Volume 11 (2024) ISSN 1438-8871 Editor in Chief: Gunther Eysenbach, MD, MPH

Contents

Original Papers

Evaluating the Construct Validity of the Charité Alarm Fatigue Questionnaire using Confirmatory Factor Analysis (e57658) Maximilian Wunderlich, Henning Krampe, Kristina Fuest, Dominik Leicht, Moriz Probst, Julian Runge, Sebastian Schmid, Claudia Spies, Björn Weiß, Felix Balzer, Akira-Sebastian Poncette, CAFQa Study Group Germany.	17
User-Centered Design for Designing and Evaluating a Prototype of a Data Collection Tool to Submit Information About Incidents of Violence Against Sex Workers: Multiple Methods Approach (e53557) Melissa Ditmore, Jose Florez-Arango.	27
Development of a System for Predicting Hospitalization Time for Patients With Traumatic Brain Injury Based on Machine Learning Algorithms: User-Centered Design Case Study (e62866) Huan Zhou, Cheng Fang, Yifeng Pan.	38
Acceptance and User Experiences of a Wearable Device for the Management of Hospitalized Patients in COVID-19–Designated Wards in Ho Chi Minh City, Vietnam: Action Learning Project (e44619) An Luu, Truong Nguyen, Van Cao, Trinh Ha, Lien Chung, Trung Truong, Tung Nguyen Le Nhu, Khoa Dao, Hao Nguyen, Phan Khanh, Khanh Le, Luu Tran, Phung Nhat, Duc Tran, Yen Lam, Catherine Thwaites, Jacob Mcknight, Nguyen Vinh Chau, Jennifer Van Nui, Vietnam ICU Translational Applications Laboratory (VITAL).	73
Exploring a Gaming-Based Intervention for Unemployed Young Adults: Thematic Analysis (e44423) Ingjerd Straand, Asbjørn Følstad, Jone Bjørnstad.	83
Evaluating the User Experience of a Smartphone-Delivered Sexual Health Promotion Program for Older Adults in the Netherlands: Single-Arm Pilot Study (e56206) Ana Correia de Barros, Mariëtte Bergmans, Kreshnik Hasanaj, Drianë Krasniqi, Catarina Nóbrega, Bruna Carvalho Carneiro, Priscila Vasconcelos, Ana Quinta-Gomes, Pedro Nobre, Joana Couto da Silva, Cristina Mendes-Santos.	103
Designing for Improved Patient Experiences in Home Dialysis: Usability and User Experience Findings From User-Based Evaluation Study With Patients With Chronic Conditions (e53691) Anna Aspelund, Paula Valkonen, Johanna Viitanen, Virpi Rauta.	118
Enabling Health Information Recommendation Using Crowdsourced Refinement in Web-Based Health Information Applications: User-Centered Design Approach and EndoZone Informatics Case Study (e52027) Wenhao Li, Rebecca O'Hara, M Hull, Helen Slater, Diksha Sirohi, Melissa Parker, Niranjan Bidargaddi.	129
Participatory Development of an Integrated, eHealth-Supported, Educational Care Pathway (Diabetes Box) for People With Type 2 Diabetes: Development and Usability Study (e45055) Daan de Frel, Mariëlle Schroyjen, Jiska Aardoom, Wesley van Gils, Sasja Huisman, Veronica Janssen, Anke Versluis, Maaïke Kleinsmann, Douwe Atsma, Hanno Pijl.	144

<p>Assessing the Utility, Impact, and Adoption Challenges of an Artificial Intelligence–Enabled Prescription Advisory Tool for Type 2 Diabetes Management: Qualitative Study (e50939) Sungwon Yoon, Hendra Goh, Phong Lee, Hong Tan, Ming Teh, Dawn Lim, Ann Kwee, Chandran Suresh, David Carmody, Du Swee, Sarah Tan, Andy Wong, Charlotte Choo, Zongwen Wee, Yong Bee.</p>	160
<p>Preferences, Needs, and Values of Patients With Chronic Obstructive Pulmonary Disease Attending a Telehealth Service: Qualitative Interview Study (e53131) Camilla Schmidt, Karen Borgnakke, Anne Frølich, Lars Kayser.</p>	171
<p>Novel Approach to Personalized Physician Recommendations Using Semantic Features and Response Metrics: Model Evaluation Study (e57670) Yingbin Zheng, Yunping Cai, Yiwei Yan, Sai Chen, Kai Gong.</p>	185
<p>Shaping Adoption and Sustained Use Across the Maternal Journey: Qualitative Study on Perceived Usability and Credibility in Digital Health Tools (e59269) Wei Ng, Ni Lau, V Lee, Smrithi Vijayakumar, Qiao Leong, Shu Ooi, Lin Su, Yung Lee, Shiao-Yng Chan, Agata Blasiak, Dean Ho.</p>	201
<p>Co-Designing a Conversational Agent With Older Adults With Chronic Obstructive Pulmonary Disease Who Age in Place: Qualitative Study (e63222) Emilie Wegener, Jenny M Bergschöld, Tina Kramer, Camilla Schmidt, Karen Borgnakke.</p>	215
<p>Views and Uses of Sepsis Digital Alerts in National Health Service Trusts in England: Qualitative Study With Health Care Professionals (e56949) Runa Lazzarino, Aleksandra Borek, Kate Honeyford, John Welch, Andrew Brent, Anne Kinderlerer, Graham Cooke, Shashank Patil, Anthony Gordon, Ben Glampson, Philippa Goodman, Peter Ghazal, Ron Daniels, Céire Costelloe, Sarah Tonkin-Crine.</p>	225
<p>Exploring the Needs of People With Chronic Low Back Pain and Health Care Professionals for mHealth Devices to Support Self-Managed Physical Activity and Pain: User-Centered Design Approach (e59897) Mathilde Berger, Anne Deblock-Bellamy, Laurence Chêze, Thomas Robert, Julie Desrosiers, Guillaume Christe, Anne Bertrand.</p>	241
<p>An Exercise-Based Precision Medicine Tool and Smartphone App for Managing Achilles Tendinopathy (the 'PhysViz' System): User-Centered Development Study (e57873) Kohle Merry, Megan MacPherson, Jackie Whittaker, Christopher Napier, Liisa Holsti, Alex Scott.</p>	260
<p>Predictive Factors of Physicians' Satisfaction and Quality of Work Under Teleconsultation Conditions: Structural Equation Analysis (e47810) Liliana Hawrysz, Magdalena Kludacz-Alessandri, Renata Walczak.</p>	277
<p>Safety in Triage by Nurses and Physicians in the United States and Israel: Narrative Review and Qualitative Study (e50676) Motti Haimi, Sheila Wheeler.</p>	323
<p>Evaluating the Usability of an mHealth App for Empowering Cancer Survivors With Disabilities: Heuristic Evaluation and Usability Testing (e51522) Rachel Adler, Kevin Baez, Paulina Morales, Jocelyn Sotelo, David Victorson, Susan Magasi.</p>	353
<p>Feasibility of Monitoring Heart and Respiratory Rates Using Nonwearable Devices and Consistency of the Measured Parameters: Pilot Feasibility Study (e56547) Kasumi Ikuta, Miya Aishima, Maiko Noguchi-Watanabe, Sakiko Fukui.</p>	367
<p>The Impact of Information Relevancy and Interactivity on Intensivists' Trust in a Machine Learning–Based Bacteremia Prediction System: Simulation Study (e56924) Omer Katzburg, Michael Roimi, Amit Frenkel, Roy Ilan, Yuval Bitan.</p>	380

Perceived Benefit and Satisfaction With a Tablet Computer and an Emergency Smartwatch by Older Adults and Their Relatives: Prospective Real-World Pilot Study (e53811)	
Patrick Wiegel, Marina Fotteler, Brigitte Kohn, Sarah Mayer, Filippo Verri, Dhayana Dallmeier, Michael Denkinge	393
User Perceptions of Visual Clot in a High-Fidelity Simulation Study: Mixed Qualitative-Quantitative Study (e47991)	
Greta Gasciauskaite, Clara Castellucci, Amos Malorgio, Alexandra Budowski, Giovanna Schweiger, Michaela Kolbe, Daniel Fries, Bastian Grande, Christoph Nöthiger, Donat Spahn, Tazio Roche, David Tscholl, Samira Akbas	406
Digital Care Pathway for Patients With Sleep Apnea in Specialized Care: Mixed Methods Study (e47809)	
Jari Haverinen, Terttu Harju, Hanna Mikkonen, Pia Liljamo, Miia Turpeinen, Jarmo Reponen	418
User Experience Evaluation of a Spinal Surgery Robot: Workload, Usability, and Satisfaction Study (e54425)	
Hyeonkyeong Choi, Seunghee Kim, Wonseuk Jang	437
Interactive Electronic Pegboard for Enhancing Manual Dexterity and Cognitive Abilities: Instrument Usability Study (e56357)	
Shih-Ying Chien, Alice Wong, Ching-Yi Wu, Sara Beckman	464
Effects of User Experience in Automated Information Processing on Perceived Usefulness of Digital Contact-Tracing Apps: Cross-Sectional Survey Study (e53940)	
Tim Schrolls, Lilian Kojan, Marthe Gruner, André Calero Valdez, Thomas Franke	475
Improving the Social Well-Being of Single Older Adults Using the LOVOT Social Robot: Qualitative Phenomenological Study (e56669)	
Cheng Tan, Vivian Lou, Clio Cheng, Phoebe He, Veronica Khoo	492
User Experience of a Large-Scale Smartphone-Based Observational Study in Multiple Sclerosis: Global, Open-Access, Digital-Only Study (e57033)	
Adriano Galati, Lito Kriara, Michael Lindemann, Rea Lehner, JB Jones	503
A Compressive Armchair (OTO) to Perform Deep Pressure Therapy in Children With Autism Spectrum Disorder: User-Centered Design and Feasibility Study (e55754)	
Thomas Gargot, Amandine Vachaud, Clémence Gilard, Alexia Audrain, Marie Gomot, Marco Guidotti, Frédéric Briend, Joëlle Malvy, Frédérique Bonnet Brilhault	521
The Use of Mobile Health Care Among Medical Professionals in the Sichuan-Chongqing Region: Cross-Sectional Survey Study (e59153)	
Yan Tang, Juan Yang, Ni Wang, Xin Wang, Wenli Hu	534
Building a Client Resource and Communication Platform for Community-Based Organizations to Address Health and Social Needs: Co-Design Study (e53939)	
Courtney Lyles, Beth Berrean, Ana Buenaventura, Svetlana Milter, Dayana Hernandez, Urmimala Sarkar, Christian Gutierrez, Nynikka Palmer, William Brown III	544
Health Care Professionals' Perspectives Before and After Use of eDialogue for Team-Based Digital Communication Across Settings: Qualitative Study (e53391)	
Lili Jensen, Ole Rahbek, Rikke Lauritsen, Søren Kold, Birthe Dinesen	554
Inefficient Processes and Associated Factors in Primary Care Nursing: System Configuration Analysis (e49691)	
Willi Tarver, April Savoy, Himalaya Patel, Michael Weiner, Richard Holden	567
Patients' Expectations of Doctors' Clinical Competencies in the Digital Health Care Era: Qualitative Semistructured Interview Study Among Patients (e51972)	
Humairah Zainal, Xin Hui, Julian Thumboo, Warren Fong, Fong Yong	580

Evaluating Factors Affecting Knowledge Sharing Among Health Care Professionals in the Medical Imaging Departments of 2 Cancer Centers: Concurrent Mixed Methods Study (e53780) Maryam Almashmoum, James Cunningham, John Ainsworth.	599
Italian Version of the mHealth App Usability Questionnaire (Ita-MAUQ): Translation and Validation Study in People With Multiple Sclerosis (e58079) Jessica Podda, Erica Grange, Alessia Susini, Andrea Tacchino, Federica Di Antonio, Ludovico Pedullà, Giampaolo Brichetto, Michela Ponzio. 6 1 3	
Exploring the Role of Complexity in Health Care Technology Bottom-Up Innovations: Multiple-Case Study Using the Nonadoption, Abandonment, Scale-Up, Spread, and Sustainability Complexity Assessment Tool (e50889) Ulla Hellstrand Tang, Frida Smith, Ulla Karilampi, Andreas Gremyr.	624
Provider Adoption of mHealth in Rural Patient Care: Web-Based Survey Study (e55443) Bryan Weichelt, Rick Burke, Burney Kieke, Matt Pilz, Neel Shimpi.	640
Evaluation of a Digital Previsit Tool for Identifying Stroke-Related Health Problems Before a Follow-Up Visit (Part 1): Survey Study (e55852) Petra Pohl, Karoline Klerfors, Emma Kjörk.	649
German Version of the Telehealth Usability Questionnaire and Derived Short Questionnaires for Usability and Perceived Usefulness in Health Care Assessment in Telehealth and Digital Therapeutics: Instrument Validation Study (e57771) Jannik Zimmermann, Harriet Morf, Florian Scharf, Johannes Knitza, Heidi Moeller, Felix Muehlensiepen, Michaela Nathrath, Till Orlemann, Thomas Voelker, Merlin Deckers.	662
Assessment of Acceptability, Usage, and Impact on Caregivers of Children With Autism’s Stress and Mindfulness: Multiple-Method Feasibility Study of the 5Minutes4Myself App’s Mindfulness Module (e54171) Elizabeth Larson, Rebecca Mattie, Sophia Riffkin.	677
Leveraging Generative AI Tools to Support the Development of Digital Solutions in Health Care Research: Case Study (e52885) Danissa Rodriguez, Katharine Lawrence, Javier Gonzalez, Beatrix Brandfield-Harvey, Lynn Xu, Sumaiya Tasneem, Defne Levine, Devin Mann. 6 9 1	
Testing Two Online Symptom Checkers With Vulnerable Groups: Usability Study to Improve Cognitive Accessibility of eHealth Services (e45275) Kaisa Savolainen, Sari Kujala.	705
Head Protection Device for Individuals at Risk for Head Injury due to Ground-Level Falls: Single Trauma Center User Experience Investigation (e54854) Susan Haag, John Kepros.	718
A Digital Health Intervention Platform (Active and Independent Management System) to Enhance the Rehabilitation Experience for Orthopedic Joint Replacement Patients: Usability Evaluation Study (e50430) Petros Papadopoulos, Mario Soflano, Thomas Connolly.	726
Evaluation of the Parkinson’s Remote Interactive Monitoring System in a Clinical Setting: Usability Study (e54145) Bronwyn Bridges, Jake Taylor, John Weber.	741

Assessing the Relationship Between Digital Trail Making Test Performance and IT Task Performance: Empirical Study (e49992)	
Tanguy Depauw, Jared Boasen, Pierre-Majorique Léger, Sylvain Sénécal.	760
Capturing Usability Problems for People Living With Dementia by Applying the DEMIGNED Principles in Usability Evaluation Methods: Mixed Methods Study (e54032)	
Thomas Engelsma, Simone Heijmink, Heleen Hendriksen, Leonie Visser, Afina Lemstra, Monique Jaspers, Linda Peute.	773
Patients' Attitudes Toward the Use of Artificial Intelligence as a Diagnostic Tool in Radiology in Saudi Arabia: Cross-Sectional Study (e53108)	
Leena Baghdadi, Arwa Mobeirek, Dania Alhudaithi, Fatimah Albenmoussa, Leen Alhadlaq, Maisa Alaql, Sarah Alhamlan.	789
Mobile App for Patients With Chronic Obstructive Pulmonary Diseases During Home-Based Exercise Care: Usability Study (e60049)	
Shih-Ying Chien.	805
Social Media Recruitment as a Potential Trigger for Vulnerability: Multistakeholder Interview Study (e52448)	
Nina Matthes, Theresa Willem, Alena Buyx, Bettina Zimmermann.	822
The Promise of AI for Image-Driven Medicine: Qualitative Interview Study of Radiologists' and Pathologists' Perspectives (e52514)	
Jojanneke Drogt, Megan Milota, Wouter Veldhuis, Shoko Vos, Karin Jongasma.	832
Supporting Patients' Use of Digital Services in Primary Health Care in England: Synthesis of Evidence From a Mixed Methods Study of "Digital Facilitation" (e52516)	
Jon Sussex, Helen Atherton, Gary Abel, Christopher Clark, Emma Cockcroft, Brandi Leach, Christine Marriott, Jennifer Newbould, Emma Pitchforth, Rachel Winder, John Campbell.	846
Factors Impacting the Adoption and Potential Reimbursement of a Virtual Reality Tool for Pain Management in Switzerland: Qualitative Case Study (e59073)	
Josefine Lurtz, Thomas C Sauter, Christine Jacob.	855
Optimizing a Novel Smartphone App to Prevent Postpartum Depression Adapted From an Evidence-Based Cognitive Behavioral Therapy Program: Qualitative Study (e63143)	
Adam Lewkowitz, Melissa Guillen, Katrina Ursino, Rackeem Baker, Liana Lum, Cynthia Battle, Crystal Ware, Nina Ayala, Melissa Clark, Megan Ranney, Emily Miller, Kate Guthrie.	867
Work Systems Analysis of Emergency Nurse Patient Flow Management Using the Systems Engineering Initiative for Patient Safety Model: Applying Findings From a Grounded Theory Study (e60176)	
Ellen Benjamin, Karen Giuliano.	878
Stunting Super App as an Effort Toward Stunting Management in Indonesia: Delphi and Pilot Study (e54862)	
Kadek Erika, Nur Fadilah, Aulia Latif, Nurhikmawaty Hasbiah, Aidah Juliaty, Harun Achmad, Anugrayani Bustamin.	893
Integrating Health and Disability Data Into Academic Information Systems: Workflow Optimization Study (e54859)	
Abdulrahman Jabour.	908
Physical Therapists' Acceptance of a Wearable, Fabric-Based Sensor System (Motion Tape) for Use in Clinical Practice: Qualitative Focus Group Study (e55246)	
Audrey Lee, Patricia Dionicio, Emilia Farcas, Job Godino, Kevin Patrick, Elijah Wyckoff, Kenneth Loh, Sara Gombatto.	918
Physicians' and Patients' Expectations From Digital Agents for Consultations: Interview Study Among Physicians and Patients (e49647)	
Andri Färber, Christiane Schwabe, Philipp Stalder, Mateusz Dolata, Gerhard Schwabe.	933

<p>Preferences for mHealth Intervention to Address Mental Health Challenges Among Men Who Have Sex With Men in Nepal: Qualitative Study (e56002)</p> <p>Kamal Gautam, Camille Aguilar, Kiran Paudel, Manisha Dhakal, Jeffrey Wickersham, Bibhav Acharya, Sabitri Sapkota, Keshab Deuba, Roman Shrestha.</p>	951
<p>Patient Perspectives on Communication Pathways After Orthopedic Surgery and Discharge and Evaluation of Team-Based Digital Communication: Qualitative Exploratory Study (e49696)</p> <p>Lili Jensen, Ole Rahbek, Rikke Lauritsen, Søren Kold, Birthe Dinesen.</p>	963
<p>The Asthma App as a New Way to Promote Responsible Short-Acting Beta2-Agonist Use in People With Asthma: Results of a Mixed Methods Pilot Study (e54386)</p> <p>Liselot van den Berg, Cynthia Hallensleben, Lisa Vlug, Niels Chavannes, Anke Versluis.</p>	980
<p>A Smartphone App to Support Self-Management for People Living With Sjögren's Syndrome: Qualitative Co-Design Workshops (e54172)</p> <p>Claire McCallum, Miglena Campbell, John Vines, Tim Rapley, Jason Ellis, Vincent Deary, Katie Hackett.</p>	995
<p>Effective Communication Supported by an App for Pregnant Women: Quantitative Longitudinal Study (e48218)</p> <p>Lukas Kötting, Vinayak Anand-Kumar, Franziska Keller, Nils Henschel, Sonia Lippke.</p>	1010
<p>Comparing Attitudes Toward Different Consent Mediums: Semistructured Qualitative Study (e53113)</p> <p>Xengie Doan, Arianna Rossi, Marietjie Botes, Annika Selzer.</p>	1026
<p>Knowledge, Skills, and Experience With Technology in Relation to Nutritional Intake and Physical Activity Among Older Adults at Risk of Falls: Semistructured Interview Study (e52575)</p> <p>Julie Kikkenborg, Emma Magelund, Maria Riise, Lars Kayser, Rikke Terp.</p>	1042
<p>Health Technology Access and Peer Support Among Digitally Engaged People Experiencing Homelessness: Qualitative Study (e55415)</p> <p>Nóra Radó, Sándor Békási, Zsuzsa Gy rffy.</p>	1054
<p>Digital Lifestyle Interventions for Young People With Mental Illness: A Qualitative Study Among Mental Health Care Professionals (e53406)</p> <p>Chelsea Sawyer, Rebekah Carney, Lamiece Hassan, Sandra Bucci, John Sainsbury, Karina Lovell, John Torous, Joseph Firth.</p>	1069
<p>Alarm Management in Intensive Care: Qualitative Triangulation Study (e55571)</p> <p>Lina Mosch, Meltem Sümer, Anne Flint, Markus Feufel, Felix Balzer, Frauke Mörike, Akira-Sebastian Poncette.</p>	1094
<p>Probing the Role of Digital Payment Solutions in Gambling Behavior: Preliminary Results From an Exploratory Focus Group Session With Problem Gamblers (e54951)</p> <p>Nathan Lakew, Jakob Jonsson, Philip Lindner.</p>	1105
<p>Digital Adherence Technologies and Differentiated Care for Tuberculosis Treatment and Their Acceptability Among Persons With Tuberculosis, Health Care Workers, and Key Informants in the Philippines: Qualitative Interview Study (e54117)</p> <p>Chung Leung, Jason Alacapa, Bianca Tasca, Andre Villanueva, Saniata Masulit, Marvin Ignacio, Kathleen Uy, Christopher Pell, Kristian van Kalmthout, Rachel Powers, Katherine Fielding, Degu Jerene.</p>	1118
<p>Co-Designing Digital Health Intervention for Monitoring Medication and Consultation Among Transgender People in Underserved Communities: Collaborative Approach (e45826)</p> <p>Emmanuel Oluokun, Festus Adedoyin, Huseyin Dogan, Nan Jiang.</p>	1130

Older Adults' Perspectives and Experiences With Digital Health in Singapore: Qualitative Study (e58641) Qiao Leong, V Lee, Wei Ng, Smrithi Vijayakumar, Ni Lau, Ingela Mauritzon, Agata Blasiak, Dean Ho.	1146
Improving Social Media-Based Support Groups for the Rare Disease Community: Interview Study With Patients and Parents of Children with Rare and Undiagnosed Diseases (e57833) Tom Doyle, Samantha Vershaw, Erin Conboy, Colin Halverson.	1156
Older Adults' Acceptance of a Virtual Reality Group Intervention in Nursing Homes: Pre-Post Study Under Naturalistic Conditions (e56278) Yijun Li, Irina Shiyanov, Beate Muschalla.	1169
Usability, Ergonomics, and Educational Value of a Novel Telestration Tool for Surgical Coaching: Usability Study (e57243) Parmiss Kiani, Roberta Dolling-Boreham, Mohamed Hameed, Caterina Masino, Andras Fecso, Allan Okrainec, Amin Madani.	1184
A Handheld Tool for the Rapid Morphological Identification of Mosquito Species (VectorCam) for Community-Based Malaria Vector Surveillance: Summative Usability Study (e56605) Saisamhitha Dasari, Bhavya Gopinath, Carter Gaulke, Sunny Patel, Khalil Merali, Aravind Sunil Kumar, Soumyadipta Acharya.	1195
Design and Psychometric Evaluation of Nurses' Mobile Health Device Acceptance Scale (NMHDA-Scale): Application of the Expectation-Confirmation Theory (e55324) Narjes Mirabootalebi, Zahra Meidani, Hossein Akbari, Fatemeh Rangraz Jeddi, Zahra Tagharrobi, Walter Swoboda, Felix Holl.	1212
Clinical Acceptability of a Quality Improvement Program for Reducing Cardiovascular Disease Risk in People With Chronic Kidney Disease in Australian General Practice: Qualitative Study (e55667) Caroline McBride, Barbara Hunter, Natalie Lumsden, Kaleswari Somasundaram, Rita McMorro, Douglas Boyle, Jon Emery, Craig Nelson, Jo-Anne Manski-Nankervis.	1226
Design and Implementation of an Opioid Scorecard for Hospital System-Wide Peer Comparison of Opioid Prescribing Habits: Observational Study (e44662) Benjamin Slovis, Soonyip Huang, Melanie McArthur, Cara Martino, Tasia Beers, Meghan Labella, Jeffrey Riggio, Edmund Pribitkin.	1236
Usability of an App for Medical History Taking in General Practice From the Patients' Perspective: Cross-Sectional Study (e47755) Klara Albrink, Dominik Schröder, Carla Joos, Frank Müller, Eva Noack.	1247
A Novel Continuous Real-Time Vital Signs Viewer for Intensive Care Units: Design and Evaluation Study (e46030) Shiming Yang, Samuel Galvagno, Neeraj Badjatia, Deborah Stein, William Teeter, Thomas Scalea, Stacy Shackelford, Raymond Fang, Catriona Miller, Peter Hu, VS viewer study group.	1262
Characterizing and Comparing Adverse Drug Events Documented in 2 Spontaneous Reporting Systems in the Lower Mainland of British Columbia, Canada: Retrospective Observational Study (e52495) Erica Lau, Amber Cragg, Serena Small, Katherine Butcher, Corinne Hohl.	1274
Usability and Evaluation of a Health Information System in the Emergency Department: Mixed Methods Study (e48445) Christina Østervang, Charlotte Jensen, Elisabeth Coyne, Karin Dieperink, Annmarie Lassen.	1290
Intention to Use an Electronic Community Health Information System Among Health Extension Workers in Rural Northwest Ethiopia: Cross-Sectional Study Using the Unified Theory of Acceptance and Use of Technology 2 Model (e47081) Tesfahun Hailemariam, Asmamaw Atnafu, Lemma Gezie, Jens Kaasbøll, Jorn Klein, Binyam Tilahun.	1304

Exploring the Use of Persuasive System Design Principles to Enhance Medication Incident Reporting and Learning Systems: Scoping Reviews and Persuasive Design Assessment (e41557)	
Kiemute Oyibo, Paola Gonzalez, Sarah Ejaz, Tasneem Naheyman, Carla Beaton, Denis O'Donnell, James Barker.	1318
Clinical Decision Support Requirements for Ventricular Tachycardia Diagnosis Within the Frameworks of Knowledge and Practice: Survey Study (e55802)	
Zhao Hu, Min Wang, Si Zheng, Xiaowei Xu, Zhuxin Zhang, Qiaoyue Ge, Jiao Li, Yan Yao.	1346
Usability of an Automated System for Real-Time Monitoring of Shared Decision-Making for Surgery: Mixed Methods Evaluation (e46698)	
Christin Hoffmann, Kerry Avery, Rhiannon Macefield, Tadeáš Dvořák, Val Snelgrove, Jane Blazeby, Della Hopkins, Shireen Hickey, Ben Gibbison, Leila Rooshenas, Adam Williams, Jonathan Aning, Hilary Bekker, Angus McNair, The ALPACA Study Team.	1360
Influence of Disease-Related Stigma on Patients' Decisions to Upload Medical Reports to the German Electronic Health Record: Randomized Controlled Trial (e52625)	
Niklas von Kalckreuth, Markus Feufel.	1378
Academic Detailing as a Health Information Technology Implementation Method: Supporting the Design and Implementation of an Emergency Department–Based Clinical Decision Support Tool to Prevent Future Falls (e52592)	
Hanna Barton, Apoorva Maru, Margaret Leaf, Daniel Hekman, Douglas Wiegmann, Manish Shah, Brian Patterson.	1389
Electronic Immunization Registry in Rwanda: Qualitative Study of Health Worker Experiences (e53071)	
Thaoussi Uwera, Mahima Venkateswaran, Kiran Bhutada, Eleni Papadopoulou, Enock Rukundo, David K Tumusiime, J Frøen.	1400
The Solutions in Health Analytics for Rural Equity Across the Northwest (SHARE-NW) Dashboard for Health Equity in Rural Public Health: Usability Evaluation (e51666)	
Elizabeth Heitkemper, Scott Hulse, Betty Bekemeier, Melinda Schultz, Greg Whitman, Anne Turner.	1413
Implementing a Hospital Call Center Service for Mental Health in Uganda: User-Centered Design Approach (e53976)	
Johnblack Kabukye, Rosemary Namagembe, Juliet Nakku, Vincent Kiberu, Marie Sjölander, Susanne Nilsson, Caroline Wamala-Larsson.	1
	4
	2
	5
Evaluation of a Computer-Aided Clinical Decision Support System for Point-of-Care Use in Low-Resource Primary Care Settings: Acceptability Evaluation Study (e47631)	
Geletaw Tegenaw, Demisew Sori, Girum Teklemariam, Frank Verbeke, Jan Cornelis, Bart Jansen.	1440
Toward Personalized Care and Patient Empowerment and Perspectives on a Personal Health Record in Hemophilia Care: Qualitative Interview Study (e48359)	
Martijn Brands, Lotte Haverman, Jelmer Muis, Mariëtte Driessens, Stephan Meijer, Felix van der Meer, Marianne de Jong, Johanna van der Bom, Marjon Cnossen, Karin Fijnvandraat, Samantha Gouw.	1460
Evaluating the Usability and Quality of a Clinical Mobile App for Assisting Physicians in Head Computed Tomography Scan Ordering: Mixed Methods Study (e55790)	
Zahra Meidani, Aydine Omidvar, Hossein Akbari, Fatemeh Asghari, Reza Khajouei, Zahra Nazemi, Ehsan Nabovati, Felix Holl.	1472
User-Centered Design and Usability of Voxe as a Pediatric Electronic Patient-Reported Outcome Measure Platform: Mixed Methods Evaluation Study (e57984)	
Samantha Anthony, Sarah Pol, Enid Selkirk, Amarens Matthiesen, Robert Klaassen, Dorin Manase, Amanda Silva, Melanie Barwick, Jennifer Stinson, Alameen Damer, Mowa Ayibowu, Selina Dong, Stephan Oreskovich, Michael Brudno.	1490

Triage Accuracy and the Safety of User-Initiated Symptom Assessment With an Electronic Symptom Checker in a Real-Life Setting: Instrument Validation Study (e55099)	
Ville Liu, Minna Kaila, Tuomas Koskela.	1507
User Requirements for an Electronic Patient Recruitment System: Semistructured Interview Analysis After First Implementation in 3 German University Hospitals (e56872)	
Alexandra Stein, Romina Blasini, Cosima Strantz, Kai Fitzer, Christian Gulden, Torsten Leddig, Wolfgang Hoffmann.	1522
Exploring Patient, Proxy, and Clinician Perspectives on the Value and Impact of an Inpatient Portal: A Reflexive Thematic Analysis (e52703)	
Simone Schmidt, Adam Boulton, Benita Butler, Timothy Fazio.	1535
Optimization of a Web-Based Self-Assessment Tool for Preconception Health in People of Reproductive Age in Australia: User Feedback and User-Experience Testing Study (e63334)	
Edwina Dorney, Karin Hammarberg, Raymond Rodgers, Kirsten Black.	1552
Nutrition Management Miniprograms in WeChat: Evaluation of Functionality and Quality (e56486)	
Hui Sun, Yanping Wu, Jia Sun, Wu Zhou, Qian Xu, Dandan Hu.	1566
Assessing the Usability and Feasibility of Digital Assistant Tools for Direct Support Professionals: Participatory Design and Pilot-Testing (e51612)	
Patrice Tremoulet, Andrea Lobo, Christina Simmons, Ganesh Baliga, Matthew Brady.	1576
Assessing the Feasibility and Preliminary Effects of a Web-Based Self-Management Program for Chronic Noncancer Pain: Mixed Methods Study (e50747)	
Pascale Marier-Deschenes, Anne Pinard, Laura Jalbert, Annie LeBlanc.	1595
A Web-Based Peer Support Network to Help Care Partners of People With Serious Illness: Co-Design Study (e53194)	
Elizabeth O'Donnell, Aricca Van Citters, Inas Khayal, Matthew Wilson, David Gustafson, Amber Barnato, Andrea Buccellato, Colleen Young, Megan Holthoff, Eugene Korsunskiy, Stephanie Tomlin, Amelia Cullinan, Alexandra Steinbaugh, Jennifer Hinson, Kristen Johnson, Andrew Williams, Ruth Thomson, Janet Haines, Anne Holmes, Ann Bradley, Eugene Nelson, Kathryn Kirkland.	1615
Gamification Approach to Provide Support About the Deferral Experience in Blood Donation: Design and Feasibility Study (e50086)	
Roberto Espinoza Chamorro, Luciano Santos, Yukiko Mori, Chang Liu, Goshiro Yamamoto, Tomohiro Kuroda.	1629
Application of an Adapted Health Action Process Approach Model to Predict Engagement With a Digital Mental Health Website: Cross-Sectional Study (e57082)	
Julien Rouvere, Brittany Blanchard, Morgan Johnson, Isabell Griffith Fillipo, Brittany Mosser, Meghan Romanelli, Theresa Nguyen, Kevin Rushton, John Marion, Tim Althoff, Patricia Areán, Michael Pullmann.	1645
Lessons Learned From Developing Dashboards to Support Decision-Making for Community Opioid Response by Community Stakeholders: Mixed Methods and Multisite Study (e51525)	
Naleef Fareed, Ramona Olvera, Yiting Wang, Michael Hayes, Elizabeth Larimore, Peter Balvanz, Ronald Langley, Corinna Noel, Peter Rock, Daniel Redmond, Jessica Neufeld, Sarah Kosakowski, Daniel Harris, Marc LaRochelle, Timothy Huerta, LaShawn Glasgow, Emmanuel Oga, Jennifer Villani, Elwin Wu.	1662
A Chatbot-Based Version of the World Health Organization–Validated Self-Help Plus Intervention for Stress Management: Co-Design and Usability Testing (e64614)	
Valentina Fietta, Silvia Rizzi, Chiara De Luca, Lorenzo Gios, Maria Pavesi, Silvia Gabrielli, Merylin Monaro, Stefano Forti.	1679
Expanding a Health Technology Solution to Address Therapist Challenges in Implementing Homework With Adult Clients: Mixed Methods Study (e56567)	
Brian Bunnell, Kaitlyn Schuler, Julia Ivanova, Lea Flynn, Janelle Barrera, Jasmine Niazi, Dylan Turner, Brandon Welch.	1699

Interest in mHealth Among Patients With Low Back Pain: Cross-Sectional Study (e48729) Jonas Ipsen, Louise Sandal, Natalie Chang, Berit Schiøttz-Christensen, Karen Sjøgaard, Anders Hansen.	1714
A Mobile Health App to Support Home-Based Aerobic Exercise in Neuromuscular Diseases: Usability Study (e49808) Tim Veneman, Fieke Koopman, Sander Oorschot, Pien Koomen, Frans Nollet, Eric Voorn.	1724
A Geospatial Drug Abuse Risk Assessment and Monitoring Dashboard Tailored for School Students: Development Study With Requirement Analysis and Acceptance Evaluation (e48139) Ahmad Al-Aboosi, Siti Sheikh Abdullah, Rozmi Ismail, Khairul Abdul Maulud, Lutfun Nahar, Khairul Zainol Ariffin, Meng Lam, Muhamad bin Talib, Suzaily Wahab, Mahadzir Elias.	1746

Abstract

Background: The Charité Alarm Fatigue Questionnaire (CAFQa) is a 9-item questionnaire that aims to standardize how alarm fatigue in nurses and physicians is measured. We previously hypothesized that it has 2 correlated scales, one on the psychosomatic effects of alarm fatigue and the other on staff's coping strategies in working with alarms.

Objective: We aimed to validate the hypothesized structure of the CAFQa and thus underpin the instrument's construct validity.

Methods: We conducted 2 independent studies with nurses and physicians from intensive care units in Germany (study 1: n=265; study 2: n=1212). Responses to the questionnaire were analyzed using confirmatory factor analysis with the unweighted least-squares algorithm based on polychoric covariances. Convergent validity was assessed by participants' estimation of their own alarm fatigue and exposure to false alarms as a percentage.

Results: In both studies, the χ^2 test reached statistical significance (study 1: $\chi^2_{26}=44.9$; $P=.01$; study 2: $\chi^2_{26}=92.4$; $P<.001$). Other fit indices suggested a good model fit (in both studies: root mean square error of approximation <0.05 , standardized root mean squared residual <0.08 , relative noncentrality index >0.95 , Tucker-Lewis index >0.95 , and comparative fit index >0.995). Participants' mean scores correlated moderately with self-reported alarm fatigue (study 1: $r=0.45$; study 2: $r=0.53$) and weakly with self-perceived exposure to false alarms (study 1: $r=0.3$; study 2: $r=0.33$).

Conclusions: The questionnaire measures the construct of alarm fatigue as proposed in our previous study. Researchers and clinicians can rely on the CAFQa to measure the alarm fatigue of nurses and physicians.

Trial Registration: ClinicalTrials.gov NCT04994600; <https://www.clinicaltrials.gov/study/NCT04994600>

Introduction

Background

Alarm fatigue is a phenomenon where health care workers in intensive care units (ICUs) become desensitized to alarms of medical devices [1]. It can make ICU staff feel stressed, and it is a substantial risk to patient safety, as it can lead to alarms being missed or acknowledged with delay [2]. When implementing interventions or IT solutions [3] that try to remedy alarm fatigue, clinicians and clinical alarm researchers need a reliable way to assess whether they were successful. However, they have not yet agreed on a standardized way of measuring alarm fatigue [4,5], even though it was recognized more than 2 decades ago [6].

Solely analyzing an ICU's alarm log data cannot serve as a measure of staff's alarm fatigue. While it is a valuable method for designing alarm management interventions [7], there is no clear association between the number of alarms on an ICU and staff's subjective alarm fatigue. For example, simply focusing on the number of alarms disregards their temporal distribution (eg, it might fatigue staff more if alarms came in random bursts than if they were evenly spaced out [8]). This could be one of the reasons why in their intervention study, Sowan et al [9] did not find that staff's alarm fatigue improved despite having managed to significantly reduce the number of alarms on their ICU.

Therefore, we recently developed the Charité Alarm Fatigue Questionnaire (CAFQa), which is a 9-item questionnaire that measures alarm fatigue in nurses and physicians [10]. Using exploratory factor analysis, we identified 2 correlated factors: one revolving around the psychophysiological effects of alarms (eg, headaches and feelings of distraction), and one revolving around ICU staff's alarm management strategies (eg, customization of alarm limits). We named the former the "alarm stress scale" and the latter the "alarm coping scale." The alarm coping scale consists of items that are reversely scored. Hence, a high score on either scale is indicative of alarm fatigue.

When developing a new questionnaire, it is essential to establish construct validity, that is, whether the questionnaire truly measures what it attempts to measure. One way to test an instrument's construct validity is to administer it to a different sample and test whether the originally proposed factor structure reemerges using confirmatory factor analysis [11,12] (for a recent example see Canivez et al [13]).

Aim

We aim to validate the exploratively derived factor structure of the CAFQa and thus underpin the instrument's construct validity.

Methods

Ethical Considerations

The ethical approval for this study was granted by the ethics committee of the Charité-Universitätsmedizin Berlin (EA4/218/20) and, if required, confirmed by the local ethics committee at the participating hospital. This study was

conducted in compliance with the relevant guidelines and regulations. All participants voluntarily agreed to take part after being fully informed about the study. In study 1, as a reward for completing the questionnaire, we offered participants the chance to enter a draw where they could win a €50 (US \$53) voucher for online shopping. Participants were asked to consent to have their data collected, analyzed, and stored anonymously.

Participants

In both studies, we included nurses, physicians, and nurses in training, while excluding other professions and non-ICU staff.

Study 1

We recruited participants from 9 ICUs of 5 large German hospitals. The questionnaire was administered on the web using REDCap (Research Electronic Data Capture; Vanderbilt University) between October 2021 and July 2022.

Study 2

Using a mailing list, we invited all members of the German Society of Anaesthesiology and Intensive Care Medicine [14] to fill out the web-based questionnaire (again using REDCap) between March 2023 and July 2023.

Questionnaire

The questionnaire used in both studies was identical and consisted of all 9 items from the CAFQa [10] and 5 general questions about the alarm situation in participants' ICUs. These general questions were not part of the analysis for this report. All 14 items were pseudorandomly arranged and required responses on a Likert scale ranging from -2 (indicating "I do not agree at all") to 2 (indicating "I very much agree"). Items with negative valences were reverse scored. Demographic items asked participants about their average number of workdays in an intensive care or monitoring area, their number of years and months of ICU experience, their workplace (campus and unit), and their profession. We made small adjustments to the original wording of 2 items (items 8 and 9) to improve readability: In item 8 we used "situation" instead of "urgency." In item 9 we used the phrase "clinical pictures" instead of "clinical symptoms."

Statistical Analysis

All analyses were conducted in R (version 4.2.1; R Foundation for Statistical Computing) using the following packages: *Tidyverse* [15], *reshape2* [16], *psych*, *semPlot* [17], and *lavaan* [18]. For study 1, we pooled the data from the participating hospitals.

Missing Data

In accordance with Heymans and Eekhout [19], we used predictive mean matching via the *mice* package [20] to impute missing data that were assumed to be missing at random (MAR). We did not impute questionnaires that were either completely empty or terminated prematurely (presumably due to survey fatigue), as the assumption of MAR was not met in these cases. We assumed that survey fatigue occurred if a participant failed to respond to at least the final 20% of the questionnaire (ie, the last 3 or more of the 9 items of the CAFQa plus the 5 general questions). In total, 0.3% of the data were MAR.

