challenges among stakeholders, including insufficient salary payments, lack of collaboration between stakeholders, lack of motivation, and prevalent biases. Proper stakeholder education and accurate information can positively impact adherence, which supports the conclusions of this research [61].

Evaluating Relationship With Previous Findings

These findings align with the suggestions of Labrique et al [35], who indicated that the WHO and other international organizations advocate for the use of digital technologies to deliver adherence interventions and suppress viral infections. Previous studies on digital innovations in health care (eg, [22,23,29,62]) demonstrate the availability of various digital solutions. These include real-time medication monitoring and SMS text message reminders, which signal medication events, as well as real-time digital interventions through SMS text message reminders and remote monitoring solutions. The study also confirmed that adolescents are at high risk of transmitting HIV, partly because many individuals with the infection are reluctant to discuss their health openly, thereby contributing to its spread. Additionally, challenges in working with stakeholders include the prevalence of contract employees with unsatisfactory pay, lack of collaboration among stakeholders, a lack of passion for the job, and significant bias. These findings are strongly supported by the study conducted by Ledda et al [62].

Limitations

This study investigated digital health care interventions for monitoring ARV medications among Nigeria's KPs through empirical analysis. It is important to acknowledge some limitations, as no research is without flaws. The study focused exclusively on Lagos, and thus, expanding it to include other regions across Nigeria could provide valuable and practical insights applicable to health care facilities nationwide. Furthermore, the study's sample size was limited to a maximum of 7 key medical actors, and data were collected using an IM approach. Future research should consider conducting mixed methods or strictly quantitative assessments to provide a more comprehensive evaluation.

Conclusions

The study investigates health professionals' perceptions of digital health care interventions for monitoring ARV medications among KPs in Nigeria. The study concluded that technology-driven solutions could improve adherence to ART and reduce HIV transmission among KPs. Based on the findings of this study, the following recommendations are made: The government should implement improved policies to encourage positive attitudinal changes among stakeholders, promoting the use of technology-driven solutions to maintain viral suppression among the HIV population in the country; additionally, local governments and international agencies should facilitate awareness campaigns to improve ART sessions among KPs. Strategies should also be developed to help Nigerian health facilities integrate suitable channels for cocreating digital solutions that will increase attendance at ART sessions.

Abstract

Background: Technology use among older adults is increasingly common. Even though there is potential in leveraging technology to help them manage their health, only a small fraction of them use it for health-related purposes.

Objective: This study seeks to understand the perspectives of and experiences with digital health (DH) among older adults in Singapore.

Methods: A total of 16 participants (age range 60-80 years; n=11, 69% female) were interviewed for approximately an hour (range 27-64 minutes) about their health, DH use, and DH experiences. The interviews were recorded, transcribed verbatim, and thematically analyzed.

Results: Five main themes emerged from the interview: support in developing DH literacy, credibility, cost and benefit considerations, intrinsic drive to be healthy, and telehealth. Older adults need support in familiarizing themselves with DH. When considering DH options, older adults often relied on credible sources and preferred DH to be free. Monetary incentives were brought up as motivators. The intrinsic drive to live longer and healthily was expressed to be a huge encouragement to use DH to help obtain health-related knowledge and achieve healthy living goals. The idea of telehealth was also appealing among older adults but was seen to be more suited for individuals who have issues accessing a physical clinic.

Conclusions: Our findings offer insights into the various aspects that matter to older adults in the adoption of DH, which in turn can help reshape their health-seeking behavior and lifestyle. As such, policy makers and DH implementors are encouraged to take these into consideration and align their strategies accordingly.

Introduction

The global population of older adults aged 65 years and older is expected to increase in the coming years. In 2015, there was an estimated 8.5% of individuals aged 65 years and older globally, and this proportion has been projected to grow to 16.7% by 2050 [1]. In Singapore, the rapid increase of an aging population is evident given the growth of the proportion of older residents from 11.7% in 2013 to 19.1% in 2023 [2]. As the median age of Singapore continues to increase (median age is 43 years in 2023), it is projected that 24.1% of the Singaporean population will be aged 65 years and older by 2030 [2]. While increased longevity can be attributed to the success of medical advancements and improvements in public health practices [3], longevity is often accompanied by an increased risk of chronic diseases and a decrease in physical and cognitive function [4]. Beyond disease burden, multiple chronic diseases in older adults have been associated with greater health care use and costs [5]. Thus, it further contributes to the increasing load on the health care system and patients themselves, which is evident in Singapore as the acute hospital admissions [6] and duration for hospitalization episodes [7] were both reported to be rising.

To meet the health demands of a growing aging population presented within Singapore, the application of digital health (DH) to encourage these healthy behaviors serves as a valuable tool to assist in the journey toward a healthy aging population. DH for an aging population can include wearable devices for health monitoring, telemedicine, and mobile phone apps [8]. While the potential of DH for health behavioral change is still being tested, findings to date have shown promising results in promoting health behaviors and improving health-related outcomes [9-11]. Such an approach can serve as an invaluable tool to assist older adults in their journey toward healthy aging through preventive health, active aging programs, and care services. Accordingly, Singapore's 2023 action plan for successful aging aims to empower seniors to take charge of their physical and mental well-being through the engagement of regular group exercises, adopt a healthy and balanced diet, and go for regular health screenings and follow-ups [12]. Nevertheless, the success of a digital tool is dependent on its uptake and sustained use by the intended population. Despite a high proportion of older adults in Singapore owning at least 1 digital device (38.1% have 1 digital device and 55.82% have 2 or more digital devices), only a small number of older adults use their devices for functional purposes such as telehealth services (10.5%) [13].

Expanding the use of DH to older adults will benefit from significant input from older adults themselves to ensure that the tool is designed around their needs, capabilities, and preferences [8]. Through engaging older adults during the design process, DH innovators can better understand what drives DH use, which can then inform downstream design considerations and implementation strategies when rolling out the tool. While Singaporean older adults consider DH useful in health management, they do not consider health care-related technology critical for their daily lives [14]. Furthermore, there is generally a strong preference for direct contact with health care professionals among this group [15].

This study aimed to explore Singaporean older adults' perspectives of DH and their experiences with existing DH tools. Through this, the study sought to understand what matters to Singaporean older adults when using DH to encourage improved health behaviors.

Methods

Recruitment

We recruited individuals through purposive sampling from the community in Singapore through outreach sessions and social media platforms (ie, Telegram and Facebook). Interested participants responded to advertisements by reaching out to the study team via email or text message, and they were provided with the participant information sheet and informed consent form. Participants were screened based on the following inclusion criteria: (1) age of 60 years and older and (2) have experience using health-related technologies. Recruitment took place over a period of 1 year (November 2021 to October 2022). None of the participants refused to participate or dropped out after consenting to the study.

Data Collection

This study used semistructured interviews to understand the older adults' perspectives of and experiences with DH in Singapore. Each interview was approximately 60 minutes and conducted either in person or via Zoom depending on the participants' preference. In-person interviews were conducted in a quiet public space (eg, conference room, cafes, and void decks). All interviews were conducted in English with at least 2 researchers from the data collection team—QYL, VVL, SV, WYN, and NYL—present. The all-female data collection team consists of 2 postdoctoral fellows and 3 research assistants (with bachelor's degrees). All researchers who collected interviews had prior training in qualitative data collection and analyses. To minimize interview bias, a standardized interview protocol and guide were used (Multimedia Appendix 1). All researchers in the data collection team underwent pilot sessions before the interviews. Peer feedback was provided during the pilot sessions. Relationships with the participants prior to the interviews were established through email, call, or messages. Participants were told about the researchers' involvement in the study and the reasons for doing the research. At the beginning of the session, informed consent was obtained, and all participants consented to audio recording of the interview for transcription purposes. Open-ended questions were asked during the interview to understand the participants' health care journey, their perspectives, and their experiences with DH. This paper focuses on the DH aspect of the interviews. At the end of the session, all participants were reimbursed for their time. All data collected, including signed consent forms and interview recordings, were deidentified, encrypted, and stored in a secure database. No repeat interviews were conducted, and transcripts were not returned to participants for comments.

Data collection ended when data saturation was achieved, and the sample had reached maximum variation by age, gender, and ethnicity.

Data Analysis

All of the interview recordings were transcribed verbatim and thematically analyzed using the method described by Braun and Clarke [16]. Each transcript was randomly assigned to a member of the data collection team for inductive coding. All coders familiarized themselves with all interview transcripts and initial coding was conducted through a process of descriptively labeling segments of data. Each coder independently analyzed their assigned transcript. As the coding process progressed, the data collection team consistently reviewed and agreed on the coded data collectively and subsequently resolved any discrepancies through discussion. Categorization of the codes was conducted by QYL, who grouped the labeled data into categories and subsequently into broader themes. Data saturation was achieved when no new theme was identified. Grouping of themes was tracked on a master Excel workbook, and data saturation was confirmed through discussion with all researchers who were involved in data collection and analysis. The final codes and themes were based on the discussions and iterations with VVL, and a final review with the other members of the data collection team. The transcribing and analyzing steps were conducted using Microsoft Word and Excel respectively [17].

To ensure credibility and confirmability, reflexivity was applied throughout the data collection process. Team discussions were conducted at the end of each week. During team discussions, the researcher's interaction with participants and thoughts on the interview was discussed and noted down. Furthermore, peer debriefing was conducted throughout the interview and coding process to obtain feedback from other members of the data collection team and minimize personal biases. As the study team had specific interests in DH, it may have influenced the team to engage with participants about DH in a positive manner.

Table 1. Technology use of participants.

Category	Technologies used
General	Zoom, Google, YouTube, Lazada App, Singtel App, and Amazon Alexa
Social media	Facebook, WhatsApp, and Telegram
Health-specific mobile apps and webpages	HealthXchange.sg, Healthy365 App, ActiveSG App, SAFRA Mobile App, HealthHub App, NUHS App, and Mayo Clinic
Health-specific devices	Bluetooth-connected GlycoLeap App, Abbott Freestyle Glucose Monitoring device, FitBit, blood pressure monitoring device, and oximeter

Interview Data

Five themes emerged from the interview data. The themes consist of support in developing DH literacy, credibility, cost and benefit considerations, intrinsic drive to be healthy, and telehealth.

Support in Developing DH Literacy

Overview

The first theme—support in developing DH literacy—refers to the endeavor to improve DH literacy among older adults. This support builds upon the foundation laid by the existing awareness of DH through education and accessibility. The participants often learned about the existence of DH by word

of mouth through family, friends, and health care professionals. Another way in which DH was made aware among older adults was through promotional materials disseminated through mass media namely newspapers and social media platforms (eg, Facebook).

Ethical Considerations

The National University of Singapore Institutional Review Board approved this study (NUS-IRB reference: NUS-IRB-2021-12). All participants provided informed consent and were informed of their right to withdraw from the study at any time. All data collected from participants were de-identified. Participants were reimbursed SGD 30 (US \$22.60) for their time and participation.

Results

Participant Demographics

The study sample consisted of 16 participants, with an age range of 60 to 80 (mean age 66.9, SD 5.9) years. They were of Chinese (9/16, 56%), Indian (5/16, 31%), and Malay (2/16, 13%) descent and were fluent in English. A total of 11 (69%) participants were female. Hypertension, hyperlipidemia, diabetes, and cardiovascular diseases were some common medical conditions reported by the participants. Other medical conditions brought up less frequently included history of breast cancer, psychosis, ulcerative colitis, and shingles. Participant demographic data are presented in [Multimedia Appendix 2](#).

During the interview, participants described their experiences with a variety of technologies. These technologies, consisting of mobile apps, web-based platforms, and DH devices, were used for multiple purposes as listed in [Table 1](#).

of mouth through family, friends, and health care professionals. Another way in which DH was made aware among older adults was through promotional materials disseminated through mass media namely newspapers and social media platforms (eg, Facebook).

Education

At the initial stage of DH adoption, education was crucial to ensure participants familiarized themselves with the DH interface, functionality, and navigation. Besides familiarization, education provided the support needed to sustain DH use. The overview of how the older adults might go from not knowing to knowing was described by participant 15, "Now the old people also trying to catch up, but someone [has] to educate

them right...how to use it. Nowadays, there are the workshop[s] for elderly, how to use the app[s], how to use Tiktok, Facebook and all that. So, it [will] take some time to...give them teaching, [it] will take time [for them] to learn.”

When asked about thoughts on creating awareness and bridging that to actual DH use through education, participant 5 described, “I think it involves...some outreach, educational programs, so people will come to know.” The participants added that outreach sessions, education programs, and workshops at community centers and hospitals are good starting points. Participant 16 shared that community centers were an ideal point of contact “because they come to the community centre to spend time sometime[s]” but also specified that this option was only available for “those who can walk.” Upon further elaboration, the same participant also shared, “The best place [to spread DH awareness] is the hospital. Hospital is the only place you can get that in...The nurses can educate them that these avenues are also open.”

These sessions should offer guidance and troubleshooting support through step-by-step instructions and video tutorials. Each session should preferably be one-to-one and in person “to get seniors used to the concept...[and] to explain to them...it’s non-threatening, it’s helpful,” as shared by participant 11. With repeated familiarization over time and easier access to avenues for education, older adults could become more receptive to DH. However, this process can be very time-consuming as it can be repetitive in nature and would require immense patience and time.

Accessibility

Accessibility reflects the ability of older adults to reach and use DH. Even though there was an intrinsic drive to learn and explore DH platforms available, participants expressed discomfort over unfamiliarity and poorer cognitive abilities. Participant 10 described, “No chance to learn [about DH]. If there is opportunity, then we pick here and there. So, sometimes we are struggling with it...The young ones will be very good. You need to start playing since young. For us...[we are] a bit slower, memory also weaker. So, what we have done earlier, we may not be able to remember. So, it’s very difficult to do it on your own to try to learn.” Concerns about slower cognition and poorer memory led to lower confidence in their ability to use DH, thereby creating barriers to DH adoption.

Support and guidance from “someone at home or...some neighbours” could act as a push factor “to help them [the older adults] understand certain things [DH platforms]” to overcome the aforementioned barriers to DH adoption, as shared by participant 11. Support beyond their own family members was especially important as pointed out by participant 6, as “the singles [elderly]...have no one to help them, they can go to the digital ambassadors.” These digital ambassadors could potentially be the younger generation. To illustrate this point, participant 11 shared, “I got [tech] problem here. How? Anybody know? Things like that. And if you have a handphone, you look for a younger colleague...So, sometimes you can [ask them], ‘help me’.”

Credibility of DH Platforms

What and Who Do They Trust

Trust emerged to be essential in the health management of older adults. Although the information was described to be readily available, the participants expressed the need to sieve through it and had to rely on trusted sources to assist in their decision-making regarding their own health. Rather than having just 1 trusted individual or organization, it was common for older adults to seek health-related information or DH platform recommendations from multiple sources such as social networks or health care professionals. For instance, participant 1 expressed, “I always trust my friend. What they tell me to do, usually I will do it” while adding on, “If doctor say that I need this, of course I will trust the doctor”. The mention of recommendations from friends emerged repeatedly. This was attributed to the trust in their friends’ testimonials to ascertain the reliability of DH platforms. In participant 15’s case, concern from friends encouraged them to take their health seriously and that included adopting DH to manage their health. “I just wanted to try out...They are so concerned [of me], they say, you are putting on weight...you must check up your health...So, your friends are so concerned about you...why not I take control for myself, that’s why I take it seriously.”

While information or suggestions from doctors or health care institutions such as hospitals and clinics were perceived as trusted sources, other individuals or organizations that made up the trusted circle of the older adults also included family members, friends, neighbors, governmental organizations (eg, Ministry of Health) and higher learning or research institutions (eg, National University of Singapore).

What Matters in Establishing the Trust

The DH recommendations from health care professionals were built on the existing doctor-patient relationship. Several considerations were brought up as crucial in forging and strengthening that bond. For instance, participant 7 expressed, “I think if the doctor has been with me for quite a while and I trust the doctor, it should not be an issue”. Beyond that, the type of artificial intelligence used in the DH, the length of medical practice as well as the level of expertise (eg, junior doctors and consultants) of doctors recommending the DH also mattered while forging this sense of trust. Participant 7 further expanded, “It depends on the doctor himself, the level of expertise. I mean you can’t compare between a houseman or a student doctor, to a consultant, right? So, to have my level of assurance that I can trust them fully, I think it depends on the level of expertise and the experience—the experience of the doctor.”

Apart from the source of DH recommendations, the mode of information delivery was also crucial. For example, vital pieces of information to establish trust could be delivered in the form of statistics. Participant 14 described a possible way of conveying this information, “Based on your precedence [medical history] and all that kind of thing, [the DH] will tell them [the users], how many percent has actually...done this and they have recovered...Some stats based on the recovery rate, that kind of thing...I think that helps.”

Furthermore, there were other considerations that cemented this trust. For example, participant 9 mentioned, “I’ll ask him [the doctor], is there any risk [of] like you go on an app and do it yourself? That way I don’t mind”. The participants also emphasized the need for DH platforms to be validated and substantiated by evidence in order to be deemed as trustworthy tools in health management.

What Makes Them Lose Trust

“Having to see the doctor personally, and he diagnose...and do it for us, that’s all I want. I would rather do that,” said participant 9, who felt that DH platforms were not as trustworthy as doctors due to the lack of human touch. Cybersecurity concerns also emerged as a factor that would erode trust in DH use. For instance, participant 13 expressed, “I don’t find [it] comfortable...when you go to the app, [and] they ask for Singpass...sometime, you may click the wrong button or you go to URL, they might take...all your information...then from there phish.”

Cost and Benefit Considerations

Types of Incentives

Two types of incentives were described by the older adults as follows: monetary incentives and results from DH engagement.

“Number one of course monetary...Even if you give me an NTUC [a local supermarket chain] voucher, it is still money”, said participant 10. The participants described that the use of gamification and financial incentives while using the DH platforms had been an effective and creative way for them to engage in DH use. The distribution of free DH devices, such as wearables, was also quoted to have similar motivating effects as financial incentives. For example, ActiveSG (Singapore government health promotion program) has 100 Singapore dollars preloaded to incentivize the onboarding of potential users and promote sustained use. As described by participant 6, “If you don’t learn...it’s forfeited from you. Then you are forced to learn.”

Without incentives, the participants were more inclined to use DH platforms simply as a means of tracking health metrics. After the initial engagement, observable health outcomes from their DH use seemed to be the driver for sustained use. To illustrate this point, participant 12 described, “I have to see the result...maybe after a month or two. If they say do this, do that, you will lose your weight, I have to see whether it happens. After that, yes, I’ll use. But I don’t mind taking the first step, yes. But after that time, if I feel it’s of no use, I will stop it.”

What Incentives Enable Them to Do

Two health-seeking behaviors consistently emerged in the data when incentives were involved—staying active and opting for healthier dietary options.

Regarding the use of incentives to encourage users to stay active, participant 6 mentioned, “They put some codes around different places for you to go and find and scan...If I am passing by [and] I know that there is a place to scan to get points, then I just make a detour...So, they got all these challenges inside [the app] to keep you more active and maybe more mentally alert.”

Furthermore, the participants were highly motivated to opt for healthier food options when incentivized by a point system through a DH platform. For example, participant 7 expressed, “That’s how I accumulated [points], this QR code from buying food...with the healthier choice logo.”

Cost

Generally, participants preferred DH use to be free. Participant 6 shared, “[The DH] must be available free, if you ask people to pay, they will be put off” and further elaborated, “I go for all the free things. Because this cost, sometimes I don’t feel it is justified.” While there was a clear preference for free DH platforms, some participants expressed that they did not mind paying a one-off or subscription fee, but only if the cost was reasonable and the DH proved to be beneficial.

Intrinsic Drive to be Healthy

Overview

“Health is already a motivating factor, nobody wants to be unhealthy.” Participant 6 succinctly summarized that this intrinsic drive, along with the aspiration to live longer and healthier, motivated older adults to adopt health-seeking behaviors. DH platforms were described to have the potential to help participants in their pursuit of realizing their healthy living goals and gaining knowledge out of necessity, or curiosity.

Healthy Living Goals

Participant 11 emphasized that addressing health-related concerns should be approached holistically - catering to both physical and mental well-being. While concomitant conditions were common, participant 7 shared, “You must treat the patient as a whole, not compartmentalize them into health issues like mental, diabetes, heart.” The idea of personalized health-related tracking also appealed to older adults. For instance, participant 10 shared that diabetic patients were motivated to use glucometers to understand how different food choices affected their blood sugar levels. Furthermore, the relevance of the materials offered by DH platforms heavily dictated their use among older adults. Although the idea of relevance varied according to each older adult’s area of interest (eg, diet, cultural practices, sleep, and medical concerns), there was a consensus that DH platforms available were too based on Western culture, too general, and lacked the touch of personalization. When seeking knowledge-based content, participant 8 shared, “[The DH should be] a one-to-one consultation and give you information that is relevant to you, specific to you, not so general that I might as well go Google you know”. This highlighted the preference for more personalized content over generic information. Another example of relevance was based on the idea of localization. Participant 14 described that “a lot of [DH platforms] are...catered to Western kind of...audience.” Accordingly, they may not be relatable to the Asian context and users. These examples demonstrate that irrelevance can impact the perceived relatability of DH platforms.

The participants expressed various aspects where DH can assist in health management and attainment of healthy living goals. First, DH platforms should have provided feedback especially if gamification was incorporated. Such feedback could be a

report of their performances based on a benchmark, or actionable recommendations based on individual health concerns. Second, participant 16 suggested that DH platforms could serve as the “one tool for common disease[s] like diabetes or high blood pressure.” Third, nudging as a form of reminder, as described by participant 15, could be “good, very helpful, like someone taking care and telling me...you must take this, you must do this.”

Knowledge

While achieving one’s health-related goals is important, participants also expressed that this pursuit needed to be supplemented by knowledge. Most described using DH out of necessity or curiosity. Participant 11 expressed, “I think that the onus is on me to do my own reading and find things also, to be more knowledgeable about my own issues.” This motivation for knowledge was not only described to be driven by the goodness of oneself, but it also extended to their partners. Such motivation was described by participant 12 who mentioned, “My husband is diabetic, so I try to look for items which is better for him”.

As such, the older adults generally appreciated health information and recommendations deployed through DH as supportive of their aspirations to live healthily. For example, participant 7 shared, “The [web-based] articles from SingHealth (health system in Singapore), when I got my treatment for my oral health...so they started giving me all these articles every now and then which I would read up.” Participant 8 also described, “Now, [the] internet [is] so convenient. A lot of YouTube [videos] advise how to...take care of diabetes...fasting...that kind of thing. So, I try everything.”

Beyond knowledge-based information, DH was also described as an ideal avenue to broadcast events that support healthy and active living. For example, participant 15 shared that happenings of interest including “a weekend activity...group walking activity, or running, simple exercise, Tai Chi...all kinds of simple exercises” could be broadcasted through DH, which could subsequently enable “most [in] my age group [to] get together and then become more active, then you get to know people”. A similar sentiment was expressed by participant 1, “I will use that [DH] if they got social [events], they will tell me, where can [I] go.”

Furthermore, the accessibility of web-based information also enabled health-seeking behaviors, such as in the case of participant 15 who shared, “During the COVID time, I was afraid to take the COVID injection, so I read through more [on websites], now I’m happy [to take the injection].”

Convenience of Telehealth

The appeal of telehealth is centered around the convenience that it offers. Telehealth not only allowed the participants to seek medical attention remotely, but it also eliminated the need and hassle of traveling to a clinic or health care institution. Participant 5 shared that their interaction with the polyclinic through telehealth made him “feel better because [there is] no need to walk all the way there [the polyclinic].”

Furthermore, the prompt responses by the medical team also made telehealth an ideal feature in DH. Participant 15 described, “It’s a good idea that nowadays...to interact with the phone, and anything you can talk faster. I think during the COVID time, it started very well...I got COVID also, so they consult me to tell me [via] this thing [telehealth], then advise me the medication, they send me through phone, then they deliver to my house. It’s quite [a] good idea.” This also demonstrates how the recent COVID-19 pandemic accelerated the shift in favor of telehealth adoption.

Nevertheless, despite the boons that telehealth offers, the participants generally still preferred to consult the doctors in person. However, they also acknowledged that under some circumstances, telehealth might be more ideal. For example, participant 1 shared, “Last time is okay...[I] don’t mind going out. But nowadays, [I am] usually very scared to go out, especially for the elderly because we are more prone to the disease. So, [it] is good that...I make appointment and zoom doctor. [The doctor] tell us, your results...you must take care, then is good. Better than we travel there for the results.” Other groups of individuals who were identified to potentially benefit from telehealth included those who “are really very sick...and are not able to move”, as shared by participant 12.

Discussion

While it is usual for older adults to use technology, using DH is not as common [18]. With the added challenges stemming from the natural progression of aging—slower cognition [19,20] and poorer memory [21]—overcoming the learning curve of DH can be daunting. Awareness and accessibility form the foundation to overcome the learning curve of DH, which in and of itself is a multi-step process. The building blocks leading to DH adoption and subsequently sustained use can be facilitated through various factors, some of which are unique to the Singaporean context, and will be discussed in this section.

While awareness of DH can be achieved through DH exposure, it is not always sufficient for obtaining access to DH. Accessibility issues expressed by the participants in this study generally centered around the need for support and assistance to help them to familiarize themselves and use the different aspects of DH (eg, interface, navigation, and functionality). Whether it was contextualized learning materials targeted to the masses or personalized guidance by DH ambassadors, participants described education as a necessity to overcome the steep learning curve—a barrier for DH uptake. Similar findings are echoed in a review that reported difficulty in technology use as the most common patient-level barrier to DH technology uptake, while facilitators included empowerment, education, and training sessions [22]. Overcoming this barrier is a mammoth effort, which was also echoed by the older adults in this study since it would require significant resources (ie, manpower, time, and funding) to ensure continual DH support ranging from step-by-step guidance to troubleshooting expertise. This understanding from our study, along with the existing qualitative work that provides invaluable insights regarding the general perception [14,22,23] and the user preferences [24] of DH among the older adults in Singapore, are critical in

informing policymakers and DH implementers, and in aligning strategies that promote DH adoption for its potential to be realized and benefits reaped.

Trust repeatedly emerges as an important factor in technology adoption, including in other populations such as women [25,26], Korean Americans [27], and patients with cancer [28]. Like the findings in this study, individuals in those studies tended to seek health-related information from multiple sources—often from health care professionals, family, and friends [26,29], which were reported to be credible. Different sources of information are used to compare, evaluate, and triangulate the information as a means of filtering the vast body of data available. The older adults in this study expressed trust in physicians and preferred to cross-check health information with them. Interestingly, even though the older adults expressed trust in physicians, several nuances mattered in establishing this trust. For instance, the older adults in this study expressed that if a physician was recommending a novel technology, they were more comfortable following the recommendation if the physician had vast experience in the technology and was a seasoned medical practitioner (eg consultant over a junior doctor). Such nuanced behavior associated with trust was also reported in a study involving Singaporean older women [29], where information regarding health-related products was not taken at face value but was closely judged. Furthermore, it is worthwhile considering the influences of ethnic norms, linguistic capabilities, and level of education in instilling trust in DH among older adults in a culturally and racially diverse country like Singapore. In 2 studies—1 in Singapore [29] and 1 in the United States [27]—ethnic language, dialects, and linguistic capabilities might have played a role in establishing trust. Additionally, it is worthwhile noting that Singaporeans are generally trusting and responsive towards most government-related directives. This is especially evident in the COVID-19 vaccination uptake during the recent pandemic. Vaccination status was shown to be positively predicted by trust in formal sources (ie, government services, local television, and radio), but not by trust in informal sources (ie, family and friends) [30].

Older adults in this study emphasized the importance of having both extrinsic and intrinsic motivation to drive DH adoption and sustained use. Externally, older adults mentioned financial incentives and tangible feedback about the results from their behavior change as drivers that would encourage greater DH use. This is in line with one of Singapore's nationwide mobile health physical activity programs, The National Steps Challenge deployed via the Healthy365 (Health Promotion Board) app, which was able to successfully reach about 26% of the Singapore population (ie, 1.3 million out of 5.0 million as of 2019) [31]. Key factors that were cited to contribute towards the success of the program's reach include monetary reward in exchange for Healthpoints (collected through steps) and free fitness wristbands offered to participants [31]. Beyond the need for external motivators, older adults in this study also demonstrated an intrinsic drive to be healthy and highlighted the potential of DH in aiding them to achieve health-related goals through education and actionable recommendations. This need for both intrinsic and extrinsic motivation in DH tools

targeted towards older adults was also described in a recent qualitative systematic review, which emphasized the need for users to first be motivated to make a change in their life with the use of extrinsic motivation to aid in device adoption and value adding towards the users' life [32]. Accordingly, DH that is being developed to induce healthy behavior change in older adults should consider tapping into both types of motivation to strengthen adoption and engagement rates.

When asked about telehealth, older adults in this study were generally receptive and brought up convenience as its main benefit. While the COVID-19 pandemic may have facilitated the shift in perception in favor of telehealth in the eyes of older adults, participants in this study still preferred in-person consultation. The preference for in-person consultation was also reported in another Singaporean qualitative study exploring the attitudes of older Singaporeans towards telehealth [33]. Furthermore, the overall awareness among Singaporean older adults about the range of telehealth services available remains low with more than 50% of participants not knowing about telehealth [33]. A consideration suggested by older adults in this study was to focus telehealth efforts on individuals who would benefit from telehealth the most (eg, immunocompromised individuals and individuals with mobility concerns). Targeted strategies to reach older adults who face barriers to in-person consultations could ensure that the technology is being used by groups of older adults whose health care experience may be enhanced the most through the adoption of telehealth.

Due to the linguistic constraints of the data collection team, the study only recruited older adults who were English speakers. As such, older adults whose first language was not English (eg Mandarin, Malay, Tamil, Hokkien, and Cantonese) were excluded. Accordingly, the study may not capture nuances that may be specific to non-English speakers. Furthermore, the recruitment strategies of using social media platforms and community outreach might miss segments of the population not active in these areas. For instance, older adults with lower socioeconomic status or socially isolated may not be captured through these recruitment strategies. Nevertheless, this study was able to explore the perspectives of older adults from the 3 major ethnicities in Singapore (Chinese, Indian, and Malay) with varying levels of health conditions. As the aim and the design of this study were to understand the perspectives of older adults in Singapore through a qualitative study, the findings contribute to the knowledge about DH in the Singapore context. To further strengthen the findings from this study, next steps can include the use of data triangulation to corroborate current findings using a different data source (eg, focus groups or observational data), and increasing the sample size or interview length to enhance comparability and generalizability of the study findings. Moreover, strategies toward the development and implementation of DH should be context-specific, and an application of the findings outside of Singapore may require additional validation.

The process of aging creates an inevitable burden not only on an individual but also on the health care system and society. A potential way to help ease this burden is to harness the potential of technology, specifically through DH. This study demonstrated

the various perspectives of and experiences with DH among older adults in Singapore. DH developers and implementors are encouraged to take these into consideration to improve DH adoption and implementation within this population, and to align their strategies accordingly.

Abstract

Background: The rarity that is inherent in rare disease (RD) often means that patients and parents of children with RDs feel uniquely isolated and therefore are unprepared or unsupported in their care. To overcome this isolation, many within the RD community turn to the internet, and social media groups in particular, to gather useful information about their RDs. While previous research has shown that social media support groups are helpful for those affected by RDs, it is unclear what these groups are particularly useful or helpful for patients and parents of children with RDs.

Objective: This study aimed to identify what specific features of disease-related support groups (DRSGs) the RD community finds particularly useful or supportive and provide a set of recommendations to improve social media-based RD support groups based on this information.

Methods: Semistructured qualitative interviews were performed with patients and parents of patients with RDs. Interview participants had to be at least 18 years of age at the time of the interview, be seen by a genetics specialist at a partner health care institution and be proficient in the English language. Social media use was not a prerequisite for participation, so interview participants ranged from extensive users of social media to those who chose to remain off all social media. All interviews were conducted by phone, recorded, and then transcribed. Interview transcripts were then coded using the 6 steps outlined by Braun and Clarke. Three researchers (TAD, SLV, and CMEH) performed initial coding. After this, the study team conducted a review of themes and all members of the team agreed upon a final analysis and presentation of data.

Results: We conducted 31 interviews (mean age 40, SD 10.04 years; n=27, 87% were women; n=30, 97% were non-Hispanic White). Thematic analysis revealed that social media DRSG users identified the informational usefulness of these groups as being related to the gathering and sharing of specific information about an RD, clarification about the importance and meaning of certain symptoms, and obtaining insight into an RD's progression and prognosis. Participants also identified that DRSGs were useful sources of practical information, such as tips and tricks about managing RD-related issues and concerns. In addition, participants found DRSGs to be a useful space for sharing their disease-related stories but also highlighted a feeling of exhaustion from overexposure and overuse of DRSGs.

Conclusions: This study identifies the usefulness of DRSGs for the RD community and provides a set of recommendations to improve future instances of DRSGs. These recommendations can be used to create DRSGs that are less prone to splintering into other DRSGs, thus minimizing the risk of having important RD-related information unhelpfully dispersed amongst a multitude of support groups.

Introduction

The National Institutes of Health estimates that 25-30 million Americans, roughly 1 in 10, are affected by rare diseases (RDs). Therefore, while a single RD may impact only a small percentage of people, the culminative sum of all RDs impacts a sizable portion of the overall population. Despite this, patients with RDs often face significant barriers to appropriate care. The rarity of their conditions means that substantive information about their health is often lacking, and patients encounter significant challenges in finding and understanding the little information that is available [1]. Coupled with a paucity of appropriate diagnostic services, they face exceptionally long and difficult diagnostic odysseys [2]. This means that patients with RD find themselves on “the journey of experiencing unexplained symptoms, seeking evaluation, experiencing symptom evolution, and seeking further evaluation, all in an attempt to obtain an accurate diagnosis” [3]. Another consequence of the rarity of these conditions is that opportunities for socializing and networking between patients are few and far between. Patients therefore often feel isolated, unprepared, and unsupported in managing their care [2,4,5], as though they had been left to undertake their medical journey alone.

Given these challenges, for many patients with RDs, the internet may provide the only medium through which they can connect with others who have the same or similar diseases. Previous research has shown that patients and guardians of children with RD often use the internet, and social media in particular, as a source of informational, emotional, and social support [5-9]. Platforms that allow users to create disease-specific groups, such as Facebook (Meta) or Reddit, have been found to be especially useful for patients and parents of children with RD. Notably, a recent study found that Facebook had over 6000 user-created groups related specifically to RDs [10].

Yet, while it is evident that the members of the RD community use social media groups to engage with one another, it remains unclear what specific features of these disease-related support groups (DRSGs) make them helpful for patients and guardians of children with RD. How do patients find support within the various RD communities on social media? In order to fill this knowledge gap, we conducted a series of in-depth, qualitative interviews with patients and their guardians who were being seen in the clinic for rare genetic disorders. The results of our study are of significance for RD advocates and organizations that hope to design, establish, and cultivate social media-based RD communities.

Methods

Participants and Procedures

The Indiana University institutional review board approved this qualitative study. The study team consisted of three researchers: (1) one male, faculty investigator (TAD) with experience in

philosophy of medicine and bioethics and doctoral-level training in qualitative research methods; (2) one male, with a doctorate in medical anthropology, advanced training in bioethics (CMEH), and extensive experience in qualitative research methods; and (3) one female research assistant (SLV) whose work focuses on improving care for the RD population.

Involvement in the study required participants to be older than 18 years of age and to have proficiency in the English language. The candidate needed either to be actively followed at Indiana University Health or to be the guardian of a minor who was being followed at Indiana University Health. Candidates were identified by genetics specialists using convenience sampling, and those individuals who expressed verbal interest in participation were scheduled for a 1-time phone interview. The recruitment strategy was agnostic as to whether candidates were intensive or casual users of social media, and even individuals who preferred not to use DRSGs at all were invited to participate. This design was meant to capture the perspectives of both individuals who do and those who do not find value in engaging in social media-based RD communities. Participants provided verbal informed consent before participating in this study. Interviews ran from April to September 2023, at which point team members agreed that the sufficient depth and richness of the data had been achieved to generate meaningful insights and themes, as is appropriate for interpretive qualitative research [11,12].

Instruments and Analysis

The interviews were structured to learn about participants' social media practices and values in relation to their RD needs and interests. The team jointly developed the interview guide based on a thorough literature review. The interview template consisted of approximately 21 questions outlining general uses of social media, including account platforms and perceptions of their typical social media usage; attitudes toward interviewees' use of social media for disease information; and how social media has influenced their social lives, both as a family and individually. It also addressed any advocacy efforts in which interviewees had participated and their interactions with peers on social media through RD groups and informational sites. In order to avoid prompting participants to discuss a particular social media site or group, these sites and groups were introduced to participants in a general, nonspecific manner (eg, “on what platforms do you have a social media account?”; “are you an active member in any social media groups?”). The interview guide concluded with basic demographic questions, including gender, race, age, religious affiliation, and highest level of education. Participants could complete the interview in whatever space they felt comfortable, while the interviewer conducted the calls from a private office in order to maintain participant confidentiality. The complete interview guide used for these interviews can be found in the [Multimedia Appendix 1](#) of this article.

One researcher (TAD) conducted the interviews while completing detailed field notes. Each interview was audio-recorded and transcribed through MacWhisper (Sindre Sorhus) or audio transcription through Microsoft Teams, both HIPAA (Health Insurance Portability and Accountability Act)-compliant, artificial intelligence-based programs. The generated transcripts were then reviewed by a member of the research team, who compared the audio recording against the transcript in order to ensure accuracy. In cases where there was a discrepancy between the audio recording and the generated transcript, the team member who conducted the interview was consulted to clarify what was said in the interview. After this, the researchers uploaded transcripts to Dedoose (SocioCultural Research Consultants, LLC), a mixed methods analysis tool especially useful for qualitative research. It was determined that reflexive thematic analysis based on the 6 steps outlined by Braun and Clarke [11] was the best method to investigate these interviews both rigorously and yet flexibly. Members of the study team familiarized themselves with the conversations and constructed a coding tree outlined by overall platform use, uses and goals of social media, information behavior, social media's impact of perception of RD, behavior on social media, advocacy and support, mental health, and portrayal of clinicians. The codes were further enhanced, as the study team met periodically to refine and clarify themes emerging from the data, thus ensuring they were used consistently by all team members. The study team conducted a review of themes, and all members approved the final analysis and presentation of data.

Ethical Considerations

Study procedures were approved by the Indiana University institutional review board (protocol 18779). The study was determined to be exempt research and thus consent was obtained

verbally after a member of the study team thoroughly explained to participants the study procedure, the risks and benefits of participating, and how their data will be protected. Participants were also provided with this information in a study information sheet. All data presented in this manuscript has undergone proper deidentification.

Results

Overview

A total of 31 participants completed an interview. The average length of an interview was 45 minutes (range 21-73 minutes). After coding the data, 3 themes were identified regarding how and why DRSGs were considered valuable to patients with RDs and families, and the themes are (1) for general information about a disease and its symptoms, (2) as a source of practical advice, and (3) for accessing and managing emotional and social support. Each of these themes is elucidated in their respective sections below.

Participant Characteristics and Demographics

Of the 31 participants who completed an interview, 8 (26%) were parents of patients with an undiagnosed or RD, and 23 (74%) were patients with an undiagnosed or RD. Overall, differences between these 2 groups were not observed; both groups shared congruent experiences that mapped onto a common set of themes and concerns.

All participants were residents of the United States. The majority identified as female (87%, 27/31) and White (97%, 30/31). The average age of participants was 40 years. Roughly half of our participants identified as Christian. Regarding educational attainment, about half had obtained a bachelor's degree. More information about their demographics is found in [Table 1](#).

Gathering Information About the Disease Process

Participants often used DRSGs to gather information about their disease. In particular, they used DRSGs to gather more

information about conditions and symptoms, a disease prognosis, or to seek further information about a disease (Figure 1).

Figure 1. Gathering information about the disease process visual summary. DRSG: disease-related support group.

Information About Conditions and Symptoms

Participants used DRSGs to gather information about the relevance or meaning of certain symptoms as well as general information about their medical conditions. One participant remarked that social media was “a good place to start your search” [P27], and another participant stated that it could be used for “crowdsourcing medicine” [P23] insofar as one could leverage the insights offered by members of a particular DRSG in pursuit of effective diagnosis and care.

Participants recounted how joining groups for a particular condition greatly bolstered their understanding of that condition. For instance, one parent recalled the usefulness of a DRSG for gathering information about her daughter’s disorder: “It was super helpful because for us, it was kind of like, ‘Here you go, this is it.’” The group members, she said, “were pretty knowledgeable of the condition and how to manage it and work with the symptoms” [P06]. In another instance, a parent remarked that “we found out that [our daughter] had hypotonia and we didn’t know what that was, [so] I was like, ‘I’m going to look that up’, and then I saw on Facebook they have a hypotonia support group, so I did join that” [P03].

Participants also used social media groups to discover the meaning behind certain symptoms. This allowed them to relate a seemingly disparate cluster of symptoms to a particular rare condition. As one of our participants put it, “we don’t even know that our symptoms are symptoms, so you can be like, ‘Oh, yeah, that’s not normal.’ It’s validating” [P29]. In one instance, a parent of a child with an ultra-RD credited her DRSG use with linking her child’s symptoms to a specific diagnosis: “A lady [...] was telling her child’s story, and I was half-listening. But then she started talking about the [symptom] and I was like, ‘What did she just say?’ and I rewound it, and then everything she said about her kid, and even a video she had of him crawling away, looked like my son” [P07]. In another case, a woman explained how she was able to use a social media group to trace “a really, really bizarre sensation” in her chest to costochondritis, a condition that is commonly experienced by those with her particular RD but one about which she had never previously heard [P12].

What to Expect

Through their DRSG usage, our participants sought information about what they should expect when living with a certain RD or caring for a child with such a condition. One participant remarked that members of DRSGs often asked whether it was normal for their child not to reach certain developmental

milestones [P01], to which other members reportedly responded by describing their own personal experiences with the condition. When asked what participants would want to get out of a DRSG, multiple interviewees cited information regarding how their particular RD progresses: “It doesn’t feel like a stagnant disease,” one participant explained, describing the unexpectedness of her child’s evolving symptoms, so she turned to social media “to just kind of compare stories” [P02]. Another participant explained that “seeing other kids, maybe that are older than [her daughter], how they’re doing and maybe the outlook on that” had been beneficial for her [P03]. Some participants, however, cautioned that hearing too much about more severe prognoses can be harmful: “You have to be in the right mindset, because you can come across very scary stories about people” [P29].

Seeking Information

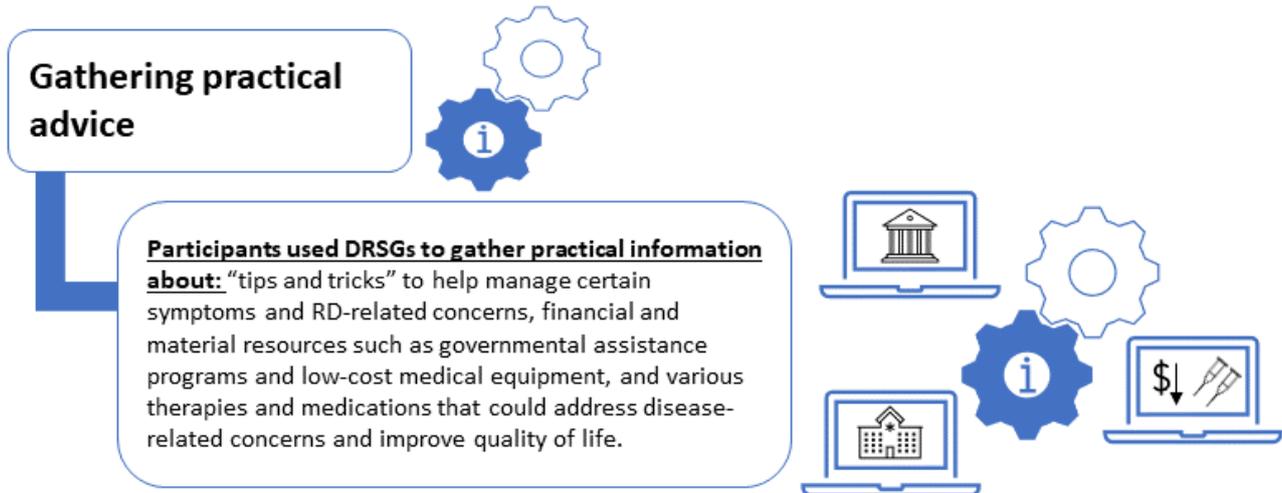

In general, our participants recalled using DRSGs to seek information about their or their child’s condition. In particular, some searched social media sites in an attempt to learn about rare genetic variants: “I search every once in a while, [for] that specific gene and tag to see if anyone else pops up” [P02]. Another participant recounted that “I did post or search for [genetic variant] and see what posts came up with that” [P01].

In contrast, participants with either medical training or a graduate degree tended to conduct research without the aid of DRSGs: “I would just go to Google Scholar. When I was at the university and I had access to the library, I would use the library to look at different articles. I might still see about access though PubMed” [P08]. Another participant, who had a background in nursing, recommended to her daughter after her diagnosis “that she had to look at more medical journal type things” rather than rely on what she could find on social media [P09]. This reticence was due to an expressed skepticism on the part of many regarding the quality of information available on such platforms. Some groups are organized for the sharing of peer-reviewed research articles, which for medically literate patients was seen as very beneficial and a way to avoid dubious information: “I can’t tell you how much I’ve learned through the [DRSG],” one young woman explained [P15].

Gathering Practical Advice

Participants used DRSGs to gather practical advice relating to their RD and related concerns. In particular, participants used DRSGs to gather various “tips and tricks” that were useful in addressing their disease-related concerns (Figure 2).

Figure 2. Gathering practical advice visual summary. RD: rare disease.

Participants often praised DRSGs as sources for useful “tips and tricks” to help manage disease-related issues. One participant explained that she used social media to gather practical rather than medical information: “It’s more about the giving and sharing of advice and tips” [P12]. This advice often took the form of recommendations for symptom management based on personal experience. Other group members regularly provide testimonials and appraisals of resources for managing symptoms, including everything from braces and topical creams to supportive mattresses and pillows. One parent of a child requiring a feeding tube mentioned that joining a DRSG was helpful initially after diagnosis because it allowed her to collect “a bunch of different tricks, or different clothing” [P04]. One parent of a child with ankle braces remarked: “I put on [the DRSG], ‘who would have thought that buying a pair of shoes for a two-year-old would be so difficult?’ and there was a couple of other moms who were like ‘Oh, go with this brand’” [P03]. A challenging task with the potential for significant trial-and-error related cost and frustration was averted by accessing others’ lived experiences through social media.

In addition to advice, our participants used DRSGs to gather practical resources to address disease-specific concerns. Participants mentioned DRSGs that focused narrowly on enabling users to acquire medical equipment and other materials. For instance, one interviewee described a group in which “families who have extra of different things” provided valuable supplies to families with limited financial means and access [P10]. One parent mentioned a local group whose sole purpose was to allow parents to provide others with “used equipment, or things that their kids have outgrown, or that they don’t need anymore [...] and you don’t know what to do with them [...] You post them on there so local people can either buy it from you or get it from you” [P07]. In other cases, resource sharing occurred through posts within general DRSGs: “People post on there if they have Aspen collars or things that they don’t need anymore,” noted one participant of a group broadly dedicated to her particular RD [P288].

Information about programs designed to assist those with disabilities was also commonly shared on DRSGs. One participant recounted that she “learned about the Medicaid waiver” for home and community-based services through DRSGs, adding that “I’m so thankful [my daughter] has that now” [P02]. This participant was also able to gather information about a program offering reduced admission to local museums for children with disabilities, and she even obtained a medical stroller and car seat through a program she learned about through a DRSG.

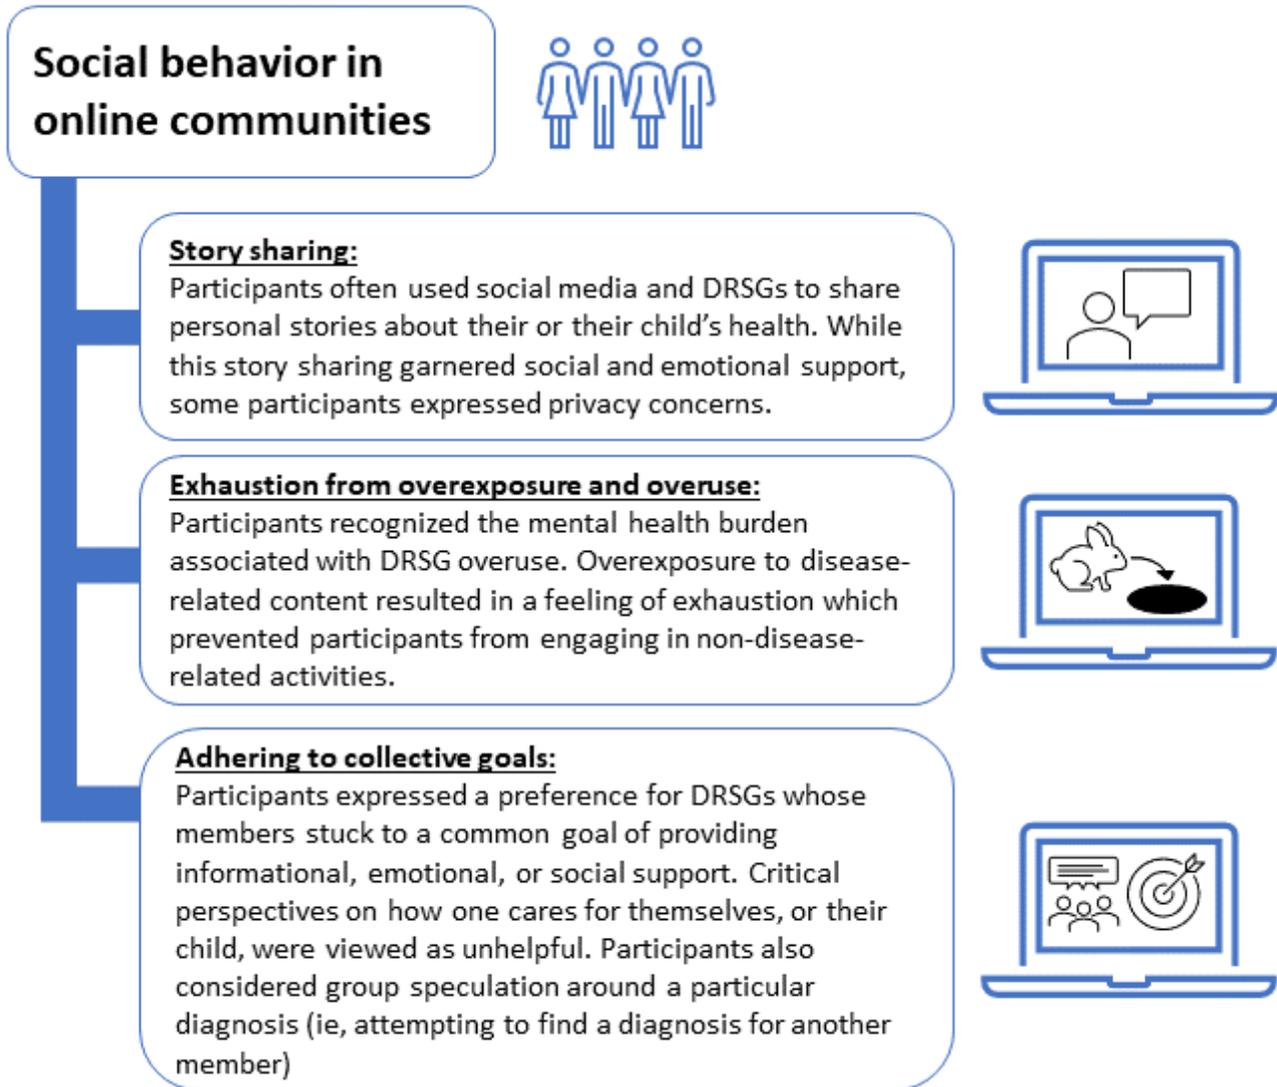

A large portion of our participants (74%, 23/31) reported using DRSGs to obtain or provide disease-related guidance. While the type of guidance they sought varied, participants used this information in a practical manner, either to discover an actionable therapy or to judge the usefulness of a particular medication. Some of our participants used DRSGs to collect information about therapies of which they had previously been unaware: “I hadn’t known about, for example, horseback riding therapy. I didn’t know that was a thing” [P01].

Our participants also found value in learning about others’ experiences with clinicians. One participant described the use of DRSGs to ascertain “people’s opinions about a doctor at a hospital or within a group: ‘Who has had this doctor? What is your feedback’ or ‘Have you tried this medication for [something]?’” [P02]. Such advice was seen as particularly useful, as interviewees felt that many clinicians whom they encountered were not sufficiently knowledgeable or otherwise disposed to care for their particular condition.

Social Behavior in Social Media–Based Communities

Participants used DRSGs to engage in social behaviors. In particular, participants used DRSGs to share stories regarding their RD experiences. However, participants also expressed concerns regarding the potential for overuse of DRSGs. Participants also believed that behavior on DRSGs should adhere to the collective goals of providing emotional, informational, and social support (Figure 3).

Figure 3. Social behavior in social media–based communities visual summary. DRSG: disease-related support group.

Story Sharing

About half of our participants (54%, 17/31) reported that they have used social media to tell their personal stories or provide updates about their own or their child’s health. Motivations for sharing personal stories and information about health status varied. One woman used Facebook to describe her experiences in a series of posts that she had intended “for educational purposes, for awareness purposes” [P25]. A mother cited social media as “a way to keep everybody in the loop” about her child’s health, which saved her the trouble of “texting 18,000 people” to provide health updates. As another participant put it, “It’s just so much easier to put out updates like that online than it is to try to explain it 30 different times to 30 different people” [P02]. However, regardless of the participants’ motivations for sharing their personal stories, they expressed that they had received sympathetic and reassuring responses to those posts. For instance, one mother remarked, “[My daughter] had eye muscle surgery, and I did a little post, and people were saying ‘thoughts and prayers’ for her and a quick recovery” [P03].

Contrarily, some participants hesitated to share their stories so openly. “I’m very careful about what I post because I just don’t want people seeing everything. I’m private,” one participant stated [P15]. “Oversharing could be very dangerous to their own privacy as well as their own health,” noted another woman [P23].

Exhaustion from Overexposure and Overuse

Our participants appraised social media as a generally supportive environment. However, many remarked that DRSGs can become emotionally burdensome when members spend too much time on them. They often mentioned limiting their consumption of DRSG content for that reason. One woman, for instance, stated that “there was a group of moms from the [DRSG] where we had a private group chat that would occur daily, all the time. I had to mute it. It was too much” [P06]. Another woman limited her participation in social media groups because “if I spend all my time in a chat room, that’s where my energy is going, and I had other things I wanted to do” [P24]. In fact, after leaving social media, she returned to school and graduated shortly after our interview. One parent highlighted how her DRSG use led to maladaptive and obsessive behavior. Particularly, she felt compelled to follow every lead related to her child’s condition:

“It gets me looking into things to see if maybe I can find that, and I’m just like, ‘Oh, maybe I can bring this to the doctor,’ you know? And sometimes it just really takes over” [P10].

Adhering to Collective Goals

Our participants often asserted that DRSGs have the best cohesion when members keep to the specific goal of providing informational, emotional, or social support to other members. One of our participants stated, “We’re all moms that are trying to figure out what the heck is going on with our kids. We don’t need anybody beating us up over a decision that we made or didn’t make [...] Just make sure [the group is] really monitored and positive. And remember that we’re all in situations together” [P04]. Another participant expressed frustration at other members of these groups who tried to play the role of a clinician rather than providing social support or practical advice: “You have a lot of parents in these groups that I guess are pushing what they feel your child’s diagnosis is, and let’s face it: they’re not the doctor. So, I can give my information on my child, and they can be like, ‘Oh, that sounds like this.’ And then they stick to that point of they strongly feel that this is what is wrong with your child.” [P10].

Discussion

Principal Findings

In many cases, DRSGs provided our participants with an understanding of their RD that was informed by others’ lived experiences. This allowed them to gather practical advice regarding how others had dealt with particular symptoms, obtain general information about a disease, and socialize with those who share similar experiences. These findings support previous research on DRSGs, which has shown that online groups provide both informational and emotional support for those who share a similar diagnosis [13]. In addition, past studies have found that DRSGs provide users a space to ask and answer specific questions about medication management, hospitalizations, and clinic visits as well as provide a supportive environment where users can disclose personal stories about their disease experience [14].

Due to random sampling used during the recruitment process, our study was also able to capture the perspectives of those who do not regularly use social media. This has been an oversight in much previous research [5-7,15,16]. We found that these participants avoided social media either due to privacy concerns or a perceived lack of benefit. Privacy concerns have been found in other studies, though they do not always rise to the level of stopping patients from participating in DRSGs [5,15,16].

Information About the Disease Process

Within the existing literature on RD and social media use, it has been found that users often turn to DRSGs for information about a diagnosis or test results or to participate in conversations about a specific diagnosis [6,7]. Another study reported that patients with RDs use DRSGs primarily as a source to share medical information about symptoms, treatments, and diagnoses [8].

Our study likewise found that participants regularly made use of social media for informational needs. However, they did not expect this information to replace communication with trusted medical professionals. Many participants understood the role of the community in these groups not as that of experts, but rather as individuals with unique and personal insight into what it is like to live with and care for someone with an RD. This aligns with previous research which has found that participants often regarded clinical advice accessed through social media as dubious and to be met with skepticism [5].

DRSGs, then, were seen not as a replacement for recommendations offered by a participant’s clinician, but rather as a complement to these clinical recommendations. This finding is congruent with a review of previous research which has found that patients often used social media-based communities to receive information and advice on how to improve their medical care or explore treatment options [17]. One study found that patients often turned to online support groups because they believed their providers lacked a sufficient amount of time to discuss each treatment option in depth. These groups allowed patients to gather information from members of the community who were actively undergoing these treatments [18]. Our participants engaged in similar behavior, which indicates that the patient perspectives gathered from DRSGs parallel information discussed in a clinical setting.

Many participants preferred internet-based databases sources such as Google Scholar or PubMed as a source of information rather than social media, due to the credibility they attached to them. Information from medical journals was generally felt to be more reliable and trustworthy than information found through the self-report of DRSG members. Such a finding corroborates a recent review of the literature regarding online health information-seeking behaviors which highlighted the central role of trust in determining patients’ information-seeking behavior [19].

One critical finding from our study is that information-seeking through social media was often seen as burdensome and could even become maladaptive. Our participants reported using the search feature on DRSGs to find information about particular genetic findings, but they also highlighted that such searching could also become obsessive and result in mental exhaustion.

Practical Advice and Lived Experience

While it is evident that our participants engaged in information sharing and gathering, it is important to emphasize that our participants often used DRSGs as more than just an informational resource. In particular, they relayed these groups’ usefulness for obtaining practical advice, for providing and seeking appraisal of medical providers, as well as for sharing and gathering guidance on how to enroll in certain government programs or to obtain certain government benefits. These “tips and tricks” allowed them to navigate and address their many concerns that fall outside of the scope of traditional clinical care. They additionally provide information related to specific products that particular RD communities have found useful, such as brands of clothing or specific kinds of medical braces. Moreover, participants sought information about others’ lived

experiences in order to forecast what to expect regarding disease progression, assisting in personal prognostication.

While previous research has identified RD-specific DRSGs as a useful resource for such general practical advice [5], one of our study's novel findings is that DRSGs are important sources of material exchange. While much of the literature focuses on social media as a place to obtain information and social support, our participants relayed the importance of DRSGs in the selling, buying, and trading of specific medical equipment. Similar to this, an additional novel finding of our study was the use of DRSGs to discover and help obtain various material and service benefits offered by federal and state governments. Previous cost-of-illness research has established RDs as a major economic burden for patients and their families [20-22]. Hence, it is noteworthy that DRSGs have the potential to alleviate particular disease-related economic burdens. Conceivably, DRSGs allow users to recuperate some of the costs associated with medical equipment by selling them directly to other patients and their guardians; in turn, those individuals may do so at a reduced price and thus do not incur the often-exorbitant cost of new equipment.

Socializing and Networking

As made evident by our study, social media serves as one possible venue for patients and their guardians to establish and maintain social connections despite physical, geographic, and medical barriers. Our findings concur with these previous findings that social media sites that allow users to create disease-specific support groups, such as Facebook or Reddit, can be helpful resources for those with chronic diseases [23,24]. Social support has been shown to have a positive impact on one's health [25]. In particular, social support can reduce psychological distress, mitigate feelings of loneliness, improve quality of life, and decrease mortality risk [26]. In light of this fact, many health organizations, such as the World Health Organization (WHO) and the US Department of Health and Human Services (DHHS), now emphasize the importance of a person's ability to establish and maintain social relationships with members of their community [27,28]. For this reason, the WHO has recently established a Commission on Social Connection in order to address social isolation and loneliness and the DHHS has established the objective of increasing social and community support as part of its Healthy People 2030 longitudinal-objective program [29,30]. DRSGs therefore have

the ability to play a critical role in improving the overall health and connectedness of RD communities.

Another novel finding of our study was participants' preference for DRSGs that adhere to the perceived objectives or goals of a support group. That is, many of our participants understood the overall purpose of these groups as providing a supportive and non-judgmental space for patients and caregivers to engage in discussions about a particular disease and its symptoms, practical tips and tricks that could improve the overall quality of life, and an environment in which they could share their personal experience with a disease if they so choose. Our participants found it off-putting when discussions deviated from these goals.

Recommendations

Quantitative analysis has shown that thousands of RD social media groups now exist [10]. While this staggering number may provide a diverse range of opportunities for informational, emotional, and social support, it also suggests that valuable resources are unhelpfully distributed across an unmanageable number of virtual locations. For instance, the aforementioned quantitative analysis found 93 unique support groups specifically for a single rare connective tissue disorder, and that number accounts only for groups dedicated to its pediatric form [10]. This suggests that patients are faced with the burden of having to figure out which specific support groups to join, how to resolve possible conflicts in information gathered from these various groups, and how to avoid oversaturating their social media feeds with disease-related information from disparate groups, which we have found is often emotionally burdensome.

It is evident, then, that the duplication of efforts is a serious problem facing DRSG administrators and their users. We contend that a solution to this substantial problem is to ensure that DRSGs are designed and operated in a manner that ensures users' informational and social needs are fulfilled by a single group. It is likely that they will then be less likely to create new, schismogenic DRSGs, thus alleviating the problem of duplicating efforts and stretching virtual resources too thin.

Based on the data from our interviews, we propose the following recommendations for creating a DRSG that patients with RDs and their guardians will find valuable, usable, and worthwhile (Table 2). While the scope of our study was limited to RD, it is possible that these recommendations may be generalizable to other, non-RD social media-based communities.

Table 2. Recommendations to Improve DRSGs^a.

DRSG usability issue	Potential solution	Explanation	Usefulness
Our results show that DRSGs are commonly used to gather practical or general advice related to a particular rare disease. This Important information may become “buried” by numerous new posts which may lack such practical relevance.	Establish and make use of pinned posts.	Posts that contain information, practical advice, or resources that the community finds particularly helpful should be “pinned” at the top of the group page.	Previous research has shown pinned posts to be a useful way to highlight and propagate important information [31]. Pinned posts can prevent members from repeatedly asking the same important questions. This allows new members to find the most helpful and important information as soon as they become a part of the group.
Certain materials, such as applications for governmental benefits, information about disability assistance programs, and other similar documents may not get proper attention when simply shared through a single post. DRSG users have identified these documents and resources as being particularly helpful to them.	Establish and make use of a “Files” section.	Official resources and documents should be archived in a set of group files. Group files can either be integrated through the social platform itself (eg, through the “Files” feature on Facebook) or through a third-party document hosting service (eg, Google or Dropbox).	A “Files” section allows users to share and store documents related to various assistance programs. This ensures that users can easily find and access important documents or resources. In addition, a “Files” section can allow DRSG users to share articles from journals for members of the community who possess a high health literacy.
In order to find relevant information related to a specific medication, therapy, symptom, or medical concern, DRSG users are often forced to conduct an imprecise search of all posts in a particular group and decipher them for potential relevance.	Introduce and encourage the use of posttags.	To enhance the searchability of the group on a particular topic, users should be encouraged to put particular keywords at the beginning of their posts that summarize the overall theme or topic of the post.	Prior research [32] has highlighted the usefulness of tags in enhancing searchability [33,34]. Posttags can assist users in searching quickly for a particular symptom, medication, or disease-related concern. This prevents repeated posting about similar issues or symptoms.
Our participants described the overuse of DRSGs as leading to exhaustion and emotional burden.	Creation and amplification of a community guide.	A community guide directs users on how to navigate the DRSG and how to make use of its various features and materials. This guide can also indicate the dangers of overuse (ie, mental exhaustion) of social media.	A community guide can help to ensure that users are “getting the most” out of a DRSG while ensuring that they do not feel overwhelmed by an abundance of information. In addition, including a section on the importance of taking breaks from social media can help users maintain healthy DRSG use.
DRSG users expressed frustration when other group members did not adhere to the perceived goal of the group (eg, to provide a supportive environment for patients and caregivers).	Creation of a group mission statement and a clear explanation of moderation decisions based on that mission statement.	In conjunction with a set of standard rules to maintain proper group decorum, a mission statement establishes the specific goals of the group and allows moderators to ensure the community focuses on these goals.	Establishing a mission statement for a DRSG can ensure that users are mindful of the specific goals and objectives of a group, preventing them from sharing irrelevant or disruptive content in an otherwise supportive environment.