Testing Assumptions of Confirmatory Factor Analysis

In both studies, the results of the Mardia test indicated that the multivariate skew did not come from a normal distribution with $P < .001$. Outliers were identified using Mahalanobis distances, with none being detected in study 1 and 4 being detected in study 2 (for both studies: χ^2_9 , cutoff=27.9; $P < .001$). Visual inspection of the data from all 4 cases revealed no unusual response patterns. Given the large sample size, we decided not to remove any outliers. The Kaiser-Meyer-Olkin statistic [21] in study 1 was 0.76, and in study 2 it was 0.8. In both studies, the Bartlett test of sphericity [22] rejected the null hypothesis that the correlation matrix was an identity matrix (study 1: $\chi^2_{36}=438.3$; $P < .001$; study 2: $\chi^2_{36}=2495.4$). There was no evidence of multicollinearity in either study as the determinant of both R matrices was greater than 0.00001 [23] and no correlations were greater than |0.7|. Overall, these results suggest that the data of both studies were suitable for factor analysis.

Confirmatory Factor Analysis

For both studies, we specified the model in line with our previous findings [10], with 2 correlated latent factors, labeled “alarm stress” and “alarm coping.” Items 1 - 5 were assigned to “alarm stress.” Items 5 - 9 were assigned to “alarm coping.” Since all CAFQa items are ordered categorical variables (due to being measured on a 5-point Likert scale) and because the Mardia tests indicated that the multivariate skew of both studies did not come from a normal distribution, we used the unweighted least-squares (ULS) algorithm based on polychoric covariances for estimating factor loadings [24-26]. We assessed the goodness-of-fit of the model using χ^2 , and the following fit indices in line with the cutoff criteria defined by Hu and Bentler [27]: root mean square error of approximation (RMSEA), relative noncentrality index (RNI), Tucker-Lewis index (TLI), standardized root mean squared residual (SRMR), and comparative fit index (CFI).

Convergent Validity

At the end of the questionnaire in both studies, we provided participants with a brief description of alarm fatigue and asked them to estimate their personal alarm fatigue as a percentage (0% indicating no alarm fatigue and 100% indicating extreme

alarm fatigue). We also asked participants to provide their perceived rate of false alarms in their ICU as a percentage (0% indicating no false alarms, 100% indicating no true alarms). To measure convergent validity, we correlated the participants' mean scores on the questionnaire with the self-provided alarm fatigue and false alarm rate estimations (in total and per factor).

Internal Consistency

As a measure of internal consistency, we report Cronbach coefficient α , the McDonald coefficient ω [28], and the mean interitem correlation for both factors.

Results

Participants

Study 1

We received 363 submissions. Among these, 23 came from participants who did not consent to have their data analyzed, 67 questionnaires were empty, and 8 showed signs of survey fatigue. Therefore, the sample size for this study was 265. The number of participants was roughly similar for each hospital (Giessen: $n=43$; Herne: $n=50$; Munich: $n=64$; Ulm: $n=57$; Vivantes: $n=51$). Most participants were nurses ($n=150$, 56.6%) and 35.8% ($n=95$) were physicians. A few participants ($n=9$, 3.4%) were supporting nurses, nurses in training, medical students, or interns, while 4.2% ($n=11$) did not state their profession.

Study 2

Of the 1564 submissions we received, 69 came from participants who refused to consent to have their data processed and 223 were empty questionnaires. We suspected survey fatigue in 60 cases. Hence, the sample size of study 2 was 1212. Contrary to study 1, more participants were physicians ($n=1002$, 82.7%) than nurses ($n=186$, 15.3%). Again, the group of supporting nurses, nurses in training, medical students, and interns was a minority ($n=6$, 0.5%). Among the participants, 1.5% ($n=18$) did not state their profession.

Confirmatory Factor Analysis

Descriptive statistics of both studies are presented in [Table 1](#) for each item.

Table . Descriptive statistics for each item and the pattern coefficients found in the confirmatory factor analysis of the 2-factor model in both studies. All loadings were statistically significant at $P < .001$.

Item	Description	Study 1					Study 2

^aNot applicable.

^bItem with a negative valence that is reversely scored.

Study 1

While the χ^2 test was significant at $\alpha=.05$ with $\chi^2_{26}=44.9$ ($P=.01$), indicating that the model did not fit the data, all fit indices suggested a good model fit: RMSEA=0.03, SRMR=0.052, RNI=0.989, TLI=0.985, and CFI=0.989. All items loaded onto their hypothesized factors as expected, with factor loadings that were statistically significant at $P<.001$, ranging from 0.35 to 0.73. The factors were moderately correlated at 0.4 (95% CI 0.21 - 0.59; $P<.001$).

Study 2

As in study 1, the χ^2 test was significant ($\chi^2_{26}=92.4$; $P<.001$), indicating that the model did not fit the data, while the fit indices showed a good model fit: RMSEA=0.046, SRMR=0.041, RNI=0.982, TLI=0.975, and CFI=0.982. Again, all items loaded onto their hypothesized factors as expected, with factor loadings that were statistically significant at $P<.001$, ranging from 0.43 to 0.81. The factors were moderately correlated at 0.44 (95% CI 0.36 - 0.51; $P<.001$) (Figure 1).

Figure 1. Diagram of the final model from each study. Factors are shown in circles (factor 1: alarm stress; factor 2: alarm coping), and items 1 - 9 in squares. In both studies, the variance of the factors was constrained to 1. The arrows connecting the factors with the items are the factor loadings and arrows pointing toward the items show the residuals. The arrows between the factors show their correlation.

Convergent Validity

In study 1, the participants' mean scores on the questionnaire correlated moderately with self-reported alarm fatigue

($r_{242}=0.45$, 95% CI 0.34-0.54; $P<.001$) and weakly with the perceived percentage of false alarms ($r_{247}=0.3$, 95% CI 0.18 to -0.41 ; $P<.001$). Similar patterns were observed in study 2 (Table 2 provides full details).

Table . Correlation coefficients, P values, and CIs used to investigate the convergent validity in each study.

Study and correlation measure	r (df; 95% CI)	P value
Study 1		
MS-SRAF ^{ab}	0.45 (242; 0.34 - 0.54)	<.001
F1S-SRAF ^c	0.42 (242; 0.31 - 0.52)	<.001
F2S-SRAF ^d	0.29 (242; 0.17 - 0.4)	<.001
MS-PPFA ^e	0.30 (247; 0.18 - 0.41)	<.001
F1S-PPFA	0.20 (247; 0.08 - 0.32)	.002
F2S-PPFA	0.29 (247; 0.17 - 0.4)	<.001
Study 2		
MS-SRAF	0.53 (1180; 0.49 - 0.57)	<.001
F1S-SRAF	0.49 (1180; 0.45 - 0.53)	<.001
F2S-SRAF	0.34 (1180; 0.29 - 0.39)	<.001
MS-PPFA	0.33 (1182; 0.28 - 0.38)	<.001
F1S-PPFA	0.26 (1182; 0.21 - 0.32)	<.001
F2S-PPFA	0.28 (1182; 0.23 - 0.33)	<.001

^aMS: mean score on the questionnaire.

^bSRAF: self-reported alarm fatigue.

^cF1S: scores on factor 1.

^dF2S: scores on factor 2.

^ePPFA: perceived percentage of false alarms.

Internal Consistency

In study 1, the Cronbach α of factor 1 was 0.72, and it was 0.49 for factor 2. Cronbach α across factors was 0.67. The mean interitem correlation on factor 1 was 0.38, and it was 0.23 on factor 2. The McDonald coefficient ω for factor 1 was 0.77, and for factor 2 it was 0.55. The overall coefficient ω for the assessment was 0.8.

Results were similar in study 2: the Cronbach α was 0.77 for factor 1 and 0.55 for factor 2. Cronbach α across factors was 0.72. The mean interitem correlation was 0.44 on factor 1 and 0.27 on factor 2. The McDonald coefficient ω was 0.8 for factor 1 and 0.59 for factor 2. The overall coefficient ω for the assessment was 0.85.

Discussion

We aimed to underpin the construct validity of the CAFQa by submitting the exploratively derived factor structure from our previous study to confirmatory factor analysis in 2 independent studies. While the χ^2 test rejected the model in both studies, all fit indices indicated a good model fit. The factor loadings ranged from 0.35 to 0.73 in study 1 and from 0.43 to 0.81 in study 2; all were statistically significant. Overall, these results support the hypothesized factor structure. The questionnaire seems to

measure the construct of alarm fatigue as proposed in our previous work [10].

The χ^2 test is known to be sensitive to large sample sizes [29], which might explain its statistical significance. We did not modify the model because all fit indices indicated a good fit and because model modifications, no matter how small or plausible, can make a model less generalizable.

In both studies, the first factor, that is, the alarm stress scale, and the overall questionnaire were internally consistent. However, the second factor, that is, the alarm coping scale, seems to have issues with its internal consistency. Here, Cronbach α and McDonald ω were 0.49 and 0.55 in study 1, respectively, and 0.55 and 0.59 in study 2, respectively. A similar pattern can be found in our previous study, where the Cronbach α of factor 2 was 0.57 [10]. An internally consistent questionnaire is desirable. However, it can also mean that items are very similar. It was our ambition to create a questionnaire that is brief while measuring the many facets of alarm fatigue. Future studies using the CAFQa should routinely assess the internal consistency of both factors. If the second factor continues to show medium internal consistency, research should be done on how it can be improved (eg, by adding additional items, which would come at the cost of a longer questionnaire).

Because no other measures of alarm fatigue exist that would allow us to estimate the CAFQa's convergent validity, we asked participants to rate their own alarm fatigue as well as the rate of false alarms they perceived in their daily work. Participants who had a high mean score on the questionnaire also rated themselves as more alarm fatigued ($r=0.45$ in study 1 and $r=0.53$ in study 2). This positive correlation indicates the convergent validity of the questionnaire. Similarly, both studies demonstrated that participants with a high mean score on the questionnaire perceived more alarms to be false in their ICU. In study 1 this association was stronger for factor 2 than for factor 1. This makes sense since a high score on factor 2 (ie, the alarm coping scale) indicates that alarms are not properly managed (eg, by means of patient-specific threshold customizations), which typically leads to more false alarms [30]. However, study 2 could not replicate this pattern. Future research should find an answer to this question: Do ICU staff with a high perceived percentage of false alarms tend to develop stronger alarm fatigue, or do staff that are more alarm fatigued tend to perceive more alarms as being false?

Limitations

The fit indices RMSEA, CFI, and TLI have been shown to overestimate model fit when using the ULS estimator [31,32], potentially leading researchers to accept a bad-fitting model. Yet, in our case, other fit indices indicated a good model fit. As

in our previous work [10], the assumption that participants can accurately reflect and express their own alarm fatigue as a percentage is likely flawed (otherwise, it would not be necessary to develop a questionnaire in the first place). However, most ICU nurses and physicians have heard of alarm fatigue, and we provided them with a brief recapitulation on the concept before having them answer the self-report item in each study. Likewise, it is also probably a flawed assumption that participants can accurately report the rate of false alarms, though Bliss et al [33] showed that participants were able to adapt their response frequencies to alarms based on the perceived probability that an alarm was not false, thus suggesting that people might have an intuitive grasp of the rate of false alarms in their unit. All in all, we believe that asking these self-rating questions is a valuable method for assessing convergent validity when no other instrument is available.

Conclusion

Our results from 2 independent studies underpin the construct validity of the CAFQa. All items consistently loaded onto the factors, as we proposed in a previous publication [10]. When conducting research or quality improvement projects in ICUs, clinical alarm researchers and clinicians can rely on this instrument to measure, compare, and benchmark the alarm fatigue of nurses and physicians.

Acknowledgments

ASP is a participant in the Charité Digital Clinician Scientist Program funded by the Charité–Universitätsmedizin Berlin and the Berlin Institute of Health. We are grateful to Nicolas Frey for supervising the logistical aspects of the survey distribution, to Sandro Amende-Wolf for his valuable clinical insights, and to Daniel Schulze for his critical examination of our statistical analysis. We are grateful to the German Society of Anaesthesiology and Intensive Care Medicine for the distribution of the questionnaire to its members. This article was extracted from the doctoral thesis of MMW.

Data Availability

The data sets generated and analyzed during the current study are available in the Zenodo repository [34].

Authors' Contributions

MMW, CS, FB, and ASP conceptualized the study. MMW, KF, DL, MBP, JR, and SS conducted the investigation. MMW and HK developed the study design and ensured methodological rigor. MMW, BW, and ASP contributed to the formal data analysis. MMW and ASP drafted the initial manuscript and contributed to its revision. MMW created all figures and tables and managed the project together with ASP. HK, KF, DL, MBP, JR, SS, CS, BW, FB, and ASP reviewed the manuscript. FB and ASP provided oversight and leadership throughout the study.

Abstract

Background: Sex workers face an epidemic of violence in the United States. However, violence against sex workers in the United States is underreported. Sex workers hesitate to report it to the police because they are frequently punished themselves; therefore, an alternative for reporting is needed.

Objective: We aim to apply human-centered design methods to create and evaluate the usability of the prototype interface for ReportVASW (violence against sex worker, VASW) and identify opportunities for improvement.

Methods: This study explores ways to improve the prototype of ReportVASW, with particular attention to ways to improve the data collection tool. Evaluation methods included cognitive walkthrough, system usability scale, and heuristic evaluation.

Results: End users were enthusiastic about the idea of a website to document violence against sex workers. ReportVASW scored 90 on the system usability scale. The tool scored neutral on consistency, and all other responses were positive toward the app, with most being strong.

Conclusions: Many opportunities to improve the interface were identified. Multiple methods identified multiple issues to address. Most changes are not overly complex, and the majority were aesthetic or minor. Further development of the ReportVASW data collection tool is worth pursuing.

Introduction

Sex workers are frequently victimized by a variety of perpetrators [1] due to lack of empathy and because people who commit crimes against sex workers know that their crimes are unlikely to be reported. Sex workers are targets of violence, with 32% to 55% reporting violent experience in the previous year [2], but they often do not report violent incidents [2] in part because they encounter problems when they seek to report violence to police. In fact, police may arrest them for sex work instead of investigating violent crimes against sex workers; sex workers have also been victimized or harassed by police [3,4]. Those who seek care after victimization may not reveal their status as sex workers because health care providers may stigmatize and discriminate against them. These factors culminate in an unfortunate lack of knowledge in the domain. Documenting violence against sex workers is a necessary prerequisite to demonstrating the need to address interpersonal violence against sex workers, and will help develop more

effective responses and raise funds for their implementation. Violence against sex workers is associated with sequelae including post traumatic stress disorder [5], HIV, and other sexually transmitted infections [6].

Opportunities to increase the likelihood of sex workers reporting violence include changing police practices such that they would accept reports and investigate violence, changing laws to decriminalize sex work or legalize sex work such that some sex work would be within the law. Legal support could help sex workers who want to report violence to police. There are at least two nonprofit organizations that offer legal services to sex workers in the United States. Sex workers share information about perpetrators of violence among themselves [7] separate from reporting to law enforcement, in order to share information about violent experiences and help others avoid their attackers; however, it is impossible to know how widely these mechanisms are used online, via text messages, or on paper. In contrast, an app was commissioned by the Asia Pacific Network of Sex

Workers and designed for sex workers in Myanmar to help them report violence committed against them to the police.

The app (iMonitor+, DureTechnology) was part of a larger program, and they used the app or a hotline that connected victims of violence to a service provider who accompanied them to the police to report violence and to health care providers [8]. Most sex workers in Myanmar have smartphones, but uptake of the app was not strong, in part because they preferred using an existing hotline to the app [8]. As the app was commissioned by sex workers who are part of a regional international network, it exhibited some aspects of user-centered design (UCD) because sex workers explained what they wanted to include; moreover, the context of use was well understood and the users specified the end requirements. The app was not used to share information about perpetrators of violence. Other apps have been developed for sex workers in Cambodia [9] and South Africa [10].

The lead author (MHD) was commissioned to evaluate the antiviolence program for sex workers in Myanmar. After conducting the evaluation and learning more about the Burmese app, MHD was inspired to try to develop something such as this for use in the United States. As a result, we developed a prototype of a data collection tool that we hope sex workers would feel confident using to report violent experiences. The prototype mobile health (mHealth) data collection tool *ReportVASW* is intended for sex workers in the United States to report violence committed against them. VASW stands for violence against sex worker, and the tool collects data reported by sex workers who have been victims of violence. The interface was designed to enable multiple options for reporting violence, including drop down menus, open text, and audio recording. *ReportVASW* can be pronounced Report Violence.

The victimization of sex workers has been a long-term focus, and we have published multiple reports and papers about violence against sex workers and documented human rights violations in multiple locations in Africa [11], Asia [12], and the United States [13,14].

Most systems are set up to be used repeatedly if not constantly; *ReportVASW* is different because as it addresses violent victimization of the end user, it is hoped that most people never need to use it, and that those who do will use it once or rarely. For this reason, we believe *ReportVASW* should be intuitive and easy to use, without a learning curve.

Methods

Design Process and Prototype

UCD was used to design this prototype because only active sex workers seeing clients face-to-face can describe their current methods for sharing information about violent people and what they do to try to avoid violence in their work. Considering that the user context is in the aftermath of a violent and possibly traumatic event, ease of use is paramount, and so developing an app that is easy to learn and quick to use is important. These are hallmarks of UCD.

The aim of UCD is to improve usability by maximizing effectiveness, efficiency, and satisfaction of end users in the

specific aim of the product in question. Careful application of UCD methods at the earliest stages should reduce user error, and limit cost and time spent redesigning after developing software.

UCD follows specific principles, including focusing on users and tasks, measuring usability empirically, and iterative testing of design and usability. UCD has been used with success to develop mHealth apps and health record systems [15,16]. These principles were at the heart of the specific methods used for each of the 4 steps. The steps of the UCD approach align with more specific methods; for example, contextualization using functional analysis and consulting potential end users, and ideation through task analysis focused on the end user group and what steps would be required to successfully complete the task; prototyping using representational analysis of the tool; and finally, usability testing using scenario-based testing and heuristic analysis. This study's design process used the 4 methodological steps associated with UCD.

Step 1 - Contextualization

While violence against sex workers has been studied, few efforts to address this violence have been evaluated in the United States [17]. The authors seek to develop a new tool to respond to violence against sex workers. Contextualization was undertaken through desk research using functional analysis and consultation with active sex workers (user analysis) to ask whether such a tool would be useful; some were interested and offered opinions on the proposed tool. In total, 4 of 5 sex workers consulted were interested in the project at least in theory. UCD with multiple methods, such as considering both end user and design use context, has been used with success in mHealth [18,19] but it is not without difficulties [20,21]. Formative research using UCD can be time consuming, and users are not always easy to engage, but the literature shows the value of engaging end users in formative processes [20,21].

Step 2 - Ideation

The lead author thought through what this data collection tool should ask, how to collect information, and what information is most important. This process included task analysis, identifying the intended task and using a flowchart on paper to plan the way the tool would collect information.

Step 3 - Prototyping

The lead author engaged in representation analysis using the final flowchart to inform illustrations of what the screen would look like at each step. This was followed with the lead author attempting to apply Nielsen Heuristics to assess and refine the prototypes. Not all steps needed extensive revision. The initial paper prototype included 7 screens.

- The prototype was designed using the free version of Figma software online tool as of April 26, 2022, which allows the creation of 3 pages only. The heuristic analysis was based on Nielsen "10 usability heuristics." [22]
- Representational analysis consisted of heuristic analysis undertaken by the authors and 2 colleagues. The form used is a spreadsheet developed by the second author based on the work of Zhang and Wallji [23,24], in which a scale of

0 - 4 is used to grade each issue, from minor (1) to catastrophic (4), and 0 used to indicate disagreement that the point is an issue. The spreadsheet also contains a column labeled "proposed solution."

Step 4 - Usability Testing

Multiple methods were used to evaluate the ReportVASW interface. After the prototype was developed, usability testing using representation analysis was undertaken via heuristic analysis and task based and scenario testing. Heuristic analysis of the prototype was undertaken by the authors and 2 colleagues.

Additionally, the lead author and a developer recruited a convenience sample of 5 end users who self-identify as female with experience in a variety of sex work venues (escorts, brothel workers, sadomasochism professionals, and strippers) to test the usability by entering data from scenarios provided (scenario based testing) in a cognitive walkthrough [25], using the proposed app to enter data from a scenario taken from interviews with sex workers; all 5 agreed to do the walkthrough with the paper prototype and verbal consent was obtained. Paper prototypes have been used with good results in developing and testing prototypes [26]. In total, 4 of the 5 end users recruited did the cognitive walkthrough during the spring of 2022, three in private locations and one in an office (one was not available after contracting COVID-19). The scenarios used were taken from our previous research [13,14] and are outlined in [Multimedia Appendix 1](#).

This protocol was submitted to the CUNY Graduate School of Public Health and Health Policy Human Research Protection Program, and was classified as exempt. No incentives were offered.

A 10 item system usability scale (SUS) was brought to the second cognitive walkthrough and asked the end user to rate the 10 statements, which were read aloud (by MHD), as a back-up evaluation method. SUS is a 10-item Likert scale, with each item's score ranging from 0 to 4. Odd numbered items are scored at the scale position minus 1 and even numbered items are scored at 5 minus the scale position; the sum of the scores is then multiplied by 2.5 to obtain the overall score [27,28].

The following sections of this paper detail the evaluation methods undertaken in usability testing with a multidisciplinary team of informatics professionals and 4 potential end users based on the known theory that this number will generally expose the majority of problems with usability [25], in our attempt to evaluate the usability of the first prototype of ReportVASW.

Ethical Considerations

This project was deemed exempt by CUNY Graduate School of Public Health and Health Policy since it focused on the usability of a data collection tool and did not involve human participants or personal information.

Results

Step 1 - Contextualization

Sex workers consulted confirmed that the data collection tool should make it easy to report incidents of violence, including location, what violence occurred, and who committed this violence. They confirmed that the site should be easy for people who are in the aftermath of a traumatic event to use, demonstrating understanding of the end user population, sex workers.

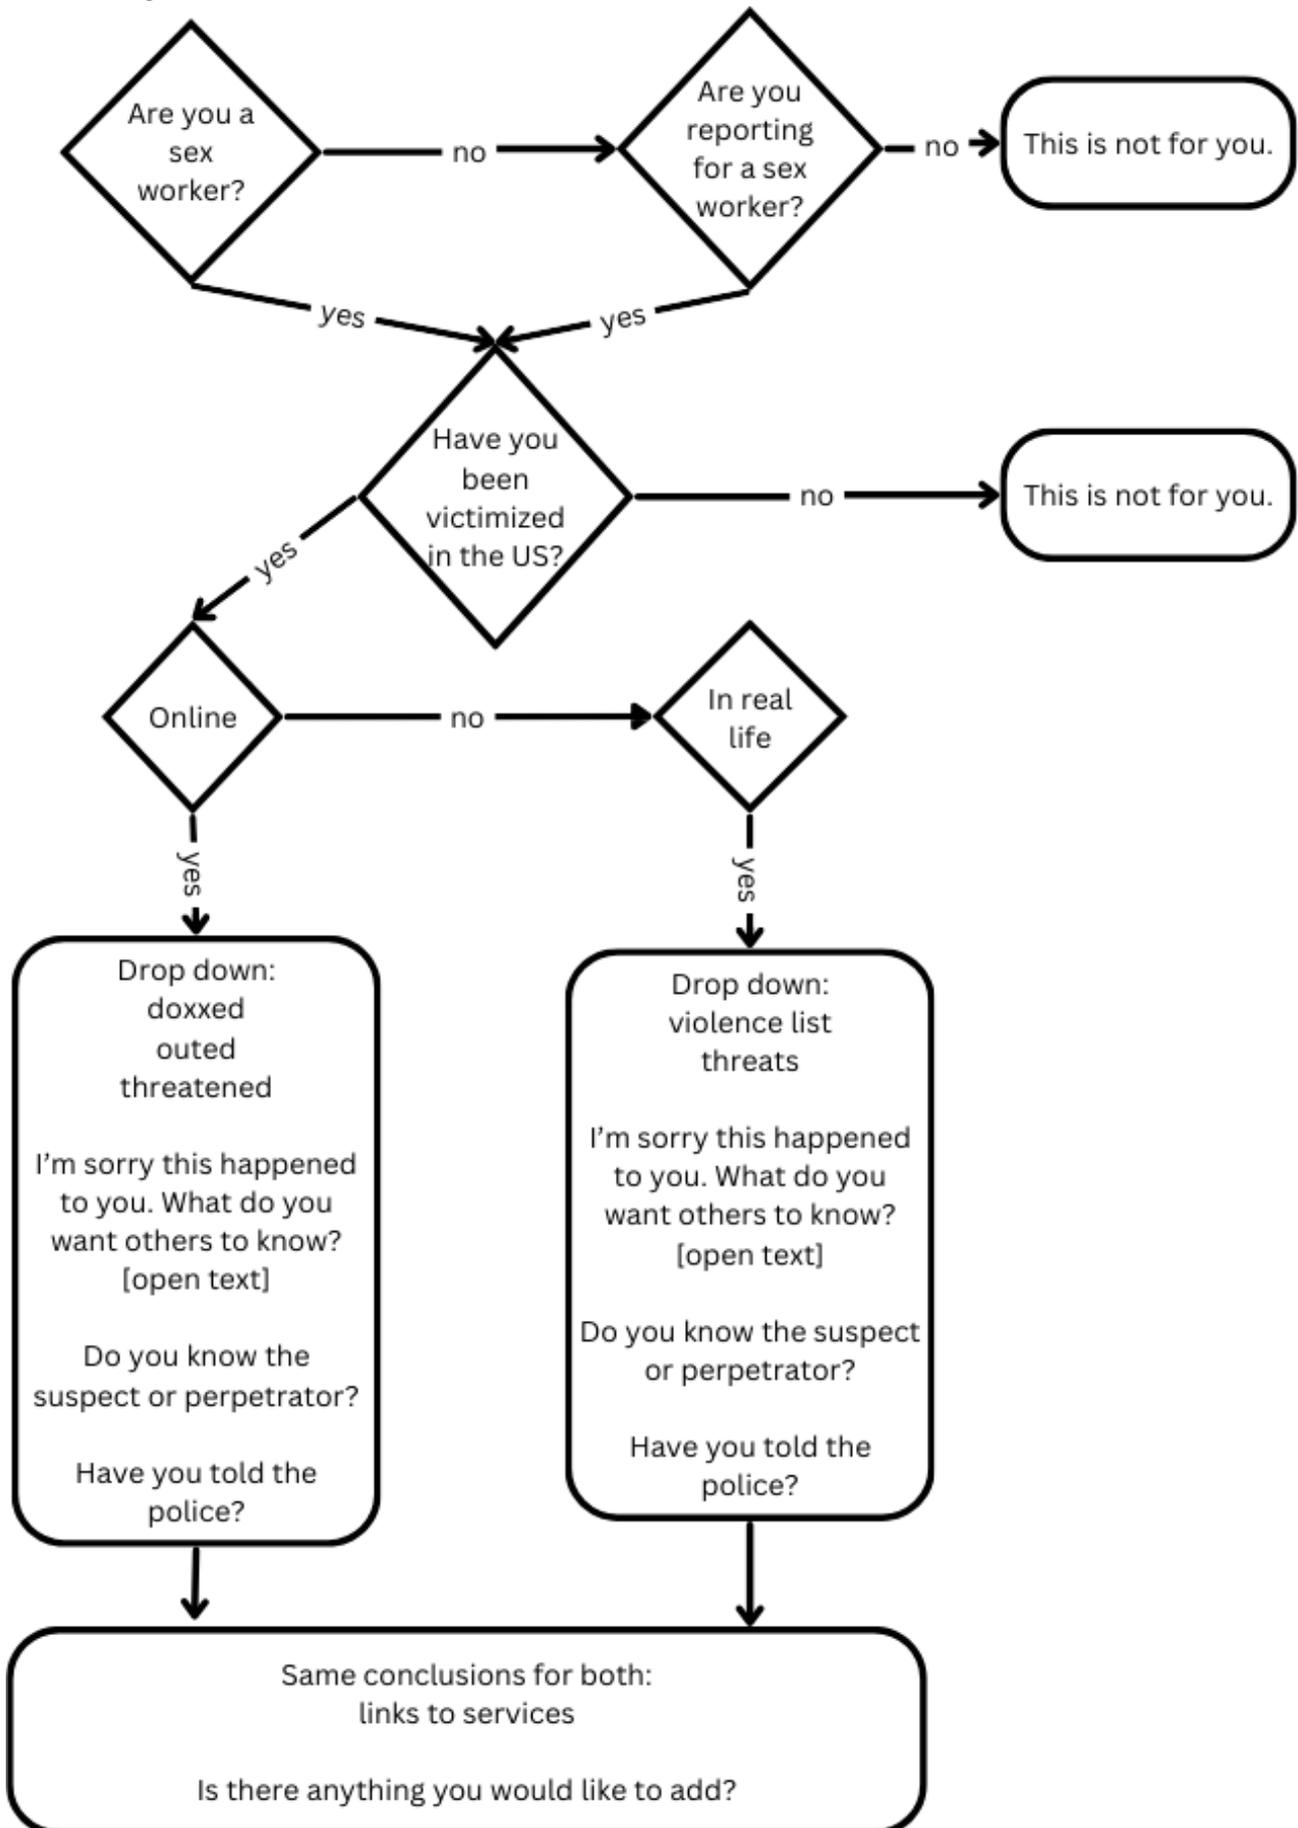

Step 1 is the functional analysis of ReportVASW. The information collected using ReportVASW could be used in multiple ways:

1. This site may facilitate information sharing in addition to documenting violence committed against sex workers and generate evidence to be used in reporting violent incidents in which sex workers are victimized.
2. Geolocation data about violent incidents can be used in the allocation of resources by organizations that work with sex workers, and in advocacy for additional resources.
3. The app could connect sex workers who have been victims of violence to an organization offering services to sex workers, perhaps including trauma-informed service providers, and possibly to attorneys in the area where the crime was committed. This would need to be determined by location; local sex worker groups would be consulted about friendly services to reach out to.

Step 2 - Ideation

The flowchart ([Figure 1](#)) went through 3 drafts in an iterative process. During this process, the ways the information would be collected and the order of questions were changed, including adding questions, each time making adjustments to the information presentation and order and ideas about how to collect it. The task analysis aspect of ideation was fruitful, because it forced the developers to clarify what should be identified and reported. The first component in the app is screening questions about sex work experience and victimization, the second component asks about the victimization, the final component would offer links to services.

Figure 1. Ideation product: flowchart.

Step 3 - Prototyping: Representational Analysis

The heuristic analysis and cognitive walkthrough using scenario-based testing methods generated similar assessments

about the ease of use of the prototype and that the aesthetics should be improved; this overall agreement would seem to indicate that the findings reflect the actual usability of the prototype ReportVASW (Figure 2).

Figure 2. Prototype screens (developed using Figma).

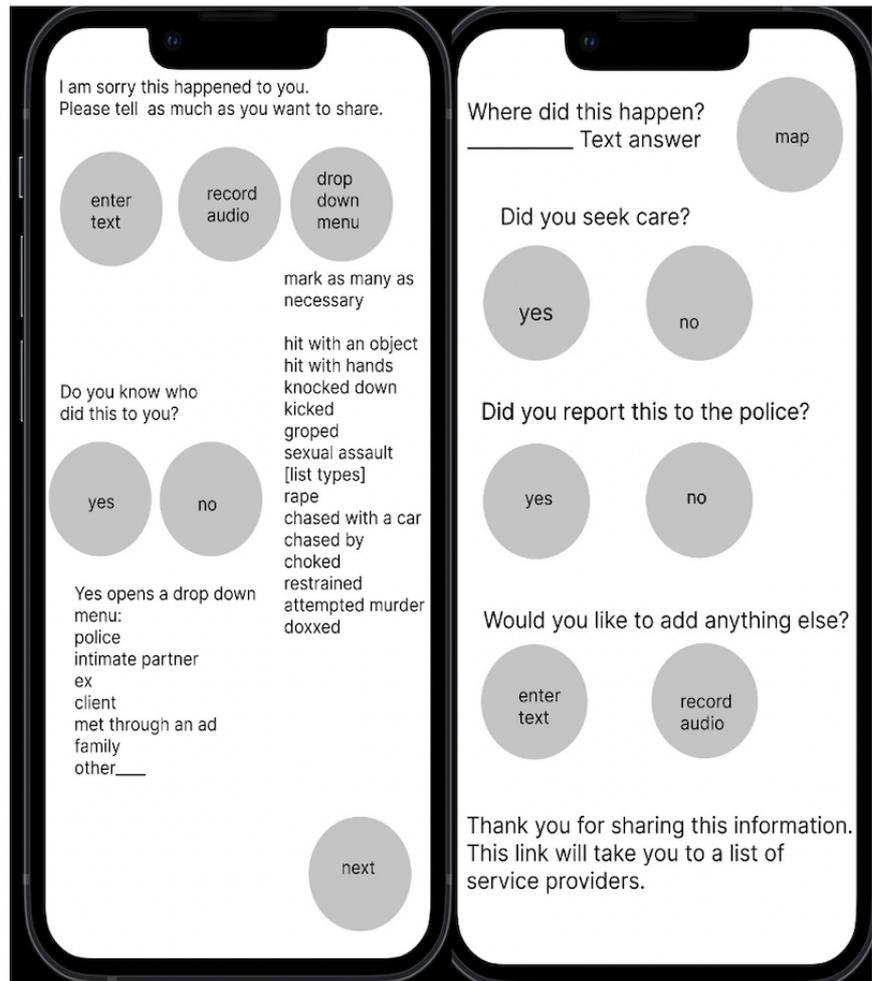

This app is for sex workers in the US to report violent incidents so that they will be counted. Information shared is not traceable and is used only to document that this happened.

Are you a sex worker?

Have you been victimized in the US?

Yes moves to page 2, No moves out of the app

Evaluation Outcomes

Responses were compiled and average scores computed; heuristic analysis scores ranged from 0.5 to 3.25 (Table 1) and revealed that most problems are aesthetic or minor. The

consistency inspection was the easiest to undertake, revealing that there were multiple problems with aesthetics:

- Buttons do not line up, looks messy.
- Labels are not uniform, labels are all over the place on the buttons.
- Color scheme is the default, and can be improved.

Table 1. Most severe problems identified by heuristic analysis, with scores over 2.5.

Problem	Heuristic violation characteristic	Average (SD)
Aesthetics	Aesthetics	3.25 (1.50)
No way for user to know if they can erase what they wrote or said or resubmit	Undo	3.25 (0.96)
Submit button missing	Minimalism	2.75 (1.26)
Wording is too direct, recommend using words that are sensitive to user so they can feel comfortable sharing	Language	2.75 (0.50)
Map: no indication if this is based on zip code, neighborhood, city, state	Visibility	2.67 (0.50)
Hard to read because there is too much on screen	Visibility	2.5 (1.29)

These are all aesthetic and minor changes, simple to address, and not an obstacle to development. The aesthetics, however, need more attention. Consolidating questions may have compromised usability by rendering the screen too crowded because they incorporate too many frames, thereby decreasing visibility and violating the heuristic of minimalism. The default color scheme should be changed.

The number of violations of each heuristic listed in the Heuristic Analysis chart were counted (Table 2). The most frequently violated heuristics were visibility (6), consistency (4), and minimalism (4). These are related: addressing violations of the heuristics of visibility and consistency will contribute to minimizing violations of the heuristic of minimalism.

Table . Frequency of heuristic violations.

Characteristic	Value (n)
Visibility	6
Consistency	4
Minimalism	4
Language	3
Control	2
Documentation	2
Flexibility	2
Feedback	1
Undo	1

Step 4 - Usability Testing: Scenario-Based Evaluation by Cognitive Walkthrough and Task Analysis

Overview

The first 2 cognitive walkthroughs and task analysis became in-depth discussions with input from the participating end user; end users confirmed the need for an application such as ReportVASW, and said that it could be a viable tool for collecting information about violence committed against sex workers, especially incidents that remain uncounted because they were not reported to police or victims did not present at hospitals, and is worth pursuing. The cognitive walkthrough process delivered positive feedback and users offered many ideas for improvements. Suggestions included new features, the collection of additional information, and aesthetic and functional comments, such as specific text for an introductory screen. Further, 4 end users completed the evaluation; the fifth was excluded because of illness.

Task Completion Time

In total, 2 people who completed the task did so in under 90 seconds. The other 2 end users offered more information than was asked during the cognitive walkthrough and so the timing of the actual task was not possible to measure; the discussion took over 20 minutes. All end users were very satisfied with the flexibility of multiple ways to submit information. Users felt that with a submit button, it would prove an effective way to collect information about the epidemic of violence against sex workers. End user testers of the prototype (Figure 2) made some recommendations, which are listed below.

Aesthetics

- Use universally recognized symbols where possible, for example, a microphone emoji for “record audio.”
- Improve attractiveness through color scheme and format; usability.

- Specify clearly that people can use any and all of these methods (text, record audio, or drop-down menu) to submit information.
- Consider 1 question per screen, which would advance without a “next” button. It may be possible to do this with multiple forms of data submission.
- Move open text field in drop-down menus to top, in order for people not to need to scroll to see it.
- Add a submit button.

Changes to Data Collection

- Change the screening question about victimization in order to capture data from people who do not identify as victims, but who have had violent experiences.
- Add a date field for the event, perhaps simply year, to distinguish recent events from long ago events.
- Add “drugged” to drop-down menu of types of victimization
- Change “did you seek care?” to specify “did you see a doctor or go to a hospital?” in order to be more clear, so that users will not include calling or visiting friends.
- Add branching questions after “did you report this incident to the police?” including “did they take your report?” and “were you treated respectfully?”
- Add demographic information about race and gender
- Ask whether the data should be shared with people collecting information about people sex workers should avoid (ie, a “bad date list”).

Additional Input

- Make more clearly anonymous, with an introductory page that emphasizes anonymity and the why of ReportVASW, emphasize that IP address and mobile numbers will not be stored, therefore “you can’t be traced or tracked” – this page must be clear, concise, and convincing.

- “Location” is ambiguous, and could be an address, as on a map, or a venue such as “car” or “brothel.” Even place names can be unclear: Springfield is a town in every state.
- Ask whether the information was shared with other sex workers, as in a “bad date list.”
- One end user tester suggested using speech to text with the audio function and enabling the speaker to edit in the moment.
- A critical point raised by the third tester was that the screening questions are good but will miss some people, highlighting that this person did not identify as someone who had been victimized, and so would be eliminated by the screening question “have you been victimized in the United States?” but had been drugged, threatened with a gun, and raped, at different times.
- A second critical point raised by the fourth tester was that the final question, “would you like to add anything else?” could lead to actionable information being shared without any way to act on this, including but not limited to suicidal

- ideation, violent impulses, and information about human trafficking situations. It was recommended that this open-ended question be eliminated to preclude the possibility of liability and to limit mental anguish for the person addressing these reports.
- All 4 agreed that entering the data from the scenarios was possible and easy, but nuance would be lost without offering open-ended formats.
- One user pointed out that recounting violent experiences takes emotional energy, prompting her to ask, “Without a clear benefit to the victim, why do it? Can there be a way to connect to targeted services for the individual to report/record?”

About SUS

ReportVASW scored 90 on the SUS; SUS scores over 68 are considered good [27,28] (Table 3). The tool scored neutral on consistency, and all other responses were positive toward the app, with most being strong.

Discussion

Step 1 - Contextualization

UCD with multiple methods was successfully implemented in the development and evaluation of this first prototype, reflecting both success [15,16,18] and difficulties [20,21] reported by others, with the additional aspect of an atypical end user for informatics.

Step 2 - Ideation

Using multiple methods to evaluate the prototype enabled the collection of new information, including phrasing for screening questions, and positive reception of ReportVASW. New knowledge was gained from the evaluation, particularly through engagement with end users, even considering the lead author’s significant expertise, particularly information about additional topics and language to incorporate in the next version of the

prototype. The literature reflects the usefulness of multiple methods, despite challenges [20,21].

We believe we have sufficient input and information to proceed to significantly improve the next draft of the prototype, because the end user evaluation aligned with the heuristic analysis. End user comments offered solutions to issues identified in heuristic analysis particularly regarding aesthetic and functional issues; these solutions will be applied in the next steps. Additionally, UCD was useful in evaluating the ReportVASW prototype interface because adaptation is necessary to bring something designed for an Asian context to the American context; input from end users will improve this adaptation. Evaluations of the interface using heuristic analysis and end user scenario-based testing will inform the revisions to the prototype.

Step 3 - Prototyping: Representational Analysis (Heuristic Analysis)

Figma's 3 screen limit encouraged the consolidation of some of the screens, thereby making the app simpler. This involved consolidated screening questions on page 1, information about a violent event on page 2, and information about seeking care and reporting and asking if there is anything more they would like to share on the final screen. This reduced number of screens may be better than the initial drawings with 1 question per screen. Each step, from the flowchart (Figure 1) to the paper draft to the digital pictures (Figure 2) offered opportunities for improvement.

The heuristic analysis forms the baseline for the evaluation of the prototype through its next iteration. This analysis offered actionable recommendations and afforded interesting discussion related to the varied backgrounds of the analysts. For example, the most technically skilled of the analysts disagreed that some things were necessary, while an analyst with experience working with different communities offered important points about sensitive language, which the lead author is confident can be addressed through consultation with end users.

Step 4 - Usability Testing: Task Analysis by Users

As shown above, end users completed the task quickly, and offered substantive input. Their interested and substantive responses indicate a need for ReportVASW. Most information offered was concrete and included suggestions that can be easily incorporated, for example, each offered ways to formulate specific questions, about seeking care and about location. However, some of the input is not as easily addressed, such as how to phrase screening questions in order not to exclude people who do not see themselves as victimized. Other input pushes the developers to find ways to benefit participants, who are expending energy to share information about potentially traumatic experiences. Possibilities include offering a list of referrals to service providers around the United States, including clinical therapists and supportive trauma-informed health care professionals, in partnership with existing services used by sex workers. Further, 1 complication is that most services for victims of violence focus on women, usually cisgender women; however, sex workers of any gender may be victimized [1-3].

Sharing the information collected with "bad date lists" about people who commit violence against sex workers is more complicated that it sounds because of recent US legislation; law enforcement efforts have led to the closure of online venues for information sharing among sex workers [29,30]. While sex workers actively share their concerns online [31], US sex worker groups are decentralized, and sex worker groups alert their members about reports of bad dates; ultimately, ReportVASW should be managed by sex workers. Each could have copies of decentralized data, and in the future we will need to explore alternatives to manage this data, for example, using blockchain.