^aDRSG: disease-related support group.

Aside from these more targeted improvements for DRSGs, clinicians and RD advocates should also be aware of the importance of patient autonomy and community sovereignty when creating or recommending support groups. While our participants expressed a preference for competent moderation and proper group governance, it was also evident that they appreciated the ability to behave in an authentic or organic manner within these groups. While clinicians and advocacy organizations have a role to play in patient-oriented social media, it is important to recognize that this role should not impede a community’s or patient’s ability to express concerns or criticisms about specific clinicians or advocacy organizations in these virtual spaces. Therefore, clinicians and advocacy organizations that either create or engage in DRSGs must recognize that a social media–based support group truly belongs to a community of patients rather than to their organizational or clinical agenda. By asserting that a group belongs to the

community and its members, clinicians and advocates help to empower patients and caregivers [35,36].

Therefore, we recommend that clinicians and advocacy organizations work to develop plans to ensure that DRSGs foster patient autonomy and community sovereignty rather than diminish it. With respect to group governance, this means giving community members a say in group moderation. Kiesler and colleagues offer useful guidance on this point [37]: They provide a total of 33 “design claims” that offer insight into the effective regulation of online spaces. Of particular relevance, they highlight that moderation decisions from members of the community are viewed as more legitimate and more effective, and that rule making which involves and incorporates the community’s feedback allows for better compliance with rules.

Conclusion

Our study provides insight into the specific ways that patients and parents of children with a RD interact with DRSGs. We found that DRSGs were used to collect and seek medical information about a disease and its symptoms, gather practical resources and advice, and socialize and network with those who share a similar experience to their own regarding a particular disease. Importantly, these results uncover and highlight the particular features and elements of DRSGs that members of the RD community find helpful, usable, and worthwhile. Through considering the practical importance of these results, we established a set of recommendations that are tailored specifically to DRSGs. These recommendations provide guidance to RD advocates and organizations that manage DRSGs, which may reduce the reduplication of efforts and the

splintering of disease-related support across an unmanageable multitude of groups, which at present is often experienced as time-consuming and emotionally burdensome.

Limitations

Our sample population featured a significant gender and race skew, with participants predominantly identifying as female and White. The collected data may therefore not necessarily represent the diverse perspectives present in the RD community. This skew could also impact the generalizability of our results to the many DRSGs found across various social media platforms. In addition, limitations related to scope and interview length prevented our study from examining how participants discovered support groups and whether certain search strategies or terms yielded information about potentially relevant social media-based support groups.

Data Availability

The datasets generated during and/or analyzed during this study are not publicly available due to the private and sensitive nature contained in the qualitative data. Relevant sections of deidentified data and/or coding trees are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Virtual reality (VR) group activities can act as interventions against inactivity and lack of meaningful activities in nursing homes. The acceptance of VR among older adults has been explored from different perspectives. However, research on the impact of older adults' individual characteristics on the acceptance of VR group activities in nursing homes is necessary.

Objective: This study investigates the impact of individual characteristics (eg, psychosocial capacities) on VR acceptance among older adults in nursing homes, as well as this group's perceptions of VR after participating in a VR intervention.

Methods: In this pre-post study conducted in nursing homes, we applied a VR group intervention with 113 older adult participants. These participants were categorized into two groups based on their naturalistic choice to join the intervention: a higher VR acceptance group (n=90) and a lower VR acceptance group (n=23). We compared the two groups with respect to their sociodemographic characteristics, psychosocial capacities, and attitudes toward new technologies. Additionally, we examined the participants' perceptions of VR.

Results: The results show that those with lower acceptance of VR initially reported higher capacities in organizing daily activities and stronger interpersonal relationships compared to older adults with higher VR acceptance. The VR group activity might hold limited significance for the latter group, but it offers the chance to activate older adults with lower proactivity. Openness to new technology was associated with a favorable perception of VR. After the VR intervention, the acceptance of VR remained high.

Conclusions: This study investigates the acceptance of VR group events as meaningful activities for older adults in nursing homes under naturalistic conditions. The results indicate that the VR group intervention effectively addressed low proactivity and interpersonal relationship issues among older adults in nursing homes. Older adults should be encouraged to experience VR if the opportunity to participate is offered, potentially facilitated by caregivers or trusted individuals.

Introduction

The absence of meaningful activities and a lack of social interaction can lead to loneliness in older adults in nursing homes [1,2]. Meaningful activities are defined as those that hold personal significance or offer enjoyment to individuals, aligning with their present and past interests, routines, habits, and roles [3,4]. In the context of nursing homes, a meaningful activity could include household tasks like cooking, which older adults may no longer be able to do on their own. A lack of meaningful activity leads to older adults' inactivity, resulting in mental and physical impairment, as well as an increased risk of mortality

[5-8]. Furthermore, several studies show that older adults in nursing homes experience more loneliness compared to those living in the community, even though they are often surrounded by other residents and caregivers [9,10]. Addressing these issues requires innovative solutions [8,11,12]. Virtual reality (VR) has emerged as a promising solution in rehabilitation [13,14], including for older adults [1,15,16]. VR technology, especially fully immersive VR technology, delivers a comprehensive and lifelike experience, creating a strong sense of presence for users by using head-mounted displays and motion-tracking controllers. These devices work in tandem to simulate a realistic, interactive environment, allowing users to see, hear, and interact with the virtual world in a manner similar to real-world experiences [17].

Various studies have shown that VR interventions can enhance cognitive capacities [18,19], improve physical strength [16,18,20]—for example, via walking training [21]—and enhance the overall well-being of older adults [16,19,21-23]. Moreover, the immersive nature of VR not only conserves resources and reduces costs but also ensures safety [24-26]. Thus, VR can be a viable choice for providing meaningful activities within nursing homes to enhance the daily activities, capacities, social activities, and well-being of older adults in nursing homes [27].

In a study on the acceptance of VR technology that included 76 older adults, it was found that participants developed a positive attitude toward VR after using it [17]. A systematic review and meta-analysis found that in most of the 54 relevant studies, older adults reported pleasant experiences with VR and expressed a desire to use it again [28]. In addition to assessing the level of acceptance of VR among older adults, it is also necessary to understand the factors that could influence this acceptance [29]. According to the Technology Acceptance Model (TAM) [30], the acceptance of a technology can be explained and positively predicted by perceived usefulness and perceived ease of use. In the context of our study, the implementation of VR technology should address specific needs, such as providing meaningful activities and combating loneliness, and the design of the VR intervention should be in alignment with the capacities of nursing home residents to ensure the perceived ease of use of the intervention. However, this requires an in-depth understanding of the characteristics of the target population. The field of gerontechnology has advanced in developing frameworks to address the unique capacities and limitations of older adults. A notable gap in the previous acceptance models [31] is the insufficient exploration of personal characteristics. In addition to collecting demographic factors, research should explore participants' cognitive capacities, social relationships, environmental influences, and psychosocial traits. Previous research about VR acceptance among older adults has similarly highlighted the importance of individual characteristics such as physical constraints, educational attainment, and socioeconomic status as predictive factors [32,33]. A qualitative analysis about the acceptance of technology among older adults [34] found noticeable differences in attitude linked to participants' educational background and work experiences, but no definitive differences were found with regard to gender and ages. Older age negatively impacted the willingness of participants to use robots [35]. Further studies are needed to confirm the acceptability of different types of immersive technology devices [28], including a detailed report on VR interventions [29]. An in-depth investigation into personal characteristics, including how the sociodemographic factors and psychosocial capabilities of nursing home residents affect their acceptance of VR group activities, will be valuable for understanding these dynamics and contributing to future design improvements.

Besides sociodemographic characteristics, technological engagement is another important factor for individual technological acceptance. Empirical findings underscore the pivotal role of openness to new experiences as a predictor of improved digital acceptance [36]. Individuals with a higher

motivation for self-actualization tend to be more receptive to new encounters and the acquisition of novel skills and ideas [37]. This propensity for continuous learning aligns with the potential for individuals to actualize their personal capacities through the acquisition of new technological skills [38]. In addition, prior knowledge about VR has been identified as a decisive factor in VR acceptance [32]. This finding resonates with the continuity theory, which posits that older adults make adaptive choices to maintain ties with their past experiences [39]. Adhering to established habits rooted in past experiences serves to mitigate the uncertainty that may accompany new environments. This preference for continuity extends to the perpetuation of personal cognitive frameworks shaped by past preferences. Attitudes toward immersive VR have been observed to change from neutral to positive after the first exposure [17]. Therefore, older adults with higher technical engagement prior to the study may have a higher acceptance of VR-based group activities.

Anxiety toward new technologies, which significantly influences technology acceptance, is rooted in factors like unfamiliarity with computers, perceived uncertainty, fear, and a general apprehension toward making mistakes [40,41]. There is a significant correlation between elevated levels of self-efficacy and reduced anxiety with increased utilization of gerontechnology [42]. In essence, this implies that for older adults to embrace novel technology, they must overcome the fear of uncertainty by taking the initial step of trying it out, preferably with sufficient support. Users tend to experience contentment with new technology once they start using it [43-45]. Therefore, after participating in a VR intervention, the acceptance of new technologies, especially VR technology and VR group events, should be maintained or even improved.

This study focuses especially on the impact of individual characteristics of older adults on the acceptance of VR-based group activities in nursing homes. A series of VR interventions was conducted to address the residents' lack of meaningful activities and loneliness. Over the course of 4 VR intervention sessions, older adults engaged in serious games involving tasks that they may no longer be able to perform within the nursing home environment, such as cooking and gardening. This aligns with the concept of meaningful activities. This study aimed to investigate whether acceptance of VR is linked to personal characteristics, such as sociodemographic background, psychosocial capacities for nursing home residency, and technological engagement. Therefore, the research question and hypotheses of this paper are the following:

- Research question: What are the differences in sociodemographic status and psychosocial capacities between older adults with higher and lower acceptance of using a VR intervention for meaningful activity in nursing homes under naturalistic conditions?
- Hypothesis 1: The group exhibiting higher acceptance of a VR group activity reports a higher level of technological engagement compared to the group with lower VR acceptance.
- Hypothesis 2: After the VR group intervention, technological engagement among older adults will either be maintained or improved.

- Hypothesis 3: After the VR group intervention, the acceptance of VR technology and willingness to participate will both align at a high level.

Our research addresses critical gaps in the existing literature. First, our investigation focused on a specific population and implementation of VR technology: older adults living in nursing homes and VR group events as meaningful activities, respectively. Second, the study focused on differences in personal capacities and was not limited to demographic background. Third, the study was done under naturalistic conditions with high ecological validity, that is, using VR in a group event in a nursing home and collecting naturalistic data. This investigation holds the potential to provide a more nuanced classification and predictive understanding of the specific demographics within nursing homes. It can pave the way for the future development of VR programs that are precisely tailored to the individual needs and preferences of older adults in nursing homes.

Methods

Research Design and Recruiting

We conducted a VR group intervention study as a pre-post observation study in naturalistic settings with older adults in 14 nursing homes in a city of 250,000 inhabitants in Germany.

In a first step, the nursing homes were contacted via telephone. After receiving confirmation of willingness to participate from the institution, an email with the participant selection criteria was sent to the social coordinator of each nursing home. The older adults were selected by the nursing home caregivers based on the following criteria: (1) the participant should be older

than 60 years; (2) they can use at least one arm and hand for interacting with the system; (3) they can see and hear, with assistive devices such as glasses allowed; (4) their cognitive and mental capacity are sufficient for individual interviews; (5) they do not have conditions that could be triggered by VR, such as epilepsy. In addition to meeting these criteria, caregivers asked the older adults about their willingness to participate in the VR intervention. Furthermore, if needed, permission was sought from legal guardians.

Procedure

In the initial study week, a structured individual interview was conducted with the older adults by a psychologist. Baseline sociodemographic characteristics, capacities, and technological inclination of the older adults were assessed (T1). Following a warm-up interview in the second week (T2), the subsequent 4 weeks included repeated exposure to VR group activities (T3-T6). During these sessions, the older adults were organized into groups, with each group consisting of a maximum of 5 members. These groups remained consistent throughout the entire VR intervention. The older adults were expected to accomplish designated tasks individually (Figure 1). After the VR intervention, participants exchanged thoughts about their experiences in small groups. Moreover, an immersive VR video was provided for relaxing after each intervention. After completion of all VR interventions, a posttest was used to assess the older adults' technological engagement (T7).

Participants declining VR intervention involvement were offered participation in a control group that underwent an identical measurement and interview procedure excluding the VR intervention (Table 1).

Figure 1. Older adults participating in a virtual reality group event.

Participants

To answer our research questions, we needed to compare participants with higher and lower acceptance of the VR intervention. The necessary sample size for group comparison with a *t* test for independent groups, with a medium effect size *d*=0.5, an α level of .05, and a power of $1-\beta=0.80$, was calculated to be 102 participants, with 51 participants in each group.

We collected data from 129 participants, of which 113 were relevant to this analysis. The composition of the groups, based on the naturalistic characteristics of the participants (higher or

lower VR intervention acceptance), was unpredictable, resulting in an unequal group size.

Initially, a total of 129 older adults in nursing homes participated in the VR intervention study, of which 12 opted for the control group and 117 opted for the intervention group. Among these participants, 27 individuals in the intervention group discontinued their involvement in the VR intervention. The reasons for dropout and nonparticipation in the intervention group were categorized as non-motivation-related (eg, health, life status; *n*=16) or motivation-related (*n*=11). Non-motivation-related reasons included illness (switch to hospital stay), limited station participation (no group

established), and cybersickness. The non-motivation-related dropouts were not investigated further in this study. Motivation-related reasons included diminished interest after the initial interview and having a preference for an alternate activity. In the end, there were 90 older adults in the intervention group who completed the posttest.

The sample that was analyzed to answer our research questions included 113 participants, that is, the initial sample (n=129) reduced by the participants who dropped out due to nonmotivational reasons (n=16). The investigated sample was categorized into two groups: individuals with higher or lower

acceptance of the VR intervention. The higher acceptance group encompassed the participants (n=90) who actively participated in the VR interventions and successfully completed the subsequent postinterview. The lower acceptance group (n=23) comprised those who dropped out of the intervention group due to motivation-based reasons and older adults who initially were not interested (control group). The higher VR acceptance group was younger (mean 80.13, SD 8.39 years) than the lower VR acceptance group (mean 83.74, SD 8.31 years), but this was not significant ($t_{111}=-1.84$; $P=.07$; $d=-.43$). For comprehensive sociodemographic details of these two groups, refer to [Table 2](#).

^aVR: virtual reality.

^bHigher VR acceptance group included the older adults who participated in at least the VR intervention and the posttest.

^cLower VR acceptance group included the older adults who did not want to join the VR intervention at the beginning (control group) and motivation-related dropouts; one of the motivation-related dropouts was excluded due to an incomplete baseline interview.

Stimuli and Equipment

The VR intervention was done with a virtual vacation home scenario. During each VR session, the participants' tasks were to complete 4 - 5 activities such as gardening, crafting, and

baking (see Figures 2 and 3 for examples). Participants started by crafting a chair, then arranged a garden around it, and finally, they could enjoy sitting on the chair while tending to the garden's plants. In the virtual environment, participants worked on tasks individually. After removing their VR headsets, they

had the opportunity to discuss their experiences with each other in a group setting. Every VR event lasted approximately 20 - 30 minutes, depending on the tasks assigned for each session.

The Pico Neo 3 Pro VR headset and Pico Neo 3 controller were used. The resolution of the head-mounted display was 1832×1920 pixels per eye, with a refresh rate of 72 Hz and 6-degrees-of-freedom inside-out tracking.

Figure 2. Virtual reality gardening task [27].

Figure 3. Virtual reality task in the kitchen: baking a pizza [27].

Data Collection

Psychosocial and cognitive capacities were assessed with the Mini-ICF-APP scale [46]. In this study, the reference context for capacity assessment was daily life in the nursing home. The Mini-ICF-APP covers the following capacity dimensions: (1) adherence to regulations, (2) planning and structuring of tasks, (3) flexibility, (4) competence and knowledge application, (5) ability to make decisions and judgments, (6) proactivity and spontaneous activities, (7) endurance, (8) self-assertiveness, (9) contact with others, (10) group integration, (11) intimate relationships, (12) self-care, and (13) mobility. Each dimension is rated on an 8-point scale (from 0 being “This is a strength of mine,” to 7 indicating “This is impossible for me”). The Mini-ICF-APP is a heterogeneous scale, covering different psychosocial capacities. Each item can be interpreted individually because all items reflect different capacities. If a mean score across the 13 items is calculated, this can be interpreted as a global capacity impairment level. The Mini-ICF-APP is a standard scale for measuring psychosocial capacities that has already been validated in different languages [46-48]. The interrater reliability in our study ranged from $r=0.446$ (untrained) to $r=0.910$ (trained).

The structured questionnaire addressing technology engagement asked for the frequency of engagement with 4 distinct technologies: televisions, smartphones, PCs or tablets, and other novel technologies. Responses were recorded on a 5-point Likert scale, spanning from 1=never/not at all to 5=several times every day/very much.

To assess the acceptance of VR technology, two questions were asked, one about the participant’s overall perspective regarding VR and another about the inclination to participate in a VR group activity again. Each item was rated on a scale from 1=not at all to 5=very good/very much.

The VR group activities and the questionnaires were conducted in the nursing home, integrated as a daily event for the participants. This is the basis for ecological validity of the data.

Statistical Analysis Plan

Older adults with higher and lower acceptance of using a VR intervention were compared. Initially, the higher and lower acceptance groups were defined. Participants were categorized into four groups: (1) no interest in the VR intervention but willing to participate in the interview (lower VR acceptance), (2) dropped out due to motivational reasons (lower VR acceptance), (3) dropped out due to nonmotivational reasons, and (4) completed the VR intervention program and the postinterview (higher VR acceptance).

Participants who dropped out for nonmotivational reasons were excluded from the study. Categories 1 and 2 were allocated to the “lower VR acceptance” group, while category 4 represented the “higher VR acceptance” group.

Sociodemographic data, psychosocial capacities, and technological engagement of the older adults were collected from both groups to enable us to answer the research question and hypothesis 1. Additionally, data on technological engagement and attitudes toward VR technology and VR intervention as a group activity were collected from the posttests of the higher VR acceptance group to analyze changes in acceptance within this group to provide answers to hypotheses 2 and 3.

Data were analyzed with the statistical software SPSS (version 29; IBM Corp [49]). We conducted t tests and χ^2 tests for group comparisons of sociodemographic factors. Psychosocial capacities and technological engagement between the higher and lower VR acceptance group were analyzed with a two-tailed t test. We used a t test for paired samples to compare the degree of technological engagement within the higher acceptance group at baseline and post interview.

Ethical Considerations

This research was funded by the German Federal Ministry of Education and Research (BMBF), project number 16SV8561 VRalive. This research was approved by the ethics committee at Technische Universität Braunschweig (FV-2020 - 18). The study was preregistered in Deutsches Register Klinischer Studien on December 11, 2020. Informed consent, confidentiality, and data protection agreements were obtained from older adults or their legal guardian under the supervision of a caregiver. There was no compensation for participation. All activities conducted in the nursing home strictly adhered to the prevailing nursing home COVID-19 prevention and treatment policy. The VR goggles were diligently disinfected after each use.

Results

There were no statistically significant differences (all P values $>.05$) in sociodemographic characteristics between both groups (Table 2).

Concerning psychosocial capacities (Table 3), older adults with lower VR acceptance were more proactive and had more robust social relationships in comparison with the older adults in the higher acceptance group.

Table . Self-reported impairment in psychosocial capacities according to the Mini-ICF-APP scale (0=that is clearly a strength of mine, 7=I am not able at all).

	Higher virtual reality acceptance group (n=90)		Lower virtual reality acceptance group (n=23)		<i>t</i> test (<i>df</i>)	<i>P</i> value	Effect size (<i>d</i>)
	Rating, mean (SD)	Impaired, % (rating≥5)	Rating, mean (SD)	Impaired, % (rating≥5)

Flexibility and adaptability	2.40 (0.92)	2 (2.2)	2.35 (1.30)	1 (4.3)	0.18 (27.89)	.86	0.05
Competence and knowledge application	2.27 (1.23)	5 (5.6)	2.04 (1.33)	1 (4.3)	0.76 (111)	.45	0.18
Ability to make decisions and judgments	2.63 (1.19)	8 (8.9)	2.39 (0.89)	0 (0)	0.91 (111)	.37	0.21
Proactivity and spontaneous activities	2.43 (1.20)	5 (5.6)	1.78 (1.44)	1 (4.3)	2.22 (111)	.03	0.52
Resilience and perseverance	2.56 (1.11)	3 (3.3)	2.57 (1.56)	3 (13)	-0.03 (111)	.97	-0.01
Self-assertiveness	2.60 (1.07)	5 (5.6)	2.13 (1.14)	1 (4.3)	1.86 (111)	.07	0.43
Contact with others	2.44 (1.43)	9 (10)	2.39 (1.44)	2 (8.7)	0.16 (111)	.87	0.04
Group integration	2.68 (1.36)	9 (10)	2.65 (1.77)	2 (8.7)	0.06 (28.99)	.95	0.02
Dyadic relationships	2.62 (1.63)	13 (14.4)	1.61 (1.56)	1 (4.3)	2.69 (111)	.008	0.63
Self-care	3.27 (1.71)	19 (21.1)	3.78 (2.43)	11 (47.8)	-0.96 (27.84)	.35	-0.27
Mobility	2.47 (1.49)	7 (7.8)	2.17 (1.30)	1 (4.3)	0.86 (111)	.39	0.20
Average score	2.62 (0.77)	5 (5.6)	2.41 (0.89)	1 (4.3)	1.14 (111)	.26	0.27

Older adults with low VR acceptance experience more self-care impairments and report a conservative stance toward adopting new technology (Tables 3 and 4). In contrast, those with higher VR acceptance report being less active, with less meaningful social connections, but with higher self-care capacity and a more open attitude toward new technology (Tables 3 and 4). There is no statistically significant difference in engagement with televisions ($P=.62$) and laptops ($P=.25$) between higher and

lower acceptance groups (Table 4). In both groups, over 90% of participants use a television at least once per day. A contrast emerged in smartphone use, with 23.3% (21/90) of the higher acceptance group using it daily, while merely 4.3% (1/23) of the lower acceptance group do the same. These results support hypothesis 1, which postulated that the group exhibiting higher VR acceptance would report a higher level of technological engagement compared to the group with lower VR acceptance.

Table . Technological engagement of lower and higher VR^a acceptance groups at baseline.

	Higher VR acceptance (n=90)		Lower VR acceptance (n=23)		<i>t</i> test (<i>df</i>)	<i>P</i> value	Effect size (<i>d</i>)
	Rating, mean (SD)	Frequent use and high willingness, n (%) with rating \geq 4	Rating, mean (SD)	Frequent use and high willingness, n (%) with rating \geq 4			
Television ^b	4.46 (0.91)	84 (93.3)	4.35 (1.03)	21 (91.3)	0.49 (111)	.62	0.11
Smartphone ^b	1.91 (1.60)	21 (23.3)	1.17 (0.83)	1 (4.3)	3.04 (67.88)	.003	0.50
Laptop/PC ^b	1.68 (1.45)	16 (17.8)	1.35 (1.15)	2 (8.7)	1.16 (41.77)	.25	0.24
Other technologies ^c	3.31 (1.72)	50 (55.6)	1.70 (1.29)	3 (13)	4.97 (44.11)	<.001	0.98

^aVR: virtual reality.

^bParticipants answered the question “How often do you use [technology]?” (1=never, 5=several times per day).

^cParticipants answered the question “Do you want to try other new technologies?” (1=not at all, 5=very much).

After their participation in the VR intervention (Tables 5 and 6), older adults’ perspectives toward VR remained very positive and even increased, with many participants reporting looking forward to the next VR group event; therefore, hypothesis 2 (“After the VR group intervention, technological engagement

among older adults will either be maintained or improved”) and hypothesis 3 (“After the VR group intervention, the acceptance of VR technology and willingness to participate will both align at a high level”) were confirmed as well.

Table . Technological engagement before and after a virtual reality intervention among higher virtual reality acceptance group participants (n=90).

	Baseline		Posttest		<i>t</i> test (<i>df</i>)	<i>P</i> value	Effect size (<i>d</i>)

Discussion

Demographic Status

There were no differences in demographic status between the groups with higher and lower VR acceptance. This finding may seem to contradict previous research that suggested that factors such as age and education could predict the acceptance of new technology or VR [32,50]. The divergence in outcomes can be

explained by the homogeneous sample in our study [51]. The participants in our study were selected based on their care requirements, creating a convergence of demographic and life status. The data from this naturalistic explorative study suggest that demographic factors have no significant impact on older adults’ VR group event participation.

Psychosocial Capacities

Individuals within the lower acceptance group had a higher reported level of organizing daily activities and building dyadic relationships with trusted individuals. A potential reason for nonparticipation in VR activities among older adults in nursing homes is motivation-related. This supports the idea that new technology should align well with users' life statuses and requests [52]. Among older adults, the adoption of technology for health purposes often aims to compensate for deficiencies [53]. Older adults with robust relationships may be better integrated with others and can meet their need for meaningful activities in their daily lives. Additionally, their capacity to organize activities may contribute to their lower intrinsic motivation for new activities, leading to a reduced perception of VR usefulness and subsequently decreased acceptance. The Senior Technology Acceptance Model [50] states that older adults with strong social relationships believed in the utility of technologies and were more inclined to use them compared to older adults with weaker social networks. Moreover, a study involving 31 participants conducted semistructured interviews, indicating that socially well-integrated older adults may not perceive a necessity to use socially assistive augmented reality systems [54]. The VR intervention in our project is oriented toward meaningful activities and entertainment, which may be less attractive for those older adults who are already engaged in social relationships within the nursing home. Therefore, the target group of VR intervention could be older adults with a lack of proactivity. These results refine the target group for VR group interventions in nursing homes, that is, older adults who are less active and have limited meaningful social networks. This aligns with the core objective of our VR study—to offer meaningful activities that enhance the activity level, capacities, and overall well-being of less active older adults.

Technological Engagement and Attitude After VR Activities

Older adults with higher acceptance of VR technology also tend to demonstrate a stronger willingness to embrace new technological advancements. This indicates that, even in the context of VR as a group activity for older adults in nursing homes, an openness to new technology can be a predictor of higher acceptance.

Considering device usage, several factors warrant attention. First, television is already widely accepted throughout society, including among older adults in nursing homes [2]. Therefore, the acceptance of television was high in both groups.

Second, costs play a significant role [55]. Although the higher VR acceptance group showed greater engagement with smartphones, the actual usage rate remained minimal. One explanation may be that some older adults are facing financial constraints that hinder access to smartphones and PCs. Socioeconomic status is a factor that should not be neglected as a potential contributor to the acceptance of VR activities among older adults [32]. The Unified Theory of Acceptance and Use of Technology model by Venkatesh et al [56] expands on the TAM [30] by incorporating additional external factors such as social influence and facilitating conditions. Social influence refers to the extent to which an individual perceives

that people they are close with believe he or she should adopt or utilize the new system. Facilitating conditions are characterized by the individual's perception of the organizational and technical infrastructure available to support system usage. Social support is crucial in affording older adults the opportunity to access new technology and in facilitating their learning process, consequently bolstering their technological engagement [44,50]. If nursing homes could provide access to new technologies such as VR, this could potentially enhance technology engagement among older adults.

Third, the difference in engagement between laptops and smartphones may be attributed to perceptions of usability, ease of use, and cost considerations. Smartphones, with their convenient accessibility and added functionality (such as phone calls), are perceived as more useful among older adults in nursing homes. This aligns with one of the key concepts of the TAM: the perception of usefulness. Therefore, it is crucial to reiterate that to enhance the acceptance of VR group activities as meaningful experiences for nursing home residents, these activities should be tailored to meet the needs and preferences of older adults.

Furthermore, after the intervention, a positive attitude toward VR was evident in participants' responses. This aligns with the idea that users often experience contentment with new technology once they use it [44,45], as well as with the Senior Technology Acceptance Model framework [50]. This suggests that more older adults, even those with lower VR acceptance, should be encouraged to give VR a chance. Such efforts could be facilitated by trusted individuals such as long-term social workers within nursing homes.

Limitations, Potential Applications, and Future Research

There are several limitations to this study. First, there was a small group of older adults with lower technological acceptance. The unequal sample sizes of the two groups resulted from the naturalistic group formation. The problem with unequal group sizes in research studies is that this can introduce bias and affect the statistical validity of the results. Additionally, unequal group sizes may impact the power of statistical tests, potentially making it more challenging to detect true differences between groups if the sample sizes are not balanced.

Second, there could be selection bias during recruitment. The initial selection of older adults was done by the caregivers, and their choices could be influenced by their expectations about the older adults. Additionally, the older adults who chose to participate in the study already had a willingness to experience the VR activity. Therefore, the results may not represent the entire population of nursing home residents, particularly those who declined to participate. This limits the external validity of the study.

Third, the behavior and responses of the older adults could be influenced by the Hawthorne effect, leading individuals to alter their actions based on the perceived expectations of the researchers. Moreover, the older adults might have enjoyed talking to the interviewer and could have overrated their attitudes toward the VR activity.

Lastly, a methodologically robust randomized controlled trial should be conducted to make conclusions about intervention effects possible.

On the other hand, this study offers a perspective from the implementation of VR group activities in a real-life setting, thus boasting high ecological validity. It specifically focuses on the acceptance of defined VR applications for residents in nursing homes as meaningful activities. This enables a better understanding of the factors influencing attitudes toward VR group activities and provides an opportunity to address the needs of the target population.

This study provides several insights regarding future VR intervention acceptance among older adults in nursing homes and rehabilitation facilities. First, demographic status does not impact the acceptance of a VR group activity among older adults in nursing homes. Second, this study underscores the importance of targeting specific groups and acknowledging individual differences in characteristics and needs. This research suggests that the target population for VR group activities in nursing homes should be residents lacking proactive capacity and social relationships. Future studies should address the particular needs of this population. Moreover, the findings emphasize the need for enhanced social support to boost technological engagement

among older adults, thereby promoting greater acceptance of digital interventions to address their needs. This may involve nursing homes providing increased access to VR and other new technologies, or nursing staff fostering trust and offering encouragement to residents to participate in VR activities. Finally, future research in the domain of older adults' technology acceptance could specify capacities such as activities of daily living or focus on specific subgroups within nursing homes.

Conclusion

This study explored characteristics of older adults in nursing homes with varying levels of VR acceptance and their perceptions of VR after participation in a VR group activity. The study found no sociodemographic differences between older adults with higher or lower acceptance of VR activities; however, the findings suggest tailoring VR interventions to older adults who are less proactive. This is in line with the purpose of the VR group event in this study—to improve activity, psychosocial capacities, and well-being for inactive older adults in nursing homes. The data suggest that it can be fruitful to motivate older adults, including those with apparently lower technology acceptance, to use the opportunity to experience VR, potentially facilitated by the support of their trusted individuals.

Acknowledgments

We thank Carlotta Wilke, MSc, for her contributions to the intervention and data collection. This research was funded by the German Federal Ministry of Education and Research (BMBF), project number 16SV8561 VRalive.

Data Availability

The data were originally collected from 14 nursing homes. The data are available from the authors upon request.

Authors' Contributions

YL conducted the study in nursing homes with technical support from IS. YL collected and analyzed the data, prepared the tables, and wrote the manuscript. BM designed the research question, supervised the research process, and contributed to writing and revision of the manuscript.

Conflicts of Interest

IS is the cofounder of the company VirtuaLounge, which developed the virtual reality program used in this study. It is possible that the developed program will be used commercially in the future.

Abstract

Background: Telementoring studies found technical challenges in achieving accurate and stable annotations during live surgery using commercially available telestration software intraoperatively. To address the gap, a wireless handheld telestration device was developed to facilitate dynamic user interaction with live video streams.

Objective: This study aims to find the perceived usability, ergonomics, and educational value of a first-generation handheld wireless telestration platform.

Methods: A prototype was developed with four core hand-held functions: (1) free-hand annotation, (2) cursor navigation, (3) overlay and manipulation (rotation) of ghost (avatar) instrumentation, and (4) hand-held video feed navigation on a remote monitor. This device uses a proprietary augmented reality platform. Surgeons and trainees were invited to test the core functions of the platform by performing standardized tasks. Usability and ergonomics were evaluated with a validated system usability scale and a 5-point Likert scale survey, which also evaluated the perceived educational value of the device.

Results: In total, 10 people (9 surgeons and 1 senior resident; 5 male and 5 female) participated. Participants strongly agreed or agreed (SA/A) that it was easy to perform annotations (SA/A 9, 90% and neutral 0, 0%), video feed navigation (SA/A 8, 80% and neutral 1, 10%), and manipulation of ghost (avatar) instruments on the monitor (SA/A 6, 60% and neutral 3, 30%). Regarding ergonomics, 40% (4) of participants agreed or strongly agreed (neutral 4, 40%) that the device was physically comfortable to use and hold. These results are consistent with open-ended comments on the device's size and weight. The average system usability scale was 70 (SD 12.5; median 75, IQR 63-84) indicating an above average usability score. Participants responded favorably to the device's perceived educational value, particularly for postoperative coaching (agree 6, 60%, strongly agree 4, 40%).

Conclusions: This study presents the preliminary usability results of a novel first-generation telestration tool customized for use in surgical coaching. Favorable usability and perceived educational value were reported. Future iterations of the device should focus on incorporating user feedback and additional studies should be conducted to evaluate its effectiveness for improving surgical education. Ultimately, such tools can be incorporated into pedagogical models of surgical coaching to optimize feedback and training.

Introduction

Telementoring studies found technical challenges in achieving accurate and stable annotations using commercially available telestration software intraoperatively [1-3].

The first challenge is the dynamic nature of the video feed; there are frequent laparoscopic camera movements, field of view changes, and deformation of anatomic structures due to the mobilization and retraction of anatomical structures, and maneuvering of the camera [4,5].

Mitigation strategies during coaching activities included freezing the video and converting it to still images [6]. This is not practical for real-time intraoperative coaching by surgeons and greatly increases the time spent on the activity to stop and restart the session during annotation.

Previous usability studies that used telestration [6-8] used a trackpad, mouse, or touchscreen during annotation mode and found that the trackpad or mouse performed best in the delineation of structures, while the touch screen was superior in conveying directional information [7]. Further, 1 study compared the usability of similar telestration devices with conventional interfacing devices such as a computer and mouse, and a tablet and stylus [4]. With the advancement of technology in the gaming world, new virtual reality (VR) or augmented reality systems have emerged as viable solutions for the development of systems for telestration.

To address the educational gap in teaching minimally invasive procedures, a wireless handheld telestration device was developed to facilitate dynamic user interaction with live video streams. This study examines the usability of a first-generation handheld wireless telestration platform.

Continuing professional education activities such as surgical coaching provide opportunities for the continued acquisition of new techniques and professional expertise.

Telestration is a technique for teaching whereby instructors annotate images or videos to enhance the learning experience for surgical trainees [9]. This technique has shown promise for improving surgical skills more effectively than traditional verbal coaching across a broad range of metrics including faster task

completion, reduced coaching time, better surgical performance, and greater trainee confidence [7,10-12]. Previous telestration studies have highlighted the importance of mentor-mentee communication in surgical training [7,11,13].

In the setting of laparoscopic surgery, the learning curve for trainees tends to be greater as the surgical field cannot be directly visualized or palpated as in open surgeries and directly pointing at surgical display screens for teaching and coaching activity raises concerns of sterility. Instead, feedback and guidance are typically verbally described without the ability to make direct references, which may lead to greater trainee confusion, miscommunication, and ultimately reduced efficacy of the teaching process. This is especially relevant with the shift to minimally invasive surgeries, which provide numerous benefits to patients over open surgeries [14]. Given the benefits of telestration seen for trainees and the adoption of minimally invasive surgery for increasingly more complex procedures, it is critical to develop better tools to improve the acquisition of these skills.

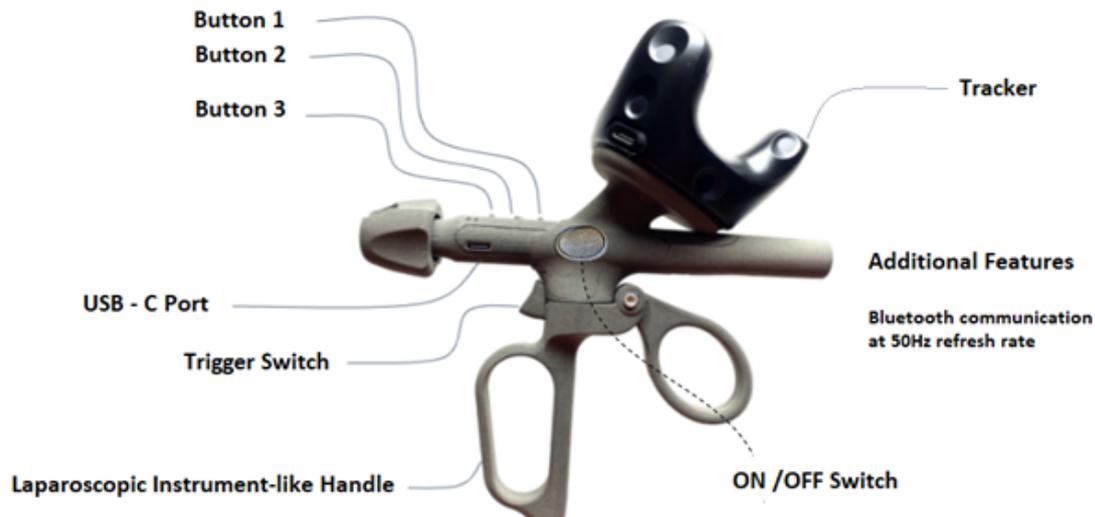

To augment the coaching experience, a wireless handheld telestration tool was developed to better address dynamic on-demand teaching requirements both intraoperatively during a procedure and postoperatively on a recorded surgical video. This study presents the usability results of a first-generation handheld wireless telestration platform.

Methods

Hardware Design

A wireless handheld telestration device prototype, hereon referred to as the pen, was designed and manufactured to enable the user (ie, surgeon coach) to interact with the surgical display field during coaching activities in both intraoperative and postoperative settings. This prototype uses a proprietary augmented reality platform.

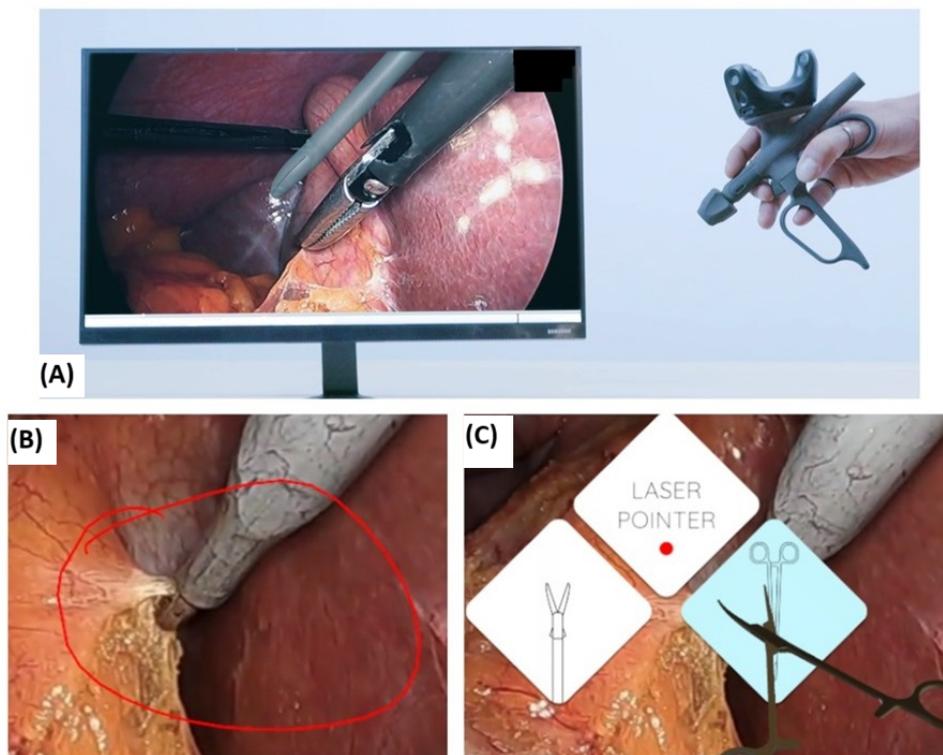

The pen (Figure 1) consists of two main parts: (1) a motion tracker mounted to (2) a 3D printed controller. The motion tracker and the controller have separate charging systems and on/off buttons. The controller has 3 buttons with various functions, a trigger, and a Maryland grasper handle to create a more realistic user experience. The pen weighs 152.76 g.

Figure 1. Telestration device.

Software Design

The four core functions of this video-based coaching platform are (1) free hand annotation, (2) cursor navigation, (3) overlay and manipulation of ghost (avatar) instruments, and (4) hand-held video feed navigation.

These functions may be completed on a live or recorded video feed. To achieve these core functions, the telestration software menu (Figure 2C) allows the user to choose from 3 interactive tools: a laser pointer for cursor navigation and annotation (Figure 2B), and 2 digital avatar instruments for dynamic coaching and positioning instructions: 1 for laparoscopy (designed to resemble a Maryland Grasper) and 1 for open surgery (designed to resemble a needle driver; Figure 2).

Figure 2. (A) Telestration device used for video-based coaching, (B) annotation feature demonstration, and (C) telestration software menu options.

System Platform Integration

The telestration platform integrates a legacy guidance and tracking system using: Vive (HTC Corp) and SteamVR (Valve Corp).

The tracker unit is mounted onto the telestration pen's hardware (Figure 1). The tracker has multiple diodes that detect the infrared signals emitted by the SteamVR lighthouse units. Lighthouse units are externally powered devices mounted at locations of high visibility around the physical space to detect and track the telestration device's movements by the user. The

number of lighthouse units is determined by the size of the room where the telestration pen is implemented. A total of 2 lighthouse units were placed 1.5 m apart to achieve optimal performance as per the manufacturer's instructions (Figure 3). The SteamVR system appears to designate 1 lighthouse as the primary source of data and another as a secondary source [15]. Figure 3 illustrates the room setup.

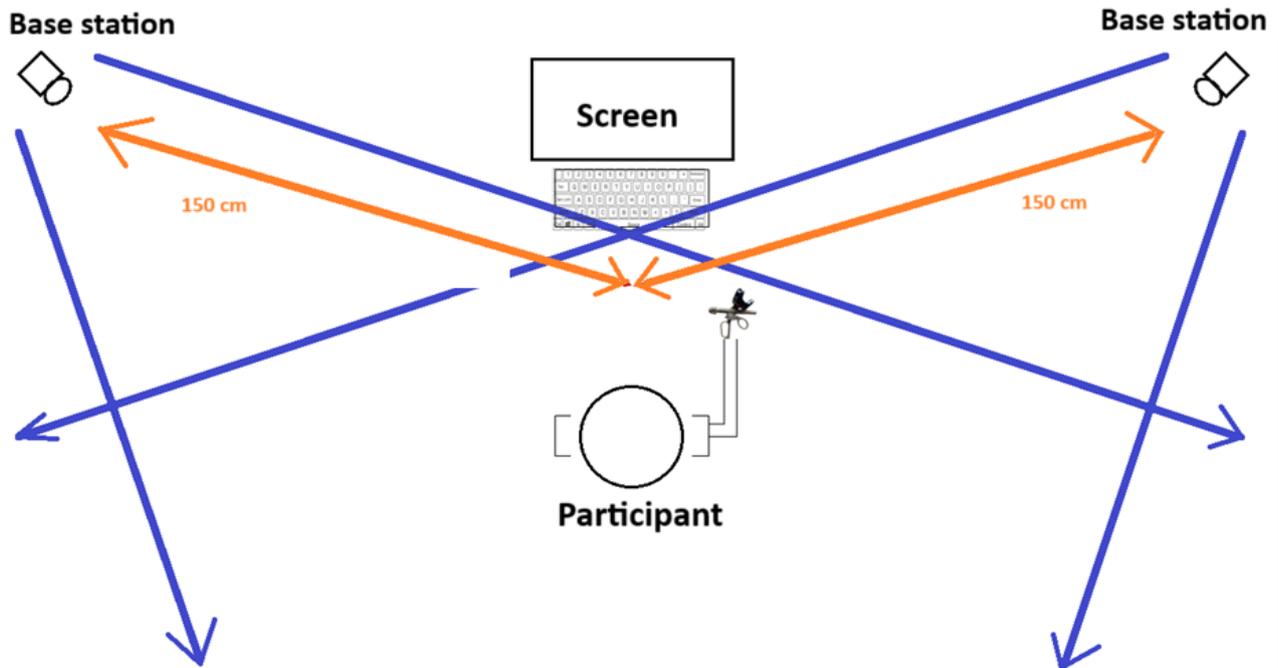

The orientation of the lighthouses per the object being tracked is crucial to the accuracy of the system. The tracking accuracy

is greatest with the pen positioned orthogonally to it. The maximum distance between the lighthouse and the tracker is the maximum distance to work effectively which is 7 m [15].

Therefore, for this study, a total of 2 lighthouse units were placed 1.5 m apart to achieve optimal performance as per the manufacturer's instructions (Figure 3).

The lighthouse units ("base stations") emit infrared light which is detected by diodes present on the tracker and this information is converted to positional data by SteamVR software.

Figure 3. Usability study room set-up.

Usability Study Design

The International Organization of Standardization defines usability as "the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use" [16]. Testing a device with end users is essential for a comprehensive evaluation of its usability. Therefore, the usability study was conducted in 3 phases (presurvey, usability testing, and post survey) and included an informal debrief at the end of the session.

Participants

All physicians who play a role in surgical education were allowed to participate. Participants were surgeons and surgical trainees recruited from a multi-site academic teaching hospital in Toronto, Ontario, Canada.

Data Collection

Phase 1 (Presurvey)

A short questionnaire was administered to gather baseline information regarding demographics and prior experience with VR and telestration technologies.

Phase 2 (Usability Testing)

The functional capability of the telestration device was designed by surgeon educators based on the needs they noted in real-world coaching situations. Scenarios were then prepared to evaluate the 4 core functions of the device in those situations. A study facilitator guided participants through the scenarios in a representative simulated environment. Examples of tasks include starting the device, menu selection, tool navigation and overlay, annotating and drawing, moving video playback or pause, and so on. A complete list of tasks is outlined in [Textbox 1](#).

Textbox 1. Tasks for telestration function assessment.

Standard tasks

- App launch and device calibration: participants were asked to start a preselected video displaying certain clips from a laparoscopic cholecystectomy.
- Play or pause video feed: participants were asked to play and pause the video at certain points throughout the session.

Video feed navigation

- Fast forward and rewind: participants were asked to fast forward and rewind the video to predetermined points of the video throughout the session.

Overlay and manipulation of ghost avatar instrument

- Menu-instrument selection: participants were asked to open the menu and select either the laser pointer or the grasper multiple times throughout the session.
- Rotate grasper tip: participants were asked to rotate the grasper tip.
- Open and close grasper tip: participants were asked to open and close the grasper tip.

Freehand annotation

- Annotation: participants were asked to open and close the grasper tip.
- Erase annotation: participants were asked to annotate where they would perform a dissection at a specific moment of a procedure and to circle the cystic duct.

Phase 3 (Postsurvey)

Participants completed the system usability scale (SUS) after testing was completed [17]. This scoring system compiles the responses from a series of 10 questions that cover topics including device complexity, ease of use, the learning curve required, and user confidence [18]. In addition to this, a questionnaire was developed by the researchers to gather the attitudes and opinions of the participants on usability, satisfaction, ergonomics, ease of task completion, confidence, and the perceived educational value of the device, using a 5-point Likert scale.

Procedure

Before the start, this study's room was set up as shown in [Figure 3](#), the VIVE tracker was calibrated to the room using SteamVR. A member of the research team was this study's facilitator. Participants began the session by completing the presurvey (phase 1). Next, the participants were asked to hold a device such as a laparoscopic grasper. The facilitator trained the participants on the functionality of the device and provided the participants with a quick tip sheet to reference during the usability test.

Participants were asked to select a video of a laparoscopic cholecystectomy that was provided for this study's purpose. Participants were then asked to calibrate the controller by following the instructions on the screen. Participants were first asked to use the telestration device while standing to emulate its use in an operating room, followed by a seated position for an office or boardroom setting. The facilitator guided the participant to complete tasks in [Textbox 1](#), testing the 4 core functions of the device in a standing position and ending the video on completion. Upon study completion, participants completed phase 3 of this study.

Outcomes

Outcomes measured in this study were perceived usability, ergonomics, overall satisfaction, and the perceived educational value of the telestration device.

Data Analysis

Descriptive statistics were used, and qualitative variables were reported as frequencies and percentages.

The results of the SUS were analyzed according to the scoring procedure documented by Brooke [17]. A product with a SUS score greater than 70 is considered to have above-average usability [18].

Ethical Considerations

Informed consent was taken before the start of this study. This study was approved by the University Health Network's (UHN) Research Ethics Board (22-5556; education research protocol dated September 14, 2022).

Results

Phase 1 Demographics

A total of 9 surgeons and 1 senior resident (n=10) participated (5 males and 5 females). The average age of participants was 36.4 (SD 6) years with a mean of 7 (SD 6.41) years of practice. All participants reported being right-handed. The majority of participants (7 out of 10, 70%) reported no previous telestration system experience. Only 1 participant reported having received training with a surgical VR system before this study. Most participants (5 out of 10, 50%) reported not using VR and gaming consoles in the last 12 months (3 out of 10, 30% monthly and 2 out of 10, 20% rarely).

About SUS

This study's average SUS was 70 (SD 12.5) with a median of 75 (IQR 63-84).

Overall Satisfaction

Participants were asked to rate their overall satisfaction using a 5-point Likert scale where 10% (1 out of 10) of participants were completely satisfied, 50% (5 out of 10) were very satisfied, 20% (2 out of 10) were moderately satisfied, and 20% (2 out of 10) slightly satisfied.

Ergonomics

When asked about the intuitiveness of the device, most participants strongly agreed or agreed (SA/A) that the device was intuitive (5 out of 10, 50%), 40% (4 out of 10) felt neutral, and 10% (1 out of 10) disagreed or strongly disagreed (D/SD). Ergonomics was further assessed by asking participants to respond specifically regarding the pen's physical comfort (4 out of 10, 40% SA/A; 4 out of 10, 40% neutral; and 2 out of 10, 20% D/SD), the weight of the pen (6 out of 10, 60% SA/A and 4 out of 10, 40% D/SD), and the ability to use the physical

features (buttons and trigger; 4 out of 10, 40% SA/A; 3 out of 10, 30% neutral; and 3 out of 10, 30% D/SD).

Participants were also asked if they preferred completing this study's tasks while in a seated or standing position. In total, 4 participants preferred to be seated, 3 preferred to be standing, and 3 had no preference at all. When asked about their confidence in completing the tasks correctly, 90% (9 out of 10) and 80% (8 out of 10) SA/A that they correctly completed the tasks seated and standing, respectively.

Open Ended Survey Responses

Participants were asked to discuss features of the pen and telestration system that they felt were design strengths as well as areas of improvement (Textbox 2). Of the 8 participants who responded, 3 participants reported the ability to annotate on the screen as a good feature of the device. Regarding areas for improvement, 6 participants indicated to have the location of the buttons moved.

Textbox 2. Open feedback responses from the participants regarding the virtual reality system.

What 3 things are good about the virtual reality system?

- Hands-on teaching, not invasive, and may be widely used.
- It allows you to draw on the image on the screen, it allows you to demonstrate the orientation of instruments, and it allows you to fast forward and rewind.
- Felt accurate in terms of location of the pointer, intuitive to use, and realistic feeling.
- Great response time, useful for annotation, and innovative.
- Teaching.
- Easy to use.
- Ability to annotate, erase, and select instruments.
- Relatively easy to use after a short guidance, it is cool, innovative, and less stressful.

What 3 things can be improved in the virtual reality system?

- Button placement, precision, and ergonomics.
- The actual instrument itself (the weight of it and location of buttons), the directionality of fast forward or rewind (to make it more intuitive), and the function of the hand holds.
- Location of buttons.
- Calibration of pen not in line with pen, instrument heavy, and hard to hold for small hands to reach the top buttons.
- Fulcrum on table.
- Calibration, weight, and function of finger loops.
- Ergonomics (handle is not needed), buttons are not easy to use, and tracking sensor drift.
- The [pen] is a little uncomfortable, the pen is heavy, and when sitting it is hard to see the animation for the Maryland.

Postsurvey Satisfaction Responses

Participants were asked to rate their level of agreement with statements on the standard tasks performed in this study (Table 1).

The majority of participants (6 out of 10, 60%) found the setup tasks (launching the video and device calibration) easy to

complete, while 30% (3 out of 10) of participants found it difficult and 10% (1 out of 10) felt neutral. On the other hand, 90% (9 out of 10) of participants agreed that fast-forwarding and rewinding, as well as annotating, were easy, and 100% (10 out of 10) of participants agreed that erasing annotations was easy.

Table 1. Ease of use in completing tasks testing the device's various functions.

Function	Agree or strongly agree, n (%)	Neutral, n (%)	Disagree or strongly disagree, n (%)
Standard tasks			
Difficulty completing initial setup: launch and calibration	3 (30)	1 (10)	6 (60)
Play or pause the video feed	8 (80)	2 (20)	0 (0)
Video feed navigation			
Fast forward and rewind	9 (90)	1 (10)	0 (0)
Overlay and manipulation of ghost instrument			
Menu-instrument selection	7 (70)	3 (30)	0 (0)
Rotate grasper tip	4 (40)	5 (50)	1 (10)
Open and close the grasper tip	7 (70)	2 (20)	1 (10)
Freehand annotation			
Annotation	9 (90)	0 (0)	1 (10)
Erase annotation	10 (100)	0 (0)	0 (0)

Confidence Levels (Pre- Versus Poststudy Comparison)

Overview

Participants were asked to rate their confidence in the system features at baseline and post study using a scale of 1 to 5, where 1 is not confident and 5 is very confident.

Set Up and Training

Participants were also asked to rate their level of confidence in their technical ability to independently set up a VR or gaming system in the post study. The majority of participants (6 out of 10, 60%) rated their confidence in system setup at a 4 out of 5, while 20% (2 out of 10) rated it a 5 out of 5, and another 20% (2 out of 10) rated it a 3 out of 5. In addition, the majority of participants felt that the system training completed by the facilitator was adequate (8 out of 10, 80%), with 20% (2 out of 10) of participants feeling the training period was too short. Lastly, the majority rated the quality of the training provided for study purposes as excellent 1 out of 10, 10%; very good 6 out of 10, 60%; and good 3 out of 10, 30%.

Navigation

The majority of participants reported a confidence rating of 4 at baseline for navigating accurately and realistically (confidence of 5: 1 out of 10, 10%; confidence of 4: 8 out of 10, 80%; confidence of 3: 1 out of 10, 10%), which then increased to a rating of 5 post study (confidence of 5: 5 out of 10, 50%; confidence of 4: 4 out of 10, 40%; and confidence of 3: 1 out of 10, 10%). No participant reported a confidence of 2 or less in either the pre or post study.

Instrument Overlay

The greatest positive change (40% increase) between pre and post study in confidence rating was present for the overlay of the digital tool. Confidence ratings for this category prestudy were (confidence of 5: 1 out of 10, 10%; confidence of 4: 4 out of 10, 40%; confidence of 3: 4 out of 10, 40%; confidence of 2: 0 out of 10, 0%; and confidence of 1: 1 out of 10, 10%), while

post study were (confidence of 5: 1 out of 10, 10%; confidence of 4: 8 out of 10, 80%; confidence of 3: 1 out of 10, 10%; confidence of 2: 0 out of 10, 0%; and confidence of 1: 0 out of 10, 0%).

Annotations

The confidence levels for performing annotations were highly rated for both pre- (confidence of 5: 2 out of 10, 20%; confidence of 4: 7 out of 10, 70%; and confidence of 3: 1 out of 10, 10%) and post study (confidence of 5: 4 out of 10, 40% and confidence of 4: 6 out of 10, 60%).

Video Feedback

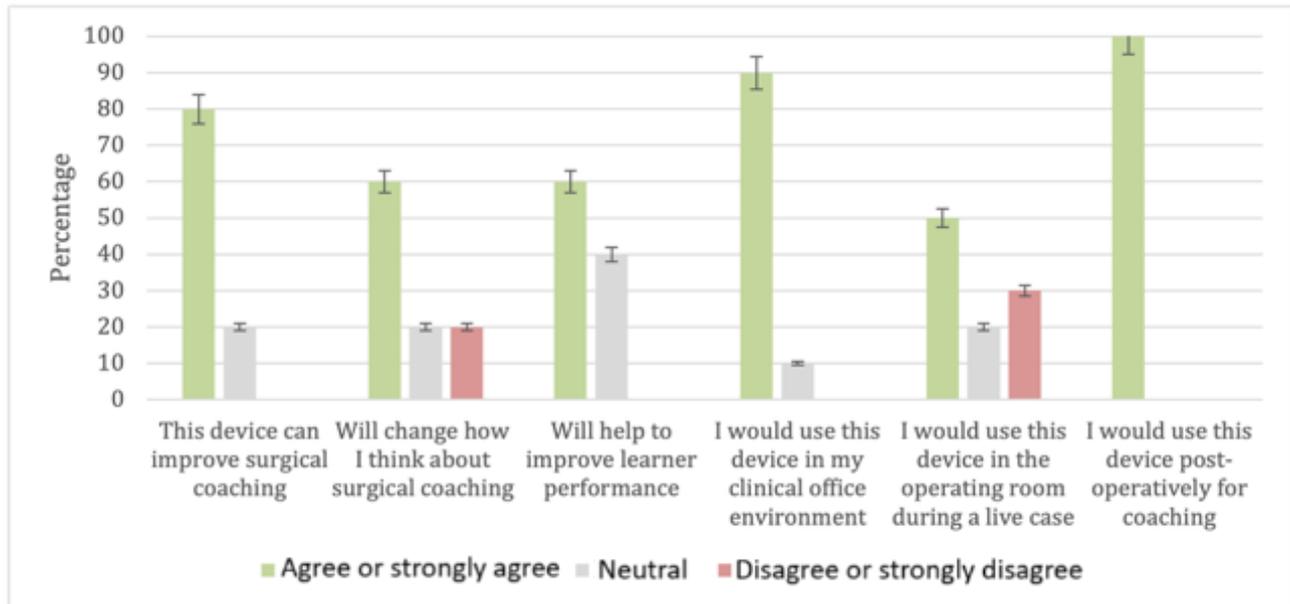

Regarding video feed playback or pause reviewing functions, confidence levels remained unchanged pre to post study (confidence of 5: 3 out of 10, 30%; confidence of 4: 6 out of 10, 60%; and confidence of 3: 1 out of 10, 10%).

Select and Change Tools

Lastly, while no participant felt very confident selecting or changing tools in the prestudy (confidence of 5: 0 out of 10, 0%; confidence of 4: 7 out of 10, 70%; and confidence of 3: 3 out of 10, 30%), 30% (3 out of 10) of participants rated that they felt very confident to select or change tools in the post study phase (confidence of 5: 3 out of 10, 30%; confidence of 4: 5 out of 10, 50%; and confidence of 3: 2 out of 10, 20%). When participants were also asked for their level of agreement about the ease of switching between digital tools, 70% (7 out of 10) of participants SA/A that it was easy to do and 30% (3 out of 10) of participants felt neutral about it.

Educational Value

Participants were asked to rate the perceived educational value of the device using a 5-point Likert agreement scale. All participants agreed that they would use this device for postoperative coaching, while only 50% (5 out of 10) of participants agreed that they would use the device in an intraoperative setting. Additional questions were asked regarding the use for educational purposes described in [Figure 4](#).

Figure 4. Participant agreement responses on perceived educational value.

Technical Difficulties

Lastly, participants were asked to report on technical difficulties experienced while participating in this study. While 40% (4 out of 10) of participants reported experiencing a delay or lag with the device positioning, only 10% (1 out of 10) of participants reported experiencing difficulties loading this study's video and 10% (1 out of 10) also noticed instructional text not displaying correctly. When participants were asked about the device's ability to track their hand movements accurately, 60% (6 out of 10) SA/A that it did and 40% (4 out of 10) of participants felt neutral about it.

Discussion

Principal Findings

A novel telestration device for surgical coaching was designed to enhance the surgeon coach and learner experience in the context of laparoscopic surgeries. This device enables a dynamic interaction with surgical display monitors with a free-hand annotation function and live overlay of 3D digital laparoscopic tool avatars.

Previously described devices and systems for telementoring had usability challenges that this device aims to mitigate. This study aimed to evaluate the overall satisfaction and usability of the first-generation prototype telestration device for use in surgical coaching activities. In terms of demographics, our study had an equal distribution of women and men, which strengthens the validity of our results.

The use of evaluation tools such as SUS during the development and testing process of user interface apps is commonly recommended in the literature [7,10]. The SUS reported an average score of 70 (SD 12.5) with a median score of 75 (IQR 63-84) indicating an above-average usability rating in comparison to thousands of other devices and systems [18]. Additionally, 60% (6 out of 10) of participants were either

completely or very satisfied with the device overall. This is an encouraging result of our first iteration prototype.

On the other hand, those who rated their overall satisfaction less than this, commented on the device's ergonomics, including the button placement, finger loops, and weight, as well as the device's precision and lagging experience. These comments on ergonomics are likely why participants had lower confidence in the post study to select or change tools compared to the other tasks. Additionally, while most users agreed that the device's weight was comfortable, only 40% (4 out of 10) felt the device's shape was physically comfortable to hold. Furthermore, 40% (4 out of 10) felt that the buttons were hard to reach; a theme that also emerged in the open feedback responses where 1 user commented "instrument ... hard to hold for small hands to reach the top buttons." Comments were also made about the usefulness of the handle piece. While confidence levels of completing study tasks accurately were similar in either position, participants did prefer using the device while sitting. The ergonomic feedback is in line with the SUS scores reported. With ergonomics being a priority for surgeons, future iterations of this device will aim at improving these scores.

With regards to task completion, including video stream controls (play or pause), annotation, and tool avatar manipulation, was generally very positive; the majority of them were considered "easy" to complete. All tasks were completed successfully with the provided training even though participants had never interacted with the device before this study. In addition, many of the participants did not experience any technical difficulties performing all the tasks—no major bugs were identified in this study. Only 40% of participants reported experiencing a lag during the usability testing period, and the time required to complete a task was comparable to that of this study's facilitator (trainer). Therefore, in future iterations of the device and software, addressing the lag experienced by users is of importance.

With regards to task completion, including video stream controls (play or pause), annotation, and tool avatar manipulation, was

generally very positive; the majority of them were considered “easy” to complete. All tasks were completed successfully with the provided training even though participants had never interacted with the device before this study. In addition, the majority of the participants did not experience any technical difficulties performing all of the tasks listed in [Textbox 1](#), as only 40% (4 out of 10) participants reported experiencing a lag during the usability testing period, and the time required to complete a task was comparable to that of this study’s facilitator (trainer). Therefore, in future iterations of the device and software, addressing the lag experienced by users is of importance.

Furthermore, participants found the majority of tasks easy to complete, most notably video manipulation (pause or play at 8 out of 10, 80% and fast-forward or rewind at 9 out of 10, 90%) and annotation (draw at 9 out of 10, 90% and erase at 10 out of 10, 100%). Overall, about task completion, this device demonstrates an acceptable level of usability; all tasks were completed successfully, and the majority of them were considered easy to complete.

In analyzing the open feedback responses, participants used language including “easy to use,” “great response time,” “accurate,” “intuitive,” and “realistic” to describe the device when allowed to provide open and anonymous feedback. This positive feedback is highly encouraging and highlights important themes relevant to usability including an acceptable level of complexity and realistic experience.

Lastly, participants evaluated the perceived educational value of the device with an overwhelming majority (8 out of 10, 80%) of users agreeing that this device can improve surgical coaching, especially in the postoperative setting (10 out of 10, 100%). However, only 50% (5 out of 10) of participants agreed that they would use the device live in an operating room, the main setting in which we intended this device to be used. Thus, participant hesitancy is an important goal of future usability assessments of the telestration device and perhaps would be better understood with testing in an operating room.

Study Limitations

While a sample size of 4 to 5 participants in usability studies is usually adequate in detecting 80% of system issues, a limitation

of our study was its smaller sample size [19]. Another limitation of our study was that the participants were asked about their thoughts on the usability of the device in different settings, specifically intraoperatively. As this study was conducted within an office setting and not within the operating room, it limits the applicability of the answers to being a preliminary thought rather than an actual observation in the asked-about scenario.

Future Considerations

Overall, the results of this first iteration study indicate our novel telestration device has a strong degree of usability, general user satisfaction, and potential concerning surgical skills coaching. Therefore, we have determined the prototype to have met a satisfactory threshold to merit further development and refinement.

Further improvements will focus on ergonomics with effort dedicated to making the device lighter and relocating the buttons to a more accessible location. Based on participant input, future iterations should also investigate either adding functionality to the device’s handle or potentially removing it altogether. This would address the majority of constructive criticisms from users. From the software perspective, improvements of priority include refinements in the software to allow for a more simplified app launch and calibration as this was the main task of difficulty for our participants.

Future studies should evaluate the educational value of the device in the operating room setting and further evaluate its effectiveness in enhancing the surgeon coach and trainee experience.

Conclusion

In conclusion, preliminary usability testing of a prototype telestration device for surgical coaching has demonstrated above-average usability and positive feedback regarding the perceived educational value and task completion. Future improvements should focus on ergonomics and design, namely weight and button location, as well as app launch and calibration. The next steps following usability testing can include the assessment of the educational value of the telestration device.

Acknowledgments

This work was funded by the UHN Foundation. The UHN Foundation and Haply Robotics Inc were not involved in this study’s design; in the collection, analysis, and interpretation of data; in the writing of this paper; and in the decision to submit this paper for publication.

Conflicts of Interest

The development of the telestration platform was provided through a collaborative research agreement between Haply Robotics Inc and the coinvestigators AO and AM. The development work provided by Haply Robotics Inc consisted of the hardware development of the telestration tool prototype and the control software and user interface development.

Abstract

Background: Malaria impacts nearly 250 million individuals annually. Specifically, Uganda has one of the highest burdens, with 13 million cases and nearly 20,000 deaths. Controlling the spread of malaria relies on vector surveillance, a system where collected mosquitos are analyzed for vector species' density in rural areas to plan interventions accordingly. However, this relies on trained entomologists known as vector control officers (VCOs) who identify species via microscopy. The global shortage of entomologists and this time-intensive process cause significant reporting delays. VectorCam is a low-cost artificial intelligence-based tool that identifies a mosquito's species, sex, and abdomen status with a picture and sends these results electronically from surveillance sites to decision makers, thereby deskillling the process to village health teams (VHTs).

Objective: This study evaluates the usability of the VectorCam system among VHTs by assessing its efficiency, effectiveness, and satisfaction.

Methods: The VectorCam system has imaging hardware and a phone app designed to identify mosquito species. Two users are needed: (1) an imager to capture images of mosquitos using the app and (2) a loader to load and unload mosquitos from the hardware. Critical success tasks for both roles were identified, which VCOs used to train and certify VHTs. In the first testing phase (phase 1), a VCO and a VHT were paired to assume the role of an imager or a loader. Afterward, they swapped. In phase 2, two VHTs were paired, mimicking real use. The time taken to image each mosquito, critical errors, and System Usability Scale (SUS) scores were recorded for each participant.

Results: Overall, 14 male and 6 female VHT members aged 20 to 70 years were recruited, of which 12 (60%) participants had smartphone use experience. The average throughput values for phases 1 and 2 for the imager were 70 (SD 30.3) seconds and 56.1 (SD 22.9) seconds per mosquito, respectively, indicating a decrease in the length of time for imaging a tray of mosquitos. The loader's average throughput values for phases 1 and 2 were 50.0 and 55.7 seconds per mosquito, respectively, indicating a slight increase in time. In terms of effectiveness, the imager had 8% (6/80) critical errors and the loader had 13% (10/80) critical errors in phase 1. In phase 2, the imager (for VHT pairs) had 14% (11/80) critical errors and the loader (for VHT pairs) had 12% (19/160) critical errors. The average SUS score of the system was 70.25, indicating positive usability. A Kruskal-Wallis analysis demonstrated no significant difference in SUS (*H* value) scores between genders or users with and without smartphone use experience.

Conclusions: VectorCam is a usable system for deskillling the in-field identification of mosquito specimens in rural Uganda. Upcoming design updates will address the concerns of users and observers.

Introduction

Background

Malaria infects an estimated 249 million individuals annually, causing >600,000 deaths worldwide [1]. The global incidence of malaria has increased since the COVID-19 pandemic, with 13 million more cases and 63,000 more deaths [2]. According to the World Health Organization, regions in Sub-Saharan Africa are particularly susceptible to malarial infection, accounting for >95% of global malaria cases and deaths; children aged <5 years account for nearly 80% of malaria deaths in the region [3]. Specifically, Uganda has one of the highest global burdens of malaria cases, costing the country US \$500 million annually [4]. In 2021, the World Health Organization estimated that there were 13 million malaria cases and nearly 20,000 malaria deaths in Uganda [4].

Currently, efforts to eliminate malaria rely on monitoring vector species composition, abundance, distribution, and behavior across different transmission geographies. Vector control strategies, such as distributing long-lasting insecticidal nets and performing indoor residual spraying of insecticide in high transmission regions, have proven to be highly effective in preventing infection [5]. However, mosquito vectors vary in their biting patterns (some may bite outdoors more frequently, and others may bite indoors more frequently) and subsequently necessitate different vector control strategies. Therefore, the Ministries of Health and their National Malaria Control Programs in almost all African countries have emphasized the need for vector surveillance, a system that allows for the collection of vector species prevalence and density data to target vector control interventions and resource allocation decisions based on the mosquito's species-specific strategies [6]. Routine vector surveillance strategies begin with mosquito collection, where mosquito specimens are collected at sentinel sites using various vector collection methods, including Centers for Disease Control and Prevention light traps, pyrethrum spray catches, and human landing catches [7]. These specimens, collected daily, are then transported to a central laboratory. There, they are morphologically identified through microscopic examination by individuals highly trained in entomology and vector surveillance, known as vector control officers (VCOs), for their species, sex, and abdominal status. A subset of the specimens is then sent for molecular analysis through polymerase chain reactions (PCRs) and DNA sequencing when resources are available. This subset is treated as a gold standard for further confirmation and quality assurance of the species identified through vector surveillance [8]. Unfortunately, the global shortage of entomologists hinders large-scale surveillance efforts, especially in areas with a high burden of malaria, where vector surveillance is needed the most [9,10]. As a result, the sites where specimens are collected and analyzed are sparsely distributed across a target region and treated as a representation of the entire country. This causes inaccuracies in the

interventions deployed, which is further worsened given the time lag between the capturing of specimens and the reporting time of usable data for decision-making [11].

To address this unmet need arising from the global shortage of entomologists, our research group at the Johns Hopkins Center for Bioengineering Innovation and Design has developed VectorCam. VectorCam is a low-cost artificial intelligence (AI)-based tool that morphologically identifies a mosquito's species, sex, and abdomen status based on a simple photograph and concurrently uploads the summary data to a central electronic dashboard, thereby deskillifying the identification and reporting process. Such a tool helps share the efforts of trained entomologists with rural community health workers, termed village health teams (VHTs) in Uganda, thereby enabling the implementation of widespread vector surveillance programs and driving better-informed, data-driven malaria intervention decisions in a cost-effective manner.

The VectorCam System: An Overview

VectorCam enables the accurate morphological identification of mosquito species using 3 core components: specialized imaging hardware, a computer vision algorithm, and a mobile app. The hardware consists of a simple light box with a built-in 15x macro lens, paired with a basic smartphone and several mosquito trays, enabling the rapid identification of multiple mosquitos with high throughput. The VectorCam Android app is powered by an optimized version of a previously published computer vision algorithm from our laboratory, which can identify >39 species across multiple genera [12]. This adapted version of the algorithm, used in VectorCam, identifies major genera (*Anopheles*, *Culex*, *Aedes*, *Mansonia*, and nonmosquitos) and 4 different groups of species within the *Anopheles* genera of interest in Uganda (*Anopheles funestus* sl, *Anopheles gambiae* sl, *Anopheles stephensi*, and other *Anopheles* species), as *Anopheles* is the only malaria-carrying mosquito genera. This computationally efficient version can run locally on low-end Android phones without access to the internet, thereby allowing users to capture images of collected mosquito specimens and instantaneously obtain the classification. The app also consists of a workflow for data inputs from the user, including logistical information about the collection site, date, and other notes for data tracing. Finally, the user can capture an image of the mosquito specimen directly within the app. The algorithm then processes this image and provides the predicted species, sex, and abdominal status of the mosquito.

The imaging hardware and software user interface and user experience have been cocreated through a multiyear human-centered design approach involving inputs from >50 VHT members and VCOs from Uganda, Zambia, and Ghana. Multiple formative usability studies have been performed with nearly 40 VHTs and 10 VCOs in Uganda to finalize the hardware and app design, as well as essential performance criteria. This study serves as a summative usability assessment

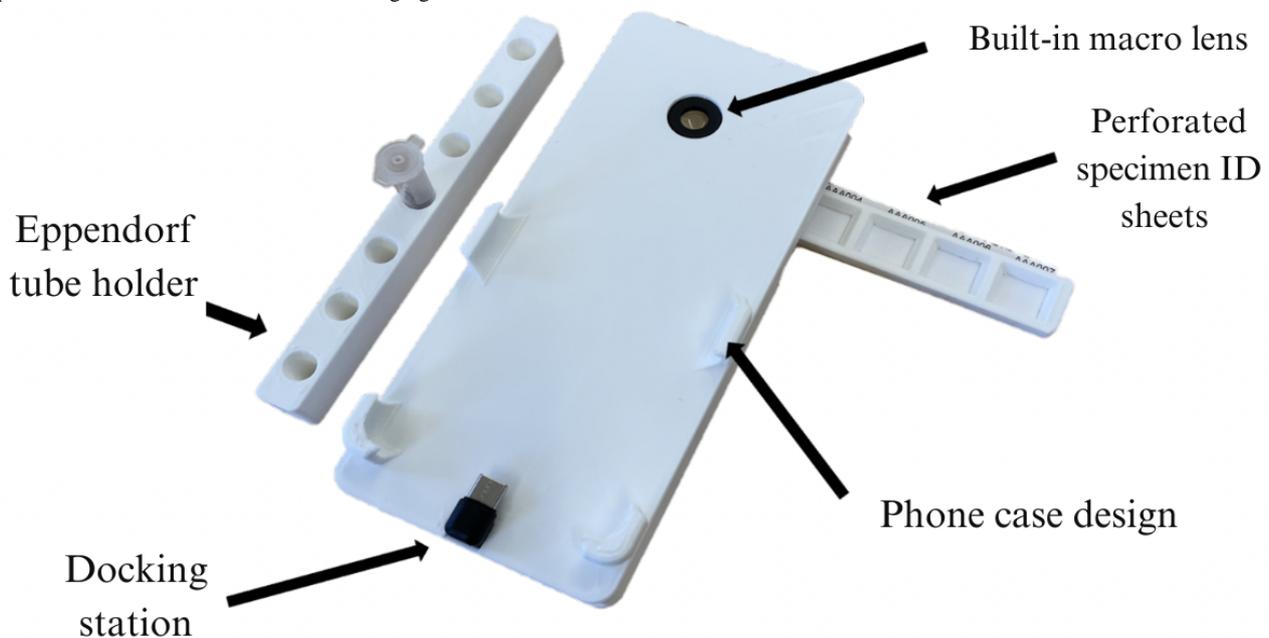

of a 2-person task-shifted vector identification strategy using the VectorCam app. This system was designed to fit easily into the current vector surveillance practices. For quality assurance purposes, careful consideration was taken to ensure that each mosquito was uniquely tagged for verification and molecular and PCR identification, as needed. The results of the study will inform future design iterations of the VectorCam system for field deployment in vector surveillance programs.

VectorCam Hardware and Software Details

VectorCam's hardware consists of a light box with a 15x macro lens attached to it. The top side of this light box comprises of a phone case, where the phone slides on, plugging into the docking charger at the bottom end of this light box (Figure 1). The charger is connected to circuitry on the interior of the box, which turns on the LEDs as soon as the phone is docked, allowing uniform lighting between each specimen. The phone's camera is then aligned with the 15x macro lens, allowing

uniform magnification. The box itself also has storage compartments for 2 mosquito trays on which mosquitos are placed for ease of imaging, as well as an associated Eppendorf tube holder to hold mosquitos with their unique tag after they have been identified on the app. Within the VectorCam workflow, each mosquito must not touch one another, as this can impact DNA contamination. Each mosquito tray has a slit where a disposable piece of paper can be inserted to limit any DNA contamination. Furthermore, these slits of paper have preprinted and perforated unique specimen ID tags attached for each well. Therefore, when storing these mosquitos for PCR identification, the user can simply tear off the specimen ID and place it as well as the corresponding mosquito specimen in an associated Eppendorf tube. The Eppendorf tube holder allows for ease of packing and labeling these mosquitos for subsequent molecular identification and maintaining its traceability to the identification generated by the VectorCam system.

Figure 1. The hardware components of the VectorCam system include the light box with a built-in 15x macro lens, a phone case design, and a docking station. Hardware also includes an Eppendorf tube holder and mosquito trays and perforated specimen ID sheets to adequately pack and store these mosquitos for molecular identification after imaging.

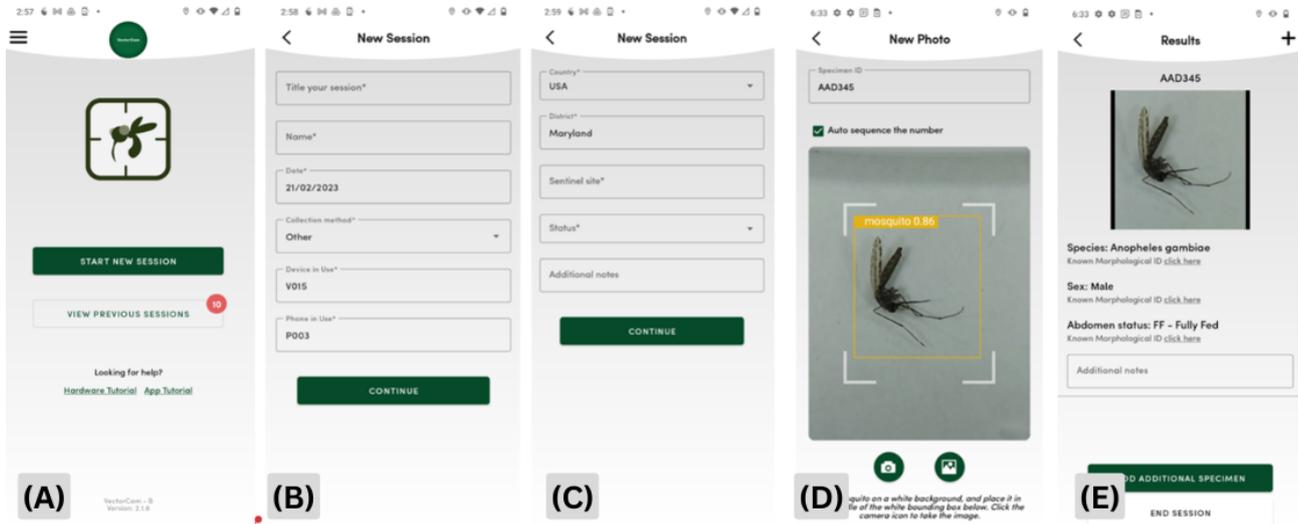

PCR identification will be facilitated after imaging the collected samples with VectorCam to grow the continued database of true labels of specimens. These true labels will be used to continually train the VectorCam computer vision algorithm, as it is still in development. In the ideal setting, a finalized VectorCam product will replace the need for PCRs. However, the specimen ID tear-off step will still be included in the workflow to allow for traceability and postimplementation verifications. Figure 1 shows how all these hardware components interact.

The app itself is hosted on a Motorola G Play (2021; Motorola, Inc) smartphone. The app consists of three primary processes:

(1) entering background information, (2) imaging mosquitos, and (3) submitting a session. Entering background information effectively stores all the information that entomologists usually write when generating reports for the Ministry of Health. This includes how these mosquitos were collected, the date they were collected, and the location where they were collected. Figure 2 shows details of each screen on the app. The goal of this summative usability study was to evaluate the usability of the VectorCam system among village health workers by assessing its efficiency, effectiveness, and satisfaction. We hypothesized that the VectorCam system will overall be usable with no significant differences between sex or users with and without smartphone use experience.

Figure 2. User interface screen sequences for entering background information and imaging mosquitos in order of appearance as the imager starts interacting with the app (from left to right). (A) The home screen of the VectorCam app allowing the imager to choose between starting the imaging session or viewing previous sessions already submitted in the app. (B) Under “entering background information,” the first screen allows users to enter the title of the session, the name of the user, the date of the imaging session, and information on the device and phone in use. (C) The second screen allows the user to input additional information, including country, district, and sentinel site of the current catch and imaging process as well as the status of the mosquito specimen (freshly collected specimens or desiccated). (D) The imaging screen for the imager to enter the specimen ID of the mosquito and image the mosquito using zooming and capture. (E) The results screen of the previous image of the specimen captured showing the species, sex, and abdomen status. This screen allows the imager to choose to add an additional specimen or end the imaging session.

Methods

VectorCam Device Workflow

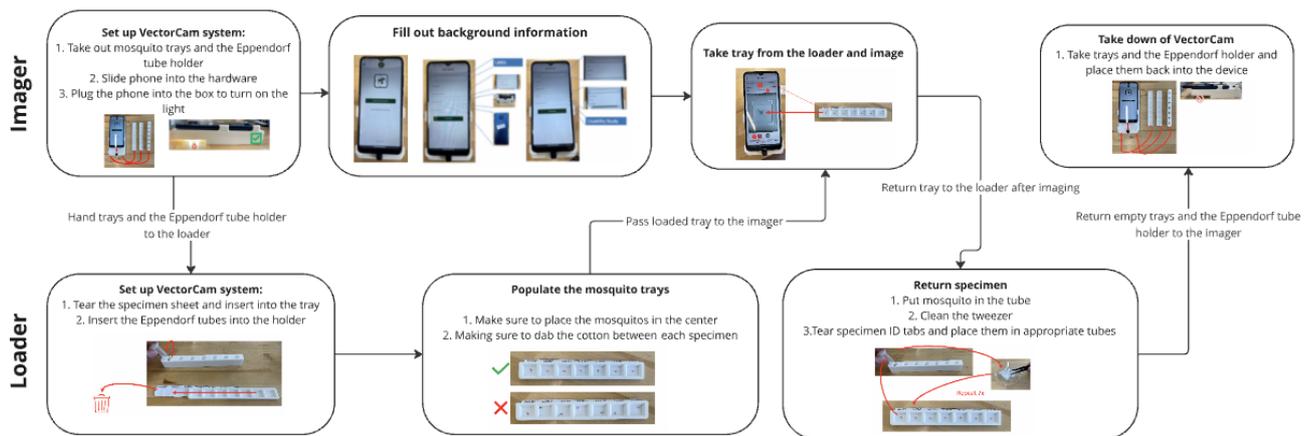

The VectorCam system involves placing collected mosquitos into the VectorCam hardware; capturing a magnified image of the mosquito using a smartphone-based mobile app for morphological identification; and storing the mosquito in an Eppendorf tube with a unique label for subsequent molecular verification, if needed.

The VectorCam system was designed to be operated by a group of 2 VHT members working in collaboration by sharing the critical pieces of the workflow, whereby one person (the loader) loads specimens and another (the imager) uses the app to capture images of the mosquitos. Having a 2-person team speeds up the morphological identification process of a large batch of mosquitos. The materials used in this process are presented in [Table 1](#), and a workflow summary of the VectorCam system is presented in [Figure 3](#).

Table 1. Materials needed to operate VectorCam in a 2-user system, their purpose in the workflow, and the role of the person using the equipment.

Equipment used	Purpose of the equipment	Person using the equipment
VectorCam light box	Contains a holder for the smartphone with the VectorCam app, 15x macro lens for magnification, and a phone-powered LED light source on the underside	Imager
Motorola G Play (2021; Motorola, Inc) smartphone	Contains the VectorCam app to enter relevant background information; capture images of multiple mosquitos per session; display corresponding species, sex, and abdominal status as identified by the algorithm; and submit sessions to the cloud-based server	Imager
Plastic mosquito trays	Contains designated wells to allow for the placement of several specimens in 1 tray and for rapidly imaging all the specimens loaded onto the tray	Both imager and loader
Eppendorf tube holder	Contains designated holes for placing 7 Eppendorf tubes to facilitate easy and rapid packing of each imaged specimen into respective Eppendorf tubes along with the corresponding specimen ID label	Loader
Sheet of specimen IDs	Perforated sheets with unique specimen IDs to allow for separation and placement into the mosquito trays. The labels can be removed and placed into specific Eppendorf tubes with their associated specimens	Loader
Petri dish with cotton	Contains cotton soaked in isopropyl alcohol for periodic cleansing of the tweezers handling the specimen	Loader
Tweezers	Used for handling the mosquito specimen during tasks in the workflow	Loader
Eppendorf tubes	Used to store the specimen after the imaging process is complete	Loader

Figure 3. The entire workflow of the use of VectorCam, including how the imager and loader roles work together in this process. The imager primarily interacts with the specialized imaging hardware, and the loader primarily interacts with the mosquito trays and Eppendorf tube holder.

Description of the Loader's Role

The loader has two primary responsibilities: (1) placing mosquitos onto the mosquito trays to streamline the imaging process and (2) storing already-imaged mosquitos in individually labeled Eppendorf tubes such that the mosquitos are uniquely tagged and can be sent to a laboratory for molecular identification via PCRs or sequencing. To properly place the mosquitos onto the VectorCam hardware, the loader takes the 2 mosquito trays provided in the hardware and slides the 8 inch (length) by 1 inch (width) specimen ID sheets inside the tray. Each of these sheets has a perforated tab that appears above the tray, displaying a specimen ID for each of the wells on the tray. This allows each mosquito on the tray to have a unique label. The loader then uses tweezers to add a singular mosquito to each well, decontaminating the tweezers with isopropyl alcohol-soaked cotton before handling each mosquito to prevent DNA cross-contamination. With this sterilization, the mosquitos can be sent for molecular identification via PCRs for quality control. Once the tray is filled, it is handed off to the imager.

Once the tray is imaged, the imager passes the mosquito tray back to the loader. At this point, the loader works to unload and store each mosquito and its associated specimen ID. The loader first adds a mosquito to an Eppendorf tube that can be held on the Eppendorf tube holder provided. This is done with tweezers that are sterilized with isopropyl alcohol between mosquito transfers to prevent DNA cross-contamination. Then, the specimen ID sheet is taken out, and each ID is torn off and placed in its corresponding Eppendorf tube along with the mosquito. This gives each mosquito a unique specimen ID when it is sent for molecular identification. Therefore, quality control can be established where the gold-standard assessment of each mosquito's species, sex, and abdominal status can also be received for further analysis.

Description of the Imager's Role

Once the imager receives the mosquito tray filled with specimens, they attach the phone to the light box, ensuring the LEDs are turned on, and then they go through the process of imaging the mosquitos on the app. This includes entering the background information, taking a photo of each specimen, zooming in to ensure that there is enough resolution in each

photograph, and finally saving the session for later uploading to our cloud-based server.

After the imager finishes imaging all mosquitos on VectorCam, they pass the tray back to the loader, who properly stores these mosquitos. Furthermore, once the entire process of imaging is finished for the day, the imager collects all mosquito trays and Eppendorf tube holders, undocks the phone, and places the materials inside the light box for storage.

Study Design: Materials and Methods

Participants and Location Selection

This summative usability study was conducted with 20 participants located in 2 malaria-endemic districts in Uganda: Mayuge and Adjumani. A sample size of 20 participants was determined using a study conducted by Faulkner [13] that collected empirical data from a sample of 60 individuals with varying levels of computer experience and varying levels of knowledge on the software used in the evaluation. In the study, a sample of 20 people was able to find a minimum of 95% and an average of 98% of the problems. Therefore, a sample population of 20 users was sufficient to encompass most of the usability problems with a device and design and a manageable number for our group to recruit, given the time constraints.

Participant recruitment criteria included those who (1) were aged between 18 and 65 years, (2) had existing status as a VHT member within Mayuge or Adjumani, and (3) had no previous experience using the VectorCam app or its previous iterations. Participants were not excluded based on prior experience with smartphone app use or with vector surveillance within their communities. Sites were selected with the support of the Ugandan Ministry of Health to ensure the heterogeneity of experience with vector control programs. At the time of the study, Mayuge had no established vector control program, while Adjumani had an established vector control program, according to the Ugandan Ministry of Health. Adjumani currently has a high burden of malaria prevalence in Uganda, as it is situated in an area of high, stable transmission of malaria [12].

Participants were recruited randomly from pools of existing VHT members in each district using the inclusion criteria described. The feedback received from the recruited VHTs

serves as a valuable resource for enhancing VectorCam's functionality and its potential impact on vector control efforts in rural Uganda.

Separating the Study Into Phases

During phase 1 of this study, 20 VHT members were paired with 1 VCO (out of a pool of 4 VCOs), and the VHT member was evaluated on the imager and loader roles in turns, with the VCO assuming the other role. This was done to limit any impact of another newly trained VHT member on the evaluation of outcome success criteria described in the *Outcomes* section. A total of 14 mosquitos were imaged or loaded during this evaluation. After 14 mosquitos were imaged, the VCO and VHT member switched roles so that the VHT member was evaluated for performance as both the loader and imager.

Phase 2 had 2 sets of trained VCOs imaging and 10 sets of paired VHT members imaging and loading a set of 28 mosquitos. After these 28 mosquitos were imaged, the 2 VCOs or VHT members swapped roles, allowing each participant to be evaluated in both roles. VCOs were evaluated using the same outcome measures as the VHT members, and this was done to benchmark their performance and compare it to that of the VHT pairs as a secondary analysis.

Ethical Considerations

This study was conducted with the approval of the Johns Hopkins University Institutional Review Board (00259683) and The Aid Support Organization Research Ethics Committee approval (2022-91) from the Makerere University School of Public Health. All participants were deidentified within the data. Each participant was compensated 10,000 Ugandan Shillings for their successful completion of their portion of the study.

Outcomes

The primary outcome of interest was the usability of the VectorCam system (device and app). This was assessed using efficiency, effectiveness, and satisfaction measurements. Each

outcome of interest was observed and recorded by an observer in real time.

Effectiveness

The effectiveness of the use of the VectorCam system was defined by the error rates caused by the failure of critical tasks of the use of VectorCam by the VHT members. For instance, phase 1 had 4 critical tasks for the imager and loader (imager: setup, imaging—entering background information, imaging—taking pictures, and takedown; loader: setup 1, setup 2, takedown 1, and takedown 2) and phase 2 had 8 critical tasks for the loader (setup 1 to 4 and takedown 1 to 4) and 4 critical tasks for the imager (setup, imaging—entering background information, imaging—taking pictures, and takedown). To calculate the error rates, the total number of failures on these critical tasks was recorded (each task had a binary pass or fail) and summed up. This was then divided by the total number of critical tasks. To evaluate this on a participant pool basis, the number of critical tasks was summed across participants and then divided by the total number of critical tasks across participants as well.

To identify these critical tasks and subtasks, each of the authors did a cognitive walk-through of the VectorCam system workflow, asking 2 key questions for each step: “Will the user know what to do at this step?” and “Will the user know that s/he did the right thing?” [14]. After a collective discussion, a comprehensive list of all the critical tasks as well as the subtasks in each of these critical tasks was finalized. The critical tasks included (1) hardware setup, (2) populating regional background information into the app, (3) imaging of the specimens, and (4) takedown of the hardware. A success criterion was then determined for each task, and a binary pass or fail metric was established. Any failure of the success criteria contributed to the total failure of the larger critical task and the error rate. [Table 2](#) includes lists of the subtasks performed by both the imager and loader and their success criteria during each of the 4 critical tasks.

Table 2. From the cognitive walk-through analysis performed by the authors of this paper, different subtasks for the process of using VectorCam for both the imager and loader roles were identified. Corresponding success criteria for both the imager's and loader's subtasks were identified during the setup of VectorCam. The subtasks and success criteria were identified for each main task of VectorCam: setup of the system, entering background information, taking pictures, and the takedown of the device.

Main task, role, and subtasks	Success criteria
Setup of VectorCam	
Imager	
Take out mosquito trays 1 and 2 and the Eppendorf tube holder and pass them to person 2.	All mosquito trays and tubes are taken out.
Slide the phone into the 3D-printed hardware.	The phone is slid into the 3D-printed box.
Place the phone into the box.	The phone is plugged into the box, and LEDs light up.
Loader	
Write specimen IDs on a sheet of paper.	All and accurate specimen IDs are written on the paper.
Place the paper in the mosquito tray and Eppendorf tubes in the tube holder and puncture the Eppendorf tube.	Paper is placed in the mosquito tray, and tubes are in the Eppendorf tube holder. Eppendorf tubes are properly punctured.
Populate the mosquito tray with 7 mosquitos (1 in each box).	All 7 mosquitos are populated into the tray.
Imaging process: entering background information	
Imager	
Create a new session on the VectorCam app and enter all the background information.	A new session is created on the VectorCam app with the correct background information and title of the session.
Enter specimen ID and click "auto-populate," if sequential.	Specimen ID is entered as stated on the mosquito tray sheet.
Loader	
Ensure mosquitos are in the center of mosquito tray 1.	All mosquitos are centered in each well in mosquito tray 1.
Pass mosquito tray 1 to the imager.	Mosquito tray 1 is passed to the imager.
Imaging process: taking pictures	
Imager	
Pinch zoom on the mosquito (pinch diagonally across the screen).	Once the mosquito is in the camera screen, it is pinch zoomed such that the entire mosquito is in frame.
Take an image by clicking the camera icon and select analyze.	The camera icon is selected, and the analyze option is selected.
Add an additional specimen and move the mosquito tray.	An additional specimen is added, and the previous specimen is not overwritten.
Once 7 mosquitos have been imaged, pass mosquito tray 1 to the loader and take mosquito tray 2 from the loader.	The mosquito tray is passed to the loader.
Add an additional specimen and place mosquito tray 2 under the camera so that the mosquito is seen.	An additional specimen from location 1 is added.
Loader	
Place the paper in mosquito tray 2.	The paper is placed in the mosquito tray, with specimen IDs visible.
Populate mosquito tray 2 with 7 mosquitos.	Mosquito tray 2 is populated with 7 mosquitos from the Eppendorf tube holder.
Ensure mosquitos are in the center of mosquito tray 2.	All mosquitos are centered in each well in mosquito tray 2.
Pass mosquito tray 2 to the imager.	Mosquito tray 2 is passed to the imager.
Move each mosquito from tray 1 to the respective Eppendorf tube. Place the specimen ID into the tube.	All mosquitos are moved from tray 2 to the correct Eppendorf tube with the correct specimen ID.
Replace the paper in mosquito tray 1 with a new sheet with the next specimen ID.	A new sheet of paper is placed in mosquito tray 1 with the correct specimen ID.
Takedown of the device	
Imager	
Click "submit session" and either upload the session or save the session to upload later.	"Submit session" is selected, and the session is uploaded.

Main task, role, and subtasks	Success criteria
Unplug the phone from the device and turn off the phone.	The phone is unplugged and turned off.
Place trays and the Eppendorf tube holder in the VectorCam hardware.	All trays and the tube holder are placed into the VectorCam hardware.
Loader	
Move each mosquito from tray 2 to the respective Eppendorf tube. Place the specimen ID into the tube.	All mosquitos are moved from tray 2 to the correct Eppendorf tube with the correct specimen ID.
Remove any remaining paper from all mosquito trays.	All pieces of paper are removed from mosquito trays.
Hand mosquito trays and the Eppendorf tube holder to the imager.	Trays and the Eppendorf tube holder are handed back to the imager.

Next, to determine potential user errors in VectorCam's workflow tasks, we performed a heuristic analysis to inspect the VectorCam's interface and identify initial usability problems using the 10 usability heuristics proposed by Nielsen and Molich [15,16], which are listed in [Textbox 1](#). Each of the 4 authors judged the product interface separately and created a unique list

of usability problems based on the usability heuristics, thereby generating a comprehensive list of user errors. After a collective discussion, a list of user errors was finalized for each subtask. These potential errors, in addition to additional errors found with VHT members during this usability study, were used to further inform future iterations of VectorCam, if needed.

Textbox 1. The 10 usability heuristics proposed by Nielsen and Molich [15,16] were used to analyze the VectorCam system's user interface to determine possible user errors and inefficiencies for future design considerations and changes.

1. Visibility of system status
2. Match between the system and the real world
3. User control and freedom
4. Consistency and standards
5. Error prevention
6. Recognitions rather than recall
7. Flexibility and efficiency of use
8. Aesthetic and minimalistic design
9. Help users recognize, diagnose, and recover from errors
10. Help and documentation

Efficiency: Phase 1

Efficiency in phase 1 was defined by how much time in minutes it took for each VHT member to both image and load 14 mosquitos while paired with a VCO doing the other role. Therefore, each VHT member performed one role with the VCO and then switched so that they were also evaluated in the other role. During phase 1, the VCO was included to limit any variation in the results due to the impact of being paired with another newly trained participant.

Efficiency: Phase 2

Comparatively, in phase 2, a "real-world" implementation of VectorCam was tested, where 2 newly trained VHTs were paired together to image a total of 28 mosquitos, switching positions afterward so that they can both be evaluated in both the loader and imager roles. Evaluators studied efficiency by timing how long the VHT member took to load or image the 28 mosquitos,

depending on their role. Therefore, in phase 2, the impact of being paired with another newly trained participant was studied. The total length of time in minutes was measured, and the average length of time to image each mosquito was calculated.

Concurrently, 2 pairs of trained VCOs worked in the 2-person system as an imager and a loader to image 28 mosquitos in 4 trays each to benchmark the performance of the VHT pairs. Because these VCOs were trained on the system for multiple months, comparing the VCOs' average length of time to load or image each mosquito with that of the VHT pairs illustrated the impact of long-term training and exposure to VectorCam on efficiency.

Satisfaction

Satisfaction was defined using the System Usability Scale (SUS), a robust and validated criterion used to measure end-user usability of the product [17]. The items constituting the SUS score are listed in [Textbox 2](#).

Textbox 2. The System Usability Scale was administered to each participant. Each item was answered on a scale of 1 (strongly disagree) to 5 (strongly agree). Items 2, 4, 6, 8, and 10 are those for which a lower numerical score is desired, and items 1, 3, 5, 7, and 9 are those for which a higher numerical score is desired. Each of these items was asked verbally by a translator.

1. I think that I would like to use this system frequently.
2. I found the system unnecessarily complex.
3. I thought the system was easy to use.
4. I think that I would need the support of a technical person to be able to use this system.
5. I found the various functions in this system were well-integrated.
6. I thought there was too much inconsistency in the system.
7. I would imagine that most people would learn to use this system very quickly.
8. I found the system very cumbersome to use.
9. I felt very confident using the system.
10. I needed to learn a lot of things before I could get going with this system.

The generated score (out of 100) from the SUS was used to evaluate user satisfaction. Because the SUS score can be similarly structured to that of a 100-point academic scale, 90 to 100 points was an A, 80 to 89 points was a B, and so on, with the standard average score being 68 [15]. A score >68 was passed for a positive usability assessment, and a score >80 indicated excellent usability. To further understand the functionality of the devices and the rationale for the scores given, open-ended interviews with participants were also conducted.

Secondary outcomes of interest included the following: (1) the impact of age and previous smartphone use on satisfaction and (2) the thematic clustering of voiced barriers to usability from open-ended interviews following the completion of study procedures.

Study Execution Procedures: Materials and Methods

Overview

Study instructions and a user ID were verbally provided to each participant. After finishing the evaluation stage of this procedure, SUS and demographic questionnaires were administered verbally to local interpreters.

The study was conducted in five segments, namely (1) initial training and certification; (2) phase 1: initial testing with a VCO partner; (3) phase 2: testing in VHT pairs; (4) SUS and demographic questionnaires; and (5) planned statistical analysis.

Initial Training and Certification

All VHT members recruited were onboarded with a standardized training protocol (Multimedia Appendix 1) delivered by expert VCOs familiar with the VectorCam hardware, software, and vector surveillance workflow. VCOs trained VHT pairs to use the VectorCam hardware and software. During the training protocol, any questions asked by participants were addressed as part of the initial training session. After initial training was completed, the VCO trainers formally assessed the ability of VHT participants to use the VectorCam system in the roles of an imager and a loader. A standardized certification checklist was used to determine whether each member of the VHT pair could independently use the VectorCam system. A detailed list

of certification criteria is presented in Multimedia Appendix 2. If a participant did not meet certification requirements, VCO trainers clarified and corrected errors before another attempt at certification was undertaken. The participants were then brought to the study session 24 hours after training certification to allow for sufficient natural decay of memory.

Phases 1 and 2: Evaluating Performance

Throughout the study sessions in both phases, an observer focused on either the imager or the loader by noting the time taken to image each tray of mosquitos, the number of errors in critical tasks in the workflow, and any observational artifacts worth noting about usability. In phase 1, one observer focused on the VHT member in the VHT and VCO pair, evaluating them in both the loader and imager roles. In phase 2, two observers were placed per pair, with 1 observer matched with 1 VHT member (so that the observer could evaluate 1 VHT member in both the imager or loader roles).

SUS and Demographic Questionnaires

The SUS was administered once to each participant in the study after the completion of both the roles, an imager and a loader. Each participant was administered this orally, with the question and the scoring scale being described. Their answers were then recorded, along with any qualitative feedback they had with each answer.

In this usability study, a variety of ages, genders, and technological savviness were encompassed in the participant population. A total of 8 participants were chosen for the study from Mayuge and 12 from Adjumani. Each participant completed an orally administered questionnaire, which collected data on their age, gender, experience using a smartphone, experience with vector surveillance processes, and the length of time served as a VHT member. Besides the question on the number of years of VHT experience, all other questions were answered using a standard yes or no format for ease of standardization. This questionnaire is presented in Multimedia Appendix 3.

Planned Statistical Analysis

A Kruskal-Wallis 1-way analysis ($\alpha=.05$) was performed to test for differences in SUS scores based on (1) the gender of the participant and (2) the participant’s experience with a smartphone. This test was selected as it would prove to be more stable in case of any outliers in the samples.

After using VectorCam, each participant was questioned individually by both a translator and the study designers (authors BG, SD, and KKM). There was no time limit set for answering questions, and all users were also able to provide qualitative comments at the end of the survey.

Results

Participant Demographics

Of the 20 participants, 14 (70%) were male and 6 (30%) were female, with a mean age of 36 (SD 9.8) years. A total of 8 (40%) participants were aged 30 to 40 years, 6 (30%) participants were aged 20 to 30 years, 4 (20%) participants were aged 40 to 50 years, and only 2 (10%) participants were aged >50 years. A total of 12 (60%) participants had experience using a smartphone, and 4 (20%) participants had experience with vector control strategies (notably, all these participants were from Adjumani).

Phase 1: Partner With VCO

Efficiency

Efficiency was defined as the time taken (in seconds) to image 14 mosquitos in phase 1. During phase 1 of the study, where each VHT member was paired with a trained VCO, each VHT member both imaged and loaded 14 mosquitos while in their 2 different roles. The average time spent imaging per mosquito for 20 VHT members was 70 (SD 30.3) seconds, and the average time spent loading per mosquito was 50 (SD 12.4) seconds.

Effectiveness

Effectiveness was analyzed based on the failure rates demonstrated by the VHT members when using VectorCam, which were categorized as a failure in the critical tasks outlined for the imager and the loader. During phase 1, for VHT members, there was an 8% (6/80 critical errors) error rate for the imager and a 13% (10/80 critical errors) error rate for the loader. The most frequently failed tasks for the imager and the loader were during imaging: entering the background information and setting up trays (3/20, 15% and 8/40, 20%, respectively). A larger breakdown of the error rates of both the imager and loader is provided in Tables 3 and 4, respectively.

Table 3. Effectiveness and error rates and number of errors for each critical task for the imager role in both phases 1 and 2, including the error rates for vector control officers (VCOs) in phase 2. Overall, 20 village health teams were evaluated in each phase, and 4 VCOs were evaluated in phase 2.

Imager	Setup, n (%)	Imaging		Takedown, n (%)
		Entering background information, n (%)	Taking pictures, n (%)	
Phase 1 (n=20)	0 (0)	3 (15)	2 (10)	1 (5)
Phase 2 (n=20)	0 (0)	3 (15)	5 (25)	3 (15)
VCO phase 2 (n=4)	0 (0)	1 (25)	1 (25)	0 (0)

Table 4. Effectiveness and error rates and number of errors for each critical task for the loader role in both phases 1 and 2, including the error rates for vector control officers (VCOs) in phase 2. Overall, 20 village health teams were evaluated in each phase, and 4 VCOs were evaluated in phase 2.

Loader	Setup 1, n (%)	Setup 2, n (%)	Setup 3, n (%)	Setup 4, n (%)	Takedown 1, n (%)	Takedown 2, n (%)	Takedown 3, n (%)	Takedown 4, n (%)
Phase 1 (n=20)	3 (15)	5 (25)	— ^a	—	1 (5)	1 (5)	—	—
Phase 2 (n=20)	7 (35)	3 (15)	3 (15)	2 (10)	2 (10)	1 (5)	0 (0)	1 (5)
VCO phase 2 (n=4)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)

^aNot applicable.

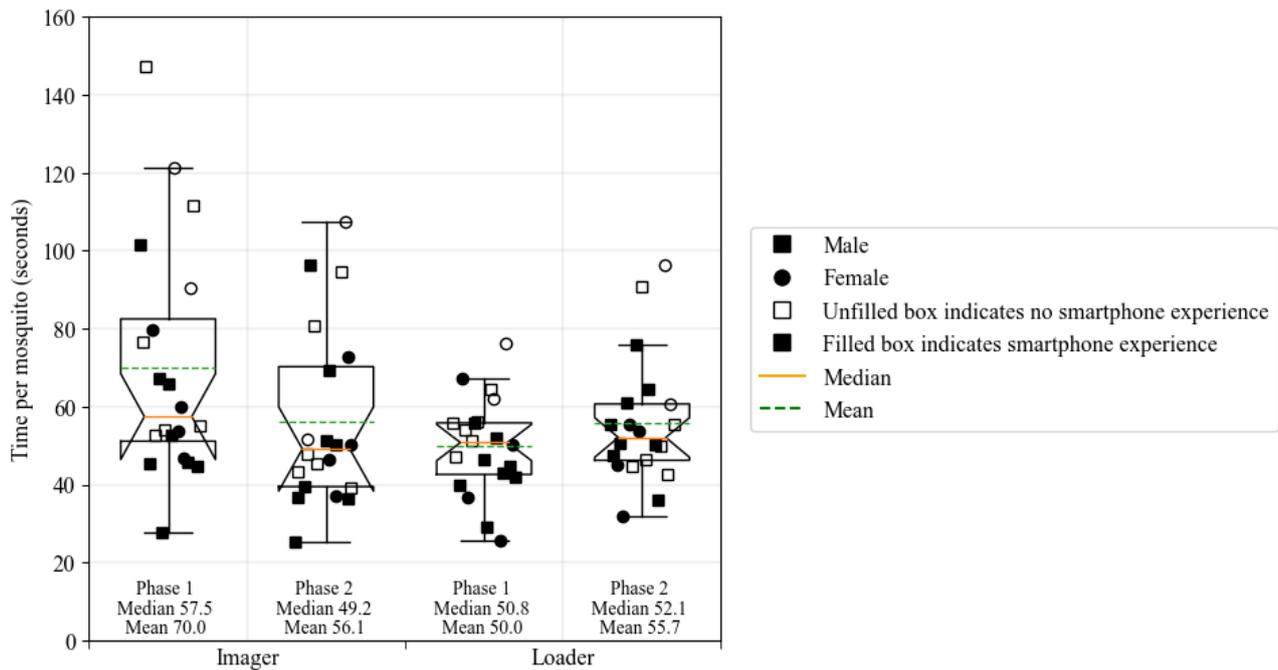

Phase 2: Two VHT Participants Working Independently

Efficiency

During phase 2, a total of 48 mosquitos were imaged by the VHT member in the imager role, and the average time spent imaging per mosquito was 56.1 (SD 22.9) seconds for the VHT

members. The average time spent loading per mosquito was 55.7 (SD 16.3) seconds. When phase 2 was performed by 4 VCOs with much higher training and previous smartphone experience, they were able to accomplish a throughput of 22.4 (SD 4.0) seconds per mosquito. The box-and-whisker plots for the 2 phases of efficiency and both roles are consolidated in Figure 4.

Figure 4. The box-and-whisker plots for efficiency metric in both phases and roles. The first 2 plots show the efficiency plots for the imager role in phase 1 and phase 2, respectively. Both the median and the mean time per mosquito decreased from phase 1 to phase 2. The third and fourth plots are the efficiency plots for the loader role in phase 1 and phase 2, respectively. Conversely, for the imager role, both the median and mean time per mosquito increased from phase 1 to phase 2.

Effectiveness

During phase 2, there was a 14% (11/80 critical errors) error rate for the imager (for VHT pairs) and a 12% (19/160 critical errors) error rate for the loader (for VHT pairs). The most frequently failed task for the imager was imaging: taking pictures. The specific subtask that was the most erroneous was the zooming in of the specimen. For the loader, the most frequently failed task was during the setting up of trays (most notably, on the first tray, as seen in Table 4), with the most erroneous subtasks being the puncturing of the Eppendorf tubes and the transfer of the mosquito specimen to the tray. When phase 2 was performed by the 4 VCOs, the total failure rates for the imager role and loader role were 13% (2/16 critical errors) and 0% (0/32 critical errors), respectively, with “imaging: taking pictures” being the most frequently failed task for the imager role. It is important to acknowledge the smaller sample

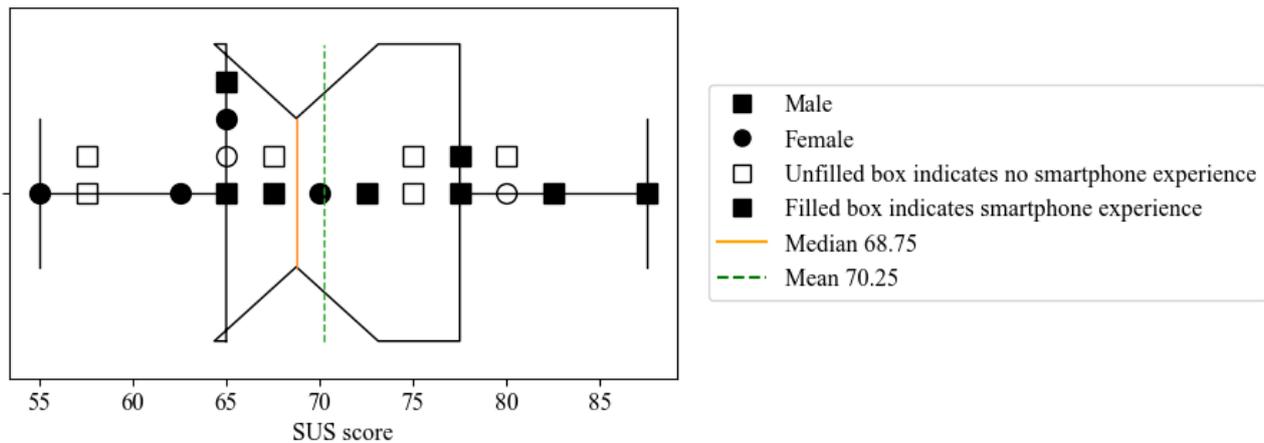

size of VCOs during this evaluation, and for a one-to-one comparison with VHT pairs, a larger sample size must be obtained.

A larger breakdown of the error rates of both the imager and loader is provided in Tables 3 and 4, respectively.

Comfort

At the end of the training and validation period, the SUS score and respective background information were collected. On average, the SUS score reported by participants was 70.25 (SD 8.99). The average scores across all positive and negative items were 4.48 (SD 0.72) and 2.86 (SD 0.71), respectively. The box-and-whisker plot for the distribution of the SUS scores is presented in Figure 5. The item that serves as a statistical outlier is item 10 (“I needed to learn a lot of things before I could get going with this system”).

Figure 5. System Usability Scale (SUS) score of study participants. Each participant is stratified by sex as well as experience with a smartphone. The mean SUS score was 70.25 (SD 8.99) for all participants. Using a Kruskal-Wallis test, it was revealed that there was no significant difference in SUS scores based on smartphone experience or gender ($\alpha=.05$).

An analysis of the satisfaction of the usability of the device was performed by looking at the difference in SUS rankings for the positive items versus the negative items in the SUS

questionnaire. Figures 6 and 7 show the distribution and percentages of each SUS ranking stratified by the positive or negative categorization of the items.

Figure 6. The distribution of the System Usability Scale (SUS) scores for each of the positive usability questions asked in the poststudy interview of the participants. The figure demonstrates that most users answered with a score of 4 or 5 (agree or strongly agree, respectively) for each question, as seen by the higher percentages.

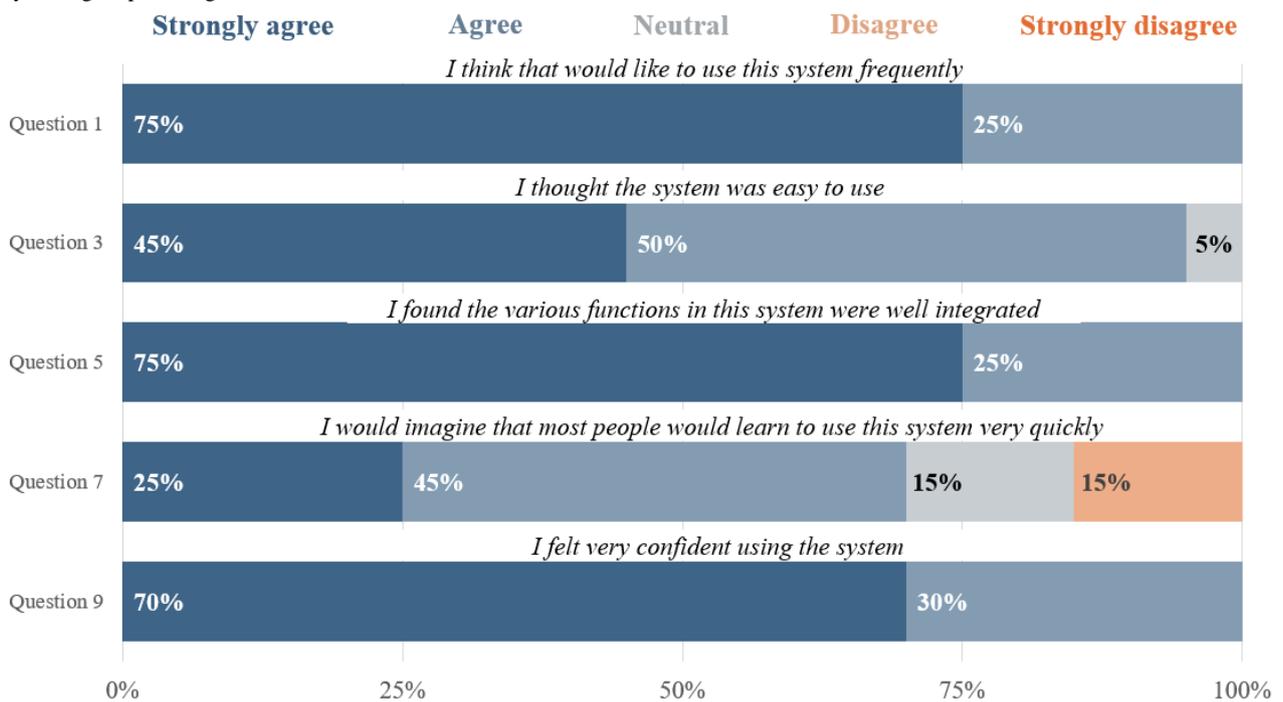

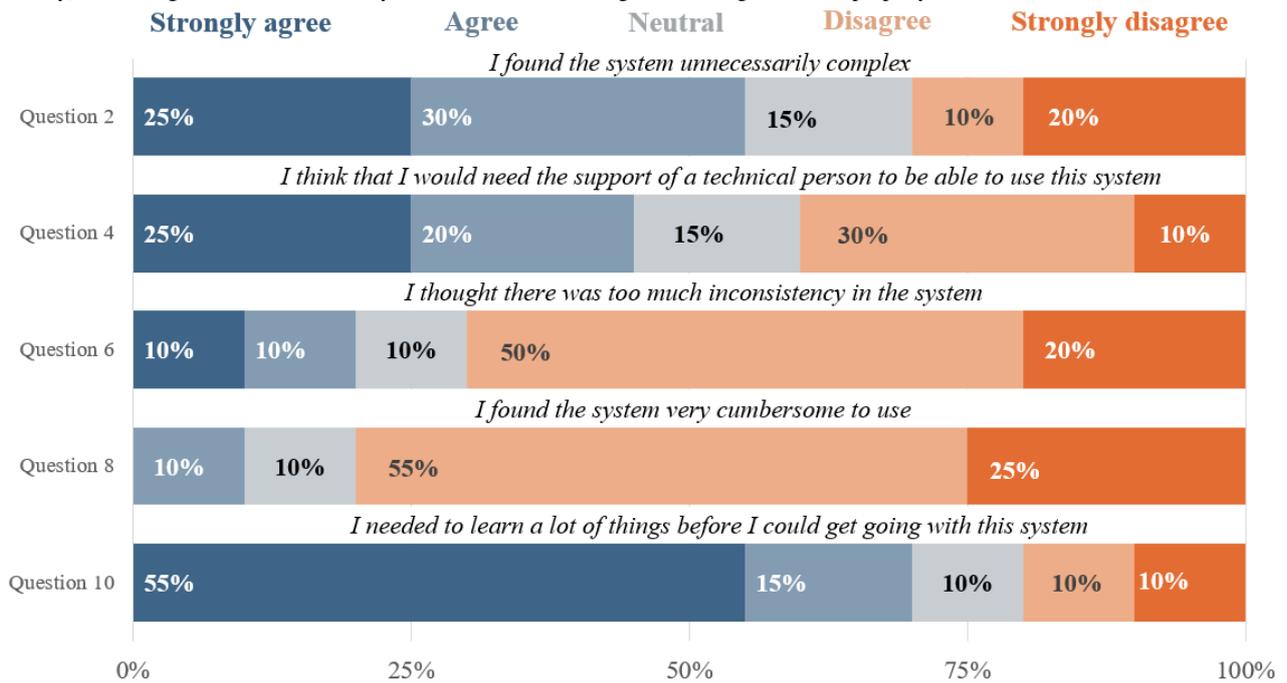

Figure 7. The distribution of the System Usability Scale (SUS) scores for each of the negative usability questions asked in the poststudy interview of the participants. The figure demonstrates that most users answered with a score of 1 or 2 (strongly disagree or disagree, respectively) for each question, as seen by the higher percentages. However, the last question demonstrates the opposite, with most users answering with 4 or 5 (agree or strongly agree, respectively), indicating that users felt that they needed extensive training before using the device properly.

Secondary Results

Kruskal-Wallis Results of the Effects of Gender and Smartphone Experience on Satisfaction

The results of this usability study furthermore revealed that the SUS scores did not exhibit significant differences between the participants across Adjumani and Mayuge (N=20) based on gender or prior experience with smartphones. Using a Kruskal-Wallis test with a significance level of α at .05, there

was no statistically significant variance in SUS scores based on gender or prior experience with smartphones (H value=0.006).

Thematic Clustering of Participants’ Qualitative Feedback

Themes from the postsession interviews were gathered from the feedback given by users about certain qualms of the workflow or interactions in the device. **Textbox 3** highlights the main themes of the concerns voiced by the users, along with participant quotes.

Textbox 3. Themes from qualitative comments provided by participants after administering the System Usability Scale. All participants are anonymized and are therefore listed as U1 to U20. Quotes were translated into English for the purposes of this research.

- Need for better training to adequately develop skills needed to use VectorCam
 - “The information from the trainer needs to be clear, or there should be something we can use to know we know we are doing [the imaging process] well.” [U15]
- Difficulty handling the specimens with tweezers
 - “It is hard to center the specimens [on the mosquito tray tables] because they break as you use [the tweezers].” [U13]
 - “The biggest challenge was the tweezers being hard to use.” [U15]
 - “Putting specimen in tubes was difficult to do with forceps.” [U20]
- Difficulty and confusion when attributing a specimen ID to each mosquito
 - “The Specimen ID is very confusing, and I do not understand how the numbers increment.” [U9]
 - “The numbers are very confusing; it is confusing to have both letters and numbers [in the specimen ID].” [U18]
 - “The names of [the mosquitos] are hard to remember.” [U20]
- Lack of understanding of the impact of the data being recorded and hesitancy in using VectorCam without knowing this impact
 - “I’m not sure where the data goes in general.” [U18]
 - “I want to know where the data is being sent to.” [U14]

Discussion

Principal Findings

This study is the first summative field usability assessment of VectorCam, an AI-based tool that automatically detects a mosquito's species, sex, and abdomen status, thereby deskilling the identification process. This tool has been designed and manufactured with multiple iterations of input from field users, VCOs, and engineers to be low cost and usable in rural regions in Africa. The results of this study demonstrated that the VectorCam system is overall generally usable in terms of its effectiveness, efficiency, and satisfaction among 20 VHTs in 2 districts in Uganda. A Kruskal-Wallis statistical test revealed that there is no significant difference in usability between sex and end users with and without smartphone user experience.

This study had inherent limitations that shaped the scope and interpretation of its findings. Due to a lower sample size and this study being underpowered, we are unable to confidently claim statistically significant differences in accuracy and throughput based on smartphone use. Furthermore, this study was conducted in an acute short-term setting, where VHT members had limited exposure to the VectorCam device and app (on the magnitude of 6 to 8 hours) before being evaluated on their use of the system. Comparatively, in a programmatic implementation of VectorCam, each VHT member would have multiday exposure to the device before using it independently. Prior usability studies involving medical or field technologies with users who have had long-term training on the device or previous experience with similar products demonstrated higher accuracy in using the device in terms of lower error rates and higher efficiency [18]. A notable example was seen in the lower error rates of medical professionals using a pulse oximeter with a new design [18]. Therefore, results on the accuracy as well as throughput using the VectorCam system may be skewed and could perhaps be improved given a longer training period.

The usability of the platform should also be reassessed following long-term use to further study its efficacy, satisfaction, and accuracy. Comparing the results of phase 1 with phase 2 of this study, the time taken to image each mosquito decreased by an average of 13 seconds per mosquito, as the participants had increased exposure to the device. Comparatively, the time taken by VCOs to image a mosquito was nearly half of that taken by the VHT members, showing that with more training and exposure to using the device, throughput could further increase. As shown in a study evaluating case studies of accessible digital technology for education in a low- and middle-income country setting, the programmatic implementation of tools over a longer period with good transfer and retention of knowledge on how to use them had more success in implementation compared with short-term training and evaluation [19]. Notably, the time taken to identify mosquito vectors using VectorCam was still a considerable improvement over prior methods of vector surveillance, which take a few days, and the time taken to image a mosquito using VectorCam (60 seconds) matched our success criteria [20].

To further improve this throughput, key design changes can be made. The 2 critical steps that took the longest time for the

imager were entering the background information on the app as well as entering the specimen ID per mosquito. This study was conducted using an app with English as the primary written language. While English is the national language of Uganda, local dialects vary heavily between regions; therefore, the app would benefit from pictographic or video-based prompts rather than written ones for generalized use or use outside of urban settings. A subgroup analysis for literacy in English was not conducted but would be important to include in further studies.

Furthermore, the outcome measures were captured by a researcher observing the participants and recording the outcome measures manually in real time. Therefore, it is possible that critical errors were missed, and efficiency times may not be as precise as they would have been if they were coded post hoc using video recordings of each participant.

The error rates of the VHT members tested in the imager and loader roles reveal that VectorCam's usability issues need to be addressed with revisions to the software and hardware. An important aspect to consider during the analysis of these rates is the training protocol provided to the VHT members by the VCOs, as mentioned previously. Because of the acute nature of the training and testing of these users, longer exposure and use of the VectorCam system will demonstrate the extent of these failed tasks and the possible reduction of high error rates. This hypothesis can be observed by the 4% (2/48 critical errors) error rate of the tested VCOs compared with the 13% (30/240 critical errors) error rate of the VHT members during phase 2. With this information, we can speculate that with longer training, the error rate would further decrease.

The task with the highest failure rate for the imager was taking pictures on the app. The subtask within taking pictures that was most prone to error was the zooming in of the specimen during the imaging process, which was omitted or not performed thoroughly by the imagers in some cases. To address these design inefficiencies, some design recommendations include a built-in auto-zoom feature that prevents the need for the user to zoom into the specimen in addition to adding a user profile to prevent typing of the background information. The specimen ID can also be automated, as mentioned previously, through an optical character recognition feature. These key design changes would create improvements in both types of error rates noted, as well as increase the throughput by putting less burden on the user to enter these metrics.

For the loader role, the task with the highest failure rate for both phases was the setting up of the mosquito trays. The researchers observed that the transfer of the mosquito specimen to the tray and puncturing of the Eppendorf tube were the subtasks prone to error in this task. Therefore, some hardware design revisions were proposed, such as a sliding edge to eliminate the use of tweezers for transferring mosquito specimens. Another design idea is a clasping apparatus with a sharp edge attached to the Eppendorf tube holder to automatically puncture the standing tubes with a single closing motion. This could prevent any accidental punctures to the skin, which is a potential hazard with the current process using tweezers.

Conclusions

Vector surveillance and entomological classification are the cornerstones of malaria prevention. Through this study, it has been demonstrated that VectorCam, an AI-based tool for task-shift vector surveillance, can effectively empower VHTs to conduct vector surveillance. This study has illustrated VectorCam's usability and accessibility, showing its potential to task-shift the time-consuming and resource-intensive process of vector identification to VHTs embedded in malaria prevention strategies within their communities. Modifications to the hardware and software solutions that are currently in progress

are needed to ensure optimal usability and are the current focus of ongoing efforts by our research group. Furthermore, from September 2023 to August 2024, our team is conducting a randomized controlled trial of VectorCam to evaluate the long-term use of VectorCam in the hands of VHTs over a 12-month period. Nevertheless, VectorCam serves as a promising technology that can transcend barriers in traditional vector surveillance through task-shifting malaria prevention efforts, creating a new 21st century approach to community-based malaria vector surveillance in rural Africa and beyond.

Acknowledgments

This study was supported by a grant from the Innovative Vector Control Consortium (IVCC). Additional support was provided by the Makerere University School of Public Health and the Johns Hopkins Center for Bioengineering Innovation and Design (CBID). The authors would like to thank the support of the vector control officers Kigongo Siriman, David Onanyang, Jovan Batte, and James Kaweesa in executing this study. The authors extend additional acknowledgments to the National Malaria Control Division (NMCD) within the Ministry of Health in Uganda for aid in identification of target districts used in the study.

Conflicts of Interest

None declared.

Multimedia Appendix 1

The VectorCam training protocol script that each vector control officer had to follow as they trained each village health team (VHT) member in the use of VectorCam. This involves an introductory script, where all parts of VectorCam are explained. Afterward, this describes the protocol that must be followed to train each VHT member in the imager and loader roles. Before completing the usability test, they must be able to perform these steps once alone, with no errors.

[PDF File (Adobe PDF File), 85 KB - [humanfactors_v11i1e56605_app1.pdf](#)]

Multimedia Appendix 2

This checklist details the steps that the village health team (VHT) members needed to perform to demonstrate their ability to complete critical tasks independently, for both the imager and the loader roles. Only when each of these tasks were checked off by a vector control officer, the VHT members were able to participate in the usability study. This was done to ensure that all VHT members were trained to a standardized level.

Abstract

Background: The use of mobile tools in nursing care is indispensable. Given the importance of nurses' acceptance of these tools in delivering effective care, this issue requires greater attention.

Objective: This study aims to design the Mobile Health Tool Acceptance Scale for Nurses based on the Expectation-Confirmation Theory and to evaluate it psychometrically.

Methods: Using a Waltz-based approach grounded in existing tools and the constructs of the Expectation-Confirmation Theory, the initial version of the scale was designed and evaluated for face and content validity. Construct validity was examined through exploratory factor analysis, concurrent validity, and known-group comparison. Reliability was assessed using measures of internal consistency and stability.

Results: The initial version of the scale consisted of 33 items. During the qualitative and quantitative content validity stage, 1 item was added and 1 item was removed. Exploratory factor analysis, retaining 33 items, identified 5 factors that explained 70.53% of the variance. A significant positive correlation was found between the scores of the designed tool and nurses' attitudes toward using mobile-based apps in nursing care ($r=0.655$, $P<.001$). The intraclass correlation coefficient, Cronbach α , and ω coefficient were 0.938, 0.953, and 0.907, respectively.

Conclusions: The 33-item scale developed is a valid and reliable instrument for measuring nurses' acceptance of mobile health tools.