Adapting standardized methods to the end user population has been challenging to others, who recommend flexibility and accommodation of end users over rigidity about standardization [21]. The prompt for end users to begin the evaluation task must be chosen wisely. Cognitive walkthroughs with 2 end users

featured interruptions with salient and helpful input. The third and fourth people who conducted the cognitive walkthrough each took approximately 90 seconds to complete the task. This time certainly does not account for the difficult nature of the material; none of the testers were recent victims of potentially traumatizing situations.

Next Steps

Follow-up is essential to the findings and implications of the project. We have received actionable recommendations through the cognitive walkthrough and the heuristic analysis that indicate clear urgent next steps. The agreement between the task analysis of the cognitive walkthrough and the input from the cognitive walkthroughs and the heuristic analysis included many recommendations addressing aesthetics, usability, data collection, and other input about ways to improve uptake and also increasing end users' confidence that ReportVASW is benign and not used for surveillance. Immediate next steps based on this input include:

- Adding all the input in changes to screening and data collection offered by end users, including adding a convincing introductory page about the use of the data and lack of tracking, as identified in heuristic analysis and with suggestions made during cognitive walkthrough,
- Making the urgent changes identified in the heuristic analysis including redesigning the interface for consistency and improving attractiveness.
- Exploring ways to link people providing input to services.

The most important next step will be to link users to services that could be helpful in the aftermath of violence, including the long-term aftermath, involving long-term effects of violence such as chronic disease [6] and post traumatic stress disorder [5]. It is not clear whether sharing links to legal and social services would meet this need. There are few low-barrier services for sex workers in the United States, presenting an obstacle to access. Considering this, it may prove beneficial to collaborate with an existing program offering legal and/or health services for sex workers. End users must be involved in the decisions about services included, in order to identify service providers that do not stigmatize or discriminate against sex workers. Additionally, geolocation data about violent events should be used to help identify where services are most urgently needed. Building more evidence will contribute to understanding reasons for sex workers to report violence against sex workers. However, police resistance to investigating violence against sex workers cannot be addressed by an app, and the data collected may be used in advocacy.

The next version of the prototype will also be evaluated using heuristic analysis. Comparing these sequential heuristic analyses will help determine priorities for changes to the following version. Using multiple methods for all 4 steps of the UCD process gave us richer information than we would have had using only 1 method at each step. While the time invested was significantly more than it might have taken using only 1 method, the benefits are great because the information gathered offers more certain next steps and reduces the chances of missing important elements that could require additional versions later.

Limitations

Figma constrained design possibilities that contributed to more creative ways to include information in less space. The number of individual end user evaluators was in the ideal range of 4 to 5 [25], while the cognitive walkthrough might benefit from another end user because of the interest in sharing additional information. The convenience sample of end users also presents a limitation, and data could have been different from people who were not familiar with the lead author, and the sample includes only self-identified women. SUS input may have been influenced by the lead author reading the questions and asking the answers, rather than the end user checking the boxes themselves. Additionally, the creator's bias impeded her ability to test the prototype, due to extreme familiarity. The small number of evaluators for the heuristic analysis presents a limitation.

Conclusions

The value of using multiple methods in UCD was clearly demonstrated in the process of designing and evaluating a

prototype data collection to submit information about incidents of violence against sex workers. Using multiple methods in the initial steps of contextualization and ideation led to multiple revisions in these early stages. Using multiple methods in prototyping and evaluating the prototype afforded the opportunity to collect informative input from people in different roles, including end users and informatics professionals. The results from each method aligned such that the representational analysis, the consistency inspection, and heuristic analysis reinforced ways to improve the prototype, reinforcing the input from each source. End users confirmed the need for an application such as ReportVASW and that developing the data collection tool is worth pursuing, and informatics personnel reinforced the feasibility and offered insight to improve its design and utility. The use of multiple methods to evaluate the prototype contributed to a greater understanding than any single method alone.

Acknowledgments

We would like to thank the end users who agreed to undertake the usability testing. We would like to thank Sadaf Ahmad, MS, and Rafaela Villacres, MS, for undertaking the heuristic analysis.

Conflicts of Interest

None declared.

Abstract

Background: Currently, the treatment and care of patients with traumatic brain injury (TBI) are intractable health problems worldwide and greatly increase the medical burden in society. However, machine learning–based algorithms and the use of a large amount of data accumulated in the clinic in the past can predict the hospitalization time of patients with brain injury in advance, so as to design a reasonable arrangement of resources and effectively reduce the medical burden of society. Especially in China, where medical resources are so tight, this method has important application value.

Objective: We aimed to develop a system based on a machine learning model for predicting the length of hospitalization of patients with TBI, which is available to patients, nurses, and physicians.

Methods: We collected information on 1128 patients who received treatment at the Neurosurgery Center of the Second Affiliated Hospital of Anhui Medical University from May 2017 to May 2022, and we trained and tested the machine learning model using 5 cross-validations to avoid overfitting; 28 types of independent variables were used as input variables in the machine learning model, and the length of hospitalization was used as the output variables. Once the models were trained, we obtained the error and goodness of fit (R^2) of each machine learning model from the 5 rounds of cross-validation and compared them to select the best predictive model to be encapsulated in the developed system. In addition, we externally tested the models using clinical data related to patients treated at the First Affiliated Hospital of Anhui Medical University from June 2021 to February 2022.

Results: Six machine learning models were built, including support vector regression machine, convolutional neural network, back propagation neural network, random forest, logistic regression, and multilayer perceptron. Among them, the support vector regression has the smallest error of 10.22% on the test set, the highest goodness of fit of 90.4%, and all performances are the best among the 6 models. In addition, we used external datasets to verify the experimental results of these 6 models in order to avoid experimental chance, and the support vector regression machine eventually performed the best in the external datasets. Therefore, we chose to encapsulate the support vector regression machine into our system for predicting the length of stay of patients with traumatic brain trauma. Finally, we made the developed system available to patients, nurses, and physicians, and the satisfaction questionnaire showed that patients, nurses, and physicians agreed that the system was effective in providing clinical decisions to help patients, nurses, and physicians.

Conclusions: This study shows that the support vector regression machine model developed using machine learning methods can accurately predict the length of hospitalization of patients with TBI, and the developed prediction system has strong clinical use.

KEYWORDS

machine learning; traumatic brain injury; support vector regression machine; predictive model; hospitalization

Introduction

Traumatic brain injury (TBI) surgery increases the risk of certain complications, posttraumatic head injury complications that can

lead to severe acute and chronic morbidity and mortality, and these complications are known risk factors for prolonged hospital stays [1-4]. In addition, the average length of stay after surgery for patients with traumatic brain trauma is an important indicator of the quality of medical management in neurosurgery

departments and the overall level of care in this disease area and to some extent reflects the severity and complexity of the patient's disease. In the current environment of insufficient supply of medical resources, it is important to predict the hospitalization time of patients with brain trauma in advance by technical means, and then combine the predicted hospitalization time with ward management methods to improve the bed turnover rate and medical service capacity, so as to improve the current situation of patients' difficulty in hospitalization, reduce unnecessary medical expenses, and alleviate the medical burden of society [5-8]. Therefore, the purpose of this study is to develop a system for predicting the length of stay of patients with brain trauma based on clinical data from hospital medical records and machine learning algorithms to provide clinical decision support for physicians and reference for nurses to coordinate ward management in advance.

Given the complexity and diversity of clinical data after brain injury, complex statistical features such as multiple nonlinearities between different factors are prevalent [9-11]; the use of traditional multifactor logistic regression (LR) analysis methods alone cannot establish a predictive model for the hospitalization time of patients with early brain trauma, at which time different machine learning models are required for statistical analysis and prediction [12,13]. Convolutional neural networks (CNNs) and support vector machines are currently the mainstream prediction models for processing and analyzing and building complex statistical data that enable feature extraction and building prediction models for clinical data information. In this study, multiple machine learning models were developed to predict the hospitalization time of patients with brain trauma, and the advantages and disadvantages of prediction models based on different machine learning algorithms were explored through a comparative analysis research method, and the model with the best performance was selected. Finally, based on the optimal machine learning models, we develop a system that can be applied to clinical decision-making.

This paper describes the development of a system for predicting the length of stay of patients with craniocerebral trauma based on a machine learning algorithm, using a machine learning method that was retrospectively applied to analyze clinical data of patients with craniocerebral trauma from the Second Affiliated Hospital of Anhui Medical University, and predicting the length of stay of patients with craniocerebral trauma from this dataset. Our objectives were to:

1. prospectively predict the length of stay of patients based on clinical data and

2. develop a system that can be applied to clinical decision-making by means of an optimal prediction model.

Methods

Data Sources and Exclusion Criteria

Our dataset was obtained from a total of 1128 case records from the Neurosurgery Center of the Second Affiliated Hospital of Anhui Medical University. The decision to discharge a patient requires discussion in the treatment group and assessment by an experienced neurosurgeon superior before a decision can be made. Therefore, in order to ensure that the output of the developed predictive length-of-stay model was determined by the assessment of experienced neurosurgeons and was not influenced by the subjective desire of the patient's family to abandon treatment or transfer to another department resulting in loss of follow-up, we set exclusion criteria for the medical records:

1. Automatic discharge of the patient at the request of the patient's family to forgo treatment.
2. Serious injuries in other areas requiring transfer to the relevant department for further treatment.
3. Patients with previous experience of craniocerebral injury.

The exclusion criteria were developed and the data that met the exclusion criteria were removed from the model we developed through natural language processing (NLP) techniques. A total of 1001 patients were successfully enrolled, and by random splitting, we used 70% of the data (700 items) for training the model and the remaining 30% (301 items) for testing the performance of the model. In addition, we also collected clinical data from 111 patients at the First Affiliated Hospital of Anhui Medical University as external test data for external validation of the model.

Ethical Considerations

This retrospective cohort study was approved by the Ethics Committee of the Second Affiliated Hospital of Anhui Medical University (S20210098). Participants or proxies signed the relevant informed consent forms within 24 hours of admission.

Feature Matrix

Table 1 summarizes the input data features used to predict length of stay. We selected a total of 28 features recorded in the medical record system that were available in our dataset, and these data can be used to prospectively determine the length of stay of patients with craniocerebral trauma in a practical application. These data were selected because of the experience provided by previous studies.

Estimation of Missing Data

For the missing data in this study, the model method is used to complete them. We will predict the missing fields as target variables based on other existing fields to obtain the most probable complementary values. If the column with missing values is a numerical variable, the regression model is used to complete it. If it is a categorical variable, the categorical model is used to complete it. The steps of [14] modeling method are as follows.

1. Determine the variables (characteristic columns) that fill in the missing values.
2. Splitting the original dataset: split the original dataset into 2 subsets according to the variables that need to be filled with missing values: (1) without missing values: dataset_train; and (2) with missing values only dataset_pred
1. Identify and test the correlation of the variables of interest: empirical analysis determines which attribute columns are correlated with the variables filled with missing values, and statistical analysis tools are applied to view the correlations between the selected attribute columns on the dataset_train dataset for validation.
1. Modeling and prediction: use the dataset_train dataset to build a linear regression model and apply the built model to estimate predictions for the missing variables in the dataset_pred dataset,
1. Merge and reduce datasets: merge and reduce the 2 subsets into 1 dataset to prepare the data for subsequent modeling.

Model Establishment

Overview

In this study, we established 6 models: random forest (RF), CNN, support vector regression (SVR), multilayer perceptron (MLP), back propagation (BP) neural network, and LR, and compared the mean absolute percentage error (MAPE) and goodness of fit of the actual and predicted values to determine the optimal model for predicting the hospitalization time of patients with craniocerebral trauma in the system. The MAPE formula is shown in equation 1, where n is the sample size, y_i' is the predicted value, and y_i is the true value.

$$(1) \text{MAPE} = 100\% \frac{1}{n} \sum_{i=1}^n |y_i' - y_i|$$

Random Forest

The RF model was chosen because we considered the following advantages of the RF model [15]:

1. It can handle very high-dimensional data and does not have to do feature selection because the subset of features is chosen randomly.
2. After training, it is able to derive feature importance.
3. When creating an RF, an unbiased estimate of the generalization error is used, and the model generalizes well.
4. The trees are independent of each other during training, which makes training fast and easy-to-make parallelization methods.

Convolutional Neural Network

CNN is a class of feedforward neural networks that contains convolutional computation and has a deep structure, which is one of the representative algorithms of deep learning and has been widely used in various fields. Compared with traditional neural network algorithms, CNN has stronger modeling ability to extract effective feature data from the input relevant data and learn the internal structure of the feature data for better prediction [16-18]. We consider that CNNs have the following characteristics, which are suitable for application in this study:

1. CNNs have a weight-sharing network structure, which reduces the complexity of the network model and reduces the number of weights.
2. The data (including image data) can be directly used as the input of the network, avoiding the complicated process of feature extraction and data reconstruction in traditional algorithms.

Support Vector Regression

SVR is suitable for solving various regression prediction problems thanks to kernel functions and a few support vectors that play a decisive role and has achieved excellent prediction results [19]. Drucker et al [20] proposed a new regression technique based on the Vapnik support vector concept in 1996. SVR was compared with regression techniques based on regression trees and ridge regression performed in the feature space. Based on these experiments, it is concluded that SVR will be advantageous in high-dimensional spaces because SVR optimization does not depend on the dimensionality of the input space. Considering that the input data of this study have 28 dimensions, the SVR machine was chosen to predict the length of stay of patients with craniocerebral trauma.

MLP, BP Neural Network, and LR

In addition, 3 classical regression models, namely, MLP, BP, and LR, were developed for application in predicting the length of stay in patients with craniocerebral trauma. These 3 models are also the most common prediction models in the field of applied clinical informatics and have achieved good results in a large number of related studies [21-29].

Training Set and Test Set Ratio

After establishing these 6 machine learning models, all valid original data samples are randomly disrupted and divided into a training set and a test set. In order to study the effect of different training set sample sizes on the modeling effect of different machine learning algorithms, the same rules are used to divide the training set and test set into 50%, 60%, 70%, 80%, and 90% of the total samples, and the MAPE of the test set samples is used to evaluate the model error.

External Dataset Validation Model

Considering that the ultimate goal of this study is to apply the system to clinical decision-making and ward bed management, external validation is needed to demonstrate that the optimal model selected in this study has a strong generalization capability, that is, the ability to predict datasets other than the modeled data. The reason for external validation is that overfitting may occur during the modeling process, in which

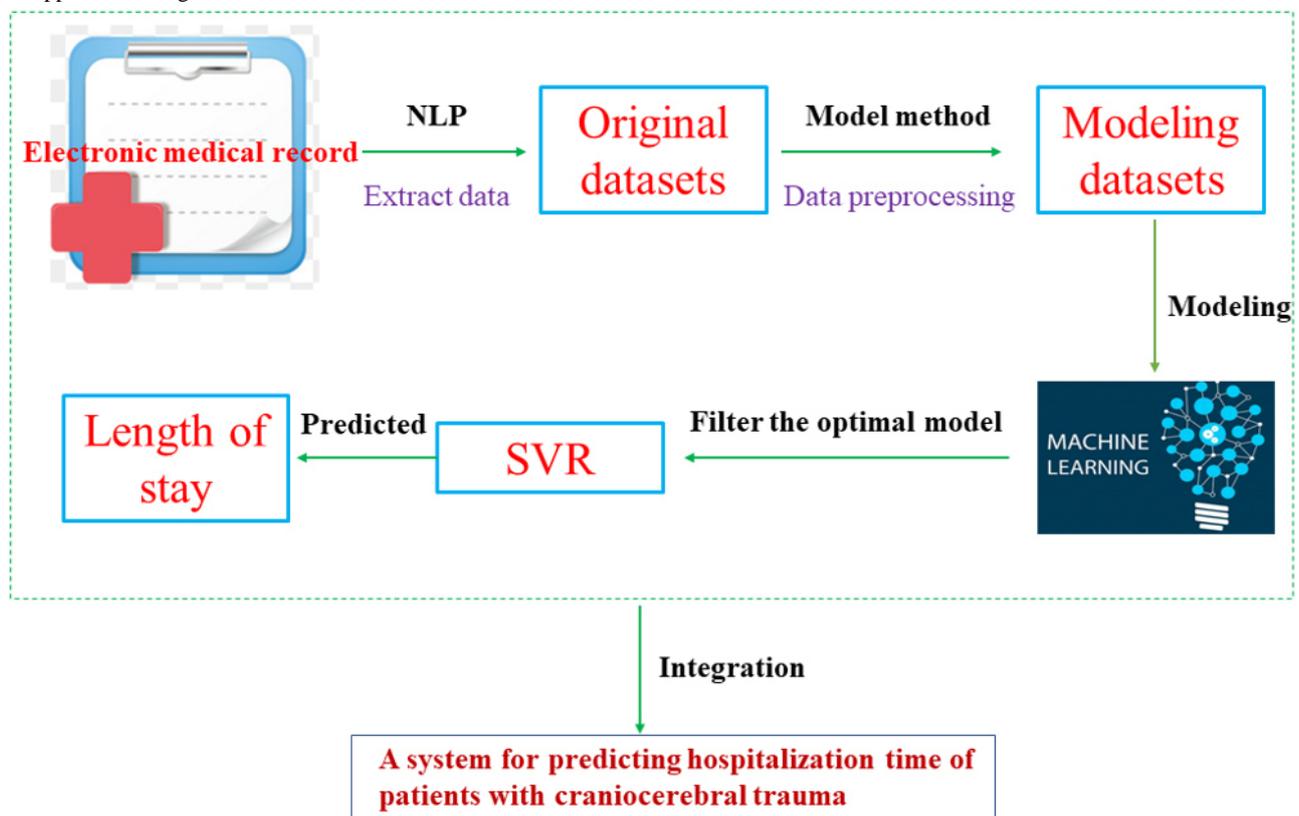

case the model predicts the modeled dataset well, but does not work well for other datasets (test set). Such a model is obviously of no application value. Therefore, the model designed in this study uses 111 data from the First Affiliated Hospital of Anhui Medical University for external validation, and once the accuracy of the external validation of the model meets the requirements of the system application, the model can be encapsulated into the system developed in this study.

Predictive Modeling Pipeline

The development of our predictive modeling pipeline is based on Python 3.9 (Python Software Foundation), PyTorch 1.9.0 (Meta), and the django framework (Adrian Holovaty and Simon Willison), and consists of the following 4 main modules, and the process of developing the system is shown in Figure 1:

1. Data extraction module: Using NLP technology to extract the 28 features we need in the medical record system for patients with craniocerebral trauma, and based on the exclusion criteria we set, the data that meet the exclusion criteria are eliminated.
2. Data preprocessing module: The input feature data are automatically filled in with missing values using the model method to ensure the integrity of each patient record.
3. Model evaluation module: Visualize and evaluate the model-based predictions using the results of various standard key performance indicators.
4. Prediction of hospitalization time module: In this study, by comparing the prediction accuracy of the 6 models established, the model with the best prediction accuracy was established as the prediction model for system application, and finally the hospitalization time of patients with TBI was predicted by the input of the input features.

Figure 1. Development process of a system for predicting hospitalization time of patients with traumatic brain injury. NLP: natural language processing; SVR: support vector regression.

The predictive modeling pipeline ensures reproducibility and process stability and features many modules for processing data from medical record systems through machine learning algorithms to predicted length of stay data, which also supports the development of applied clinical systems for predicting the length of stay of patients with TBI.

Results

Proportion of Optimal Training and Testing Sets for Different Models

There is no fixed value for the partition ratio between the training set and the test set, and approximately 2 of 3 to 4 of 5

of the samples are usually used for training. The most common training set and test set ratios are 7:3 or 8:2. In order to achieve the best prediction accuracy of these 6 machine learning models designed in this study, the same rules are used to partition the training set and test set. The training set samples account for 50%, 60%, 70%, 80%, and 90% of the total samples. The MAPE of the test set samples was used to evaluate the prediction accuracy of these 6 models, and the experimental results are shown in Table 2.

The experimental results in Table 2 indicate that the optimal training and testing set ratios for different models may not necessarily be the same. Based on the experimental results, we selected the optimal training and testing set ratios for CNN,

SVR, LR, RF, BP, and MLP as 0.7, 0.7, 0.8, 0.7, 0.8, and 0.7, respectively.

Table . Comparison of accuracy of 6 machine learning model test sets under different sample ratios of training sets.

Modeling set/test set	MAPE ^a (%)					
	CNN ^b	SVR ^c	LR ^d	RF ^e	BP ^f	MLP ^g
0.5	30.76	28.46	40.57	32.74	35.93	33.70
0.6	24.83	22.78	35.14	25.63	28.65	26.49
0.7	12.19	10.69	27.68	13.47	21.37	18.41
0.8	15.63	18.25	22.75	15.40	19.28	21.76
0.9	28.43	26.71	34.13	26.24	32.17	28.43

^aMAPE: mean absolute percentage error.

^bCNN: convolutional neural network.

^cSVR: support vector regression.

^dLR: logistic regression.

^eRF: random forest.

^fBP: back propagation.

^gMLP: multilayer perceptron.

Model Accuracy

Divide all 1001 valid samples into training and testing sets. Divide the training and testing sets based on the results of the optimal ratio of the 6 models in Table 2. Then, start using these 6 algorithms to train the model for predicting hospitalization time, including cross-validation data. Repeat the training and testing 5 times and take the average value. For the prediction model of TBI patients' length of stay, the goodness of fit and the MAPE of the test set are used to check the model performance. The reason for using the test set results to evaluate the model is that the test set results can screen out models with

strong generalization ability for us, which is universal in our system. Based on this, we can directly adjust the parameters of different models through the errors of the model on the test set, making the predictive ability of the model better and the applicability of the system for predicting hospitalization time stronger.

From Table 3, we can see that in the test set, SVR has the lowest MAPE and the best goodness of fit, and CNN and RF perform well in the test set. The higher the error of LR, BP, and MLP than that of the other 3 models, the poorer the applicability of these 3 models, which should be considered for exclusion.

Table . MAPE and R^2 of 6 models in the test set.

Model	MAPE ^a (%)	R^2
CNN ^b	11.98	0.862
SVR ^c	10.22	0.904
LR ^d	21.83	0.718
RF ^e	14.27	0.827
BP ^f	18.35	0.785
MLP ^g	19.14	0.772

^aMAPE: mean absolute percentage error.

^eRF: random forest.

^fBP: back propagation.

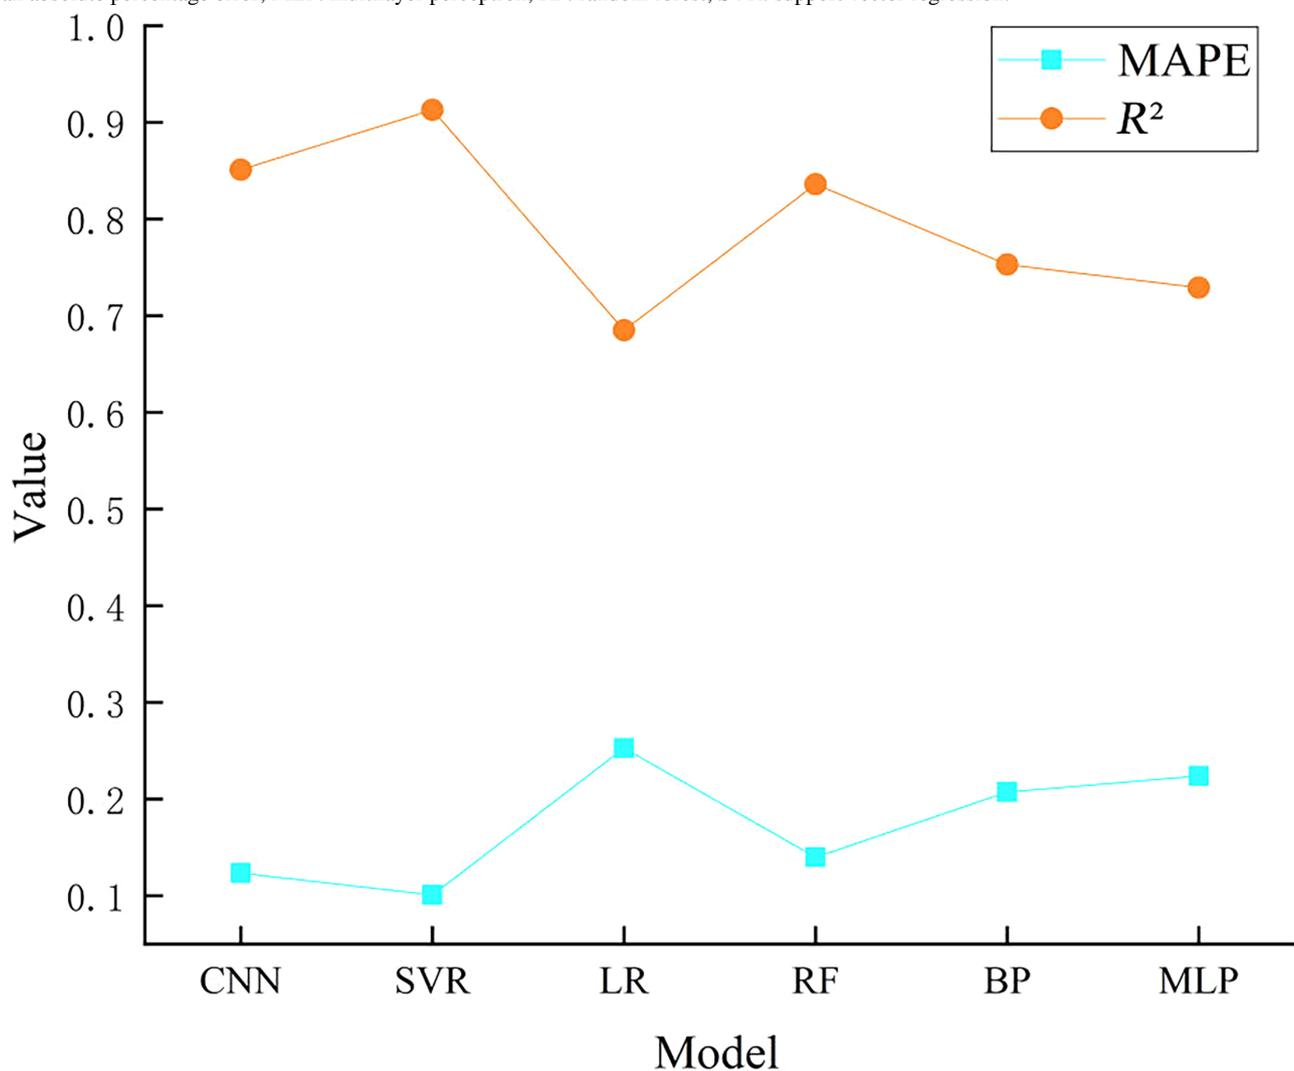

^gMLP: multilayer perceptron.

External Dataset Validation Results

Considering that the data of the test set and training set in this study are from the medical record system of the Second Affiliated Hospital of Anhui Medical University, in order to avoid contingency of the model prediction accuracy, consider using the data from the medical record system of other hospitals to assist in verification. If the predictive performance of data input from other hospitals into the system is poor, consider developing different models for data from different centers to ensure the high accuracy of the system. If the prediction accuracy is excellent, it proves the universality of the system and can be applied more widely.

Therefore, in order to further compare the reliability of the algorithm, 111 data records from the First Affiliated Hospital of Anhui Medical University were used for external validation. A total of 28 types of input variables required by our model were extracted through NLP from the collected medical records and input into 6 models to compare the advantages and disadvantages of different models in the external dataset. The experimental results are shown in Figure 2. The experimental results show that the SVR-based hospital stay prediction model has the lowest error and the highest R^2 in the external dataset, greatly maintaining the accuracy of the predicted data. It is the best machine learning model for predicting hospital stay. Therefore, the system we developed chose SVR as our prediction model.

Figure 2. MAPE and R^2 of 6 models in external test sets. BP: back propagation; CNN: convolutional neural network; LR: logistic regression; MAPE: mean absolute percentage error; MLP: multilayer perceptron; RF: random forest; SVR: support vector regression.

Satisfaction Evaluation of Patients, Nurses, and Doctors

After determining SVR as the final prediction model, this study ultimately designed a system to predict the hospitalization time of patients with TBI using data from an electronic medical record system. In order to verify the applicability of the clinical

system, this study designed survey questionnaires for nurses and doctors to obtain satisfaction evaluations.

A total of 88 doctors and nurses from the First Affiliated Hospital of Anhui Medical University and the Second Affiliated Hospital of Anhui Medical University participated in the questionnaire. We set the following questions to assess health care workers' satisfaction with the system:

1. Have you learned about and used our newly developed system for predicting length of stay for patients with TBI?
2. How well do you think the system supports clinical decision-making?
3. Do you think the system can improve your work efficiency?
4. How accurate do you think the system is?
5. Do you think the system's predictions will help you better manage your patients' length of stay?
6. Do you think the user interface of the system is user-friendly?
7. How well do you think the system protects data security and privacy?
8. Would you recommend the system to other colleagues or health care organizations?
9. Whether the system's predicted outcomes will affect your treatment plan or patient management plan?
10. Do you feel the system integrates seamlessly with your existing workflow?

The above 10 questions will receive 1 point for agreement, 0 point for disagreement, and a maximum score of 10 points. The final average score is 9.18 points. The questionnaire results indicate that the system has strong practicality for patients. During the application process, most doctors and nurses stated that informing patients of the accurate length of stay during hospitalization can help alleviate their own stress, reduce fear of illness, and plan their life after discharge in advance.

Discussion

Principal Findings

The main finding of this study is that by using machine learning models, we can effectively predict the length of hospital stay for patients with TBI, which is of great significance for their rehabilitation and efficient use of medical resources. Specifically, the prediction system can help medical professionals more accurately evaluate the patient's condition and develop treatment plans, thereby arranging surgery, medication treatment, and rehabilitation training reasonably; reducing waste of medical resources; and avoiding frequent hospitalization due to unstable patient recovery, reducing medical costs. In addition, predicting hospitalization time can also help patients and their families better plan their lives, understand treatment progress and rehabilitation plans, and improve confidence in treatment and rehabilitation outcomes. This study used a large amount of clinical data on TBI accumulated over the years at the Second Affiliated Hospital of Anhui Medical University, combined with machine learning algorithms, to develop a complete system from data extraction, preprocessing, and hospital stay prediction to model evaluation. This system realizes fully automatic operations from electronic medical records to hospital stay prediction and visualization. Users only need to query the hospital stay number to obtain the prediction results, which is convenient and fast to use and has high practicality. This research result not only provides assistance to doctors in clinical decision support but also significantly improves the rehabilitation effect and quality of life of patients.

In the 4 modules of system development, this study focuses on the prediction of hospitalization time module. We use NLP technology to extract enough clinical data from the electronic medical record for processing and screening, as the input variable of the model, and the length of stay as the output variable. Using input-output datasets, 6 machine learning models (CNN, SVR, LR, RF, BP, and MLP) were compared and constructed. In order to avoid the impact of the same proportion of training and testing sets on the prediction accuracy of different machine learning algorithms, and to achieve the best prediction accuracy of these 6 machine learning models designed in this study, the same rules were used to divide the training and testing sets into 50%, 60%, 70%, 80%, and 90% of the total samples and use the MAPE of the test set samples to evaluate the prediction accuracy of these 6 models. For these 6 models (CNN, SVR, LR, RF, BP, and MLP), we ultimately chose the optimal training and testing set ratios of 0.7, 0.7, 0.8, 0.7, 0.8, and 0.7, respectively. Divide the optimal ratio of training and testing sets and then start using these 6 algorithms to train models for predicting hospitalization time. Evaluate the performance of the prediction model based on the results of the testing set. The experimental results show that the minimum MAPE of SVR is 10.22%, and the best goodness of fit is 0.904. The CNN and RF perform well on the test set. The errors of LR, BP, and MLP are very high, and the goodness of fit is low, which indicates that these 3 models have poor clinical applicability, and should be excluded. At the same time, in order to further validate the reliability of the algorithm, the universality of the system for predicting hospitalization time of patients with TBI was verified through external datasets. The experimental results showed that the SVR-based hospitalization time prediction model had the lowest error and the highest R^2 in the external dataset, maintaining the accuracy of the predicted data to a great extent. It is the best machine learning model for predicting hospitalization time. Therefore, the system we developed chose SVR as our prediction model.

Although in this study we compared and applied different machine learning algorithms to select the best algorithm SVR for application in the system and developed a system to predict the hospitalization time of patients with TBI through electronic medical records, the model adjustment and data-preprocessing steps were too specific, resulting in the current prediction mechanism being limited to local hospitals, while for hospitals in sparsely populated areas, it is not yet known whether the system has applicability. In addition, the differences in the electronic medical record systems of different hospitals can also lead to the inability to obtain the 28 input data required by this system through NLP, resulting in the inability to complete predictions or a decrease in prediction accuracy. Therefore, in the future, it is necessary to adopt a unified length of stay prediction framework to generate more reliable estimates and use them in different hospitals, where the system structure of electronic medical records for patient populations is similar. Finally, considering the inherent complexity and uncertainty of the system for predicting hospitalization time for TBI, as well as the relevant data currently being collected from different hospitals, we hope that the model needs to be widely applicable in subsequent system updates [30].

Nowadays, the application of machine learning models in the field of clinical decision support has become increasingly widespread [31-33]. However, this system can only predict the hospitalization time of patients with TBI. Therefore, more predictive indicators can be added in future research. In addition to hospitalization time, consideration should be given to increasing the treatment cost, readmission rate, rehabilitation time, and so on. Through these indicators, patients' rehabilitation status can be more comprehensively reflected, helping doctors make better treatment decisions, and at the same time, precise medical plans can be formulated to provide better support and assistance for patients' rehabilitation.

In addition to the fact that the system discussed above can only predict the length of hospital stay of patients with traumatic brain injury, the system itself still has certain limitations. First, the prediction accuracy of the system is too dependent on data quality, and the prediction accuracy of machine learning models depends on the quality of the data used. If the data quality is poor, it may affect the accuracy and stability of the model. Second, due to incomplete and insufficient data collection, there may be deviations in the data. This may affect the prediction results of the model and lead to misjudgment. Finally, machine learning models are often difficult to explain, which may lead to doctors not trusting the model's prediction results. Therefore, in order to avoid data quality issues and biases, it is necessary to use multisource, multicenter, and diverse data as much as possible to train the model. In addition, data augmentation techniques can be used to expand the scale and diversity of the dataset, in order to improve the generalization ability of the

model. In addition, to improve the interpretability of the model, interpretable machine learning techniques such as decision trees, rule learning, linear regression, and other models can be used to construct predictive models. At the same time, methods such as model visualization and feature importance analysis can be used to explain the predicted results of the model, enabling doctors to better understand the model's decisions. In a word, to solve the limitations of the system, we need to combine domain knowledge and data analysis and mining technology to constantly optimize and adjust the model to meet the actual clinical needs.

Conclusions

This study successfully developed a prediction model based on SVR by applying machine learning methods, which can accurately predict the hospitalization time of patients with TBI. This achievement not only demonstrates the strong potential of machine learning in the field of medical prediction but also provides strong support for clinical practice. By analyzing the medical data of patients in depth, the model can capture key factors that affect hospitalization duration and make accurate predictions based on them. This prediction system not only helps doctors better plan patient treatment and rehabilitation plans but also helps optimize the allocation of medical resources and improve the efficiency and quality of medical services. Therefore, the prediction system developed in this study has strong clinical practicality and is expected to become an important auxiliary tool for medical decision-making in the future, bringing patients a more personalized and efficient treatment experience.

Acknowledgments

We would like to thank Bing Zhao for his assistance and guidance in this research. This study was funded by Natural Science Research Project of Anhui Province (KJ2021A1160), Quality Engineering Project of Anhui Province (2022sx060; 2022jyxm659), Natural Science Foundation of the Anhui Xinhua University (no. 2023zr013), and Anhui Provincial University Students Innovation and Entrepreneurship Program (S202212216037; S202212216022; S202312216119).

Authors' Contributions

YP and HZ researched literature and conceived the study. YP and CF were involved in protocol development, gaining ethical approval, patient recruitment, and data analysis. HZ wrote the first draft of the manuscript and is the guarantor. All authors reviewed and edited the manuscript and approved the final version of the manuscript.

Abstract

Background: The National Research Mentoring Network (NRMN) is a National Institutes of Health-funded program for diversifying the science, technology, engineering, math, and medicine research workforce through the provision of mentoring, networking, and professional development resources. The NRMN provides mentoring resources to members through its online platform—MyNRMN.

Objective: MyNRMN helps members build a network of mentors. Our goal was to expand enrollment and mentoring connections, especially among those who have been historically underrepresented in biomedical training and the biomedical workforce.

Methods: To improve the ease of enrollment, we implemented the split testing of iterations of our user interface for platform registration. To increase mentoring connections, we developed multiple features that facilitate connecting via different pathways.

Results: Our improved user interface yielded significantly higher rates of completed registrations ($P < .001$). Our analysis showed improvement in completed enrollments that used the version 1 form when compared to those that used the legacy form (odds ratio 1.52, 95% CI 1.30-1.78). The version 2 form, with its simplified, 1-step process and fewer required fields, outperformed the legacy form (odds ratio 2.18, 95% CI 1.90-2.50). By improving the enrollment form, the rate of MyNRMN enrollment completion increased from 57.3% (784/1368) with the legacy form to 74.5% (2016/2706) with the version 2 form. Our newly developed features delivered an increase in connections between members.

Conclusions: Our technical efforts expanded MyNRMN's membership base and increased connections between members. Other platform development teams can learn from these efforts to increase enrollment among underrepresented groups and foster continuing, successful engagement.

Introduction

The need for mentoring networks is critical in the biomedical sciences, where the shortage of available mentors contributes to a scarcity of students pursuing biomedical careers. Funded by the National Institutes of Health (NIH) in 2014, the mission of the National Research Mentoring Network (NRMN) is to increase opportunities for mentorship and professional development in the biomedical sciences, especially among

underrepresented populations. As part of the NIH-sponsored Diversity Program Consortium, the program works to diversify the biomedical research workforce through programming, training, mentorship, and advocacy efforts [1,2].

The MyNRMN platform [3] enables mentors and mentees nationwide to connect one-on-one or in groups with mentors and peer mentors. As of April 2024, MyNRMN has grown to include over 30,000 members from across the nation, engaging more than 15,700 mentees and 8400 mentors who represent

more than 4000 institutions and organizations from all 50 US states and US territories. Within the platform, more than 7800 learners have taken online courses and training and have created more than 500 online collaboration and discussion groups with over 9900 participants. There have been more than 12,000 connections made between mentees and mentors in the network, with strong representation from underrepresented faculty, researchers, and students. To expand the reach of this mentorship platform, the MyNRMN development team continually revises the user interface and platform design and adds new features.

The MyNRMN platform faced the following two challenges: increasing enrollment and expanding network connections. Pivotal aspects of creating an online network are continually increasing the number of people in the network and providing opportunities for members to make connections with others and increase engagement. To increase enrollment, especially the enrollment of diverse users, our team sought to improve the ease and appeal of the enrollment process by using split testing (ie, A/B testing)—a method that is used widely to compare two variations of a form or content [4-9]. For web forms, this testing is accomplished by randomly serving one version of a form to half of the platform visitors and a different version to the other half. A post analysis reveals which variation is the most effective in motivating users to complete a task (eg, enrollment). Additionally, we designed and implemented an array of features to facilitate mentoring connections. This paper details the strategies and underlying technology that supported our efforts. By empowering members from diverse backgrounds to join MyNRMN and connect, our platform expands personal networks and increases career opportunities for those who have been traditionally underrepresented in the biomedical sciences.

In this paper, we describe how we conducted the iterative split testing of three enrollment forms to determine how to increase enrollment in a nationwide networking platform for the biomedical workforce. We also discuss the additional mentoring, networking, and professional development features that we created to further encourage enrollment and increase engagement in the platform.

Methods

Overview of MyNRMN

MyNRMN was developed by TAS in 2016 as part of the NRMN. Various forms of individual guided mentoring,

free-form mentoring, and group mentoring are offered by the NRMN [1,2]. Prior to the development of MyNRMN, the NRMN online resources consisted of a website with information about the program. Since 2016, the MyNRMN platform has supported many online features and resources for mentors and mentees to connect, seek peer or group mentoring, provide guided online mentoring, and create a network of mentors.

Enrollment—Attracting Individuals to Join MyNRMN

The first step to finding a mentor was joining MyNRMN. To begin the enrollment process, the users registered by using a third-party service—Auth0 (Okta Inc)—to authenticate their sign-in information via Gmail, LinkedIn, Facebook, or email address and password. This service was especially beneficial when integrating the social sign-ins, particularly while modifying the required registration fields throughout this study.

To finish the process, users completed an online enrollment form that included demographic information. An enrollment form was already used at the time Vanderbilt University Medical Center inherited the MyNRMN registration process during the Phase II U24 award period. This “legacy” form, which was designed primarily for data collection, included 19 fields arranged in 2 columns, with all fields required to complete enrollment (Figure 1). The lengthy slate of questions contained potentially sensitive fields, such as fields for ethnicity, disability, and gender. We observed that many users dropped out of the enrollment process after creating an Auth0 account and before completing the form. We became concerned that having sensitive questions early in the process hindered our efforts to recruit diverse members. An additional fear was losing potential members by not offering alternative log-in methods, particularly logging in via social media, which younger users may prefer.

In hopes of increasing enrollment completion, we created the version 1 form and tested it against the original legacy form. The version 1 form asked the same questions in an improved user interface. In contrast to the legacy form, the version 1 form used a wizard format with 3 tabs. The first 2 tabs presented 11 required fields, while the third tab contained optional fields (Figure 2). When implementing the multipage format, we anticipated reduced perceptions of the form being burdensome.

Figure 1. Legacy enrollment form. NRMN: National Research Mentoring Network.

Figure 2. Version 1 enrollment form. NRMN: National Research Mentoring Network.