KEYWORDS

mobile health; acceptance; psychometric evaluation; nursing; Expectation-Confirmation Theory; smartphone

Introduction

Mobile phones and other electronic devices are becoming increasingly important for health care professionals [1]. These tools, along with mobile apps, provide numerous benefits for health care professions [2], including time savings [3]; cost-effectiveness [4]; enhanced self-efficacy [5]; greater access to evidence-based resources [6]; reduced medication errors [5]; decision support [6]; medication guides and guidelines [5]; video consultations with other physicians, alerts, and patient education [7]; and improved communication [5]. Given that the majority of hospital staff are nurses [8], and with an estimated 140,000 nurses in Iran according to a 2018 report by the Ministry of Health [9], it has been reported that approximately 80% of these nurses use mobile phones [8]. Another study found that 98% of nursing students use mobile phones to access drug guidelines, and 83% use them to look up medical terminology [10]. Unfortunately, hospitals do not provide personal mobile phones, and their use may raise concerns for health care organizations, potentially prompting them to implement policies to restrict mobile phone usage [11]. These concerns include distractions for nurses [12], infection control issues [13], and patient privacy risks [14]. Given the importance of mobile phones in nursing practice and the large population of nurses [15], health care stakeholders, managers, and planners should develop policies that support the appropriate use of mobile phones in nursing care and ensure its continuity [16]. The first step in achieving this is to assess the current situation, which requires a suitable tool. This tool should propose and validate a comprehensive model that considers individuals' characteristics, technology, and tasks. The model should address factors such as user satisfaction, confirmation, mobile health (mHealth) continuance, maturity, mobility, individual performance, perceived usefulness, and personal habits [17]. In similar studies, tools specifically designed to identify the unique needs of different stakeholders—such as physicians, nurses, and patients, who have distinct priorities and requirements for using mobile tools—have not been developed. Many of these tools are general questionnaires used in health care and other industries, such as mobile banking and e-commerce, rather than being tailored specifically for nursing [18]. Despite the emphasis on the sociotechnical perspective, which highlights the importance of identifying behavioral and social factors alongside technical ones among users of information technology tools [19], the tools used in these studies often fail to adhere to appropriate psychometric principles. Moreover, they frequently overlook essential background, individual, social, organizational, and cultural factors in their design [20]. Research studies have yet to identify a tool with a suitable theoretical framework specifically designed and localized for nursing based on research and psychometric principles. Additionally, some health care organizations are actively working to establish mHealth stations. Therefore, this study aimed to design and psychometrically validate a Mobile Health Acceptance Tool for clinical nurses in Iran, based on the constructs proposed in the Expectation-Confirmation Theory. According to behavior change theories such as the Expectation-Confirmation Theory, nurses who have a positive perception of using mobile devices in health care, and who believe in their usefulness, effectiveness,

and ease of use, are more likely to adopt mHealth tools. The concept of acceptance is explained through the constructs of the Expectation-Confirmation Theory. The scale measuring nurses' acceptance of mHealth tools includes questions addressing various dimensions of attitude, belief, and intention to use mobile tools in providing nursing services, based on Expectation-Confirmation Theory structures. The study's key strength was the application of the Expectation-Confirmation Theory to define acceptance of usage behavior, with a focus on the principles and stages of tool design according to the theory. Additionally, the study considered diverse research units based on individual characteristics, particularly employment context.

Methods

Overview

The researchers initially aimed to identify factors influencing nurses' adoption of mobile devices using the Expectation-Confirmation Theory. They identified key factors such as security risk, new technology anxiety, subjective norms, perceived ease of use, and approval. Following this, they reviewed other studies on mobile app evaluation and developed a preliminary list of measurement items.

This research used a tool design and psychometric validation approach, which was conducted in 2 phases.

Preliminary Phase: Designing the Initial Version of the Tool

In the preliminary phase, the tool was designed using the 4-stage approach proposed by Waltz et al [21]. First, the concept to be measured and its constructs were identified based on the Expectation-Confirmation Model. Second, measurement objectives were established based on the characteristics of the acceptance concept in the Expectation-Confirmation Theory, focusing on 8 constructs: perceived ease of use, social influence, new technology anxiety, personal habit, perceived security risk, confirmation, maturity, and perceived usefulness. In the third stage, the initial draft of the tool was developed. This involved a comprehensive search of both Persian and English articles in national and international databases, including PubMed, Ovid, Scopus, Web of Science, Magiran, IranDoc, Noor Mags, Science Direct, Jihad Daneshgahi Scientific Information Center, ProQuest, CINAHL, and SAGE, without time restrictions. The search utilized keywords related to mHealth, nursing, acceptance, scale, and attitude. All articles were critically reviewed to identify scales used to measure the acceptance of mHealth tools. Items from existing tools, including perceived usefulness, user satisfaction, and acceptance [22-25], were gathered from relevant texts, reviewed, categorized, and then integrated. Overlapping and inappropriate items were eliminated, and the research team determined the appropriate number of items for each decision domain. In the fourth phase, the tool's development involved defining the wording of items based on the conceptual constructs of the theory. The researchers formulated item wordings according to the theory's conceptual structures, revised them, and established scoring rules. Considering the cultural context of Iranian society and the organizational structure of Iranian hospitals, the research team

reviewed and adjusted the items designed based on existing tools.

For item scoring, a 7-point Likert scale (ranging from 1=completely disagree to 7=completely agree) was used, in line with common principles in attitude measurement tool design. Reverse scoring was applied to negatively phrased questions [26]. The total score of the tool was calculated as the average score of all items.

Phase 2: Psychometric Validation of the Tool

Step 1: Face and Content Validity Assessment

The preliminary questionnaire was reviewed by 10 experts in nursing, tool design, psychometric validation, health information management, and health informatics to assess qualitative content validity. Initially, a qualitative approach was used to gather expert opinions on the questionnaire's comprehensibility, grammar, language, scoring, key aspects, essential components of the concept, and the clarity and simplicity of the items [27]. Based on their feedback, necessary revisions were made to the instrument.

For quantitative content validity assessment, the content validity ratio CVR_{strict} , content validity index (CVI), and modified Kappa statistic (modified Kappa) were used. CVR_{strict} was calculated for each item, considering its necessity. Additionally, CVI and modified Kappa were calculated for each item based on the relevance criterion [28]. The Lawshe table, Waltz and Bausell index, and Polit and Beck criteria were used to evaluate the results for CVI, CVR, and modified Kappa. Additionally, the overall CVI for the entire instrument was calculated using the S-CVI_{Average} method [29].

To assess face validity qualitatively, in addition to the expert review, the first author (NM) read each question in the questionnaire aloud to 10 clinical nurses. Their interpretations of each question were compared with the original intent. The research team revised items in cases of ambiguity, inconsistency, or difficulty understanding the questions [30]. A professional Persian language editor was also consulted during this phase.

For the quantitative face validity assessment, nurses provided individual opinions on the importance of each item. They rated each item's importance on a 5-point Likert scale. Based on these ratings, an item impact score was calculated for each item, with scores above 1.5 considered desirable [31].

Step 2: Questionnaire Item Analysis, Construct Validity (Factor Analysis, Concurrent Validity, and Comparison of Known Groups), and Ceiling and Floor Effects

Experts recommend a sample size of 100-300 individuals for psychometric validation of a tool, regardless of the number of items [31]. Therefore, this study targeted a sample size of 250 individuals. The inclusion criteria were working in clinical settings (direct patient care), a minimum of 6 months of clinical experience, holding a university degree in nursing, no known psychological disorders, Iranian citizenship, and consent to participate. The exclusion criteria were unwillingness to continue cooperation or withdrawal from completing the questionnaire during the study.

After assessing the face and content validity of the instrument and obtaining the necessary permissions, the first author (NM) visited the nursing offices of hospitals and conducted sampling with an introduction letter. The sampling was performed in a stratified random manner between 2021 and 2022, based on the type of clinical ward. Different clinical wards within hospitals under the coverage of Kashan University of Medical Sciences were identified, and a list of qualified nurses in those wards was compiled. A simple random sample of participants was selected from each ward using a random number table, in proportion to the required sample size and the number of nurses employed in each ward. A questionnaire was used to collect demographic data, including personal and occupational information such as age, gender, education, marital status, work experience, ward of employment, predominant shift, positions in nursing management, smartphone ownership, type of smartphone operating system, daily internet usage duration, and smartphone usage duration. This was accompanied by the initial version of the Mobile Health Acceptance Tool (validated in the final phase of face and content validity assessment) and a single-item tool to assess nurses' attitudes toward using mobile-based apps in nursing care, rated on a scale from 1 (completely disagree) to 7 (completely agree). At the beginning of each shift, the ward was visited. After obtaining the nurses' consent and providing general instructions on completing the tools, the questionnaires were collected at the end of the shift. If a questionnaire was not completed on time, arrangements were made with the respective nurse. If access was impossible or cooperation was not obtained from the selected individual, a replacement was randomly chosen from the same ward.

After collecting the data, item analysis was initially performed using the loop method. Exploratory factor analysis was then conducted using the maximum likelihood method with varimax rotation. Eigenvalues greater than 1 and scree plots were used to determine the number of factors. A factor loading above 0.44 was used as the threshold for item retention. Items were assigned to the factor that conceptually aligned with them based on their common factor loads. After conducting the factor analysis, ceiling and floor effects were evaluated. The instrument's ceiling and floor effects were assessed based on the relative frequencies of samples with the highest and lowest achievable scores [32].

Concurrently, the known-groups comparison method was used to assess the construct validity of the final version of the instrument. Nurses were categorized into 7 groups, ranging from "1=completely agree" to "7=completely disagree," based on their responses to a question evaluating their attitude toward using mobile-based applications in nursing care. The acceptance scores on the Mobile Health Tool Acceptance Scale were then compared across these groups.

Step 3: Reliability Assessment

The internal consistency of the final version of the instrument and its subscales (factors extracted during factor analysis) was assessed for the entire sample using Cronbach α coefficient and McDonald ω .

The test-retest method [33] was used to assess the instrument's stability. Ten randomly selected participants from the study completed the final version of the instrument again 1 week later.

The intraclass correlation coefficient between the scores from the 2 assessments was calculated, and standard error of measurement (SEM) and smallest detectable change (SDC) were also estimated [34].

Data Analysis

Data analysis was conducted using SPSS version 16 (IBM Corp.). Quantitative variables were described using measures of central tendency and dispersion, while categorical variables were described using absolute and relative frequencies. Content validity was assessed quantitatively using CVI, CVR, and the modified Kappa statistic, and quantitative face validity was determined using the impact factor. The normality of quantitative data was assessed using skewness and kurtosis indices (for both parameters, the range of -2 to $+2$ was considered as the normal distribution). To check construct validity, exploratory factor analysis was performed using the maximum likelihood method with varimax rotation. The suitability of the data for exploratory factor analysis was evaluated using the Kaiser-Meyer-Olkin statistic and Bartlett test. The concurrent validity of the instrument was assessed using the Pearson correlation coefficient with the single-item attitude measurement scale. One-way ANOVA was used to compare known groups. The internal consistency of the instrument was assessed using Cronbach α and ω coefficients. Intraclass correlation coefficients were calculated to evaluate the correlation of scores between the 2 assessments in the test-retest. The SEM was computed using Equation 1, where SD represents the SD of scores and r is the Cronbach α coefficient.

SDC was reported based on Equation 2. A significance level of $<.05$ was considered in all analyses.

$$\text{SDC} = 1.96 \times \sqrt{(2 \times \text{SEM})} \quad (2)$$

Ethics Approval

This study was approved by Kashan University of Medical Sciences (KAUMS), Kashan, Iran (ethical code number IR.KAUMS.NUHEPM.REC.1401.039).

Results

Preliminary Phase

The initial draft of the instrument consisted of 33 items across 8 domains: perceived ease of use, social influence, new technology anxiety, personal habit, perceived security risk, confirmation, maturity, and perceived usefulness. These domains included 5, 6, 4, 3, 3, 5, 3, and 4 items, respectively.

Psychometric Phase

Stage 1: Content and Face Validity Assessment

In the qualitative content validity assessment, some items were revised. For example, the item “Nurses can easily use mobile app-based applications in patient care” was changed to “The interaction of nurses with mobile tools for providing nursing services is a simple task.” Additionally, the item “The use of mobile apps by nurses in patient care saves time” was added to the perceived ease of use domain.

In the quantitative content validity assessment, the $\text{CVR}_{\text{strict}}$ for all items, except 1 that was removed, was equal to or higher than the acceptable value specified in the Lawshe table (the minimum acceptable CVR for 10 experts is 0.62). The CVI and the modified Kappa statistic for the 33 retained items were within the range of 0.80-1. Additionally, the $\text{S-CVI}_{\text{Average}}$ was calculated to be 0.98.

In the face validity assessment, no changes were made to the items. Additionally, in the quantitative face validity assessment, the impact score for all items was above 1.5.

In summary, following the revisions in the initial psychometric phase, the final version of the instrument retained 33 items.

Stage 2: Questionnaire Item Analysis, Construct Validity (Factor Analysis, Concurrent Validity, and Comparison of Known Groups), and Ceiling and Floor Effects

During the sampling process, 357 (44.1%) eligible nurses out of 810 were selected. Of these, 107 (30%) did not consent to participate, resulting in data analysis for 250 (70%) individuals.

The mean age of the participants was 35.6 (SD 7.6) years, with an average work experience of 11.6 (6.7) years; 231 (92.4%) participants owned mobile phones, which they had used for an average of approximately 9.5 years (Table 1).

Item analysis revealed that removing items with correlation coefficients less than 0.30 or greater than 0.70 with the total score would not significantly impact the instrument's α coefficient. Therefore, all items were retained.

The Kaiser-Meyer-Olkin measure was 0.943, and the Bartlett test of sphericity yielded a chi-square value of 8651.805 ($df=528$, $P<.001$), indicating the suitability of the 33-item instrument for factor analysis. All items had factor loadings above 0.44, and none were removed during this phase. Factor analysis extracted 5 factors that accounted for 70.539% of the total variance in the Mobile Health Tool Acceptance Scale score (see Tables 2 and 3, and Figure 1).

Table 1. Characteristics of clinical nurses working in hospitals under the coverage of Kashan University of Medical Sciences, 2022 (n=250).

Categorized variables	Values, n (%)
Gender	
Male	44 (17.6)
Female	206 (82.4)

^aFactor naming is as follows: factor 1 encompasses 10 questions consisting of items 17, 18, 19, 20, 21, 22, 23, 24, 25, and 26, which were named "application and performance"; factor 2 encompasses 7 questions consisting of items 6, 7, 8, 9, 10, 11, and 16, which were named "social impact"; factor 3 encompasses 5 questions consisting of items 1, 2, 3, 4, and 5, which were named "perceived ease of use"; and factor 4 encompasses 7 questions consisting of items 27, 28, 29, 30, 31, 32, and 33, which were named "effectiveness"; and factor 5 encompasses 4 questions consisting of items 12, 13, 14, and 15, which were named "new technology anxiety."

^bA minimum factor loading of 0.44 was considered. Factor loadings less than 0.44 are not included in the table.

^cNot available.

^dFor common factor loadings, the item was loaded on a factor that conceptually aligned with the item's content.

Figure 1. Scree plot of the Nurses' Mobile Health Device Acceptance Scale (NMHDA-Scale).

Based on the instrument validated in the exploratory factor analysis (33 items), the mean Mobile Health Tool Acceptance Scale score for nurses was 4.207 (SD 0.740) on a 1-7 scale. With 95% CI, this score is estimated to range between 3.29 and 5.12 for the nursing population working in hospitals under the coverage of Kashan University of Medical Sciences. The mean

score for nurses' attitudes toward using the mobile app-based programs in nursing care, as measured by the single-item tool on a 1-7 scale, was 4.340 (SD 1.510). With 95% CI, this score is estimated to range between 2.468 and 6.212 for the target population. In the concurrent validity assessment, a significant positive correlation ($P < .001$) was found between the Mobile

Health Tool Acceptance Scale score and the single-item tool score measuring nurses' attitudes, indicating that higher acceptance scores were associated with more positive attitudes (Table 3). In the known-groups comparison, one-way ANOVA revealed a statistically significant difference in the Mobile Health Tool Acceptance Scale scores among groups based on

their level of agreement or disagreement with using the mHealth tool ($P < .001$; Table 4).

In the floor and ceiling effect assessment, the relative frequencies of nurses' lowest and highest possible scores on the Mobile Health Tool Acceptance Scale were both less than 15%.

Table 4. Acceptance Score of the Mobile Health Tool Acceptance Scale in nurses, differentiated by their overall agreement or disagreement regarding the use of the mobile app-based nursing care (single-item tool score; $n=250$)^a.

One-way ANOVA results	Nurses' agreement or disagreement with the use of the mobile app-based tools in nursing care (single-item tool)							Mobile Health Tool Acceptance Scale
	Completely disagree (n=13)	Disagree (n=22)	Somewhat disagree (n=27)	Neutral (n=64)	Somewhat agree (n=67)	Agree (n=43)	Completely agree (n=14)	
Score, mean (SD)	3.263 (0.782)	3.484 (0.833)	3.678 (0.546)	4.019 (0.324)	4.489 (0.443)	4.820 (0.436)	4.869 (1.195)	Welch statistic=31.266 ($P < .001$)

^aIn terms of comparing the 2 groups, the Games-Howell post hoc test showed that there is a significant difference between the acceptance scores of the mobile health tool in the following group pairs: 1 and 7 ($P < .006$), 1 and 6 ($P < .001$), 1 and 5 ($P < .001$), 2 and 5 ($P < .001$), 2 and 6 ($P < .001$), 2 and 7 ($P < .02$), 3 and 5 ($P < .001$), 3 and 6 ($P < .001$), 3 and 7 ($P < .03$), 4 and 3 ($P < .001$), 4 and 5 ($P < .001$), and 6 and 5 ($P < .004$).

Stage 3: Internal Consistency and Stability

In the assessment of internal consistency, the Cronbach α coefficient and the ω total coefficient for the entire instrument were 0.938 and 0.953, respectively. The coefficients for the 5 extracted factors were also above 0.88 (Table 2).

In the tool's stability assessment, the intraclass correlation coefficient between test and retest scores was 0.907 (95% CI 0.615-0.977, $P < .001$).

The SEM for the designed instrument was 0.184, and the SDC was 1.19, with 95% CI.

Discussion

Principal Findings

Previous studies have used measurement tools to assess the use of mHealth tools in various health care and other groups [18,35,36]. However, none of these studies utilized a psychometrically tested tool specifically designed for nurses. Therefore, this study aimed to develop and validate the Nurses' Mobile Health Device Acceptance Scale (NMHDA-Scale) based on the Expectation-Confirmation Model.

A 33-item questionnaire was designed to assess the acceptance of mHealth tools among clinical nurses, demonstrating strong validity and reliability within the target population.

The draft of the NMHDA scale was developed using Waltz's 4-step approach and the Expectation-Confirmation Model. This study, grounded in its theoretical framework and the principles of the Expectation-Confirmation Model [37], offers a broader range of acceptance dimensions compared with other existing tools [38,39]. Experts argue that a theoretical foundation for defining the content domains of a tool leads to the creation of relevant items and is crucial for ensuring the tool's validity [40].

In the content validity assessment, revisions to the tool were made based on expert feedback from various relevant and specialized fields. The CVR, CVI, and modified Kappa statistics

for all retained items were higher than 0.62, 0.80, and 0.74, respectively. Additionally, the overall S-CVI (S-CVI_{Average}) for the entire tool was greater than 0.90. Experts agree that assessing content validity is crucial to ensure the tool covers all essential aspects of the intended concept. The reliability of this process increases with the expertise of the individuals involved in this stage [21]. Moreover, an S-CVI_{Average} greater than 0.90 is considered desirable for content validity [41]. Based on the presented information, the developed tool meets the criteria for establishing content validity.

In the face validity assessment, modifications were made to the tool based on feedback from clinical nurses, the target group. Additionally, the impact scores for all retained items were above 1.5. Connell et al [42] highlighted that face validity is crucial for addressing the needs of the target group, as what researchers consider essential may differ from the perspective of the primary group. Therefore, face validity can enhance the measurement's acceptability, relevance, and quality [42]. Thus, it can be claimed that the tool's items are well understood by the target group, confirming its face validity.

The exploratory factor analysis identified 5 factors: "application and performance," "social impact," "perceived ease of use," "effectiveness," and "new technology anxiety." These factors collectively explained more than 50% of the total score variance, with each contributing over 5%. Additionally, all items had factor loadings exceeding 0.44, and there was one common factor among them. Some experts argue that for construct validity, the identified factors should account for at least 40% of the total variance [43], with each factor explaining more than 5% of the total variability [44]. Additionally, other sources suggest that for robust construct validity, the factors should collectively account for more than 50% of the total variance [45]. Given that the identified factors in this study explained over 50% of the total variance, each contributing more than 5%, the construct validity of the tool is well-established. Therefore, the exploratory factor analysis results suggest the construct validity of the tool. The high factor loadings of the items and

the existence of only one common factor further support the desirable structure of the tool [46].

The content of the items loaded onto the extracted factors aligns well with the intended acceptance concept. For instance, factors such as “technology anxiety,” “social impact,” and “perceived ease of use” directly correspond with theoretical expectations. The factor “usefulness and performance” aligns with the “security risk” factor, while “confirmation” and “effectiveness” correspond with “maturity” and “perceived benefit.” Compared with other tools used to assess the acceptance of mHealth tools [47], the structure of this tool is notably more desirable.

A comparison of known groups revealed a significant difference in acceptance scores among nurses based on their agreement or disagreement with using mHealth tools. This finding indicates that the designed tool can effectively differentiate between nurses with varying levels of agreement regarding mHealth tools. Such a result supports the structural validity of the tool, as it is intended to distinguish between groups expected to have differences in a specific characteristic. The observed significant differences further validate the tool’s structure [48].

In our study, the relative frequency of the minimum and maximum possible scores obtainable from the acceptance measurement tool was 0, indicating the absence of floor and ceiling effects. Floor and ceiling effects are observed when more than 15% of respondents achieve the highest or lowest possible score on a tool. The absence of such effects in this study suggests that the tool’s items are appropriately distributed across the scale, supporting both the content validity and reliability of the instrument [49].

In our study, the total Cronbach α coefficient of the tool was 0.938. According to Shrestha [50], an acceptable lower limit for Cronbach α for reliability is 0.70. Values between 0.60 and 0.80 are considered average, while those between 0.80 and 1.00 are deemed very good [51]. Thus, the high Cronbach α value indicates that the tool demonstrates excellent internal consistency.

The correlation coefficient between the scores obtained from the 2 test sessions was 0.655. Lotfi et al [52] suggested that a correlation coefficient between scores from 2 test sessions indicates the test’s stability and repeatability, with coefficients above 0.70 considered acceptable and those above 0.80 very good. Although the coefficient in this study is slightly below the optimal threshold, it still reflects the tool’s satisfactory stability and demonstrates higher consistency compared with similar tools [39].

In our study, the SEM was estimated to be 0.184, with the SDC being 1.19. This means that if the test is repeated for an individual, their score may vary by up to 0.184 points. The small SEM supports the tool’s stability and reliability [53]. Given the

tool’s score range, this SEM value indicates the tool’s robustness in terms of stability, repeatability, and overall reliability.

Study Limitations

This study has several limitations: data collection during the COVID-19 crisis, which coincided with a high workload for nursing staff, led to a significant number of nurses being unwilling to cooperate. Additionally, the lack of appropriate Persian language tools for assessing convergent validity presents another constraint.

Application of Findings

The current research serves as a valuable tool across various organizational dimensions. It assists senior managers and decision makers in evaluating the potential success of new technologies. For instance, it can contribute to reshaping nursing education curricula by integrating organizational and environmental variables, developing guidelines and regulations for app design, and more. This tool assists nurses in understanding the benefits of technology use by focusing on perceived usefulness, ease of use, adoption concerns, security perceptions, user satisfaction, habit maturity, acceptance, and societal impact. The integration of mobile tools among nurses underscores the need for national policies that provide a clear framework for the design, implementation, and evaluation of mobile apps in nursing.

Conclusions

This study details the development and psychometric evaluation of the Mobile Health Tool Acceptance Scale for nurses, grounded in the Expectation-Confirmation Theory. Exploratory factor analysis confirmed a 5-factor model with 33 items. The factors—usability and performance, social influence, perceived ease of use, effectiveness, and anxiety about new technology—are distinct and collectively capture nurses’ intention to accept mHealth tools for professional and job-related purposes. Future studies can utilize this tool to assess the intention of nurses and other health care professionals to use mobile phones for work purposes. This approach allows for the exploration of predictors and outcomes related to both theoretical frameworks and practical applications.

This tool provides valuable insights for managers at various levels, aiding in the creation of guidelines and strategies related to the design and use of mobile apps in the health sector. It also supports the Ministry of Health and Medical Sciences Universities in revising nursing education curricula to enhance the integration of information technology tools and expand their usage based on key efficiency factors. Given that health service providers share common missions and goals and collaborate as a team during clinical activities, it is likely that, with appropriate modifications and psychometric testing, the revised scale could be adapted for use with other target groups within the health care field.

Abstract

Background: Future Health Today (FHT) is a technology program that integrates with general practice clinical software to provide point of care (PoC) clinical decision support and a quality improvement dashboard. This qualitative study looks at the use of FHT in the context of cardiovascular disease risk in chronic kidney disease (CKD).

Objective: This study aims to explore factors influencing clinical implementation of the FHT module focusing on cardiovascular risk in CKD, from the perspectives of participating general practitioner staff.

Methods: Practices in Victoria were recruited to participate in a pragmatic cluster randomized controlled trial using FHT, of which 19 practices were randomly assigned to use FHT's cardiovascular risk in CKD program. A total of 13 semistructured interviews were undertaken with a nominated general practitioner (n=7) or practice nurse (n=6) from 10 participating practices. Interview questions focused on the clinical usefulness of the tool and its place in clinical workflows. Qualitative data were coded by 2 researchers and analyzed using framework analysis and Clinical Performance Feedback Intervention Theory.

Results: All 13 interviewees had used the FHT PoC tool, and feedback was largely positive. Overall, clinicians described engaging with the tool as a "prompt" or "reminder" system. Themes reflected that the tool's goals and clinical content were aligned with clinician's existing priorities and knowledge, and the tool's design facilitated easy integration into existing workflows. The main barrier to implementation identified by 2 clinicians was notification fatigue. A total of 7 interviewees had used the FHT dashboard tool. The main barriers to use were its limited integration into clinical workflows, such that some participants did not know of its existence; clinicians' competing clinical priorities; and limited time to learn and use the tool.

Conclusions: This study identified many facilitators for the successful use of the FHT PoC program, in the context of cardiovascular risk in CKD, and barriers to the use of the dashboard program. This work will be used to inform the wider implementation of FHT, as well as the development of future modules of FHT for other risk or disease states.

Introduction

Background

The 2011 - 12 Australian Health Survey revealed that 10% of Australian adults had biochemical signs of chronic kidney disease (CKD) [1]. CKD is a significant risk factor for cardiovascular disease [2], which is Australia's leading cause of death [3]. Early intervention can slow the deterioration in kidney function and reduce the risk of cardiovascular complications [4]. Australian CKD guidelines recommend the use of angiotensin-converting enzyme inhibitors (ACEis) or angiotensin-receptor blockers (ARBs) in the presence of albuminuria or hypertension (defined as a blood pressure above 130/80 mm Hg), and statins are recommended for everyone with CKD over the age of 50 years or for younger individuals with CKD in the presence of comorbidities [5].

CKD is underrecognized and undertreated in Australian general practice. One study found that 76.8% of people with biochemical results consistent with CKD did not have the diagnosis recorded in their medical file [6], and another found that only 65% of people with a formal diagnosis of CKD were prescribed an ACEi/ARB while 56% were prescribed a statin [7]. A known barrier to achieving quality improvement in chronic disease is the lack of timely and straightforward access to clinical guidelines [8,9]. Electronic clinical decision support tools aim to address this barrier by integrating with clinical records to automatically provide key information from appropriate clinical guidelines.

Prior Work

The Future Health Today (FHT) program is a general practice quality improvement technology platform developed by the University of Melbourne and Western Health. FHT integrates with the electronic medical record to provide 2 components: a clinical decision support tool active at the point of care (PoC) and a web-based dashboard that facilitates practice-wide audit. Screenshots of FHT are available in [Multimedia Appendix 1](#). FHT was developed using a service design approach, whereby clinicians were involved throughout an iterative technical development process [10]. It underwent optimization at 12 general practice clinics, using guidelines for CKD, cardiovascular disease, and cancer prevention. A qualitative optimization study for the cancer recommendations has been described elsewhere [11]. A cluster randomized controlled trial was completed in 2022 (trial registration: ACTRN12620000993998) with the aim of exploring whether the FHT platform increased the prescription of ACEis/ARBs and statins in people with CKD at high cardiovascular disease risk [12]. This paper reports on barriers and facilitators of clinical performance improvement as reported by clinicians themselves.

Methods

Study Setting

General practice provides primary care to more than 8 in 10 Australians each year [13] and operates on a fee-for-service model, with rebates available through Medicare, the health care

insurance scheme funded by the Australian Government Department of Health and Aged Care. General practices may bulk bill (payment covered in full by Medicare), privately bill (patients pay a fee in excess of the Medicare rebate), or mixed bill (variably bulk bill or privately bill patients).

The FHT trial was conducted in 39 general practices in Victoria and 1 general practice in Tasmania, Australia. In summary, clinics were randomized into 2 arms: cardiovascular risk reduction in people with CKD or identification of cancer risk, with each group acting as the control for the other [12]. Twenty-one general practices were allocated to the CKD arm, with 19 practices completing the trial. The trial ran from October 2021 to September 2022. The CKD algorithm was deactivated in December 2021 after errors in algorithm deployment were noted and was reactivated in February 2022. The interviews analyzed in this paper occurred between May and July 2022. The state of Victoria was subject to a COVID-19 pandemic declaration throughout the duration of the trial.

Study Design

This qualitative implementation study focuses on the clinical experience and use of FHT for medication management to reduce cardiovascular risk in people with CKD. Semistructured interviews were conducted with general practitioners (GPs) and practice nurses (PNs) participating in the CKD intervention arm of the FHT trial.

Participants

Participating clinics were recruited via VicREN (Victorian Primary Care Practice-Based Research and Education Network) at the Department of General Practice and Primary Care, The University of Melbourne, and The University of Tasmania's Northern Tasmania General Practice-based research network. Each practice was asked to nominate a practice champion at the beginning of the trial; this tended to be a PN or practice manager. The practice champion was requested to assist with the recruitment of GPs and PNs to participate in one-on-one interviews held between 8 and 10 months into the trial. Recruitment was also facilitated by the FHT trial coordinator. Potential participants were emailed a plain-language statement and consent form to complete if they were interested in participating. Participants were reimbursed with a AUD \$50 (US \$33.69) debit card voucher.

Data Collection

Interviews occurred over the phone and were recorded for transcription. There were 3 interviewers: CM, NL, and KS. CM is an academic GP registrar, NL is a research fellow, and KS is a research assistant. All are female and are affiliated with the University of Melbourne. NL acted in a liaison role for practices during the trial. An interview guide ([Multimedia Appendix 2](#)) was developed to focus on questions regarding the clinical usefulness of the recommendations, impact on clinical workflows, and perceived change in clinical performance.

Data Analysis

Interview data were analyzed using Clinical Performance Feedback Intervention Theory (CP-FIT), a theory for designing, implementing, and evaluating feedback specifically in the health

care context [14]. The theory proposes 42 variables that influence a feedback cycle via 7 mechanisms. Each step in the cycle is vital for successful feedback to occur. Each interview was independently coded by CM and BH (a qualitative researcher) using a combination of NVivo (Lumivero) and Microsoft Excel. Any discrepancies in coding were discussed and a consensus was reached.

Ethical Considerations

The overall FHT trial protocol was approved by the Department of General Practice University of Melbourne Human Ethics Advisory Group and the Faculty of Medicine, Dentistry, and Health Sciences Human Ethics Sub-Committee. The ethics ID is 2056564. These ethics committees use the National Statement on Ethical Conduct in Human Research published by the Australian Government National Health and Medical Research Council.

Results

Overview

A total of 13 interviews were held, with staff from 10 clinics. The demographic and clinic details of the 7 GP and 6 PN

participants are summarized in Table 1. Participants were assigned a code based on their role (GP or PN) and their clinic's allocated number within the trial. All 10 clinics were located in the state of Victoria and varied in their location (regional Victoria or metropolitan Melbourne) and billing policy (mixed or bulk billing). The sample size aimed to gather perspectives from as many staff at the 19 intervention practices as possible but was limited by the response rate. A total of 5 practices did not respond to the request for interview, 1 canceled citing personal reasons, and 1 canceled citing lack of use of FHT. Duration of interviews ranged from 14 to 39 minutes (average 21 min).

All interviewees had used the FHT PoC tool (N=13), with only 7 interviewees having experience using the FHT dashboard. The 5 GPs not using the dashboard were not aware of it, were not able to access it due to technological issues, or had not had time to use it. Five of the PNs had used the dashboard, but none had used it to recall patients.

^bGP: general practitioner.

^cPoC: point of care.

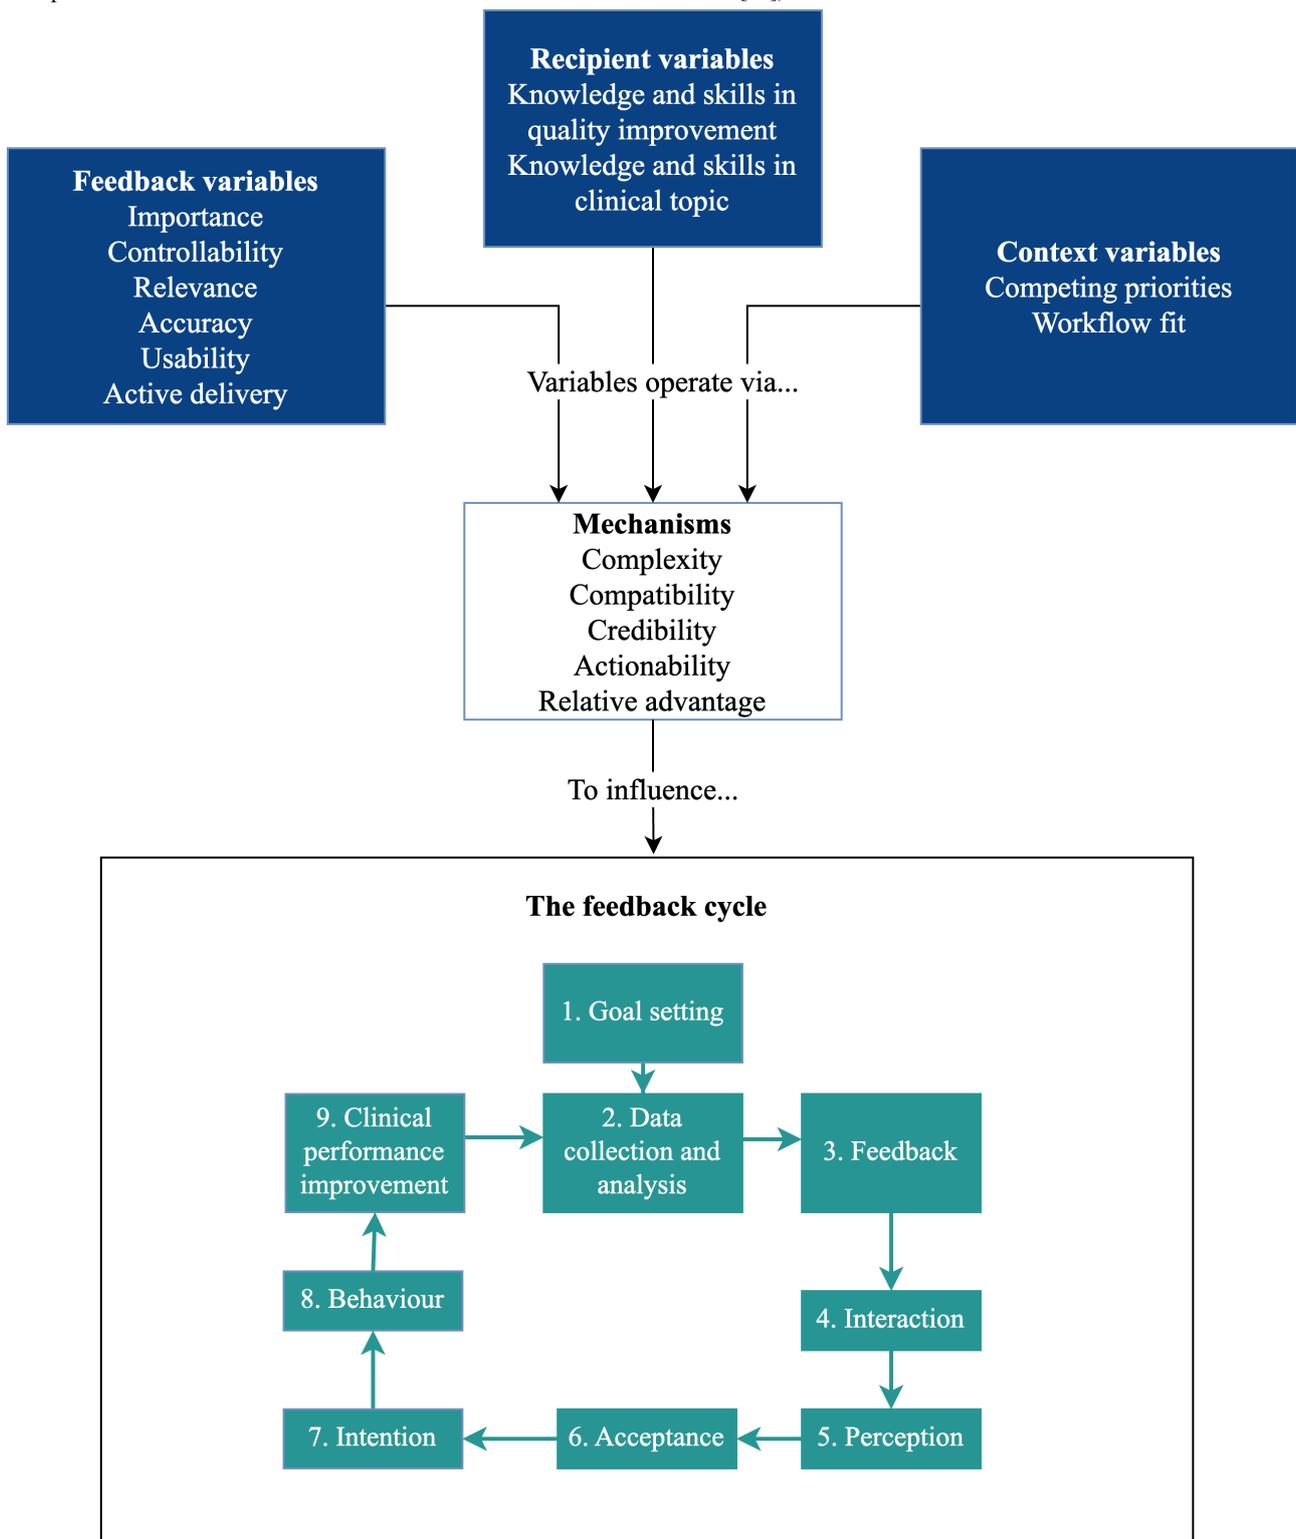

^dPN: practice nurse.

Interview Findings: The CP-FIT Feedback Cycle

Results were mapped to the CP-FIT feedback cycle. An adapted version of CP-FIT is shown in Figure 1, with variables and

mechanisms relevant to this study included in the diagram. In total, 10 explanatory variables and 5 mechanisms were identified as influencing how clinicians used FHT.

Figure 1. Clinical Performance Feedback Intervention Theory variables, explanatory mechanisms, and feedback cycle (adapted from Brown et al [14], which is published under a Creative Commons Attribution 4.0 International License [15]).

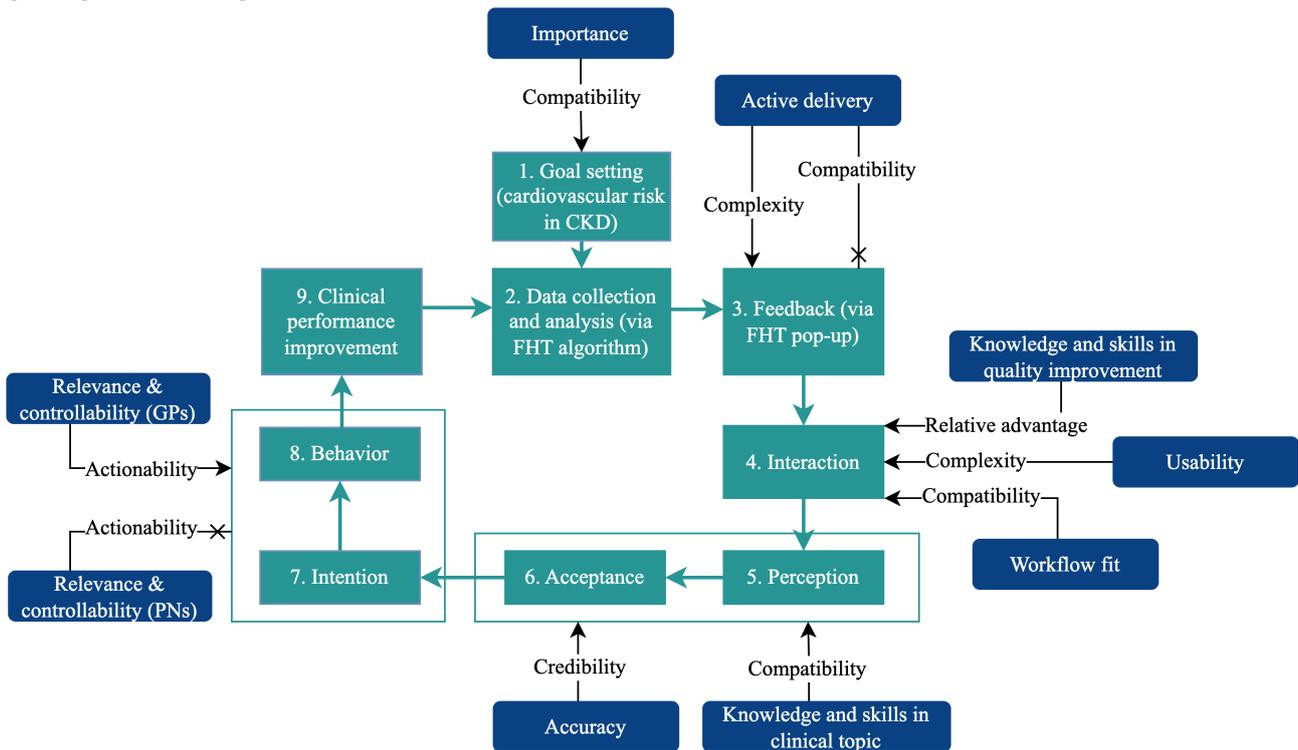

Interview Findings: The PoC Tool

Results for the PoC tool are presented in sequential order following the CP-FIT feedback cycle as shown in Figure 2, with

key quotes to illustrate themes. Some steps of the feedback cycle are presented concurrently, reflecting that participants described these processes occurring simultaneously.

Figure 2. The Clinical Performance Feedback Intervention Theory feedback cycle when using the point of care tool (adapted from Brown et al [14], which is published under a Creative Commons Attribution 4.0 International License [15]). CKD: chronic kidney disease; FHT: Future Health Today; GP: general practitioner; PN: practice nurse.

Goal Setting: Importance

It was universally agreed that CKD is an area of importance in general practice. Clinicians reflected on how CKD is underrecognized and undertreated.

It's certainly an area that seems to be pretty poorly documented in the patient's records and then consequently not always particularly well treated either. [GP7A]

It's actually really important, because it's – probably 10 per cent of the clinic patients have chronic kidney disease, according to the statistics and probably I don't have all of them already coded in my computer [GP31]

Data Collection and Analysis

Step 2 occurred automatically via the FHT software program, without needing intervention by clinicians.

Feedback: Active Delivery

Active delivery of feedback via the PoC pop-up facilitated ease of use. Put simply:

It's just there. It just pops up. I read it. [PN5]

The method of delivery was designed to not be intrusive, and this is consistent with how it was perceived.

It's quite a minimal popup. Well, it has to be big enough that you see it, but it's small enough that it doesn't just take over the whole of the screen. [GP7A]

Two participants identified concerns about notification fatigue.

[Interviewer: have people been receptive to learning how to use it?] Yeah. But also...that's one more thing we have to deal with. There has been a little bit of reluctance. [PN5]

Any decision support software...you get notification fatigue [GP7B]

Interaction: Knowledge and Skills in Quality Improvement, Usability, and Workflow Fit

GPs demonstrated a keen interest in quality improvement and proactively reviewed information from the PoC tool to facilitate this.

It's always good to review your management. [GP31]

There will be a patient that they are not on what's recommended just because of an oversight there. So I think that it's a good double check. [GP23]

Clinicians found the PoC tool to be usable because of its information clarity and lack of complexity.

They are useful because they're clear, or clear-cut and they're not a big swath of information coming through, and that gives you an opportunity to go into the resources as you need to. [GP7A]

For GPs, the PoC tool was compatible with existing workflows. Most GPs reported reading and verifying the information in the PoC tool prior to bringing the patient into their consulting room, as part of their usual preconsultation file review. This process was described as very quick (GP23, GP31), and the recommendations were able to be actioned within their standard consultation structure.

I usually familiarise myself with the patients before calling them, so I go through the history, recalls, results or whatever, including if there was any popups [GP31]

It's pretty straightforward. The discussion goes something like, "so Mrs. Jones, just looking at your recent renal function, the current recommendations is that we add a statin or you should be on an ACE or ARB. what do you think about that?" They usually say, well, what do you think? And we go down that path of shared decision making. [GP7B]

PNs described more variation in how they interacted with the PoC tool and integrated it into their workflows. Two described using the program opportunistically (PN5, PN19) during consultations or when reviewing existing recalls. One reviewed the recommendations only when the patient was booked for a long appointment such as a care plan or health assessment. Practices nurses mostly acted on the recommendations by documenting in the patient file or directly discussing with the patient's GP.

It's for patients who have long appointments. For example, they're in for a care plan or a health assessment wherein we actually review and check the file for a longer period of time. Unlike those who are only here for, let's say, vaccinations where they will be in and out of the treatment room and we don't really have that much time to review and study. [PN22]

I usually will just alert the doctor and then...the doctor will, based on their own view and they would decide whether or not to follow the advice [PN6]

Perception and Acceptance: Knowledge and Skills in Clinical Topic and Accuracy of Recommendations

When asked directly, each GP reported a good pre-existing knowledge of CKD; none of the information in the PoC tool was new or surprising. They expressed confidence in interpreting and actioning the recommendations in the context of each patient.

Guidelines are guidelines. That's exactly what they are. They're not - they don't actually always - are not always appropriate for the person sitting in front of you. we go down that path of shared decision making. [GP7B]

Every patient that I have I have a look at the recommendations to see what their recommendations are and if it comes up in orange or that I consider their recommendations and follow them unless there's a reason not to. I review my medication and have a good think about it. [GP23]

Most PNs reported less confidence with CKD management in general but were empowered by the PoC tool to learn more.

I don't think I know that area so well, yeah, so it is quite useful to have this pop-up icon. [PN6]

GPs largely found the recommendations to be accurate. The process for verifying information was straightforward and they

felt comfortable discounting recommendations when appropriate. The format of clinical data storage and the way data were recorded in the electronic medical record were identified as potential sources of inaccuracy.

I think it seems to be pretty accurate most of the time...normally I will go having a look through the most recent result eGFR and any albumins that are there and just see if there is anything that does meet the criteria for a diagnosis. Then if not, then I'll leave it. [GP7A]

I think a lot of them are on it. It just wasn't documented in the right place...one of the limitations in this clinic in particular is that [GP] handwrites scripts [PN19]

Intention and Behavior: Usability, Relevance, and Controllability

Themes related to controllability and relevance diverged according to role, due to the recommendations having a focus on medication and prescribing. GPs found that the PoC recommendations were well within their scope and control, and most GPs found them relevant to their patient population.

Every time, if it came up with a recommendation, I would act on it to decide whether they should be on it or whether there's a reason not to. [GP23]

In contrast, PNs described how the PoC had limited direct relevance to their role, which excludes prescribing.

I can't prescribe anything, and a lot of it is about prescribing [PN5]

Clinical Performance Improvement

Overall, these themes reflected the view that the PoC tool was seen as a "prompt" or "reminder" that reinforced pre-existing knowledge in a straightforward manner consistent with usual practice.

It's a nice little way of reminding people to do it really.... I think just having it coming up is always reminding me to check what are the best practice principles, things like the ACE and ARB. [GP7A]

I think it's just a good prompt because it does pop up there, when you can get really busy. [PN19]

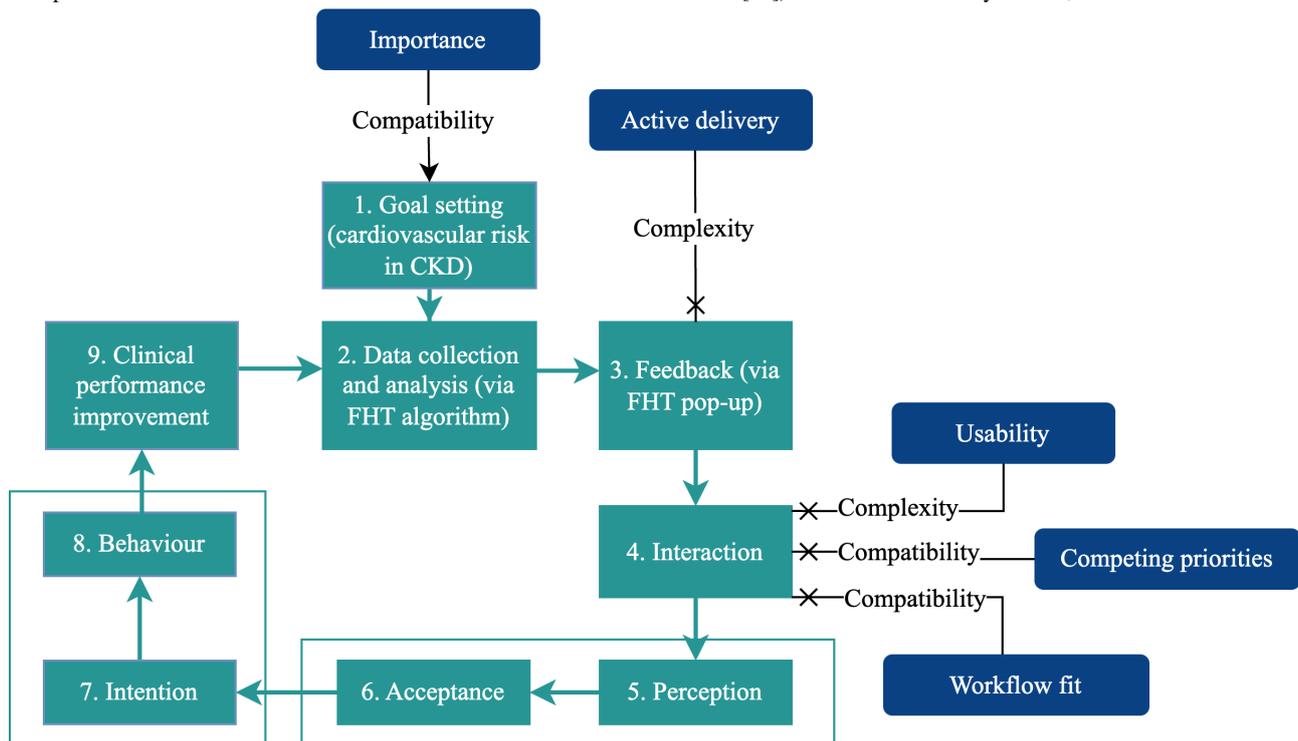

One GP reflected on how the presence of FHT had the effect of encouraging more general clinical performance improvement.

It certainly does focus particularly in general consults on preventative health and flags that as an issue to discuss and might then prompt me to not only look at the CKD, but make sure they've had a recent blood pressure and height and weight and make sure their cancer screening is up to date; all of those sorts of things as well. [GP7A]

Interview Findings: The Dashboard Tool

Results for the dashboard tool are shown in [Figure 3](#). Feedback cycle steps 1 and 2 (goal setting and data collection) operated in the same manner as the PoC tool. However, participants became "stuck" at either steps 3 or 4.

Figure 3. The Clinical Performance Feedback Intervention Theory feedback cycle when using the dashboard tool (adapted from Brown et al [14], which is published under a Creative Commons Attribution 4.0 International License [15]). CKD: chronic kidney disease; FHT: Future Health Today.

Feedback: Active Delivery

Use of the dashboard was significantly limited by its lack of active delivery; multiple clinicians were not aware it existed.

Interaction: Usability, Competing Priorities, and Workflow Fit

Clinicians who had used the dashboard reported some difficulty learning how to navigate the tool, and use of the dashboard was largely incompatible with existing workflows. This was exacerbated by time constraints associated with additional clinical tasks and workforce pressures, particularly with the impacts of the COVID-19 pandemic.

I get a little bit lost still in [the dashboard]. [PN19]
A lot of it is just timing. We're still so busy. I would love to have a bit more time to sit down and just work through things. We're starting to do a little bit now but, really, it's just time. [PN5]
With the Pfizer vaccines and all that we are inundated with work... COVID has really taken over [GP22]

Discussion

Principal Results: The PoC Tool

In this qualitative study exploring the implementation of FHT using CP-FIT, we found that the FHT PoC tool was well received by clinicians and facilitated guideline-informed care. When mapped to the CP-FIT feedback cycle in Figure 2, we could see that they were able to move rapidly through all steps of the process, facilitated by the variables identified. GPs found that the tool was compatible with their quality improvement goals and clinical workflows; was simple to use; and provided credible, clinically useful information. This was supported by

their pre-existing confidence in managing CKD, so the tool was seen as a quick reminder system that prompted further personalized review and discussion. Clinicians in our study worked across a range of location and billing styles, but all described similar workflows and clinical knowledge that supported uptake of the tool. This concept of a clinical decision support tool working most effectively as an “aid-memoire” is supported by existing literature [16]. PNs had a slightly different experience given their self-reported lesser knowledge of CKD and limited role in medication prescribing, but nonetheless, they described the PoC tool as useful and simple to use.

Principal Results: Dashboard Tool

Use of the FHT dashboard tool was limited. Most GPs did not get to the “feedback” stage of accessing the dashboard, and most PNs did not progress past initial interactions with the software. During the co-design phase, clinicians had expressed a desire for FHT to facilitate both planned and spontaneous interactions [10], but in practice, most interactions occurred spontaneously. The functions available in the dashboard did align with the goals described by clinicians in both the co-design phase and this implementation study, but this was insufficient to overcome competing clinical priorities, particularly the lack of time and staff resources in the context of the COVID-19 pandemic.

The barriers to the use of the dashboard tool stood in clear contrast to the facilitators for the PoC tool. Whereas the PoC tool was simple to access by virtue of being a “pop-up,” the dashboard required clicking away from the patient file. The visual design of the PoC tool and wording of the recommendations were designed with simplicity and conciseness as a priority. By contrast, the dashboard tool has multiple aspects of functionality, allowing for extensive customization

([Multimedia Appendix 1](#)). The few clinicians who reached the tool described being overwhelmed or not having enough time to learn how to use the tool.

The nature of Australian general practice funding tends to incentivize opportunistic rather than systematic preventative health activities [17]. Medicare uses a fee-for-service model, whereby patients receive a rebate for attendance either in person or via telehealth/telephone. Alternative payment mechanisms have been proposed that allow for more of a focus on proactive, coordinated care that includes funding non-face-to-face care, such as that required to interact with tools like the FHT dashboard in any meaningful way [17].

Limitations

All clinicians we interviewed had used FHT in their workplace; by nature of agreeing to be interviewed, they were able to describe the enablers that led them to progress along the CP-FIT feedback pathway. Respondent bias is a limitation of our study, as those who feel most strongly are most likely to speak with us. We also acknowledge that the sample size may not encompass the experiences within the diverse general practice context. However, given the impact of the COVID-19 pandemic on primary care, we are grateful to the 13 participants who took the time to speak with us. The barriers remain unknown for clinicians who did not use FHT, although they can be hypothesized, as discussed below.

While this study focused on the implementation of FHT from the clinical perspective, there are of course other important considerations. In particular, other studies have identified concerns related to the financial costs of staff time and the software itself [18].

Comparison With Prior Work

Many electronic quality improvement programs in current use in Australian general practice have not been evaluated in a research context, and as such, there is a lack of data exploring implementation factors for these programs. The Australian Government Department of Health has recognized the need for clearer policy around the governance of general practice data and the development of clinical decision support tools. In particular, concerns have been raised about the variable quality of existing clinical decision support tools and lack of implementation considerations, which may create general distrust in electronic clinical decision support by GPs [19].

A commonly reported barrier to the use of clinical decision support systems is that of “too much information,” either in the content of a prompt or in the total volume of prompts [20,21]. This notification fatigue is an important consideration for any clinical decision support tool that activates automatically. There is a delicate balance between “active delivery” to facilitate easy interaction with a tool, and unobtrusiveness to the extent that clinicians are not aware of a tool, which is what occurred with the FHT dashboard. Clinicians in our study praised the physical size and placement of the PoC pop-up on the screen, as well as the simplicity of wording of the recommendations. Only 1 GP brought up concerns about notification fatigue, although did not report it as a barrier for their own use of the PoC tool. As more FHT modules are developed in the future, it will be vital to account for potential alert fatigue in how the pop-ups are deployed and displayed.

Lack of time has similarly been cited as a widespread barrier to clinical care for both GPs and nurses [9,18]; however, clinicians in our study did not describe time as a barrier to the use of the PoC tool. This is likely due to the speed at which they interacted with the tool, which itself was due to the usability of the tool and knowledge of the GPs. The marginal time required to interact with the tool, however, will inevitably become more significant as more FHT modules are added. It will be important for the sustainability of the FHT program to take this into account, to reduce the risk that lack of time becomes a barrier to the use of the entire PoC tool.

A study in 2015 in the United States reported barriers to the implementation of a clinical decision support tool specific to CKD, which included limited knowledge of CKD guidelines, lack of interest or confidence in technology, concerns about patient engagement, and time and competing demands [22]. In our study, clinicians’ knowledge of CKD and interest in technology for quality improvement were strong facilitators for FHT, and they were confident in discussing recommendations with their patients. Lack of knowledge in the identification and management of CKD has been cited as a general barrier to care [9]. Overall, it appears that our group of clinicians were particularly knowledgeable and proactive, and this greatly facilitated their engagement with FHT. The PoC tool had been designed with usability and clarity in mind, but these health professional characteristics were vital for uptake.

Acknowledgments

We would like to thank the general practices, health care professionals, and consumers who provided input to the development of Future Health Today (FHT), piloted the tool in their practices, and participated in the trial and the interviews presented in this study. We would also like to acknowledge Adrian Laughlin, Patty Chondros, Shilpanjali Jesudason, Jan Radford, Megan Prictor, Paul Amores, and An Tran-Duy for their role in the chronic kidney disease arm of the FHT trial. The Paul Ramsay Foundation has provided funding for staff costs related to the technical development of FHT and the Implementation and Evaluation team members. They have also provided funding for professional staff support and general practice and consumer advisory groups. The Melbourne Academic Centre for Health provided funding for the development of FHT, and the FHT trial is affiliated with the CanTest Collaborative (funded by Cancer Research UK C8640/A23385). CM is supported by The Royal Australian College of General Practitioners with funding from the Australian Government under the Australian General Practice Training Program. The design, management, analysis, and reporting of the study are entirely independent of the funders.

Conflicts of Interest

Future Health Today (FHT) software was developed by The University of Melbourne in collaboration with Western Health. Intellectual property related to FHT is owned by The University of Melbourne.

Abstract

Background: Reductions in opioid prescribing by health care providers can lead to a decreased risk of opioid dependence in patients. Peer comparison has been demonstrated to impact providers' prescribing habits, though its effect on opioid prescribing has predominantly been studied in the emergency department setting.

Objective: The purpose of this study is to describe the development of an enterprise-wide opioid scorecard, the architecture of its implementation, and plans for future research on its effects.

Methods: Using data generated by the author's enterprise vendor-based electronic health record, the enterprise analytics software, and expertise from a dedicated group of informaticists, physicians, and analysts, the authors developed an opioid scorecard that was released on a quarterly basis via email to all opioid prescribers at our institution. These scorecards compare providers' opioid prescribing habits on the basis of established metrics to those of their peers within their specialty throughout the enterprise.

Results: At the time of this study's completion, 2034 providers have received at least 1 scorecard over a 5-quarter period ending in September 2021. Poisson regression demonstrated a 1.6% quarterly reduction in opioid prescribing, and chi-square analysis demonstrated pre-post reductions in the proportion of prescriptions longer than 5 days' duration and a morphine equivalent daily dose of >50.

Conclusions: To our knowledge, this is the first peer comparison effort with high-quality evidence-based metrics of this scale published in the literature. By sharing this process for designing the metrics and the process of distribution, the authors hope to influence other health systems to attempt to curb the opioid pandemic through peer comparison. Future research examining the effects of this intervention could demonstrate significant reductions in opioid prescribing, thus potentially reducing the progression of individual patients to opioid use disorder and the associated increased risk of morbidity and mortality.

KEYWORDS

opioids; peer comparison; quality; scorecard; prescribing; design; implementation; opioid; morbidity; mortality; opioid usage; opioid dependence; drug habits

Introduction

The United States is in an opioid epidemic originally partially fueled by legitimate but inappropriate rates of opioid prescriptions [1-4], with additional waves associated with

nonprescription opioids [5]. Reducing inappropriate opioid prescribing by health care providers is a key element of mitigating the risk of long-term opioid use and potential dependence for patients [6-10]. A well-established way to combat the opioid epidemic is to reduce the number of tablets

and duration of opioid therapy prescribed by health care providers [9,10]. Many guidelines have been created for this purpose; yet, prescribers routinely do not adhere to them [11,12]. Peer comparison holds the potential to improve care [13]. Research on other prescribing habits has demonstrated that when individuals identified as outliers are presented with information about how they defer from their peers, they tend to appropriately alter their prescribing habits [14,15].

The Health Information Technology for Economic and Clinical Health (HITECH) act of 2009 has made electronic health records (EHRs) ubiquitous. By 2017, 95% of US hospitals have been using EHRs [16]. EHRs and the technologies associated with them have been successfully used to combat the opioid epidemic. Electronic prescribing of controlled substances (EPCS) can improve medication safety, and a 2017 study reported that an increasing number of prescribers are prescribing electronically [17]. Prescription drug monitoring programs, which require prescribers to review prior controlled substance prescriptions prior to prescribing, have shown reductions in opioid prescribing rates [18]. Passive clinical decision support at the time of order entry has also demonstrated alterations in opioid prescribing habits [19-24], including that at Thomas Jefferson University [23,25,26].

One advantage of EHR technology is that reliable and accessible data can be used for the generation of informatics-based reports and analytics. Despite the aforementioned efforts to curb the epidemic, there remains a need for health care providers to review prescribing habits and take the initiative to improve their practice [27]. Hayes and Mycnk [27] state the following: "Better understanding of our own behavior will impact those same behaviors. Mindful practice will lead to more deliberate practice and, hopefully, improved patient care." Though peer comparison has demonstrated positive effects with prescribing of antibiotics [14,15], research on peer comparison of opioid prescribing has been limited to the emergency department (ED) setting [28-30] and urologists [31] and has been proposed for oral maxillofacial surgeons [32]. These interventions predominantly focused on the number of prescriptions ordered and do not include other metrics such as morphine equivalent daily dose (MEDD) and how these compare to established prescribing guidelines.

In this paper, we describe the process of designing and implementing an "opioid scorecard" that demonstrates key metrics in opioid prescribing (ie, number of tablets, number of prescriptions, MEDD, and calculated day supply). These metrics include a focus on established guidelines for MEDD thresholds, previously not described in other peer comparison interventions. The thresholds for these metrics are determined at the department level, thus comparing prescribers of similar clinical backgrounds. These scorecards are released electronically on a quarterly basis and present prescribing information at the provider level, and they are distributed to individual prescribers, their department chairs, service-line leaders, and chief medical officers. Here we describe the development of the scorecard, the architecture of its implementation, and plans for future research on its effects.

Methods

Setting

This implementation occurred at a single hospital system: Jefferson Health (an operating division of Thomas Jefferson University). Jefferson Health includes 18 hospitals and over 50 outpatient locations across the greater Philadelphia metropolitan area. Philadelphia is a multicultural and diverse city with large Black and Hispanic populations [33]. Unfortunately, our system is partially located in the county that includes the highest estimated frequency of overdose deaths in the state [34] and contains the neighborhood cited as the source of much of the illicit trade on the East coast [35].

Jefferson Health services over 170,000 inpatient and 6.2 million outpatient visits. The system encompasses 3 divisions: the Center City Division (Thomas Jefferson University Hospital, Jefferson Hospital for Neuroscience and Methodist Hospital), Jefferson New Jersey (Washington Township, Cherry Hill and Stratford Hospitals), and the Northern Division (Abington, Lansdale, Torresdale, Bucks, and Frankford Hospitals). Within the enterprise hospital system, there are 5231 licensed prescribers, ordering over 130,000 opioid prescriptions per year. Our medical leadership noticed variability in opioid prescribing practices across the organization, prompting a need for a novel way to provide asynchronous feedback to reduce practice variation and the impetus for development of the scorecard.

Ethical Considerations

This research was approved by the institutional review board of Thomas Jefferson University (IRB# 21E.083).

Participants

Participants included any individual health care provider who had ordered or authorized an ambulatory prescription for an opioid medication at Jefferson Health in the last 12 months prior to the study period, regardless of division or provider specialty. Health care providers who did not order an opioid prescription in the prior 12 months were excluded.

Defining Metrics

The author's development group consisted of physicians, clinical informaticists, nurses, and analytics experts who are passionate about combating the opioid epidemic. Metrics were first established on the basis of prescribing guidelines developed by the Opioid Task Force (hereinafter referred to as "the task force") for the institution, a governing body that is responsible for vetting policies and procedures for all health care providers within the health care system [36]. The task force, established in the fall of 2017, is a multidisciplinary group composed of over 40 physicians, pharmacists, nursing, and trainees who volunteer their time monthly to promote safe prescribing of opioids and promote the evidence-based management of opioid use disorder (OUD). The task force's thresholds were influenced by recommendations from the Centers for Disease Control and Prevention (CDC) [9,10]. With this insight and guidance, the following metrics were established: (1) total number of opioid prescriptions prescribed, (2) total number of patients to whom opioids were prescribed, (3) total number of prescriptions

ordered for nonchronic patients with OUD greater than a 5-day supply, (4) total number of prescriptions ordered for nonchronic patients with OUD with an MEDD greater than 50, and (5) total number of prescriptions ordered for chronic patients with OUD with an MEDD greater than 90.

Defining the Cohort

To generate the cohort of prescribers and prescriptions, the authors first analyzed EHR data stored in the enterprise clinical data warehouse. The analysis was managed through third-party analytics software (Qlik). The authors generated a data set at the granularity of the prescription level based on various pharmaceutical classes of opioid analgesics, opioid antitussives, and their combinations for all prescriptions ordered or filled (or both) at the institution. Variables included prescriber name and unique identifier codes, the authorizing provider (if one existed for prescriptions ordered by advanced practice providers or house staff) and EHR security identifiers, patient name and identifier codes, and characteristics of the prescriptions including medication name and formulation, dosage, quantity dispensed, duration of treatment, and number of refills. The data set was stored server-side for further analysis. Through previously defined methods, the authors also generated the calculated duration of based on the number of tablets and dosage instructions for each prescription [25]. Our organization is divided into 3 divisions. Prescribers were associated with their primary division and clinical department as documented in the EHR. Providers were included in the analysis if they had ordered an opioid prescription in the last 12 months. This analysis automatically occurs quarterly on a 3-month period. The system architecture is described below.

Calculating Thresholds

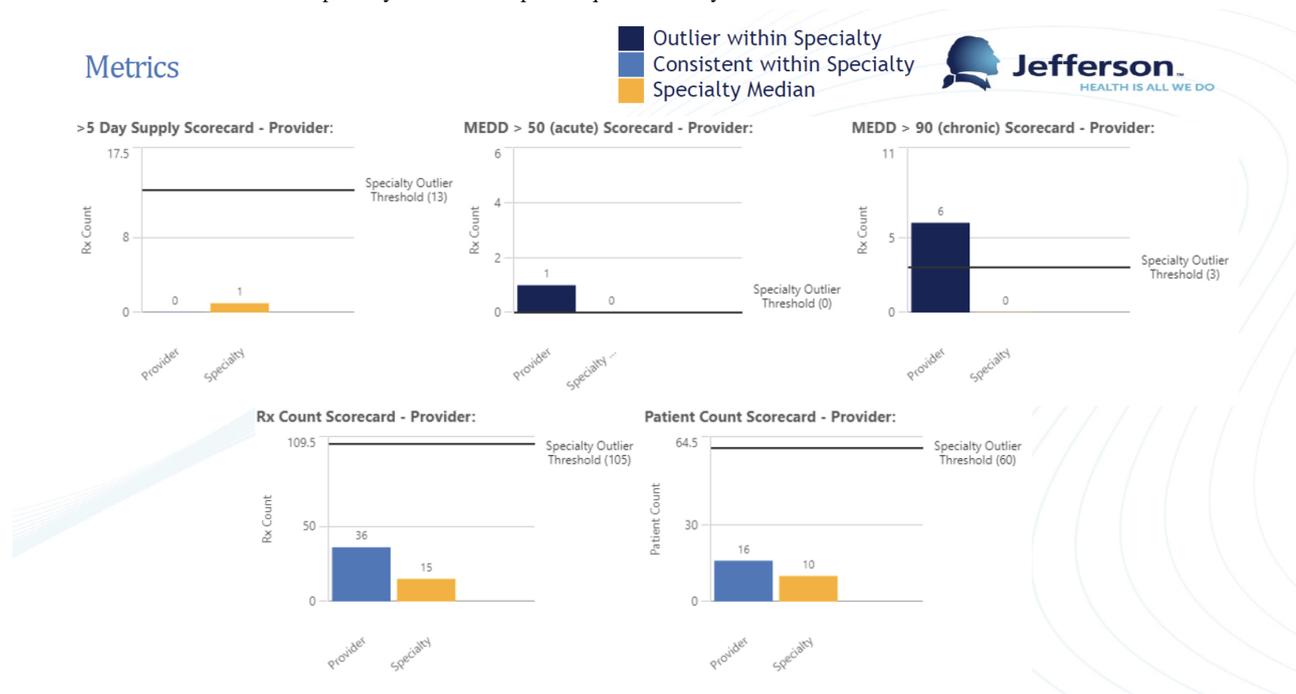

For each specialty within each division, the authors calculated the median number of opioid prescriptions ordered, the median

number of patients to whom prescriptions were ordered for, and the median number of prescriptions for nonchronic patients with OUD greater than 5 days. The authors also calculated the median number of nonchronic patients with OUD per provider who had prescriptions greater than 50 MEDD and the number of chronic patients per provider for prescriptions greater than 90 MEDD. Chronic opioid use was defined as ≥ 3 opioid prescriptions in the last year with an active opioid prescription, which automatically includes the patient in a chronic-opioid use registry. Using the distributions of these same metrics, the authors calculated the IQRs for each specialty per division. The authors defined outlier thresholds for each specialty within the divisions as 1.5 times the IQR for the previously described metrics, and extreme outliers as 3 times the outlier threshold.

Generating Individual Provider Reports

For individual providers, the authors calculated their values for the metrics described above. These values are compared to the calculated thresholds for outliers for their specialty within their division. If the provider is above the specialty threshold for a given metric, they are labeled an outlier. Provider-level scorecards present each of the 5 metrics as bar charts, with the value in question in the y-axis and separate bars for the provider and specialty median on the x-axis. Additionally, a line is drawn parallel to the x-axis to denote the outlier threshold. Graphical representations are color-coded: navy blue when an outlier and teal blue when consistent with their specialty for metrics with thresholds defined by the task force (greater than a 5-day supply, greater than 50 MEDD for nonchronic patients, and greater than 90 MEDD for chronic patients). The specialty medians are represented in yellow. Each scorecard contains a title page, a list of definitions, and the page containing the graphical representations of the metrics. Figure 1 demonstrates a provider score card.

Figure 1. Example of a provider-level opioid scorecard representing the 5 opioid prescribing metrics, specialty metrics for comparison, and graphical representations of thresholds for that specialty. MEDD: morphine equivalent daily dose.

Generating Leadership Scorecards

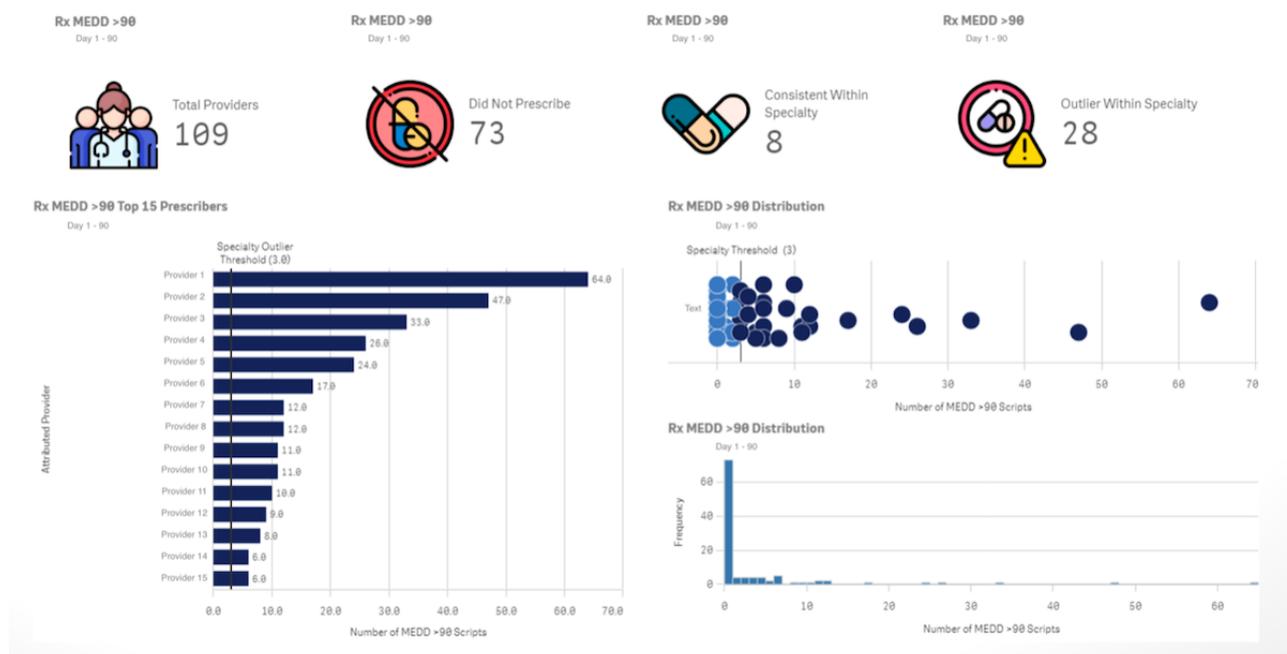

While it is important for individual prescribers to understand their prescribing habits and perhaps reflect on and potentially modify them, it is also important for individuals in leadership positions to understand the trends in prescribing within their department. To this end, the authors created a scorecard that summarizes the prescribing habits of a department in an easy-to-interpret way with graphical representation for service-line leaders and department chairs. This allows them to discuss prescribing habits with individual prescribers and understand trends within their specialty.

A list of departmental leaders including faculty chairs and service-line leaders was compiled for the enterprise. A crosswalk was generated for each specialty to their service-line leader or chair (or both), with some leaders representing more than 1 specialty.

The same metrics described in the individual provider scorecard are represented for specialty leadership with a graphical representation of the providers in their specialty. Each scorecard includes a cover letter and definitions sheet. Each metric gets a dedicated page including descriptive statistics of the number of providers included according to the criteria, the number of those who did not prescribe any opioids in that quarter, the number of those who prescribed opioids but were within the specialty threshold, and the number of individuals prescribing outside the threshold. Leaders also receive a bar chart with the name of each of the top 15 prescribers with a line on the x-axis for the specialty threshold and color-coding indicating whether each provider is within or outside the threshold. They also receive a scatter plot of all providers color-coded as under or over the threshold to better understand the distribution within their department, and a histogram of the total number of prescriptions used for the calculation of that metric. [Figure 2](#) demonstrates a leadership scorecard example of the greater than 5-day duration metric.

Figure 2. Example of a specialty leadership scorecard with described metrics and a graphical representation of top 15 prescribers by name, a color-coded scatter plot of prescribers above (dark blue) and below (light blue) specialty threshold, and a histogram of prescription frequencies.

MEDD >90

Generating Chief Medical Officer Scorecards

Given that the authors’ enterprise organizational structure has 4 separate divisions, the authors wanted to create a report that allowed division chief medical officers (CMOs) and the enterprise CMO the opportunity to comprehend and potentially interview those individuals far outside the threshold of their department. While some individuals (such as pain management or hospice care) may be appropriately prescribing outside of what a typical physician would prescribe, others may be unaware

of their habits and require intervention. To this end, the authors created an automated report of individual prescribers and their metrics, which includes the previously described extreme outlier threshold set at 3 times the specialty threshold. The report is generated as an Excel (Microsoft Corp) file and distributed via email. This report is automatically shared on a quarterly basis, one for each divisional CMO representing their division and a combined summary for the enterprise CMO. An example of the CMO score card is presented in [Figure 3](#).

Figure 3. Example of the chief medical officer scorecard representing top outliers for the greater than 5 days’ supply metric. MEDD: morphine equivalent daily dose.

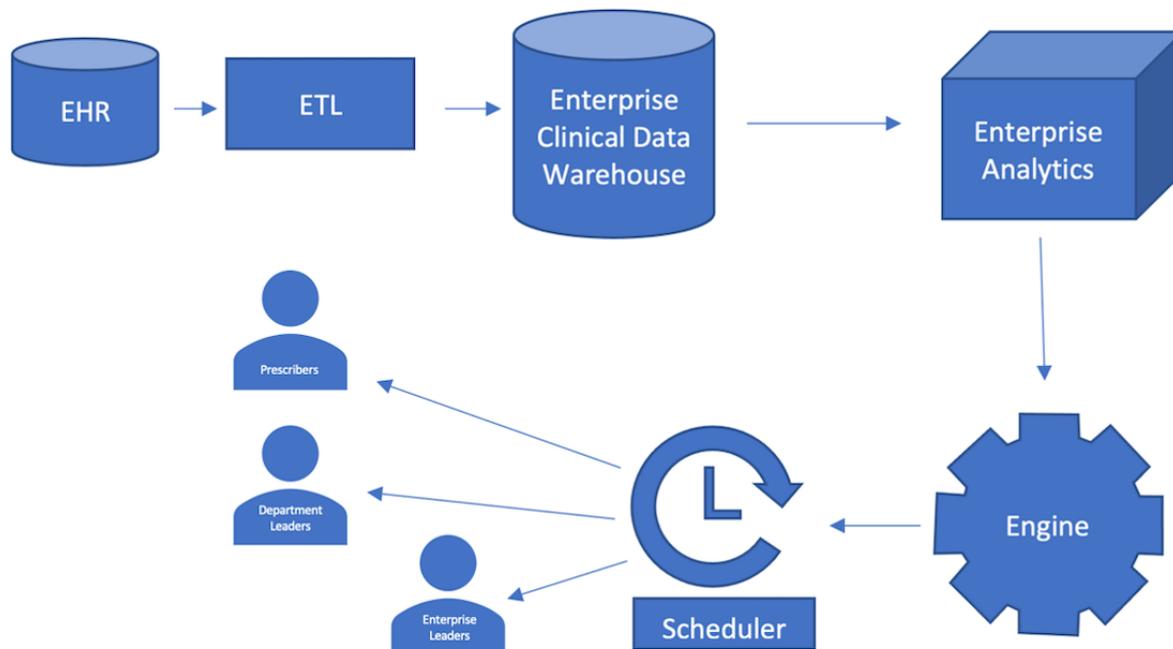

Top Prescribers for Prescriptions for >5 Days						
Division	Attributed Provider Specialty	Specialty Threshold for Opioid Rx >5 Days Duration (any value over this is a statistical outlier)	Attributed Provider	Attributed Provider Count of Opioid Rx >5 Day Duration in Last Quarter	% of Opioid Rx with >5 Day Duration out of Opioid Rx by Authorizing Provider	Factor over Specialty Threshold

System Architecture

The enterprise health system has a robust data analytics system using third-party analytics software. Data from the production EHR are extracted into a database that lives in the enterprise clinical data warehouse (CDW). We used third-party analytics software to extract and manipulate data for analysis and visualization. This third-party software uses its own proprietary language similar to SQL, which is coded by dedicated analysts from the organization’s analytics team. Through an iterative process, metrics were generated, and values were validated via the CDW query and review by clinical informatics experts. Scorecard metrics were also compared to other enterprise reports on opioids to confirm validity. Tabular and graphical representations of the data are refreshed daily and are accessible

to end users via web browser. Quarterly, a report is created by the Enterprise Analytics team, through the third-party analytics software, generated automatically using the established visualizations, and is disseminated as PDF or XLS files to the appropriate recipients via secure enterprise email. Individual prescriber and leadership reports are generated as PDF files attached to individual emails with hyperlinks to the source analytics software to allow easy access by the individual recipient. There is a web-browser version of the reports that is accessible to those who have been granted access, given the sensitive nature of the reports in question. The CMO scorecards are generated as XLS files per the request of the medical leadership who wanted a quick reference report without graphical representation. Figure 4 demonstrates the system architecture.

Figure 4. System architecture for opioid score card based on enterprise analytics workflows. EHR: electronic health record; ETL: Export, Transform, and Load.

Implementation

The authors used a staged approach to the implementation based on access to clinical data in the CDW. Through the development of these scorecards multiple sites came upon the enterprise EHR providing a natural iterative implementation schedule but also

a chance to confirm the enterprise systems could handle increasingly larger calculations and distributions of scorecards. We first piloted in the Center City division, then advancing to the New Jersey and finally the Northern division as each site generated a preimplementation 3-month period of prescribing data in the EHR, to allow for the quarterly nature of the

calculations. Phased go-lives also allowed for ongoing learning and iterative improvements in these processes. Providers received an email from their divisions CMO notifying them of pending receive of the first scorecard, and each quarterly scorecard contains a cover letter from the respective CMO, but no additional education was provided outside of referring providers to their clinical leaders with additional questions. CMOs also provided information to clinical leaders about the scorecard via email prior to initial release.

Statistical Analysis

Statistical analysis was performed using R statistical software (The R Foundation, 2021) to calculate proportions and confidence intervals. We also calculated reduction in prescription frequencies via Poisson regression analysis. To compare proportions of prescriptions outside CDC and Hospital guidelines, we performed a chi-square analysis of the first scorecard data (based on the quarter prior when no individual had ever received a scorecard) to the subsequent 4 quarters.

Results

Overview

A pilot version of the first scorecard was distributed in October 2019. The authors performed a staged approach to distribution, starting with the Center City Division, then expanding to New Jersey, then finally the Northern Division. Completed distribution was successful in September 2021.

To date, the authors have distributed 5 iterations of the quarterly score card over 15 months.

A total of 170 scorecards have been released to 81 service line leaders and departmental chairs over 68 departments within the 3 divisions.

Table . Cumulative counts and percentages of outliers from the first 5 scorecards released for each of the 5 metrics from the 5 largest clinical specialties in the organization.

Specialties	Providers, n	Rx count outliers, n (%)	Patient count outliers, n (%)	>5 day supply outliers, n (%)	>50 MEDD ^a outliers, n (%)	>90 MEDD outliers, n (%)
1	212	33 (15.57)	35 (16.51)	42 (19.81)	60 (28.30)	6 (2.83)
2	195	26 (12.26)	28 (13.21)	63 (29.72)	41 (19.34)	39 (18.40)

^aMEDD: morphine equivalent daily dose.

Prescribing Impact

We examined the iterative scorecard releases to determine if there was an effect on opioid prescribing. Given the phased implementation process, the Center City Division was the only division of the organization with a full 5 quarters of scorecard releases, so this division was isolated for analysis. There were 2,147,710 opioid prescriptions ordered by this division during the study period. From the date of initial release, there was a

Five scorecards have been released to the 4 CMOs across 3 divisions and 1 enterprise CMO.

Prescriber Demographics

Upon the most recent distribution, which was the first to include all divisions, 2034 prescribers (38.9% of the eligible 5231 prescribers) received opioid scorecards from 68 specialties. As described above, this indicates that they have prescribed an opioid in the last 12 months, regardless of outlier status. Of these individuals, 1416 (69.7%) were attending physicians, 331 (16.3%) were nurse practitioners, 168 (8.3%) were physician assistants, and 111 (5.5%) were residents with independent Drug Enforcement Administration licenses.

Outlier Demographics

There were 386 (19.0% of 2034 opioid prescribers, 7.31% of the 5231 licensed prescribers) individuals who were considered outliers in their specialty for at least 1 metric. Of them, 188 (48.7%) were outliers for total number of prescriptions, 162 (42.0%) were outliers for the number of patients prescribed opioids, 125 (32.4%) were outliers for prescriptions ordered for nonchronic patients with prescriptions greater than 5 days, 118 (30.6%) were outliers for prescriptions greater than 50 MEDD for unique nonchronic patients and 113 (29.3%) were outliers for prescriptions greater than 90 MEDD for chronic patients.

Table 1 demonstrates cumulative counts and percentages of outliers from the first 5 scorecards released for each of the 5 metrics from the 5 largest clinical specialties in the organization, deidentified to protect participating physicians. Notably, at least 10% of providers were considered outliers in at least 1 metric during the initial 5 scorecard releases.

significant reduction in the frequency of opioid prescriptions at the division, with an associated 1.60% reduction per quarter ($P < .001$). There was a significant reduction in prescriptions for nonchronic patients longer than 5 days' duration before versus after intervention. There was also a significant reduction in the proportion of prescriptions >50 MEDD for nonchronic patients and an increase in that of prescriptions >90 MEDD for chronic patients (Table 2).

Table . Pre- and postintervention proportions, 95% CIs, and *P* values for >5-day durations, >50 MEDD^a for nonchronic patients with opioid use, and >90 MEDD for chronic patients with opioid use^b.

Study period	>5-days duration		>50 MEDD for nonchronic patients		>90 MEDD for chronic patients

Discussion

Principal Findings

The objective of this study is to describe an evidence-based peer comparison opioid scorecard. By sharing this process of design and distribution, we hope to inspire similar processes at other organizations. Here we demonstrate the successful distribution of scorecards to 19% (386/2034) of eligible opioid prescribers over a 5-quarter time frame. Initial analysis demonstrates that in all 5 of the largest specialties, at least 10% of providers were outliers in at least 1 metric (Table 1). This is most notable in specialties 1 and 3 where over 20% of providers had prescriptions greater than 50 MEDD for nonchronic patients, and over 19% of providers in specialties 1, 2, and 4 had prescriptions over 5 days' supply for nonchronic patients. These results demonstrate the need for intervention and providing information to individual providers on their prescribing practices at the organization.

Over the study period, the authors demonstrated a quarterly reduction in overall opioid prescriptions of 1.6% per quarter. When comparing the data that were used to generate the initial scorecard (the quarter prior to scorecard release) versus the subsequent 4 quarters, there was a small but significant reduction in the proportion of prescriptions longer than 5 days' duration and greater than 50 MEDD for nonchronic patients (0.6% and 0.3%, respectively). While the proportions were small overall, the median quarterly prescribing rate at this division was over 420,000 prescriptions, yielding a quarterly reduction of over 2500 prescriptions over 5 days and 1200 prescriptions over 50 MEDD. There was also a very small but significant increase in chronic patient prescriptions greater than 90 MEDD (0.16%), resulting in approximate 672 additional patients with this level of MEDD per quarter. Given the nature of this study, it is unclear if these are patients who transitioned from nonchronic to chronic dosage changes, or if this change was due to other external factors that influenced prescribing habits.

Since the early 1990s, opioid prescribing has consistently increased [37] to the point that in 2016, there were 66.5 opioid prescriptions for every 100 persons in the United States [38]. There is a link between long-term use of prescription opioids and a transition to illicit heroin [39] with increasing mortality [40]. Higher doses and longer treatment time of prescription opioids have been linked to an increased risk of chronic opioid use [6-8]. Therefore, a principal method of combating the opioid epidemic is to reduce prescribing by health care providers. To this end, the CDC's 2016 guidelines recommend that caution

be exercised when increasing doses to greater than 50 MEDD, and doses greater than 90 MEDD should be avoided. The CDC also states that 3 days or less is often sufficient for acute pain, and more than 7 days is "rarely needed" [9,10]. Our organization has accordingly recommended maintaining prescriptions for acute pain at 5 days and less than 50 MEDD, based on these guidelines. The inclusion of these evidence-based metrics in the scorecard justifies its evidence-based nature.

Peer comparison has been demonstrated to be an effective means of modifying unwanted or unintended behavior among health care providers [14,15,28-31]. Andreck et al [28] and Boyle et al [29] both demonstrated reductions in prescribing rates after peer comparison reports were initiated in their EDs. Michael et al [30] performed a randomized controlled trial of ED physicians and demonstrated a relationship between the perceived rate of prescribing and a reduction when presented with peer comparison data. Suffoletto and Landaou [41] demonstrated that peer comparison was an important contributor to improved prescribing habits compared to audit and feedback alone. While limited to the ED, these research studies justify our approach to peer comparison and confirm that prescriber's own perceptions of their prescribing habits are critical to successful intervention.

Research beyond the ED is limited regarding peer comparison of opioid prescribing. Jacobs et al [31] demonstrated that peer comparison, as well as education and audit feedback, contributed to significant reductions in prescribing by urologists. Weiner et al [42] describe a system-wide initiative that successfully reduced opioid-related morbidity and mortality. They include a mention of "benchmarking reports" with peer comparison elements but do not further detail what was included in these reports or how they were delivered.

Despite evidence of its positive impact on prescribing, a report such as the one presented in this paper has never been produced outside of isolated EDs nor has it been implemented as broadly. The intervention described here is sent to all prescribers, regardless of level of training or clinical specialty, providing them with detailed metrics on their opioid prescribing habits and peer comparison based on clinical specialty. Additionally, most of the previously described department-level interventions focus on opioid prescribing frequency without consideration toward prescribing guidelines such as those recommended by the CDC. The only other system-wide effort described in the literature contains limited information on what was included in their reports, how information was portrayed, and how they were delivered, but rather focused more on other elements of their substantial and impressive system-wide intervention.

The methods described in this paper have the potential to change clinical practice paradigms by using a novel intervention implemented at a larger scale than previously described in the literature. While peer comparison has been used previously in this manner (as described above), little is known about how such a tool could be used on an enterprise hospital level, with multiple divisions encompassing multiple practice specialties across 2 states. As longer and higher doses of opioids are associated with long-term use and potential for OUD, educating prescribers on their opioid prescribing habits can potentially reduce the prescription quantity and duration at the prescriber level, thus potentially mitigating the risk of long-term use at the patient level.

The scorecards received by prescribers contain multiple metrics including the number of prescriptions, number of patients, and MEDD thresholds. Outlier thresholds based off IQRs are calculated quarterly. We appreciate that overtime variability in prescribing patterns may reduce, resulting in lower thresholds that are incapable of driving impact. Currently, all scorecards are delivered with instructions on how the metrics are derived, and they are informational and nonpunitive in nature. Providers are instructed that concerns regarding metrics should be discussed with departmental chairs or service line leaders to determine whether intervention is required. Reinforcement of appropriate prescribing guidelines by leaders was not systematically carried out; however, such systematic enforcement holds promise for further reduction in inappropriate prescribing.

The authors intend to continue to prospectively track the metrics associated with each scorecard release. By measuring descriptive statistics for each specialty to determine whether there are changes in that specialty's prescribing habits before and after intervention, as well as through a time series post intervention, the authors hope to demonstrate the impact that the scorecard and enterprise-level peer comparison can have on opioid prescribing beyond the initial results presented here. The authors will also evaluate frequencies with which individual prescribers are identified as outliers and track any changes in metrics of individual high-prescribing providers. The authors are also tracking quarterly thresholds as a measure of improvement in practice variation and to determine whether prolonged periods of stasis imply that no further reduction in practice pattern variability can be achieved.

Given this effective implementation, positive results could allow for broadening of the scope of the study and for massive scalability. The system described is EHR-agnostic given the use of third-party reporting software, meaning that data sources from other hospital systems could be integrated and similar reports can be generated on a regional, state, or even federal level.

Additionally, while this project is intended to address opioid prescribing for which clear practice guidelines have been established by the CDC, the application of automated peer comparison reports and assessment of their effects on practice patterns can be extended to topics including but not limited to antibiotic prescribing, imaging usage, laboratory test ordering,

and specialty consultation. Automated peer comparison could have the potential to reduce cost and improve the quality of care when designed around appropriately established clinical guidelines.

Limitations

There are several limitations that should be addressed. Our study was performed at a single hospital system, and it is unclear if our intervention would have similar effects at institutions dissimilar to ours in different geographical regions. Additionally, we cannot account for all confounders that may have been contributed to reductions in opioid prescribing outside of our intervention. Our organization has historically used multiple interventions to curb the opioid epidemic including but not limited to requiring the review of state prescription drug monitoring programs prior to outpatient prescribing and standardized dosing for opioids in our EHR. However, there were no concurrent internal interventions during the time of the implementation, though external influences such as state and regional educational efforts could have impacted prescribing. As mentioned above, we also cannot account for possible transitions of patients from nonchronic to chronic cohorts during the study period, which may have contributed to the small increase in nonchronic prescribing, though it is also unclear if external factors may have contributed to this finding. Additionally, with regard to prescriptions, we only examined trends in opioid prescribing and did not examine whether there were any contrary changes in other nonopioid medications as an unintended consequence of this intervention. Finally, in late 2022, the CDC updated their opioid prescribing guidelines, which have transitioned from the specific acute and chronic thresholds for MEDD to more general recommendations on prescribing the lowest dose of opioids possible to achieve pain control, with detailed information on the risks of doses above 50 MEDD [43]. The intervention detailed here was developed for the 2016 guidelines, and our organization still supports the prescribing thresholds developed from them. Modifications to this intervention will be developed while pending institutional transitions to the new prescribing guidelines.

Conclusions

Modern EHR technology, advanced analytics, and a robust reporting infrastructure allowed for the generation of an enterprise-level opioid prescribing scorecard that uses peer comparison to provide individual providers with feedback on their prescribing habits. The authors also have successfully developed departmental leadership and CMO reports for oversight and advanced intervention regarding potentially problematic prescribers. Initial results over a 5-quarter period imply reductions in overall opioid prescribing rates as well as improvement in the duration and dose for nonchronic patients, though there was a small increase in prescriptions over 90 MEDD. Future research on the impact of such a scorecard could be pivotal in combating the opioid epidemic, potentially scaling such an intervention to larger geographical regions, and broadening the use of such a tool outside the opioid epidemic. Investment in informatics and analytics holds the potential to have profound impacts on the quality of care and patient safety.

Authors' Contributions

BHS drafted the manuscript with significant contributions to the final version from all authors. The intervention was designed by SH, MM, CM, TB, ML, and BHS with supervision by EAP. SH provided the data with initial analysis by SH, MM, and CM. Further analysis and interpretation were provided by all authors.

Abstract

Background: A future shortage of physicians, especially in general practice, will result in an increasing workload for health care providers as a whole. Therefore, it is important to optimize patient-encounter processes to increase time efficiency related to visits. Utilizing digital tools to record patients' medical histories prior to a consultation offers great potential to achieve this goal. The collected information can be stored into the practice's electronic medical record, allowing for the general practitioner to review structured information of the patients' complaints and related medical history beforehand, thereby saving time during the encounter. However, the low usability of new digital developments in this setting often hinders implementation.

Objective: The aim of this study was to evaluate the usability of an app designed for medical history taking in general practice to capture the patients' perspective.

Methods: Between November 2021 and January 2022, we recruited 406 patients with acute complaints in one out-of-hour urgent care and seven general practice clinics. These study participants used the app during their waiting time and subsequently assessed its usability by completing the System Usability Scale (SUS), a robust and well-established 10-question survey measuring the perceived usability of products and technologies. Additionally, we collected general participant information, including age, sex, media usage, health literacy, and native language. Descriptive and inferential statistics were applied to identify patient characteristics associated with low or high SUS scores.

Results: We analyzed data from 397 patients (56.7% female, 43.3% male). The mean total SUS score was 77.8 points; 54.4% (216/397) of participants had SUS scores of 80 points or higher, indicating high usability of the app. In a multiple linear regression predicting SUS score, male sex and higher age (65 years or older) were significantly negatively associated with the SUS score. Conversely, a higher health literacy score and German as the native language were significantly positively associated with the SUS score.

Conclusions: Usability testing based on the SUS anticipates successful implementation of the app. However, not all patients will easily adapt to utilizing the app, as exemplified by the participants of older age in this study who reported lower perceived usability. Further research should examine these groups of people, identify the exact problems in operating such an app, and provide targeted solutions.

Introduction

As in many countries, demographic change is becoming evident in the German health care system, resulting in more complex, multimorbid patients [1] and a shortage of physicians [2]. Moreover, the proportion of older people in the population is rising steadily [3] and people tend to use medical services at a higher rate as they increase in age [4]. In Germany, one group that is particularly affected by this development are general practitioners (GPs) who are the first point of contact for patients requiring medical care and serve as the “gatekeepers” in the German health care system [5]. Approximately 80% of the German population aged 18 years and older are treated by a GP at least once a year [6]. A considerable number of GPs will retire in the upcoming years, resulting in 11,000 GP vacancies expected by 2035. These vacancies will disproportionately impact structurally weak and rural areas [7,8]. Without a sufficient workforce to replace the retired GPs and meet the greater demand for physicians, remaining GP workloads are expected to increase significantly within the next decade [9]. These developments challenge the German health care system at various levels and require attention to address the following key issues: future financing, improving allocation of resources, ensuring access to care, increasing efficiency and effectiveness of health care provision, and strengthened collaboration between providers [10].

To streamline patient care in the upcoming years, it is of importance to optimize patient-encounter processes to increase time efficiency related to visits. In this respect, digital tools offer great potential to support GPs in patient management, documentation workload, and the collection of medical history before consultation.

Digital tools designed to collect patients’ medical history can ensure that information is always collected and documented thoroughly in a structured manner and with consistent quality. As many conditions can be diagnosed via a thorough medical history [11,12], these tools can be helpful in maintaining quality of care when time constraints may lead to an otherwise superficial medical history.

As part of our project titled “Digitally assisted information acquisition before medical consultation” (DASI), we developed an app for medical history taking in general practice settings. The app is used by the patient prior to the medical consultation, which could be either in the waiting area or at home. The collected information can be stored in the practice’s electronic medical record and eventually be transferred to the individual electronic patient file, which statutory health insurers in Germany have been entitled to use since 2021 [13]. In the electronic patient file, patient data such as medical reports, X-rays, immunization records, and other medical data can be stored and shared among medical providers involved in the care of a particular patient by using the telematics infrastructure [14].

One advantage of the app is that the GP can review structured information of the patients’ complaints and related medical history before the encounter. This is particularly helpful for patients that are unknown to the provider, those with many complaints, or those who have a comprehensive medical history.

These situations are especially prevalent in out-of-hour urgent care practices. Furthermore, the tool might help patients to reflect on their conditions and enable them to better address their needs when seeing the provider. In this way, we expect that the limited consultation time can be used more efficiently.

Despite Germany’s progress in digitalization within the health sector, concerns remain about the limited usability of new digital tools, hindering their full implementation. More than half of German practices see low usability as a strong obstacle to digitalization [15]. The evaluation of a digital tool’s perceived usability is of special interest as it is a key determinant of performance for end users. Therefore, the aim of this study was to assess the usability of the app from the patients’ perspective and to identify features in need of improvement. The broader aim is to ensure that the app is suitable for implementation in everyday practice, considering that GPs treat a broad range of patients of all ages and various educational and cultural backgrounds [16].

Methods

Study Design and Recruitment

This was a cross-sectional study conducted in Germany in one out-of-hour urgent care practice and seven GP practices to assess the usability of an app designed for medical history taking in general practice settings.

Software and Hardware

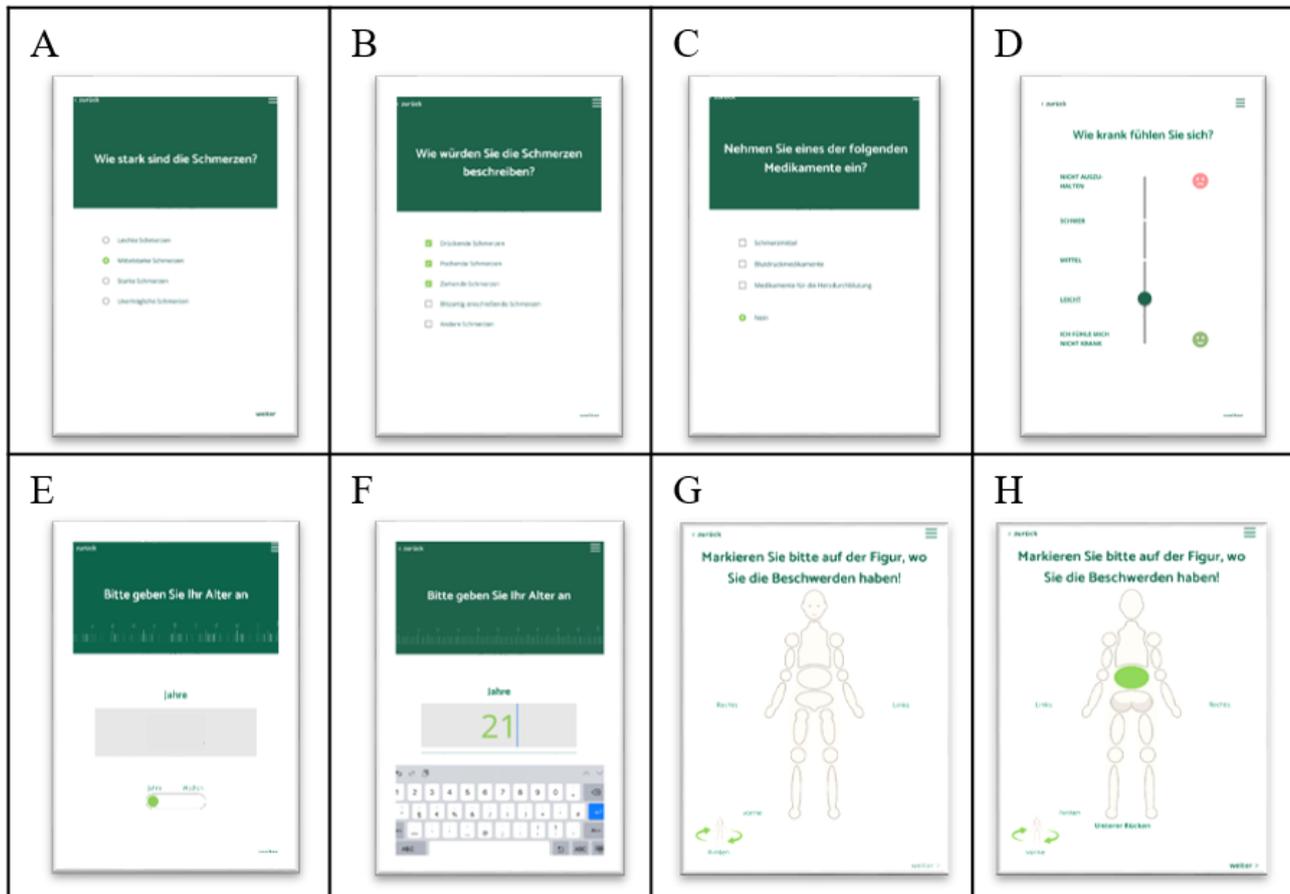

The app was developed to take a medical history based on general medical complaints directly from the patients. While there are no international standards for the composition of a standardized patient history, this app was developed based on guidelines and health literature by medical experts from aidminutes GmbH (Hamburg/Buchholz in der Nordheide, Germany). For this study, the content and query structure were further refined for primary care (general practice and out-of-hour practices) by aidminutes GmbH in collaboration with experienced researchers from the Department of General Practice at the University Medical Center Göttingen, Germany. The app was designed to be used by patients in the waiting room before they see the doctor. Patients select one or several complaints and are then guided through a symptom-related questionnaire. In the sense of a branching logic, the app is adaptive to patient responses, which trigger further specific questions about the selected key complaints (eg, how and when a symptom started). Patients are also asked about preexisting conditions, previous treatments and surgeries, current medication, living habits, and chronic conditions in the family history. Information such as biological sex, height, weight, age, as well as the subjectively perceived severity of the complaints are inquired from all patients. More details can be found in the published study protocol [17].

The app was designed to be intuitive for the user such that no prior knowledge or any kind of instruction for its use is necessary. The user interface was designed to be simple to follow and only one question is asked per screen. As the app is operated in the waiting area, sound and video output of an earlier version [18] was omitted due to data protection. The questions

are phrased in plain language; medical terminology is avoided or otherwise explained. The questions are substantially comprised by single-choice or multiple-choice questions that can be answered by tapping but also include several data fields (for age, height, and weight) and slider-type questions (Figure

1). The color scheme was designed to ensure reading accessibility for patients who may be color blind. A zoom function can be used for users who may experience visual impairment.

Figure 1. Screenshots of the app for medical history taking in general practice showing different types of questions: (A) single-choice question; (B) multiple-choice question; (C) hybrid question (ie, patients can either select several options or negate all of them); (D) slider for questions including a ranking between items (depicted here as “How sick do you feel?”); (E, F) data entry field (here: “Please enter your age”); and (G, H) selection of a body region on a figure (depicted in figure: “Please mark on the figure where you are suffering from the problems”).

As this is a web-based app, it relies on a permanent internet connection. For this study, the app ran on an iPad Mini 4 (Apple Inc, Cupertino, CA, USA) held in an upright position. Tablets were equipped with haptically and visually inconspicuous cases (dark grey polyurethane leather outside and microfiber inside).

Setting

In Germany, GP practices aim at providing preventive, acute, and rehabilitative health care with long-lasting patient-doctor relationships. Out-of-hours urgent care practices provide urgent medical care for acute but not life-threatening cases when other practices are closed. Urgent care practices are often staffed with doctors of various specialties and an established relationship of care between the patients and doctors is not common. These aspects can lead to challenges in efficiently obtaining an accurate medical history and identifying serious health problems. Although the app was designed for general practice, it is also suitable to be used in out-of-hour urgent care practices.

Data Collection

The recruitment of patients was carried out by three study nurses and took place from November 22, 2021, to January 12, 2022. Patients were approached by study nurses in the waiting room of the respective practices before seeing their GP.

Patients meeting the following criteria were eligible to participate in the study: (1) seeking care in a participating practice because of acute somatic and/or psychological complaints, (2) at least 18 years old, and (3) consenting to participate in the study. Patients meeting the following exclusion criteria could not participate in the study: (1) younger than 18 years old (legal minor), (2) patients in an apparent emergency, (3) patients who required immediate medical treatment, and (4) patients who were unable to provide consent.

After the study nurses obtained written informed consent, a tablet on which the app was run on was handed over to the study participants. Participants used the app to report their medical history without an introduction on how to navigate the app. Once finished, they were asked to answer questions on personally perceived usability, media usage, and further

sociodemographic data, which were digitally attached to the medical history-taking document. The study nurse in charge was present to observe any problems study participants may have had with using the app and was available to answer questions about the app's content and usability if specifically requested. Data were collected in an anonymized format without any personal information (eg, name or address) linking the results to each study participant. More detailed information on the data collection can be found in the study protocol [17].

Ethical Considerations

The Medical Ethics Committee of the University Medical Center Göttingen approved the study (approval number 26/3/21). A written informed consent form was collected from all patients before their inclusion in the study. Participating in the study was voluntary for patients. Patients could withdraw from participation without giving a reason at any time before they had completed the survey. Subsequently, their data could no longer be deleted because it could not be traced back to the individual.

Measures

The main outcome “usability” was measured using the System Usability Scale (SUS) [19], a commonly used instrument for this purpose [20]. The SUS was developed based on Standard ISO 9241-11 [21], in which usability is measured by the three

main attributes of “effectiveness,” “efficiency,” and “satisfaction” [22,23]. Compared to other instruments, the SUS offers several advantages: (1) it can be analyzed quickly, (2) it is relatively easy to understand by academics from other disciplines [24], (3) it contains only 10 statements for easy completion, and (4) it can be used to evaluate almost any type of user interface [25]. We used the translated and validated German version of the SUS [26] and modified the statements to suit our purpose (see [Multimedia Appendix 1](#)).

The SUS consists of 10 statements ([Table 1](#)), where statements 1, 3, 5, 7, and 9 are positively connoted and statements 2, 4, 6, 8, and 10 are negatively connoted [19]. The scores for these statements are therefore inverted when calculating the sum. The raters decide on the extent to which they agree or disagree to these statements on a 5-point Likert scale ranging from 0 (strongly disagree) to 4 (strongly agree). The final sum score is multiplied by 2.5, resulting in a score range of 0-100 with higher scores indicating better usability [19].

Lewis and Sauro [27] developed a curved grading scale for SUS scores by comparing more than 200 industrial usability studies and using the percentile ranges, resulting in grades “C” (scores of 62.7-72.5), “B” (scores of 72.6-78.8), and “A” (scores of 78.9-100). As a SUS score of 80 proves an above-average user experience, it has become a common industrial goal. This threshold was therefore used for interpreting our results.

Table 1. Items of the System Usability Scale (SUS) [19].

Items	English version of the statement
SUS 1	I think that I would like to use this system frequently
SUS 2 ^a	I found the system unnecessarily complex
SUS 3	I thought the system was easy to use
SUS 4 ^a	I think that I would need the support of a technical person to be able to use this system
SUS 5	I found the various functions in this system were well integrated
SUS 6 ^a	I thought that there was too much inconsistency in this system
SUS 7	I would imagine that most people would learn to use this system very quickly
SUS 8 ^a	I found the system very cumbersome to use
SUS 9	I felt very confident using the system
SUS 10 ^a	I needed to learn a lot of things before I could get going with this system

^aThe scores of negatively connoted SUS items were inverted when calculating the sum.

Covariates

Consultations in general practice are attended by patients of different ages and educational as well as cultural backgrounds, who have a different quantities of digital interactions in everyday life. To determine whether these factors have an influence on the personally perceived usability, we surveyed age, sex, media usage, health literacy, and native language. Information about age and sex were part of the app-taken medical history. In addition to the SUS, we asked patients about which digital media tools were available to them in everyday life (possible answers: cell phone/smartphone, computer/laptop/notebook, tablet, television, none, and others; multiple answers were possible)

and how many hours a day they used digital media (possible answers: 0-≤1, 1-≤2, 2-≤3, 3-≤4, or 4 or more hours). We asked three questions concerning health literacy as a proxy for education attainment, given that educational achievement is the central determinant of health literacy [28]. Questions covering the three aspects of finding/accessing, evaluating/appraising, and understanding health-related information and content were derived from the European health literacy survey [29,30] adapted for the German language (HLS-GER 2 [31]). The HLS-GER 2 uses a predefined 4-point Likert scale.

Statistical Analysis

Data from the app were saved into a database and subsequently exported to a tab separated format for further analyses. Participants with two or more missing values of the SUS questionnaire were excluded from statistical analysis. In the case of one missing SUS response, we substituted the missing value with a neutral score of 2, as this method has been used with the SUS in previous research [32].

Sociodemographic data are presented as number and percentage of patients for each categorical data point. Mean and SD were utilized for interval or ratio-scaled data, which has become a common industrial goal. Sociodemographic data were compared between participants with SUS scores <80 and ≥ 80 using the Fisher exact test for 2×2 tables or the Fisher-Freeman-Halton test for categorical variables and the Wilcoxon rank-sum test for continuous variables. A multiple linear regression was conducted using sex, age, native German language, health literacy score, media usage duration per day, sickness level of the participants, and number of stated complaints in the app as

independent variables and the SUS score as the dependent variable. Additionally, the individual SUS items were compared according to sex, age (<65 years vs ≥ 65 years), German native language, and tablet usage with the Wilcoxon rank-sum test. Data are visually presented as boxplots and radar charts. All analyses were carried out using R (4.1.3 under a GNU license) with the packages fmsb [33], psych [34], tidyr [35], dplyr [36], and ggplot2 [37].

Results

Patient Characteristics

We aimed to include approximately 400 patients for this study. This target was set to be able to form subgroups and to ensure that all types of patient complaints were included in our sample, including those selected on a limited basis. In total, individual data from 397 participants were included, with 5 participants having one missing SUS item. Figure 2 shows the flowchart of included patients and Table 2 shows the patients' characteristics.

Figure 2. Flowchart of patient inclusion in the cross-sectional study capturing patients' perceived usability of the app. SUS: System Usability Scale.

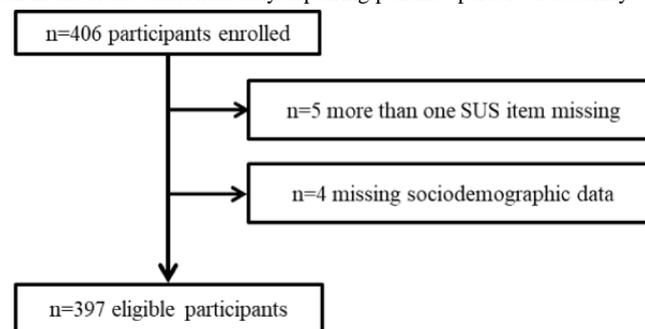

Table 2. Characteristics of the participants of the cross-sectional study capturing patients' perceived usability of the app (N=397).

Characteristics	Value

^aMultiple selection possible.

^bMeasured on a 4-point (0-3) Likert-scale (higher scores indicate higher health literacy levels).

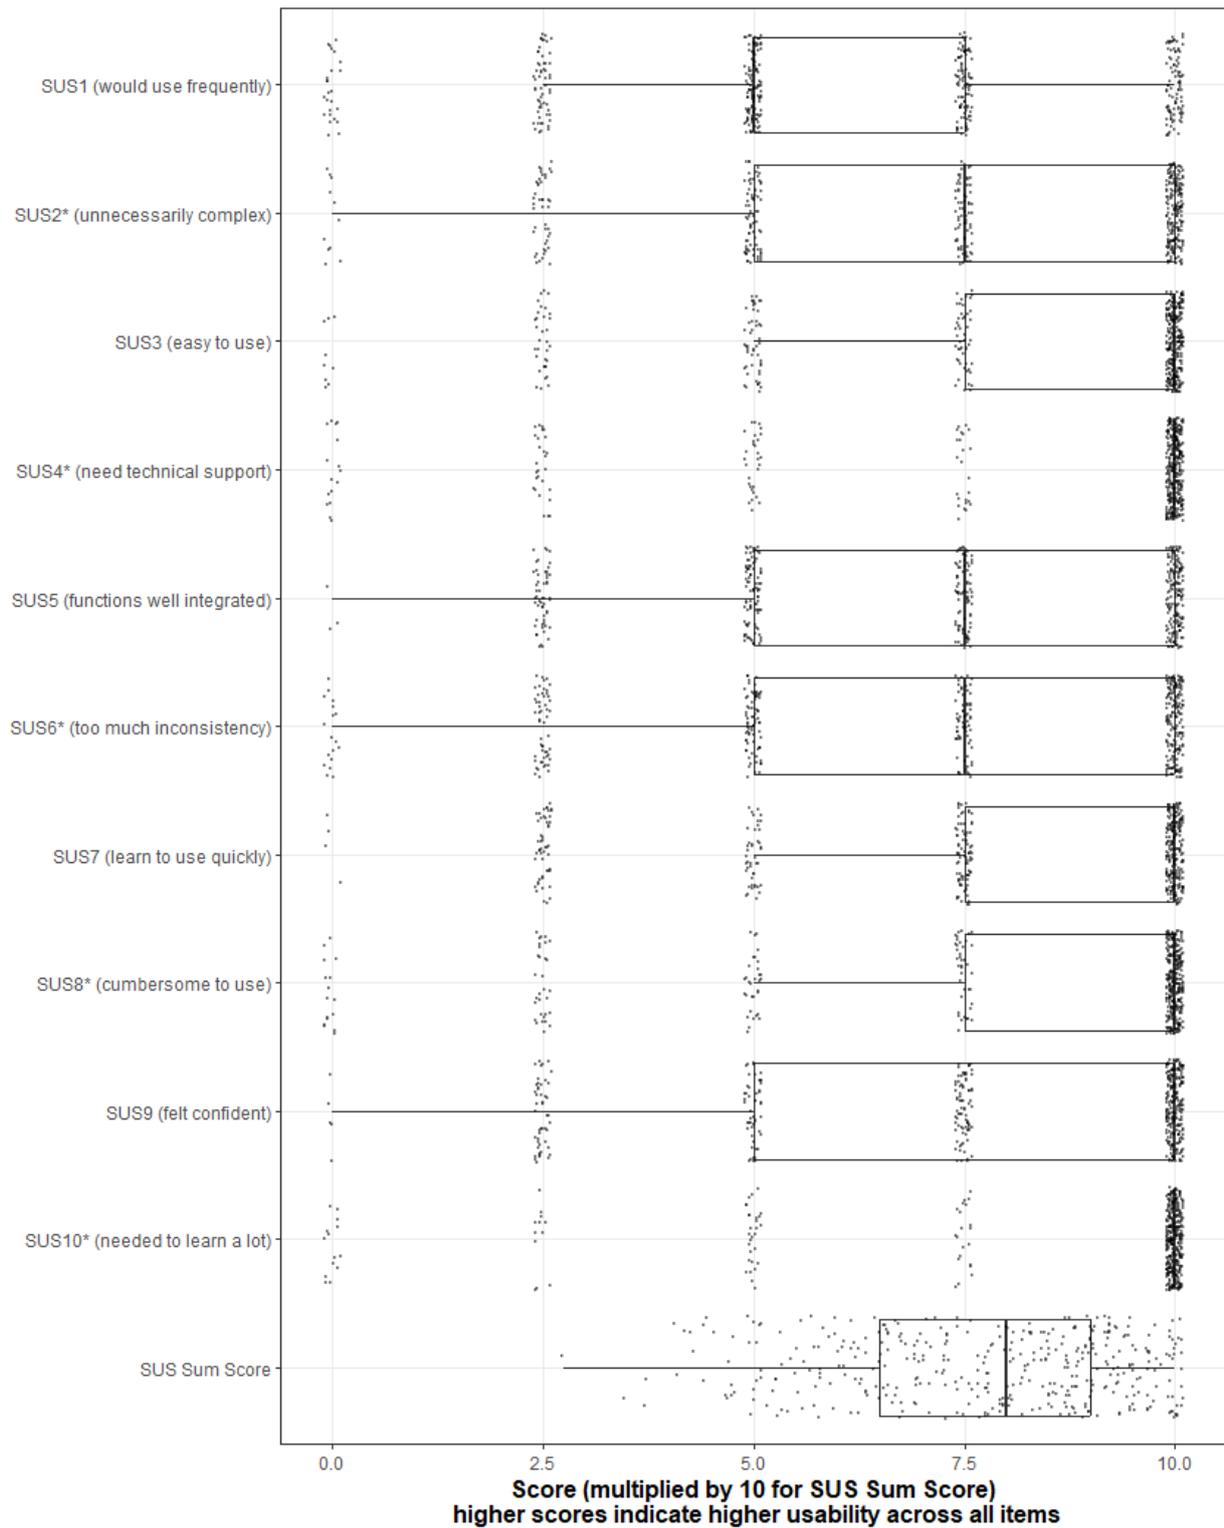

^cPerceived severity of acute complaint.

Usability for All Participants

We found a mean total SUS score of 77.8 points, with 54.4% (216/397) of participants having SUS scores of 80 points or higher, indicating high usability of the app overall. [Figure 3](#)

shows boxplots of the individual items in which the scores were calculated for each statement. Irrespective of a positive or negative connotation, a higher score indicates a better result. The maximum score that can be achieved for each item is 10.

Figure 3. SUS items and sum scores for all study participants (N=397). SUS: System Usability Scale. *Scoring was inverted.

Usability Stratified by Sociodemographic Factors

We divided the sample into two groups with the cutoff at a SUS score of 80. Participants with a SUS score of at least 80 were

significantly younger, reported higher levels of technology device usage, and higher levels of self-assessed health literacy compared to participants with a SUS score below 80 (Table 3).

Table 3. Sociodemographic variables of study participants stratified by System Usability Scale (SUS) score.

Variable	SUS score<80 (n=181)	SUS score≥80 (n=216)	P value
Sex, n (%)			.09 ^a

A multiple linear regression predicting the SUS score was conducted, including sex, age, native German language, health literacy score, media usage duration per day, sickness level of the participants, and number of stated complaints in the app as independent variables (see Table 4). Age, sex, health literacy score, and German native language were significantly associated

with SUS score. A higher age ($t_{385}=3.30$, $P=.001$) and male sex ($t_{385}=1.98$, $P=.05$) were negatively associated with SUS score, whereby a higher health literacy score ($t_{385}=2.83$, $P=.01$) and German as a native language ($t_{385}=2.51$, $P=.01$) were positively associated with SUS score.

Table 4. Multiple linear regression predicting the System Usability Scale sum score.

Variable	β (95% CI)	<i>P</i> value
Male sex (reference=female)	-3.21 (-6.40 to -.02)	.05
age (per year)	-.17 (-.27 to -.07)	.001
German not native language (reference=yes)	-5.39 (-9.61 to -1.17)	.01
Does not use tablet (reference=yes)	-1.44 (-4.66 to 1.79)	.38
Average daily media usage (reference=<2 h)		
2-4 h	3.21 (-.95 to 7.37)	.13
>4 h	.01 (-4.46 to 4.48)	.99
Health literacy score (scale 0-9) ^a	1.48 (.45 to 2.51)	.01
How sick do you feel? (score 1-5) ^b	-1.05 (-2.92 to .82)	.27
Number of stated complaints (1-11)	-.98 (-2.11 to .15)	.09

^aHigher scores indicate a higher level of health literacy.

^bPerceived severity of acute complaint; higher values indicate a higher level of discomfort.

Differences in Individual Items of the SUS

Stratified according to sex, age, native language, and tablet usage (see Figure 4), significant differences were detected in SUS items 2 (“unnecessarily complex”), 4 (“need technical support”), 7 (“learn to use quickly”), 8 (“cumbersome to use”), and 10 (“needed to learn a lot”).

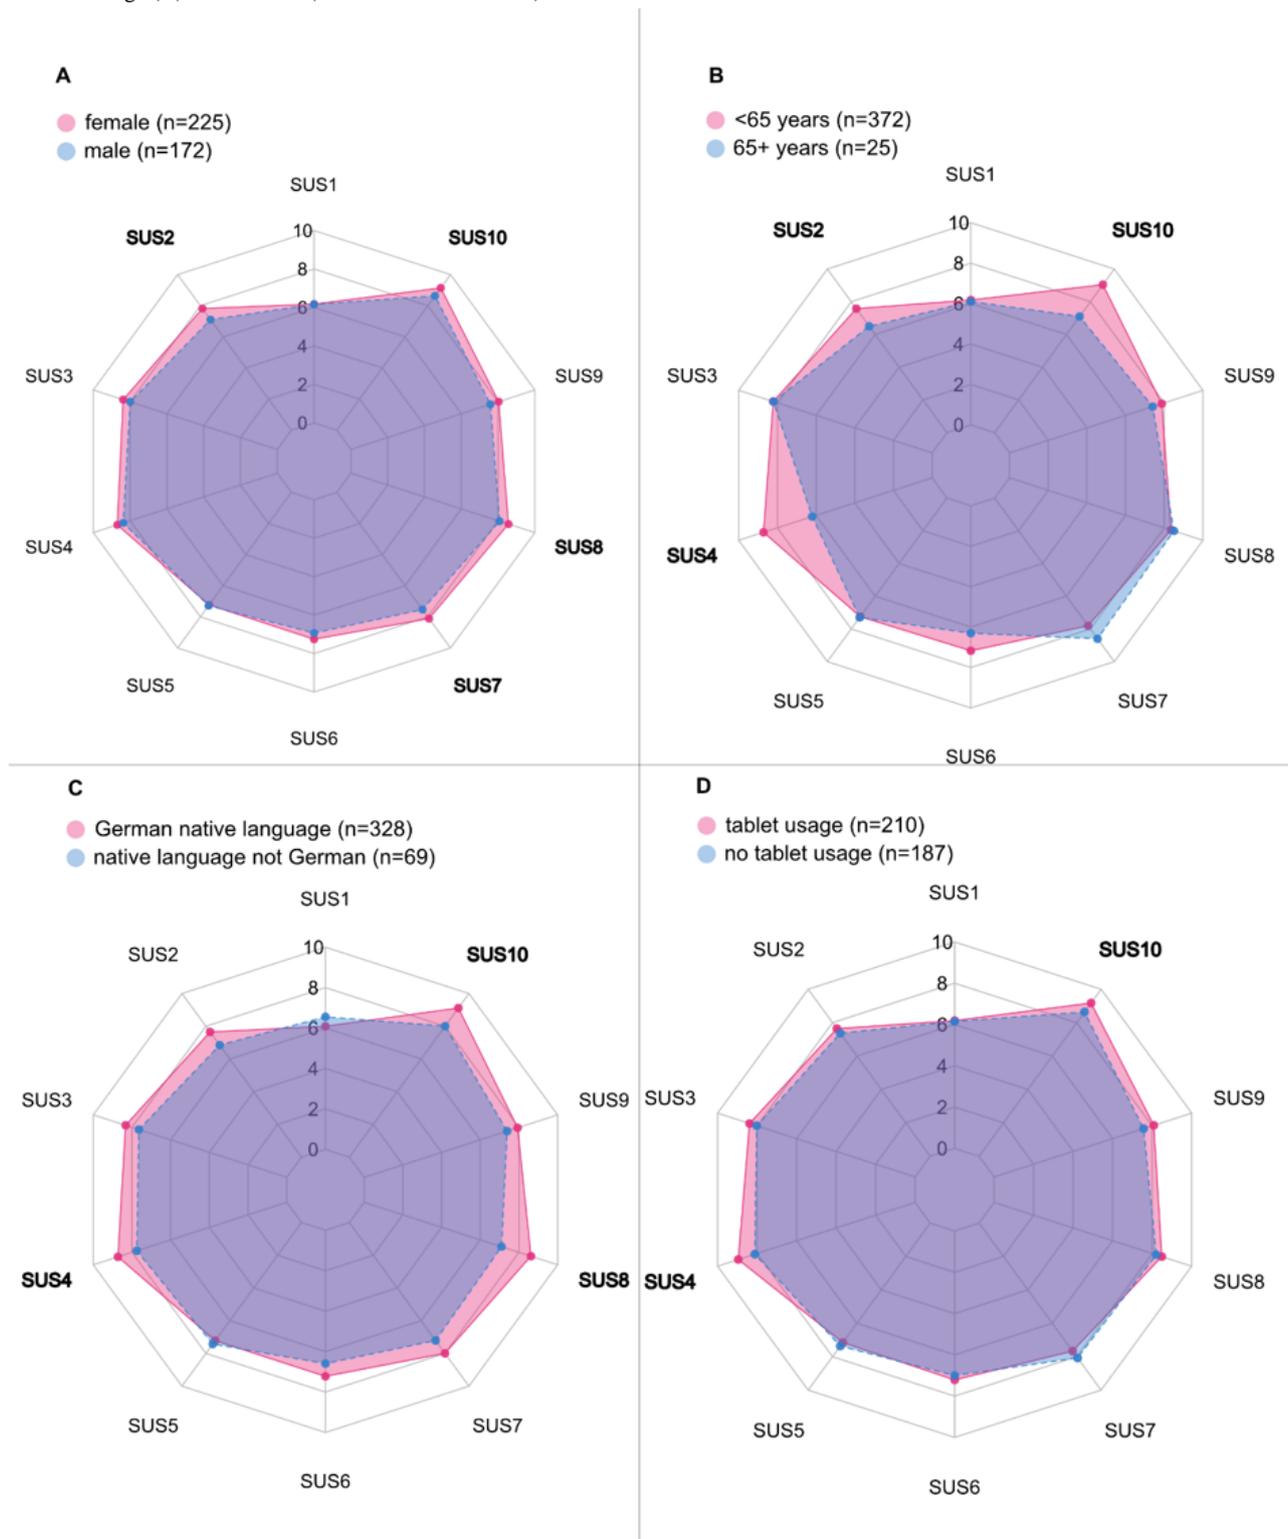

In comparing female and male respondents, all statements were rated more positively by female participants, except for items 1 (“would use frequently”) and 4 (“need technical support”). Female participants also scored significantly higher than male participants on items 2 (“unnecessarily complex”) (mean 7.82 vs 7.11; $P=.02$), 7 (“learn to use quickly”) (mean 8.11 vs 7.53; $P=.05$), 8 (“cumbersome to use”) (mean 8.57 vs 8.08; $P=.05$), and 10 (“needed to learn a lot”) (mean 9.14 vs 8.63; $P=.03$).

Respondents aged 65 years and older scored significantly higher on items 2 (“unnecessarily complex”) (mean 7.58 vs 6.50; $P=.04$), 4 (“need technical support”) (mean 8.72 vs 6.20; $P<.001$), and 10 (“needed to learn a lot”) (mean 9.05 vs 7.; $P<.001$) compared to their counterparts.

German native language speakers scored significantly higher on items 4 (“need technical support”) (mean 8.73 vs 7.75; $P=.001$), 8 (“cumbersome to use”) (mean 8.62 vs 7.10; $P<.001$), and 10 (“needed to learn a lot”) (mean 9.11 vs 8.01; $P<.001$) relative to nonnative speakers.