From July 1, 2019, to August 26, 2020, we used split testing to evaluate the different registration forms to optimize enrollment. To conduct split testing, we programmed the system to randomly redirect each user, after Auth0 sign-in, to 1 of 2 enrollment forms—the legacy form or the version 1 form. Despite seeing some improvement in enrollment among users who were provided with the version 1 form, the improvement was not as significant as anticipated. This motivated us to continue revising the form to develop the version 2 form (Figure 3). The version 2 form allowed users to create an Auth0 account and enroll synchronously. Sensitive questions were removed from the first steps in the version 2 form, and members were prompted, but

not required, to complete these questions after enrollment. We observed that removing the requirement to complete the sensitive fields prior to enrollment significantly increased user enrollment. The NRMN’s goal is to increase diversity in the biomedical workforce. To measure the impact of our mentoring platform, we collect demographic data during the user enrollment process. Beginning with the version 2 form, the only demographic information that has been collected during enrollment is race. Since August 26, 2020, all new users have been redirected to the version 2 form, which replaced the legacy and version 1 forms.

Connections—Finding a Mentor and Building a Personal Network of Mentors

The MyNRMN platform's goal is to help members increase connections to build and expand their networks. The larger the network, the greater the opportunity to engage with members who are diverse with respect to gender, racial and ethnic background, and other demographics. To facilitate finding and acquiring new connections on MyNRMN, we developed the following new features and modes:

1. Member search engine: Members use the powerful search engine within the *Find a Mentor* feature to search for mentors or peer mentors. Keywords are used to search by name, institution, location, or areas of interest. Additionally, the keyword search is applied to curricula vitae, résumés, and publications that are synced within the platform via natural language processing–based indexing and retrieval.
2. Recommendation engine: Through the use of Neo4j (Neo4j Inc)—a robust graph database technology—the platform's recommendation algorithms suggest new connections to members. Fresh recommendations appear when a member accesses their personal dashboard.
3. Profile: A member's profile page contains detailed information, including research interests, institutions, locations, and publications, and excludes any profile questions that may be deemed "sensitive." A mentee can view the profile of any mentor and request to connect.

Data Analysis

We estimated descriptive statistics for variables in SAS 9.4 (SAS Institute Inc). To examine the effect of form type on form completion, odds ratios (ORs) and 95% CIs were estimated for odds of completing enrollment by form type and within demographic subgroups. Subgroup analyses were conducted for demographic subgroups with sufficient data available (eg, White, African American, and Asian race subgroups) and on the basis of which fields were required for enrollment completion. After implementing the version 2 form, some demographic fields were converted to optional fields, which resulted in some users leaving these fields blank, hence the incomplete ("Missing from Total") data in our data set.

Ethical Considerations

This study was approved by the NRMN's institutional review board (reference number: 2015 - 0720). All user data were protected under and provided by the North Texas Regional Institutional Review Board and stored securely.

Results

Growth in Enrollment

Prior to August 26, 2020, a user joining MyNRMN was required to complete the following two steps: (1) create an account with Auth0 and (2) fill in all required fields in the enrollment form. Our analysis showed improvement in completed enrollments

that used the version 1 form when compared to those that used the legacy form (OR 1.52, 95% CI 1.30-1.78). The version 2 form, with its simplified, 1-step process and fewer required fields, outperformed the legacy form (OR 2.18, 95% CI 1.90-2.50).

[Table 1](#) describes the proportions of users who completed enrollment by form type and demographic characteristics. [Figure 4](#) displays the users who completed enrollment by form type and self-identified race. In the version 1 form, the field for ethnicity was optional. In the version 2 form, the fields for ethnicity, gender, and education were optional.

^aPercentages were calculated by using the N values in the corresponding row headings as the denominator.

^bThe percentages in these rows were calculated by using the total number of users who self-identified as each subgroup for each form type as the denominator.

^cBecame an optional field; this “Missing from Total” value includes users who completed enrollment and users who did not complete enrollment.

Figure 4. Proportions of users who completed the enrollment form by form type and race.

We performed subgroup analyses to determine if enrollment completion differed within demographic subgroups by form type (Table 2). We compared the legacy and version 1 forms for gender, race, education, and log-in method subgroups, since these were required fields. The version 1 form performed better than the legacy form for male users, female users, White users, Black or African American users, Asian users, graduate students, nonstudents, and persons who used the username-password method. We compared the version 2 and legacy forms for race

and log-in method subgroups, since these were required fields. The version 2 form performed better than the legacy form when users used the username-password method (version 1: OR 1.69, 95% CI 1.39-2.04; version 2: OR 3.70, 95% CI 3.07-4.46) or LinkedIn (version 1: OR 1.63, 95% CI 0.93-2.85; version 2: OR 2.52, 95% CI 1.55-4.12). The version 2 form also performed better than the legacy form in terms of facilitating enrollment completion among White, Black or African American, and Asian users.

Table . Odds ratios (ORs) and 95% CIs for enrollment completion within demographic subgroups.

	Version 1 form vs legacy form (reference), OR (95% CI)	Version 2 form vs legacy form (reference) ^a , OR (95% CI)

^cNot applicable.

Growth in Connections

After implementing the version 2 form, the amount of mentoring requests grew for all types of mentor-mentee connections, including peer-to-peer connections (Figure 5). However, the percentage of accepted connection requests has remained relatively consistent. Of the total requests to connect, roughly

half have been accepted. Although very few requests have been actively declined, a large percentage remain pending.

Networking connections originated via several pathways (Table 3). Both mentors and mentees made extensive use of the *Recommendations* feature that suggests connections on the user dashboard. Via the *Search* and *Profile* connection pathways, mentees initiated more connections than mentors.

Figure 5. Cumulative mentoring connections.

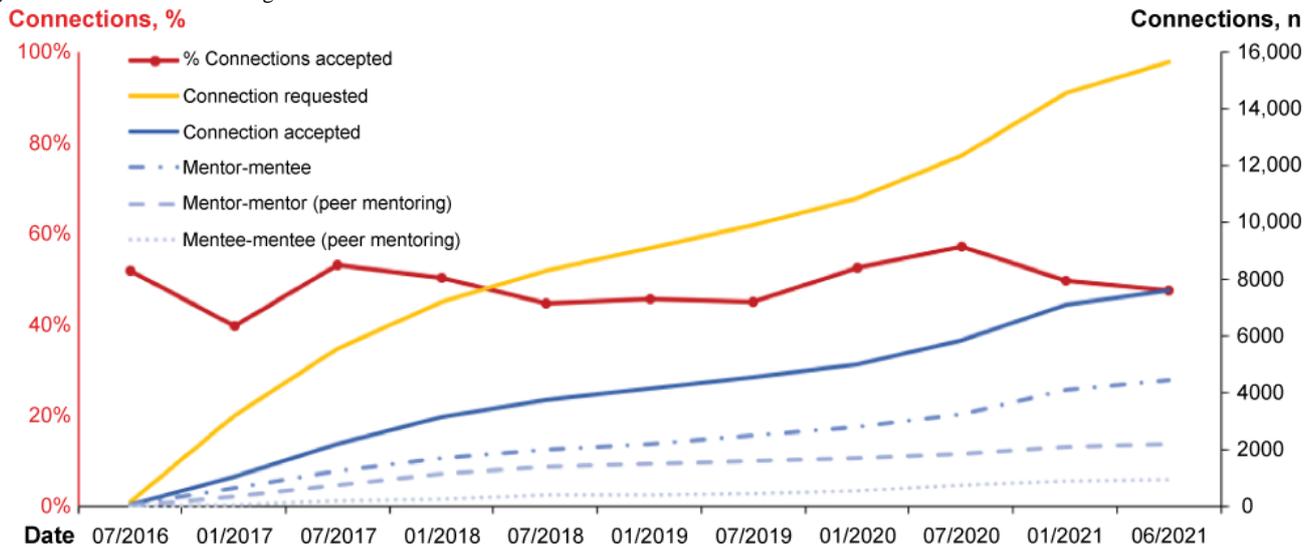

Table . Origins of connection requests.

Pathway	Mentees		Mentors	
	Number of connection requests	Requests accepted, n (%)	Number of connection requests	Requests accepted, n (%)
<i>Recommendations</i> feature	601	231 (38.4)	724	285 (39.4)
<i>Search</i> connection pathway	577	277 (48)	331	171 (51.7)
<i>Profile</i> connection pathway	633	320 (50.6)	148	74 (50)

Discussion

Principal Findings

Providing access to mentors and meeting the need for mentoring are essential to grow and enhance the biomedical workforce, and the value of mentorship in accessing the connections needed to advance professionally has been long established [10,11]. Research shows that the probability of individual success increases when multiple mentors with differing backgrounds and levels of expertise are tapped for support [12]. This *network of mentors* facilitates growth that is tailored to an individual's goals by providing the multiple perspectives needed for professional and personal growth [13-15].

Our results show that our enrollment forms work similarly well for female and male users, and the version 1 form performed better (enrollment rate of male users: 260/280, 92.9%; enrollment rate of female users: 663/718, 92.3%) for both groups than the legacy form (enrollment rate of male users: 236/291, 81.1%; enrollment rate of female users: 526/677, 77.7%). This is an important consideration in decreasing traditional gender disparities in the biomedical sciences—a situation that the NIH has recognized by designating female individuals as underrepresented. Although the version 1 form was established as superior to the legacy form in terms of enrollment completion, it did not perform as anticipated. We discussed the shortcomings of the existing forms with MyNRMN stakeholders, including the NRMN-Resource Center, the Product Council (which included representative NRMN members), and the NIH project scientist. After collaborative discussions, we simplified the enrollment process in the version 2 form. We discovered that the design of the user interface did not negatively affect enrollment, which was instead affected by the length and sensitive nature of the information required. After reducing the number of required questions and moving sensitive questions to an optional postenrollment form, our rate of registration completion increased significantly ($P < .001$; Table 1). Moreover, improved registration completion was observed for racial subgroups that used the version 2 form when compared to those that used the legacy form.

In fostering mentoring connections, we found that most mentors (724/1203, 60.2%) extensively used more passive features, such as the *Recommendations*. In contrast, mentees were more likely to proactively use the *Search* feature or the *Profile* feature to build connections when compared to mentors. Both of these features use the personalized recommendation algorithm and natural language processing when providing results. The recommendation algorithm pulls information from a user's profile, as well as from their network connections within the

platform. To promote the further expansion of personal networks, we developed the following five new features: (1) the *Groups* feature (members can join discussion and collaboration groups to connect with others who shared common interests); (2) the *Ask Me A Question* feature (members can ask questions prior to requesting a connection and then initiate the connection request); (3) the *Invites* feature (members can invite peers, colleagues, or friends to join MyNRMN and connect); (4) the *My Cohort* feature (institutions and organizations can bring their members to the platform to connect within the cohort and throughout MyNRMN); and (5) the *Administrative Match* feature (mentees can request a system administrator to initiate a mentoring request to a mentor). Because these features are relatively new, we did not include them in our results. Favorable initial data, however, demonstrate the value of continually adding novel features. Providing the online platform to facilitate mentoring connections, in conjunction with providing additional professional development resources and multiple, easy-to-use enrollment options, has aided the growth of MyNRMN, which now has 30,000 users (as of April 2024). Developing new strategies to promote networking connections may further support MyNRMN platform engagement for additional resources.

We were successful in increasing enrollment on our platform and understanding users' preferences for the enrollment form. However, we identified a limitation in our A/B testing process, and we believe that a longer testing period and more iterations could provide us with more data for enhancing the user enrollment process. In our future work, we will aim to study how we can encourage participation from underrepresented groups, such as Native Hawaiian or Pacific Islander individuals or people who do not identify within the gender binary.

Future Directions

The MyNRMN platform's goal is to ensure that mentoring connection requests are seen and are acted upon. Requests to connect are too frequently languishing, especially those made through the *Recommendations* feature; these may appear less personally targeted than those made through other features. Therefore, we are examining how to strengthen the relevancy of our recommendation algorithm by using machine learning and our graph database for more tailored recommendations. To nudge those receiving a connection request, the platform will remind members immediately upon logging in and will also send email reminders. To ensure that the enrollment and connection emails are received, we will continually monitor spam filter rules and comply with changes and updates that are implemented by email services. In addition, pending requests

for connections will be displayed prominently on the dashboard or as a pop-up.

Our goal is to quickly increase each new member's network from the initial node of 1 to an ever-widening web of connections. We plan to begin including embedded recommendations in a monthly email. In addition, when a connection is accepted, the confirmation email will include additional recommendations.

Conclusion

We built a platform for online mentoring to meet the needs of our members and to add value by increasing their connections. By conducting the A/B testing of enrollment forms, we were able to identify and overcome a barrier to enrollment and thus provide mentoring, networking, and professional development resources to a broader audience, which in turn promotes the

diversification of the biomedical workforce. We continue to evaluate our paradigm and improve our engagement. Many of our ideas are generalizable to those building other membership networks. These entities can learn from our experience that creating multiple pathways, such as by providing social media options for account creation, achieves better results than a single track and that removing sensitive questions, such as those about gender and sexual identity, can attract a more diverse membership. For MyNRMN, our key value proposition is increasing network connections, which we achieve through the technology solutions described herein. By making the enrollment process less onerous and sensitive, ensuring that new members feel instantly welcome, and constantly developing and implementing novel engagement features, MyNRMN fosters an environment that engages an increasingly diverse population of mentors and mentees.

Abstract

Background: Web-based physical activity interventions often fail to reach the anticipated public health impact due to insufficient use by the intended audiences.

Objective: The purpose of this study was to use a human-centered design process to optimize the user experience of the Interrupting Prolonged sitting with ACTivity (InPACT) at Home website to promote youth physical activity participation.

Methods: Qualitative interviews were conducted to assess engagement and pain points with the InPACT at Home website. Interview data were used to create affinity maps to identify themes of user responses, conduct a heuristic evaluation according to Nielsen's usability heuristics framework, and complete a competitive analysis to identify the strengths and weaknesses of competitors who offered similar products.

Results: Key themes from end user interviews included liking the website design, finding the website difficult to navigate, and wanting additional features (eg, library of watched videos). The website usability issues identified were lack of labeling and categorization of exercise videos, hidden necessary actions and options hindering users from decision-making, error-prone conditions, and high cognitive load of the website. Competitive analysis results revealed that YouTube received the highest usability ratings followed by the Just Dance and Presidential Youth Fitness Program websites.

Conclusions: Human-centered design approaches are useful for bringing end users and developers together to optimize user experience and impact public health. Future research is needed to examine the effectiveness of the InPACT at Home website redesign to attract new users and retain current users, with the end goal of increasing youth physical activity engagement.

Introduction

Physical activity is one of the most efficacious pathways to promote child health, well-being, and academic achievement [1,2], yet most children and adolescents in the United States are classified as inactive. Less than half (42%) of children ages 6-11 years participate in the recommended 60 minutes of daily physical activity, and this percentage declines as children transition into adolescence [3-5]. Children living in low-resource communities report even lower rates of physical activity [6,7], and the recent COVID-19 pandemic exacerbated these disparities [8,9] by contributing to a 17-minute decline in youth physical activity [8-10]. We have an urgent and unmet need to increase youth physical activity engagement to improve child and adolescent health.

The COVID-19 pandemic also brought renewed attention to prioritizing virtual methods of physical activity promotion as families were sheltering in place and children were attending schools online [11]. Web-based interventions have the potential to improve youth physical activity participation because of their extensive reach, high convenience, immediate feedback, diverse delivery formats, anonymity, and use across different contexts [12-14]. Web-based interventions can reach children and adolescents nearly anywhere at any time through desktops, laptops, and mobile devices [15,16]. Because this generation of children and adolescents spend large amounts of time watching or using screens (4 - 6 hours per day for children ages 8 - 12 years and up to 9 hours for teens) [17], web-based interventions represent a feasible and accessible strategy to promote youth physical activity engagement.

Evidence is lacking, however, for achieving sustainable physical activity behavior change through the internet. A recent review of web-based physical activity interventions highlighted that despite large developments in internet technology and knowledge of how to design and implement web-based physical activity interventions, website quality remains low [18]. These websites also provided limited social support and educational content [18].

Families play a crucial role in shaping a child's activity levels by providing various forms of social support [19,20]. This support includes encouragement, participating in activities together, and observing a family member's involvement in physical activities or sports. For instance, Tandon et al [21] found that in predominantly White households, parental support was linked to an extra 12 minutes of moderate-to-vigorous physical activity per day. Similarly, a study by Graham et al [22] in a diverse population showed that parental support, including role modeling, influenced adolescent activity levels.

Our Interrupting Prolonged sitting with ACTivity (InPACT) at Home program, for example, confirmed the importance of parental support. InPACT at Home was a television and web-based intervention designed to help elementary and secondary school students in kindergarten through grade 12 (K-12) stay physically active and maintain healthy lifestyles during the COVID-19 pandemic [23]. Our preliminary research assessing the feasibility of children using InPACT at Home exercise videos demonstrated that parents encouraging their children, reminding them, and establishing schedules and routines significantly facilitated participation in the program (LR Beemer et al, unpublished data, 2024). These findings underscore the pivotal role of parents in promoting virtual home-based physical activity for youth. Consequently, the design of the InPACT at Home website targets parents, where parental engagement leads to parent support and subsequent increased participation by their children in the exercise videos.

Problems associated with attracting, engaging, and retaining participants in web-based interventions have also been observed [24,25]. While the reach of the InPACT at Home program through public television broadcasting averaged 15,000-20,000 daily viewers, there were only 23 registered users on the program website 1 year after the program launch (website data unpublished). These findings illustrated the potential need for enhanced website design quality and the incorporation of end user input to reach the intended audiences and achieve the planned behavior change.

Proper design has become a critical element needed to engage website users. Poorly designed websites may frustrate users and result in a high "bounce rate," or people visiting the home page without exploring other pages within the site [26]. On the other hand, a well-designed website with high usability has been found to positively influence visitor retention (revisit rates) and engagement behavior [27,28]. A comprehensive analysis of the usability heuristics of the InPACT at Home program website was not conducted before its launch. Human-centered design represents a unique approach for tailoring web platforms to fit end users, narrowing the gap between efficacious interventions and public health impact. This approach places end users (ie,

real people) at the center of the development process, enabling website developers to create programs and platforms that are tailored to the intended audiences' needs. The end users' wants, pain points, and preferences are prioritized during every phase of the process to enhance engagement and accessibility of the web-based program [29]. Given the problems associated with attracting, engaging, and retaining users to the InPACT at Home program website, the purpose of this study was to use a human-centered design process to evaluate and optimize user experience to promote website engagement and subsequent youth physical activity participation.

Methods

InPACT at Home Program

The InPACT at Home program is an evidence-informed family physical activity program that uses high-quality instructor-led physical activity videos to promote exercise in the home [23,30]. The InPACT at Home website is run on a WordPress platform, hosted by the university, and was developed by a professional web design company. The website is published publicly with log-in features to allow both the program developers and end users to track their completed activities and rewards. End users are awarded badges upon completion of the exercise videos. This feature was added based on previous research conducted in classroom settings that demonstrated significant improvements in youth moderate-to-vigorous intensity physical activity engagement when game design elements were added to the program [31]. Rewards have also been identified as facilitators of youth participation in virtual reality exergaming interventions [32].

A "Challenges" page was added to the website to highlight one health theme each month. Finally, to encourage mindfulness after each workout a postworkout survey was added to the website. End users are encouraged to answer the following questions: "In one or two words, please describe how participating in physical activity makes you feel?" and "If you could tell your friends one or two words about why physical activity is important, what would you say?" Previous research has demonstrated that engaging in self-reflection activities after a positive exercise experience can aid in the continuance of the behavior [33].

Physical education teachers, fitness professionals, pediatric exercise physiologists, athletes, and high school students from across the state of Michigan were recruited and hired to develop exercise videos that were developmentally appropriate and could be completed at home with no or minimal equipment. The types of exercises included were aerobic, isometric strength training, motor skills, sports skills, yoga, and mindfulness training. To supplement the exercise videos, physical activity play cards and family engagement tool kits were developed to provide another opportunity for children and families to move and play together. The movement-based play cards included cardio, strength, mindfulness, flexibility, and "with a buddy" activities. School psychologists, regional school health coordinators, and teachers from across the state of Michigan were hired to develop family engagement tool kits that focused on the following topics: resilience, well-being, focus, nutrition, sleep, family team

building, family discussion, personal best, health choices, lifelong skills, substance misuse, schedules, and routines. Each module also included a 20-day challenge that incorporated movement activities. All program materials are hosted on the InPACT at Home website [34].

Recruitment

Parents of children and adolescents in grades K-12 (ages 5 - 17 years) were recruited to participate in this study using a variety of methods: registration opt-in for user research on the parent permission form on the program website, advertisements on the university clinical trials website, and sending out email advertisements to current users. Participants were eligible for inclusion in this study if they had a desktop computer and internet access in their homes, were able to answer questions and complete tasks on a computer, and were able to understand English. Participant eligibility was determined by parents answering a screening questionnaire, after which a member of the research team contacted them by email to confirm their eligibility and schedule the interview. Informed consents were obtained before the start of the study via a web-based survey using Qualtrics software (Qualtrics International Inc). If participants did not agree to participate in the study, the survey ended.

Qualitative Interviews

One-on-one semistructured interviews with parents of child users were conducted to assess engagement and pain points with the InPACT at Home website. Pain points were defined as specific problems faced by current or prospective website users and included any problems the user experienced when engaging with the website [35]. Interviews were conducted by trained research staff using videoconferencing. Four trained research staff members, all fourth-year undergraduate students at the University of Michigan School of Information, conducted the data analysis. Their training involved four years of coursework and real-world experiential learning through internships within the university's school. The same research staff conducted all aspects of the research study.

Purposive sampling was used to select participants from the pool of participants who responded to the advertisement. The criteria used for selection included accounting for diversity in race, gender, and age of their child. Using a standardized interview schedule, all participants were asked the same interview questions. Interviewers also asked additional unplanned questions to further assess new information introduced by participants. During the interview, interviewers were able to see participants' computer screens. Interviews ranged from 45 to 60 minutes in duration and were audio recorded and transcribed verbatim using a transcription company. Participants were compensated US \$25 for their time.

Affinity Mapping

An affinity map involves gathering qualitative information about a target population and organizing it into categories. Initially, it is a useful method for compiling extensive information and data about users from various stages of development, such as user testing, surveys, observations, and feedback collection.

The goal is to create an affinity diagram, a tool that visualizes the brainstorming process.

Professional user experience teams typically follow a flexible set of instructions, starting with selecting a topic, forming a cross-functional team, gathering facts and ideas, categorizing items, and devising an action plan. Throughout the session, team members collaborate to generate ideas pertinent to the chosen topic, with each brainstorming session yielding potentially different outcomes. An essential principle of affinity mapping is the absence of absolute right or wrong ways to categorize data; different teams may interpret the data differently and create distinct groups of data points based on collective decisions.

Approaching the data with a fresh perspective is advisable, avoiding premature labeling based on past experiences, as each data set is unique. Moreover, there are no rigid rules on how observations should be articulated; the focus is on gathering data in a manner that aligns with the team's dynamics.

Using a phenomenological approach, a thematic content analysis was used to examine the data and identify themes that elucidate each participant's experiences with physical activity programming and the InPACT at Home website. Qualitative data from semistructured interviews were organized into an affinity map using Miro software version 3.11.8 (RealTimeBoard, Inc).

The research staff reviewed the qualitative information, jotting down each observation on a movable card (ie, sticky note). The visual aspect of using sticky notes aids the team in physically visualizing connections between key data points, facilitating a literal connection between ideas. Sticky notes also allow for easy rearrangement and modification of groupings throughout the brainstorming process. The raters collaborated in a single room to jot down observations and identify themes, benefiting from collective brainstorming and free exchange of thoughts.

Using a large whiteboard, patterns in the observations were identified and categorized into groups. Each group was named, and a summary statement was provided regarding what was learned about each group. The analysis team also looked for outlier observations to understand instances where individual participant perspectives differed from the main findings, thus allowing for multiple perspectives and mitigating bias. Regular research meetings were held throughout the data analysis process with research team members possessing qualitative expertise to discuss the progress.

Heuristic Evaluation

A heuristic evaluation serves to systematically review the current state of a product, identifying usability and experience issues [36,37]. This evaluation is conducted based on Jakob Nielsen's 10 usability heuristics, which are high-level guidelines grounded in an understanding of human behavior, psychology, and information processing. These principles cover various aspects such as system status visibility, matching with the real world, user control, consistency, error prevention, recognition over recall, flexibility, minimalist design, error recovery assistance, and the provision of help and documentation [38]. These

heuristics can be grouped into four main quality components: learnability, efficiency, memorability, and error management.

The term “heuristic” refers to a rule of thumb, and this process is particularly valuable in the early stages of a project due to its cost-effectiveness in analyzing the product being worked on. While it does not replace user research, it aids in identifying and defining the problems within a product. For instance, during evaluations of the InPACT at Home website using Figma software version 3.30 (Figma, Inc), usability issues were identified through the Nielsen process. These issues, such as dead links leading to a blank screen, were detected during internal product evaluations.

All issues identified during evaluations are based on team member observations, while the affinity map consolidates key data points from various sources collected before the evaluation. These data points, derived from user surveys and interviews, represent insights from the target users. Initially, all identified issues are assessed for severity to prioritize them effectively.

Each evaluator assigned a severity rating to usability issues on a scale of 0 (ie, no issue) to 4 (ie, usability catastrophe), accompanied by documentation of the specific violation and recommendations for fixing the problem. These ratings reflect a consensus reached by the group of evaluators, and they help guide decision-making regarding issue resolution.

Competitive Analysis

The purpose of conducting a competitive analysis is to gain strategic insights into how your product compares to the design solutions offered by competitors. This analysis covers various aspects such as functions, features, user flows, and the emotional response elicited by competitors’ products. The goal is to strategically design your product to outperform the competition. Typically, this analysis is conducted initially to understand how you want your new product to differentiate itself. However, it is beneficial to approach this process iteratively, as competitors are constantly evolving. The key is to draw inspiration from competitors’ solutions and determine what aligns best with your product and its intended users.

We specifically selected the Presidential Youth Fitness Program, YouTube, and Just Dance because we believe their features closely align with those of InPACT at Home. Presidential Youth Fitness Program offers a youth fitness training program aimed at promoting health-related fitness and providing quality resources for physical education, which aligns well with InPACT at Home’s goals of engaging families and promoting physical activity. Similarly, YouTube offers a vast array of functionalities, including promoting healthy lifestyles, and its user-friendly video experience and large user base make it a strong competitor for analysis. Just Dance targets a younger audience and encourages active engagement through video platforms, aligning with InPACT at Home’s objectives. Therefore, we identified these three competitors for comparison based on their alignment with InPACT at Home’s goals and features.

The research team conducted a competitive analysis using Figma software to identify the strengths and weaknesses of InPACT at Home’s competitors offering similar online products

promoting physical activities. Research staff analyzed both direct and indirect competitors to identify gaps or opportunities that could give InPACT at Home an edge over its competitors [39]. Five aspects of each website were compared: target audience, first impressions, interactions, visual design, and content, chosen based on their relevance to InPACT at Home’s goals.

Each aspect was rated as “Outstanding,” “Good,” “Okay,” or “Needs work” based on the observed pros and cons. An example of a con for first impressions would be “too many features and complicated user flow,” while a pro would be a “clean, minimalist design.” Our approach involved individual reporting followed by consolidation to generate comprehensive insights based on key takeaways. Information from the competitive analysis was not compared against the InPACT at Home website for benchmarking but instead used as inspiration to determine what aligns best with our website and intended users.

Ethical Considerations

This study was approved by the institutional review board of the University of Michigan (HUM00192745).

Results

Overview

Of the 98 eligible participants who responded to study advertisements, seven parents of children in grades K-12 were contacted and agreed to be interviewed. There were three non-Hispanic White male participants, 1 Asian female participant, two non-Hispanic Black female, and one non-Hispanic White female (average age 41.3, SD 10.2 years). On average, parents had 1.6 (SD 0.8) school-age children (average age 8.4, SD 4.5 years) residing in their household. Of the seven parents, three reported being regularly physically active, and five parents reported their children participated in regular physical activity.

Affinity Mapping

Thematic saturation was achieved, and [Textbox 1](#) displays the themes and supporting quotes from participants derived from the qualitative interviews conducted. Participant interview responses were categorized into specific website components and included the following: landing/home page, video, current progress and badges, play cards, and overall experience with the website. Responses were further categorized into “likes,” “dislikes/struggled with,” and “wants” as they related to each component. The following themes emerged from the interview responses. The first theme related to “website likes” included the *website design*. Parents noted that they liked that the website was gamified, colorful, and included pictures. Parents also commented on the variety of exercises and resources available to parents. The second theme related to “website dislikes” included *difficult navigation*. Parents noted that there was too much scrolling on the home page. The reflection/record progress survey was difficult to find, and some parents were unable to find the play cards. Finally, the third theme related to “website wants” included *added features*. Parents suggested adding a progress button, a library of watched videos, and more information about the “Challenge” page.

Textbox 1. Themes emerging from the end user qualitative interviews.

Theme related to website likes: liked website design (eg, gamified, colorful, pictures, exercise variation, resources for parents)

- “The design is simple and a very colorful website.” (P02 Sarah)
- “More motivated to earn badges.” “Like how it provides resources for parents, not only kids.” (P07 Molly)

Theme related to website dislikes: difficult navigation (eg, too much scrolling on home page, reflection/record progress survey difficult to find, unable to locate play cards)

- “Too much information and scrolling on the home and landing page.” (P02 Sarah)
- “Could not find the record your progress survey button.” “Was expecting the survey to pop up immediately after finishing the video.” (P03 Matt)
- “Thinks the reflection survey process was challenging because had to click on the back button to go back to the original page.” (P04 Janice)
- “Did not know what a play card is so it was hard to find, and the search bar did not work on the website.” (P06 Nina)

Theme related to website wants: added features (eg, progress button, library of watched videos, challenge information)

- “It would be better if there was a feature that stated my progress to put the individual’s current physical activity progress.” “It would be nice to have a library to show already watched videos.” (P03 Matt)
- “Give more information about what kind of badges and what you can do with the challenges.” (P07 Molly)

Heuristic Evaluation

Table 1 presents the results of the heuristic evaluation conducted on the InPACT at Home website. For the heuristics of consistency and standards, and helping users recognize, diagnose, and recover from errors, the website received a score of 0, indicating that the evaluators did not perceive these as usability issues. Two other heuristic categories, recognition

rather than recall and help and documentation were assigned a score of 2, indicating minor usability problems. For three categories, namely match between the system and the real world, flexibility and efficiency of use, and aesthetic and minimalist design, the website received a score of 3, indicating major usability problems. Finally, the heuristics of visibility of system status, user control and freedom, and error prevention were rated with a severity score of 4, representing usability catastrophes.

Table . Heuristic evaluation for the Interrupting Prolonged sitting with ACTivity (InPACT) at Home website.

Heuristics	Violation	Recommendation	Severity
Visibility of system status	<ul style="list-style-type: none"> Does not show the user how much time they must wait before a new page is loaded. When the user clicks on the tab, there's nothing that indicates that the user has clicked on it or is currently clicking on it. 	<ul style="list-style-type: none"> Having a loading icon that pops up when the user clicks on a tab to go to another page to show the user that the new page is loading. When the user clicks on a tab in the navigation bar, have the tab color change to a different color to show the user that the system knows they're clicking on the right tab. 	4
Match between system and the real world	<ul style="list-style-type: none"> Require the user to think hard about what the category means and what the language implies. For instance, "Topics, Challenges" are not familiar categories to the user. They'll be thinking about what topics and challenges the website is referring to. 	<ul style="list-style-type: none"> Replace category names with more familiar categories to the user such as replacing "Topics" with "Explore." 	3
User control and freedom	<ul style="list-style-type: none"> Users do not have the control to exit the reflection survey after finishing watching a video. 	<ul style="list-style-type: none"> Add a button that allows the user to exit the survey if they do not want to fill it out. 	4
Consistency and standards	<ul style="list-style-type: none"> All pages are consistent. 	<ul style="list-style-type: none"> Nothing to change. 	0
Error prevention	<ul style="list-style-type: none"> The reflection survey leads to a dead screen, so users must click the back button to return to the InPACT at Home website. Users can accidentally click log-in on the register page, leading to users having no actual registration and needing to enter all personal information again. 	<ul style="list-style-type: none"> Include another button that allows the user to go back to the home page or have the original button add a new tab that can be closed. Remove the log-in option on the register page. 	4
Recognition rather than recall	<ul style="list-style-type: none"> Users must remember to scroll down to complete the reflection survey since it is not on a screen once you complete an activity. Users must remember which videos are their favorites for future uses. 	<ul style="list-style-type: none"> Move the reflection survey to within the screen when users finish a video/challenge. Incorporate a favorite section where users can easily see which videos they have enjoyed. 	2
Flexibility and efficiency of use	<ul style="list-style-type: none"> While there is an option for progress recording, the information is not displayed on the screen, hindering users from decision-making. Video titles are not descriptive enough to communicate the video content (eg, "Scott Przystas-Short Video 2"). 	<ul style="list-style-type: none"> Notify the users when they complete the video and guide them for progress recording. Subcategorize videos and make each title distinct to one another. 	3
Aesthetic and minimalist design	<ul style="list-style-type: none"> The profile section is not designed with proper grouping and colors—badge colors do not communicate their meaning. 	<ul style="list-style-type: none"> Include section that explains what each color represents or substitute the colored badges into word tags. 	3

Heuristics	Violation	Recommendation	Severity
Help users recognize, diagnose, and recover from errors	<ul style="list-style-type: none"> InPACT at Home uses this heuristic by providing error messages when the user tries to log in, and if the log-in is incorrect, there will be a message that says why the log-in is not working. 	<ul style="list-style-type: none"> Nothing to change. 	0
Help and documentation	<ul style="list-style-type: none"> Users must understand that their most recent badges and ranks are on their profile page. Users not only have to navigate back from the reflection survey but also must remember which video was most recently watched. 	<ul style="list-style-type: none"> Incorporate a notification that users have earned a badge or reward right after it was achieved. Either a banner or pop-up notification, so users do not need to remember or navigate anywhere else. 	2

Competitive Audit

Table 2 displays the competitive audit comparing the online physical activity experience of each website. YouTube received the highest ratings of the three competitors with “outstanding” ratings in six of the seven categories (ie, desktop web/game experience, accessibility, user flow, navigation, brand identity,

and descriptiveness). Just Dance received the second highest ratings with “outstanding” ratings in five of the seven categories (ie, desktop web/game experience, user flow, navigation, brand identity, and descriptiveness). The Presidential Youth Fitness Program website was the lowest-rated website with “good” ratings in three of the seven categories (ie, navigation, brand identity, and descriptiveness).

Table . Competitive audit comparing the online physical activity experience of the Presidential Youth Fitness Program (PYFP), YouTube, and Just Dance websites.

	First impressions	Interactions				Visual design	Content	
	Desktop web/game experience	Features	Accessibility	User flow	Navigation	Brand identity	Tone	Descriptiveness
PYFP	<p>Okay</p> <ul style="list-style-type: none"> (+) Clean design (-) Too many features and complicated user flow 	<p>Okay</p> <ul style="list-style-type: none"> (+) Resource guide for parents and educators (+) Awards store for recognition (-) No progress recorder (-) Not able to log in unless users are part of the organization 	<p>Needs work</p> <ul style="list-style-type: none"> (+) Video speed options (+) Only offers 1 language: English (-) No subtitles or closed captions (-) No color-blind mode 	<p>Needs work</p> <ul style="list-style-type: none"> (-) Overwhelming number of user interface elements and content 	<p>Good</p> <ul style="list-style-type: none"> (+) Clear indication of clickable elements (-) Some unfamiliar navigation patterns 	<p>Good</p> <ul style="list-style-type: none"> (+) Visual design communicates organization ethos (-) Visual design does not always support content intuitively 	<p>Professional and informative</p>	<p>Good</p> <ul style="list-style-type: none"> (+) All key information is present (-) Too descriptive

Discussion

Principal Results

Given the problems associated with attracting, engaging, and retaining users to the InPACT at Home program website (15,000-20,000 daily viewers through public television broadcasting vs 23 registered website users) [23], the purpose of this study was to use a human-centered design process to evaluate and optimize the user experience to promote website engagement and subsequent youth physical activity participation. Using qualitative methodologies and evidence-based heuristic evaluation approaches, we conducted a series of assessments to examine end user engagement and pain points as well as completed a competitive analysis to identify the strengths and weaknesses of competitors who offered similar products. Both the affinity maps developed from end user interviews and the heuristic evaluation of the InPACT at Home program website revealed several major problems and usability catastrophes in three of the four Nielsen quality components: *learnability*, *efficiency*, and *errors*. All these issues resulted in low usability (difficult to navigate) of the InPACT at Home program website and likely contributed to the low user retention (registration rates) and engagement behavior previously observed. The competitive analysis identified YouTube as the highest-rated competitor with “outstanding” ratings and revealed key features that the InPACT at Home program website could benchmark (ie, desktop web/game experience, accessibility, user flow, navigation, brand identity, and descriptiveness). Taken together, these findings suggest the InPACT at Home website needed numerous modifications to enhance usability. Appropriately,

the YouTube website interface provided a road map by which we could improve our design interface to fit end user goals and preferences.

Comparison With Prior Work

Previous research has demonstrated that parent support is an important determinant of child and adolescent physical activity participation. Data from vEngage, a virtual reality exergaming intervention, suggest that while parents would rather their child perform “real-world” physical activity, they believed the key to engagement was through technology and were willing to support their child’s participation in exergaming [40]. Our recent findings from the InPACT at Home program demonstrated that parent support in the form of encouraging their children, reminding them, and establishing schedules and routines significantly facilitated participation in the program (LR Beemer et al, unpublished data, 2024). These findings provide the rationale for why parents were selected as the target audience. Understanding the pain points of parents in using the InPACT at Home website was vitally important to achieving a “trickle-down effect” for child engagement, and accordingly, issues with learnability, efficiency, and error needed to be addressed.

Nielsen’s usability heuristics framework conceptualizes *learnability* as the ease with which users can accomplish basic tasks the first time they encounter the website design [41]. The goal is to design a clear interface that users can quickly learn and understand. Previous research has demonstrated that users can receive more value from a website with high learnability compared to websites with lower learnability [42]. This is due

in part to users being able to adopt the learnable interface much quicker and subsequently accomplish their goals in a shorter amount of time using the website. By having an easier time navigating the website, users will also have an overall better experience with the website, which can contribute to a better retention rate and lower bounce rates [43,44]. Best practices for creating a learnable interface include consistency (eg, giving all the web pages a similar look by positioning elements in the same location), feedback (eg, link color changes that tell the user that an element is clickable), using well-known user interface elements (eg, sticking to industry design best practices), familiarity (eg, user can learn the new interface based on previous knowledge), and testimonials (eg, visual storytelling enabling users to learn and remember information).

In this study, the *learnability* of the InPACT at Home website was deemed low as the program website did not provide timely feedback and used unfamiliar concepts, thereby increasing the time needed to learn how to use the website. The website also contained extraneous information that competed with relevant information needed to complete a task, making it difficult for the end user to understand how to use the website. Themes from end user interviews also confirmed that the website was difficult to navigate. Accordingly, substantial attention to creating a learnable user interface on the InPACT at Home program website was needed to optimize user experience and engagement with program resources.

The *efficiency* of the InPACT at Home website was also deemed low, and *errors* were deemed high. Efficiency measures the speed (or quickness) with which a user can accomplish a task once they have become familiarized with the website design [45]. In other words, *efficiency* is the number of keystrokes or clicks it takes a user to complete a task. Like *learnability*, the more efficient an interface design is, the greater value a user can gain from a website as they can complete a task in a shorter amount of time [27,42]. *Errors* on the other hand are software problems that come from a misconfigured website design, making it difficult to complete a task resulting in user frustration [45]. The InPACT at Home program website did not enable users to have control to exit the reflection survey after finishing watching a video; there were no options for progress reporting on the website, and video titles were nondescriptive; all these factors led to website inefficiencies. In addition, some pages on the website led to dead screens, and there were several error-prone conditions on the registration page; these factors contributed to errors on the website.

Optimization of the InPACT at Home Website

Based on the recommendations provided by the end users and website evaluators, we have made several updates to the InPACT at Home program website. To overcome the barriers related to *learnability*, we have created custom module content that can easily be searched and filtered by topic and automatically archived. Users can select the type of exercise videos they want to engage in as well as select the family engagement tool kit topics they are most interested in. A recent review identified personalization as a key mechanism of web-based interventions that elicited positive changes in physical activity behaviors [14]. To overcome the barriers

associated with *efficiency*, we have created a modified log-in process to direct the visitor to their content. Rather than having to scroll through all 132 exercise videos, their personalized profile page now hosts their preferred content, making resources quicker to access. To overcome the barriers with *errors*, we have identified and removed dead screens throughout the website and redesigned the registration page. The removal of these errors and error-prone conditions should reduce user frustration with the website.

To also be responsive to user preferences, we added exercise intensity levels to each video and a brief description of the video content to each video so that children know which activities they will be doing and what equipment is needed. We have also created QR codes for customized workouts to further enhance the personalization of the site. Many of these improvements were modeled after YouTube features identified in the competitive analysis for website design. Our next step in the website optimization process is to conduct additional user testing to confirm these updates are meeting end user needs. We will begin to monitor engagement with the website and program resources.

This study has several important strengths that are worth mentioning. First, we used a common evidence-based heuristic evaluation and competitive analysis to determine the usability of the InPACT at Home website. Second, analyses were conducted by experienced user interface evaluators and researchers with expertise in qualitative interviewing. Finally, our human-centered design approach enabled end users, evaluators, and website developers to come together to evaluate and optimize the user experience to increase website engagement and eventual youth physical activity engagement.