Lastly, patients who regularly use a tablet had significantly higher SUS scores on items 4 (“need technical support”) (mean 8.95 vs 8.11; $P<.001$) and 10 (“needed to learn a lot”) (mean 9.18 vs 8.64; $P=.02$) in comparison to those of participants who reported reduced levels of tablet use.

Figure 4. Mean System Usability Scale (SUS) score items (see Table 1) stratified according to sex (A), age (B), German as native language (C), and current tablet usage (D). bold: $P < .05$ (Wilcoxon rank-sum test).

Discussion

Principal Findings

In this study, we evaluated the usability of an app in taking medical histories in general practice directly from patients using the SUS [19].

The app achieved a mean SUS score of 77.9, which corresponds to a B+ grade on the curved grading scale [27] and represents a “better” product that does not necessarily need improvement [25]. Other medical devices, even those widely used at home, have lower SUS scores. Kortum and Peres [38] assessed the usability of home health care devices among students, thus representing relatively young, healthy, and well-educated participants. SUS scores for these devices ranged from 65 for

an epinephrine injector to 67 for a pregnancy test kit and 81 for a thermometer, even with previous experience using these devices.

To ensure patients can be active participants in the digital medical history-taking process, the app must be easy and intuitive to use without technical introduction or support. This importance is reflected in items 3 (“easy to use”), 4 (“need technical support”), 7 (“learn to use quickly”), and 10 (“needed to learn a lot”). Mean values between 7.8 and 8.9 for these items indicate that intuitive use has been successfully addressed in the development of our app. Item 1, assessing the frequency of app usage, scored the lowest (6.2), which can be explained by the app’s implementation solely in a medical setting and not utilized regularly in leisure time. As such, this finding is the least meaningful for our purpose.

In a pilot study by Melms et al [39], a self-completed tablet-based digital questionnaire designed for collecting medical histories in an emergency department was found to score high with respect to perceived usability. The design and content were similar to those of our app; however, their questions were only based on the SUS, which does not allow direct comparison. Other comparable instruments, although also for emergency departments, have been tested for usability in pilot studies using self-developed satisfaction surveys [40,41], a single question, and researcher or staff documentation of a patient’s need for assistance [42]. In these studies, patients were mostly satisfied with the self-administered medical history-taking tools and reported good ease of use. Taken together, these results give hope that it is possible to design a medical history app that is perceived as user-friendly.

Nonetheless, obstacles to implementing a digital tool in general practice settings can be multifaceted. Surprisingly, we found that sex was significantly associated with usability; female participants had significantly higher SUS scores than male participants. The fact that men scored higher than women for item 4 (“need technical support”) suggests that men felt more confident than women with using the app. Previous studies demonstrated that men tend to report overconfidence in their abilities, especially in fields with a male connotation [43], which computer science certainly represents [44]. Therefore, it is unclear whether men really would have needed less help or whether they overestimated themselves in their technical skills.

Our study suggests that older people are more likely to have difficulties with the handling of such an app. This aligns with a study showing that from the retirement age of 65 years, digital media use among the German population begins to decline dramatically [45] and a positive attitude toward digitalization decreases with increasing age [46]. Older age has a negative impact on the broad usability score given to a user interface [25]. To that end, this study cannot definitively conclude if the older participants of this study actually perceived the app to be of relatively low usability or if their more negative attitude toward the benefit of new technologies prompted them to give lower scores. Due to the small sample size of participants aged 65 years and older, it is not possible to assert how older people in general would cope with the handling of the app. Since GPs are consulted predominantly by older people [47], further

research should focus on app testing with older patients to obtain specific feedback, including suggestions for improvement.

Having learned German as a native language was positively associated with a higher SUS score, although only patients with sufficient German language proficiency were included in the study [17]. This could be due to two different reasons: despite the app’s plain language, it is possible that some of the medical history questions or SUS items were not understood properly.

Daily media use was not associated with the SUS score, which suggests that the app is designed to also ensure that people with limited digital experience do not feel overstrained with its operation.

Limitations

Despite our efforts, this study comes with several limitations. The number of older participants (ie, aged 65 years and above) was relatively low in comparison to their constituents in GP practice settings [47]. One potential reason could be a more pronounced skepticism toward digital tools in older generations, leading to an increase in refusal for participation in the study among older patients. However, as no screening lists were maintained, this is mere speculation. A screening list should be obtained in future studies to be able to characterize individuals who declined participation. Another consideration is that people with lower levels of digital media literacy use may not have agreed to participate in the study.

Data collection was performed during the SARS-CoV-2 pandemic, which may have disproportionately impacted study participants as certain patient groups may have avoided seeing a doctor or were more likely to refuse to participate in the study to avoid unnecessary contact. This could have included especially vulnerable groups such as older people or those with multimorbid conditions.

The Likert scale of the SUS questions shown with clickable singular dots was replaced by a slider on December 8, 2021. In the dot-based representation, it was compulsory to make an entry before continuing, whereas the slider was automatically set to the neutral center and could be shifted. This may have led to incorrectly rated items. For example, this may have occurred in instances of the internet faltering or the patient having double-clicked without noticing. Since there were repeated questions about the word “Inkonsistenzen” (SUS item 2), we replaced it by the more common synonym “Unstimmigkeiten” (English translation: discrepancies). Furthermore, hardware as well as the operating system may have influenced the evaluation of the personally perceived usability of a system [48]. For this study, iPad Minis with the iOS operating system were exclusively used. Therefore, possible differences in assessment related to the operating system and hardware are not part of this study.

The SUS is able to classify the usability of a system but is unable to identify specific usability issues nor capture the usability of the system in its entirety. For a more in-depth usability evaluation, different methods could be used (eg, interviews and observations). During data collection, staff were able to observe usability problems. In their observations, multiple-choice, single-choice, and hybrid questions as well as the slider did not

appear to cause any difficulties. In contrast, problems concerning the handling of the app arose when participants were required to input free-text entries (eg, age, height, weight). Further, some study participants were unclear on how to open and close the on-screen keyboard. Some participants also did not understand that the figure on which a pain or an injury could be assigned to a body region (see [Figure 1E](#)) could be rotated by clicking on an icon at the bottom left of the screen. This means that, for example, back pain may have been falsely reported as abdominal pain. Lastly, an unstable internet connection arose during data collection, which caused the app to be unresponsive intermittently. These factors may have influenced the SUS score.

Conclusion

The app examined in this study for medical history taking passes the usability test based on the SUS and appears to function on par with other digital tools that have become well-integrated in our everyday lives. However, not all people adapted equally well to the app. For successful implementation, all end users, regardless of age, technical affinity, health literacy, or preferred language, must be able to use such a tool. Only if that is attained, providing practical digital solutions can contribute to the efficient and effective delivery of health care services. Therefore, further research should focus on the identification of causes for difficulties of using the app as well as finding appropriate solutions.

Acknowledgments

We would like to thank Julie Ngo, MD for proofreading. We sincerely thank all patients for their participation. We are very grateful to the physicians and their teams who allowed data collection in their practices despite the SARS-CoV-2 pandemic and the extraordinary burden that came along for health care workers. We thank the team at aidminutes GmbH for their commitment and support. This research is funded by the German Innovation Fund (funding number 01VSF19050) of the Federal Joint Committee (G-BA). The funders have not influenced the design of this study and did not play any role during its implementation (eg, data collection and analysis, interpretation, and publication of the results).

Data Availability

The data sets used and analyzed during the study are not publicly available due to the decision of the research ethics board but can be obtained from the authors upon reasonable request within a data sharing agreement.

Authors' Contributions

KA wrote the original draft. KA and EMN were mainly responsible for writing the manuscript. KA, EMN, and DS conceived the study design and analyzed the data. FM and CJ revised the manuscript. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Clinicians working in intensive care units (ICUs) are immersed in a cacophony of alarms and a relentless onslaught of data. Within this frenetic environment, clinicians make high-stakes decisions using many data sources and are often oversaturated with information of varying quality. Traditional bedside monitors only depict static vital signs data, and these data are not easily viewable remotely. Clinicians must rely on separate nursing charts—handwritten or electric—to review physiological patterns, including signs of potential clinical deterioration. An automated physiological data viewer has been developed to provide at-a-glance summaries and to assist with prioritizing care for multiple patients who are critically ill.

Objective: This study aims to evaluate a novel vital signs viewer system in a level 1 trauma center by subjectively assessing the viewer's utility in a high-volume ICU setting.

Methods: ICU attendings were surveyed during morning rounds. Physicians were asked to conduct rounds normally, using data reported from nurse charts and briefs from fellows to inform their clinical decisions. After the physician finished their assessment and plan for the patient, they were asked to complete a questionnaire. Following completion of the questionnaire, the viewer was presented to ICU physicians on a tablet personal computer that displayed the patient's physiologic data (ie, shock index, blood pressure, heart rate, temperature, respiratory rate, and pulse oximetry), summarized for up to 72 hours. After examining the viewer, ICU physicians completed a postview questionnaire. In both questionnaires, the physicians were asked questions regarding the patient's stability, status, and need for a higher or lower level of care. A hierarchical clustering analysis was used to group participating ICU physicians and assess their general reception of the viewer.

Results: A total of 908 anonymous surveys were collected from 28 ICU physicians from February 2015 to June 2017. Regarding physicians' perception of whether the viewer enhanced the ability to assess multiple patients in the ICU, 5% (45/908) strongly agreed, 56.6% (514/908) agreed, 35.3% (321/908) were neutral, 2.9% (26/908) disagreed, and 0.2% (2/908) strongly disagreed.

Conclusions: Morning rounds in a trauma center ICU are conducted in a busy environment with many data sources. This study demonstrates that organized physiologic data and visual assessment can improve situation awareness, assist clinicians with recognizing changes in patient status, and prioritize care.

clinical decision-making; health information technology; intensive care units; patient care prioritization; physiological monitoring; visualization; vital signs

Introduction

Clinicians working in intensive care units (ICUs) must be able to see, understand, and respond quickly to the complex and ever-changing clinical environment of the ICU. They need to be able to collect, analyze, and interpret what is happening and what it means [1]. Situational awareness is essential for ICU clinicians to provide safe and effective care to their patients. When clinicians have good situational awareness, they are better able to identify and respond to changes in their patients' condition and to coordinate care with other members of the health care team. However, clinicians are immersed in a cacophony of alarms and a relentless onslaught of data. Within this frenetic environment, clinicians make high-stakes decisions using multiple data sources and are often oversaturated with information of varying quality. While modern hospitals are equipped with bedside monitors collecting various physiological data in a real-time, continuous, and automated way, these data are not always easily accessible remotely or available to be viewed as a continuous trend [2]. The enormous amount of unprocessed data adds an additional burden on ICU clinicians who work in a dynamic environment with voluminous decision-making requirements. Traditional bedside monitors only show a single patient's instantaneous (static) vital signs (VS) data, limiting the clinician's scope to view a patient's physiological trajectory within a clinically meaningful period of time. Clinicians must rely on separate nursing charts—handwritten or electronic—to review a patient's physiological status. Moreover, auditory alarms often cause “alarm fatigue” instead of increasing situational awareness [3]. Many bedside monitors only display 1 or 2 patients' information; the ability to view an entire unit or ward allows a clinician to prioritize attention to those in most need of critical care support [4]. Improved visualization of patient information may help clinicians cope with information overload in critical care settings by improving situational awareness and supporting clinical decision-making [5]. An automated physiological data-organizing and information-summary system that presents aggregated information from multiple data sources while providing at-a-glance summaries of clinical data can assist ICU clinicians with prioritizing care for multiple patients.

Developed initially for use in aircraft transporting multiple patients who are critically ill, this VS viewer has 2 outcomes of direct and important clinical applicability. First, the VS viewer can provide clinicians with the capability to monitor individual patient trends, improving overall decision-making. Since patients in the ICU require multiple life support treatments to ensure ideal long-term outcomes, improved display of VS patterns could improve patient assessment and clinical decision-making. Second, the VS viewer system allows remote monitoring of groups of patients through a display that provides clinicians with the ability to quickly identify patients in need of rapid intervention. The objective of this work is to evaluate the use of a VS viewer in ICUs at a high-volume level 1 trauma

center. We hypothesized that clinicians would subjectively report improved situational awareness and enhanced ability to make clinical decisions with the use of a VS viewer.

Methods

Data and System Design

In the ICUs of the University of Maryland Medical System, GE Marquette Solar 7000/8000 (General Electric) patient VS monitors are networked to provide a collection of real-time patient VS data streams. Each patient monitor collects real-time 240 Hz waveforms and 0.5 Hz trend data, which are transferred through the secure intranet to a dedicated BedMaster server (Excel Medical Electronics) and archived [6]. To increase the system's availability and reliability, a triple-redundant design was used, in which 3 BedMaster servers were used in parallel to collect data from all bed units [7]. Physiological data collected through this system, when they are displayed on the GE Marquette monitor, include electrocardiographic, photoplethysmographic, carbon dioxide, arterial blood pressure, and intracranial pressure (ICP), among others. Trends include heart rate (HR), respiratory rate, temperature, oxygen saturation, end-tidal carbon dioxide, and ICP, among many others. This information provides continuous VS data that relays important physiological information regarding brain perfusion, cardiac stability, overall tissue perfusion, and respiratory status.

During the design of the VS viewer for ICU, our goal was to create a novel physiological data displayer that can reduce ICU clinicians' workload, enhance clinical decision-making, and improve communication in a noisy and confined ICU environment. To achieve the goal, we considered the factors of usability and patient safety, which can be closely related in this application. For usability, current bedside monitors often suffer from insufficient time windows to display physiological trends, a lack of clear indications of patients' physiological status, and a lack of overview of multiple patients for prioritizing [4]. To enhance the clinicians' efficiency while maximizing patients' safety, we adopted the following design strategies: First, the viewer should reduce the information overload for clinicians to access patients' physiological data, current or past, individual or group [8-10]. Second, it should be compatible with the existing patient monitor system so that clinicians can reuse their existing knowledge about the monitor, which may increase the acceptance of the VS viewer [8]. Third, in the user experience design, the viewer should place the user in control [11]. It should use simple colors and graphs to convey efficient information while still providing detailed data for advanced users to access with simple operations [12]. Fourth, the viewer should have reasonable reliability for patients' safety. Redundance was introduced in the design for key components in the system, such as the data collection, database, and web server [7].

The VS viewer adopted a client-server architecture. The server handles 2 types of clients: the bedside monitors and the users. It receives and persists in real-time physiologic data that are

transmitted from the bedside monitors. A database records each bedside VS value, bed name, and timestamp. The server also responds to users' requests for viewing data within a given time frame. To continuously present the latest data to the user with low latency, the VS viewer uses the asynchronous Javascript and XML technique to pull the most recent data from the database every minute [13]. Such a method allows the VS viewer to automatically redraw all VS trajectories without refreshing the entire viewing page.

The VS viewer provides a rich interface for data monitoring, exploration, and recording. Data are depicted according to each clinical area of operations, such as the trauma resuscitation unit or emergency department, operating room, computed tomography suite, and individual critical care units. **Figure 1** demonstrates the grouping of bed units. On the left panel, a list of all groups can be used as a shortcut to bed units. Selecting a specific unit, a default 24-hour view is displaced for shock index ($SI=HR/systolic\ blood\ pressure$), HR, systolic blood pressure, ICP, cerebral perfusion pressure, brain trauma index, and end-tidal carbon dioxide concentration. If ICP data are not collected, the space is used to plot the next available VS, optimizing the view.

When a bed is selected, a page for this bed (unit view) is displayed. **Figure 2** demonstrates the structure of the

information. The page is partitioned into multiple areas for navigation, viewing, and tools. Its center is assigned for presenting the selected patient's physiologic data in a time frame (up to 72 hours). VS trajectories are stacked vertically in order of predefined importance. The bottom is reserved for plotting bar segments of all VS that summarize the colored warnings without showing the value changes. This provides a summary of all available VS trends in a condensed space, which could be used to view the physiological stability of the patient over time. To provide an at-a-glance view of other rooms in this group, the left panel lists all the rooms in the current group and updates their VS trajectories in real time. The color-coded warning in the thumbnails enhances situation awareness even when the users are focusing on 1 patient.

The VS viewer has additional diagnostic tools. For example, SI is a commonly used blood transfusion diagnosis tool [14]. The VS viewer adds a 2D SI diagram to show a changing trajectory (**Figure 3**). To present the temporal information, a heat map is plotted, ranging from blue (cold) to red (warm); blue colors represent past events, whereas red colors represent current data trends. Similarly, the brain trauma index (which is ICP or cerebral perfusion pressure) can also be visualized in the 2D plot [15].

Figure 1. The vital sign viewer in the "group" mode, with a default 24-hour display.

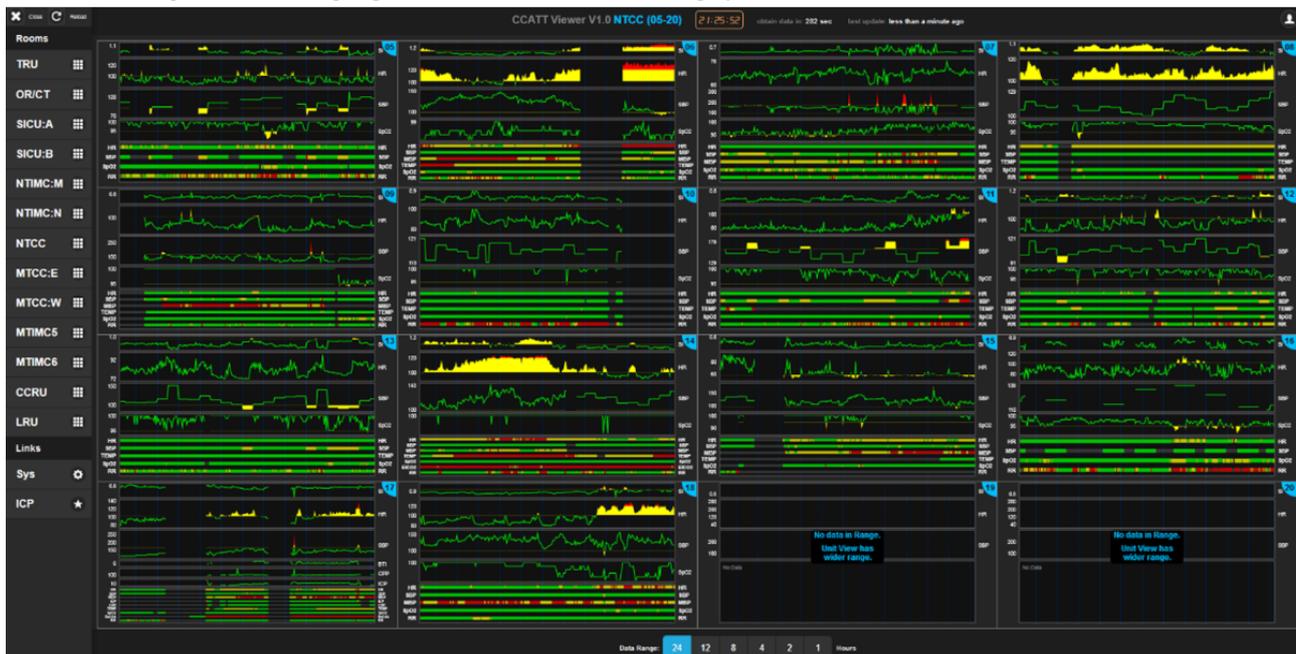

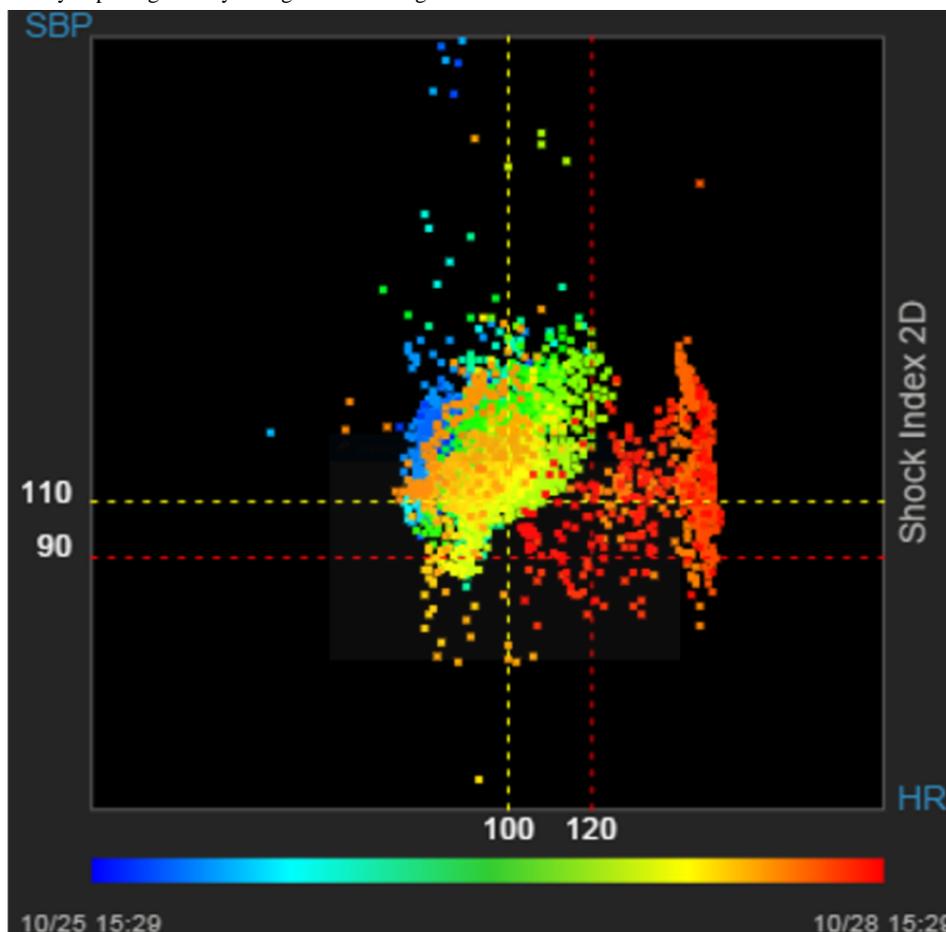

Figure 2. Vital sign (VS) viewer in the “unit” mode, with default 24-hour display. Labeled area 1: navigation menu to other room groups. Area 2: title information for room name, current time, and the next update time. Area 3: user portal. Area 4: list of beds in the same group with their current VS thumbnails. Area 5: the main area to display selected room VS trajectories and the summarization with color-coded patterns. Area 6: diagnostic tools for 2D scatter plots of shock index (=heart rate/systolic blood pressure) and brain trauma index (=intracranial pressure/cerebral perfusion pressure). Area 7: functional buttons for selecting various time ranges for viewing.

Figure 3. An example 2D shock index plot. The colored scatter plot shows the change in shock index (heart rate/systolic blood pressure) from past (blue) to recent (red), thereby depicting a 3-day change in worsening shock index.

Clinical Thresholds

Colored warnings are an effective means to gain a clinician's attention and may be more effective than audible alarms, especially in a noisy, busy, and confined environment [16]. In the VS viewer, VS trajectories with colors may be viewed to highlight the sections where the VS are outside of normal clinical thresholds. For example, too low or too high HR segments are displayed differently from normal HR. Clinical thresholds for VSs were developed after surveying 47 clinicians (24 medical doctors, 18 registered nurses, and 5 respiratory therapists). Among them, 36 clinicians were from the University of Maryland, Baltimore, and 11 from the University of Cincinnati. After the survey was completed, a team of clinicians met to review the results to reach a consensus on the viewer's opinion of their visual appearance. [Multimedia Appendix 1](#) summarizes the optional threshold distributions for some important VS. Based on these threshold values, a consensus set of color-coded cutoffs was determined ([Multimedia Appendix 2](#)). These values were set as fixed parameters under consideration of a simplified and consistent user interface.

Survey Design

Clinicians who were scheduled to work in the ICU or on the trauma teams were contacted and trained on how to use the VS viewer. Once trained, ICU and team clinicians were asked to participate in the study. Clinicians were surveyed anonymously from Tuesday to Friday and were asked to conduct rounds normally, using data reported from nurse charts and briefs from fellows to inform their clinical decisions. None of those clinicians participated in the design of the VS viewer. A total of 2 questionnaires were designed to collect clinicians' opinions about a patient's condition and satisfaction with the VS viewer.

Clinicians were given a preview survey upon their assessment and formulation of their plan for each patient after traditional rounds and before accessing the viewer. Immediately following the completion of the pre-view survey, the VS viewer was presented to the clinicians on a tablet, displaying the patient's past physiologic data visualized and summarized for up to 72 hours. After reviewing the viewer for up to 1 minute, clinicians completed the postview questionnaire. In both questionnaires, the clinicians answered questions regarding the patient's stability, status, and need for a higher or lower level of care. In the post-view questionnaire, clinicians were also asked if they intentionally planned to implement any of the following interventions after seeing the viewer: (1) changing any current medications, (2) ordering additional medications, (3) ordering additional diagnostic tests, (4) changing ventilation settings, (5) ordering additional labs, (6) physically reexamining this patient, (7) providing fluid bolus, or (8) providing a blood transfusion.

Statistical Methods

A participant's perceiving of the VS viewer's usefulness is represented by a vector consisting of the percentage of the 5 categories (strongly agree, agree, neutral, disagree, and strongly disagree) that he or she assigned to the question "the viewer enhanced my understanding of the patient's condition." We used the Ward method, a hierarchical clustering method, with Manhattan distance to group the participants based on their ratings to the question "the viewer enhanced my understanding of the patient's condition" [17,18]. Between those clusters, we compared the participants' opinion changes on the patients' conditions in 7 questions ([Table 1](#)) before and after using the viewer. The chi-square test was used to compare percentage differences.

Table 1. The number of opinion changes for 7 questions (Q1-Q7) before and after seeing the viewer, with respect to the 5 clustered user types.

Questions ^a	Total changes, n (%)	Unique participants, n (%)	C1, n	C2, n	C3, n	C4, n	C5, n	Like (C1 and C2), n (%)	Dislike (C3, C4, and C5), n (%)
Q1	129 (14.2)	16 (66.7)	46	31	10	42	0	77 (59.7)	52 (40.3)
Q2	112 (12.3)	15 (62.5)	38	34	8	32	0	72 (64.3)	40 (35.7)
Q3-6	145 (16)	18 (75)	58	54	3	30	0	112 (77.2)	33 (22.8)
Q7	92 (10.1)	17 (70.8)	20	32	9	31	0	52 (56.5)	40 (43.5)

^aPlease refer to [Textbox 1](#) for the question.

Textbox 1. Questions.

- Q1: Having reviewed the last 24 hours of information during rounds and before and after seeing the 24-hour viewer, do they feel that in the past 24 hours the patient has shown evidence of (a) infection, (b) hemodynamic instability, (c) uncontrolled bleeding, or (d) respiratory deterioration?
- Q2: Over the past 24 hours, has the patient's condition (a) improved significantly, (b) improved slightly, (c) unchanged, (d) deteriorated slightly, or (e) deteriorated significantly?
- Q3: Can the patient be transferred to a lower level of care?
- Q4: Can the patient be transferred to a higher level of care?
- Q5: Does the patient have a traumatic brain injury?
- Q6: Did the patient have intracranial pressure problems in the past 24 hours?
- Q7: Due to the viewer, do they plan for any changes in interventions, including (a) changing any current medications, (b) ordering additional medications, (c) ordering additional diagnostic tests, (d) changing ventilation settings, (e) ordering additional labs, (f) physically reexamining this patient, (g) providing a fluid bolus, or (h) providing a blood transfusion?

Note: These are the questions referenced in [Table 1](#).

Ethical Considerations

The study has been approved by the institutional review board of the University of Maryland School of Medicine (HP-00063086).

Results**Survey Collection**

From February 2017 to June 2017, the survey team followed clinicians who agreed to take the surveys. A total of 908 surveys were collected from 24 participants with unbalanced proportions. Among the 908 rounds, 48 (5%) were patients who were newly admitted, and 860 (95%) were not. When asked if the VS viewer enhanced their understanding of the patient's condition, clinicians strongly agreed 45 (5%) times, agreed 514 (56.6%) times, were neutral 321 (35.4%) times, disagreed 26 (2.9%) times, and strongly disagreed 2 (0.2%) times. [Figure 4](#) lists the total surveys each participant contributed and the proportions of ratings on whether the viewer enhanced his or her understanding of the patient's condition during a round.

Results show that physicians' clinical assessments and plans could be influenced by viewing the VS viewer for 1 minute or less, indicated by a "yes" answer to at least 1 of the 8 questions (Q7 in the survey). Of the 908 rounds, a total of 92 (10.1%)

rounds had at least 1 "yes" as planning on some changes to the interventions. The most common change was (Q1) changing current medications (36/908, 4%). The next most common changes were (Q6) physically reexamining the patient (31/908, 3.4%), (Q2) ordering additional medications (20/908, 2.2%), and (Q7) providing a fluid bolus (20/908, 2.2%).

We used the Ward method with Manhattan distance to group the participants based on their ratings to the question "the viewer enhanced my understanding of the patient's condition" [17]. For example, 1 participant contributed 62 surveys and rated 2 "strongly agree," 22 "agree," 32 "neutral," 5 "disagree," and 1 "strongly disagree." The vector of percentages (0.03, 0.35, 0.52, 0.08, and 0.02) represents the overall rating that this participant had about the viewer. The 24 participants were clustered into 5 groups, as shown in [Figure 5](#). The 5 groups correspond to the participants who are mostly in favor (C1) of the viewer to those least in favor (C5). There are 6 in C1, 6 in C2, 3 in C3, 7 in C4, and 2 in C5, which shows a very balanced grouping, with half of the participants in the C1 and C2 groups and the other half in the other 3 clusters. This shows that the sampled rounds were done by participants with almost similar proportions of different attitudes toward the viewer. In other words, the survey team sampled the rounds randomly enough so that the collected data were not biased by participants with certain preexisting feelings about the viewer.

Figure 4. Distribution of each participant’s rating on if the viewer enhanced his or her understanding of the patient’s condition during a round.

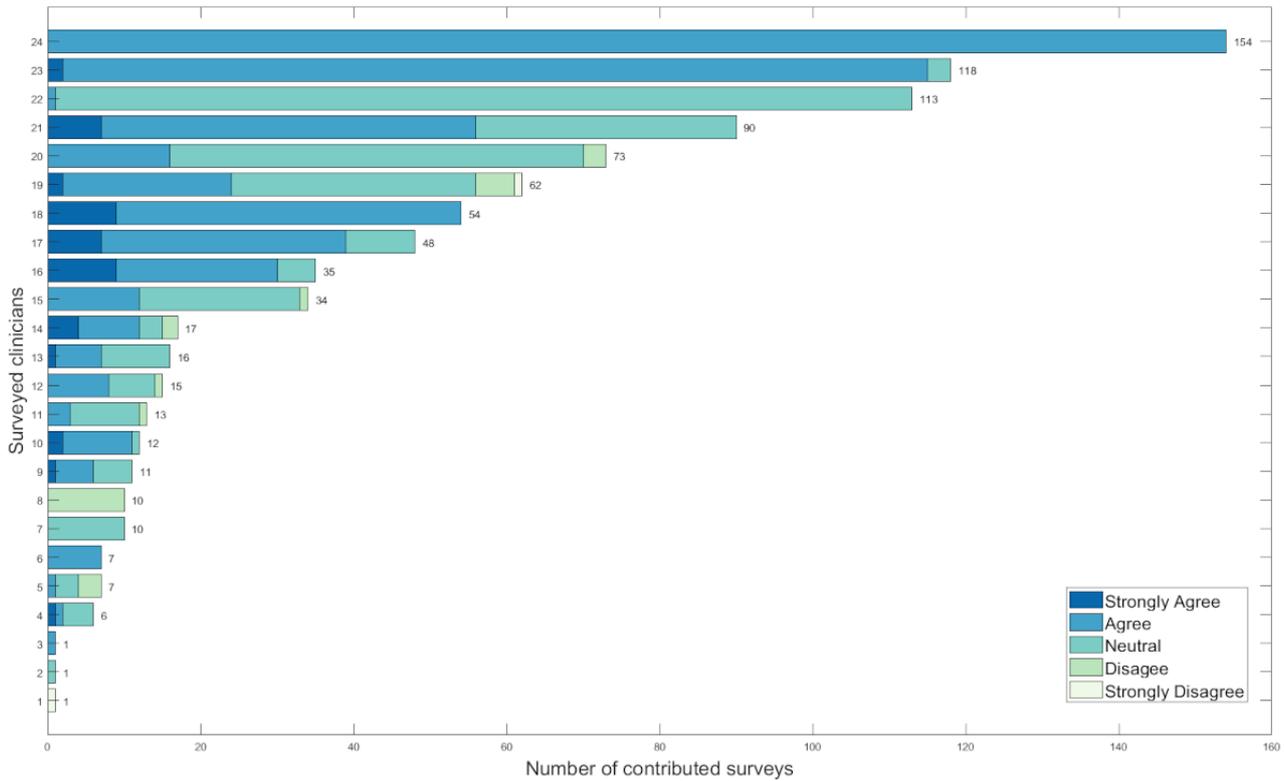

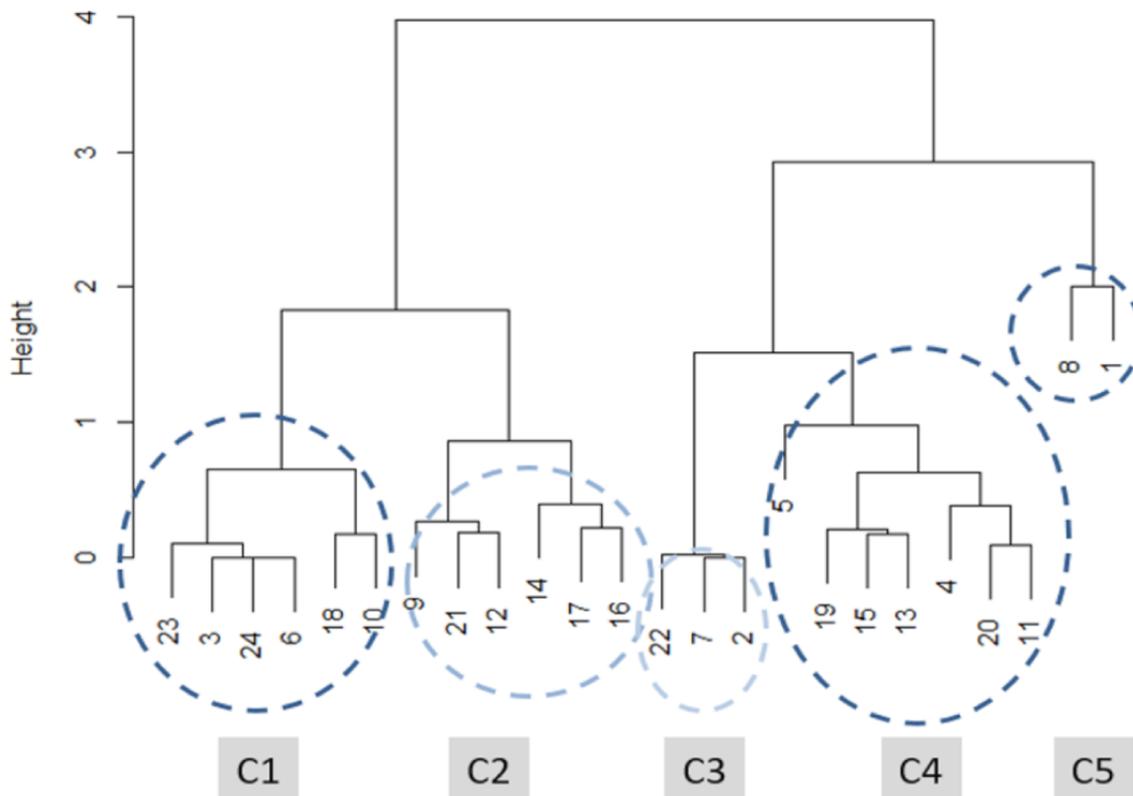

Figure 5. Clusters of participants with similar feelings about the viewer. In total, 24 unique participants are grouped into 5 groups, corresponding to “strongly favor,” “favor,” “neutral,” “dislike,” and “strongly dislike.”.

Comparisons

We analyzed the opinion changes before and after seeing the viewer, regarding the patient’s stability, status, and need for a

higher or lower level of care. Instead of summarizing the total changes in opinions, we compared them with respect to the clusters of user types. The participants who were “neutral” (C3) or “strongly dislike” (C5) had low numbers of opinion changes

for all 7 questions. Those who were in clusters C1, C2, and C3 had more numbers of opinion changes (Table 1). For simplicity, we can further group the participants into 2 types: those who liked the VS viewer (C1 and C2) and those who disliked it (C3, C4, and C5). The clinicians who liked the VS viewer had a higher rate of changed opinions than those who disliked the VS viewer regarding Q1 to Q6 (Q1: 59.7% vs 40.3%, Q2: 64.3% vs 35.7%, and Q3-6: 77.2% vs 22.8%). When asked if they planned for any changes for interventions (Q7), there was no significant difference between the 2 major groups of clinicians (56.5% vs 43.5%, $P=.10$).

Discussion

Principal Results

With the development of sensor and computing technologies, vast amounts of high-quality, continuous electronic data, including VS, alarms, and clinical interventions, are collected at the bedside. Those data have the potential to provide an unprecedented view of dynamic physiologic responses to injury, illness, and treatments. Therefore, data gathered from bedsides could assist clinicians in care planning and decision support. However, massive amounts of data that are not well organized or presented still create a barrier for clinicians making full use of them in a busy resuscitation or intensive care environment. Bedside monitors often only display instantaneous readings or a short strip of recent physiologic VS for diagnosis. Clinicians need to rely on separate nursing charts, handwritten or electronic, to review a patient's developing conditions. The VS viewer, which automates physiological data by displaying clear color-coded trends, presents aggregated information from multiple data sources, provides at-a-glance summaries of clinical data, and assists with the prioritization of care for multiple patients.

The use of the VS viewer was subjectively assessed with 908 observations from clinicians working in ICUs at a high-volume level 1 trauma center. Clinicians generally perceived the use of the VS viewer favorably, as evidenced by survey data. The VS viewer was originally developed for the United States Air Force Critical Care Air Transport Teams [19,20]. Critical Care Air Transport Teams transport up to 3 patients who are critically ill in the back of the aircraft, allowing trauma surgeons to perform far-forward damage control surgery, knowing that these patients could be quickly transported rearward with full support. This rapid transport of complex patients with multisystem trauma, shock, burns, and respiratory failure who are in hemodynamic flux requires continual resuscitation, stabilization, advanced care, and life-saving interventions during air transport; however, currently available advanced ICU monitoring systems suitable for the needs of such patients were developed for use in stable, hospital-based settings, not in the crowded, noisy, vibrating, and sometimes frankly jolting environment of air evacuation or long-distance air transport. The noise levels, confined space, limited access to patients, vibration, and overall limited patient visibility make using a VS viewer advantageous in such a setting. Such technology can also be valuable in enhancing emergency medical personnel's decision-making for initial triage. While traditional VS are useful in guiding

prehospital care and triage, they represent isolated points in time, and trends and fluctuations in vitals may not be apparent.

In this study, we set the clinical thresholds for colored warnings to be uniform across all beds. This was to make the user interface simplified and more consistent during a survey. Additionally, a set of predefined thresholds from a group of experienced clinicians could be a useful out-of-the-box feature when the VS viewer is deployed in the field. That said, the clinical thresholds could be personalized for each bed. For example, if the bedside monitor allows alarm threshold settings, such settings could be used as the colored warning thresholds in the VS viewer for each bed.

The VS viewer has expanded from ICUs to trauma resuscitation units, operating rooms, neuro ICUs, and pediatric ICUs at the University of Maryland Medical Center. In 2020, during the COVID-19 pandemic, it was deployed to monitor 150 beds in biocontaminated units to reduce the risk of infection and improve efficiency for clinicians in treating their patients.

Innovations

The VS viewer is a multipatient physiological monitor. To the best of our knowledge, we could not find any articles that describe a viewer system with a similar design. In a comprehensive review by Waller et al [5], a total of 17 information displays in ICU settings were designed for specific disease states or body systems, such as cerebral perfusion monitoring for individual patients or monitoring for arterial blood gas trends. The novel user interface presented in this study was designed with the aim of conveying information more efficiently to ICU clinicians in a noisy, confined, and busy environment. It uses color-coded warnings to indicate a patient's status and highlight data that needs attention. The side panel provides a peek at the physiological status of other patients, which can help clinicians keep an eye on other patients even if their attention is focused on a single patient. It uses advanced web front-end techniques to hide large quantities of data behind simple line charts and reveal them when needed.

Clinical Impact

The use of the VS viewer can have several possible influences on clinical assessment and plans. It can help clinicians quickly recognize critical changes in the patient's physiologic status and provide early interventions to prevent further deterioration. The VS viewer can potentially improve patient outcomes by providing clinicians with a concise overview of key information, reducing cognitive load and errors, and improving compliance with evidence-based safety guidelines [12]. It may also help to improve communication efficiency within the ICU team by providing easy access to a shared platform of patient longitudinal data. It can reduce the workload of the ICU team by automating routine tasks such as extracting data from nursing charts.

To prioritize care in high-volume ICUs, intensive care clinicians must be able to rapidly identify physiological events and the need for intervention. The VS viewer can help organize a large amount of data in a busy, noisy ICU environment where close monitoring of patients who are critically ill is essential to detect potentially harmful physiological trends. The presentation of data with temporal, color-coded patterns, and the ability of the

VS viewer to provide at-a-glance data for entire units is advantageous for clinicians working in high-volume ICUs.

The color-coded patterns may reduce the “alarm fatigue” issue in noisy ICUs. The noise burden is common in modern physiologic monitoring systems and has been recognized as a critical patient safety concern in the hospital care setting [21-23]. In noisy environments, such as ICUs, helicopter transportation, or aeromedical evacuation, loud and continuous alarms could reduce their specificity in getting clinicians’ responses. Another issue with audible alarms is that they are transient and cannot be replayed once they are gone. While the visual alert patterns could show the longitudinal patterns of physiologic change.

Related Work

The VS viewer with organized and easy-access information could be part of the effort to build the smart ICU or the tele-ICU. The concepts of smart ICU and tele-ICU aim to maximize the use of bedside clinical expertise in assessing and treating patients by providing integrated monitoring and actionable information [24-26]. A survey study of 86 ICU staff in a German university hospital summarized that health providers expect ICU monitoring could be improved by reducing false alarms, using wireless sensors and mobile devices, preparing for the use of AI, and enhancing the digital literacy of ICU staff [27,28]. The VS viewer could be used in both centralized and decentralized architectures of tele-ICU for extending coverage and facilitating patient transfer between hospitals because of its flexible configuration of grouping ICU beds virtually [29]. By making essential clinical information available remotely, the VS viewer allows clinicians to provide care plans when on-site support is infeasible or limited [30,31]. It may potentially reduce exposure to contagious diseases and, hence, increase patient safety.

With continuous physiologic data and other clinical information, the VS viewer has the ability to process real-time data into predictive algorithms, which is also desired for tele-ICU [30]. Beyond being a plain display, the VS viewer could embed risk-prediction algorithms that use continuous VS as inputs and may promote more efficient interventions to reduce ICU risk [31]. For example, ICU mortality prediction [32,33], secondary insults after severe brain traumatic injury [34], needs for transfusion [35,36], and neurologic decline in the ICU [37] are reported to have good predictive performances by using variables derived from continuous VS. We have also shown that using risk scores calculated from continuously measured VS, patients requiring endovascular resuscitative interventions can be identified with high accuracy [38]. Moreover, the VS

viewer could serve as a platform for predictive model diagnosis by providing clinicians with explainable artificial intelligence [39]. With patient VS data, we can use the Shapley Additive exPlanations algorithm to calculate each variable’s contribution to the prediction result [40]. Therefore, the clinicians would know not only the prediction but also the contribution of each variable to the prediction. Such information may help clinicians make more personalized care plans.

Limitations

There are limitations to this work that are worth noting. We collected data from a large number of ICU clinicians compared to trauma team clinicians. Trauma team clinicians are surgeons responsible for the same patient throughout the entire length of stay, regardless of the acuity of the patient. ICU clinicians are intensivists and are only responsible for patients in the ICU. Hence, disparities between both groups of clinicians are inevitable, as each group has different clinical perspectives and patient workloads. As occurs in nearly all survey work, response rates and receptiveness to the surveys varied. Some clinicians were more amenable to being surveyed compared to others. In the collected forms, there were more surveys from some clinicians than from others. To reduce this potential bias, we clustered the participants based on their overall rating on each round, from which we estimated each participant’s a priori attitude toward using this viewer. The results show that there was a balanced “favoring” and “non-favoring” of using this viewer.

We only evaluated the viewer based on clinicians’ satisfaction and efficiency (potential changes in interventions before and after seeing the viewer). In future studies, randomized controlled trials can be designed to analyze the viewer’s impact on patients’ outcomes and safety [12].

Conclusions

We designed, implemented, and evaluated an automated physiologic data organizer and visualization platform. It provides at-a-glance summaries and assists with prioritizing care for multiple patients. The VS viewer demonstrates a method to assemble large quantities of data from multiple sources and represents trends in each patient’s condition with simple color codes, greatly improving situational awareness. It has the potential to be used in en route care, hospitals with multiple branches, and understaffed hospitals in remote areas. The survey shows that organized physiologic data and visual assessment could assist clinicians in recognizing changes in patient status and prioritizing care.

Abstract

Background: Robust adverse drug event (ADE) reporting systems are crucial to monitor and identify drug safety signals, but the quantity and type of ADEs captured may vary by system characteristics.

Objective: We compared ADEs reported in 2 different reporting systems in the same jurisdictions, the Patient Safety and Learning System–Adverse Drug Reaction (PSLS-ADR) and ActionADE, to understand report variation.

Methods: This retrospective observational study analyzed reports entered into PSLS-ADR and ActionADE systems between December 1, 2019, and December 31, 2022. We conducted a comprehensive analysis including all events from both reporting systems to examine coverage and usage and understand the types of events captured in both systems. We calculated descriptive statistics for reporting facility type, patient demographics, serious events, and most reported drugs. We conducted a subanalysis focused on adverse drug reactions to enable direct comparisons between systems in terms of the volume and events reported. We stratified results by reporting system.

Results: We performed the comprehensive analysis on 3248 ADE reports, of which 12.4% (375/3035) were reported in PSLS-ADR and 87.6% (2660/3035) were reported in ActionADE. Distribution of all events and serious events varied slightly between the 2 systems. Iohexol, gadobutrol, and empagliflozin were the most common culprit drugs (173/375, 46.2%) in PSLS-ADR, while hydrochlorothiazide, apixaban, and ramipril (308/2660, 11.6%) were common in ActionADE. We included 2728 reports in the subanalysis of adverse drug reactions, of which 12.9% (353/2728) were reported in PSLS-ADR and 86.4% (2357/2728) were reported in ActionADE. ActionADE captured 4- to 6-fold more comparable events than PSLS-ADR over this study's period.

Conclusions: User-friendly and robust reporting systems are vital for pharmacovigilance and patient safety. This study highlights substantial differences in ADE data that were generated by different reporting systems. Understanding system factors that lead to varying reporting patterns can enhance ADE monitoring and should be taken into account when evaluating drug safety signals.

Introduction

Over 2 million Canadians visit an emergency department every year because of an adverse drug event (ADE), an unintended and harmful event related to medication use [1,2]. ADEs incur over 700,000 hospital admissions, and cost over CAD \$1 billion (USD \$7.48 million) in annual health care expenditures across Canada [2,3]. The importance of addressing this issue cannot be overstated: the World Health Organization (WHO) has identified the prevention of ADEs as an urgent global public health priority [4].

In response to this pressing concern, Canada implemented regulations outlined in the Protecting Canadians from Unsafe Drugs Act (Vanessa's Law) which came into full effect on December 16, 2019. This federal legislation mandates prompt reporting of serious adverse drug reactions (ADRs; a subtype of ADEs) and medical device incidents from hospitals to Health Canada within 30 days of documentation [5]. These regulations serve as a safeguard to protect patients and improve drug surveillance.

Postmarketing pharmacovigilance is crucial in the detection, assessment, and prevention of ADEs under real-world conditions [6,7]. Among the various methods used, spontaneous reporting stands out as one of the most widely adopted approaches in pharmacovigilance [8]. When patients or health professionals spontaneously report ADEs, drug safety monitoring agencies evaluate and integrate these reports into databases, enabling ongoing identification of safety signals [7,8]. This method of surveillance captures data from a broad population and allows us to detect drug safety signals that may not have been identified in the randomized trials used for drug licensing and monitor rare ADEs to medications [9].

It is important to recognize, however, that there is considerable variation in ADE reporting systems worldwide in terms of their design, data fields, terminologies [10], and implementations, which may impact the volume and type of ADEs reported [11]. Variation in design also leads to a lack of standardization of reports, which can in turn prohibit interoperability or effective exchange of ADE reports between systems and may prevent comparisons of ADE events, rates, and risk factors across systems [10].

Despite this variation, the diversity of systems may also be a strength. Each system has the potential to complement others, enhancing the overall quantity and quality of ADE data, if variation in design leads to variation in reporting behaviors or the types of reports that can be entered [12]. To leverage this untapped potential, we need to better understand and compare the events collected through diverse reporting systems [13]. Understanding similarities and differences between systems will enable researchers and drug safety monitoring agencies to more effectively use existing data for accurate signal detection, especially for new or rare ADEs, and prioritize the investigation of drug safety signals. This knowledge will also aid stakeholders in optimizing the design and implementation of new reporting

systems to enhance ADE data collection and drug safety surveillance and better align systems with their intended purpose [10].

Health Canada, the regulatory authority for postmarketing pharmacovigilance in Canada, oversees the Canada Vigilance Program, collecting reports of suspected ADEs since 1965. Health professionals and consumers can voluntarily submit reports through various channels, including a web-based platform, phone, fax, or mail. Hospitals are required to submit written reports within 30 days, and Health Canada allows them flexibility by permitting the use of existing systems and processes to meet reporting requirements. With Health Canada's approval, hospitals may use a third party, such as a regional health authority or other reporting programs, to submit reports [14].

The province of British Columbia (BC) currently uses 2 approved spontaneous reporting systems that enable hospitals to comply with Vanessa's Law mandates: the BC Patient Safety and Learning System–Adverse Drug Reaction (PSLS-ADR) reporting form and ActionADE. Briefly, PSLS-ADR was developed and implemented as the first province-wide, web-based platform and supports hospitals in meeting the mandatory reporting requirements [14]. ActionADE, implemented later in the timeline, is a research-driven, web-based app that aims to prevent unintentional redispensation of harmful medications by facilitating the sharing of ADE information between providers across health care settings. ADE reporting occurs as a byproduct of enabling safer care provision (Multimedia Appendix 1) [15].

These 2 systems enable a comparison of the quality and quantity of ADE data generated using 2 different designs. Our objective is to describe and compare the ADEs that health care providers documented using PSLS-ADR and ActionADE during the first 3 years following the implementation of Vanessa's Law.

Methods

ADE Reporting Systems

About PSLS-ADR

BC Patient Safety and Learning System (PSLS) is an initiative of the BC Patient Safety Task Force, developed in collaboration with all 6 provincial health authorities and the Health Care Protection Program, which is part of the Risk Management Branch of the Ministry of Finance that insures BC hospitals [16]. BC PSLS is a web-based safety event reporting and management information system designed to support the identification, investigation, and analysis of safety and risk-related events, including safety hazards, near misses, and adverse events [17]. The system underwent a pilot phase in 2007 and was subsequently implemented province-wide in 2008. BC PSLS has been instrumental in promoting patient safety within the health care system in BC [16].

In response to the introduction of Vanessa's Law and in collaboration with Health Canada, BC PSLs launched PSLs-ADR as a new add-on to the existing system in 2014 and released an updated version in 2019 [18,19]. PSLs-ADR is accessible to health care facilities in all health authorities across BC, including acute care hospitals, long-term care facilities, and outpatient clinics. Authorized health care professionals with access to the secure health authority network, including employees, medical staff, paramedics, contractors, students, and volunteers, can submit reports to PSLs-ADR [15]. Once a report is submitted, the system notifies the medication safety officer in the respective health authority to review and respond to the event [20]. The health authorities send eligible reports to Health Canada for Vanessa's Law reporting requirements. Reports are not made available to care providers and not integrated into the electronic medical record. They are only generated for the purposes of pharmacosurveillance (Multimedia Appendix 2).

The PSLs-ADR data fields are based largely on the Canada Vigilance Adverse Reaction Reporting Form, with additional questions enabling medication safety officers, pharmacy representatives, and others to follow-up with reporters or patients, if necessary [20]. The PSLs-ADR reporting form contains 26 required data fields that collect information about the patient, the adverse reaction (eg, seriousness), the suspected health products (types, name, route used, therapy dates, and treatments), and the reporters.

About ActionADE

Previous studies found that 32.5% of ADE cases observed in emergency departments are repeat events [21], often occurring due to the unintentional represcription or redispensation of the same or a same-class medication as one that previously caused harm [22]. This recurrence is attributed to the lack of effective means to communicate and integrate ADE information into clinical workflows. ActionADE, a research-driven initiative, was developed to address this communication gap [23,24].

In collaboration with the Ministry of Health, Vancouver Coastal Health, a technology partner, and health professional organizations and clinicians, our research team developed and piloted ActionADE between 2016 and 2019 using participatory design principles and data standards that were evaluated and subsequently pilot tested to optimize the system's usability [10,11,15,24-28]. In 2020, we began the implementation of ActionADE in 1 hospital (Vancouver General Hospital) and then expanded its use to 6 hospitals operated by Vancouver Coastal Health and Providence Health Care as part of a research initiative. Although providers were encouraged to use ActionADE, they maintain complete autonomy in choosing between the PSLs-ADR and ActionADE systems to meet their needs.

ActionADE is a web-based app that allows providers to document and communicate ADE information, bidirectionally through its integration (or linkage) with BC's central drug database (PharmaNet). ActionADE was accessible to a subset of care providers with an eligible prescriber identification number issued by their respective regulatory college (ie, physicians, pharmacists, and nurse practitioners) [29]. Eligible

clinicians submit reports to ActionADE from a designated health authority network, and the data are shared with clinicians within the patient's circle of care via PharmaNet and used to create safety alerts when community pharmacists attempt to redispense culprit or same-class medications. ActionADE complements the PSLs-ADR system by automating ADE reporting to Health Canada (Multimedia Appendix 3).

The ActionADE data fields were developed based on a systematic review of ADE reporting systems worldwide and participatory action research with clinician end users and are compatible with Health Canada's Canada Vigilance Adverse Reaction Reporting Form [10,11,15,27,30]. As ActionADE is integrated with PharmaNet, several fields auto-populate based on the patient's personal health number, including patient's personal and demographic information (ie, name, date of birth, and sex), reporter's information (ie, name, role, and site), and patient's 14-month medication dispensation history. To create a new report, the system auto-populates the patient's information and medication dispensation history, as well as the reporter's information. ActionADE contains 5 required data fields that collect information about the suspect drugs, which is auto-generated based on the medication dispensation history or added manually, the ADE type, and details of the event (eg, symptoms or diagnosis, outcome, and certainty; Multimedia Appendix 4).

Study Design

In this retrospective observational study, we analyzed reports documented in PSLs-ADR and ActionADE entered by providers at health care facilities operated by the Vancouver Coastal Health Authority (excluding Providence Health Care, as PSLs-ADR data were unavailable from those facilities) in BC, Canada, between December 1, 2019, to December 31, 2022.

For PSLs-ADR, we included reports documented by authorized health care professionals (eg, employees, medical staff, paramedics, contractors, students, and volunteers) from >120 health care facilities across the province, including hospital, urgent and primary care, long-term care facilities, and community health centers' clinics. For ActionADE, we included reports documented by eligible clinicians from 4 hospitals where ActionADE is implemented: Lions Gate Hospital, Richmond Hospital, UBC (University of British Columbia) Hospital, and Vancouver General Hospital (Multimedia Appendix 5) [31].

We divided this study's period into 4 phases: baseline period, when all hospitals across BC only used PSLs-ADR (December 2019 to February 2020); year 1 (March 2020 to November 2020), when 1 hospital (Vancouver General Hospital) had the option to use ActionADE for piloting purposes while all other sites in BC exclusively used PSLs-ADR; and year 2 (December 2020 to November 2021) and year 3 (December 2021 to December 2022), when the 4 hospitals had the option to use PSLs-ADR or ActionADE and all other sites in BC exclusively used PSLs-ADR (Multimedia Appendix 6).

Data Sources

For this study, we requested ADE reports from PSLs-ADR from the BC PSLs central office and retrieved reports documented in ActionADE during the same period from the ActionADE database. We obtained information about hospital

characteristics through the Information Access and Privacy Services at Provincial Health Services Authority, including number of beds, population served, and the number of emergency department visits per year.

Data Extraction

To allow for direct comparisons between the 2 systems, we combined similar variables wherever possible. A clinical pharmacist classified all free-text drug entries from the PLSL-ADR reports into the equivalent generic drug name that would be present if the same report were entered into ActionADE based on the provincial formulary. We translated continuous age from ActionADE into the age categories in PLSL-ADR. We combined information across platforms to produce combined variables for report date, patient demographics (age group and sex), types of ADE (ADRs and nonadverse drug reactions), ADE outcomes (death, emergency visit, hospitalized or hospital extended, life threatening, worsened preexisting condition, permanent disability and fetal defect, other, and unknown) [27], and reporter information (role and facility).

Statistical Analysis

Comprehensive Analysis

First, we performed a comprehensive statistical analysis to provide a global view of coverage, usage, and the types of information captured by both reporting systems. We included all events from both reporting systems, excluding reports related to user errors (eg, duplicate reports), refuted allergies, and reports with incomplete data. We calculated descriptive statistics (eg, means and SDs or frequency and percentages) for the following variables: total number and types of the reporting facilities (hospital vs nonhospital), patient's age group, patient's sex, roles of reporters, proportion of serious events, and the 10 most reported culprit drugs for all events and serious events. We defined serious events based on the Health Canada's definition. This definition includes ADEs that require in-patient hospitalization or prolongation of existing hospitalization, cause congenital malformation, result in persistent or significant disability or incapacity, are life-threatening, or result in death [14].

ADR Analysis

To allow for direct comparisons between the 2 systems, we then conducted a subsample analysis that only included ADR reports (a subtype of ADE) that met Health Canada's definition and that could have been reported in both systems. According to Health Canada, ADRs encompass harmful and unintended responses to a health product, including any undesirable patient effects suspected to be associated with health product use. This definition includes unintended effects, health product abuse, overdoses, interactions (including drug-drug and drug-food interactions), and unusual lack of therapeutic efficacy, all of which are considered reportable adverse reactions [14,32,33]. We included eligible ADR reports from both reporting systems from sites where both systems were available, excluding reports related to user errors (eg, duplicate reports), refuted allergies,

and reports with incomplete data. We calculated descriptive statistics for the following variables: patient's age group, patient's sex, proportion of serious events, the 10 most reported culprit drugs, and mean monthly counts of all events and serious events during each phase of this study period, stratified by reporting system. We conducted all analyses using SAS statistical software (version 9.4; SAS Institute).

Ethical Considerations

The UBC (University of British Columbia) clinical research ethics board approved of this research (H18-01332 and H22-00312) and provided a waiver for obtaining informed consent as this study meets the Tri-Council Policy Statement minimal risk criteria.

Results

Comprehensive Analysis

We extracted 3248 reports from both reporting systems. After removing 213 reports related to refuted allergies, erroneous reports, and reports with incomplete data, the analytic cohort for the comprehensive analysis comprised 3035 unique ADEs reported in either system (Figure 1). Of these, 12.4% (375/3035) were entered in PLSL-ADR and 87.6% (2660/3035) were reported in ActionADE.

Approximately 50% of the events occurred in male patients in both PLSL-ADR (178/375) and ActionADE (1285/3035). The highest proportion of events were from patients aged 45-64 years (32.8%, 123/375) in PLSL-ADR and aged 75-84 years (25.3%, 674/2660) in ActionADE. In total, 12 facilities (5 hospitals and 7 nonhospital facilities) entered reports in PLSL-ADR. The primary reporters in PLSL-ADR were medical imaging staff or technicians (170/375, 45.3%) and pharmacists (174/375, 46.4%). Of the 4 hospitals that entered reports in ActionADE, pharmacists were the reporter for 92.1% (2451/3035) of the events. The proportion of serious events was 36% (135/377) in PLSL-ADR and 28.2% (749/3035) in ActionADE (Table 1).

In PLSL, the most common culprit drugs were iohexol, gadobutrol, and empagliflozin, accounting for 46.2% (173/375) of all events. Empagliflozin, ibuprofen, and iohexol represented 11.8% (16/135) of serious events (Tables 2 and 3). Iohexol and gadobutrol are both contrast agents used for diagnostic imaging, whereas empagliflozin is an oral medication primarily prescribed for managing type 2 diabetes mellitus and ibuprofen is an oral, over-the-counter nonsteroidal anti-inflammatory drug used to relieve pain, reduce inflammation, and alleviate fever.

In ActionADE, the most common culprit drugs were hydrochlorothiazide, ramipril, and apixaban, which accounted for 10.5% (356/3391) of all events; hydrochlorothiazide, empagliflozin, and apixaban represented 11.1% (105/951) of serious events (Tables 2 and 3). Hydrochlorothiazide and ramipril are commonly prescribed for hypertension. Apixaban, an oral anticoagulant, is primarily used for stroke prevention in patients with atrial fibrillation and for treatment and prevention of venous thromboembolism.

ADR Analysis

We included a total of 2728 reports that met Health Canada's definition of an ADR from facilities that had the option of using either reporting system during this study's period (Figure 1) [32,33]. Of the included reports, 12.9% (353/2728) were entered in PSLs-ADR, while the majority (2357/2728, 86.4%) were reported in ActionADE.

The distribution of ADR reports by patient sex, age, primary reporters and proportion of serious events for both systems were similar to the comprehensive analysis (Table 4). However, each reporting system revealed distinct patterns of reporting. In PSLs-ADR, iohexol, gadobutrol, and empagliflozin accounted for 44.8% (168/353) of all events, while empagliflozin, ibuprofen, and nivolumab represented 12.1% (16/133) of serious events. In ActionADE, hydrochlorothiazide, ramipril, and

apixaban accounted for 12% (284/2357) of all events. Furthermore, hydrochlorothiazide, empagliflozin, and apixaban represented 13.4% (88/671) of serious events (Tables 5 and 6).

A direct comparison in events reportable through both the PSLs-ADR and ActionADE systems revealed an increase in event reporting, including serious events, following the implementation of ActionADE (Figures 2 and 3). Baseline measurements indicate that the mean monthly counts of all events and serious events across sites were 2.9 (95% CI 2.2 to 3.6) and 1.7 (95% CI 0.8 to 2.5), respectively. In period 3, the mean monthly counts of all events and serious events across sites escalated to 27.2 (95% CI 20.4 to 34.0) and 7.0 (95% CI 4.9 to 9.2), respectively, reflecting a 9- and 4-fold increase over time. Furthermore, the mean monthly counts of all events and serious events during this study's period within the ActionADE system were 6- and 4-fold greater than that of PSLs-ADR.

Table 4. Descriptive statistics of events meeting Health Canada's ADR^a definition^b across common reporting sites^c by reporting system.

Characteristics	PSLS-ADR ^d (n=353), n (%)	ActionADE ^e (n=2357), n (%)

Discussion

Principal Findings

Our study aimed to describe and compare ADEs reported using 2 distinct reporting systems that were developed and implemented in different ways. Both PSLS-ADR and ActionADE are currently in use in BC in the first 3 years following the implementation of Vanessa's Law. We observed differences in reports between the 2 systems regarding their coverage, usage, and the type of ADE data captured.

PSLS-ADR had broader coverage, collecting data from various health care facilities including community health centers, vaccination clinics, and outpatient clinics. Its user base was

more diverse including physicians, nurses, medical imaging staff or technologists, nurse practitioners, pharmacists, and other professionals. In contrast, ActionADE coverage was limited to ADEs identified in patients presenting to 4 participating hospitals, with clinical pharmacists as its primary user. The broader coverage of PSLS-ADR can be attributed to its established position as a provincial safety event reporting platform; its accessibility to a broader range of health professions; and a federal mandate for hospitals to stimulate reporting using health authority wide communication efforts including email blasts, information on health authority websites, and presentations to provider groups. Leveraging the insights gained from PSLS-ADR, our research team is actively collaborating with key stakeholders to broaden ActionADE's

app. The Vancouver Coastal Health Authority, where ActionADE is presently in use, has recently endorsed it as a standard practice for ADE reporting in new care settings, including long-term care homes, in-patient wards, and community clinics.