Limitations

Limitations of this study also warrant attention. First, we acknowledge that our parent sample exhibits some diversity; however, it is essential to consider other characteristics to ensure a truly diverse sample in this context. These include the age range of children from K-12, geographical distribution, levels of digital literacy, income levels, and patterns of technology use. Further testing may be necessary to ensure that the InPACT at Home website adequately caters to the diverse needs of parents and families across the state of Michigan and beyond. Second, there were few existing registered users at the initiation of this analysis; hence, most of the interviews were conducted with parents who were unfamiliar with or not currently using the InPACT at Home website. This could have led to biased responses and recommendations that are only appropriate for first-time users. Third, while 98 eligible participants responded to study advertisements, time and cost constraints limited our ability to conduct more interviews. Nevertheless, we did achieve thematic saturation, and many of the themes identified in the qualitative interviews were confirmed in the heuristic evaluation. Fourth, we used subjective assessments (evaluator ratings) to determine the accessibility and usability of the InPACT at Home program website, thereby increasing the potential for inconsistency in scoring. To overcome this limitation, all four evaluators completed the affinity mapping and heuristic evaluation together; scores reflected a group consensus. The

competitive analysis was completed independently (ie, each team member researched one competitor) and then discussed as a group. Finally, the observational nature of the study precluded our ability to directly conduct comparative user testing of the InPACT at Home website along with its competitors. Despite these limitations, our analysis provided valuable information to our website developers from experienced evaluators and end users that enabled us to make substantive changes to the website to improve usability.

Conclusions

Most children in the United States are classified as inactive because they do not participate in the recommended 60 minutes of physical activity per day [1,2]. Online and web-based interventions have the potential to improve physical activity engagement because of their extensive reach and accessibility across different contexts [14]. Because this generation of

children and adolescents is the first to have their entire childhood influenced by the internet and mobile devices [46], web-based interventions may be uniquely positioned to promote sustainable physical activity participation in this age group. Like most other web-based physical activity interventions, the InPACT at Home program website failed to reach its anticipated impact due to insufficient use by the intended audiences. Problems associated with attracting, engaging, and retaining participants in web-based interventions were likely the result of using a website design with low *learnability*, low *efficiency*, and high *errors*. Human-centered design was an evidence-based approach for optimizing the InPACT at Home program website to fit end user goals and preferences. Behavioral interventionists should consider conducting a comprehensive usability heuristic evaluation *before* the website launch to narrow the gap between efficacious interventions and public health impact.

Acknowledgments

We would like to thank Insun Kim, Alaa Shahin, Dr Florian Schaub, and the University of Michigan School of Information client engagement team for their helpful assistance throughout the research process. We are also grateful to our study participants and their families for their involvement. Finally, we are appreciative of the team of website developers who created the website and made subsequent improvements. The results of this study are presented clearly, honestly, and without fabrication or inappropriate data manipulation.

Abstract

Background: Wearable devices have been used extensively both inside and outside of the hospital setting. During the COVID-19 pandemic, in some contexts, there was an increased need to remotely monitor pulse and saturated oxygen for patients due to the lack of staff and bedside monitors.

Objective: A prototype of a remote monitoring system using wearable pulse oximeter devices was implemented at the Hospital for Tropical Diseases in Ho Chi Minh City, Vietnam, from August to December 2021. The aim of this work was to support the ongoing implementation of the remote monitoring system.

Methods: We used an action learning approach with rapid pragmatic methods, including informal discussions and observations as well as a feedback survey form designed based on the technology acceptance model to assess the use and acceptability of the system. Based on these results, we facilitated a meeting using user-centered design principles to explore user needs and ideas about its development in more detail.

Results: In total, 21 users filled in the feedback form. The mean technology acceptance model scores ranged from 3.5 (for perceived ease of use) to 4.4 (for attitude) with behavioral intention (3.8) and perceived usefulness (4.2) scoring in between. Those working as nurses scored higher on perceived usefulness, attitude, and behavioral intention than did physicians. Based on informal discussions, we realized there was a mismatch between how we (ie, the research team) and the ward teams perceived the use and wider purpose of the technology.

Conclusions: Designing and implementing the devices to be more nurse-centric from their introduction could have helped to increase their efficiency and use during the complex pandemic period.

Introduction

The popularity of portable wearable technologies that monitor health has increased substantially over the past decade due to their perceived utility, relatively simple implementation, and immediate feedback [1]. Wearable technology is used in both personal and clinical settings, and more recently in the context of the COVID-19 pandemic for diagnosis, remote monitoring, and other applications in both inpatient and outpatient settings [1-3]. Using wearable devices for COVID-19 care can result in infection control by reducing the amount of time that health care workers (HCWs) are physically with patients and providing continuous monitoring of vital signs for the early identification and potential treatment of deteriorating patients [2]. Specifically, remote monitoring of oxygen saturation using wearable devices became increasingly common during COVID-19 in hospital settings [4,5].

Despite the potential benefits, there have been many challenges noted in implementing and using wearable devices during COVID-19, including technical, social, and political spheres [1]. Technical challenges often include battery life, Wi-Fi or Bluetooth connections, and device communication. A few examples of social challenges are patients lacking technological confidence (eg, in older patients) and repeated device alerts or continuous monitoring making patients nervous, while political challenges could include regulatory issues for expanding the approval of devices for COVID-19-related medical situations [1]. Many of these challenges may be enhanced in low- and middle-income countries (LMICs), while the need for such integration is crucial, especially during pandemic situations [6,7].

There are several studies exploring the technical challenges of integrating wearable devices in trial settings during COVID-19 (eg, see [8]), but there is a lack of research surrounding the acceptability of such devices within these contexts and how attitudes may impact actual use [9]. Portable wearable devices could be a potential solution to allow for continuous monitoring of vital signs remotely and affordably for COVID-19 wards in LMIC settings; however, while advantageous, these devices cannot meet their full potential if the users do not agree to use them or realize their potential value [10]. Understanding user perceptions and needs as well as the context in which the technology is implemented is crucial for successful implementation [1]. User-centered approaches stress the importance of integrating both human factors and technical factors [11] while also paying attention to avoid excluding certain populations in the design [7]. User-centered approaches have been cited as a “critical success factor” in a variety of health-related technology projects [12].

From August to December 2021, when COVID-19 cases were increasing more rapidly than at any time previously in Ho Chi Minh City, Vietnam, there was an opportunity to integrate a prototype wearable device and monitoring system into the COVID-19-designated wards at the Hospital for Tropical Diseases (HTD). At this time, the HTD was overwhelmed with patients with COVID-19 and we needed to deploy something urgently that could help. Using pragmatic methods during the

rollout of the device, we describe stakeholders’ use of the wearable device, aspects of acceptability, and under which circumstances its use would be most beneficial for improving the care of patients with COVID-19. The primary objective of this work was to support the implementation process of the wearable device in the hospital to improve patient care during a catastrophic period of the COVID-19 pandemic in Ho Chi Minh City, Vietnam.

Methods

Study Setting

This work took place within a larger project called the Vietnam ICU Translation Application Laboratory (VITAL) at the Oxford University Clinical Research Unit (OUCRU) and HTD. The goal of VITAL is to design and implement innovative technologies to improve patient care within the intensive care unit (ICU) at the HTD, with a longer-term goal of expanding these technologies regionally. In addition to the clinical and technological studies, there is an ethnographic study to explore the sociotechnical contexts of the ICU at the HTD and within ICUs in Vietnam more broadly. The VITAL multidisciplinary team was in place at the start of the COVID-19 pandemic.

In the first 100 days of the COVID-19 pandemic, Vietnam rapidly implemented a variety of public health measures resulting in relatively few cases and zero deaths [13]. Since that time, there were a few concentrated outbreaks (for example, in Da Nang in July 2020 and December 2020 in northern Vietnam). In May 2021, the cases started to increase on a countrywide basis, and by August 2021, the hospitals began to fill with patients with COVID-19. It was within this pandemic context that the wearable device was implemented at the HTD, and the VITAL study teams worked together throughout to improve its implementation.

The wearable device was selected by the company and was already integrated into a locally developed platform based on an available application programming interface, licensing, and availability. The device was medical grade and measured heart rate and blood oxygen levels, similar to a pulse oximeter. The wearable device was battery powered and each one connected to a tablet that was kept at the patients’ bedside. The tablets had a 3G or 4G sim card and sent the data to a cloud where multiple patients’ data were viewable by HCWs outside the patients’ rooms and isolation area.

Study Design

The aim of this work was to support the ongoing implementation of the wearable device rather than to follow a predefined, replicable study protocol, as would be used in trial settings, for example. Therefore, the work here describes the pragmatic rollout of the device. We used an action learning approach, including integration of multiple methods to assess the use and acceptability of the wearable device [14]. Action learning approaches rely on an iterative process of assessing local contexts, learning from relevant stakeholders, and using the information to improve an implementation or further develop a technology specific to the context [15,16]. As the wearable device started to be implemented in the HTD wards, our team

of HCWs, social scientists, and technology developers took the opportunity to work together to inform the implementation. Therefore, we adapted the methods as the situation changed and more insights were gained [14].

Participants

Potential participants included the HCWs from the HTD who were using the device in the wards during the implementation and corresponding ward heads. We estimated that a total of 30 doctors and 60 nurses would have worked in the wards where the wearable device was implemented and potentially used it in some form; therefore, we planned to recruit participants from this larger sample.

Data Collection Methods

Informal Discussions and Observations

We used an iterative process of engaging in informal discussions coupled with sense-checking discussions and observations during the implementation period. The informal and sense-checking discussions and observations were conducted with the team who was working directly in the wards, as well as with head nurses from the wards where the wearable device was being implemented. The informal discussions and observations were conducted during the implementation of the device.

Feedback Survey Form

We created the feedback form based on the components of the technology acceptance model (TAM) to assess the use and acceptance of the device. The TAM is used in a variety of disciplines to determine how individuals accept (or not) and use (or not) a given technology. Davis [17] developed this model based on components from the theory of reasoned action [18] and it consists of the following variables: use motivation (with perceived ease of use and perceived usefulness) and behavioral intention [17,19]. The model suggests that an individual will accept the use of a technology (ie, their behavioral intention) based on their perception of the technology's usefulness and ease of use. Perceived usefulness refers to the perception that using the technology will enhance one's work; for example, the wearable device will provide physicians and nurses some advantages (eg, remote monitoring). Perceived ease of use refers to the perception that the use does not add more work or effort to the work that could be enhanced; for example, using the wearable device will not increase nurses' workload, despite its utility and simplicity [17]. The TAM framework was expanded twice to include attitudes as well as several other external factors [20]. The use of the TAM in health research has shown how perceived usefulness and perceived ease of use relates positively to attitude and behavioral intention [21]. The TAM has been criticized for being insensitive to the context or social factors, being simplistic, and following an assumption that users are rational decision makers, when indeed other factors play into decision making [22-24]. We used the TAM framework for its simplicity and because the categories of perceived usefulness and perceived ease of use were of relevance, but we also integrated other data collection methods alongside it to counter these limitations to some extent.

Based on the components of the TAM, we included 23 questions related to usefulness (n=5), ease of use (n=5), attitude (n=5), and behavioral intent (n=8) [25]. We asked these questions using a 5-point Likert scale (with scores of 5 being more favorable). We also added 2 open-ended questions and collected a variety of relevant demographic information ([Multimedia Appendix 1](#)). We piloted the tool in both English and Vietnamese and adjusted the form as needed. We used Google forms for electronic self-completion of the form and offered paper forms for hand-written self-completion. We explained the feedback form to the ward staff during team meetings and provided the link. The feedback form was distributed and completed in Vietnamese. We kept the feedback form link open for 7 weeks in total and started data collection after the implementation had been integrated into the wards so that users would have had experience using the device.

User-Centered Workshop

We held a user-centered workshop with a selection of HTD ward staff to explore user needs and ideas for development in more detail. Because we already had the technology and knew the spaces where implementation would be held, we followed an adapted version of the process described by Cooper et al [26]. With this approach, the workshop participants and facilitators set the scene as a busy COVID-19 ward during the peak of the pandemic. Then, the facilitators described the shells of users (personas), including a nurse and a doctor persona shell, and we had the workshop attendees describe who they imagined the nurse and doctor to be, as well as their behaviors and needs and the values each user group would find most essential. We based the conversation on the wearable technology that the participants had already used. Then, the group discussed solutions to the issues identified [26].

Data Analysis

Using the principles of action learning, we integrated the responses from informal discussions and observations into subsequent data collection, as well as summarized the content and grouped it into themes. For the analysis of the feedback survey form, we calculated mean scores for each variable and compared scores by profession. For the open-ended survey questions, we used content coding to summarize the responses topically. We presented the demographic data descriptively. We documented the responses from the user-centered design workshop as notes and summarized the results into main themes.

Ethical Considerations

In this paper, we are describing the processes that occurred as part of the development and implementation of a monitoring system; therefore, the work did not require ethics approval. Prior to the initiation of any activities, we held a meeting with ward heads to describe the work in more detail and obtain their agreement.

Results

Device Implementation Within the HTD Context

The wearable device was implemented in 3 wards starting in August 2021, including the adult ICU, Ward A, and Ward E.

We describe the implementation over a 5-month period from August to December 2021. During this period, these wards changed from COVID-19–designated and then back again to routine patient care settings, depending on the number of patients. Although the HTD was one of the COVID-19–designated hospitals, throughout the pandemic they offered routine patient care for specific diseases (eg, tetanus).

In addition to the rapidly changing physical spaces, the hospital management quickly deployed remote monitoring capacity using existing closed-circuit television cameras as a temporary solution to monitor very sick patients from outside the patients' rooms. The remote monitoring was useful as it allowed for multitasking and prevented nurses and doctors from checking on patients more routinely in person. The hospital wards were at capacity during the study period. Prior to the pandemic, however, it was not unusual for the wards at the HTD to often be at maximum patient capacity. For example, in the adult ICU or during the rainy season, the number of dengue patients increases dramatically and the wards tend to be full.

Also, the workflow was organized differently during the pandemic period. Instead of nurses taking care of a few specific patients for the whole shift, 2 nurses and 1 doctor would instead go into the ward (in full personal protective equipment) as a team for 3 hours at a time while the other 2 nurses on shift completed admin work in the office. This meant that more coordination was needed, and often the team with the patients “need[ed] someone else to be [their] memory” as it was not easy to remember everything about all patients. The health care team’s workload, especially that of the nurses, ended up being more extensive for many reasons. One important reason is that, because of COVID-19 restrictions, there were also no families allowed in the wards who would help to look after patients in non–COVID-19 times; therefore, the majority of the care was

left to the nurses. The patients were also more severely ill than previously in these wards and required more care by fewer staff.

Device Use and Acceptability

When we first distributed the feedback form, out of 90 potential participants, only 22 completed the survey (19 electronic and 3 paper forms), and 1 person stated that they did not use the technology and therefore no responses were recorded for that participant. Of the 21 respondents who completed the feedback form, 48% (n=10) were doctors and 48% (n=10) were nurses, with 52% (n=11) of the participants coming from Ward E (Table 1).

Overall, when assessing the TAM variables, the mean (SD) scores ranged from 3.6 (0.8) for perceived ease of use to 4.4 (0.6) for attitude, with behavioral intention (mean 3.9, SD 0.6) and perceived usefulness (mean 4.2, SD 0.7) scoring in between. Those working as nurses scored higher on perceived usefulness, perceived ease of use, attitude, and behavioral intention than did physicians (Table 2).

When asked, as an open-ended question, why participants would or would not use the wearable device in the future, of the 19 responses inputted, 15 participants wrote that they would use the system because of its convenience and usefulness in monitoring patients. However, in 2 of those responses, they also added comments that the device had limited perceived accuracy and transmission problems. Of the remaining 4 participants, 1 participant simply stated that the monitor was still in use, 2 participants wrote that they did not use the system anymore due to job location changes, and 1 participant wrote a few sentences about why the wearable device is not the “best choice,” highlighting its limited battery life, how the system had become additional work for the already overworked staff, and how it is not yet completely implemented.

Table 1. Demographic characteristics of the survey respondents (n=21).

Characteristic	Value
Gender, n (%)	
Women	13 (62)
Men	8 (38)
Age (years), median (IQR)	35 (30–38)
Occupation, n (%)	
Doctor	10 (48)
Nurse	10 (48)
Other: nurses' aid	1 (5)
Primary ward during the implementation phase, n (%)	
Adult intensive care unit	6 (29)
Ward A	1 (5)
Ward D	3 (14)
Ward E	11 (52)

Table 2. Mean technology acceptance model (TAM) scores by variable. The maximum score was 5.

TAM variable	All participants, mean (SD)	Nurses, mean (SD)	Doctors, mean (SD)
Perceived usefulness	4.2 (0.7)	4.3 (0.8)	4.1 (0.6)
Perceived ease of use	3.6 (0.8)	3.8 (0.7)	3.4 (0.8)
Attitude	4.4 (0.6)	4.6 (0.6)	4.2 (0.6)
Behavioral intention	3.9 (0.6)	4.0 (0.6)	3.7 (0.7)

Integrating User Perceptions for Improved Implementation

As part of the action learning process, we supplemented the feedback form results with data from the observations and informal discussions during the 5-month period. There were 3 main observations. First, there was a mismatch between how we (ie, the research team) and the ward teams perceived the use of the technology. We quickly realized, from our observations and from informal discussions with the implementation team, that many of the nurses either did not use the wearable device or did not think that they used it even if they used it in some aspect (eg, connecting the device for the patients or changing batteries). Even after we clarified what we meant by “use,” there were still not additional participants who filled in the feedback form because they felt like they did not use the technology.

Second, the ward teams had varying perceptions of the technologies that are routinely implemented by the OUCRU team in the HTD wards as part of research projects. We heard from informal discussions with colleagues that the nurses assumed the wearable devices were from a research project, as is often the case with OUCRU projects, and therefore the nurses, in particular, ignored the device even if they had some role in its use. They did not see its potential benefit.

Finally, in order to make the device more useful for the ward staff, we realized during the meetings and informal discussions with the team that we needed to make the implementation and use of the device more “pro-nurse,” meaning we would need to emphasize how the device and its data were also useful and relevant to them. When discussing with the head nurse, the data were only displayed on the main screen in the staff room for one department. One suggestion was to move the tablet to the wall so that the nurses and others in the room (including the patients) could potentially see their vital signs. Because the devices and corresponding data were not in sight, it was easy to think that it was not relevant for the nurses and made it easier for them to ignore the device while with the patients.

User-Centered Design Workshop

With the information we had learned from the informal discussions, observations, and feedback form, we held a follow-up workshop on January 17, 2022, to discuss how we could make better use of the technology in the wards in

COVID-19 situations in the future. The attendees included 2 doctors (1 man and 1 woman) and 3 nurses (2 women and 1 man). The participants discussed the behaviors and needs of the nurse and doctor persona. For both roles, the needs centered on having equipment and improved coordination. The nurses also mentioned more training needs, while the doctors’ needs were about the accuracy of monitoring (Textboxes 1 and 2).

There were 3 main value prop themes, including medical, technical, and patient themes. For medical aspects, the attendees discussed how the device should be able to provide highly accurate data, with appropriate alarms and cut-offs. For the technical theme, the device and software should be simple to connect and use, with a long battery life and stable connections during charging or switching devices. The display should be large and clear, and the data should be stored for a long period of time (ie, 7-10 days). Finally, for the patient theme, the device should be comfortable for the patients to wear to avoid them removing it.

There were several solutions discussed in the group to improve the use and efficacy of the wearable device (Table 3). Solutions included improving the credibility of the data, ideas to improve the ease of use, ways to make the alarms more consistent, and ideas for more ideal placement. One very specific issue that the group mentioned was that the alarms went off too much on the large display and the alarms were always red or black and blinking, and it was difficult to know if the device was turned off (due to patient discharge) or actually disconnected, which would require an intervention. The solution was to refresh the devices; however, if the alarms were excessive and not always indicating a real issue, trust in the device would remain low, so this was an important priority. They also suggested that the alarms and display on the tablet should be the same as the big screen, as they preferred screen consistency.

Another in-depth discussion was about moving the tablets to the walls and having the device plugged in all the time, which would solve the battery issues. They felt that the tablet could be set up on the wall but that brought up other issues about how to keep the device and watch safe after use. For some of the topics, the group used features of another wearable device that they had used in the wards in the past to inform their solutions (eg, device graphs and a line on the device for finger placement).

Textbox 1. Behaviors and needs of the nurses.

Participant: Nurse Van is a 36-year-old woman. She is an administrative nurse and has a management job. She likes to have fun and has a family and 2 children. She is also responsible for bringing the kids to school and back.

Behaviors:

- Visit and provide direct patient care and monitor vital signs
- Carry out medical orders (ie, medications, blood tests, and nutrition)
- Assess, monitor, and hand over patients
- Work night duty
- Night shifts inform doctors on vital signs as prescribed

Needs:

- Equipment (eg, to measure blood pressure, temperature, oxygen levels, and heart rate)
- Training on diseases
- Teamwork and coordination

Textbox 2. Behaviors and needs of the doctors.

Participant: Doctor Huong is a 30-year-old woman. She is flexible and very active. She is not married and has no children and currently lives in a hotel. She is on night shift every 4 nights, and at times she visits her home in another town in Ho Chi Minh City, which is far from the Hospital for Tropical Diseases.

Behaviors:

- Prescribe medications
- Update medical records
- Perform examinations and change treatments
- Data entry
- Check vital signs in patient rooms (with a portable monitor that they move around) for examination and to detect abnormalities

Needs:

- Equipment (eg, monitors)
- Coordination with nurses (progress: medical records)
- Re-evaluation and working with other doctors
- Accuracy of vital sign monitoring

Table 3. Solutions for improvement.

Topic	Specific solution
Data credibility	Adding a graph for signal strength
Ease of use	<ul style="list-style-type: none"> • Adding a finger placement mark on the device • Increasing the font size on the watch and tablet • Tablets should be fixed on the wall
Alarms	<ul style="list-style-type: none"> • Reduce the alarm colors and blinking on the screen • Use the same display on the screen and the tablets for consistency • Refresh the tablets for more accurate alarms
Battery issues	Keep the tablet plugged in
Device placement	Placement on the wall (but only with an increase in font size)

Discussion

The HTD and OUCRU teams, along with the technology company, rolled out the wearable device in an extremely complex pandemic situation with a prototype system. In the end, the team used the device on over 100 patients. We assessed the usability and acceptance of the device over the implementation period when COVID-19 cases were peaking in the hospital and into the period when the COVID-19 cases were reducing. Similar to the literature on the topics, we found that the importance of understanding the users and their experiences using the device was crucial to get the most use out of these technologies.

There was a mismatch between our perception of who was using the device and those who thought that they were using or benefiting from the device on the ground. From the start, the device was designed and set up with doctors in mind, but in practice, the nurses' roles and use were overlooked, even though they could also routinely use and benefit from the device. In our study, we found that the nurses who filled in the feedback form, on average, had slightly higher scores on 3 of the 4 TAM domains (ie, perceived usefulness, attitude, and behavioral intention), while the doctors, on average, scored the perceived ease of use slightly higher than the nurses. We know from the challenges with acquiring feedback that many nurses did not feel that they used the device even though they had some role in the device set-up and monitoring. Designing the device to be more nurse-centric from the early phases could have helped to increase the efficiency and definition of who is meant to use it. In the future, it is important to consider that the way the device is used might be dependent on the form of its use (eg, for triage, use in a pandemic emergency, or routine hospital use). We recommend the involvement of staff who could benefit from the technology, especially nurses in the hospital context, in the full implementation process. This could help to avoid mismatches in the perceptions of who the users are and who could and should benefit from the new technology. Research on integrating wearable devices during COVID-19 in Singapore also highlighted that device simplicity would encourage its use and the importance of making the technology fit into the current environment while not increasing or disrupting workflows [27].

The trust in the device and its data was an issue brought up several times during the implementation and feedback sessions. There are a variety of potential explanations for inconsistent data (eg, incorrect device placement or averaging of data); however, it reduced the credibility of the device for both doctors and, importantly, nurses. Data concerns about technology in clinic settings has been noted in other studies. For example, Faria et al [28] found that study clinicians reported that 36% of the data from a remote monitoring project were "invalid" for a variety of reasons, including low literacy of the patients and complexity of the device. Involvement from users from the beginning of the design and implementation process is crucial for design purposes but also to build trust and confidence in the devices [11]. While this project took place during COVID-19, which is a very specific circumstance, the broader findings resonate with research conducted prior to COVID-19 that focused on the implementation and scaling up of digital health technologies in LMICs. The recommendations also included integration of end-user feedback and engagement with all stakeholders throughout the design and implementation process [12].

There are limitations to this work. First, we did not collect data on the clinical worth or the accuracy of the data transmitted from the devices. Second, we focused on feedback from only health care staff (ie, doctors and nurses), and from only a subset of those who perceived that they used the device, which may have excluded some users and limited the overall sample size. We did not include patients who could also inform device acceptance, especially if used in noncritical cases where patients are moving around and conscious. Finally, the implementation setting for this work is not typical of other hospital settings in Vietnam or possibly other LMICs, as the HTD is a large referral hospital with an international research institute attached to it.

In anticipation of future (novel) pandemic situations or integration of wearable technologies into a range of clinical settings more broadly, it is important to fully understand if and how the wearable devices could be used more effectively by doctors, and importantly, nurses in the wards, for monitoring of deteriorating patients, especially in LMICs where resources are already stretched. Using an action learning approach during the implementation process highlights the importance of integrating user perspectives, ideas, and solutions into development and design.

Acknowledgments

We would like to acknowledge Nguyễn Đ i Phú and Nguyễn Th Tin from the Hospital for Tropical Diseases and Nguyễn Th Di m Trinh and Đ ng Ph ng Th o from the Oxford University Clinical Research Unit for their support and commitment in operating the remote monitoring system.

Abstract

Background: Promoting positive psychologies that promote resilience such as a growth mindset could be beneficial for young, unemployed adults, as many lack the self-esteem and self-efficacy to cope with job search adversity. These young people may be reached at scale through the web-based delivery of self-administered positive psychology interventions. However, past studies report unsatisfying user experiences and a lack of user engagement. A gaming-based experience could be an approach to overcoming these challenges.

Objective: Our research objective was to explore how young, unemployed adults experience a positive psychology intervention designed as a game to extract learning and principles for future intervention research and development.

Methods: To respond to the research question, a team of researchers at the University of Stavanger worked with designers and developers to conceptualize and build a gaming-based intervention. Feedback from the users was collected through formative usability testing with 18 young adults in the target group. Retrospectively, recordings and notes were transcribed and subjected to thematic analysis to extract learnings for the purposes of this paper.

Results: A total of 3 themes were identified that pinpoint what we consider to be key priorities for future gaming interventions for unemployed young adults: adaptation to user preferences (eg, need for responding to user preferences), empathic player interaction (eg, need for responsiveness to user inputs and a diverse set of interaction modes), and sensemaking of experience and context (eg, need for explicit presentation of game objectives and need for management of user expectations related to genre).

Conclusions: Feedback from end users in usability-testing sessions was vital to understanding user preferences and needs, as well as to inform ongoing intervention design and development. Our study also shows that game design could make interventions more entertaining and engaging but may distort the intervention if the game narrative is not properly aligned with the intervention intent and objectives. By contrast, a lack of adaptation to user needs may cause a less motivating user experience. Thus, we propose a structured approach to promote alignment between user preferences and needs, intervention objectives, and gameplay.

Introduction

Positive Psychology for Unemployed Young Adults

Young people who are not in education, employment, or training (NEET) comprise, on average, 12.8% aged between 15 and 29

years in the Organisation for Economic Cooperation and Development countries [1]. Studies show that negative self-perceptions and a lack of perseverance are barriers to successful labor market inclusion [2-4], as the new labor market requires highly skilled workers who are not afraid of change,

challenges, and acquiring new skills [5,6]. For young people with weak beliefs in their capacity to learn, this could be a major risk factor for labor market exclusion, and this may in turn impact their overall well-being. Several researchers have studied the relationship between unemployment and mental health. McGee and Thompson [7] found a relationship between unemployment and depression in young adults and suggested the use of psychological interventions for the young and unemployed. The Norwegian NEET group is more likely to be recipients of health-related benefits, have poorer mental health, and lower levels of education compared with the average of the Organisation for Economic Cooperation and Development [8,9]. A qualitative inquiry into young people's own experience of unemployment in Norway points to poor self-efficacy and lack of self-esteem that are reinforced through challenges and setbacks, even when these initially occur beyond the individual's control [10,11], such as when there are insufficient training placements on offer for the vocational school pupils, a problem leading to a relatively large number of unqualified school dropouts in Norway [9]. Thus, there is a substantial rationale for exploring further how the public can offer training, not only in job-seeking skills, such as curriculum vitae (CV) writing and gaining work skills, but also in building psychological well-being and resilience to cope with such setbacks and challenges [12,13].

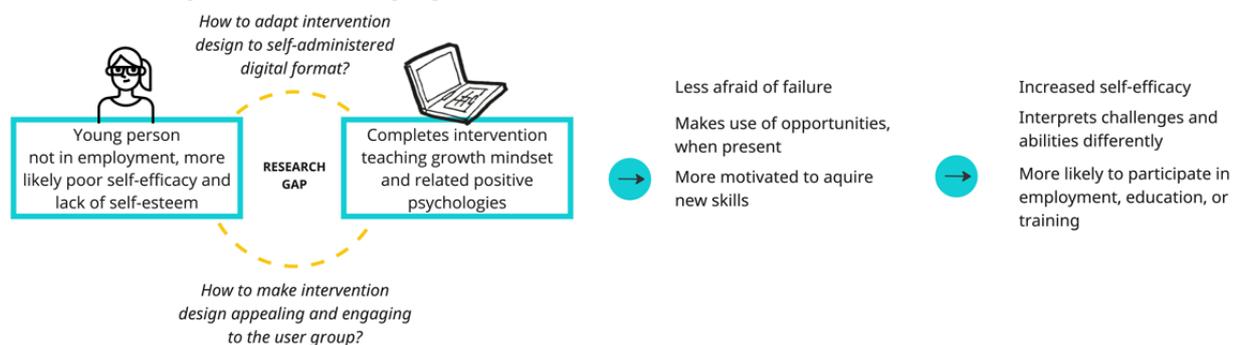

In the context of a broader research project, the Career Learning App, our study investigates the design and development of a web-based intervention using positive psychology to achieve beneficial changes [14]. Our broader research idea is that young people in the NEET group, henceforth referred to as *young, unemployed adults* (for the sake of simplicity and to reduce stigma), could benefit from building confidence in the possibility of learning and improving. The research idea stems from a body of work that has demonstrated positive results from offering high school students self-administered positive psychology interventions (PPIs) centered on growth mindset and

challenge-seeking behaviors [15,16]. A growth mindset is the belief that human capacities are not fixed but can be developed and increased in response to one's own efforts, good strategies, and help from others [17]. If a simple web-based PPI can influence high schoolers' mindsets in ways that lead to positive academic outcomes [15,16,18-20], then it could also likely be beneficial to the young unemployed, leading to changes in how they engage with their contexts. Despite this strong rationale for the applicability of PPIs to facilitate well-being and personal growth in vulnerable populations, they have only, to a limited extent, been tested and used in the context of unemployment [13,21]. However, we cannot simply apply the PPIs designed for educational contexts; they need substantial adaptation to be relevant or usable for this new target group of young, unemployed adults [17]. For instance, the school-related examples used within the PPI to make them relatable are not relevant to this new target population. Furthermore, there is a lack of shared context to piggyback on to deliver the intervention and ensure that users will adhere to it. Thus, there is a need to design and develop a web-based PPI designed specifically for young, unemployed adults and their context. If successful in user studies, a resulting intervention may be used in forthcoming large-scale randomized controlled trials in Norway.

Problems With Self-Administered Interventions

Self-administered web-based interventions have the potential to support well-being and positive health changes in a large number of people at a moderate cost [22]. However, this introduces new challenges, illustrated in Figure 1. First, there is the challenge of adapting current PPIs to self-administered digital formats that are fit for the purpose of the intended user population. Second, there is the challenge of user motivation to obtain the users to complete and adhere to the intervention [23,24]. Past research suggests that users are not interested in or do not enjoy using digital mental health interventions [25], suggesting a need to work on the actual interventions themselves to increase engagement and user motivation.

Figure 1. How mindset change may positively impact young, unemployed adults and the challenges of adherence, which we see as related to a research gap with a lack of knowledge of intervention designing.

Exploring PPI as Gameplay to Be Relevant for Young People

Past research suggests a need to adapt to the media preferences of young people and make the apps more visual and interactive to increase engagement and motivation among young people [26]. One possible approach to increasing engagement is to explore games and game elements. Starting from “where the

young people are at” makes pedagogical sense [27], thus the application of game design is founded on young people's own interests as a way to foster engagement and learning of positive psychologies. Although play and games are not unique to young humans [28,29], the average age of video game players is now 33 [30]. However, playing video games continues to be popular among young people [30,31]. Interactive digital games are increasingly used for purposes beyond entertainment, as

exemplified by the rise of health gaming apps for video gaming consoles. Game design elements are also increasingly applied to nongame contexts, for instance, by adding points and badges to nongame experiences, such as social media networks [32,33] or learning contexts [34]. When game design and game concepts are being applied for purposes beyond fun, they may be termed “serious games,” “learning games,” or “gamification” [35-40]. Game design applied to learning may be seen as a form of experiential learning (eg, learning-by-doing) [41,42]. Game design has been successfully applied to mental health interventions [43,44] and educational contexts [34,38] in the past. Game design offers an approach to creating engaging experiences. Engagement is a complex and ambiguous term [45]. Our use of the term is in the sense of “emotional involvement” as in offering a pleasurable experience [32] and to describe how motivational, usable, and acceptable [46] the game would be in the eyes of the target audience, because this could be an important predictor of adherence. In general, there

is insufficient research on the application of gaming and gamification to mental health, particularly in the well-being domain [47], and we have not found empirical studies that pursue to gamify positive psychology targeted specifically toward unemployed young people. There were no available gaming-based PPIs that could be used for the purposes of this study.

Research Objective

Our limited knowledge of how to adapt the intervention from an educational setting to a game-based format suggested a highly explorative approach, where we identified the need to design a game to explore this topic and to overcome the gaps in knowledge summarized in Figure 2. Thus, the research objective and question of this study were how to design a self-administered and digital PPI in a gaming format targeting young, unemployed adults and to explore how they engage with the game and whether they like using it.

Figure 2. How the research question is linked with the research gap identified. PPI: positive psychology intervention.

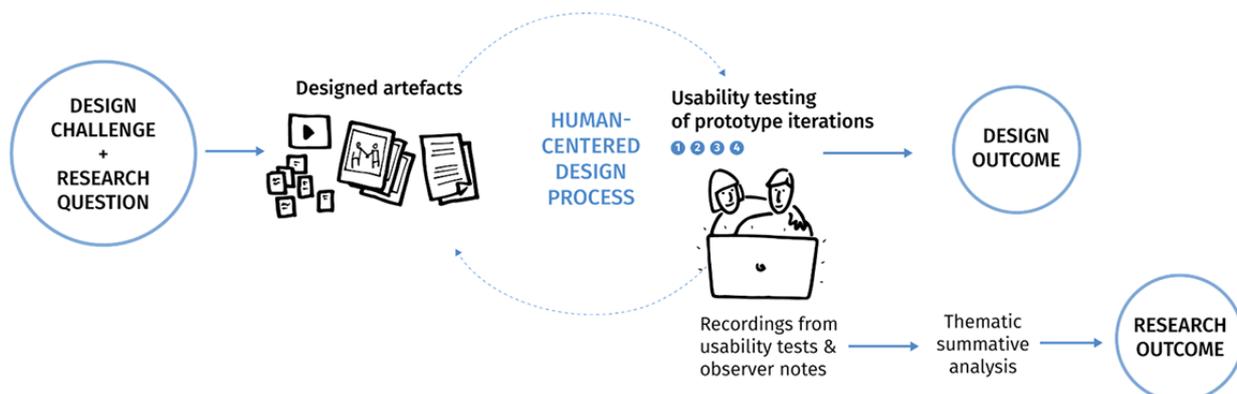

Methods

Setting: Learning in “Action”

To answer our research question, this study used a human-centered design process [48,49], an approach that allows input from target users during design and development. The human-centered design process is a form of research with design as the primary outcome [50]. The collection of feedback from users during design and development impacts not only the design of the game but also the production of knowledge. As such, it

is a form of participatory action-research [51,52] where “doing research” and “doing action” happen simultaneously. In the design research literature, this may also be referred to as “Research through Design” [53,54], where knowledge is produced through the design of the artifact and through the experience of the artifact. At the end of the project, we analyzed user feedback data thematically [55] to extract the learnings and design principles for the potential application toward creating user-friendly and user-relevant gaming-based PPIs for vulnerable populations. Figure 3 summarizes the “Research through Design” approach of this study.

Figure 3. A Research through Design process with design outcomes and research outcomes.

Data Collection Through User Testing

We used testing with users to capture the user experience. Testing with users is important as a tool for obtaining the “design right” in game design [56]. Our project-specific usability study [57] was formative, and we were qualitatively evaluating early prototypes to answer how and why questions as a means to improve the design [58,59]. We aimed to capture participants’ *thinking*, for example, opinions, reasoning, and attitudes toward the prototype experience. The various prototypes thus functioned as exploratory “hypothesis testing” [60,61] and as boundary objects [62-64] that framed conversations with end users. These sessions with the end users lasted from 45 to 90 minutes, where users were asked to briefly describe their background and interests, followed by open “think-aloud” questions [65] related to a prototype experience, such as “What do you think about what you see here?” “What do you expect will happen now?” and “What do you think this is?” Thus, the participants were encouraged to verbalize their thoughts and experiences. Afterward, the participants were asked follow-up questions that were equally open, such as “What are you thinking now that you have seen this?” and “How would you describe this to a friend?” The objectives of usability testing were to collect feedback related to broad aspects of the intervention experience, namely its (1) engagement, (2) reliability, (3) understandability, and (4) potential for improvement.

Sample and Recruitment

The NEET group includes anyone not in economic activity from the age of 15 to 29 years [1]. The European Foundation for the Improvement of Living and Working Conditions has defined 7 subgroups of NEETs [66], ranging from the “classically unemployed” to young people who are caretakers, unable to work, or simply listed as “inactive.” How long an individual remains a NEET also varies significantly. The diversity of the population is not necessarily problematic for our study; when designing with users, one would usually strive for variance [49,67] rather than representativeness. Our study is exploratory and does not require large samples [68]. Our estimate required 20 users; however, this sample size was highly approximate, in line with qualitative studies in general [69,70]. Pragmatic needs in the design process guided the number of participants to a large degree and not, for instance, theoretical saturation.

We recruited from the Norwegian Labour and Welfare Administration (NAV), the national welfare institution of Norway that pays out unemployment wages and social support, and from a regional Individual Placement and Support (IPS) program, which offers placement support to young people with first-episode psychosis. We also recruited through the user testing platform, Teston (UserTesting). Our inclusion criteria were an age range of 18 to 29 years, with a “NEET background,” and because of the language in the game prototype, living in Norway and speaking Norwegian. We say “NEET background” and not “NEET status” because our participants from the IPS program were no longer in the NEET group by definition. We made a deliberate choice not to exclude based on the length of NEET status and unemployment. Although those who are entering the NEET group in the short term, the “in-betweeners” [66], often find new employment without assistance [71] relatively quickly, even a short time out-of-work may increase the risk of exclusion [72]. We did not recruit participants on permanent disability allowance. Using multiple channels enabled quicker recruitment during the COVID-19 pandemic and increased the variance in our sample (as desired), as young people without the rights to receive unemployment benefits have fewer incentives to register with NAV [73]. We did not compare the experience of the intervention based on the recruitment channel because the groups were overlapping and experienced varying prototypes depending on the stages in the design process.

Participants

In total, 18 participants (12/18, 67% females, 6/18, 33% males) took part in the study during the 21 testing sessions; thus, some participants were involved more than once. Recruitment was particularly challenging because of the COVID-19 pandemic, and we found that it was difficult to recruit young, unemployed men. Remote participation through web-based technologies, such as the Zoom (Zoom Video Communications) platform, enabled the study to continue during the lockdown. We also experienced that this user group continued to prefer remote participation, even when restrictions were lifted. [Table 1](#) summarizes the participant statistics and format of the usability test.

Table 1. Age distribution of participants and format of user testing.

The Design and Development Process

Researchers at the University of Stavanger worked with designers and developers from a consulting company and potential future end users in an agile [60] and human-centered design [48,49] process. The objective of the process was to create an enjoyable gaming-based PPI targeting unemployed young adults. This process took place in 4 steps over approximately 9 months, from 2019 to 2020. In the first step, (1) *design exploration* in the form of a design sprint, a 5-day design and prototyping process [61], produced a minimum viable product of a gaming concept that was tested with 5 participants. Following a brief period for planning and procurement, we moved on to (2) *agile development*, consisting of 3 sprints, each lasting about a month. During this step, usability tests were conducted on 6 participants. This was followed by (3) *refinement* of content and prototypes, with involvement from behavioral intervention researchers to further

develop and “add-in” the necessary intervention content. Finally, the prototypes were evaluated using (4) *testing*. In this step, 10 participants participated in usability testing and provided feedback on the final set of prototypes. Figure 4 summarizes the stepwise design and research process.

The intervention content needed to be adapted to be meaningful and relatable to the user group [74]. The basis for our gaming-based PPIs were growth mindset interventions from the “National Study Learning Mindset” [16] and its translated Norwegian version, “U-SAY” [5,15]. These are interventions that target high school students [15,16]. We added selected parts of cognitive behavioral therapy [75], specifically management of negative emotions, panic, and anxiety, to offer a more productive interpretation of stressors [76] that may occur during job search adversity [77,78]. During the first few days of the initial design sprint, a gaming concept, VitaNova, was developed where players can build a “new life” in a fictional narrative.

The Gaming-Based Intervention

The VitaNova gaming concept is a one-player fantasy game where the user plays a “no name,” an android character that can take on any skin to morph into another character with their skills and abilities. In particular, the player can choose between being Noomi and Twizzlesprock. However, as we learn through the game, your character has a backstory as the male character Abel, a former engineer and an outcast who sees himself as a failure. The game is designed in 3D and split into episodes (missions). The game starts with very little information and instructions, landing the user right into action. This was a design tactic to spark curiosity and make the users intrigued by the game so that they would want to explore it further. As a player, your first task is to escape from captivity, and then, gradually, more and more information is being revealed to you as the game progresses. Refer to [Textbox 1](#) for an overview of the game narrative.