Although PSLS-ADR exhibited broader coverage, ActionADE demonstrated higher usage. Our comparative analysis revealed that the average monthly counts of all events and serious events in ActionADE were 6 and 4 times higher, respectively, than in the PSLS-ADR system. Several factors might contribute to these discrepancies in reporting rates. First, PSLS-ADR was designed solely for Vanessa's Law compliance, with reports forwarded to Health Canada for surveillance purposes. ActionADE, on the other hand, serves the dual purpose of functioning as both a clinical communication tool and a means of complying with Vanessa's Law, thus improving patient safety [15]. Reports entered into ActionADE are used to generate preventive alerts in community pharmacies when pharmacists attempt redispensation of a drug that has previously caused the patient harm, which have demonstrated preliminary effectiveness [34]. The potential impact of reporting in ActionADE on patient safety is likely a motivating factor for providers to report ADEs [35]. Furthermore, ActionADE has a proactive implementation support mechanism, which has been shown to be instrumental in enhancing providers' adoption of the reporting platform [35]. Finally, ActionADE used participatory design principles to optimize its design to facilitate use by end users and is integrated with PharmaNet to enable prepopulation of fields to allow reporters to generate reports ≤ 2 minutes, whereas PSLS-ADR users noted that reports can take 20 minutes to complete [34].

The 2 systems captured adverse events to different culprit drugs. This can be attributed to the more limited accessibility of ActionADE. The most reported drugs in PSLS-ADR were iohexol and gadobutrol, and correspondingly, medical imaging staff or technologists made up a significant proportion of reporters. This suggests that the current workflow for ADR reporting of radiopharmaceuticals is designated to medical imaging staff or technologists. Imaging staff or technologists were unable to use ActionADE at the time of this study due to PharmaNet legislation, which requires that users have prescriber ID restricting use to physicians, pharmacists, and nurse practitioners. This restriction has resulted in fewer radiopharmaceutical ADRs to be reported, as pharmacists generally do not work in radiology departments.

ActionADE frequently captured hydrochlorothiazide-related events, while only a few of such events were captured in PSLS-ADR. Among the ADRs associated with hydrochlorothiazide, electrolyte disturbances, and acute kidney injury were found to be the most common [34], involving multiple additional contributing factors. The specific functionality offered by ActionADE, such as the ability to specify the provider's certainty that the patient's presentation and the option to update or refute events based on new information or alternative diagnoses, likely played a role in encouraging clinicians to report these more complex events [11,15,27,30].

Ibuprofen was the second most commonly reported culprit drug related to serious events in PSLS-ADR, but it barely made the top 10 in ActionADE. This discrepancy may be due to the over-the-counter status of ibuprofen, which means patients can access the medication without a prescription and bypass communication about ADEs from ActionADE that is built into the prescription dispensation process.

While our study primarily focused on comparing these 2 systems, it is crucial to view these findings in the broader context of ADE reporting. Despite these disparities, both systems play vital roles in contributing to patient safety by capturing valuable information on ADEs. PSLS-ADR is an effective means of capturing radiopharmaceutical-related ADEs by imaging staff and technicians who are not trained in taking medication histories or ADE assessments, while ActionADE is more effective for pharmaceutical-related ADEs by clinical pharmacists that are reported and communicated on a patient-level to improve safety. These systems work in a complementary manner, catering to different areas of the health care system and capturing unique data and thus offering a more comprehensive picture of ADEs. For example, a common signal between the 2 systems might indicate a more serious issue for a specific drug irrespective of context (eg, empagliflozin). These findings suggest the need for careful attention to the design and implementation of these systems to ensure they effectively serve their intended users and context of use and ensure data resulting from each system are interpreted correctly by end users. The absence of reporting of one type of event may reflect design, implementation, or user characteristics rather than the absence of these events.

Limitations

To our knowledge, this is the first study to directly compare 2 ADE reporting systems operating within the same jurisdiction. While the results of our study provided valuable insights into the differences between these systems, it is important to acknowledge several limitations that warrant consideration in interpreting the results. First, our study sample was confined to 2 reporting systems, which may not fully encapsulate the diversity of all systems employed across health care settings globally. As a result, the findings may not be generalizable to other reporting systems. Second, our data set was limited to facilities that used PSLS-ADR or ActionADE for reporting. This reduces the generalizability of our findings to the wider array of health care facilities in BC or nationally. It is plausible that unaccounted-for variations in data and reporting practices among facilities not deploying these 2 systems could exist. Third, our study may be susceptible to unmeasured and uncontrolled confounding variables. For example, the level of organizational emphasis on ADE reporting, differences in implementation, available resources, and providers' perceptions could have affected the usage and coverage of the 2 systems under study. This variability might have further influenced the nature of ADE information reported. Fourth, the relatively small number of drugs resulting in ADEs prevented us from conducting a robust quantitative comparison of these events. Furthermore, the data we used were a snapshot in time and may not reflect changes in reporting systems or health care facilities that have occurred since then. Lastly, we consciously chose not

to draw comparisons with other studies examining the frequently reported culprit drugs from spontaneous reporting systems in other jurisdictions. This decision stems from the recognition that the diversity in ADE reports—both in terms of numbers and types—is intricately tied to factors such as system design, geography, population characteristics, drug exposures, and the medical system itself. To facilitate meaningful comparisons across studies, a more robust surveillance system is needed.

Conclusions

Understanding the differences between reporting systems can inform future systems design and improvement, including

changes to user training and implementation, and inform the use of forthcoming data and procurement decisions for reporting systems. Further research could explore how to integrate the strengths of both systems, potentially leading to more comprehensive safety data to facilitate drug and patient safety and inform pharmacoepidemiologic studies. Continuous evaluation and improvement are essential considering the significant role these systems play to improve our health systems.

Acknowledgments

The ActionADE platform is funded by the Canadian Institutes of Health Research, with support from the Ministry of Health British Columbia, Vancouver Coastal Health, the Lower Mainland Consolidated Pharmacies, and the BC SUPPORT Unit. CMH is supported by the Michael Smith Foundation for Health Research Health Professional-Investigator award. EYL is supported by the Michael Smith Health Research BC Research Trainee Award (GR018656). The funder has no role in the design, conduct, analysis, interpretation of data, or the drafting of scientific papers.

Authors' Contributions

All authors contributed to this study's conception and design. EYL requested access and analyzed the data and wrote the first draft of this paper. AC, CMH, and SSS contributed to the refinement of the data analysis. All authors contributed to the interpretation of the findings and commented on previous paper versions. All authors read and approved the submitted paper and have agreed to be personally accountable for their contribution.

Abstract

Background: A lack of information during an emergency visit leads to the experience of powerlessness for patients and their family members, who may also feel unprepared to cope with acute symptoms. The ever-changing nature and fast-paced workflow in the emergency department (ED) often affect how health care professionals can tailor information and communication to the needs of the patient.

Objective: This study aimed to evaluate the usability and experience of a newly developed information system. The system was developed together with patients and their family members to help provide the information needed in the ED.

Methods: We conducted a mixed methods study consisting of quantitative data obtained from the System Usability Scale questionnaire and qualitative interview data obtained from purposively selected participants included in the quantitative part of the study.

Results: A total of 106 patients and 14 family members (N=120) answered the questionnaire. A total of 10 patients and 3 family members participated in the interviews. Based on the System Usability Scale score, the information system was rated close to excellent, with a mean score of 83.6 (SD 12.8). Most of the participants found the information system easy to use and would like to use it again. The participants reported that the system helped them feel in control, and the information was useful. Simplifications were needed to improve the user experience for the older individuals.

Conclusions: This study demonstrates that the usability of the information system is rated close to excellent. It was perceived to be useful as it enabled understanding and predictability of the patient's trajectory in the ED. Areas for improvement include making the system more usable by older individuals. The study provides an example of how a technological solution can be used to diminish the information gap in an ED context.

Introduction

Background

Clear communication and information are essential to improving care and patient outcomes in the emergency department (ED) [1-5]. A lack of information during ED visits causes patients and their family members to experience a sense of powerlessness and to feel unprepared to cope with acute symptoms [2,3,6]. Due to the hectic nature of the ED and the constant interruptions, communication from health care professionals is often inadequate or not tailored to patients and their families [4,7]. While this problem has been known for many years, it still persists to this date [1].

Health technologies are implemented in many parts of health care systems to promote quality care and treatment [8]. The design and purpose of health technologies range widely from organizational [9] to person-centered intentions [10]. In the ED, technologies may be used as quality dashboards [9] and more personal information systems on patients' own devices to support the delivery of health information [11]. However, the successful use of technology in clinical practice is likely to be ineffective if user needs are not carefully addressed and incorporated before attempting a full-scale implementation [9,12]. Thoroughness in integrating and understanding user perspectives will have a direct impact on how well the technology is suited for clinical practice [13,14].

Based on the current findings, patients in the ED and their family members have unmet information needs [1-4]. Hence, guided by the principles of user-driven activities [15], a health information system was developed [16]. The health information system, which is called "Cetrea Clinical Logistic (CCL) for patients," is available for patients in the hospital's emergency room and displays real-time information, including (1) person-centered activities, (2) information videos, (3) a notepad, (4) waiting time, and (5) the nurse and physician responsible for care.

Usability is one of the factors affecting the acceptance of health information systems by users, and it is essential for the effective use of the system [17]. A usability evaluation can identify problems and weaknesses in the design and functionalities in the early development phase [18]. Usability tests allow developers to address and adjust concerns and, thus, avoid

implementing technologies that will not be useful in the clinical context.

Therefore, a usability evaluation from an end-user perspective was completed to obtain a nuanced understanding of the sustainable use of the system, specifically from the perspective of patients and their family members.

Objective

The objective of this study is to gain knowledge about the usability and experiences of the newly developed information system, CCL for patients. This study reports on patients' and family members' evaluations of this system.

Participatory Design and Technology

This study is the final phase of a 3-phase participatory design study (Figure 1) [19]. Participatory design is a research methodology based on the epistemological position of genuine involvement and understanding of the needs of future end users. A new technology can be designed to improve a real-life problem [20]. The core principles in participatory design methodology have been the theoretical framework of the overall study. In the initial phase, the author group identified the essential needs of patients in the ED, their family members, and ED clinicians [2,3]. The results from phase 1 informed the second phase, in which an information system, CCL for patients, was developed in a cocreation process [16]. The third phase involved testing and evaluation of the system, which is reported in this study. Reporting the evaluation of participatory-designed health technology is a common part of the research methodology [21,22].

The author group has had no financial interest in the system owners of CCL for patients and has no interest in either marketing or promoting the system.

CCL for patients provides information directly to patients and their family members during their stay in the ED. The information provided relates to treatment and time factors and is adjusted toward the individual patient. CCL is an already existing and implemented system for task management for clinicians' use only [23], whereas CCL for patients is a redesign and further development of the system for patients' use.

The functionalities of the CCL for patients' screen are presented in Figure 2.

Figure 1. Overview of the 3-phase study, highlighting the evaluation phase, which is reported in this study.

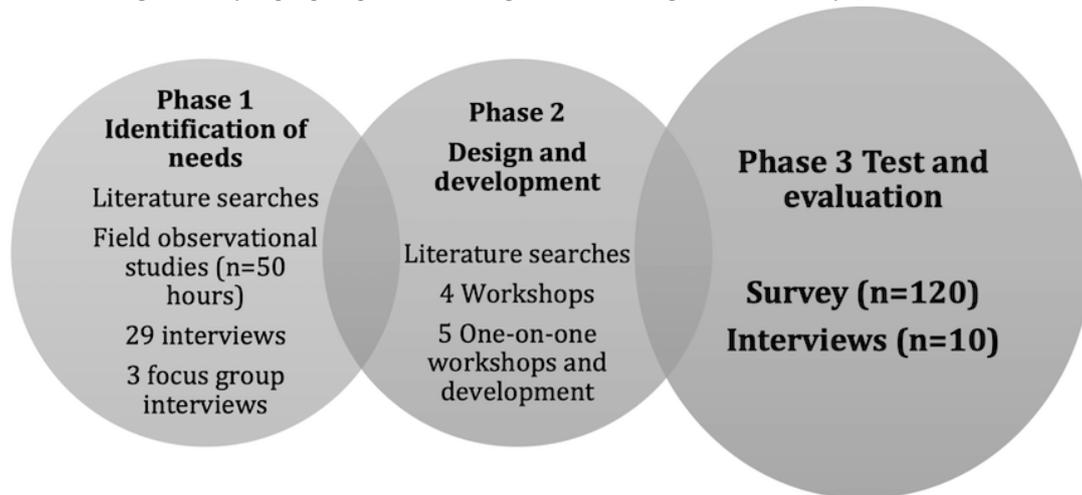

Figure 2. Cetrea Clinical Logistics (CCL) for patients and its functionalities, as displayed to patients and their family members, developed in the second phase of the overall study (the figure has been previously published by Østervang et al [16]). (1) Number of the ED room. (2) Name of the hospital department. (3) The name of the patient (no sensitive information is displayed). (4) The nurse who is responsible for care. (5) The physician who is responsible for treatment. (6) Process line with activities. Displaying nurse assessments, blood samples, electrocardiograms, physician assessments, X-rays, etc. (7) Clarification of the different colors in the process line. Gray: not started; blue: activity scheduled; and green: activity finished. (8) Clarification of special activity names. (9) Link to information videos (eg, information on discharge). (10) Three diverse colors indicate the estimated waiting time: less than 4 hours, equal to 4 hours, or more than 4 hours, respectively. (11) The shared note pad for the patients to write questions to health care professionals or messages from family members.

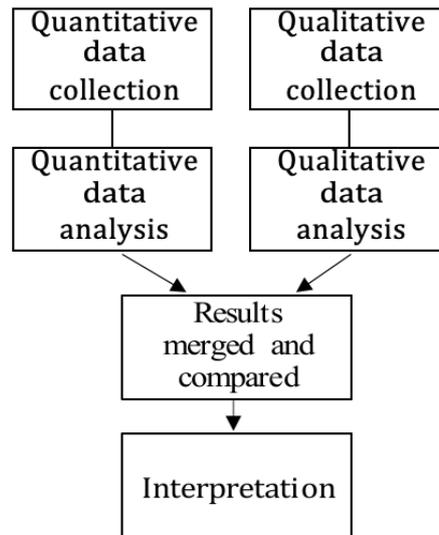

Methods

Research Design

This is a mixed methods study inspired by a convergent parallel design [24]. This design was chosen to obtain nuanced insights into the usability of the system. Further, we adopted this approach to usability testing because quantitative data can

identify usability issues and dissatisfaction with program design, while qualitative data can provide detailed information about the causes of the usability issues and point at potential methods for program optimization. As shown in Figure 3 [24], the study contained the following two parts, ending with a merged result: (1) a questionnaire and descriptive characteristics of the participants, and (2) semistructured interviews with patients and their family members.

Figure 3. Diagram for a study using convergent design (Creswell and Clark) [24].

Setting

The data were collected in Odense University Hospital's ED between August 22 and September 29, 2022, on weekdays from 8 AM to 5 PM. The information system was displayed on a laptop personal computer (PC) sitting on the bedside table in the ED room. Four PCs were used during the test phase. They were installed in the specific ED room where the patients participating in the study were admitted.

Inclusion Criteria and Recruitment

All patients admitted to the medical area of the ED without a final plan for treatment and care were eligible for participation. Patients were excluded if they were severely ill or cognitively unable to use the technology. However, patients who were excluded due to a cognitive inability to use the screen but who were still able to give consent for their family members' participation were enrolled if the family member was interested in participating. Patients were recruited by the first author (CØ) or one of 2 research assistants, all of whom have a Master of Nursing Science degree and research experience. Potential participants were identified and discussed with the responsible care nurse before they were approached to reduce the possibility of any concerns.

Quantitative Phase

A survey was conducted to elicit the opinions and experiences of patients and their family members using the information system.

The Questionnaire

The questionnaire, the System Usability Scale (SUS), contained questions regarding the usability of the system. Answers are rated on a 5-point Likert scale from "strongly disagree" to "strongly agree," with 5 representing the highest score (strongly agree) [25]. The participants answered 10 questions from the SUS and 2 questions specific to this study (questions 11 and 12) [25]. These 2 extra questions were added to obtain general information about the participants' experience with CCL for patients (question 11: "I think the system provided a great overview of my stay," and question 12: "I think the information

in the system made sense to me"). As SUS has been translated and validated in a Danish hospital context previously (Cronbach $\alpha=.87$) [26], it was considered suitable for this study.

Sample Size

A total SUS score between 70 and 90 indicates good to excellent usability of the tested system [27]. Based on previous research conducted in Scandinavia using SUS in health care with a reported mean score of 79.81 (SD 14.28), we would gain a 95% CI for a mean score between 77.2 and 82.4 if a total of 120 patients were included [28].

Data Collection

If a patient agreed to participate, the researcher cooperated with the local IT department at the hospital to ensure the patient's access to the system. Initially, the researcher sent the IT department an SMS text message providing information on the PC number and the ED room number. The IT specialist matched the PC and room numbers. Then, the researcher double-checked that the correct information was displayed before handing it to the patient. All participants were given oral guidance on how to use CCL for patients.

The PC with individual information was placed on the bedside table until either the patient left the ED, the patient had used the system for a minimum of 2 hours, or the patient felt ready to perform the evaluation. All of this had to happen no later than 5 PM, when the IT department closed. When returning the PC, the participants were given an iPad to fill out the questionnaire. The data were stored on the logged server OPEN [29], which is part of Odense University Hospital and the University of Southern Denmark.

Qualitative Phase

Interviews were conducted with individual patients or with the patient together with a family member to get a deeper insight into their experiences using the information system.

Interviews

The qualitative part included a subset of the participants from the quantitative part. Before making CCL for patients available

to the participants, they were asked whether they were interested in participating in an interview.

All interviews were conducted by the first author (CØ). By taking a phenomenological-hermeneutical stance, CØ was allowed to recognize her perceptions as an experienced emergency nurse within hermeneutic interpretation [30]. To bridle her preconceived ideas, CØ wrote down her preunderstandings of why patients lack information in the ED. This reflection provided an initial focus for both the overall research question and the interview questions.

The interviews were conducted in the hospital room after the participants had completed the questionnaire. Notes and quotes were taken during the interview. A summary of the conversation was generated at the end of the interview in the form of member checking [31]. A semistructured interview guide inspired by Kvale was used [32]. An example of a question is: "What was your experience of using CCL for patients?" The interviews lasted up to 30 minutes. The interviews were conducted until no new themes arose [33].

Sample Size

To obtain maximal variation, a purposive sampling strategy was used [33]. The inclusion criteria were the same as for the quantitative part of the study, but they also ensured representation of differences in age and gender.

Analysis

Analysis of the Questionnaires

Only fully completed questionnaires were analyzed (N=120). There were no missing data, as the questionnaire was only considered complete if all the questions were answered. According to the SUS guidelines, we performed an individual analysis of each participant's SUS score as well as the mean value for the entire population. We separated the 2 self-constructed questions from the original SUS questions in the calculation and interpretation process to ensure that they were accurate and reliable. The final score was between 0 and 100, where a higher score indicates better usability. Odd-numbered questions were positive in tone, and even-numbered questions were negative in tone, so the scale was converted into points ranging from 1 to 5 (1=strongly disagree to 5=strongly agree). The final score was calculated as follows: $X = \text{the sum of the points for all odd-numbered questions} - 5$. And $Y = 25 - \text{the sum of the points for all even-numbered questions}$. $\text{SUS score} = (X + Y) \times 2.5$ [34]. A system needs a score above 70 to be considered acceptable; better systems will score from the high 70s to the high 80s, and excellent systems will score above 90 [27].

Analysis of the Interviews

The qualitative interviews were analyzed and reported based on Malterud's [35] systematic text condensation. This process

consisted of four steps: (1) transcriptions were read several times to get a total impression of the data and to find preliminary themes; (2) we identified and sorted meaning units based on the preliminary themes and arranged them into code groups; (3) the code groups were reviewed, and the content was reduced into condensates; and (4) the meaning and content of the condensates were synthesized and interpreted [35]. The analysis was completed by CØ using NVivo (version 12; QSR International). The trustworthiness and rigor of the qualitative part of the study were evaluated using Guba's [36] definition of quality criteria. As part of steps 2, 3, and 4 in the analysis, the emerging themes and codes were discussed in the author group toward strengthening the credibility and reflexivity of our interpretation of the interviews. Using a systematic approach toward the analysis strategy of all interviews ensured confirmability in the data collection and analysis process.

The SQUIRE 2.0 checklist [37] was used to create transparency and ensure that no important information was missed in the reporting of the study.

Integration of Quantitative and Qualitative Results

To achieve an expanded understanding of the results, the qualitative and quantitative results were compared and integrated as the final step of the analysis using joint display tables [24]. In a joint display table, the 2 results are presented in a way that allows comparison, leading to confirmation, disconfirmation, or expansion of each other [24]. The results from the SUS (quantitative results) are presented on a Likert scale, showing the variation of the grades in the different questions. To elaborate on and verify the answers, supportive qualitative quotes were presented for each question. We divided the grades into low (1-3) and high (4-5) to separate the different perceptions of CCL for patients.

Ethical Considerations

All the participants received verbal and written information about the study in accordance with applicable ethical rules [38] and provided their oral and written consent. The study is registered with the Danish Data Protection Agency, Fortegnelsen (19/22672). Approval of the project was granted by the Regional Committee on Health Research Ethics for Southern Denmark (S-20192000-111).

Results

Quantitative Results

In total, 14 family members and 106 patients agreed to participate. A total of 27 patients declined to participate for three main reasons: (1) no interest, (2) no technical skills, and (3) a lack of mental ability due to the acute situation.

Table 1. Demographic descriptions of the participants.

Demographic description	Patients (n=106)	Family members (n=14)	Total (N=120)
Gender, n (%)			
Female	55 (51.9)	8 (57.1)	63 (52.5)
Male	51 (48.1)	6 (42.9)	57 (47.5)
Age (years), mean (SD)	55.5 (SD 18.7)	66.5 (SD 11.6)	57 (SD 18.3)
Civil status, n (%)			
No partner	39 (36.8)	2 (14.3)	41 (34.2)
In a relationship	67 (63.2)	12 (85.7)	79 (65.8)
Children, n (%)			
Having children	81 (76.4)	14 (100.0)	95 (79.2)
Having children living at home	32 (39.5)	6 (42.9)	38 (40.0)
Technology, n (%)			
Having a smartphone	96 (90.6)	14 (100.0)	110 (91.7)
Using technology on daily basis	102 (96.2)	13 (92.9)	115 (95.8)
Education, n (%)			
Low	21 (19.8)	1 (7.1)	22 (18.3)
Medium	71 (67.0)	9 (64.3)	80 (66.7)
High	14 (13.2)	4 (28.6)	18 (15.0)

The respondents were equally represented by gender, with a mean age of 57 years. The mean age of family members was higher than that of the included patients. Most participants had medium education levels, but low and high educational levels were also represented.

Overall, the participants answered the survey positively. As displayed in [Tables 2](#) and [3](#), each item could have a score contribution between 1 and 5. All the odd-numbered (positive) questions had a score contribution above 4.27-4.53, and all the

even-numbered (negative) questions had a score ranging from 1.52 to 1.99. Question 1 had the most positive answers: 94.2% (113/120) strongly agreed or agreed that they would like to use the system if they were hospitalized again. Question 4 had the highest negative score value, indicating that the participants felt they needed help using the system. Of the participants, 50.8% (61/120) indicated that they were confident using the system, answering “strongly agree” to question 9, and 87.5% (105/120) strongly agreed or agreed that most people would be able to learn to use this system.

Table 2. Results of the System Usability Scale for all participants (N=120) and the System Usability Scale score contribution of individual items.

System Usability Scale analysis item	Value per 5-point Likert scale response, n (%)					Score contribution (1-5), mean (SD)
	1 (strongly disagree)	2 (disagree)	3 (neutral)	4 (agree)	5 (strongly agree)	
1. I think I would like to use this system, if I am admitted again.	0 (0)	0 (0)	7 (5.8)	42 (35)	71 (59.2)	4.53 (SD 0.61)
2. I found the system unnecessarily complex.	61 (50.8)	41 (34.2)	11 (9.2)	5 (4.2)	2 (1.7)	1.72 (SD 0.92)
3. I thought the system was easy to use.	1 (0.8)	1 (0.8)	8 (6.7)	39 (32.5)	71 (59.2)	4.48 (SD 0.73)
4. I think that I would need help from the staff to be able to use this system.	49 (40.8)	44 (36.7)	11 (9.2)	11 (9.2)	5 (4.2)	1.99 (SD 1.12)
5. I found the various functions in the system to be well correlated.	1 (0.8)	1 (0.8)	8 (6.7)	65 (54.2)	45 (37.5)	4.27 (SD 0.69)
6. I thought there was too much inconsistency in this system.	56 (46.7)	52 (43.3)	8 (6.7)	1 (0.8)	3 (2.5)	1.69 (SD 0.84)
7. I would imagine that most people would learn to use this system very quickly.	0 (0)	0 (0)	15 (12.5)	53 (44.2)	52 (43.3)	4.31 (SD 0.68)
8. I found the system very cumbersome to use.	70 (58.3)	42 (35)	5 (4.2)	2 (1.7)	1 (0.8)	1.52 (SD 0.73)
9. I felt very confident using the system.	2 (1.7)	6 (5)	4 (3.3)	47 (39.2)	61 (50.8)	4.33 (SD 0.89)
10. I needed to learn a lot things before I could get going with this system.	67 (55.8)	42 (35)	7 (5.8)	4 (3.3)	0 (0)	1.57 (SD 0.75)

Based on the answers to the 2 self-constructed questions, (Table 3), 57.5% (69/120) of the participants strongly agreed that CCL for patients provided a great overview of their stay, and 87.5% (105/120) agreed or strongly agreed that the information in the system made sense to them.

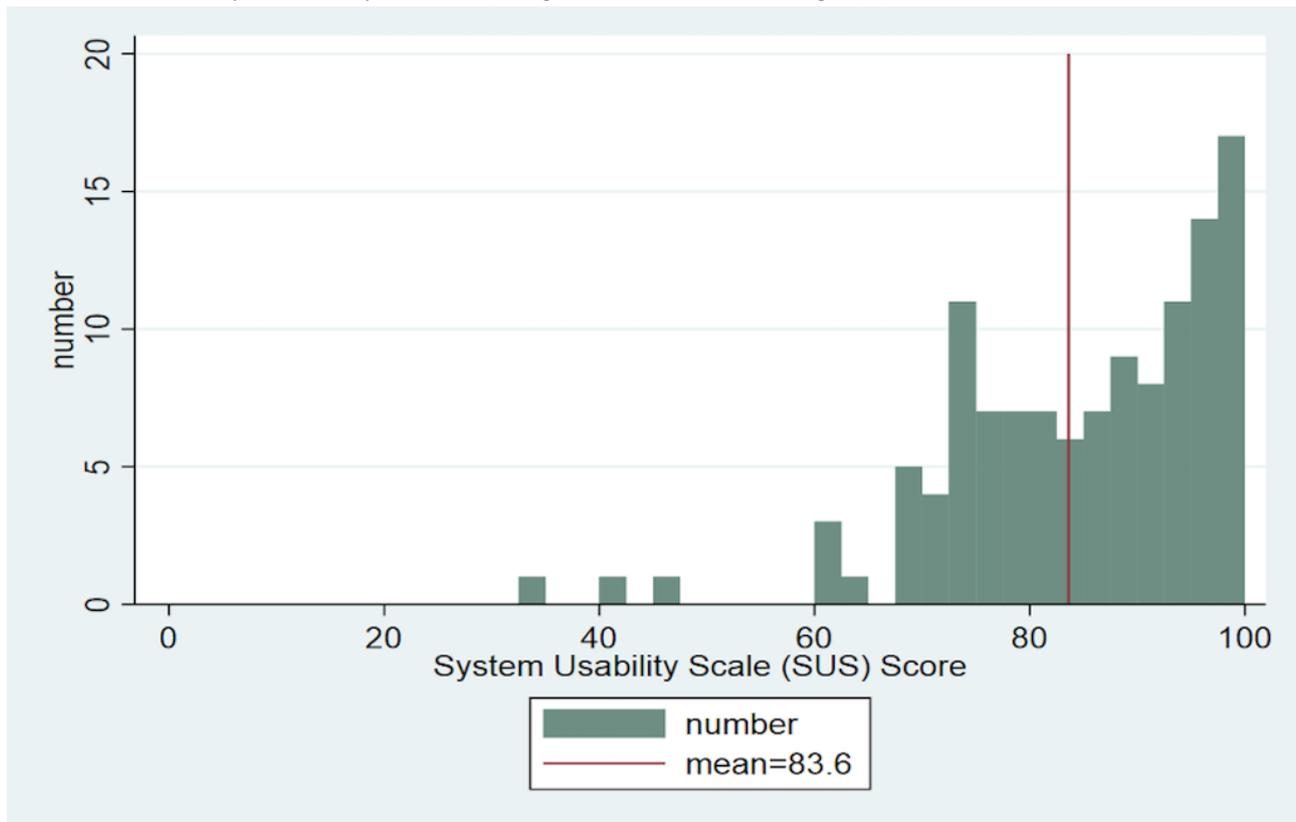

Table 3. Results of general questions calculated by System Usability Scale principles for all participants (N=120) and the System Usability Scale score contribution of individual items.

System Usability Scale analysis item	Value per 5-point Likert scale response, n (%)					Score contribution (1-5), mean (SD)
	1 (strongly disagree)	2 (disagree)	3 (neutral)	4 (agree)	5 (strongly agree)	
11. I think the system provided a great overview of my stay.	0 (0)	2 (1.7)	10 (8.3)	39 (32.5)	69 (57.5)	4.46 (SD 0.72)
12. I think the information in the system made sense to me.	1 (0.8)	5 (4.2)	9 (7.5)	45 (37.5)	60 (50)	4.32 (SD 0.85)

For all participants, the total mean score for the SUS scale was 83.6 (SD 12.8), indicating that the system had close to excellent usability.

The median score was 85, and Figure 4 [27] shows the distribution of the individual answers. The scores covered the entire range from 0 to 20 persons per score, and the majority of individuals scored above 70.

Figure 4. Overview of the System Usability Scale (SUS) rating table with inserted value ranges [27].

Qualitative Results

A total of 10 patients and 3 family members (1 daughter aged 55 years, 1 son aged 65 years, and a husband aged 37 years) were interested in elaborating on their experience of CCL for patients after they had tested the system, and the questionnaire was completed. The patients were aged between 32 and 96 years, with equal representation of men and women, and 3 patients were retired.

The following three main themes emerged from the analysis: (1) future perspectives on usability and design; (2) means toward empowerment; and (3) family implications. These themes will be elaborated on using quotes in the upcoming sections.

Future Perspectives on Usability and Design

The majority of the participants expressed a very positive attitude toward CCL for patients but also offered ideas for the future design of the system. The part of CCL for patients that displayed the estimated waiting time in the ED was found to be intuitive and easy to understand and provided informative insights that prepared the participants for their length of stay. This reduced their frustration with not knowing. However, they expressed concerns about the system's lack of familiarity and that it could be improved if the design was like other systems they used in everyday life, such as email or smartphone apps.

The system was not difficult at all but I think it would benefit from more recognizability with others systems, for example, email or iPhone applications. [Male in his 60s]

Most participants valued the line that displayed the boxes with activities the most. They found this part of the system to be

essential, as it was the only part that provided direct, personalized information. While they all expressed that they were able to understand the meaning of the changing colors, they also suggested that the text in the boxes could be provided in plain language or a “help” function with text or video could be used to explain the activity in the box.

The line with the boxes could be much larger, as this is the most important part! It would be great if you could choose whether you would like to see only the line or all actions on the screen. [Joint interview, male patient in his 80s and daughter in her 50s]

The participants all watched more than one video, and there was a consensus that the content in the videos was helpful. A few patients who were placed in the hallway due to crowding found it difficult to listen to the videos not only because of the general noise but also because they were afraid of disturbing others. However, the information provided by using videos instead of text was appreciated.

The content in the videos was exactly the information I needed. It was nice to be able to revisit the information in the video. [Female patient in her 50s]

A participant found CCL for patients to be too general. More personalized information, such as individual test results, should be incorporated. Moreover, patients who were visually impaired found the system difficult to use.

I have difficulties with my vision, and I do not think I would have been able to use this without help. [Female patient in her 60s]

Means Toward Empowerment

All of the participants agreed that the system provided an overview that otherwise would not have been accessible for them. Knowing who their treating nurse and doctor were calmed the participants. They described a feeling of not being forgotten in the hectic environment of the ED. Moreover, they valued being able to follow when activities changed from passive to active. Consistency between actions on the screen and in real life provided them with confidence in health care professionals.

When you are here, you can hear people working, but you do not know if anyone is taking care of your situation, or you are forgotten. The system helped us to believe we were not forgotten (...) We loved that when something happens on the screen then it was also reflected in real life. E.g. when the screen said the doctor was on his way- he actually came. [Joint interview, female patient, and husband in their 30s]

Several of the participants stated that having CCL for patients available made them feel calm, as the system provided predictability. Further, having an overview helped them to remain in control of the course of treatment in the ED. Some of the participants said this system could save the nurses' time, as they felt they were more empowered to handle the situation in the ED since they knew what they were waiting for.

The questions that I would have needed a nurse to answer were provided by the system; that was really great. [Female patient in her 30s]

A few of the participants were worried that CCL for patients would need resources from health care professionals that were already scarce.

I am worried that the system takes time away from the patients to support the system. [Joint interview, male patient in his 80s and daughter in her 50s]

Family Implications

Both patients and family members indicated that giving family members direct access was important. CCL for patients gave the family up-to-date information about the care and treatment-related interventions as soon as they attended the hospital room, and they did not need to wait for a nurse or doctor to get an idea of what was planned.

My mother is not able to remember what she is planned for today. I think it was great for me to see she is waiting for X rays. [Female patient in her 90s and son in his 60s]

Furthermore, the family members reported that the system helped them to support the patient, as they could keep track of the interventions provided by CCL for patients. Family members of older patients felt the system was too complicated for the older individuals to use but appreciated that the system was available for them because it allowed them to talk the patient through the stay in the ED. Moreover, a family member stated that the system made it possible for him to let his wife go to sleep, as they agreed that he would wake her up when he saw that activities were about to happen.

It was nice for me to have a system that told us when things were going to happen. My wife fell asleep, and I knew I did not need to wake her up before I could see the box turned into the blue color. It was easy to understand. [Joint interview, female patient, and her husband in their 30s]

Merged Data

We combined the quantitative and qualitative data in a joint display ([Multimedia Appendix 1](#)), providing an assessment of the quantitative and qualitative data together. In this way, the data allow us to expand our understanding of patients and their family members' experiences with CCL for patients. For example, in question 1, the participants were asked whether they would like to use CCL for patients again. The participants who gave a lower score (1-3) to that question were concerned if the system would replace personal appearance from health care professionals, whereas those who gave it a high score (4-5) valued how the systems helped them to keep control.

Furthermore, question 7 regarding people's ability to learn to use the system revealed that the participants who gave a low score (1-3) wanted more simplicity, fearing that the older patients would find the system difficult. Meanwhile, the participants who gave high scores (4-5) felt that the system was easy to use. Regarding question 11, the majority of the patients and their family members stated that CCL for patients provided a great overview of the patient's pathway. They further elaborated on this in the interviews, as they felt that the overview of care in the system helped them to feel less stressed and better understand the treatment pathways.

Discussion

Principal Findings

In this study, we report that the perceived overall usability of the health information system CCL for patients is good to excellent, providing information that is needed during the entire emergency process. The participants rated the system highly (a score of 83.6 points) and reported that the system gave them an opportunity to remain in control, as they knew what they were waiting for and who was responsible for care and treatment.

Technology as a Means to Empower Patients and Family Members in the ED

Looking into previous research on testing systems using SUS [28], a mean score of 83.6, as found in this study, would indicate that the tested system was successful. However, while CCL for patients was evaluated positively overall, we also uncovered technical concerns regarding usability limitations, specifically regarding the older individuals. Our results showed a mean patient age of 57 years, which represents a relatively young ED population. However, the mean age of the family members was almost 10 years (9.5 years) older. The older individuals found the system to be complicated to use and felt that it needed simplified functions, such as a zoom function and recognizability (eg, other well-known systems). Echoing these findings, Verma et al [39] investigated the level of eHealth literacy among older adults and caregivers and found that one main barrier to the adoption of eHealth was a lack of familiarity with the tools

available. In the development phase of CCL for patients [16], decisions had to be made for the system to work in a clinical setting. One decision was the use of an interface design, which did not allow us to integrate well-known functions, for example, from email or application symbols. Our results highlighted that it might not be possible to design technologies using a one-size-fits-all approach. However, in line with previous research [40], we discovered that the usability testing allowed the developers to adjust and isolate functionalities to provide improved usability outcomes in the future. For example, we found that the participants valued the display with the boxes, which could be promoted in a revised version by the availability of a zoom function.

Furthermore, the participants expressed concerns about whether CCL for patients would influence the health care professionals' available time to provide actual care. Barriers to the adoption of technology systems in clinical settings include the workflow or demand for more human resources [12]. As the information system is a redesigned patient flow system, it would not require changes in workflow or unduly burden professional health care resources. Another consideration was the need for personal test results. They could not be provided in the current form of the system, as it would require a personal log-on to avoid safety issues related to General Data Protection Regulations.

The participants who rated the usability the highest explained that the system made them feel that they were in control of the situation without the fear of being forgotten. The system provided an overview of the care transition and, therefore, offered predictability. This need to be in control has been identified in another study, which described patients' and their relatives' dissatisfaction when visiting the ED [6], as they felt powerless in the ED. Not having knowledge or information available led to such feelings of powerlessness. Nursing rounds were suggested in that study to improve information support [6]. Our results showed that the patients felt more independent because they were able to find the needed information using technology.

Being acutely ill places individuals in a vulnerable situation, and their cognitive capabilities are challenged [2]. Communication from health care professionals and how information is presented have a significant influence on how that information is comprehended [2,41,42]. In this study, we developed information videos related to the journey within the ED, and the participants reported that they were an accessible and usable way to understand information in a stressful situation. Patients and their family members declared that this gave them a feeling of empowerment. Indeed, empowering patients to be in control and involved in their own care is recognized as a core value of high-quality patient-centered care [43]. As Emmamally et al [44-46] noted, improved partnering with family members in the ED is needed. If the family is not included, there is an increased risk of miscommunication and poor understanding of health-related matters [2,44,47-49]. However, creating a closer partnership of care has been described as challenging within the ED due to the high workload, overcrowding, and multitasking [47]. This is echoed in recent findings from studies conducted in a Danish context [2,3], in which family members requested more systematic inclusion in the ED. In this study,

the results showed that CCL for patients was perceived as usable and as a useful way to systematically include families during the ED stay.

An update of the Medical Research Council's guidelines for developing and evaluating complex interventions in health care states that appropriate users should be involved in every part of the development, process, and outcome analysis of a complex intervention to ensure sustainable interventions [50]. In line with best practices, the information system has been developed together with representatives of future users of the system, including health care professionals, managers, patients, family members, and IT specialists [16]. For decades, the ED context has been a hectic environment [4,42,51,52]. This creates challenges at both the information and communication levels, affecting whether patients and their families feel in better control during their stay in the ED [1,4,42,51,52]. In this study, we presented and evaluated a simple but unique system that provides timely information to empower individuals without straining health care professionals' resources. The usability test was a crucial and important step to inform changes in functionalities and experiences of using IT in the ED.

Strengths and Limitations

Questionnaires are a common and recognized method for evaluating the usability of health technologies. However, the contextual factors affecting the results are difficult to determine [53]. The SUS did not provide insights on the effectiveness or efficiency of the system, but it is a validated questionnaire and provided an overall understanding of the system [27]. The mixed methods approach [24] enabled the integration of quantitative and qualitative data. This allowed us to obtain an understanding of how the usability was rated and why the results emerged for the specific questions, which is considered a strength of usability testing [40,54].

Additionally, our findings serve as an inspiration to others about how a participatory design process can develop a technology that is aligned with some of the essential needs described by the users of the ED. The findings provide an example of how a technological solution can be used to reduce the information gap in an ED context, as the provision of adequate information to patients and their families is found to be a major challenge in an ED context [2,4,42].

This study also had some limitations. Using a broader evaluation method, for example, a qualitative evaluation questionnaire or an evaluation instrument with more domains, could potentially have provided the study with more nuances [55]. Patients attending the ED outside of the IT department's business hours were not able to use the system. Therefore, we do not know if patients attending the ED in the late evening hours or at night would rate the usability differently. Moreover, no cognitive debriefings or adjustments were made specifically for individuals attending an ED, as these tests were conducted before introducing the questionnaire. [Multimedia Appendix 2](#) [26,56] contains further details about the process as well as final modifications to the questionnaire. In addition, our results are based on a relatively young population (with a mean age of 57 years). Another weakness is that we did not include all users in the evaluation phase, as health care professionals, IT specialists,

and managers were only involved in the development phase and not in the usability testing. For the system to be fully useful, it must run on its own or be serviced directly in the ED. These aspects will be considered in the planning of a future implementation process. Moreover, the transferability of the results is limited to countries with comparable access to and understanding of technologies, as in the Danish population and health care system.

Conclusion

Based on the results of this study, the usability of CCL for patients is rated close to excellent by patients and family

members. CCL for patients was perceived to be useful, as it enabled understanding of the ED treatment and pathway. The patients indicated that they, from the technology, were able to understand what was going to happen, experienced the feeling of being in control, and found the information to be useful. Areas for improvement include making the system more usable for the older individuals. It is concluded that a technological solution can be used to minimize the information gap in an ED context from the perspective of patients and their family members.

Acknowledgments

The authors would like to thank all those who participated in this study, OPEN [29], and Niels I Agerbek for data management.

The authors received financial support for the research, authorship, and publication of this study from the Region of Southern Denmark, the University of Southern Denmark, and Odense University Hospital.

Authors' Contributions

CØ, CMJ, KBD, EC, and AL wrote the protocol for the study. CØ and AL performed the data analysis. CØ wrote the first draft of the manuscript. All the authors reviewed and edited the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: IT has brought remarkable change in bridging the digital gap in resource-constrained regions and advancing the health care system worldwide. Community-based information systems and mobile apps have been extensively developed and deployed to quantify and support health services delivered by community health workers. The success and failure of a digital health information system depends on whether and how it is used. Ethiopia is scaling up its electronic community health information system (eCHIS) to support the work of health extension workers (HEWs). For successful implementation, more evidence was required about the factors that may affect the willingness of HEWs to use the eCHIS.

Objective: This study aimed to assess HEWs' intentions to use the eCHIS for health data management and service provision.

Methods: A cross-sectional study design was conducted among 456 HEWs in 6 pilot districts of the Central Gondar zone, Northwest Ethiopia. A Unified Theory of Acceptance and Use of Technology model was used to investigate HEWs' intention to use the eCHIS. Data were cleaned, entered into Epi-data (version 4.02; EpiData Association), and exported to SPSS (version 26; IBM Corp) for analysis using the AMOS 23 Structural Equation Model. The statistical significance of dependent and independent variables in the model was reported using a 95% CI with a corresponding *P* value of <.05.

Results: A total of 456 HEWs participated in the study, with a response rate of 99%. The mean age of the study participants was 28 (SD 4.8) years. Our study revealed that about 179 (39.3%; 95% CI 34.7%-43.9%) participants intended to use the eCHIS for community health data generation, use, and service provision. Effort expectancy ($\beta=0.256$; $P=.007$), self-expectancy ($\beta=0.096$; $P=.04$), social influence ($\beta=0.203$; $P=.02$), and hedonic motivation ($\beta=0.217$; $P=.03$) were significantly associated with HEWs' intention to use the eCHIS.

Conclusions: HEWs need to be computer literate and understand their role with the eCHIS. Ensuring that the system is easy and enjoyable for them to use is important for implementation and effective health data management.

Introduction

Though IT has demonstrated remarkable promise in closing the digital divide in resource-constrained regions and advancing the health care system, there is a global shortage of health workers, which prevents at least half of the world's population from receiving essential health services [1,2]. Training community health workers (CHWs) in low- and middle-income countries has been a recommended approach to closing the global shortage of health workers [2].

Ethiopia has been implementing the Health Extension Program (HEP) since 2003, comprising female health extension workers (HEWs) to improve the health status of its population [3]. Though various strategies were implemented, and substantial progress was observed in enhancing the community health information system (eCHIS), the performance of HEWs has remained low. The possible reasons for the low performance of HEWs are increased workload; lack of motivation; negligence; and skill gaps in health data production, use, and service provision [4-8].

Due to individual, organizational, and interpersonal level impediments, in most resource-constrained countries, particularly in sub-Saharan regions, health care data generated and used for decision-making are incomplete and inaccurate [9,10]. Likewise, quality health data generation and evidence-based decision-making practices are the remaining challenges for the health care system in Ethiopia [8,11,12].

The growing evidence shows that the penetration of mobile technology improves health service delivery and health outcomes across the world [13-19] and is becoming a solution to strengthen health care industries [8,20-22]. Previous studies in Ethiopia [23], Ghana [24], Uganda [25], South Dakota [26], Indonesia [27], Canada [28], Taiwan [29], South Korea [30], and Jordan [31] indicate that data collection using electronic systems may save time over manual data collection [32,33], and there is the potential to improve health care and the productivity of health staff. For example, digital health solutions may enable CHWs to generate quality health data [34], improve health care delivery [35], and help CHWs be more effective in their job at the community level [32,36].

The eCHIS is one of the evidence-based mobile platforms for CHWs in resource-constrained countries [37], which is an easily customizable mobile health (mHealth) platform for health workers to track and support their interactions with clients. It replaces the conventional practice of a CHW manually tracking their work and carrying large client data and documentation [37].

To tackle the challenges that existed with manual health data generation, use, and service provision, the Ethiopian Federal Ministry of Health has taken the initiative to digitize the existing paper-based Community Health Information System through the eCHIS and started piloting it in 6 districts of the Central

Gondar zone, Northwest Ethiopia. The ultimate goal of its implementation is to improve the quality of health data production and service delivery at the community level by transforming the culture of information use by using tablet devices.

The first component of the eCHIS is the HEW component, which supports HEWs in family folder management and the provision of reproductive, maternal, newborn, and child health service delivery and follow-up. The second component is the health center referral component, which enables health center workers to confirm referrals and provide referral feedback to HEWs. The focal person component is the third component, which assists focal persons who are designated at the health center level to provide technical and programmatic support to the HEWs. Therefore, it enables HEWs to manage health post-level data and service provision, as it facilitates referral linkage of clients from health posts to health centers and vice versa.

Although using health system technology has expanded worldwide to leverage quality health data production and use, there is a paucity of evidence on users' behavioral intention to use health system technology [38]. The intention to use a new system is how much a health care provider intends, plans, and predicts their future behavioral readiness to use health care technology [39]. Studies show that users' behavioral intention is one of the significant factors of technology acceptance and use.

Hence, it is critical to evaluate the level of users' intention to use IT before implementing it in the health care system [40-42], as it has a significant role in planning and designing effective implementation strategies for health care programs [43]. Moreover, identifying the level of intention to use the eCHIS for community health data production, use, and service provision and its influencing factors could help to be effective in the implementation and strengthening of the program. To the authors' understanding, the level of HEWs' intention to use the eCHIS for community health care data generation, use, and service provision has not been tested using the Unified Theory of Acceptance and Use of Technology 2 (UTAUT2) model.

The UTAUT2 model is one of the most mature IT models [44] that has emerged from 8 theoretical models that were primarily developed in psychology and sociology [45]. These include the Technology Acceptance Model, Theory of Planned Behavior, Combined Technology Acceptance Model and Theory of Planned Behavior, Theory of Reasoned Action, Motivational Model, Social Cognitive Theory, Model of PC Utilization, and Innovation Diffusion Theory [45,46].

The UTAUT2 has 3 broad types of integration of concepts. First, the integration was examined in new contexts, new users, and new cultural settings [46]. Second, the addition of new constructs increased the scope of dependent predictors [45]. Third, including independent predictors of the Unified Theory

of Acceptance and Use of Technology (UTAUT) variables made comprehension easier [46]. Its extensive replications, applications, and integration extend the theoretical limits of technology adoption. Therefore, the addition of the 3 predictors (hedonic motivation, price value, and habit) to the previously existing 4 constructs in the original UTAUT model (performance expectancy, effort expectancy, social influence, and facilitating conditions) leveraged the adoption and use of technology (eCHIS in this case). This changes the existing relationships of constructs in the original UTAUT and introduces new relationships among constructs known in the UTAUT2.

We used the UTAUT2 constructs to determine HEWs' behavioral intention to use the eCHIS [46], as UTAUT2 perspectives are applicable in the health system and the eCHIS is a form of health system technology. Understanding the intention of HEWs using the UTAUT2 model would give insights to health system leaders on how to digitize community health systems in local settings.

Therefore, this study aimed to investigate HEWs' intention to use the eCHIS and its predicting factors using the UTAUT2 model among HEWs who had received familiarization training on the eCHIS in 6 pilot districts of Northwest Ethiopia.

Since the eCHIS is a form of health system technology, the relationships between UTAUT2 perspectives on accepting and using technology apply to the eCHIS, and the following hypotheses were speculated:

- Hypothesis 1: performance expectancy positively influences HEWs' behavioral intention when using the eCHIS.
- Hypothesis 2: effort expectancy positively influences HEWs' behavioral intention when using the eCHIS.
- Hypothesis 3: social influence positively influences HEWs' behavioral intentions when using the eCHIS.
- Hypothesis 4: facilitating conditions positively influence HEWs' behavioral intentions when using the eCHIS.
- Hypothesis 5: hedonic motivation positively influences HEWs' behavioral intention in using the eCHIS.
- Hypothesis 6: self-efficacy positively influences HEWs' behavioral intention when using the eCHIS.
- Hypothesis 7: habit positively influences HEWs' behavioral intention when using the eCHIS.

In this study, price value was not included in this model because HEWs, the participants in this study, were not directly involved in purchasing the system. Furthermore, the model was not tested on behavioral intention to use the eCHIS among HEWs in Ethiopia.

Methods

Study Design, Period, and Setting

A cross-sectional study design was conducted from January to February 2021 in the Central Gondar zone, Northwest Ethiopia. The Central Gondar zone has 15 districts, of which 6 districts (Wogera, Mirab Dembia, Misrak Dembia, Enfranz, Takusa, and Belesa) were selected as pilot districts for eCHIS implementation in the zone. The estimated total population of the zone was 2,288,440. The zone has a total of 75 health centers

and 404 health posts, and there were 897 HEWs (59 urban and 848 rural) during the study period (Central Gondar Zone Health Bureau report, unpublished data, 2020).

Population and Participants of the Study

The source population of the study was HEWs at the primary health care unit level. The study participants were HEWs who were in the pilot districts of the Central Gondar zone and had received initial training for eCHIS implementation. The intervention was skill-oriented training for the implementers of mobile-based community health information system applications based on the training manual prepared by the Ministry of Health, and the training was provided for 1 week by trainers from the regional health bureau and the Ministry of Health. Following the training, each *woreda* (district) led household registration, tablet usage guideline provision, technical support and mentoring, and periodical communications for 1 year.

Provision of Mentorship and Technical Assistance

The University of Gondar assigned three supporting team members who provided technical assistance for implementers with a local mentor every 2 weeks throughout the intervention period. In addition, 1 health information technician (a local mentor) was assigned to provide mentorship and solve eCHIS-related problems during implementation.

Sample Size and Sampling Procedures

The initial sample size was calculated using a single population proportion formula, considering the following assumptions: 50% proportion of intention to use the eCHIS, as there was limited evidence in the area; 95% confidence level for estimations; and 5% margin of error. Using these inputs, the initial sample size was estimated at 385. Considering a 10% nonresponse rate, the final sample size was 422. In the pilot districts, however, the total number of HEWs was 460. Therefore, as the initially determined sample size was closer to the population size, it was planned to include all eligible HEWs in the study.

Study Variables and Measurement

The dependent variable was the intention to use the eCHIS for health data generation and service provision. Based on the UTAUT2, 8 constructs with a 5-point Likert scale were used to assess the intention to use the eCHIS and were considered potential predictors of the study [46].

1. Performance expectancy: the extent to which people believe that using a new technology can improve their job performance [47].
2. Effort expectancy: the degree of ease of use associated with the usage of a new technology [46].
3. Social influence: the degree of importance others recognize in using a new system [45].
4. Facilitating conditions: the degree to which a person perceives that an organization and a technical infrastructure exist to support the intention of people to use technology [45].
5. Hedonic motivation: the motivation to do something due to internal satisfaction [48].

6. Habit: the degree to which users perform the usage of technologies behaviors automatically because of learning [46,49].
7. Self-efficacy: judgment of one's ability to use technology to accomplish a particular job or task [45].
8. Behavioral intention: the degree to which a person has formulated conscious plans to perform or not perform some specified future behaviors [50].

Data Collection Tools and Procedures

Data collection tools were adapted from the source instrument used in the UTAUT2 model [46] in the context of the eCHIS to enhance comprehension by the respondents. The items in the constructs were performance expectancy (4 items), effort expectancy (4 items), social influence (3 items), facilitating condition (4 items), hedonic motivation (3 items), self-expectancy (4 items), habit (4 items), and intention to use (3 items). The source language of the instrument was translated forward into the local language of Amharic, and a backward translation was done to ensure the consistency of the tool. Experts with health management information system backgrounds were invited to review the relevance of each question in the instrument. The experts reviewed the instrument and checked its content and face validity, and the instrument was refined according to the comments given. A pretest was conducted on 5% of the study participants before actual data collection was started, and the tool was refined based on the pretest results. A total of 4 data collectors and 2 supervisors were recruited and trained on the purpose, tools, and procedures of the study. Self-administrated questionnaires were used to collect data from HEWs with the assistance of data collectors and supervisors. The data collection period was from January 28 to February 13, 2021, after 2 weeks of eCHIS familiarization training had been given.

Data Management and Analysis

The data were entered into Epi-data (version 4.02; EpiData Association) and exported to SPSS (version 26; IBM Corp) for descriptive statistics such as frequency, cross-tabulations, and univariate analysis of sociodemographic and model constructs.

Simple and multiple structural equation models were carried out using the AMOS 23 Structural Equation Model in order to test the relationship between observed and latent variables and identify the predicting variables of the intention to use the eCHIS. During analysis, we applied a parceling technique to increase model efficiency [51]. The subset-item-parcel approach was used in order to aggregate items into several parcels and use them as indicators of the target construct [52]. Accordingly, we created 2 parcels for each factor of target latent constructs (such as performance expectancy, effort expectancy, facilitator conditions, self-expectancy, and habit) by aggregating randomly grouped items within each scale [53]. The remaining 3 latent target constructs with 3 indicators per construct, such as social influence, hedonic motivation, and intention to use, remained as they existed in the original UTAUT2 model [46].

The overall model's fitness was measured and assessed using the goodness of fit indices such as chi-square ratio (<3), the goodness of fit index (>0.9), adjusted goodness of fit index (>0.8), normal fit index (>0.9), comparative fit index (>0.9), Tucker-Lewis index (>0.9), and root mean square error of approximation (<0.08). For the structural equation model, standardized path coefficients of the regression weight values were used to estimate the path coefficients of the dependent and independent variables. Standardized coefficients are not dependent on the scales as they vary from -1 to 1 , where 0 indicates no relationship, 1 indicates a strong positive relationship, and -1 indicates a strong negative relationship. A critical ratio (regression weight or standard error) was used to evaluate whether the constructs had a significant relationship. The absolute value of a critical ratio greater than 1.96 is an indication of the significance of the path coefficients. In this study, the CI and its P value were calculated using bootstrapping, and the statistical significance of dependent and independent variables in the model was reported using a 95% CI with a corresponding P value of $<.05$ (Table 1). The square multiple correlation (R^2) was used to report the proportion of variance so that the intention to use the eCHIS could be explained by the model.

Table 1. Structural equation modeling fitness for intention to use electronic community health information system among health extension workers in Northwest Ethiopia, 2021.

Fit indices	Threshold value	Authors	Results obtained	Conclusion
Chi-square	<3	Bentler [54] (1990)	2.67	Accepted
Goodness-of-fit index	>0.9	Chau [55] (1997)	0.92	Accepted
Adjusted goodness-of-fit index	>0.8	Chau [55] (1997)	0.88	Accepted
Comparative fit index	>0.9	Bentler [54] (1990)	0.97	Accepted
Root mean square error of approximation	<0.05	Browne and Cudeck [56] (1993)	0.08	Accepted
Normed fit index	>0.9	Bentler and Bonett [57] (1980)	0.95	Accepted

Reliability and Validity of the Research

Regarding the reliability and validity of the study, Cronbach α reliability coefficients were computed to determine the internal consistency of the constructs. Cronbach α of $.7$ or above indicates high reliability; between $.5$ and $.7$ indicates moderate

reliability; and less than $.5$ indicates low reliability. We have used 4-item Likert questions to assess the reliability of the constructs. Accordingly, the reliability of the constructs assessed by 3-item questions as follows: performance expectancy ($\alpha=.92$), effort expectancy ($\alpha=.87$), facilitating condition ($\alpha=.75$), self-expectancy ($\alpha=.88$), habit ($\alpha=.84$), social influence

($\alpha=.78$), hedonic motivation ($\alpha=.90$), and intention to use eCHIS (Table 2). In this study, the magnitude of intention to use the eCHIS was assessed by a 3-item Likert question with a reliability test of Cronbach $\alpha=.93$.

Table 2. Reliability of the constructs on intention to use the electronic community health information system (eCHIS) among health extension workers in Northwest Ethiopia, 2021.

Constructs	Sample size	Number of items	Cronbach α
Performance expectancy	456	4	.92
Effort expectancy	456	4	.87
Social influence	456	3	.78
Facilitating conditions	456	4	.75
Hedonic motivation	456	3	.90
Self-expectancy	456	4	.88
Habit	456	4	.84
Intention to use the eCHIS system	456	3	.93

Ethical Considerations

Study approval and ethical clearance were obtained from the University of Gondar's ethical review board (R.NO. V/P/RCS/05/2020) and a support letter from the ethical review committee of the Amhara Regional Health Bureau Research and Technology transfer office. Study permission was sought at all levels of governmental administration systems including health offices and health facilities. Written consent was obtained, and participants were informed about the objective, importance of the study, procedure and duration, risk and discomfort, benefits of participating in the study, confidentiality, and the right to refuse or withdraw during data collection. To ensure confidentiality, their names and other personal identifiers were not registered. Participants were not compensated for study participation. We confirm that the provided ethics approval documentation covers the study presented in this manuscript.

Results

Sociodemographic and Other Characteristics of the Study Participants

A total of 456 HEWs participated in the study, with a response rate of 99%. The mean age of the study participants was 28 (SD 4.8) years. More than two-thirds ($n=314$, 68.9%) of the study participants had work experience of more than 5 years. About half of the participants ($n=232$, 50.9%) were level 4 (10+4) in their educational status, and the majority of the respondents ($n=307$, 67.3%) were married. The number of HEWs who had difficulties recharging mobile phones was 307 (67.3%). Our study found that 147 (32.2%) HEWs used Microsoft applications daily, 331 (72.6%) had experience using mobile phones for more than 5 years and above, and 421 (92.3%) had informal mobile phone usage practices or were using personal mobile for health predict-related activities (Table 3).

According to the findings of this study, 122 (26.8%), 132 (28.9%), and 162 (35.5%) HEWs strongly agreed to intend, predict, and plan to use the eCHIS, respectively (Table 4).

Mean Score of All Predictors and Intention to Use the eCHIS Using the UTAUT2 Model

The mean scores of performance expectancy, effort expectancy, facilitating condition, self-expectancy, and habit with 4-item Likert questions were 17.09 (SD 2.58), 16.22 (SD 2.41), 12.07 (SD 3.46), 13.94 (SD 3.62), and 14.75 (SD 3.14), respectively. On the other hand, social influence, hedonic motivation, and intention to use the eCHIS with 3-item Likert questions had a mean score of 11.63 (SD 2.32), 12.23 (SD 2.01), and 12.57 (SD 2.00), respectively.

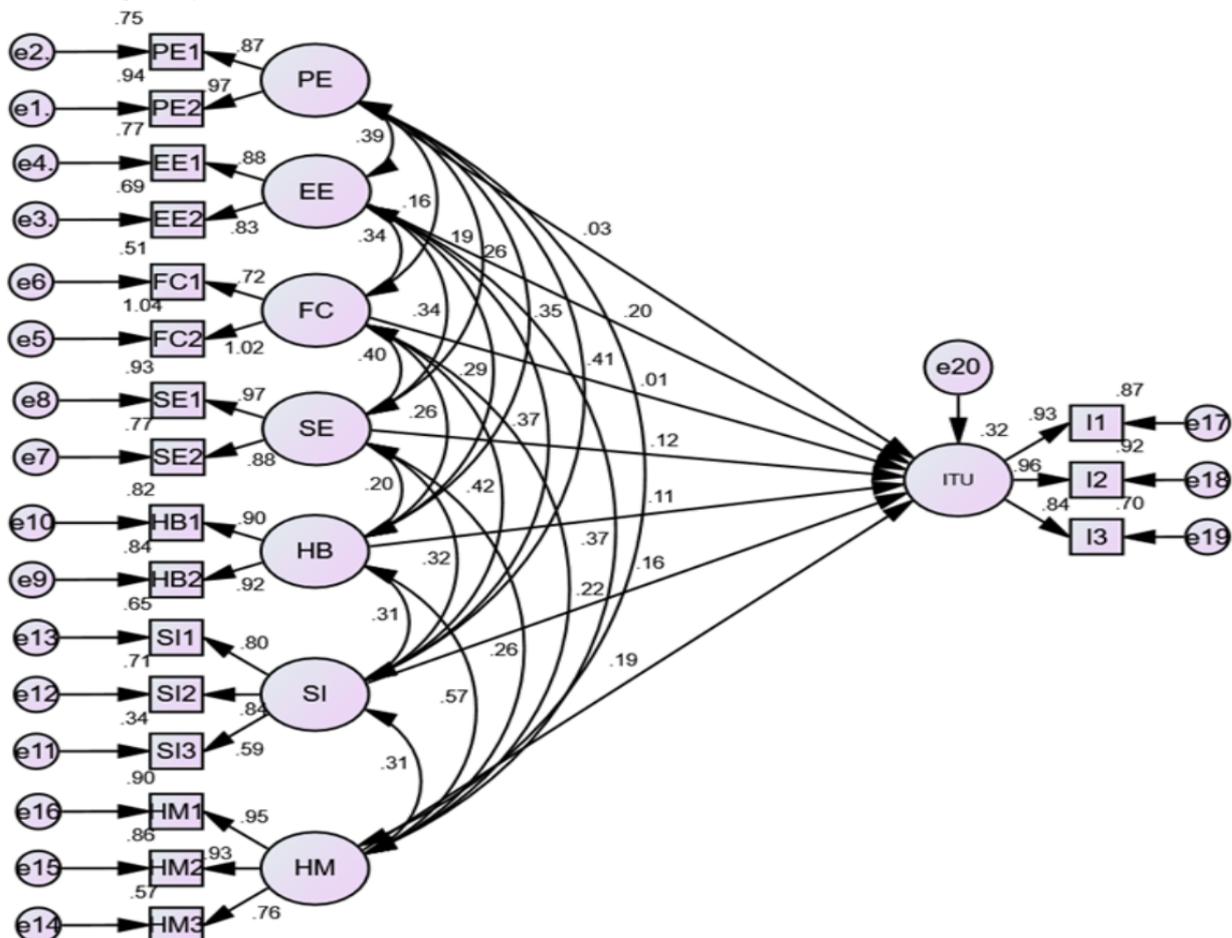

Our study revealed that 179 (39.3%; 95% CI 34.7%-43.9%) participants who had the intention to use the eCHIS for community health data generation, use, and service provision had scored above the mean. The mean score of the intention to use the eCHIS was 12.57 (SD 2.00). The maximum score of intention to use the eCHIS was 15, while the minimum score was 3.

Simple Structural Equation Model Analysis

The variance in the dependent variable explained by the independent variables was interpreted using square multiple correlation (R^2). The overall R^2 of the intention to use the eCHIS is found to be 32%, the variance that was explained by the independent variables in the model. The bootstrap method with

a 95% bias-corrected CI was applied to investigate the significance of path coefficients and factors predicting the model. The predictors with $P < .20$ in the simple structural equation model were considered candidate variables for multiple structural equation model analysis. Due to its undependability to scale, we used a standardized beta coefficient to interpret the influence of predictors on the intention to use the eCHIS. A 95% CI with $P < .05$ was considered to declare an association between dependent and independent variables. The study indicated that effort expectancy has the highest direct effect on HEWs' intention to use the eCHIS, followed by hedonic motivation. The remaining model constructs that have a direct influence on predicting intention to use the eCHIS are social influence and self-expectancy. The structural equation model predicted, with the path coefficients and R^2 , is represented in Figure 1, and the path coefficients and P value found from the depicted model are presented in the Results section. Moreover, the absolute value of the critical ratio of effort expectancy (3.701), self-expectancy (2.468), social influence (2.782), and hedonic motivation (3.311) indicated that predictors had a significant influence on HEWs' intention to use the eCHIS. Overall, 32% of the variance with respect to intention to use the eCHIS was reasonably explained by the predictors in the model.

Figure 1. Predictors and intention to use the electronic community health information system among health extension workers at Central Gonda zone, Northwest Ethiopia, 2021. EE: effort expectancy; FC: facilitating condition; HB: Habit; HM: hedonic motivation; ITU: intention to use; PE: performance expectancy; SE: self-expectancy; SI: social influence.