The visual design of games can influence how motivational and acceptable they are to the target population [46]. Therefore, to make the game look polished, cool, and professional and to keep users immersed and engaged [79], emphasis was placed on 3D design and detailing. The game was divided into episodes, or missions. The first 3 episodes were developed into a nearly fully functional game in Unity WebGL, a platform for building

3D games that can be used in a web browser. During user testing, we also showed the prototypes and the wireframes that were made in Figma. [Figure 5](#) shows the prototype iterations of the game design.

Psychological content and tasks are entered into the gameplay to foster psychological well-being, teach a growth mindset, and offer psychoeducation and mental health tips. Some of this is interwoven into action in the form of interactive quizzes, dialogues, or other forms of interaction, such as a CV builder applied within the game. This was intended to be transferable to the end user situation to increase relevance, although the acquisition of such practical skills was not a target of the intervention. Furthermore, there was also psychological content that was external to the gameplay, such as embedded videos. When using externally sourced content, this was implemented in the game as “ruins from the past,” which the player could “find” in the game. The player would need to watch this content and use the information provided to complete the challenges and the in-game quizzes. Upon completing an episode of the game, the player was requested to write an answer to a reflective question where the user should answer as himself or herself, to encourage internalization of the messages that had been taught in the intervention through self-persuasion [80], and to transfer learning to the user’s own situation. We have included a further description of the prototypes in [Multimedia Appendix 1](#).

Textbox 1. Description of the game narrative. (The 2 final missions were not included in the user testing.)

1. Introduction
 Wake up in the trunk of a moving vehicle. Use hacking skills to hack the lock. Find a tavern and interact with a bodyguard who refuses your entry as “no name.” Find the Noomi skin and power unit and turn them on to enter the tavern.

2. Tavern
 Interact with Griff and Mia at the tavern to learn about this world. Try to receive help. Tell them that you must go to an old public office to pick up energy bars if you are going to receive any help.

3. Learn
 Find an abandoned public office where, among other things, you will discover many pieces of ancient psychological knowledge as ruins from the past.

4. The sidekick
 Use newly acquired knowledge to help out the depressed and anxiety-ridden droid Griff, who now becomes your sidekick, and help Mia the bartender.

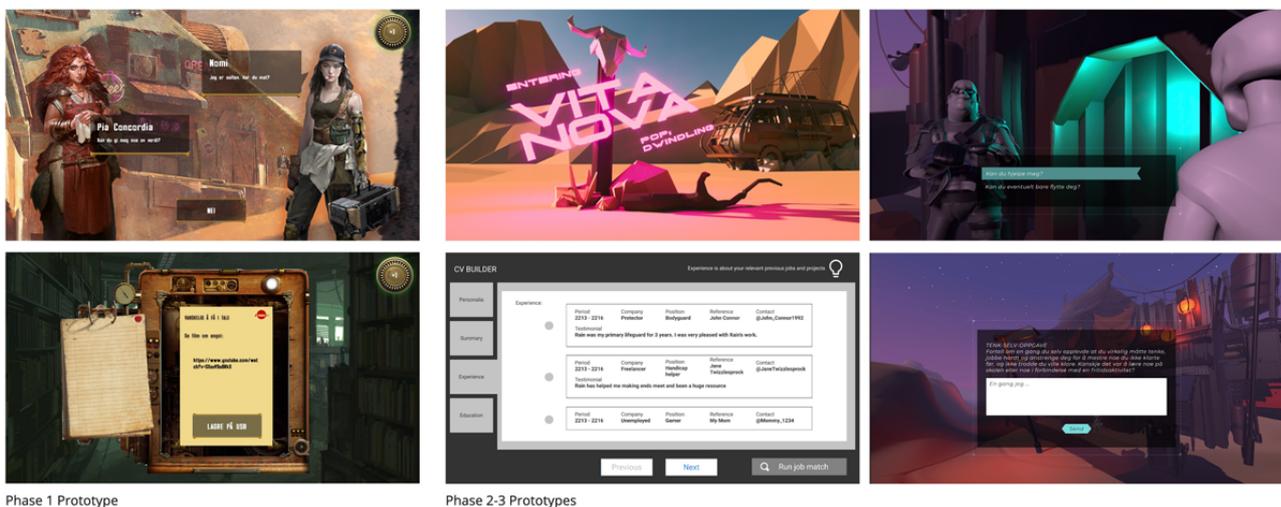

5. The bully
 A bounty hunter is out looking for you to receive a reward from the boss at BetterJu Janus. Threatens your new friends at the tavern. Why are they after you?

6. The chance
 You discover that the only way to obtain all the answers is to try to join into BetterJu. Your friends tell you of a job posting that is open. Interactive curriculum vitae and job application process.

7. The job interview
 The job requires a different set of skills, which you acquire through entering the skin of Twizzlesprock. Job interview at the company BetterYou as Twizzlesprock.

8. The escape
 Discover who you really are from the overhearing conversation between your new boss, Janus, and a droid. Find your ex-girlfriend, who has been trapped but confirms your true identity. You both escape from the evil boss. The end.

Figure 5. Prototype iterations of VitaNova.

Analysis

The purpose of the usability testing was to synthesize findings that led to improvements and changes in the designed outcome. Retrospectively, we also conducted thematic analysis with the steps from Braun and Clark [55,81] as a practical guide: (1) data familiarization, (2) initial code generation, (3) search for themes, (4) review themes, (5) define and name themes, and (6) produce reports [81]. All 21 usability-testing sessions were recorded. The 7 most comprehensive usability tests were transcribed verbatim. The remaining data were analyzed based

on recordings, researcher notes, and memos. Specifically, we used the transcribed data as our starting point and went back to recordings and memos to review codes and themes. The analytic process was iterative and creative, where we often moved back and forth between the data and codes [82]. All authors independently familiarized themselves with the data. Author 1 started with coding using the qualitative analysis software ATLAS.ti (ATLAS.ti Scientific Software). As a group, we discussed the findings and the initial codes in a workshop before moving over to paper-based coding and printing quotes from participants organized on large paper sheets. We used

diagramming, both digitally in Miro and in pen-and-paper sketches, to iterate themes and review codes in consensus meetings. Findings and concepts were discussed with other researchers, some of whom had acted as observers for the user testing or had watched recorded sessions. The quality of the analysis was ensured by researcher reflexivity, end user involvement, and method triangulation. *Researcher reflexivity* concerns activities that consider how researchers might have informed the research or biased outcomes [69]. Reflexivity was enabled through critical discussion of assumptions, themes, and codes in the team of researchers. The team also involved researchers not involved in the user testing or in the design process as an approach to validate the analysis based on these methods. *End user involvement* was supported through the iterative design process, where participant perspectives were sought at different levels of concept and design maturity. Specifically, we found it valuable to involve users from different recruitment sources (IPS, Teston, and NAV) to strengthen the credibility and transferability of the findings. *Method triangulation* was conducted by applying different approaches to design and user involvement at different phases of the process, allowing the assessment of themes or constructs from different perspectives. In particular, including data from the different phases of exploration, design, and evaluation was found to strengthen the credibility of the findings.

Ethical Considerations

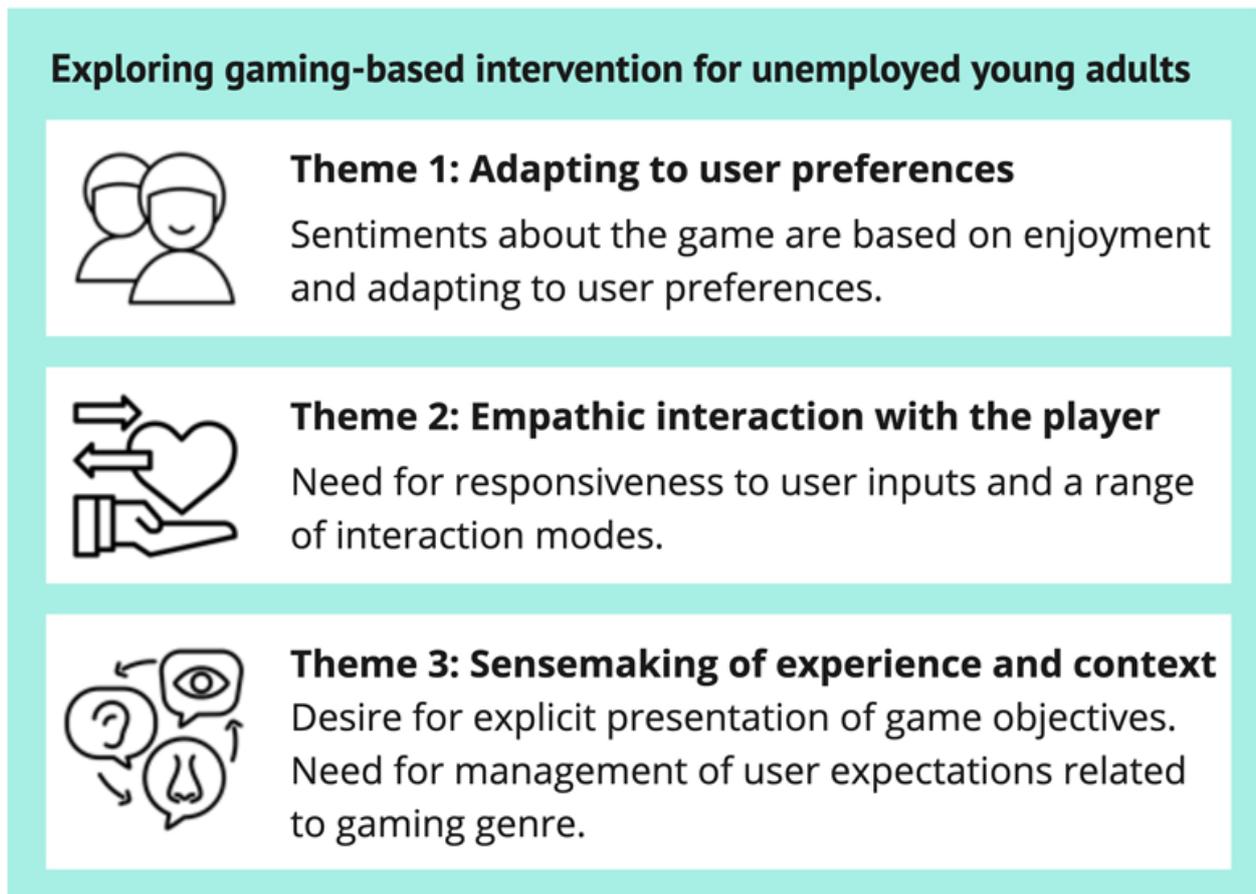

All participants provided explicit and written consent to participate in the study and were rewarded with gift cards (approximately US \$30/session) for their participation. The study was evaluated and approved by the Norwegian Centre for Research Data (approval number 131074) and the regional committees for medical and health research ethics in Norway (approval number 42128).

Results

Overview

As a tool to motivate and help young adults engage in work or education, the idea of an interactive and digital game was regarded by all participants as a “good idea”; it was described as “cool,” “unexpected,” and “motivating” upon first impression. Upon closer experience with the different gaming prototypes, we received different and more specific feedback. A total of 3 themes were constructed by the researchers through active analytic engagement with the data [55]. The themes pinpoint what we consider key priorities for future gaming interventions for unemployed young adults: (1) adapting to user preferences, (2) empathic player interaction, and (3) sensemaking of experience and context. Refer to [Figure 6](#) for an overview of the themes and their key characteristics.

Figure 6. Themes and theme characteristics.

Theme 1: Adapting to User Preferences

Sentiments about the game are based on enjoyment of the game experience, the genre, and whether the game meets user preferences, either by being targeted toward them or by allowing for experience customization. The participants expressed positive feelings and excitement related to the game. It was described as much more of an *actual game* than was expected:

I liked it; it was unexpected. [P3]

Seems like a cool concept. Never heard of it before. [P17]

The participants pointed to the use of humor and compared the game to pure entertainment media, such as commercially available games, or other parts of popular culture, such as films or television series:

It was actually pretty exciting [laughs]. Kind of funny, considering that you have included the welfare administration here. [P6]

The story was funny, it seemed a bit like a video game. [P10]

The game concept was further described as “something to do” or “something to allow the time to fly,” as pure entertainment or for relaxation purposes. The relaxing features were described as something that could make one more receptive:

If it's like that you get new assignments once a week, then it can seem exciting. At least that is something to do. [P7]

So you are pretty relaxed when you get these questions, so then it is probably a little easier to answer... a little easier to reflect over this. [P4]

Others felt that the gameplay story could motivate them to do something by creating a sense of urgency, where the story would drive them to make more effort. A participant wanted proof within the game that it would be worth the effort to perform mundane tasks, such as updating their CV:

That's how it is in life too: You have to make an effort yourself to get ahead; when you have to do something here [...], then you have to hurry, because someone is after you. Then you get the adrenaline to do it. [P16]

If there's something in the game that can prove to me that it's worth it, like writing a resume is worth it... [P18]

However, several participants expressed uncertainty about whether the game would be “something for them,” suggesting either other preferences or not quite the right conceptual fit. In particular, the concept likely needed “aging up,” as it was perceived as something for a younger population. Furthermore, we learned from the participants, who spent more time gaming, that they had started out playing “adventure games” and “role-playing games” when they were younger, but that they had since moved on to playing “first-person shooter” games or other kinds of games:

It's not a game I would have bought in the store. [P15]

I think if I had been younger then, yes. Because I have a lot of different types of games that I like to play, and now I like to play games where you shoot people, but earlier I liked playing games like that, where you follow a story, for example, it's very different in... it's very different for people what kind of games they like to play. [P2]

Designing for mobile phone use was considered important and was brought up as an improvement suggestion by nearly all users. Participants expressed that mobile phone use would make it easier to meet their own user preferences or the user preferences that they expected other young people to have:

I would have chosen an app or a mobile game. Or a course, if it was on [a] mobile [phone]. [P7]

Not everyone has a PC with them everywhere, so I wondered if this was on mobile. [P17]

If the game could be turned into a mobile game, that would be better. [P1]

Adapting to user preferences could also mean designing a customizable or more personalized experience. In particular, the choice of characters in the game is usually an arena for customization and personalization. One user commented that she would prefer to customize a character by selecting hair length, and body shape, etc rather than choosing between predefined female and male characters:

if you can choose male or female or... you don't have to have these two, but you can choose what that person looks like. Since now a lot of young people... there are some young people who don't want to be a man or a woman, so I think you... it's very smart to make something like 'do you want long hair' 'do you want short hair' 'do you want...' [laughs] [P2]

Others mentioned different strategies for choosing characters by either choosing a character that resembled themselves or identifying with them. Others would deliberately choose the extreme opposite of themselves. As one participant mentioned, “if your choice was the big male character, then you were likely ‘more vulnerable on the inside’ and ‘in need of protection.’”

Theme 2: Empathic Interaction With the Player

This theme describes the need for responsiveness to user inputs and the desire for a range of interaction modes. Although initially intrigued and enthused by the game design, users quickly became disappointed by the lack of functionality. Thus, this theme is based on the need for empathic interaction with the player in the game, where the game needs to take the user seriously by being responsive to user inputs, thereby allowing for actual contribution to the experience:

It's very... you can see very easily that your answers don't make much of a difference. It doesn't matter what you choose. And I think if you're going to have a game like this, you have to have a little change in what you say, how will it affect the game. [P2]

No, it's just that I want to see that the people you're talking to have something else or something more to

say. *That they have other reactions than just “no [laughs].”* [P2]

It was, it’s not a challenging game, it’s not a difficult game... the game itself [laughs]. It’s designed to be clicked through. You don’t need to spend a week on it. [P3]

Participants find the graphics visually appealing, although they do not feel that this is the most important aspect, saying that how the game works and how exciting and entertaining the game is are the most important parts:

I think it looks pretty nice. There are many different types of games that can be in like... many different types of ‘art’ [styles] and so, yes, there are many games that can look one way, but can still be really good, but some games that look really nice, can be boring. So, don’t worry about how the game looks, but how the game works, that’s very important. [P2]

Visually it was very nice... The story I am more unsure of... [P12]

Some of the feedback indicates that our game was perhaps not fully developed as a game with the necessary combination of rules, goals, feedback, fantasy, and fun [32]. Participants wish for a wider range of interaction modes, such as moving more freely around in the game, having more challenges and tasks in the game, and having different ways of interacting with the characters. Users expect game-like interactions, not just choosing answers, reading, and writing:

It is unusual for me that you cannot move around [in the game]. [P4]

But I think that it would be a bit boring if it was just like that you had to read, and then click to choose answer options. [...] if I was sitting at home, and this was something I had to go through every week[...] then I’d just click quickly through it. And then I hadn’t properly read what it said. [P7]

To support the learning objectives of the game, players had to answer reflective questions at the end of each gaming session, where they answered as themselves and not as the gaming character. This felt a bit “off” to the participants. Furthermore, several participants expressed a problem with articulating answers to those kinds of questions, expressing that they would not know what to write when asked:

I didn’t expect that an assignment came up where you have to write about an experience from reality, sort of, which seems a little unusual to me since you are sitting inside this alternate world. But I had probably only written something about skateboarding. But it was very unusual for it to be like that. [P4]

I don’t know... at least I struggle a lot with tasks like that[...] I probably wouldn’t have written anything here. [P5]

Although not as exciting as hoped for, the challenges and tasks in the game can still provide the user with a sense of achievement and act as an awakening for new thoughts; if not for them, then perhaps for someone else:

You kind of get a little more confidence in yourself then. That you have actually managed something. [P6]

...after all, it raises thoughts and yes... new ways of looking at things, I think. that it can start something in someone. [P7]

Theme 3: Sensemaking of Experience and Context

This theme comprises a desire for an explicit presentation of the game objectives and a need to manage user expectations related to the gaming genre. The game was described as “cool but confusing:”

Uh, well, it seems kind of cool, but it was a little hard to understand, I felt. [P5]

Many participants mentioned *sensemaking* or lack of understanding in some form or another; they struggled to understand the point, the objective, or the mission to be completed in the game. Some participants pointed to a lack of logic or strangeness in the storyline and over-the-top reactions to what they perceived as minor happenings:

So people want to buy parts of dead people so they can look how they want? Hum. That’s a very strange concept! [laughs]. [P2]

She is stabbed now! ... And the taverna is burning. That was over-the-top. She just came for some food. This is over-the-top. [P12]

The intervention messages in the game were not perceived by any of the participants. They were uncertain about what they were learning from the game experience. They were focusing on the details of the game narrative, trying to make sense of that, and, thus, the intervention part seemed “part of the fiction” and not clear what this was meant for:

Didn’t learn anything. Well... I learned that there can be different ways to solve things, but I didn’t really learn anything[...] It was a bit difficult to understand the whole story, that is the whole thing. [P1]

Lots of talk about the brain, that the brain is a muscle, but don’t know what it can help with, it doesn’t make sense. [P2]

The gameplay added complexity and was confusing to the participants. For most participants, there was a desire for an explicit presentation of game objectives, both in terms of what it should ultimately achieve for the end user (as an intervention) and what the objectives in the game narrative are. However, other participants felt that this uncertainty was part of the excitement:

...I should have known a little more what the goal was and what the meaning behind the game was. Because it seemed a bit like that, yes... a bit out of the blue. And you didn’t quite know what an anonymous person was and whether this was the future or whether this was a completely different world. [P7]

It was very interesting. It was very unusual for me with that kind of game. But I liked how it was. And you didn’t have very much information about what

you were doing so you kind of had to find out a bit about the skins and such. And I liked that. [P4]

One user expressed explicit concern about how relatable the contents could be if you use a context that is far removed from everyday life:

If it becomes too sci-fi, I think it might be difficult to transfer to reality. [P18]

Furthermore, we also identified a need to manage gaming genre expectations. The participants expressed a preference for certain genres over others; it may be difficult to cater to different preferences in terms of what games they like best to play. There are also certain expectations connected with different gaming genres that we were not so aware of in the research team, where users were trying to make sense of the game prototypes *in relation to* established genres, with expectations of gaming interaction to be similar to games in that genre. The participants asked us about the game in relation to genre concepts such as “open world,” “adventure,” and “role-playing” games:

So, I have a question, is this an open-world type of game where you go out to different places and pick up things or is this a text where you just follow what happens in the story? [P2]

I have a question: Is this open world—or just to follow a track, like? [P17]

It seems that the game genre was not clear to the participants, who pointed to different features of the gameplay prototypes that would take the game in different genre directions.

Discussion

Principal Findings

This study has used an iterative design process with active participation from potential users to develop an interactive game that aims to be user-friendly and engaging to be able to provide a vulnerable population with positive psychologies. As pointed out by past research, there is a strong rationale for promoting psychological well-being, for instance, to improve resilience [83] in the face of setbacks and challenges that occur as part of job search and being “out-of-work” [12,13,78], and may thus alleviate suffering [84]. A total of 3 themes were constructed from the user-based research that occurred through the design process of the gaming-based intervention: (1) adapting to user preferences, (2) empathic player interaction, and (3) sensemaking of experience and context. In the following section, we discuss the themes and how they could potentially be applied as designing principles for future self-administered gamified PPIs. Thus, the study sheds light on the application of game design for PPIs that aim to promote well-being and increase challenge-seeking in young, unemployed adults.

Comparisons With Previous Work

Adapting to User Preferences

This study expands the knowledge found in other studies on PPIs for young people, where the need to offer interactive, visual, and more engaging experiences has been identified [26,85,86]. Most participants expressed uncertainty about

whether the game would be “something for them,” suggesting other preferences or not quite the right conceptual fit with their preferences. We interpret this to mean that there is a need to consider gaming genres and user preferences specifically, where a more refined user segmentation may be necessary [87,88]. For instance, in our group, some participants said that they only had an interest in certain kinds of games. Future studies could consider a more fine-grained targeting strategy based on preferences and interests and not simply age and employment status. A possibility would be to segment the population based on player types [89,90] or motivation [89,91-93], and to think more carefully about user preferences for different gaming genres before choosing a concept. In our study, we found that the selected game genre was perceived as engaging “not to them,” but “someone younger.” This was particularly true for the active gamers, who found the genre to be immature. Furthermore, most participants stated that they would have preferred a game designed for mobile use, indicating another kind of context of use than our initially planned use on PCs at home.

Empathic Player Interaction

Inside the game experience itself, the participants in our study were disappointed by the lack of features, functionalities, and opportunities to influence what was going to happen in the game, for example, player autonomy. A lack of autonomy may cause a more negative interpretation of an experience [94]. We interpret this as underdelivery, partly because of the overpromise of the first impression and the esthetics of the graphics [95,96]. The participants expressed bleakly that in-game actions “do not matter” because, as players, they experienced an insufficient influence on the string of events in the game. Autonomy is an important motivator in self-determination theory (SDT) [97] and a lack thereof may contribute to reduced user motivation [13,35,97]. In part, the lack of autonomy and interactivity was caused by the requirements for a structured intervention set by the broader research project; each player needed to experience the same sequence of events. However, even within this frame, the game should be built to cater for somewhat more variation and focus on the interaction between the game and the player to meet user expectations. There is also a more specific need to be aware that within this target group of young, unemployed adults, many may feel *in general* that what they do does not matter [98]. Gameplay with insufficient df may unintentionally reinforce that message.

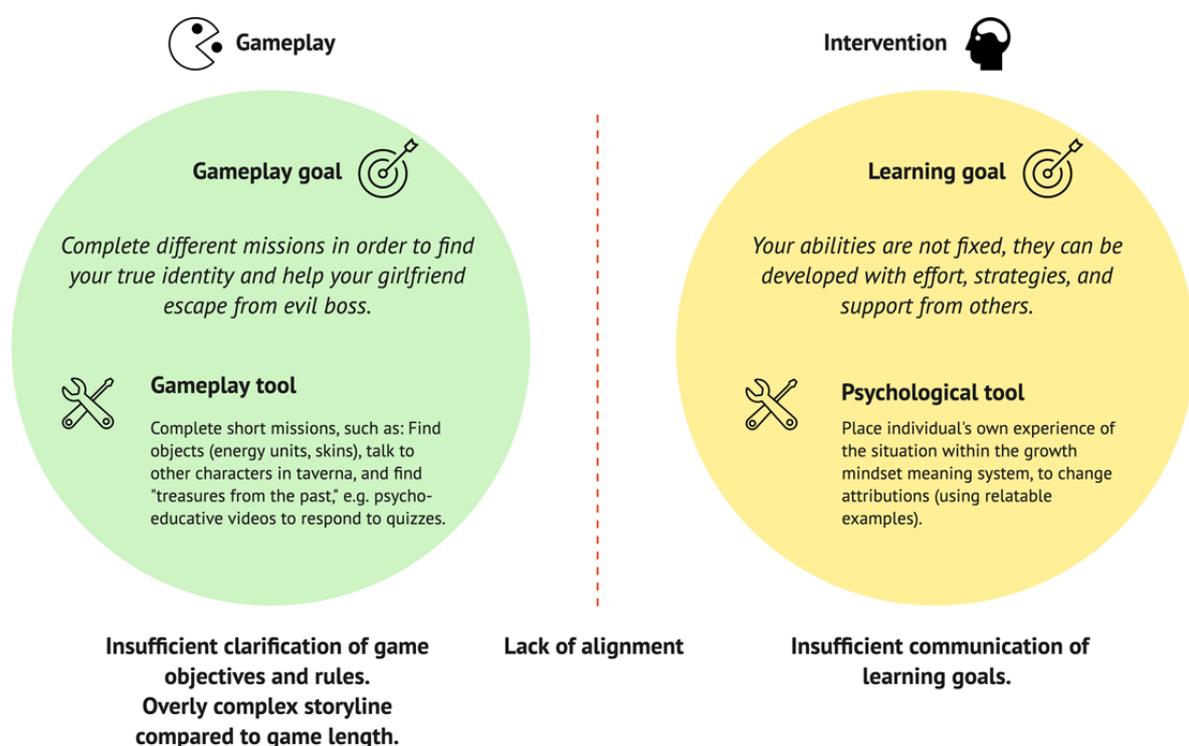

Sensemaking of Experience and Context

Participants had trouble making sense of the experience: our prototypes did not meet the participants’ expectations for genre, not fitting with role-playing games based on narratives and dialogues or open-world type games, where you move around freely in a 3D world to pick up items and battle with other characters. Furthermore, the game objective and rules were either not clearly presented to the participants or did not cater to sufficient player-game dialogue and manipulation of the experience. We found that there were tensions between the gameplay and the messages of the intervention, which could undermine the intervention and potentially threaten its effectiveness. This finding is depicted in Figure 7. The PPI

gameplay had a complex storyline, which confused the participants and made them miss out on their learning objectives. Past studies have pointed to psychological affordances and the importance of a “fertile soil” to make positive psychological interventions more likely to work [99-101]. In instructional or serious games used in education, Young et al [38] concluded the need to ensure that game objectives and learning objectives correspond and, further, that an overly complex gameplay can lead to misunderstandings and interfere with understanding. This seems transferable to gaming-based interventions. Other authors have referred to this as “relevant narrative,” which states that the narrative of the game should be relevant to the subject matter [102]. The choice of gameplay as a strategy for creating engagement for an intervention introduces a new context, which

becomes the background for interpreting the messages of the intervention. The game design concept should be selected carefully and tested early with inexpensive methods, such as roleplay or paper sketches [32,56], to explore whether the gameplay is supportive of the intervention. In VitaNova, the gameplay goals implicitly reflected the learning goals, as the development of abilities was presented through the completion of in-game missions. However, because these learning goals were not explicitly communicated, the effectiveness of the intervention depended on the users themselves seeing the connection and transferring this knowledge to their own situation. Combined with the lack of clarity of game objectives and rules as well as an overly complex storyline, this led to confusion.

Figure 7. Mismatch of goals between intervention and gameplay, in combination with insufficient clarity overall.

Practical Implications for Future Gaming-Based Interventions

When revisiting the 3 themes and comparing them to related work, there appears to be a similarity between the identified findings of this study and the 3 basic psychological needs in SDT [103], which are: needs for autonomy, relatedness, and competence [92]; refer to Figure 8. As such, this study provides a form of bottom-up support for the usefulness of these constructs in designing and evaluating future gaming-based PPIs to understand how they might be more motivating to the user [92]. Further research should also investigate how and if a gaming-based PPI experience that does satisfy the relevant needs of autonomy, relatedness, and competence may contribute *in itself* to positive psychological outcomes for this population, as has been suggested [13].

Striking the right balance between learning and fun is a significant challenge, along with producing a relevant narrative [102] that supports intended learning. Ferrara [32] suggests a strategy for identifying the “gameness” that already exists in a context or situation rather than trying to *tack it on*. This may make it easier to transfer learning from the gaming space to everyday life [56,104]. However, moving from an idea to a game that works conceptually is challenging [105], and good intentions may be undermined by a seemingly fun yet unfit idea or concept, for example in the case of Disney and their first version of the game and exhibit “Habit Heroes,” intended to support healthy eating but rather reinforced stereotypes and made children feel bad about themselves [106]. Choosing an approach that “gamifies life” should thus be done with empathy, care, and frequent testing with users to avoid banalizing the situation and experiences of a vulnerable population, such as the young and unemployed. As such, a human-centered design approach is ideal because it starts with empathy [48]. However,

frequent playtesting [56] and usability evaluation [57] are also needed to reduce the risk of developing a concept that is not engaging with the intended audience [88] or that undermines or does not foster learning. Established game genres and concepts could be used as inspiration in early explorative ideation. The characteristics of existing games may be viewed as opposing values on a spectrum [32], and by imagining what the game-based PPI would look like in the form of existing game genres, a large volume of different ideas can be formed that may be tested early for fit with the PPI objectives and user preferences.

In Figure 9, we propose a broad but structured approach for how game-based PPI exploration may be executed, based on the lessons learned from our study and the discussion points in the preceding section. In this approach, insight into the user,

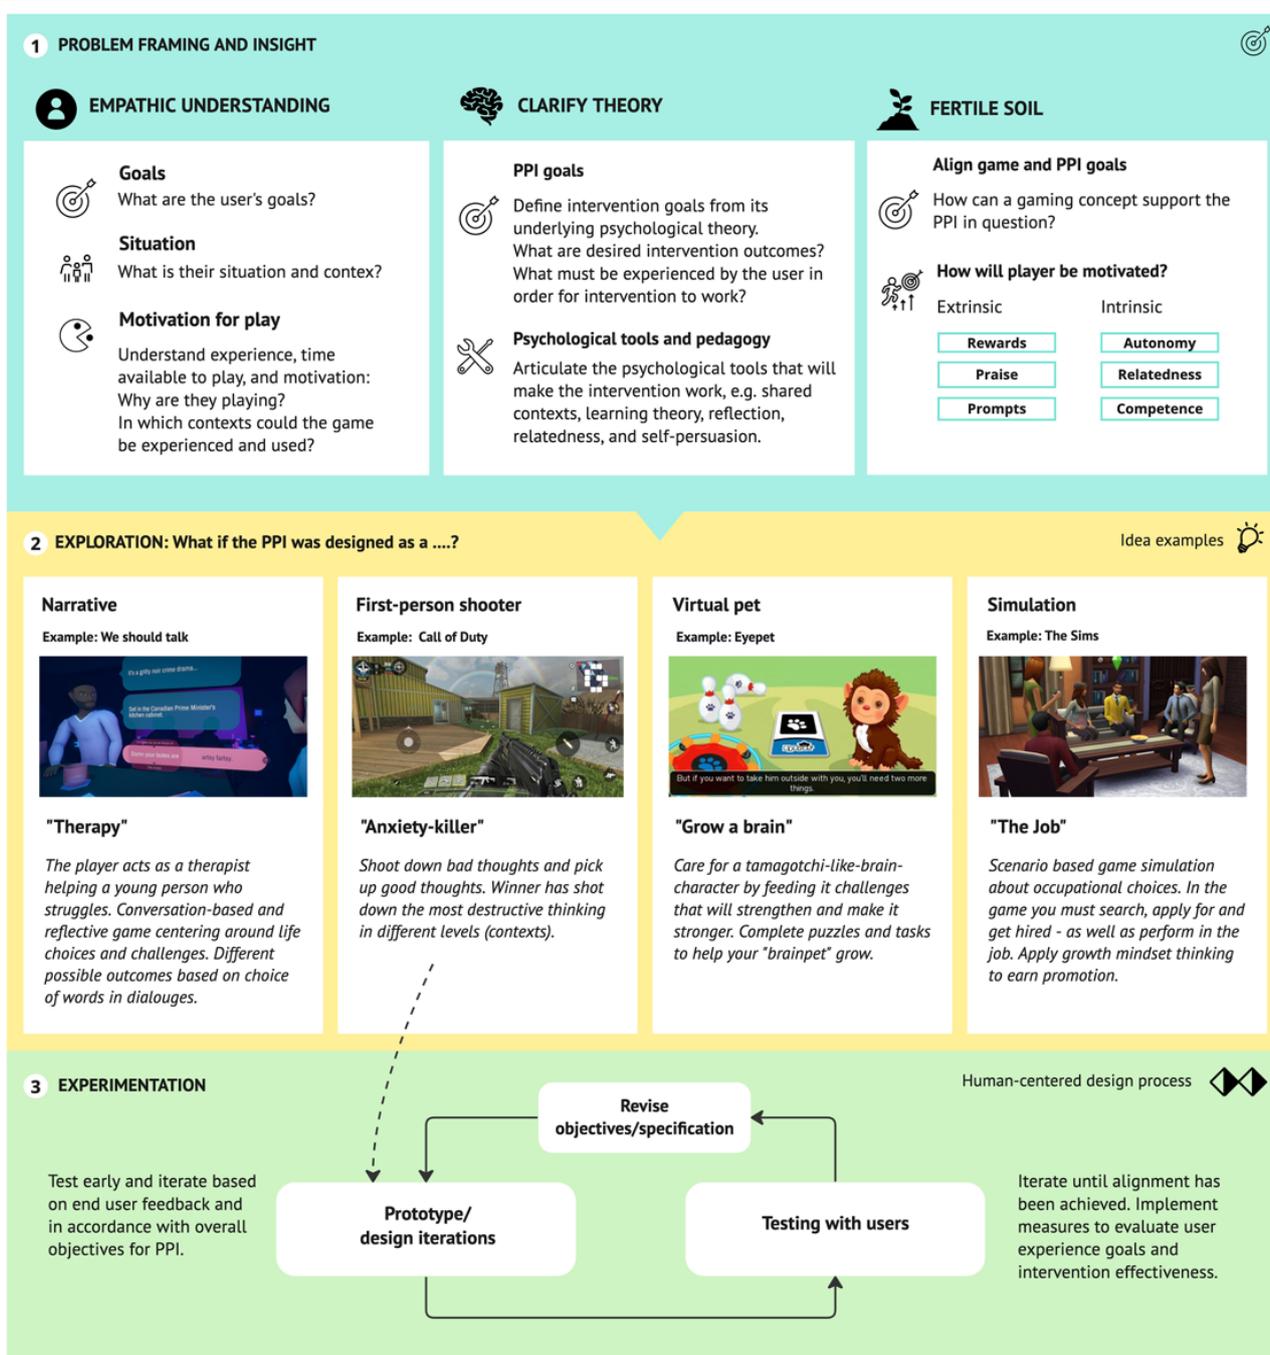

context, gaming preferences, and gaming interests frames the design problem. It is also necessary to establish a clear and precise definition of PPI, including its underpinning mechanics, theories, and strategies that can help make the intervention effective. An alignment between the 2, forms the necessary “fertile soil” for the intervention game, where we ask how gameplay may support both user preferences and goals and PPI goals. Next, we propose working with existing genres and games to quickly generate many different ideas of what our gaming-based PPI may look and feel like. Promising concepts should be evaluated against relevant criteria, such as gameplay and user experience objectives and PPI objectives, and then made into prototypes for validation with user research.

The approach outlined here should be further detailed, refined, and validated in future research.

Figure 8. How the 3 themes correspond to basic psychological needs for relatedness, autonomy, and competence, in line with self-determination theory (SDT).

Figure 9. A proposed approach for designing future gaming-based positive psychology interventions (PPIs).

Pointers for Future Research

There is a range of possible strategies to choose from to work to improve an intervention and increase user motivation. In this specific study and for the purposes of this paper, we explored one possible strategy: to attempt to make the PPI more engaging, user-friendly, and relevant for young, unemployed adults by creating a gaming-based intervention. There are other alternative strategies that could increase relevance, appeal, and adaptation to the needs of the target audience. Kelders et al [24] suggest the use of design and persuasive design techniques, including reward, praise and reminders [107] as a tool to increase motivation and retention. Others [13] suggest the use of SDT

[97], as we also found some support for this study. These strategies should be explored further in future studies.

Furthermore, the alignment between gameplay and intervention does not rely solely on the crafting of the game. Although our study grounded ideas on learning from past empirical research where PPIs had been applied to different contexts, there was a lack of clarity and theoretical grounding for the user experience in itself, including a clear definition of the learning [35] that should happen within the game design space. Incorporating learning theory, such as experiential learning [41], along with motivation theory, such as SDT [97] and persuasive design [108], as a more complete theoretical framework for the game designing process may provide a stronger direction to the conceptual work for the practitioners involved. Designing for

behavioral and mindset change is increasingly relevant for design research and professional design practice [109], and there seem to be several gaps in understanding for design researchers and design teams who find themselves grappling with psychological and behavioral theories to produce interventions to support problem-solving of societal problems, such as youth unemployment.

Limitations

In this study, relevant participants were involved in a design process to capture their experience with designs in-the-making and take feedback into consideration in the design of revisions. We consider such early involvement a strength of the study. However, it also holds limitations; as the results are drawn from user experiences with *prototype* PPIs, the study does not provide user experiences resulting from a completed and verified PPI. Although the knowledge gained through the different stages of the design process is of substantial value to this area of research, future work is needed on experiences with fully functional gameplay PPIs to validate the findings of this study and to measure engagement, effectiveness, and adherence to the intervention. In addition, considering the fact that the positive psychologies implemented in the game mechanics were, to some extent, unclear to the participants after exposure, we cannot draw any conclusions on the experience of these in themselves at this stage. However, this was also not the purpose of this study.

Another limitation is the choice and availability of participants in the study. The population of unemployed young adults is highly heterogeneous. With our recruitment strategy, we are aware that we do not cover the entire range of end users, especially because we in part relied on voluntary registration and on contact with specific public welfare systems. Nevertheless, we find the involved participants to be within the scope of the studied PPI, and their feedback, hence, is of substantial benefit in understanding how the PPI may be experienced by representatives of this target group.

The third limitation concerns the context of the usability testing. Being observed by another person influences behavior (eg,

Hawthorne effect), and participants likely spent much more time considering the prototypes than they would normally have. However, this approach was chosen because our interventions were prototypes and had unfinished functionality, which required a moderator to “fill the gaps” [110,111]. A fully self-administered and unmoderated use of a gameplay PPI would be a natural next step in future research.

Finally, it is important to note that, although our exploratory approach to insight into user perceptions of a game-based intervention for this target group is an important starting point for this area of investigation, future research is needed to establish the knowledge base needed to reliably provide such interventions. As part of this, we envision future studies with larger sample sizes and established scales as part of randomized controlled trials to gain further knowledge of the effectiveness of game-based interventions for this group and a basis for improvements in intervention design.

Conclusions

The study contributes insights into key user perceptions of game-based interventions for unemployed young adults. The contribution has implications for future game-like intervention design for this purpose. Our principal contribution is to explore engagement through a PPI, designed as an interactive game. We have described the iterative process of the development of a 3D-game concept, VitaNova, and have explored participants' thoughts and feedback on their experiences. Although the participants were positive about the general idea of a game targeted toward unemployed young people, we found tensions between a PPI and an exciting game play and 3 themes that pinpoint priorities for future gaming implementations. Our study shows that interactive game design could make interventions more entertaining and engaging but can easily come into conflict with or undermine the intervention. We recommend aligning the gameplay narrative, objectives, and mechanics with intervention content and objectives to create engaging, relevant, and effective gaming-based PPIs that promote a more productive view of the challenges experienced by the young and unemployed.

Acknowledgments

The authors would like to thank the researchers at the University of Stavanger who contributed to this study: Venke F Haaland, Espen Sagen, Mari Rege, Hilde Ness Sandvold, and Wenche Ten Velden Hegelstad. The authors would also like to thank the Norwegian Welfare Administration in Sandnes and Skole- og Jobbresept at the University Hospital of Stavanger, as well as all the participants who took part in the study and gave their feedback on the different prototypes. The project is funded by the Norwegian Research Council (grant number 296390).

Conflicts of Interest

None declared.

Abstract

Background: Sexual health is an important component of quality of life in older adults. However, older adults often face barriers to attaining a fulfilling sexual life because of issues such as stigma, lack of information, or difficult access to adequate support.

Objective: We aimed to evaluate the user experience of a self-guided, smartphone-delivered program to promote sexual health among older adults.

Methods: The mobile app was made available to community-dwelling older adults in the Netherlands, who freely used the app for 8 weeks. User experience and its respective components were assessed using self-developed questionnaires, the System Usability Scale, and semistructured interviews. Quantitative and qualitative data were descriptively and thematically analyzed, respectively.

Results: In total, 15 participants (mean age 71.7, SD 9.5 years) completed the trial. Participants showed a neutral to positive stance regarding the mobile app's usefulness and ease of use. Usability was assessed as "Ok/Fair." The participants felt confident about using the mobile app. To increase user experience, participants offered suggestions to improve content and interaction, including access to specialized sexual health services.

Conclusions: The sexual health promotion program delivered through a smartphone in a self-guided mode was usable. Participants' perception is that improvements to user experience, namely in content and interaction, as well as connection to external services, will likely improve usefulness and acceptance.

Introduction

Background

Sexual health is a component of general health [1] and quality of life in older age [2]. However, older age is also associated with barriers to a fulfilling sexual life [3-5]. Many older adults are sexually active [6] but are at a higher risk than the general population to present sexual difficulties and dysfunctions. Older women often report decreased libido or lack of vaginal lubrication, whereas erection issues, reduced sexual desire, or being unable to reach orgasm are difficulties regularly reported by men [7]. In health care services, sexual difficulties are often untreated [8] and aggravated by poor communication related to lack of appropriate and case-specific information, lack of training among clinicians, or negative social beliefs and societal stigma, which makes it difficult for both patients and clinicians to bring about the topic [9]. Therefore, identifying the means of circumventing societal stigma and providing timely and adequate support are 2 important courses of action to promote sexual health among older adults.

As the prevalence of smartphone ownership and access to the internet increase [10], there is an opportunity to use these technologies to deliver ubiquitous sexual health support in an inconspicuous manner, that is, one that does not overly expose support seekers to fear of social judgment. Smartphones, as they are intimate technologies that ubiquitously accompany their owners, seem to be an adequate means for the delivery of sexual health promotion programs. Although there is evidence of the efficacy of internet-based sexual health interventions for sexual dysfunction [11] or sexual health education [12], the literature is nonexistent on smartphone-based sexual health interventions targeting older adults [13].

Critical to the acceptance and adoption of such technologies is the user experience they provide [14,15]. Coined by Don Norman [16], the term “user experience” was used by the author to characterize all the sets of experiences a user has with a product throughout a user journey, from intention to use until postuse reflections [17]. Therefore, the concept goes beyond usability, defined by International Organization for Standardization as “the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use” [18]. Designing positive user experiences with mobile digital technologies for older adult users has been a focus of many studies because the levels of engagement have been low, thus hampering the potential health benefits of such technologies [19]. Research has found that older adults’ user experience with mobile digital health could be improved if the technology considered potential user sensorimotor and cognitive issues, users’ motivation, and social support [19] as well as if it promoted more personalized experiences and trust [20]. Although there are general guidelines on designing for accessibility and inclusive design [21,22], best practices for designing digital technologies for sensitive topics such as sexuality and intimacy are lacking [23]. Understanding older adults’ experiences with such technologies in the topic of sexual health is critical to improving their acceptability, usability, and

adoption, so that they can deliver positive outcomes. However, no study has yet reported on older adults’ user experiences with smartphone-delivered sexual health promotion programs.

To address these gaps, we have designed a smartphone-based sexual health promotion program [24] under a European project called Anathema (reference AAL-2020-7-133-CP). This program was made available to older adults in a longitudinal study during which we assessed the participants’ user experience with the software. The findings contribute to the body of knowledge on older adults’ preferences, use, and appropriation of digital technologies for sexual health and the design of smartphone-based sexual health promotion programs targeting this population.

Aim

The aim of this study was to evaluate the user experience of Anathema, a self-guided, smartphone-delivered program to promote sexual health among older adults.

Anathema Mobile App Overview

The mobile app used in this study was developed using a participatory design approach [25], which involved users from 3 European countries using the following methods: questionnaires, interviews, focus groups, usability tests, and co-design workshops [23,26].

The app is available for Android and iOS operating systems and contains a sexual health promotion program tailored to older adults. The program, which has an 8-week duration, is organized into 5 modules (which include chapters and subchapters):

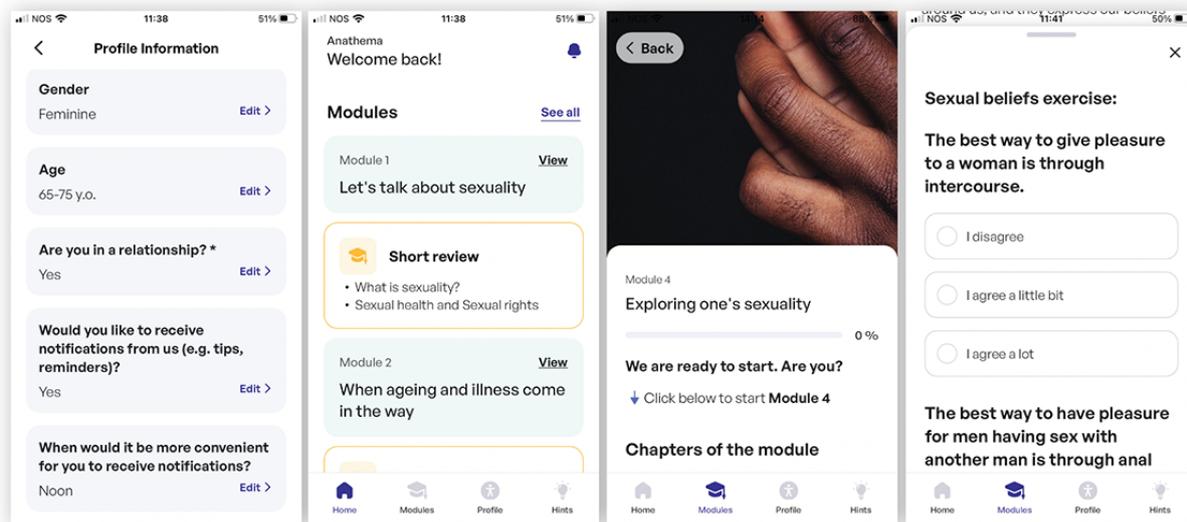

- *Module 1—Let’s talk about sexuality (week 1)*: features information on male and female anatomies, sexual response, the importance of sexual pleasure, and sexual rights.
- *Module 2—When age and illness come in the way (week 2)*: addresses successful aging; the physiological, cognitive, and emotional changes in older age; and the main sexual problems and sexual dysfunction in older age.
- *Module 3—Emotional and physical intimacy (weeks 3-6)*: covers psychoeducation on the cognitive behavioral therapy model and the impact of sexual beliefs, thoughts, and emotions on sexuality. It includes exercises for cognitive restructuring, mindfulness, and communication skills training.
- *Module 4—Exploring one’s sexuality (week 7)*: delivers information on sex aids and strategies to enhance sexual pleasure and satisfaction and includes sexual skills training and mindfulness exercises.
- *Module 5—Planning for a long-term fulfilling sex life (week 8)*: targets on relapse prevention with a focus on strategies to maintain progress and prevent setbacks. It also shares strategies to promote a healthy lifestyle and sexual health.

Each module is unlocked upon the completion of the previous module to ensure knowledge and skills acquisition. The chapters and subchapters are made of content in the form of text, images, and videos. The program also includes exercises such as written reflections or answers to multiple-choice questions using radio buttons (Figure 1). The app is available in English, European Portuguese, German, and Dutch languages.

The mobile app performs passive data collection through timestamp logs of interactions (eg, module completion date) as well as active data collection through logs of users' inputs on

exercises. Another tool, Trial Monitor [27], fetches data from the database and shows visualizations thereof to the research or therapist teams.

Figure 1. Sample screenshots from the Anathema app (left to right): personal information, overview of modules, introduction to module, exercise.

Methods

Study Design

The study design was a single-arm pilot study with older adults (aged ≥ 55 years) testing the self-guided format of the sexual health promotion program in its Dutch version. The pilot study was conducted to assess user experience of the program. The content, structure, and format were also preliminarily evaluated toward the identification of improvements to the program and technological means of its delivery.

Inclusion and Exclusion Criteria

The inclusion criteria for participation in this trial were as follows: (1) being able to provide informed consent, (2) being aged ≥ 55 years, and (3) having digital skills and internet access. The exclusion criteria were as follows: (1) having a severe psychiatric disorder or alcohol or substance abuse; (2) taking medication that could interfere with sexual response; (3) having an uncontrolled medical condition that could interfere with sexual health; and (4) currently being on psychotherapy for sexual or intimate problems or for other psychological problems or current participation in another intervention study or clinical trial (or both).

Study Procedures

In a previous phase of this research, 1119 older adults, recruited through the contact list of the Dutch senior organization Katholieke Bond van Ouderen - Protestant Christelijke Ouderen Bond (KBO-PCOB), answered a questionnaire on unmet sexual needs [26]. In this questionnaire, the respondents were asked to indicate whether they would be available for future research within the same research project. Respondents who gave a positive reply were regularly invited to participate in user research activities throughout the research project [23], including the pilot study described in this paper. The majority of this

subsample (N=346) were men (69.4%), had a high education level (53.2%), and were retired (89.9%). For the pilot study, further potential participants were contacted via other KBO-PCOB channels, including KBO-PCOB's employees.

Upon signing the informed consent form, participants were asked to complete a web-based screening questionnaire. If deemed eligible to participate in the study, the participants were asked to answer a web-based sociodemographic questionnaire. After completing the questionnaire, participants were provided access to the Anathema app and were prompted to complete the program in 8 weeks.

Once they had completed the 5 modules in the app, participants were asked to fill in a web-based, self-developed user experience questionnaire (Multimedia Appendix 1), which also included the System Usability Scale (SUS). Participants were then invited to participate in a semistructured debriefing interview about (Multimedia Appendix 2) their experiences with the program.

Metrics and Data Analyses

The main outcome of the study was user experience, which included dimensions of usefulness and usability. User experience was assessed after the intervention with a self-developed multiple-choice list of characteristics (answer options: *accessible, arousing curiosity, attractive, boring, elegant, fascinating, helpful, instructive, meets expectations, and strenuous*), a question on free grading of the app from 1 to 10, with 10 being the highest grade, a Net Promoter Score question (answer options: *Yes/No/Don't know*), and a semistructured debrief interview with questions addressing usefulness, usability, feasibility, clinical aspects, and implementation (Multimedia Appendix 2). Perceived usefulness was assessed using a self-developed 5-point Likert scale assessing the program in general, each module, and exercises. Usability was assessed using a self-developed 5-point Likert scale on perceived ease of use and perceived readability, as well as with the Dutch

version of the SUS [28]. Assessment of the self-perceived contribution of the program to changes in satisfaction and pleasure in sex life was also performed postintervention with a single-item question (4-item descriptive rating scale).

To characterize the study sample, sociodemographic variables were collected using a self-developed questionnaire assessing age, education, professional status, gender, sexual orientation, marital status, current sexual partnership status, satisfaction with current sex life (5-point Likert scale), self-rated quality of life, and degree of satisfaction with their own health (based on items 1 and 2 from World Health Organization Quality of Life Brief Version [29]).

The interviews were audio-recorded and partially transcribed for relevant content. The transcriptions, written in Dutch, were then translated into English by a native Dutch speaker (MB) for analysis by a non-Dutch speaker (ACB). The questionnaire and the interview data were analyzed descriptively and thematically, respectively.

Ethical Considerations

The study was approved by the Ethics Committee of the Faculty of Psychology and Educational Sciences, University of Porto (reference 2022/01-05b). All potential participants were informed about the study objectives and procedures. The participants who agreed to participate signed the informed consent form. There was no compensation or payment offered to the participants.

Results

Participants

A total of 400 participants were approached to participate in this study. Most participants did not provide a reason for

declining or not answering the invitation. Among those who did (n=47), the reasons given were that participants were no longer interested (n=15), considered the pilot required too much commitment or effort (n=12), felt uncomfortable with the topic (n=9), considered they did not meet the criteria (n=5), or had a malfunctioning email (n=5). We also received information that one person had died.

In total, 23 participants agreed to participate and completed a web-based screening questionnaire to confirm the eligibility criteria. All participants were deemed eligible and were given access to Anathema after answering a sociodemographic questionnaire.

A total of 8 participants dropped out of the study. Of them, 4 participants did not provide any reasons for abandoning the study. Those who did shared the following reasons: discontinued access to the internet (n=1), dissatisfaction with the fact that future content modules were locked (n=1), inability to install and open the app (n=1), and lost motivation to use the app (n=1). A total of 15 participants used the Anathema app, having completed all the modules and completed the final questionnaire on user experience and usability. In total, 8 participants agreed to participate in a debriefing interview.

The 15 participants who used the app and answered the final questionnaire were 7 cisgender women and 8 cisgender men aged between 56 and 85 years (mean 68.3, SD 9.5 years). Most (n=12) were retired, and most (n=10) had completed higher professional education. Overall, 6 participants were married, 4 were single, 3 were cohabiting, and 2 were widowed (Table 1).

Table 1. Sociodemographic characteristics of the sample (N=15).

Characteristics	Values
Gender, n (%)	
Female	7 (47)
Male	8 (53)
Marital status, n (%)	
Single	4 (27)
Cohabiting	3 (20)
Married	6 (40)
Widowed	2 (13)
Professional status, n (%)	
Employed	3 (20)
Retired	12 (80)
Education, n (%)	
Secondary professional education	2 (13)
Higher professional education	10 (67)
University or scientific training	3 (20)
Age (years), mean (SD; range)	71.7 (9.5; 56-85)

Most of the 15 participants were exclusively heterosexual (n=12), most had sex with a partner in the context of an exclusive relationship with that person (n=11), and the level of sexual satisfaction was heterogeneously distributed, as shown,

together with complete sexual characteristics (Table 2). The sample comprised participants who tended to positively rate their quality of life and health (Table 3).

Table 2. Sexual characteristics of the sample (N=15).

Characteristics	Baseline, n (%)
Sexual orientation or preference	
Exclusively heterosexual	12 (80)
Mainly heterosexual	2 (13)
Exclusively homosexual	1 (7)
Current sexual partners	
Sex with a partner, in the context of my exclusive relationship with him or her	11 (73)
Casual sex with a partner	1 (7)
No sexual partner	3 (20)
Satisfaction with current sex life	
Very satisfied	3 (20)
Satisfied	5 (33)
Neither satisfied nor dissatisfied	4 (27)
Dissatisfied	3 (20)

Table 3. Perceived quality of life and health satisfaction (N=15).

	Baseline, n (%)	After the test, n (%)
Rating of quality of life^a		
Very good	8 (53)	9 (60)
Fairly good	7 (47)	5 (33)
Neither good nor bad	— ^b	1 (7)
Satisfaction with health^c		
Very satisfied	8 (53)	7 (47)
Satisfied	7 (47)	7 (47)
Neither satisfied nor dissatisfied	—	1 (7)

^aOriginal wording: How would you rate your quality of life? Responses were rated on a 5-point Likert scale: 1=very bad to 5=very good.

^bNot available.

^cOriginal wording: How satisfied are you with your health? Responses were rated on a 5-point Likert scale: 1=very dissatisfied to 5=very satisfied.

User Experience

In this section, we present the quantitative and qualitative results of the participants' user experience (Table 4). As we do so, we

provide interpretations of the results mostly because of the interpretation required by the analysis of the interview data. Therefore, we discuss some of the results as we present them.

Table 4. Results of the user experience questionnaire (N=15).

	Values
Would recommend Anathema to friends or family (net promoter score)^a, n (%)	
Yes	6 (40)
No	6 (40)
Doesn't know	3 (20)
Perceived usefulness of app^b, n (%)	
Very useful	2 (13)
Useful	6 (40)
Neither useful nor useless	6 (40)
Useless	0 (0)
Extremely useless	1 (7)
Perceived usefulness of exercises^c, n (%)	
Very useful	0 (0)
Useful	7 (47)
Neither useful nor useless	3 (20)
Useless	3 (20)
Extremely useless	2 (13)
Perceived ease of use^d, n (%)	
Very easy	1 (7)
Easy	7 (47)
Neither easy nor difficult	5 (33)
Difficult	2 (13)
Readability^e, n (%)	
Very easy	1 (7)
Easy	7 (47)
Neither easy nor difficult	5 (33)
Difficult	2 (13)
System Usability Scale score, mean (SD; range)	56.3 (19.1; 20-85)
Score (1-10) given to Anathema app, mean (SD)	6.5 (1.8; 2-9)
Perceived impact of Anathema app in satisfaction and pleasure^f, n (%)	
Positive impact	4 (27)
No change	7 (47)
Negative impact	1 (7)
Doesn't know	3 (20)

^aOriginal wording: Would you recommend the Anathema app to friends and/or family members?

^bOriginal wording: How useful do you think the Anathema app is for older adults? Responses were rated on a 5-point Likert scale: 1=extremely useless to 5=very useful.

^cOriginal wording: How useful did you find the (writing) exercises you were offered? Responses were rated on a 5-point Likert scale: 1=extremely useless to 5=very useful.

^dOriginal wording: How easy was it for you to use the Anathema app without any help from others? Responses were rated on a 5-point Likert scale: 1=extremely difficult to 5=very easy.

^eOriginal wording: How readable did you find the content of the Anathema app? Responses were rated on a 5-point Likert scale: 1=extremely difficult to 5=very easy.

^fOriginal wording: Do you have the impression that the Anathema app can help you change satisfaction and pleasure in your sex life? Rated using a

descriptive scale: Don't know; No, no change; Yes, namely less satisfying and fun; Yes, namely more satisfying and fun.

Most participants showed a neutral to positive stance toward the app regarding its *usefulness*. There are some nuances when analyzing the perceived usefulness per module, as illustrated in [Figure 2](#). Modules 2 and 3 had slightly more polarized responses. Modules 1 and 2 were found to be “very useful” for more participants, likely because of the reasons given in the interviews: participants learned new concepts, learned to understand what is normal in aging (“I end up thinking about

the part about body ageing. That’s reliable information that I can’t easily get anywhere else today” [P03]), were made to rethink the way in which they faced sexuality, and also learned about the genitalia of other sexes:

Nice to read some details about genitals[...] also from the opposite sex, how something works. [P11]

Enlightening. I did benefit from seeing what a prostate looked like. [P04]

Figure 2. Visualization of perceived usefulness by module.

Module 1	Module 2	Module 3	Module 4	Module 5
Extremely useless

Very useful	Very useful	Very useful	Very useful	Useful
Very useful	Very useful	Very useful	Very useful	Useful
Very useful				

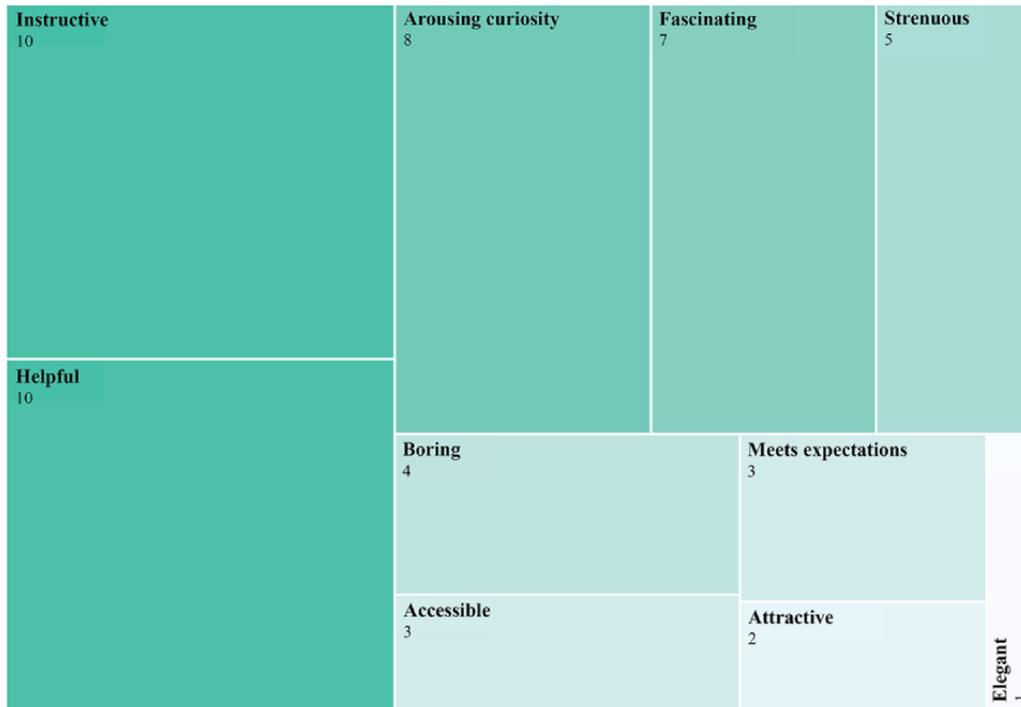

Other highlighted learning points from the program are the importance of communication and the fact that sexuality does not need to be equated with penetration. Something some participants missed was the possibility to ask the app questions about their specific problems, ask questions anonymously, or to be able to search for certain themes that could be of more interest to them.

Seven participants evaluated the *exercises* as useful, whereas the other 8 found them neutral (n=3), useless (n=3), or extremely useless (n=2). Crossing these results with the information provided in the interviews, one can infer that there were 2 aspects that hindered the experience with the exercises: on the one hand, participants struggled with long text input on their smartphone keyboards; on the other hand, for this group, the feeling of being “schooled” by the app was not equated with

positive emotions, thus negatively impacting the experience. Finally, in the interviews, participants revealed that some exercises helped them think of sexuality in a different way, which they experienced as being positive.

When asked to attribute *characteristics* to the *Anathema app*, most participants selected a set of descriptors displayed in [Figure 3](#), but the number of choices varied from a single adjective to 6 adjectives. Most of the qualifiers have positive valence, with the exception of “boring” and “strenuous,” with 4 and 5 mentions, respectively. In line with the data collected through the interviews, the participants perceived that they had learned from the app. However, only 5 participants assessed the app as having the potential to help change their sexual satisfaction and pleasure.

Figure 3. Visualization of qualifiers attributed to the Anathema app and how often they were attributed.

The interviews also revealed that participants appreciated the app aesthetically, which connects to the descriptors that were chosen, as well as the tone of voice that was adopted for the content, which, in some cases, helped them deal with a sensitive topic:

I admire that this can be done in an app. Good looking and doesn't scare someone. I managed to deal with such a sensitive topic. [It's] friendly and nicely constructed. [P22]

For 2 participants, the communication style options were not the most appropriate, for example, when showing an animated video of an anthropomorphized clitoris. Although the photographs were selected based on a survey conducted by the research team about the characteristics of photos that were appreciated by Dutch older adults, 2 interviewees did not find them totally appropriate, for example, some having a comical or childish tone, representing too young people, or not representing enough diversity.

Taking the *net promotor score* as an indicator of satisfaction, we can see that opinions were divided. Three participants did not know whether they would recommend the app to friends or family, whereas the remaining 12 participants were equally divided between wanting to recommend and not wanting to do so. In the debriefing section of the interviews, participants who were not certain whether to recommend Anathema expanded on this. They explained that they think the app has potential but that it needs certain improvements, as described earlier, for them to confidently recommend it to others.

The average SUS score, which measures *usability*, stood at 56.3, which, according to the scoring standards, corresponds to an

assessment of "OK/Fair" [30]. Based on the averages per item, we can see that participants tend to think that they do not need help in using the system, although usability is not perceived to be at the excellent level. The level of confidence felt by participants while operating the app was high. Participants generally showed a neutral to positive stance toward the app regarding its *ease of use* and its *readability*. Although most people did not experience trouble reading because of font size or contrast, this was an issue for one of the participants who dropped out:

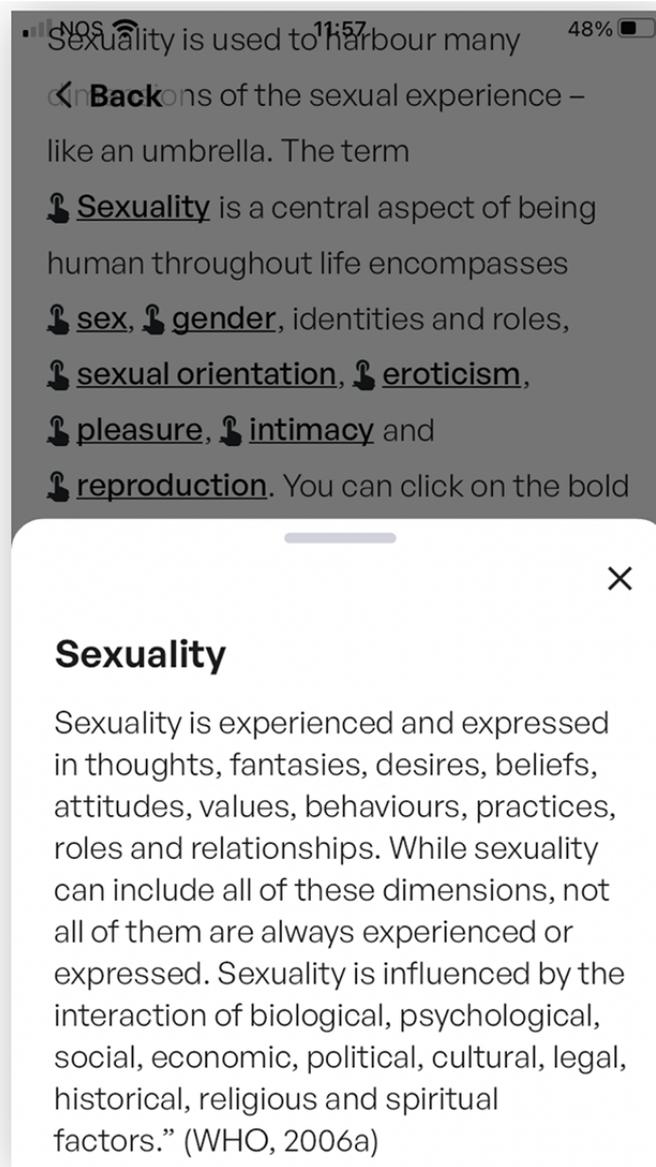

I also found the fine print difficult. They are clear but with deteriorating eyes good reading requires more effort. [P04]

The interviews revealed that the app worked well on participants' phones and that they found it very convenient. However, participants often wished that the app would also be easy to use on a tablet device or desktop:

Excellent [the experience of using the app on the phone]. Preferably on an iPad, because of the larger screen. On the phone it worked. The smaller keyboard asked more caution, but [it] went fine. [P11]

With the exception of 2 participants, who suggested direct speech, easier wording, and shorter sentences, interviewees found the wording easy to understand. In total, 2 participants reflected on whether the scientific explanation should be highlighted as is (Figure 4), for instance, on starting the first module with the definition of sexuality or whether it should be made more digestible to engage readers.

Figure 4. Screenshot from the definition of sexuality, which appears in a slide-up pop-up when the user taps the word “Sexuality” shown in the gray-faded part of the image. WHO: World Health Organization.

Another aspect of readability that was touched on was finding one’s place in the content structure. For 2 participants, it was hard to understand at which stage they were in navigating the app, originating the feeling of being lost: “In a book you can browse through that and then you see where you are. In the app this overview is not so clear” (P06). For those who felt lost, as well as for one participant who would like to revisit specific parts of the content, a possible solution was provided by one participant who said that they missed a way to bookmark “Favorites.”

The participants *appropriated* the app in different ways. There were reports of people using the app only randomly when they found the time, defining a fixed schedule (eg, evening, late at night), or defining a place to use the app (eg, kitchen, home). Common to the participants was the need to use the app alone and undisturbed.

One participant asked the partner to also go through the app, but they did not want it because it was a taboo topic. Three

mentioned how they talked to friends or their partners later about the app and what they had learned, for example:

Through the app I can easily talk with my partner about sexuality. The participation, together with my partner, in the previous workshops for Anathema, also contributed to this. The openness of other participants was a good example for me. [P04]

While 5 participants stated that there would be no place or time when they felt uncomfortable using the app, the remaining 3 gave some indications thereof. For these participants, it would be important to use the app alone and in a private place. Participants also reflected on how they would like to discuss what they were learning in the app with others but found it stigmatizing:

When I talk to friends about food, for example, all the experiences can be discussed. Apparently, that is not possible when talking about sex. [P20]

When I try to discuss with seniors of an association with a Catholic background that I am participating in this project, the reaction is that does not suit our people. [P18]

Half of the participants found an 8-week period to be too long, whereas the other half felt it was an acceptable or good duration. However, participants struggled with the idea of this being time bound in some way because they could not understand why this specific duration was chosen. In 1 case, the participant felt that this indication of duration could send the wrong message: “I have to be ready in 8 weeks” (P03).

Being presented with content that had a specific reading order was cumbersome to some participants. This was because, on the one hand, they could feel schooled, and, on the other hand, they did not want to feel that they were losing time in content that they were not interested in. One participant shared their technique for when something like this happened: they just scrolled the content very quickly to get to the bottom and move to the next chapter. Despite negative comments about the locked content (eg, “I wanted to look at a topic in Module 4. But didn’t do that out of irritation at the locks in the extended Module 3” [P04]), participants generally agreed that the content is well structured, being easy to follow. Mindfulness is something that some interviewees found unnecessary. On the other hand, some interviewees would expect to read more about love and affection. There were also other suggestions of curated lists of contacts for further support (eg, participants stated they would like to be able to ask questions to therapists over email) and fitness exercises (eg, pelvic floor muscle exercises).

Although 9 of 15 participants in the questionnaire assessed module 5 as useful or very useful, the interviews revealed a slightly different picture. The interviewees had mixed opinions regarding the usefulness of the last module. With the exception of 1 person, those who found it useful as a recap also reflected on the possibilities of *coupling the app* with curated contacts to therapists to continue exploring the topic or to find tailored help to a specific issue. One interviewee thought about accompanying the app with television or radio shows, stating that this was the reason why they bought a book on sexuality. Another possible extension would be a course, workshops, or group activities that would let people discuss and further explore what they had learned and experienced:

In addition to using the app, it could be interesting to be in a discussion group with other couples as a couple. That could help improve communication about sex. The app provides plenty of conversation material for that. [P11]

Interviewees had mixed opinions regarding *whether the app should be paid*. On the one hand, participants shared that they are not used to paying for apps, but on the other hand, they recognized that they might pay for extra services (eg, consultations) and that free apps do not have as much credibility. Credibility is something that participants cling to when reflecting with the interviewer about how to make the app available to more people. Participants concluded that the app could be credibly made available through medical doctors, therapists, or reliable associations. Although this was not asked, participants

also shared ideas on how to raise awareness about the Anathema app, for example, through advertisement, television or radio shows, or leaflets.

Discussion

Principal Findings

The pilot study conducted in the Netherlands with a group of 15 community-dwelling older adults was a novel study in the field of mobile health apps in sexual health. Although the dropout rate was high (65%), no participants were lost to follow-up or nonuse cases, that is, participants answering the questionnaires without having used the mobile app until the end. We found that the app was usable, that participants showed high levels of self-confidence in using it, that the smartphone can be a useful and private way to have access to reliable sexual health information, that participants foresee how extra services could help tailor the program to their specific needs, and that certain improvements in content and in interaction are likely to increase user experience for this smartphone-delivered sexual health promotion program.

As with other studies in the literature [20], the user experience was negatively affected by a lack of social support for users’ specific issues. In the interviews, participants gave examples of further content on love and affection, a curated list of resources and fitness exercises that they would like to see, and options to search through the content to get the information they were looking for. The lack of social support, ranging from relatives to professionals, also seems to have negatively affected participants’ user experiences. In their systematic review, van Acker et al [19] noted how social support (ranging from relatives to professionals) was an important factor in user experience. In our study, with the exception of 1 participant who could not convince their sexual partner to also use the app, there were no reports of available or lacking support from relatives, but participants specifically mentioned that professional support would be useful in addition to the existing offer. A nuance with relation to the literature [19] is that participants in our study did not require much professional support to interact with the program, but rather as an extension to it, often to attain the personalization requirement we have just described earlier. Furthermore, the participants struggled with the locked content. Although the tunneling technique has been used to increase engagement with intervention or technology, in our study, it did not seem to have this effect. This is similar to recent findings with an intervention for a younger generation [31].

As noted in the literature [20], trust is also an important dimension in user experience. Although not directly asked about it, our interviewees alluded to the element of credibility regarding willingness to pay, which was considered by Hurmuz et al [20] as a metric of user experience. For the participants in our sample, the channel via which they access the app is an important factor at the time of choosing whether to use and ultimately pay for the app.

As measured by the SUS instrument, self-confidence among the participants in our study was high. This might also have been influenced by the level of education and digital literacy of

the sample. The level of education might also explain why the participants often alluded to the experience of “being schooled” as a negative valence. Although the tone of voice for the program regarding visual and written content was co-designed [23], it might not have been implemented properly to eliminate this negative experience. This aspect is further discussed in the “Limitations” section below. On the other hand, some users also reacted negatively to content that seemed “too scientific,” and some commented that some terms might not be easy to understand for the wider population. This is at odds with the higher educational level of this sample, but the explanation for the dislike might be related not to the understandability of the content but rather to a kind of experience that users expect when they are using an app that is related to sexuality.

The participants stated that the topic of sexuality was not embarrassing. However, there were some accounts of users requiring privacy when going through the content, one user whose partner did not want to use the app because of the topic, or users commenting on how they did not feel free or at ease discussing the topic with their peers. Therefore, the topic of taboo still requires further research in terms of how much of a barrier it is to accept and use technology around this topic. Participants’ statements in the interviews suggested that a smartphone-based intervention can bring the advantages of ubiquity, intimacy, and anonymity to an intervention that is likely to elicit stigma in some contexts. The program itself was regarded as a trustworthy source of information that participants think is difficult to find on this topic. On the other hand, it could be coupled with more targeted personal services for users who would like to interact with therapists or even join groups willing to openly discuss topics of sexual health. Future research should study the provision of such discussion groups either in person or through moderated and anonymous forums inside the app.

Our study included participants interested in sexual health. In any case, even within our small sample, we witnessed a wide spectrum regarding taboo. For instance, some participants felt blurring genitalia photographs by default with overlaid text: “Sensitive content. Click to view” was condescending, whereas others felt that suggesting exercises for sexual pleasure was going too far. As with other types of apps targeting older adult users, our study saw a large heterogeneity in user preferences. Even if resources are allowed for the software development team to implement ultrapersonalization, we could place a large burden on users upon onboarding to set up preferences, which, in itself, would have a negative effect on technology acceptance. One way of addressing this could be to create certain user profiles and adapt scaffolding techniques that have been used for usability [32] for the purpose of conspicuousness degrees. Future research should work on this balance between a certain level of tailoring to one’s needs and preferences, with time invested in customizing the app.

Strengths

This was the first study to evaluate the user experience of a self-guided, smartphone-delivered program to promote sexual health among older adults. The mixed methods approach was a strength of this study in the sense that it provided a rich description of participants’ experiences with the app and the

program. Without the interviews, we would hardly have had such detailed information that would indicate how to improve the app and the program, as well as a first understanding of how participants appropriated the app.

Our study did not aim at generalizability but rather at an in-depth understanding of user experience, which justified the emphasis on the qualitative data. Through this approach, we derived actionable insights to improve the content, structure, and format of the program.

Although our study was conducted with a small and specific sample of older adults in the Netherlands, the methodology we used allowed us to unveil nuances that can be useful for researchers to consider when implementing smartphone-based programs for sexual health in different populations: the relevance of social support, the credibility of the program, the opportunities that smartphone-based interventions may bring to sexual health interventions in terms of privacy or convenience, and the variability among program users about what might be considered a taboo and how this might impact users’ preferences, practices, and attitudes toward the programs.

Limitations

As we conducted a user experience pilot study to obtain in-depth feedback, the results might not reflect the characteristics of the older adult population in the Netherlands. Although further research is needed to reach generalizability, this study constitutes a stepping stone in this journey.

The sample characteristics in our study are its greatest limitation. Only one-fifth of our participants were dissatisfied with the current state of their sex lives, and most considered themselves to be in fairly good or good health, which may not be representative of the older adult population. These characteristics may have biased how participants responded to a sexual health promotion program tailored to help users identify and cope with issues related to their sexual health. Our sample also comprised participants with a high level of education. This might explain why some participants felt schooled, as they were already in possession of information that was provided by the program. As participants have suggested, for a future pilot study, it would be advisable to increase the number and type of channels used for dissemination and recruitment, such as the mainstream media. This would help increase the visibility of Anathema and reduce, if not altogether, prevent, selection bias.

The features implemented on the app responded as much as possible to the user research requirements, but this was not always possible or perhaps implemented at its best. In some cases, there were technical limitations that did not allow their implementation. For instance, the app began to be implemented as web based so that it would also run on desktop browsers if participants preferred, but the identification of a problem in a technical component ahead of the implementation process forced the software development team to develop natively for Android and iOS.

We expected this lack of flexibility in the device type to be a negative aspect for some participants. On the other hand, at least once, the preferences collected from participants in user research studies preceding the pilot study were not aligned with the

preferences of the pilot study sample. We describe 2 instances of this problem.

The first example relates to the choice of imagery. To select the photos for the app, we conducted a survey with 111 older adults in the Netherlands, in which we showed 10 different pictures and asked participants to rate the pictures, select their favorites, and justify their choices. The survey revealed that participants preferred uplifting, cheerful, and romantic images of participants who were not young but also not too old. The interviews in the pilot study revealed that, for some participants, these images were not appropriate.

Another example was the language used: a series of tests on the preferred tone of voice were used to create the original content in English [23]. The content was translated into Dutch, which went through content reviews from native speakers with experience in older adult care. Nevertheless, for some participants in the sample, the language was described as “too scientific.” It is also possible that the research team was not able to correctly implement the insights from the user research phase, thus causing a mismatch between the users’ expectations and the implemented app. Further research should revise the feedback from the user research phases and cross it with the results from the pilot study to understand where the app can be improved to meet users’ expectations.

Further research should also focus on interaction and content issues to improve current mobile apps toward improving user experience. In particular, there is a need to understand how to balance the quantity and type of content with an engaging user experience. Once an improvement in user experience has been noted through further formative testing, the pilot should be repeated. As there was a mix of negative and positive comments provided by the participants and because the results from the SUS score are aligned with the comments from the interviews, we do not think that social desirability influenced participants’ answers. However, as social desirability plays an important role in sex research surveys, a future pilot study could include a questionnaire (eg, [33]) to control for this effect. Further research should focus on a larger and more diverse sample regarding sexual satisfaction, health status, and literacy level.

Future pilots should include study designs that enable the collection of fine-grained data about the user experience

combined with an assessment of the program’s efficacy in improving sexual health so that the aspects of appropriation and how the app fits into participants’ practices could be better understood and, in turn, inform strategies to improve sexual health outcomes, engagement, and user experience with such an intervention.

Conclusions and Implications for Design

The mobile app of Anathema with a sexual health promotion program delivered in a self-guided mode to a sample of older adults in the Netherlands was assessed as usable. Most participants tended to assess the app and program as useful, but both the app and the program would benefit from certain improvements, which we group under “content” and “interaction” as possible guidelines.

Content wise, readability and engagement can be improved by using plainer language in general, revising sections that sound “too scientific” (eg, definition of sexual health) or too medical (eg, content regarding erectile problems was very focused on the urological aspects). Although for some participants, the content was too long, and participants would also prefer not to have locked content, in which case the length would not be a barrier to engagement. It is clear that participants would appreciate more curated content that would refer them to support the community or to further services.

Regarding *interaction*, there are suggestions to enable searching and asking questions so that the user could be directly guided to the content that is of most interest to them or so that they could center their learning in their own experiences. This implies that content is unlocked by default. Participants would also like to bookmark certain sections and have the means to know where they are in the app. Finally, although participants shared that some exercises made them reflect—they saw this as positive—they struggled with the exercises that involved text input. Therefore, the interaction modes in the exercises can be improved. Although participants state they do not want to be schooled, they highlight “learning” as one of the advantages of using the app. In the future, the Anathema app should meet the goal of teaching without resembling a schoolbook. This was highlighted by participants who were expecting more interactivity from the app rather than an app that reads like a book.

Acknowledgments

Beyond the participants in this study, ≥1400 older adults from 3 different countries were involved in the design and testing of the program. The authors are very thankful to all the participants and to the secondary and tertiary users who provided valuable feedback.

The authors would like to acknowledge the European Commission through the Active Assisted Living (AAL) Programme (reference AAL-2020-7-133-CP) and the Member States: Fundação para a Ciência e a Tecnologia, in Portugal; the Austrian Research Promotion Agency (FFG), in Austria; and ZonMw, the Netherlands Organisation for Health Research and Development, in the Netherlands for funding this project.

Abstract

Background: Chronic kidney disease affects 10% of the population worldwide, and the number of patients receiving treatment for end-stage kidney disease is forecasted to increase. Therefore, there is a pressing need for innovative digital solutions that increase the efficiency of care and improve patients' quality of life. The aim of the eHealth in Home Dialysis project is to create a novel eHealth solution, called eC4Me, to facilitate predialysis and home dialysis care for patients with chronic kidney disease.

Objective: Our study aimed to evaluate the usability, user experience (UX), and patient experience (PX) of the first version of the eC4Me solution.

Methods: We used a user-based evaluation approach involving usability testing, questionnaire, and interview methods. The test sessions were conducted remotely with 10 patients with chronic kidney disease, 5 of whom had used the solution in their home environment before the tests, while the rest were using it for the first time. Thematic analysis was used to analyze user test and questionnaire data, and descriptive statistics were calculated for the UMUX (Usability Metric for User Experience) scores.

Results: Most usability problems were related to navigation, the use of terminology, and the presentation of health-related data. Despite usability challenges, UMUX ratings of the solution were positive overall. The results showed noteworthy variation in the expected benefits and perceived effort of using the solution. From a PX perspective, it is important that the solution supports patients' own health-related goals and fits with the needs of their everyday lives with the disease.

Conclusions: A user-based evaluation is a useful and necessary part of the eHealth solution development process. Our study findings can be used to improve the usability and UX of the evaluated eC4Me solution. Patients should be actively involved in the solution development process when specifying what information is relevant for them. Traditional usability tests complemented with questionnaire and interview methods can serve as a meaningful methodological approach for gaining insight not only into usability but also into UX- and PX-related aspects of digital health solutions.

usability; UX; user experience; PX; patient experience; user-based evaluation; patients; eHealth; digital health solution; kidney disease; home dialysis

Introduction

Chronic kidney disease is a global health problem that leads to kidney failure, cardiovascular disease, and premature death. Chronic kidney disease affects 10% of the population and is one of the leading causes of mortality worldwide [1]. Dialysis, along with kidney transplant, is a lifesaving treatment for people with end-stage kidney disease. Dialysis can be delivered in hospital or home settings, and home dialysis is associated with a higher or equal quality of life for patients [2] and lower costs for the health care system [3]. As the number of patients receiving treatment for end-stage kidney disease is forecasted to rise [4], innovative digital solutions that maximize efficiency, improve patients' quality of life, and facilitate care delivery and monitoring are needed.

eHealth solutions, such as digital patient engagement platforms (DPEPs), are increasingly developed to support self-care, enhance patient-clinician collaboration, and increase the efficiency of care delivery [5-7]. In dialysis care, new DPEP solutions have the potential to improve disease management, health outcomes, and patient experience (PX) among patients with chronic conditions [8,9]. To achieve these goals, a human-centered design approach to development is a necessity. Human-centered design is an approach that aims to make digital systems usable and useful by applying human factors and usability techniques, such as user-based testing, guidelines for interaction design, prototypes, user observations, and user requirements specifications [10]. Usability refers to the interaction between the end user and the system, whereas the user experience (UX) includes aspects like emotions, beliefs, and perceptions [10,11]. Originating from the UX, the PX has also become an important and acknowledged concept as the health care sector has shifted to a more customer-oriented approach. PX has been used to describe patients' interactions and care experiences across the care continuum [12,13], but it lacks a consensus definition [14]. Regarding eHealth solutions, numerous factors influence PX, such as the solution type and quality, risks and concerns, communication, remote interaction, and patients' attitudes toward digital solutions [14].