Effort expectancy (the extent to which people believe that using the eCHIS can improve their effort) has a positive influence on HEWs' behavioral intention ($\beta=.256$; $P=.007$). Similarly, self-efficacy and social influence had a positive influence on HEWs' behavioral intention ($\beta=.096$; $P=.04$), and ($\beta=.203$; $P=.02$), respectively. Likewise, hedonic motivation to use eCHIS

due to internal satisfaction was found to be ($\beta=0.217$; $P=.03$) and had a significant effect on intention to use the eCHIS. Facilitating conditions ($\beta=0.005$; $P=.92$), habit ($\beta=0.103$; $P=.07$), and performance expectancy ($\beta=0.034$; $P=.61$) had no significant influence on intention to use the eCHIS (Table 5).

Table 5. Multiple structural equations modeling association between predictors and intention to use the electronic community health information system among health extension workers in Northwest Ethiopia, 2021.

Discussion

Principal Findings

In this study, nearly 2 out of 5 HEWs had an intention to use the eCHIS for community health data generation, use, and service provision. Effort expectancy, self-expectancy, social influence, and hedonic motivation were statistically significant predictors of intention to use the eCHIS. The intention to use the eCHIS by HEWs could be associated with the fact that using the eCHIS is not difficult to understand. It saves time and reduces the amount of effort required to complete health-related tasks [58,59]. Furthermore, it simplifies activities and helps them access data easily. The other could be people around them who have the ability to influence their intention to use the system [58]. For example, HEWs' activities should be monitored and evaluated by health system leaders. If they give them more attention, they will be encouraged to use the system. The other could be previous exposure to using informal phone for health system activities, such as reminding clients about their health care appointments and facilitating referral linkage between health centers and health posts, as mHealth enhances communication between health workers and clients [58]. Moreover, using the eCHIS creates a conducive environment for HEWs since their usual data handling approach is exhaustive and takes much time to execute activities at the health post level, and using the eCHIS not only helps them to save their time but also creates motivation to do their job at health post level [58,60].

Regarding factors associated with intention to use the eCHIS, effort expectancy had a positive influence on the intention to use the eCHIS among HEWs. This finding was in accordance with a study conducted in Ethiopia [61], Kenya [61], the United States [62], and Portugal [63] and had a positively significant association with the intention of health care providers to use technology. A possible explanation could be the fact that the less effort the user devotes to using the system, the more likely he or she is to continue to use it. A study in this regard showed that individuals often want to face a system that is easy to use [64]. HEWs might perceive that the eCHIS could help them to do their job aids shortly with less strain and increased work efficiency [65], as using the eCHIS would simplify the tasks they are expected to deliver at health post level. A review in this regard showed that using digital tools simplifies work and helps to access data easily [59]. Furthermore, studies indicate that digital health solutions reduce workload and improve work performance [24,25], reduce errors [34], create motivation and learning opportunities [66], promote health care appointment [67], and are easy to use and improve work efficiency [59]. Using the eCHIS could reduce the workload of HEWs since manual data management practice at health post level is exhaustive and takes much time to collect data and conduct routine activities [59]. Moreover, the referral linkage integrated into the eCHIS, including HEWs, midwives, and focal persons, will harmonize HEWs' activity flow from health posts to health centers and vice versa. Furthermore, using mHealth motivates

CHWs and enables them to perform multiple tasks quickly, reducing efforts and improving performance [60].

The intention to use the eCHIS among HEWs who perceived people around them could influence their behavioral intention was positively associated. The current finding corroborates studies conducted among health care providers using the UTAUT2 model in Ethiopia [61], Morocco [68], Taiwan [62], South Korea [30], and the United States [69], showing that social influence significantly predicted health care providers' intention to use technology. The possible explanation could be that HEWs might perceive peer pressure from health care staff at the *woreda* and facility levels toward using the eCHIS, which could positively influence their intention to use the eCHIS. The other justification could be the fact that HEWs might get trust from the community for the job aids or activities they are expected to deliver. Hence, health system staff need to understand that peer influence has a positive effect on using a new system. Moreover, making people aware of a new system at the *woreda* and facility levels in general and at the kebele leaders, women's development army, and voluntary service providers' levels, in particular, could influence HEWs' behavioral intention to use the eCHIS. A study in this regard showed that the more health workers connected to colleagues, the more they improved the use of digital tools and the quality of care [58].

Our study revealed that the magnitude of intention to use the eCHIS among HEWs who had self-expectancy was positively correlated. The findings of past studies in Ethiopia [61], Malaysia [70], Taiwan [71], and Iran [72] showed that digital literacy was correlated with the intention to use technology in health care industries. The possible reason might be that those who had self-expectancy could not face difficulty in adapting the emerging technology to community-level data management and service provision. The current evidence in the feasibility and effectiveness study on digital health indicated that the level of computer literacy had influenced digital health implementation among CHWs [73]. A possible explanation might be the fact that informal mobile phone usage practices of CHWs for health post-related activities could influence behavioral intention to use the eCHIS. A study indicated that in many different settings, CHWs use their personal phone informally for community-based activities so as to fill the gaps in the health care system [74].

Our study revealed that there is a significant association between intention to use the eCHIS and hedonic motivation or perceived enjoyment from using the eCHIS for community health data generation, use, and service provision. A possible explanation could be the fact that using a new system instead of the usual approach to manage community-level data and service provision may create intrinsic motivation for HEWs to obtain fun or pleasure. A study showed that motivation is an important construct for eHealth users, and it could even be a sufficient reason to adopt newly emerging technology in a contextual environment [75]. In addition, using eHealth technology to deal with community health data generation, use, and service provision may be an enjoyable process and will have a positive influence on the behavioral intentions of the users [72].

HEWs were optimistic about using the eCHIS because it could be related to the production of quality health data, ease of data management, reduced errors and false reports, data protection, and increased accessibility. A study also indicated that using digital tools could enhance the productivity of CHWs [76]. Community health digitization using mobile apps support the services delivered by CHWs [77]. Furthermore, studies show that the digitization of health care data has promising results in improving both health care and health outcomes [13-19] and improving health staff productivity and work efficiency [65]. In our study, the level of users' optimistic perceptions of using the eCHIS could be an advantage in implementing the intervention, as compared to the existing approach [78]. Studies showed that digital health solutions enable CHWs to generate quality health data [34], improve health care delivery [35], and help them to be more effective in their job aids [32,36]. Moreover, digital tools could help them follow the correct order or the required service elements that clients should receive when providing services. It also enables them to communicate with clients in a better way as compared to manual communication since the tool has prespecified data elements that should be asked by CHWs during service delivery [58].

Likewise, it creates enjoyment among users [66] and benefits them by keeping data safe from human and natural factors that could damage the data. In addition, enjoyment could emanate due to the fact that using digital tools can improve data capturing, storing, and reporting of more items that could be more time-consuming during manual data handling and reduce the motivation of health workers to keep data recording [59]. Even though HEWs are optimistic to use the eCHIS, lack of adequate resources for eCHIS implementation at the implementation district could hinder its successful implementation, and therefore resource availability is vital to be effective in community health digitization. Studies show that challenges during digital health solutions implementation, such as the initial and ongoing capacity-building training [73], poor network access and poor access to electricity [58,79], low financial investment [73], and unreliability or absence of infrastructure (eg, electricity and network) [80,81], hinder the implementation. As the skills and knowledge of HEWs vary from one to another, there should be mentoring and supportive supervision during the implementation. Studies showed that the inability to use the system could affect its implementation [26], and intensive training with continuous refreshment could help them realize the digitization of the community health information system [82].

Limitations of the Study

The findings of this study should be interpreted in light of some limitations. Due to the nature of the study, which was cross-sectional, the inability to infer cause-and-effect relationships is present. As the study was focused on HEWs' intention to use the eCHIS in a pilot district in Northwest Ethiopia, the sample size could affect the findings of this study, and covering larger areas at the regional and national levels is possible, including urban HEWs. Finally, the parcel approach used in this study may introduce parameter estimation bias.

Conclusion

In conclusion, 39.3% (179/456) of HEWs scored above the mean of intention to use the eCHIS for community health data management and service provision. Factors associated with the intention to use the eCHIS were effort expectancy, self-expectancy, social influence, and hedonic motivation. The eCHIS has numerous advantages and a promising future in terms of improving data quality, use, and service delivery. Its adoption in the country, however, should focus on identifying all necessary prerequisites for successful implementation and

advancing the community health information system. The implementation of the eCHIS should not skip factors that had no significant effect on intention to use the eCHIS, and further studies at the regional and national levels are recommended to investigate their correlation with intention to use the eCHIS. Model explainability was found in the study using factors that existed in the UTAUT2 model; however, it is recommended to examine the moderating effects of CHWs' related variables to examine how the model constructs could influence HEWs' intention to use the eCHIS.

Acknowledgments

We would like to thank the Central Gondar Zone Health Department, electronic community health information system pilot district health offices, and the University of Gondar Comprehensive Specialized Hospital for their provision of necessary information and support during data collection. Our gratitude also goes to the study participants, data collectors, and supervisors who took part in the study. This work would not have been possible without the financial support of the Doris Duke Charitable Foundation (grant 2017187). The mission of the Doris Duke Charitable Foundation is to improve the quality of people's lives through grants supporting the performing arts, environmental conservation, medical research, and child well-being, and through the preservation of the cultural and environmental legacy of Doris Duke's properties.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

TH conducted the study. All authors conceptualized the design of the study, provided a review of the methodology and results, contributed to the reviewing the manuscript, and read and approved the final manuscript.

Abstract

Background: Medication incidents (MIs) causing harm to patients have far-reaching consequences for patients, pharmacists, public health, business practice, and governance policy. Medication Incident Reporting and Learning Systems (MIRLS) have been implemented to mitigate such incidents and promote continuous quality improvement in community pharmacies in Canada. They aim to collect and analyze MIs for the implementation of incident preventive strategies to increase safety in community pharmacy practice. However, this goal remains inhibited owing to the persistent barriers that pharmacies face when using these systems.

Objective: This study aims to investigate the harms caused by medication incidents and technological barriers to reporting and identify opportunities to incorporate persuasive design strategies in MIRLS to motivate reporting.

Methods: We conducted 2 scoping reviews to provide insights on the relationship between medication errors and patient harm and the information system-based barriers militating against reporting. Seven databases were searched in each scoping review, including PubMed, Public Health Database, ProQuest, Scopus, ACM Library, Global Health, and Google Scholar. Next, we analyzed one of the most widely used MIRLS in Canada using the Persuasive System Design (PSD) taxonomy—a framework for analyzing, designing, and evaluating persuasive systems. This framework applies behavioral theories from social psychology in the design of technology-based systems to motivate behavior change. Independent assessors familiar with MIRLS reported the degree of persuasion built into the system using the 4 categories of PSD strategies: primary task, dialogue, social, and credibility support.

Results: Overall, 17 articles were included in the first scoping review, and 1 article was included in the second scoping review. In the first review, significant or serious harm was the most frequent harm (11/17, 65%), followed by death or fatal harm (7/17, 41%). In the second review, the authors found that iterative design could improve the usability of an MIRLS; however, data security and validation of reports remained an issue to be addressed. Regarding the MIRLS that we assessed, participants considered most of the primary task, dialogue, and credibility support strategies in the PSD taxonomy as important and useful; however, they were not comfortable with some of the social strategies such as cooperation. We found that the assessed system supported a number of persuasive strategies from the PSD taxonomy; however, we identified additional strategies such as tunneling, simulation, suggestion, praise, reward, reminder, authority, and verifiability that could further enhance the perceived persuasiveness and value of the system.

Conclusions: MIRLS, equipped with persuasive features, can become powerful motivational tools to promote safer medication practices in community pharmacies. They have the potential to highlight the value of MI reporting and increase the readiness of pharmacists to report incidents. The proposed persuasive design guidelines can help system developers and community pharmacy managers realize more effective MIRLS.

Introduction

Overview

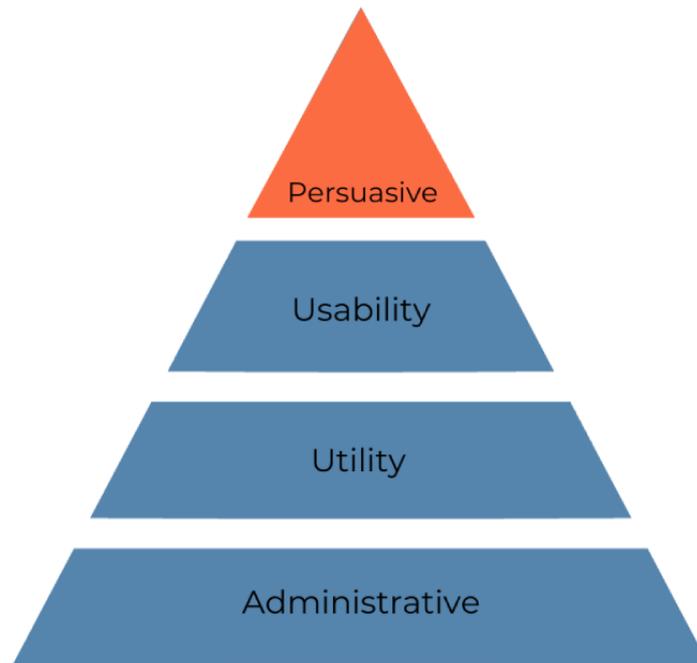

Medication errors are one of the leading causes of death in many countries worldwide [1,2]. For example, in the United States alone, 7000 to 9000 patients die annually owing to these errors. In Canada, where medical errors (labeled as the third leading cause of death after cancer and heart disease) account for 28,000 deaths annually, every minute and 18 seconds a patient gets harmed because of unintended errors, with medication errors being the most frequent [3]. Wrong medication (eg, because of similar naming, similar packaging, illegible handwriting, and incorrect drug selection) and wrong dose are among the most common medication errors in community pharmacies [3-5]. In particular, advanced drug preparation and administration without double checking [6] and heavy workflow [7] have been identified as key contributing factors to medication errors. However, there may be many more contributing underlying factors that go unreported by pharmacists and other health professionals. For example, a survey on medication administration errors among nurses in South Korea showed that 63.6% of the respondents had been involved in medication errors once or more in the previous month. However, only 28.3% of the participants reported the incidents [6]. Underreporting of medication errors, which is a global issue [8-11], has several implications bordering on shared learning, patient safety, and financial cost. In the United States, for example, psychological or physical pain and distress aside, “the total cost of looking after patients with medication-associated errors exceeds US \$40 billion each year, with over 7 million patients affected” [4]. Moreover, underreporting of medication errors and incidents might limit individual and organizational learning from their occurrence [12,13].

The continuous evolution of pharmacotherapy and changing demands on the community pharmacy necessitate constant vigilance to detect new types of medication errors [14]. In a study among hospital pharmacists in South Korea, Hee-Jin et al [15] found that “five or more near misses per month were experienced by 14.8%, 4.3%, and 43.9% of respondents for dispensing, administration, and prescribing errors, respectively.” Moreover, research has shown that medication errors that lead to patient harm are common in medical care including community pharmacy [2,16-19]. Frequent reporting of all

medication incidents (MIs) and near-miss events has the potential to improve patient safety through shared learning, which will enable the reduction of recurrence and prevention of MIs in the future [20,21]. Without adequate user reporting, none of the laudable objectives of reporting systems, including identification of gaps and resource development to support patient safety, can be achieved [7]. Medication error reporting is a common metric used to assess the quality of care provided by the health care system [21]. However, research has shown that employees are less motivated to report medication errors [22-25]. Hence, there is a need to find ways to motivate pharmacists and pharmacy technicians to report MIs more often to foster shared learning, prevention of recurrence, and patient safety. The question then is, *How can we motivate pharmacists and pharmacy technicians to report MIs more frequently using persuasive design principles embedded in digital technologies?*

Although some guiding principles have been proposed to alleviate the barriers to MI reporting, these principles, from a user experience (UX) design perspective, are not aimed at motivating pharmacists to report MIs regularly. From our literature search, we identified 4 categories of principles that can guide the design of Medication Incident Reporting and Learning Systems (MIRLS) to improve their adoption and usability. They include administrative principles, usability, utility principles, and persuasive design principles (Figure 1). Administrative principles refer to the organizational processes and policies implemented to enable and encourage employees to report medication errors regularly without fear of consequences. These principles form the basis of MIRLS, upon which the other categories of principles build. Usability and utility principles refer to the UX features that enable a user to report medication errors with ease, effectiveness, efficiency, and satisfaction [26]. Persuasive principles refer to the motivational affordances of a system that facilitate, nudge, and motivate a user to report medication errors. Current MIRLS mainly focus on the administrative, usability and utility-based principles. Typical examples of administrative principles include voluntary use, anonymity, confidentiality, and nonpunitive consequences. Examples of usability and utility-based principles, particularly in the Think Research and Pharmapod system, include ease of use, use of a standard taxonomy, searchability, retrievability, report generation, and root cause analysis [7,14,27].

Figure 1. Four key design principles for Medication Incident Reporting and Learning Systems in community pharmacy.

Apart from the administrative, usability, and utility principles, we argue that persuasive design principles hold potential to increase MI reporting among pharmacists. Persuasive design principles embedded in digital technologies, also known as persuasive technology, can motivate increased reporting of MIs from community pharmacies, as research in other health domains has shown [28]. Hence, this study proposes the use of persuasive design principles, which build on the 3 other categories of principles (Figure 1), to motivate users of MIRLS to report incidents and near misses more often.

Using Think Research, also known as Pharmapod, a cloud-based MIRLS for reporting and reducing incidents in community pharmacies [29], as a case study, this study (1) assesses 1 MIRLS based on the Persuasive System Design (PSD) taxonomy proposed by Oinas-Kukkonen and Harjumaa [30] and (2) proposes persuasive design guidelines to help community pharmacy stakeholders at multiple levels (eg, facility, provincial, and national) integrate persuasive features into their MIRLS. The PSD taxonomy is a widely used framework in the persuasive technology domain for analyzing, designing, implementing, and evaluating persuasive systems. Persuasive strategies from the PSD taxonomy can enhance MIRLS, making them more effective in promoting patient safety and shared learnings among practitioners [31,32]. Moreover, the study presents a summary of the results on the relationship between medication errors and harm and the information system-based barriers to MI reporting to ground the research.

Background and Related Work

In this section, we present an overview of relevant studies on the relationship between medication errors and patient harm and the organizational and information system barriers to reporting.

Medication Errors and Patient Harm

Several studies have been conducted to investigate the prevalence, nature, severity, and effects of MIs. West et al [16] investigated the relationship between medical errors and patient harm in primary care. They found that clinical harm to patients was reported in >10% of the 608 primary care medical error reports, with prescription-related errors most frequently linked to clinical harm. Similarly, Robb et al [17] investigated the relationship between medication and patient harm in hospitals in New Zealand. The authors confirmed the findings of earlier studies that showed that medication-related harms were common in both hospitals and the community, posing a substantial burden for patients and the health care system. In particular, they found that 923 harms were identified among 751 patients, with 28% of them experiencing ≥ 1 of the medication-related harms. They also found that older and female patients and those who had an increased length of stay were more likely to be harmed. Moreover, 65% of the harms occurred during an inpatient stay and 29% originated from the community and resulted in an admission. Riordan et al [18] investigated discharge prescription errors and their propagation after the discharge of patients. They found that 43% of the patients included in the study experienced postdischarge medication errors, with 86% of them being at risk of moderate harm. Moreover, 88% of the errors were discharge prescription errors that persisted after the discharge.

Most recently, Alqenae et al [2] conducted a systematic review, which they regarded as the first, to explore the prevalence and nature of medication errors and adverse drug events after hospital discharge. The review found that the median rate of medication error was approximately 50% among adult and older patients after hospital discharge, with approximately 20% of the patients in the studies reported to be affected by adverse drug events (such as antibiotics, antidiabetics, analgesics, and cardiovascular drugs) after hospital discharge. Panagiotti et al [19] conducted a systematic review and meta-analysis of the

prevalence, severity, and nature of preventable patient harm across a range of medical care settings. They found that 5% of the patients were exposed to preventable harm in medical care and 25% of the incidents, which are drug related, accounted for the largest proportion of preventable patient harm, with 12% of the preventable patient harms being severe or leading to death. They asserted that there are limited quality improvement practices specifically targeting incidents that cause preventable harm to patients. They added that designing and implementing evidence-based mitigation strategies specifically targeting preventable patient harm could lead to substantial service quality improvements that are cost effective. This conclusion by Panagiotti et al [19], coupled with the prevalence of medication errors in community pharmacy, partly informs this conceptual paper aimed to incorporate persuasive principles in MIRLS to increase medication error reporting and patient safety.

Organizational Barriers to MI Reporting

Researchers have identified several organizational barriers (both administrative and personal) leading to underreporting of medication errors and incidents in community pharmacy [21]. In the long run, these barriers can adversely affect patient safety

owing to lack of shared learning among pharmacists within and across organizations because of underreporting [12,13]. Key barriers include fear of consequences such as punitive and disciplinary actions, negative or lack of administrative feedback, poor work climate or culture, inadequate training, and time constraint (Textbox 1) [7,8,21]. For example, Bahadori et al [9] found that the most important reasons for not reporting medication errors were administrative factors including the process of reporting and fear of the consequences of reporting. Research has also shown that personal (ie, sociodemographic) factors can impact medication error reporting. For instance, Aljabari and Kadhim [8] found that younger and lesser experienced professionals and staff with shorter employment periods were less likely to report medication errors. We argue that administrative barriers (such as time constraint and high workload) and perceived low value of the reporting system could be mitigated by using persuasive technologies to facilitate and ensure convenient reporting of MIs and errors. For example, persuasive design features (such as reminders to complete saved draft reports, notifications about the utility and value of reporting, and encouraging messages) may facilitate MI reporting.

Textbox 1. Administrative barriers to reporting medication errors and incidents.

<p>Fear of consequences</p> <ul style="list-style-type: none"> Negative consequences such as blame, shame, professional reputation damage, relationship damage, loss of privileges, medical malpractice lawsuit, relief from certain duties, and loss of job [4,9,33,34]. <p>Lack of feedback</p> <ul style="list-style-type: none"> Lack of useful feedback or negative feedback from administrative teams, such as pharmacy managers, regarding previously reported medication errors [33,34]. <p>Poor work climate or culture</p> <ul style="list-style-type: none"> Blaming staff and not the system or culture, poor support system, poor teamwork, poor organizational leadership, and lack of confidentiality in handling reports [33,35]. <p>Miscommunication</p> <ul style="list-style-type: none"> Poor communication among staff or between staff and patients [36]. <p>Inadequate training of staff</p> <ul style="list-style-type: none"> Difficulty in using the reporting system, poor understanding of the importance or value of reporting, poor understanding of errors, lack of clear definition of incident or near miss, and lack of a well-defined protocol on what events need to be reported [21,35]. <p>Time constraint</p> <ul style="list-style-type: none"> Work pressure and the lack of budgeted time to properly report errors, especially in the midst of a busy work schedule and high workload resulting in lack of enough breaks [7,35,36].
--

Information System Barriers to Patient Safety

Research has identified technological barriers that hamper patient safety in different health information systems and domains [37-40]. The primary barrier among them is the usability and poor design of health information systems [41]. Ratwani et al [42] found across 3 health care institutions that the usability of electronic health records accounted for more than a third of medication errors in 9000 pediatric patient safety reports. Kushniruk et al [43] evaluated the usability of a handheld prescription writing application. They found various

usability problems (most of which relate to interface design) and actual errors in entering prescription data. In particular, they found that certain types of usability problems such as display visibility and ergonomics-related wrong data entry were closely linked to the occurrence of specific types of errors in medication prescription. More recently, Adams et al [37] investigated the medication errors associated with health information technology use and the harm caused to the patient. They found that 55.85% (1508/2700) of the manually reviewed reports described a medication error associated with information technology use and 49.7% (750/1508) of these caused harm to

the patient. In particular, they found that 97.35% (1468/1508) of the medication errors associated with information technology were related to usability issues including data entry, workflow support, and alerting. On the basis of these findings, in the current MIRLS domain, we set out to uncover the information technology barriers that border on the usability and utility principles (Figure 1), which may lead to the low perceived value, utility, and use of MIRLS.

PSD of MIRLS

PSD was pioneered by Fogg [44] in the early 2000s in his seminal book, “Persuasive technology: using computers to change what we think and do.” This entails the application of behavioral theories from social psychology in the design of technology-based systems to motivate behavior change. Hence, persuasive technology is defined as a motivational tool intentionally designed to change human attitudes and behaviors through persuasive techniques grounded in social psychology [44]. Fogg [44] first proposed a set of 7 persuasive strategies to motivate behavior change. Subsequently, Oinas-Kukkonen and Harjumaa [30] extended the list to 28 persuasive strategies, which are categorized into 4 functional groups (primary task support, dialogue support, social support, and system credibility support), each comprising 7 persuasive strategies. Oyibo [45] extended the primary task support and dialogue support groups with goal setting and verbal persuasion, respectively, increasing the total number of strategies in the PSD taxonomy to 30. The primary task support category, which includes tunneling, tailoring, and self-monitoring, is aimed at helping the user to perform a target behavior easily and effectively. The dialogue support category, which includes praise, reward, and suggestion, is aimed at motivating the user to perform the target behavior through feedback and dialogue with the persuasive system. The social support category, which includes social learning, social comparison, and competition, is aimed at motivating the user through social influence to perform the target behavior. Finally, the system credibility support category, which includes trustworthiness, surface credibility, and authority, is aimed at increasing the user’s trust in the system by making the system look professional and credible [46].

Incorporating persuasive features into MIRLS has the potential to improve the rate of error reporting. St-Maurice et al [28] showed that, on average, the percentage of same-day data entries can be increased by 10% for each user by introducing new persuasive design features into a data entry system. On the basis of this prior research finding, we propose guidelines for incorporating persuasive design principles, drawn from the PSD taxonomy, into MIRLS using the Think Research or Pharmapod Incident Management (IM) system as a case study. The PSD taxonomy, which comprises 4 categories of persuasive strategies (primary task support, dialogue support, social support, and system credibility support), is a framework for analyzing, designing, implementing, and evaluating persuasive systems. A systematic review by Win et al [47] showed that primary task support and dialogue support are the most commonly used categories of persuasive strategies in medication management information systems. The review reported that tailoring, self-monitoring, and reminders, which belong to the primary task support category, are more likely to be implemented in

medication management information systems than other persuasive strategies. In the case of MIRLS, the proposed persuasive strategy guidelines are aimed at enhancing system utility and facilitating the reporting of near misses and incidents. Research shows that the higher the perceived usefulness of health systems, the higher the number of users who find them more persuasive [48].

Methods

Overview

A total of 2 types of methods were used to address 3 research questions (RQs). They include scoping review and assessment of an existing MIRLS based on administrative, usability, utility, and persuasive features. The RQs are as follows:

1. RQ1. Is there a relationship between medication errors and patient harm?
2. RQ2. What are the information system-based barriers preventing pharmacists and pharmacy technicians from reporting medication errors?
3. RQ3. How can we motivate them to report MIs more frequently using persuasive design principles embedded in digital technologies?

Ethical Considerations

The assessment of our target system was aimed at quality improvement, thus ethical approval was not required [49,50].

Scoping Reviews

To address the first 2 RQs, the authors (KO, SE, and TN) conducted 2 scoping views in August 2023. The first review investigated the relationship between medication errors and patient harm in the pharmacy domain. The second review aimed to uncover usability and utility-related barriers to medication error reporting. We retrieved articles from 6 databases for each study, screened the articles, extracted the relevant data, and presented the results. For the first review, a total of 820 articles were retrieved from PubMed (n=41), Public Health Database (n=89), ProQuest (n=451), Scopus (n=97), ACM (n=42), and Global Health (n=22) using the search string: “(Medic* OR prescri* OR administ* OR drug*) AND (error* OR incident* OR accident* OR nearmiss* OR ‘near miss*’ OR mistake*) AND patient AND (harm* OR hurt* OR injur* OR wound* OR bruise* OR impairment* OR afflict*) AND pharmac*.” A total of 215 duplicates were removed to arrive at 605 unique articles. These articles were screened based on title or abstract to arrive at 91 articles. Next, a full-text review was conducted to arrive at 14 included articles after excluding 77 ineligible articles. Finally, 3 more articles were included to the 14 through Google Scholar search, resulting in 17 articles for the final data analysis. For the second review, a total of 849 articles were retrieved from PubMed (n=268), Public Health Database (n=44), ProQuest (n=90), Scopus (n=448), ACM (n=10), and Global Health (n=45) using the search string: “(Medic* OR prescri* OR administ* OR drug*) AND (error* OR incident* OR accident* OR nearmiss* OR ‘near miss*’ OR mistake*) AND (report* OR submi* OR log*) AND (system* OR application* OR website* OR tool* OR platform* OR interface* OR technolog*) AND pharmac* AND (barrier* OR hinderance*”).

OR obstacle* OR drawback* OR setback* OR deterrent* OR limitation* OR shortcoming*.” A total of 303 duplicates were removed to arrive at 546 unique articles. These articles were screened based on title or abstract to arrive at 12 articles. Upon the full-text review, we arrived at zero article for data extraction and analysis. Moreover, based on Google Scholar search, we found 1 article [13] that investigated the usability of MIRLS called the Medication Error Reporting App. However, this study did not investigate the relationship between the usability of the app and medication error.

Overview and Initial Assessment of an Existing MIRLS

The authors (KO and PAG) analyzed the Think Research or Pharmapod MIRLS, which is a cloud-based software platform for reporting medication errors (incidents and near misses). As stated on its website, Think Research or Pharmapod describes itself as “the first platform of its kind to pool and share patient safety data across borders, monitoring trends and causes behind medication errors, and empowering healthcare professionals locally to improve their practice” [29]. Our initial review of the system assessed it against the 3 key design principles shown in Figure 1. To assess the administrative and usability and utility principles, the first 2 authors went through the Think Research or Pharmapod system from one interface to another to elicit the supported principles. Next, we used the PSD taxonomy as an assessment framework and 3 assessors (study participants) to identify persuasive strategies fully or partially implemented in the Think Research or Pharmapod IM system. We first assessed the system to identify the existing persuasive strategies and then gathered data from 3 experienced users to propose opportunities for improvement. One of the authors, the vice president of the Quality Improvement and Innovations of Think Research or Pharmapod, arranged for 3 independent and experienced users of the Think Research or Pharmapod IM system from different pharmacies to assess the system against the PSD taxonomy and items. The first assessor was a pharmacist who had 1.5 years of experience using the system. The second assessor was a director in a health care company focused on patient and staff safety, with 1 year of experience working with the system. The third assessor was a senior technology manager at a leading Canadian pharmacy company, with 4 years of experience working with the system.

The authors (KO and PAG) asked the assessors to independently indicate whether each persuasive strategy in the PSD taxonomy is important or useful, present in the system or not, and where it could be found in the system. The implementation of each strategy from the PSD taxonomy was described to the

participants in a tabular form. The participants independently responded to the questions and then came together to discuss and confirm their responses and resolve their differences with the first 2 authors. If at least 2 of the 3 assessors indicated or agreed that a given persuasive strategy is important and useful, “yes” is entered into the associated cell in the table, otherwise, “no.” Similarly, if at least 2 assessors agreed that the strategy was present in the system (ie, said “yes”), “√” is entered into the cell associated with the status column. However, if ≥ 2 assessors agreed that the strategy was not present in the system (ie, said “no”), “X” is entered into the associated cell under the status column. Moreover, if at least 1 of the assessors agreed that the strategy was present in the system, but the implementation was limited, “√*” standing for “present but could be improved” is entered into the associated cell under the status column.

Results

In this section, we present the results of the scoping reviews and the initial assessment of the Think Research or Pharmapod IM system.

Scoping Reviews

Medication Errors and Patient Harm

In the first review, 41% (7/17) of the included articles originated from North America (United States [16,51-53], Canada [54,55], and Mexico [56]), 29% (5/17) from Europe (United Kingdom [12], Ireland [18], the Netherlands [57], Sweden [58], and Spain [59]), 23% (4/17) from Asia (Saudi Arabia [60,61], China [62], and Korea [63]), and 6% (1/17) from Oceania (New Zealand [17]). The articles were published between 2001 and 2023, with most of the articles (3/17, 18%) published in 2023. Most of the target populations were from North America (7/17, 41%), followed by Asia (5/17, 29%), Europe (4/17, 23%), and Oceania (1/17, 6%). Of the 17 articles, 1 (6%) each focused on target populations in Africa and South America. Table 1 shows 16 types of harms elicited from the included articles. These were caused by 59 types of medication errors such as wrong drugs, missing or wrong patient weight, prescription errors, dosing error, wrong or unclear dose or strength, wrong patient, and wrong duration, each of which was reported by at least 2 articles. Significant or serious harm was the most frequent harm; it was reported by 65% (11/17) of the articles, followed by death or fatal harm (7/17, 41%) and no harm or potential harm (4/17, 23%).

Table 1. Type or severity of harm caused by medication errors and the number of articles associated with them (N=17).

Type or severity of harm	Articles, n (%)
Significant or serious harm	11 (65)
Death or fatal harm	7 (41)
No harm or potential harm	4 (23)
Inconvenience	3 (18)
Adverse drug events	3 (18)
Mild harm	2 (12)
Moderate harm	2 (12)
Temporary injury or harm	2 (12)
Prolonged hospitalization	2 (12)
Life-threatening harm	2 (12)
Nonlife threatening	1 (6)
Risk to patient or others	1 (6)
Unstable situation	1 (6)
Unknown harm	1 (6)
Permanent harm	1 (6)
Intervention required	1 (6)

Information System Barriers to MI Reporting

One article [13] that investigated the usability of an MIRLS prototype called Medication Error Reporting App found that there was significant improvement in the mean usability score throughout the development process ($P < .001$). However, this mean improvement in usability did not impact the mean time to report medication errors using the app because the mean time was not significantly different between the phases of the development process. Overall, it was found that the testers including pharmacists found the app easy to use, but doctors and nurses were unfamiliar with the medication terms used, especially the medication process in which error occurred and type of error. More importantly, the authors reported that although testers might be willing to adopt the app to make reports in the future, they were apprehensive about data protection issues such as security and abuse of feedback featured in the app [13].

Initial Assessment of Existing MIRLS

In this section, we present the results that emanated from the initial assessment of the Think Research or Pharmapod IM system based on administrative, usability, utility, and persuasive principles.

Administrative and Usability and Utility Principle Support

The assessed system supported at least 75% (6/8) of the administrative guiding principles shown in [Textbox 2](#), including voluntariness, anonymity, confidentiality of information, and nonpunitive measures. It also supported all 7 usability and utility-based principles, including ease of use, searchability and retrievability, standard taxonomy, report generation, and root cause analysis ([Table 1](#)).

Textbox 2. Items and questions asked of assessors.

<p>Strategy code</p> <ul style="list-style-type: none"> • A codeword representing the persuasive strategy. <p>System capability</p> <ul style="list-style-type: none"> • A description of the persuasive strategy. <p>Important or useful</p> <ul style="list-style-type: none"> • An indication of the importance or usefulness of the strategy (yes or no). <p>Present in system</p> <ul style="list-style-type: none"> • An indication of the presence of the strategy in the system (yes or no). <p>Interface, tab, or comment</p> <ul style="list-style-type: none"> • Provision of the system interface or tab where the persuasive strategy can be found or a comment by the assessor.

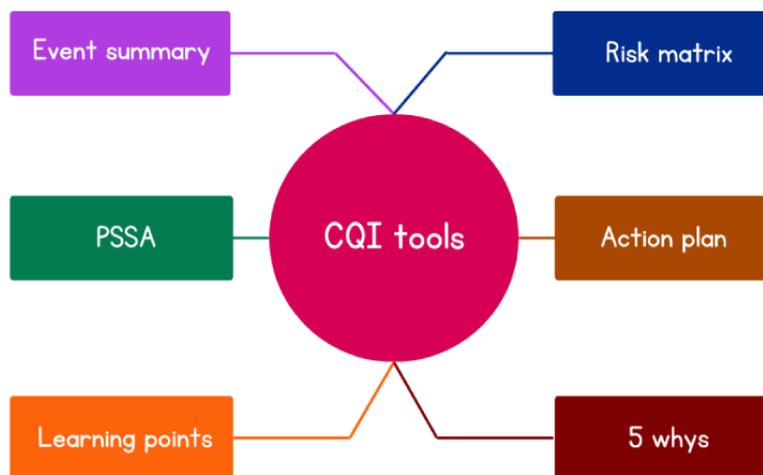

Moreover, the system promotes 4 key elements of patient medication safety: report, document, analyze, and share (Figure 2). The analyze and share elements are in addition supported by 6 main continuous quality improvement (CQI) tools. These tools are intended to foster patient safety in community pharmacy within a pharmacy team [20,64]. The tools include event summary, risk matrix, 5-whys template, action plan, learning points, and pharmacy safety self-assessment (Figure 3). An event summary is an incident and a root cause analysis tool. The risk matrix is a color-coded matrix that facilitates the assignment of a risk score based on the probability of recurrence of the incident or near miss at a specific severity level and its

impact on a patient if it were to recur. The 5-whys is a tool that facilitates the analysis of an incident or near miss by answering the fundamental question, “Why did the incident occur?” 5 times. The 5-whys is a simple and well-recognized tool for determining the cause and effect of an incident objectively. Action plans is a tool to create and track smart actions of improvement. Learning points organizes identified gaps, for example, in workflows and processes and provides a means to share these learnings. Finally, the pharmacy safety self-assessment is a tool that allows the pharmacy team to proactively identify risks that may compromise patient safety and implement safe medication measures to address them [64].

Figure 2. Four key elements of patient medication safety.

Figure 3. Six continuous quality improvement (CQI) tools in the studied system aimed at fostering fundamental change among pharmacy team members. PSSA: pharmacy safety self-assessment.

Persuasive Principle Support

Tables 2-5 show the results of the assessment of the Think Research or Pharmapod IM system based on the primary, dialogue, social, and credibility support categories of the PSD taxonomy, respectively. The first column of Table 2 captures the coded name of the strategy and its description, the second

column describes a yes or no response on the importance and usefulness of the strategy, and the third column describes a yes or no response on the presence of the strategy in the system (ie, status). A fourth column was also provided for the assessors to comment on the assessment of each strategy, for example, the location of the strategy in the system.

Table 2. Guidelines for incorporating the primary task support principles into Medication Incident Reporting and Learning Systems.

Strategy and implementation	I or U ^a	Status
Reduction		
Break down the medication incident and near-miss reporting process into a few simple steps to facilitate reporting [65].	Yes	✓ ^b
Tunneling		
Guide the user through the reporting process in a step-by-step fashion, just as a software installation wizard [47].	Yes	X ^c
Goal setting		
Allow the user to set a goal, for example, minimum number of errors or CQI ^d reports to be submitted over a given period such as a week or month.	Yes	X
Self-monitoring		
Allow the user to track their progress after setting a report-based goal or when submitting a report, for example, through the display of a progress bar.	Yes	X
Allow the user to view their number of completed and uncompleted reports and averages per week, month, or year (eg, on their dashboard).	Yes	✓
Allow the user to track the levels of usefulness of their reports (eg, CQI, incident, or near miss) to others, for example, other users or colleagues “like” their anonymous reports as obtainable in YouTube and Facebook.	Yes	X
Tailoring		
Tailor what the user sees (eg, user profile, chart, content, and information) using group-based characteristics such as work experience and designation or role.	Yes	✓* ^e
Personalization		
Personalize the system (eg, information, report, and reminder) based on their interaction, for example, letting the user know where they left off or reminding them about incomplete tasks when they log in [7,66].	Yes	X
Customization		
Allow the user to customize the system (eg, profile, chart, content, information, and reminder) to suit their needs and preferences [66].	Yes	✓*
Simulation		
Show the user a cause-and-effect relationship of the benefit of incident or near miss or CQI reporting, for example, a study chart showing the higher the incidents reported, the lower the number of recurrences.	Yes	X
Rehearsal		
Provide a new user with a simulated environment to rehearse before making an actual report relating to an incident, near miss, or CQI.	Yes	✓*
Provide a new user with video tutorials on how to report a medication incident or near miss.	Yes	✓

^aI or U: important or useful.

^bCurrently implemented.

^cNot currently implemented.

^dCQI: continuous quality improvement.

^ePartially implemented and could be improved.

Table 3. Guidelines for incorporating dialogue support principles into Medication Incident Reporting and Learning Systems.

Strategy and implementation	I or U ^a	Status
Praise		
As a show of appreciation, praise or congratulate the user for submitting a near-miss or incident or CQI ^b report or for reaching a milestone using textual, visual, or audio-based feedback messages [67].	Yes	X ^c
Reward		
Reward the user with points, badges, etc, when they submit a report (early), achieve a goal or milestone, or others find their report useful (eg, by liking it), etc.	Yes	X
Allow the user over time to grow in the value of their contribution to the community. This can be based on the number, frequency, quality, earliness, and usefulness of their reports (to others), for example, from a silver to a gold valuable contributor of the community.	Yes	X
Reward the user for reporting or sharing action plans that improved safety in the pharmacy.	Yes	X
Reward the user for reporting positive experiences that led to improved safety in the pharmacy, for example, “good news” stories in addition to the negative “error” reports.	Yes	X
Suggestion		
Suggest to the user from time to time based on their profile, role, or interaction with the system new reports that may be interesting and beneficial to their practice [65].	Yes	X
Suggest to the user ways, processes, or methods through which others in the community prevent or address recurrence of certain near misses and incidents.	Yes	X
Suggest to the user standard, process-based solutions (eg, from the user’s pharmacy, province, or professional organization) for addressing certain types of recurring incidents and near misses [65].	Yes	X
Provide the user with a list of “high-alert” medications or types of incidents that occur most often or require extra precautions and suggest best practices to reduce incidents and near misses associated with them [68].	Yes	✓* ^d
Feedback^e		
Provide the user with summary feedback on their progress toward reaching their monthly, quarterly, or yearly goal (eg, “You have achieved 30% of your goal”).	Yes	X
Provide the user with summary feedback on the usefulness of their reports to others (eg, “5% of the system users in the province [nation] found your report helpful”).	Yes	X
Provide the user monthly, quarterly, or yearly summary feedback highlighting the most recurring types of near misses and incidents (eg, “Poor drug naming caused 5% of the near misses last year”) [65].	Yes	✓ ^f
Reminder		
Remind the user from time to time (eg, based on self-set goals) about the need to report near misses and incidents and about the benefits to other users and patient safety.	Yes	X
Remind the user from time to time to complete their CQI action plan that they have started.	Yes	X
Verbal persuasion^e		
Allow management such as pharmacy managers and supervisors through personally sent messages to encourage users from time to time to report near misses and incidents, for example, “Alice, remember to report your near misses and incidents to improve patient safety. Yes, you can!”	N/A ^g	N/A
Emotional appeal^e		
Use motivational messages to encourage users to report errors, for example, “To err is human, to share is divine” [69].	Yes	X
Liking		
Make the system to be visually attractive, for example, by using visually pleasing or appropriate colors to present charts, content, and important information.	Yes	✓*

^aI or U: important or useful.

^bCQI: continuous quality improvement.

^cNot currently implemented.

^dPartially implemented and could be improved.

^eNot originally listed in the Persuasive System Design taxonomy.

^fCurrently implemented.

[§]N/A: not applicable.

Table 4. Guidelines for incorporating social support principles into Medication Incident Reporting and Learning Systems.

Strategy and implementation	I or U ^a	Status
Social learning		
Notify the user by email when other anonymous users submit an incident report (eg, containing the key points) or CQI ^b report that may be of interest to the user, just as in ResearchGate, for example, “John [a pseudonym], here’s a new report we think you’ll be interested in.”	Yes	X ^c
Support chat room and discussion room to foster social support and shared learning [47]. This room can be anonymous.	Yes	X
Support a newsfeed (eg, as in Facebook) to highlight important reports the user may find useful and foster shared learning.	Yes	X
Social comparison		
Allow the user to compare their weekly, monthly, quarterly, or yearly reports with others, maintaining confidentiality (eg, at the city, zone, provincial, or national level).	Yes	✓* ^d
Competition		
Allow the user to see where they are compared with other anonymous (eg, on a leaderboard) at the pharmacy, provincial, or national level based on the total number, frequency, quality, or usefulness of their report to others (eg, over a weekly, monthly, or yearly period).	Yes	X
Cooperation		
Provide users the choice of being paired with another anonymous user, with the goal of motivating one another to achieve individual or collective goals.	No	X
Normative influence		
Inform users about the number of other anonymous users in the pharmacy, province, or nation that are reporting errors in a given period (eg, “10 other people submitted their incident reports today”).	Yes	X
Social facilitation		
Make users, who are logged onto the system know that there are other anonymous users elsewhere (eg, in the facility, province, and nation), who are submitting or just submitted a report (eg, “5 other people are currently submitting their incident reports”).	Yes	X
Social recognition		
Provide a means for committed user to be publicly recognized for being one of the “most valuable players” of the month, quarter, or year at the pharmacy, provincial, or national level based on certain criteria (eg, number, frequency, quality, or usefulness of their reports to the community).	Yes	X
Allow other users to rate users’ reports anonymously based on how useful or helpful it is to them.	No	X

^aI or U: important or useful.

^bCQI: continuous quality improvement.

^cNot currently implemented.

^dPartially implemented and could be improved.

Table 5. Guidelines for incorporating system credibility support principles into Medication Incident Reporting and Learning Systems.

Strategy	Implementation	I or U ^a	Status
Authority	Present authority-based information and messages (eg, on the value of reporting incidents and near misses and the benefits it can have for the profession, staff, or patient safety) [47].	Yes	X ^b
Third-party endorsement	Demonstrate that the system is approved by authorities such as professional organizations, regulatory bodies, and government, for example, by displaying their corporate logos [65].	Yes	X
Expertise	The visual and functional design of the system should reflect professionalism, expertise, and be up to date to motivate users to use it.	Yes	✓ ^c
Trustworthiness	Build trust into the system, for example, by fostering anonymity, data aggregation, and keeping promises such as it not being used as a punitive tool to hold users accountable [65].	Yes	✓ [*]
Surface credibility	Build surface credibility into the system through its visual design, for example, by reducing advertisements and ensuring users enter accurate information using taxonomy-based pre-defined options, checklists, and drop-downs [47].	Yes	✓ ^d
Verifiability	Ensure presented information and messages (eg, on the value of error reporting to the profession, staff, or patient safety) are verifiable, for example, through a link to authority-based websites such as Institute for Safe Medication Practices and World Health Organization.	Yes	X
Real-world feel	The design of the system should mimic the paper-based error reporting forms (eg, [70]) as closely as possible to reduce the cognitive effort required by a new user to make the transition [71].	Yes	✓

^aI or U: important or useful.

^bNot currently implemented.

^cPartially implemented and could be improved.

^dCurrently implemented.

Primary support strategies facilitate the key behaviors promoted by the system, such as reporting. Dialogue support strategies enable users to interact, engage with, and receive feedback from the system through text-, image-, audio-, and video-based dialogue. Social support strategies motivate users through social influence. Finally, credibility support strategies enable users to trust and rely on the system. In summary, based on the assessors' responses, most of the persuasive strategies (29/31, 94%) in the extended PSD taxonomy were considered important or useful, with approximately one-third (14/29, 48%) of them identified as present in the current Think Research or Pharmapod system. Approximately 23% (7/31) and 26% (8/31) of the strategies were considered fully or partially implemented (although they could be improved), respectively. More than 50% (16/31) of the strategies were considered not implemented, with most of them falling under the social support category.

Discussion

We have presented the results of 2 scoping reviews and the initial assessment of the Think Research or Pharmapod system. The following sections discuss the results with a focus on the persuasive design guidelines shown in Tables 2-5, which can inform the persuasive design of future MIRLS.

Summary of Scoping Review Findings

Table 1 shows the types of harm uncovered in the first scoping review. More than half (11/17, 65%) of the included articles reported that medicated errors caused serious harm to patients. In particular, 60% (3/5) of the articles reported serious harm, and 40% (2/5) of the articles reported fatal harm or death caused by medication errors such as wrong dose, drug, patient, and

ambulatory pump (eg, [58]). Prescription error [16,18,59,63], wrong drugs [12,58,63], and dosing error [58,59,63] were the most frequent medication errors. For example, in the study by Fyhr and Akselsson [58], most severe medication errors occurred during prescribing and transcribing by physicians. The findings are an indication that medication errors have the potential to cause serious harm to patients, including death; hence, there is a need for interventions aimed to reduce them and increase patient safety (eg, by increasing reporting and shared learning within and across organizations). Moreover, in the second review on the usability of MIRLS, George et al [13] found that an iterative design has the potential to improve the usability of an MIRLS. However, their study suggested that there is a need to address issues surrounding data security and report validation to increase user acceptance and use.

Summary of Administrative and Usability and Utility Assessment

Our assessment shows that the Think Research or Pharmapod system implemented most of the administrative, usability and utility-based principles shown in Textboxes 1, 3 [7,14], and 4 [7,14]. Prior studies advocate most of these principles as essential actions and capabilities aimed at improving incident reporting and shared learning [7,9,14,33-36]. An anonymous reporting, for example, can mitigate the punitive perceptions of incident reporting [20]. However, the system only partially supported persuasive design principles. Persuasive design principles are intended to complement the administrative, usability and utility-based principles by improving the UX and motivating users to see value in reporting MIs and completing the CQI and learning tool reports. Persuasive design may in

turn mitigate some of the persistent barriers identified in [Textbox 1](#).

Textbox 3. Administrative guiding principles for designing Medication Incident Reporting and Learning Systems [7,14].

Voluntariness

- Medication reporting will be voluntary.

Inclusiveness

- Professionals and consumers will be encouraged to participate.

Aggregation

- The reporting system will support anonymity and aggregation.

Confidentiality

- The system will provide confidentiality of reported information.

No consequence

- The system will clearly define and support a nonpunitive approach to reporting.

Type of report

- The system will encourage reporting of both potential and actual incidents and near misses.

Feedback

- The system will provide feedback on incident analysis and timely recommendations.

Workflow alignment

- The system should fit with the users' workflow.

Textbox 4. Usability and utility-based guiding principles for designing Medication Incident Reporting and Learning Systems [7,14].

Usability

- The system will be easy to use and time efficient.

Format multiplicity

- The system will support both electronic and paper formats.

Taxonomy

- The system will support standard taxonomy.

Outcome severity

- The system will support levels of severity of outcomes.

Searchability and retrievability

- The system will support searchable and retrievable data.

Report generation

- The system will support report generation.

Root cause analysis

- The system will support root cause analysis.

Summary of Persuasive Design Assessment

In this section, we discuss the results of the system assessment and persuasive design guidelines for designing future MIRLS, taking each category of the PSD taxonomy at a time.

Primary Support Assessment and Guidelines

In the primary support category ([Table 2](#)), all the persuasive strategies were considered important or useful, whereas over

55% (5/9) of them were deemed partially or fully implemented by the system.

Reduction

Reduction, which is considered important and present in the system by the assessors, entails breaking down the performance of a complex behavior into a few steps. In the context of MI reporting, this means making the reporting process simple and easy to carry out by users. Reduction is vital to ensuring and facilitating the report of MIs and near misses given the relatively high workload health professionals such as pharmacists handle on a daily basis [65]. In the Think Research or Pharmapod system, for example, to speed up the reporting process, predefined fields and system design widgets such as drop-downs are used to enter information about prescribed drugs, what happened, contributing factors, and harm caused. A critical aspect in realizing the effectiveness of the implementation of this and other PSD guidelines is the fit of the MI reporting task into users' workflow to facilitate regular reporting [7]. However, this examination is beyond the scope of this conceptual study.

Tunneling

Similar to reduction, tunneling (aka guided persuasion) aims at motivating users to report MIs and near misses. The tunneling strategy, which can be likened to the process of installing software on a computer using an installation wizard [72], is used to walk the user through predetermined steps in a structured manner. Two of the assessors agreed that tunneling is important or useful but not present in the studied system, with 1 of them remarking, "the report has four sections, then the CQI has colour coded features but they do not tunnel you in any direction." Once an incident report is completed and saved, the incident analysis interface (an event summary page containing a variety of management tools to prevent the recurrence of similar events in the future) opens automatically. However, the system does not tunnel the user in a specific direction. The third assessor, however, did not find tunneling useful in this context and commented, "No this MIRLS is not like an installation wizard. We like the flexibility provided today." Hence, owing to the mixed responses, a more comprehensive study among a larger target audience is required to understand the perceived usefulness of tunneling.

Goal Setting

Related to the commitment principle proposed by Cialdini [73], goal setting is known as one of the cornerstones of persuasive systems [74]. According to the commitment principle, people are more likely to follow through with a behavior if they make a commitment in written or verbal form to perform the behavior [75]. Studies have shown that people, regardless of culture, are more motivated by the commitment principle than by the other 5 principles of persuasion proposed by Cialdini [76,77]. Goal setting is more likely to be effective if set goals are specific, measurable, achievable, relevant, and timebound (SMART) [77]. The assessors agreed that goal setting is important or useful in MI reporting. One participant thought that the feature was present in the system already. Here, the assessor meant the CQI action planning. In general, both goal setting and action planning are related. However, action planning is concerned with how set goals can be achieved [78]. In the studied system, the CQI

actions tool captures both actions (which can be regarded as CQI goals) and action plans (eg, addressing gaps in workflows and processes) [64]. Although we can submit the system-supported CQI goals, it did not support incident reporting goals. Regarding the former, one of the assessors stated that the action plan tab in the system allows a free-form type (such as textboxes that allow the user to type in anything without restrictions). However, it "could be improved by adding prompts for SMART [plans] to guide the user to complete [them] correctly. These action plans are incident specific. They do not allow overall SMART goals around frequency and quality of reporting. [Although], [t]here are dashboards of measurements, they do not include goals or thresholds as a comparison or guide."

Self-Monitoring

Self-monitoring goes hand in hand with goal setting in most implementations [78,79]. In other words, users should be able to visualize their progress toward the realization of their set goals. Self-monitoring is one of the cornerstones of persuasive systems [78] and one of the most requested persuasive features in health apps such as fitness apps [45]. In a systematic review, Matthews et al [80] found that 70% of the included articles evaluated physical activity apps that supported self-monitoring as a persuasive feature to motivate behavior change. Self-monitoring fosters self-reflection and raises users' consciousness of their responsibilities, which culminates in self-regulation and behavior change [78,81,82]. Self-monitoring can be compared with holding a mirror up to the user's face, and if the user does not like what they see, they do something about it. In work environments, employees' engagement in self-monitoring is considered a prerequisite for professional development [82]. In the studied system, self-monitoring is implemented in the form of incident and near-miss reports at the pharmacy, province, or national level. In the data warehouse interface, users can view the number of cases (incidents and near misses); number of events by harm levels, top 5 drugs; and what, why, and when they happened. However, because there is no goal setting for incident report, the system does not support the type of self-monitoring that allows the user to track their progress after setting a report-based goal or when submitting a report, for example, through the display of a progress bar. In addition, the system does not allow the user to track the levels of usefulness of their reports (eg, incident, near miss, and CQI plans) to others. For example, it does not allow other users or colleagues to "like" the user's anonymous reports or to indicate their usefulness.

Tailoring, Personalization, and Customization

All 3 persuasive strategies are related and can be defined as the act of tailoring the user interface elements and content of a system to suit the user's needs, preferences, designation, or role. Tailoring and personalization are carried out by the system, whereas customization is carried out by the user. Although tailoring is enacted by the system based on users' predetermined information (eg, gathered through surveys before using the system), personalization is enacted by the system using information gathered in real time (ie, during user interaction with the system) [81,83]. We observed that tailoring was implemented in the assessed system. This system provides

role-based access to certain features. However, the assessors remarked that the tailoring feature can be improved depending on what users need. However, we found that the system does not support personalization. Hence, we recommend MIRLS be personalized based on user interaction, for example, letting the user know where they left off or reminding them about incomplete tasks when they log in [7,66]. In addition, we recommend that users be allowed to customize the system (eg, user profile, chart, content, information, and reminder) to suit their needs and preferences [66].

Simulation

Simulation is a persuasive strategy used to demonstrate the cause and effect of a given behavior. Although the assessors considered it important, it was not currently implemented in the system. Thus, we recommend that MIRLS provide a means for the user to observe a link between the cause and effect of incident and near-miss reporting [80,84]. A typical implementation of the strategy is demonstrating to the user using a graph or chart that the higher the MIs reported using the system, the lower the number of recurrences.

Rehearsal

Rehearsal is a trial performance or practice of a given task so that the user can perform it correctly and easily later. In the assessment, we found that the system already provides a new user with video tutorials (organized in modules) on how to report a MI or near miss. In addition, we recommend that MIRLS provide a new user with a practice environment, in which they can rehearse before using the system to make an actual report.

Dialogue Support Assessment and Guidelines

In the dialogue support category (Table 3), all the persuasive strategies were considered important or useful; however, only 50% (4/8) of them (eg, reminder, feedback, and suggestion) were considered partially implemented by the system.

Praise and Reward

They entail acknowledging, appreciating, and recognizing the user for their effort and time taken to report incidents and near misses for the benefits of other pharmacists and patient safety. As Holden et al [6] noted, “reward and punishment structures may affect individual reporting decisions (e.g. if nurses are rewarded more for productivity than for reporting), as may culture (e.g. blame vs. just culture).” It is yet to be seen how the web-based rewards implemented in a system may influence error reporting. Enacted through well-worded motivational text and well-designed motivational images, symbols, and sounds [67], praise fosters an intimate relationship between the user and the system, making the user feel valued, appreciated, and more open to persuasion [85]. Although considered important by 2 of the assessors, 1 of them had some reservation. The participant stated, “This would emphatically not be wanted. Reward messages coming from an MIRLS technology should not emulate a sports watch. As an advanced user of the system I would find this annoying and a waste of time. If the system helps reduce incidents, a trend report shows proof, that is praise enough.” However, praise and rewards can be targeted to

aggregated reports (eg, a pharmacy) on the basis of the number of incidents that reached and did not reach the patient.

Suggestion

This strategy is considered important and partially implemented in the system and can be used as a means of informing users about certain important reports (especially from other anonymous users or generated from the system), which may be useful to them in their practice. A typical suggestion in this context could be a list of “actions to take” for a specific MI or a list of “high-alert” medications that require extra precautions. Other suggestions include new research reports that may be interesting and beneficial to the user or ways, processes, or methods through which other anonymous users in the community prevent or address recurrence of certain medication errors [65]. For example, upon completing a report, the user can be recommended a set of preventive guidelines by the system to mitigate future incidents.

Feedback

Several behavior change theories such as social cognitive theory, goal setting theory [86], and feedback intervention theory consider the provision of feedback as an important ingredient in behavior change [87,88]. An example implementation of the self-monitoring-type of feedback is providing the user with summary feedback on their progress toward reaching their goal (eg, “You have achieved 30% of your goal”). Moreover, feedback entails information about one’s behavior or system-generated figures and statistics. In the context of MIRLS, informational feedback is the information of the user about the impact of their error-reporting behavior on the community or health providers’ medication errors on patient safety. An example of informational feedback is informing pharmacists about the usefulness of their reports to other users in the community (eg, “5% of the system users in the province [nation] found your report helpful”). Another example is providing users with monthly, quarterly, or yearly summary feedback highlighting the most recurring types of errors relevant to their work [65] (eg, “Poor drug naming caused 5% of the near misses last year.” In addition, the solution to this medication error can be included in the feedback message as well; for example, “Poor drug naming caused 5% of the near misses last year; remember to use TALLman lettering when necessary.” The use of uppercase letters in a portion of a drug name helps to draw attention to the dissimilarities between look-alike and sound-alike drug names. Moreover, it helps to alert health care professionals that the name of a given drug can be confused with another drug that has a similar name [89].

Reminder

This refers to an alert on task completion and compliance with certain behavior or expectation [90]. Reminder is closely tied to goal setting in a certain regard. For example, if the user sets a goal (eg, report at least X errors per month), then the user should have the opportunity to set reminders so that they could be reminded at certain preset times to report incidents or near misses if they have any. Reminder has been widely and successfully used in persuasive systems, especially in the health domain, to motivate behavior change [80,91]. In MIRLS, reminders, considered important and partially implemented,

can be based on users' self-set goals on medication error reporting as well as CQI-based action plans. For example, based on self-set goals, the system can remind the user at preset times about the need to report near misses and incidents when they occur and about the benefits of the reports to other users in the community and patient safety. For instance, the system can prompt the user at a preset time with a message such as, "Did you have any near misses today or in the last one week? Please report if you did." Moreover, the system can remind the user through this type of message if the user has not logged into it or submitted a report within a certain period. In addition to this reminder-based messages, a direct link to a reporting wizard can be included, allowing users to easily submit a report by simply clicking on the provided link. Persuasive reminders have been widely used in health self-management such as taking one's daily medication and have been effective [92]. Although reminders may be more effective if they are just-in-time [87], in the context of MIRLS, they can be well ahead of time, for example, during the period when a user such as a pharmacist resumes their shift. They can also be at the end of the pharmacist's shift. Therefore, research, in the context of MIRLS, is required to show which of the periods (start or end) is more likely to be effective in motivating reporting of medication errors. In summary, reminders can be general or specific. General reminders are aimed to remind users from time to time to report incidents if they have any. Moreover, specific reminders are aimed to remind users to complete incident report drafts (ie, reports that they started but have not completed). Nevertheless, reminders should be used with caution as they can be overwhelming if overused. As stated by 1 of the assessors, "Reminders can also be annoying to the point of reminder fatigue and disregarded instantly, and overkill for this type of solution." Therefore, users should be allowed to turn them on and off.

Verbal Persuasion

This refers to the act of mentoring and providing encouragement and feedback to help individuals achieve their goals. It is also defined as "the act of telling or convincing a person to perform a task or action to change a behavior or put into action a set of events to achieve an objective" [93]. Research shows that organizational and leadership coaches use verbal persuasion effectively to increase the self-efficacy of their clients and the results they create. The tools for carrying out verbal persuasion include praise (kind words about the user), encouragement (words of affirmation about the user's ability), stories (personal or allegorical stories to help reframe the user's struggle with the task), positive feedback (assessing the user's performance favorably), strengths focus (intentionally linking the task to the user's strengths), and past achievements (acknowledging past wins as an indication of the user's ability to complete the current task) [94]. In the context of MIRLS, praise and encouragement may be used effectively by community pharmacy managers and supervisors to motivate users to report near misses and incidents. However, the use of individual feedback and past achievements may not be possible in MIRLS if, at the pharmacy level, managers and supervisors do not have access to individual users' performance owing to anonymity. In the event that managers had access to individual users' performance, as may be the case

in certain pharmacies owing to corporate policy, managers and supervisors could enact verbal persuasion through personal feedback and strengths in addition to praise and encouragement. Although verbal persuasion can be said to be related to the praise and emotional appeal strategies, the main difference is that verbal persuasion is coming directly from a superior (eg, a pharmacy manager) that the user knows rather than the system. A typical message a pharmacy manager can send to an employee to verbally persuade them is, "Alice, remember to report your near misses and incidents to improve patient safety. Yes, you can." Moreover, a typical feedback message from a pharmacy manager is, "Alice, thanks for your constant reporting of near misses—keep it up!" Users (whether reporting frequently or not) may find this type of message motivational. This may motivate users who have not been reporting their errors using the system in recent times to start reporting. Moreover, this type of positive feedback will help address one of the administrative barriers presented in [Textbox 1](#): "Underreporting due to lack of useful feedback or negative feedback from administrative teams such as pharmacy managers" [8].

Emotional Appeal

It is a persuasive strategy designed to elicit an emotional response based on feelings [95]. We argue that motivational messages that appeal to emotion and feeling, such as "To err is human, to share is divine" [69], have the potential to motivate users in the medication error-reporting domain, similar to other domains [81]. In the fitness app domain, for example, Oyibo [96] found that, regardless of gender, health messages that appeal to emotion, such as "Those who do not find time for exercise will have to find time for illness," have the potential to motivate people to start or continue exercising. However, in this study, we found that although a motivational message such as "To err is human, to share is divine" may motivate some pharmacists, as evident in 1 of the assessors' responses ("would love it"), it may demotivate others. One of the assessors commented that the use of emotional appeal is inappropriate in a professional domain such as community pharmacy. The assessor stated, "It is a regulatory requirement to report incidents—no need for motivational messages...like a sports watch or fitbit. It seems unprofessional for a tool such as this to have this. I would NEVER accept this or turn this feature on." The mixed reactions to the use of emotional appeal to motivate incident reporting, similar to praise and reward, require further empirical studies.

Liking

This entails making a system visually attractive and engaging to make it persuasive. This strategy in the PSD taxonomy is drawn from the 6 principles of persuasion proposed by Cialdini [73]. According to Cialdini [73], the more people like someone, the more likely they are to be persuaded by the person. Similarly, in the context of PSD, the more esthetic a system is, the more persuasive users find it and the more likely the users are willing to use it to motivate their behavior change [48,97]. In the context of MIRLS, designers can use visually pleasing user interfaces and appropriate colors to present charts, content, and important information to improve the overall UX.