Several studies have evaluated the usability of eHealth solutions aimed at patients with chronic and serious conditions. These have included solutions targeted to patients with cancer for monitoring and managing their illness or treatment-related symptoms [15-17], digital self-management programs for patients with juvenile idiopathic arthritis [18] and chronic obstructive pulmonary disease [19], and an electronic patient-reported outcome tool for patients with complex chronic disease and disability to set and monitor their health-related goals [20]. Common usability problems identified across these studies have included terminology issues [15,18], navigation problems [15,17], and challenges with the way information is presented to the patients [16,18]. Regarding UX, studies have found that patients' illness-related problems and limitations should be taken into account when designing eHealth solutions for patients with chronic and serious conditions [16,19,20]. Further, customization of the solutions, for example, based on the stage or severity of the illness or type of treatment should be possible to provide a pleasant UX [16,17,19]. Some prior

studies have also reported PX-related findings, such as patients fearing that the eHealth solutions will replace in-person consultations with clinicians [20], and patients generally welcoming the additional digital communication channel [16,17]. However, these results have not been analyzed or described in relation to PX, and it seems that PX-related aspects were not systematically explored in the evaluation studies.

In this paper, we report a user-based evaluation study of the novel eHealth solution: a DPEP targeted to patients with chronic kidney disease in CKD stages 4-5, for example, to patients undergoing predialysis and patients undergoing home dialysis (both peritoneal dialysis and home hemodialysis). Patients with functioning renal transplants were excluded. This study is part of the larger eHealth in Home Dialysis project [21], which is coordinated by HUS Helsinki University Hospital, Finland. The solution is designed to facilitate advanced home care: enable patients with chronic kidney disease to document their treatment data, monitor their clinical and health data, order dialysis supplies, and report their symptoms as well as enhance patient-provider communication. The objective of our study was to evaluate the first version of the DPEP solution, called eC4Me, and support deployment of the solution and promote end user participation in later phases of the development. The research questions are as follows: (1) What kind of usability problems does the evaluated DPEP solution have? (2) What kind of UXs, expectations, and improvement ideas do patients with chronic kidney disease have about the new DPEP solution? and (3) How can the new DPEP solution support positive PX for patients with chronic conditions?

Our user-based evaluation study aims to widen the scope of usability evaluations of eHealth solutions targeted at patients with chronic and serious conditions to include PX-related aspects alongside usability and UX. Additionally, to our best knowledge, this is the first study to evaluate a DPEP solution specifically targeted to patients with chronic kidney disease.

Methods

Study Design

Our study design was based on a formative user-based evaluation approach [22]. The formative evaluation aims to support the improvements of the system, particularly the user interface, as part of an iterative design process [22]. A typical method of formative evaluation is a think-aloud usability test, which includes 4 stages: preparation, introduction, the test itself, and debriefing [22]. Usability testing is stated to be the most fundamental usability method since it provides direct information about how people use the systems and what their exact problems are [22]. In practice, the think-aloud method involves the test participants continuously thinking aloud while performing the predefined test tasks. The researcher's role is to make observations and continuously prompt the participant to think aloud by asking general questions [22].

The usability assessment methods recommended for gathering supplementary data are observations, questionnaires, and interviews [22]. For the questionnaire, we used the UMUX (Usability Metric for User Experience) [23], which closely

conforms to the 3 widely acknowledged attributes of usability—effectiveness, efficiency, and satisfaction [10]—and strongly correlates with other commonly used usability metrics such as the System Usability Scale [24,25]. UMUX questionnaire is considered compact since it includes four question items: (1) the system’s capabilities meet my requirements, (2) using the system is a frustrating experience, (3) the system is easy to use, and (4) I have to spend too much time correcting things with this system [23].

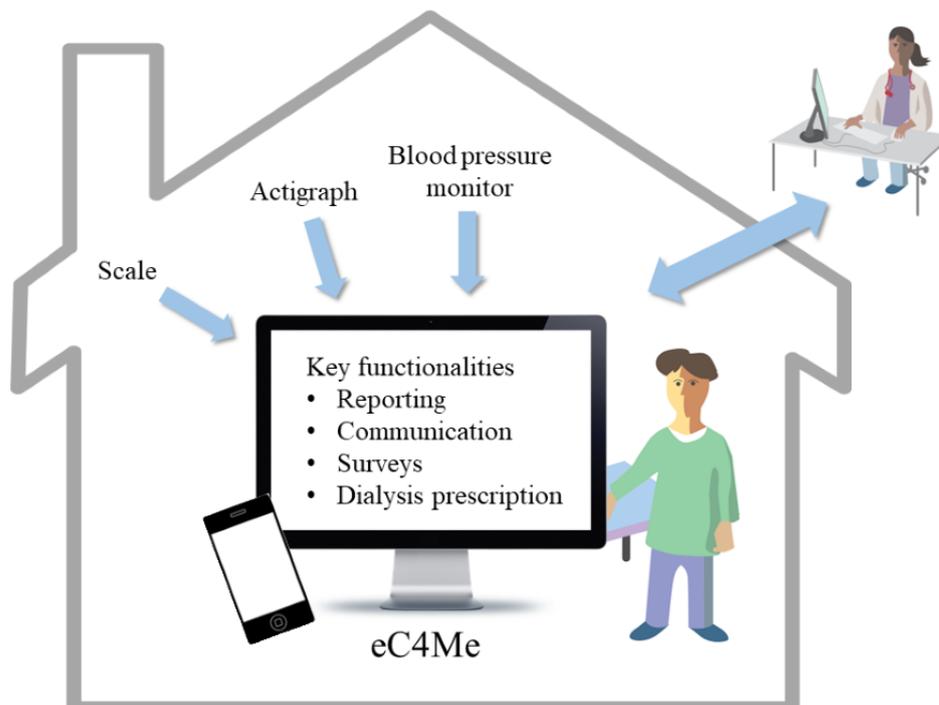

Due to the COVID-19 pandemic, we conducted the evaluation sessions remotely. Experiences from previous studies have shown that high-quality research data can be collected remotely [26]. However, compared to traditional face-to-face usability testing, remote evaluations require more pedantic preparation. Researchers must pay attention to building trust and confidentiality [26], choose tools that are familiar and easily accessible for the participants [27], focus on body language and facial expressions to establish rapport [26,28], and provide the participants with technical support as needed [29]. Other

recommendations include having multiple researchers participate in remote test sessions [28], and using a synchronous approach, which makes it possible to observe participants’ screens in real-time [30].

Evaluated DPEP Solution

The first version of the eC4Me solution was introduced in autumn 2021. A core part of the solution was an app, which had both computer and mobile interfaces and included the following key functionalities: monitoring of treatment-related data (reporting functionality), messaging between patients and nurses (communication functionality), answering quality-of-life surveys (survey functionality), and access to patient’s dialysis prescriptions (dialysis prescription functionality; see Figure 1). In addition, the solution delivered to the patients included external monitoring devices, such as a blood pressure monitor, a scale, and an actigraph, which, together with clinical data collected from electronic health records, enabled patients to monitor their conditions.

Figure 1. First version of the eC4Me solution.

Participants

The participants were recruited from a large university-affiliated nephrology clinic with the help of research nurses. All participants were familiar with the eHealth in Home Dialysis project since they had participated in an interview study that was conducted earlier as part of the project.

Eleven patients with chronic kidney disease were originally invited to participate in this study. As 1 test participant was particularly interested in technology development and came to his test session with pre-drafted design ideas, we decided to modify his test session to focus on discussing these ideas. Consequently, he did not perform the test tasks in our test

procedure, and the data from his session was omitted from this study. Therefore, data from 10 user-based evaluation sessions were included in this study.

The background information collected from the participants included age, gender, type of treatment, occupational status, and technical skills. Technical skills were evaluated by asking participants to give their own estimation of their technical skills, with response options being “good,” “basic,” and “weak.” Half of the participants (n=5) had the solution delivered to their homes 1-3 weeks before the tests, whereas the other half (n=5) were using the solution for the first time in their test session. Participant characteristics are shown in Table 1.

Table 1. Participant characteristics (N=10).

Characteristics	Participants, n (%)
Type of treatment	
Predialysis (not yet in dialysis treatment)	4 (40)
Peritoneal home dialysis	3 (30)
Home hemodialysis	3 (30)
Experience with the solution before the test session	
No experience	5 (50)
1-3 weeks of experience	5 (50)
Sex	
Male	6 (60)
Female	4 (40)
Age (y)	
30-60	4 (40)
>60	6 (60)
Occupational status	
Fully working	2 (20)
Partially working	2 (20)
Not working (fully retired or sick leave)	6 (60)
Technical skills (own estimation)	
Good	2 (20)
Basic	7 (70)
Weak	1 (10)

Test Procedure

In our study, we used synchronous remote usability testing with Microsoft Teams as a tool, and 2 researchers were present in each session. During the test sessions, patients used the eC4Me solution with a computer, enabling the researchers to monitor their task performance via screen share on Microsoft Teams.

Each test session followed the traditional structure and stages of usability testing [22], lasted about 2 hours, and included the following phases: (1) introduction—participants were introduced to the evaluation study and given an opportunity to become familiar with Microsoft Teams; (2) test tasks—run-through of predefined usability test tasks, which included logging in, searching for information and functionalities, viewing and interpreting health-related data, reporting treatment-related data, and filling in the surveys; (3) questionnaire—participants answered the UMUX questionnaire; and (4) interview—participants answered semistructured interview questions to elaborate their UMUX scores and give overall feedback on the solution based on the usability test tasks. The interview consisted of 4 open-ended “Why did you give this score?” questions, which were asked for each of the UMUX items separately, and a question on how participants would improve the solution.

Before the actual tests, the test procedure was piloted with 2 research nurses. To ensure privacy, all patients used the solution

with test login IDs and dummy health data during the test sessions. The exact test tasks varied slightly between the participants, depending on their prior experience with the solution, illness stage, and type of treatment, as not all functionalities of the solution were relevant for all patients. The participants who had used the solution before the tests were also encouraged to provide feedback on the entire solution including the research devices and a mobile interface. This study was performed in the Finnish language.

Data Analysis

The qualitative data included video recordings from remote usability tests, observation notes, and transcripts from semistructured interviews. The qualitative data were analyzed following a thematic analysis method [31], which involved collaboration between 3 researchers (AA, PV, and JV). The data were first coded by 1 researcher (PV), and the findings were discussed by the 3 researchers. Further, 2 researchers (AA and JV) then continued the analysis by categorizing the codes into thematic groups, following the principles of the affinity diagram method [32]. The following main three thematic groups were used: (1) *usability*, which includes findings about users' interactions with the DPEP solution; (2) *UX*, which includes findings about users' experiences and feelings toward using the DPEP solution; and (3) *PX*, which includes findings about how the DPEP solution can support patients' interactions and care experiences across the care continuum.

The researchers (AA and JV) then continued the analysis with several rounds of iterations. Along with other data, improvement ideas expressed by the participants were thematically grouped. At the end of the analysis, the thematic grouping of observations was discussed, approved, and finalized collaboratively by the 3 researchers.

The quantitative data consisted of UMUX item scores, which were analyzed following the UMUX scoring scheme [23]: to obtain the overall UMUX score, items 1 and 3 were scored as [score-1] and items 2 and 4 as [7-score], and the sum of the item scores was then divided by 24 and multiplied by 100. In addition to the overall score, the means and SDs for each of 4 question items were calculated separately for 2 participant groups (patients who had or had not used the solution before the test). The differences between the groups were analyzed using *t* tests for independent samples. The tools used for data analysis were ATLAS.ti (ATLAS.ti Scientific Software Development GmbH) and Microsoft Excel for qualitative data analysis and Microsoft Excel for statistical analysis.

Ethical Considerations

This study has a research permit from the ethical committee of the Hospital District of Helsinki and Uusimaa (HUS/1649/2020).

Results

Overview

The results are divided into 5 topics: usability, UX and PX findings each, UMUX results, and improvement ideas.

Usability

The *usability* findings of the evaluated eC4Me solution consisted of 8 subthemes (Table 2).

Navigation includes findings about whether patients could locate the functionalities, content, and commands that they were looking for. Nine out of 10 users had at least some problems navigating the app, and the most common navigation challenges were related to users not understanding the content structure or the terminology used in the menus.

Table 2. Usability, UX, and PX findings of the user-based evaluation. “All findings” includes positive, negative, and neutral findings. For the *usability* theme, negative findings, that is, the identified usability problems, are also reported separately under “problems.”

Subtheme	All findings		Problems	
	Codes, n	Users, n	Codes, n	Users, n
Usability				
Navigation	41	10	19	9
Terminology	35	10	22	8
Front page	21	10	3	2
Presentation of data	35	9	17	5
Login	10	9	4	4
Survey functionality ^a	12	7	2	2
Reporting functionality ^a	50	6	29	6
Dialysis prescription functionality ^a	6	5	0	0
UX^b				
Technical functionality	26	9	— ^c	—
Use of access devices (computer, tablet, or mobile)	26	9	—	—
Workload and effort	16	7	—	—
Perceived benefits	12	7	—	—
Security	8	4	—	—
PX^d				
Content-related needs	67	10	—	—
Situation of use	57	10	—	—
Communication with clinicians	52	10	—	—

^aThe survey, reporting, and dialysis prescription functionalities were tested with some of the participants only (n=7, n=6, and n=5, respectively).

^bUX: user experience

^cNot applicable.

^dPX: patient experience

Terminology includes findings about the comprehensibility and clarity of the terminology used. Eight users (80%) had problems understanding the terminology, and approximately half (10/22) of the terminology challenges were related to problems with understanding medical- or treatment-related terminology. Other terminology issues included problems with the terms used in the menus as well as the use of a foreign language.

Front page includes findings about the comprehensibility and clarity of the front-page contents. The front page of the tested version contained relatively little information and functionalities, and most users found it simple and clear.

Presentation of data includes findings about the comprehensibility and clarity of the presentation of health data, such as health measurements. Five users (50%) had issues understanding or viewing the data. The most common challenges were not comprehending the data or graphs or not knowing how to adjust the scales and timelines to view the data in a meaningful way.

Login includes findings about the ease of logging in. Four users (40%) had problems logging into the system. Typical challenges included not understanding where to input the login information or making errors while typing the login details.

Surveys, reporting, and dialysis prescription functionalities include findings about the ease of use of these functionalities. All users who tested the reporting functionality (6/6) had problems using it. Users struggled with not understanding what they should type in the input fields, feeling that options in the fields did not match the way treatment was provided in the real world, or not comprehending the medical- or treatment-related terminology. In this study, there were few usability issues in the survey functionality and none in the dialysis prescription functionality.

About UX

The *UX* findings of the evaluated eC4Me solution consisted of 5 subthemes (Table 2).

Technical functionality includes patients' experiences and feedback regarding the technical aspects of the eC4Me solution. Four users (40%) expressed frustration because some information they thought should be transferred automatically between the app, the research devices, the home dialysis machine, and patient information systems had to be typed manually. For the same reason, 2 users (20%) felt that they needed to use several systems for essentially the same purpose, such as monitoring their health data.

Use of access devices includes patients' expressed preferences regarding using the solution with different access devices: desktop computer, tablet, or mobile phone. Two users (20%) said they would prefer to use the computer interface, as they have found tablet and mobile keyboards difficult to use or feel that the mobile interface would give them less information. In contrast, 3 (30%) users indicated that they preferred a mobile phone or tablet as they are readily at hand and easier to use during the treatment, while another 3 (30%) said that their choice of access device would depend on the task they were performing.

Workload and effort includes findings about the perceived time and effort required to use the solution. Six users (60%) felt that the solution was not burdensome to use as such and that filling in the surveys or documenting treatment details did not take too much time. However, 4 users (40%) expressed concern that the solution might nevertheless increase their burden if it does not replace any other service, thus becoming one more thing to use and keep track of on top of all the other health-related solutions.

Perceived benefits includes patients' thoughts about the benefits and added value of the eHealth solution. One (10%) user saw value in using the solution primarily for the benefit of the health care personnel, while 2 (20%) others said that they needed to see clear benefits for themselves to be motivated to use the solution. Yet another user mentioned that the data generated by the solution could benefit all patients, as it could be used for research and treatment development.

I'm uncertain what this is meant for, is it for my benefit or someone else's? The remote measuring devices that I have had, I have found the data very useful for myself.... But I don't understand the thinking behind this (the solution), do I benefit or is it someone else? [P7]

Security includes findings about potential security issues and patients' concerns regarding the use of the eHealth solution. Only 2 (20%) users gave direct comments on security aspects, while most findings related to security were observations of behaviors that could introduce potential security risks, such as the user closing the browser instead of logging out when asked to do so.

About PX

The *PX* findings of the evaluated eC4Me solution consisted of 3 subthemes (Table 2).

Content-related needs includes patients' comments regarding health-related data that they want to see so they can monitor and manage their treatment and health. The expressed needs and what was considered most important varied between the users, but overall, patients were interested in seeing all the types of data that the tested version of the solution provided. Only 1 user (10%) gave a general comment that the solution "should not contain anything unnecessary or useless," but other than that, none of the users reported that they would not need or want to see some of the information or data that was available to them.

Situation of use includes patients' comments and feedback about how well the solution fits their situations and supports their everyday lives with the disease. Users had numerous, often variable comments regarding how often and in what situations they would likely use the solution. They also commented on how well the functionalities fit their care and treatment schedules, as in the following quote:

I fill these during my home dialysis treatment, so I may write notes about yesterday's treatment. I don't necessarily have time to use [the solution] after the treatment. [P8]

Communication with clinicians includes findings about how the new solution supports patient-clinician communication. Users expressed interest in using the messaging function and saw benefits in using the documented data to facilitate their communication with clinicians during face-to-face appointments. It was not clear to the users how actively and by whom their data were being monitored and if messages were noticed and replied to. Three users (30%) were hoping for immediate feedback, while 4 others (40%) considered the messaging function appropriate for nonurgent communication. In addition, 5 users (50%) expected their own nurse to read and respond to

their messages, while 3 users (30%) thought that the work was handled by a care team.

UMUX Results

The UMUX score of the first version of eC4Me was 70.6 (SD 18.6), which indicates an average level of usability [25].

Means for individual UMUX items are presented in Table 3. Users with 1-3 weeks of prior experience with the solution rated it more favorable overall compared to users without prior experience. However, the differences between the groups were not statistically significant.

Table 3. UMUX^a item scores per user groups on a scale of 1 “strongly disagree” to 7 “strongly agree.”

UMUX questionnaire item	All users (n=10), mean (SD) score	Users with no prior experience using the solution (n=5), mean (SD) score	Users with 1-3 weeks of experience using the solution (n=5), mean (SD) score
The solution’s capabilities meet my requirements	4.5 (1.4)	4.0 (1.6)	5.0 (1.0)
Using the solution is a frustrating experience	2.5 (1.9)	3.0 (2.3)	1.9 (3.0)
The solution is easy to use	5.7 (1.5)	5.0 (1.9)	6.4 (0.5)
I have to spend too much time correcting things with the solution	2.8 (1.9)	3.0 (1.4)	2.6 (2.5)

^aUMUX: Usability Metric for User Experience.

Improvement Ideas

In total, 66 improvement ideas (Table 4) for the eC4Me solution were identified from the data, with all 10 users expressing at least one improvement idea. Two-thirds of the ideas (40/66) came from users who had used the solution before the test.

The most common theme for improvement ideas was *content-related needs*. Seven patients (70%) expressed interest in monitoring some health-related measurements that were not available in the tested version, and 3 (30%) patients wanted to see benchmark values or descriptions that would enable them to better understand their health data.

Table 4. Improvement ideas and their most common subthemes.

Subtheme	All improvement ideas	
	Codes, n	Users, n
Content-related needs	28	9
Situation of use	15	7
Communication with clinicians	15	6
Presentation of data	8	6
Ease of using reporting	13	5
Technical functionality	8	5
Other ^a	26	8

^aSubthemes with fewer than 5 ideas (combined).

In addition, the participants brought up improvement ideas related to the following: (1) *situation of use*—ideas on how the solution could be improved to better fit the patient’s situation, everyday life, and treatment schedule; (2) *communication with clinicians*—ideas on how the solution could better support communication and data exchange between patients and clinicians; (3) *presentation of data*—ideas on how health data could be presented to make them more meaningful for the patients; (4) *ease of using reporting*—ideas on how to improve the reporting functionality to make it easier to use; and (5) *technical functionality*—ideas regarding automatic data exchange between the solution and other devices or services.

Discussion

Main Contribution

Our user-based evaluation study of the novel DPEP solution targeted to patients with chronic kidney disease with 10 participants resulted in a wide variety of usability-, UX-, and PX-related findings.

Most usability problems of the first version of the solution were related to navigation, the use of terminology, and the presentation of health data. Many participants struggled with the reporting functionality, which was one of the key functionalities of the solution. A considerable number of patient

participants also expressed improvement ideas related to these themes. We decided not to classify usability problems by severity, as a proper severity rating should consider not only usability aspects but also potential medical- and health-related consequences of users' mistakes and misunderstandings. However, the usability challenges identified in our study were remarkably similar to those found in evaluations of other eHealth solutions aimed at patients with chronic and serious conditions [15-18]. Our findings thus emphasize the importance of using terminology and presenting health data in a way that is understandable and meaningful to patients. Our results also highlight the need to consider patients as end users when designing user interfaces for eHealth solutions.

Our study identified several challenges related to the UX of the evaluated DPEP solution. Largely due to deficiencies in integration and data exchange, the participants feared that the solution might create additional tasks and thus increase their burden. Our results also showed considerable variation in the expected benefits of the solution. Some patients wanted to see direct value for themselves, whereas others mentioned benefits for the health care professionals as their primary motivation of use.

Despite the usability and UX challenges, the patients' overall ratings of the evaluated solution were surprisingly positive. This may be at least partially explained by findings from previous studies, which have shown that patients with chronic and serious conditions often express high interest in disease-specific eHealth solutions [17,18], even when experiencing severe usability challenges [20]. In our study, patients who had used the solution for a few weeks in a home setting evaluated it more positively than patients who were using the solution for the first time. Although the differences were not statistically significant due to the small number of participants, these initial findings could simply be explained by the fact that learning to use the solution makes it easier and thus more pleasant to use. However, they could also indicate that after having used the solution in their home setting with their own health data, patients have a better understanding of the benefits and potential value of the solution.

Regarding PX, our study generated insights on how the DPEP solution can support patients with chronic conditions in monitoring and managing their conditions and how the DPEP solution could better fit their everyday lives with a disease. From the patients' perspective, it is not enough that an eHealth solution is easy or pleasant to use if it does not support their health-related goals, feel meaningful, and fit their real-life situations and daily care activities. Special attention needs to be paid to ensure that these PX-related considerations are included in user-based evaluations of eHealth solutions, as generic usability questionnaires, classifications, and frameworks do not adequately capture these aspects [33,34]. As our study shows, traditional usability tests, complemented with questionnaire and related interview methods, can serve as a meaningful methodological approach for collecting information about PX-related aspects of eHealth solutions.

In our study, the participants generated a considerable amount of improvement ideas. In particular, nearly all patients had ideas on what health-related data they would like to see to better

manage their condition. This implies 2 things. First, many patients with chronic conditions are interested in taking responsibility for their own care. Although the participants selected for our study are likely to represent the most motivated and active patients with chronic kidney disease, it would seem meaningful to support and empower these motivated patients to take more responsibility by providing them with the information they view as important and meaningful, not only the information that makes the most sense from a health care professionals' point of view. Second, patients should be actively involved in the co-design process in the early phases of solution development and when specifying what kind of information is relevant for them.

The user-based evaluation was a crucial step in the eHealth solution development process and generated findings that helped to make substantial changes in the solution to make it more suitable for the end users (patients), thus helping the solution reach its goals. The evaluation of usability-, UX-, and PX-related aspects of the solution will continue in a future research project. We aim to conduct a similar study in a further phase of the development project to examine how the usability and UX of the solution have been improved.

Limitations

Due to the COVID-19 pandemic, our study used remote testing as an evaluation method. In comparison to in-context evaluations, this limited the scope of our evaluation, as we could not fully observe participants in their home environments. We also decided not to include research devices that were part of the DPEP solution in the test procedure, as this would have been difficult to realize in the remote setup. However, when compared to face-to-face usability testing in laboratory settings, our arrangement also had some advantages. As contextual factors are well known to influence emotional experiences and expressions [35], allowing patients to remain in their natural home settings during test sessions likely produced more reliable data, especially regarding experience-related topics like UX and PX.

Further Research

Our findings indicate that including participants who have used the evaluated solution before the test can have a nonnegligible effect on the quality and amount of information that the evaluation study generates. Half of the participants in our study had used the evaluated solution in their home environment with their own health data, while the other half were using the solution for the first time in their test session. As the number of participants was small (n=10) and the groups were heterogeneous in terms of other background variables, it was not meaningful to make more comprehensive comparisons between the 2 groups. However, participants with prior experience evaluated the solution more favorably and generated more improvement ideas. Many UX- and PX-related aspects, such as perceived benefits, workload, and compatibility with everyday life, can be difficult to assess using a solution only in a test setting, especially considering that privacy issues often prevent researchers from using patients' own health data in user tests. This could have implications on how user-based evaluation

studies of eHealth solutions should ideally be arranged, and it is therefore an important topic for further research.

In addition, further research is needed to explore the relationship and connections between the concepts of UX and PX, as suggested by recent review studies [14,36]. This includes planning and practicalities of user-based evaluation studies, considering the PX perspective, for the assessment and improvement of eHealth services.

Conclusions

User-based evaluation can produce valuable findings about usability aspects but also about the UX and PX of the evaluated DPEP solution. The findings of our study can be used in the

development process to improve the evaluated solution from the perspective of patients with chronic conditions. Evaluation is a useful and necessary part of the solution development process, especially considering the high number of novel eHealth solutions that are currently being developed.

Our study also highlights the importance of understanding how digital health solutions for patients with chronic and serious conditions support patients' own health-related goals and fit their lives with disease. To fully understand the motivation for using such solutions, it is necessary to understand how patients perceive the benefits versus the effort required to use the solution in their everyday lives.

Acknowledgments

The eHealth in Home Dialysis project was part of the CleverHealth Network ecosystem. The project was funded by participating companies, the Hospital District of Helsinki and Uusimaa (HUS), and Business Finland. Abstract

Background: In the digital age, search engines and social media platforms are primary sources for health information, yet their commercial interests–focused algorithms often prioritize irrelevant content. Web-based health applications by reputable sources offer a solution to circumvent these biased algorithms. Despite this advantage, there remains a significant gap in research on the effective integration of content-ranking algorithms within these specialized health applications to ensure the delivery of personalized and relevant health information.

Objective: This study introduces a generic methodology designed to facilitate the development and implementation of health information recommendation features within web-based health applications.

Methods: We detail our proposed methodology, covering conceptual foundation and practical considerations through the stages of design, development, operation, review, and optimization in the software development life cycle. Using a case study, we demonstrate the practical application of the proposed methodology through the implementation of recommendation functionalities in the EndoZone platform, a platform dedicated to providing targeted health information on endometriosis.

Results: Application of the proposed methodology in the EndoZone platform led to the creation of a tailored health information recommendation system known as EndoZone Informatics. Feedback from EndoZone stakeholders as well as insights from the implementation process validate the methodology's utility in enabling advanced recommendation features in health information applications. Preliminary assessments indicate that the system successfully delivers personalized content, adeptly incorporates user feedback, and exhibits considerable flexibility in adjusting its recommendation logic. While certain project-specific design flaws were not caught in the initial stages, these issues were subsequently identified and rectified in the review and optimization stages.

Conclusions: We propose a generic methodology to guide the design and implementation of health information recommendation functionality within web-based health information applications. By harnessing user characteristics and feedback for content ranking, this methodology enables the creation of personalized recommendations that align with individual user needs within trusted health applications. The successful application of our methodology in the development of EndoZone Informatics marks a significant progress toward personalized health information delivery at scale, tailored to the specific needs of users.

KEYWORDS

information recommendation; crowdsourcing; health informatics; digital health; endometriosis

Introduction

Background

Members of the general public predominantly resort to search engines such as Google or social media platforms such as Facebook, YouTube, and TikTok as their initial source of health information [1-7]. These platforms use intricate recommendation algorithms to curate the information made accessible to users [8]. The algorithms are designed to rank information based on certain criteria, presenting it in the order of the ranking score. However, the underlying architecture of these ranking systems is by default crafted with commercial intent as opposed to health-centered intent. As a result, information that entices interactions that lead to increased revenue, such as more time spent on the platform or increased traffic to advertisements, gets ranked more prominently. Meanwhile, the information that accurately reflects people's medical needs is buried under large amounts of unrelated articles and posts and becomes difficult to find [9,10].

As the preference for web-based information seeking continues to grow, the development of web-based health information applications by trusted sources has become increasingly popular [11,12]. Through these applications (eg, websites or mobile apps) [13], people can readily access a wealth of health information generated by trusted sources. These interactions present an opportunity to shape an alternative ranking architecture for recommending web-based health content, one that is grounded in health outcomes. The information curated by these trusted platforms is considered superior in quality. Using user behavior after content access to rank health information could pave the way for more effective algorithms. This improved method could be integrated into search engine and social media algorithms through regulatory measures, challenging the current prioritization of web-based health content.

The existing body of research lacks comprehensive guidance on integrating content-ranking algorithms into applications centered around health information delivery. In this paper, we outline a generic methodology to guide the design and implementation of health information recommendation functionality within web-based health information applications. In this methodology, the health information recommendation interface and logic are co-designed with medical experts and application users such as patients and their supporters. This ensures the credibility of the health information provided, as well as accurate reflection of users' preference when interacting with the application. The health information recommended to users is ranked and presented using crowdsourcing technology based on feedback from users who have similar demographic and medical profiles. This ensures that health information can be delivered to people according to their situations and needs. The methodology can be easily integrated into new or existing health information applications. By implementing this ranked

health information recommendation feature, we foresee improvements in user experience (UX) and the relevance of health information provided.

This methodology for enabling health information recommendation was first formulated based on our experience and expertise in informatics system development and implementation. It was then further refined and validated through the process of designing and implementing the informatics features of a medical information platform named EndoZone [14]. The platform is funded by the Australian government and Jean Hailes for Women's Health and provides evidence-based information to address symptoms and strategies for managing endometriosis. We illustrate the applicability of the methodology through its application in the EndoZone platform to enable its tailored health information recommendation system known as EndoZone Informatics. The implementation process shows that the methodology is practical for enabling information recommendation functionalities for web-based health information applications that have targeted health content-sharing requirements. Early data show that the solution built using this methodology is effective in reflecting users' feedback and providing highly personalized information recommendations and is also highly flexible in adjusting information recommendation logic. It has also been observed that the design of the user engagement process and user interface (UI) is highly relevant to the rate of users providing feedback and hence can affect the outcome of an information recommendation solution significantly.

The aim of this paper was to outline a generic methodology to guide the design and implementation of health information recommendation functionality within web-based health information applications and demonstrate its application in designing and implementing the informatics features of the EndoZone health information platform.

Related Research

A substantial amount of the articles and videos recommended by search engines and social media platforms have quality issues. They may contain biased content, are not comprehensive enough to cover the topic, are not evidence based, and provide limited coverage or content irrelevant to the topic [5,6,9,10,15]. A review by Osman et al [6] highlighted that >40% of the videos on YouTube on lumbar discectomy, cardiopulmonary resuscitation, and stroke are not useful, while more than half of the videos about vaccination as well as phototherapy and excimer laser treatment for psoriasis reflect bias due to commercial interests. A study assessing the quality of diabetes-related content on TikTok found that the quality of the content varies significantly depending on the types of creators and does not fully meet the health information needs of patients [5]. From billions of web pages and videos on the internet, commercial recommendation algorithms of search engines and social media platforms show those with the highest rank first,

where the ranking criteria often have nothing to do with whether the content could meet people's medical needs [16]. To obtain a higher rank, which leads to a higher visibility rate and eventually a better commercial outcome, billions of dollars have been invested by companies for search engine optimization [8]. This compounds the situation because trusted health information sources such as research organizations and noncommercial health organizations often do not have the financial capacity to compete with commercial companies. As a result, the recommendations made by search engines and social media platforms lead people to unrelated articles, commercial advertisements, or even misinformation. As people generally lack the skills and experience to evaluate the accuracy of the information they are recommended [17], incorrect and harmful medical decisions could be made.

In comparison, web-based health information applications developed by trusted sources such as governments, credited health organizations, and universities provide health information with criteria that people value, such as trustworthiness, expertise, and objectivity [18]. In recent years, many of these applications have been developed globally to bypass the information recommendation algorithms of search engines and social media platforms [11,12,19,20]. Several applications contain mechanisms that provide personalized recommendations of nutritional information, medications, treatment plans, diagnoses or disease predictions, physical activities, or other health care services, based on users' profiles and inputs [21]. However, these recommendation features have not yet been applied extensively in health informatics and medical scenarios [22] and are typically created on an app-to-app basis, targeting a specific disease or recommendation context [12].

The lack of effective information recommendation functionality can be eliminated by enabling health information recommendation capability at scale. Many web-based health information applications could apply similar methodologies in design, development, and evaluation in terms of health

information recommendation functionality due to their similarities in context, purpose, and category of recommended items. Tran et al [12] summarized 4 basic recommendation techniques: collaborative filtering, content-based filtering, knowledge-based recommendation, and a hybrid recommendation that combines these 3 techniques. In terms of evaluating the recommendation quality and the effectiveness of the recommendation mechanism, users' feedback is considered to be a major quality criterion [23]. Crowdsourcing technology has been applied in health care and has proven to be an effective approach to collecting retrospective data, such as user feedback, from a large number of dispersed participants [24]. With the development of health informatics technology and current trends of population preferences toward seeking information on the web, the use of crowdsourcing technologies for validating the effectiveness of health information recommendations is promising.

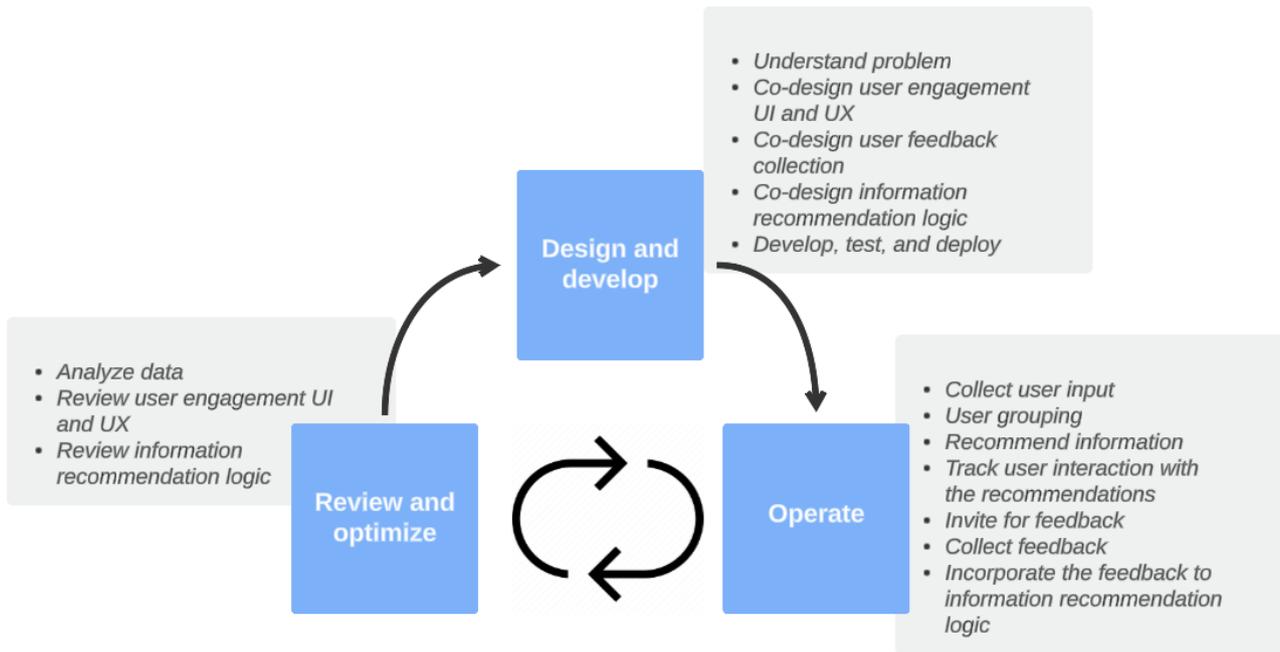

Methods

Overview

In this section, we present the concept of the methodology as well as implementation-related design, including software components, software development, and maintenance considerations, during 2 different implementation phases.

The methodology for enabling health information recommendation functionalities involves medical experts, researchers or data analysts, software developers, designers, and users of the web-based health information application. As shown in Figure 1, the methodology consists of 3 stages: *design and develop*, *operate*, and *review and optimize*. At a high level, the methodology can be summarized thus: first, co-design and codevelop the information recommendation solution; second, recommend information to, and collect feedback from, users to improve the recommendation logic; and third and last, periodically review the statistical data to identify issues and continually adjust the solution.

Figure 1. The information recommendation solution life cycle. UI: user interface; UX: user experience.

Design and Develop

Overview

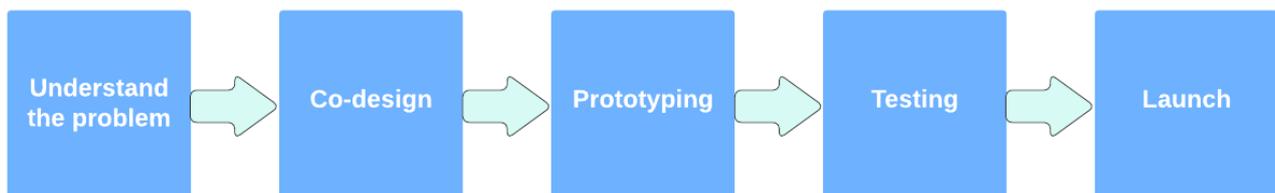

The implementation of the health information recommendation functionalities in the web-based health information application starts with the design and development of a solution that meets the specific requirements of the application. The design and development process adopts a human-centered design thinking model [25,26]. It considers the need of users to be the main factor that drives the design decision-making process. Figure 2 shows the design and development process for the methodology.

The solution designer first needs to understand the problem and develop detailed requirements for the information recommendation functionalities. To engage in the cocreation process, users can be invited to participate in observation

sessions or interview sessions to explore the key challenges and their needs. During these sessions, the questions to be answered could include *What problem is the application trying to solve? What is the status of the application (launched/unbuilt)? What information will be recommended? How is the information expected to be recommended? What data are available for the recommendation logic to be based on?* and *If the application already exists, what does it look like and how is the information recommendation component expected to be integrated?*

Once all requirements have been clearly defined, a series of co-design or ideate sessions are carried out by the solution designer and the medical experts who have comprehensive domain knowledge about the condition or disease the application covers. The co-design process aims to deliver several outcomes, as outlined in the following subsections.

Figure 2. The design and development process.

The Engagement Process

This is also called UI or UX, that is, the UI and the process that the user interoperates with the application’s information recommendation functionalities. It will need to be co-designed with medical experts to fully consider users’ medical needs.

The Feedback Collection Method

This includes the feedback questions to be asked and the form of questions to be delivered, and it needs to be co-designed with the medical experts as well as the researchers or data analysts,

making sure that good UXs and the data collected can properly serve the purpose of the feedback collection.

The Information Recommendation Logic

This specifies how health information that is recommended to users can be realized via different data structures and algorithms. On the basis of the EndoZone Informatics example that we will present later, the recommendation logic could include things such as a list of expert-verified information, a set of rules for information recommendation, an algorithm for user grouping, an algorithm for feedback analysis, an algorithm for feedback incorporation, and an algorithm for information

recommendation. In the co-design process for this deliverable, medical experts should be closely involved in the design of all included components, providing insights that are as detailed as possible and making sure that the recommendations are appropriate (ie, evidence based) and meet users' medical needs. Specifically, the list of expert-verified information and the set of rules for information recommendation should be based on medical experts' input and available research data. Taking a rule in EndoZone as an example, a recommendation of yoga as a self-management strategy is made for a user who has severe pelvic pain and does not experience heavy bleeding during menstruation. In addition to medical experts, researchers or data analysts should also participate in the co-design process, making sure that the algorithms are correctly designed.

The Develop, Test, and Deploy Processes

To ensure that the design fully reflects the users' needs while fully considering the complexity and professionalism of the design activities, a smaller group of user representatives can be invited for consultation, where staged co-design outcomes, as mentioned previously, are sent for review and feedback.

After the co-design process is completed, the solution designer translates the outcomes into system design and architecture specifications, which are then used by software developers to develop, test, and deploy the system. How the develop, test, and deploy processes are carried out depends on the preference of the software development team, where no restrictions are imposed by the methodology. However, it is necessary for stakeholders, including researchers, medical experts, and users, to participate in testing early versions of the solution and provide feedback, where design issues and recommendation logic issues can be identified and resolved in time. The tests can be carried out differently by different stakeholder groups; for example, medical experts and researchers can be asked to test specific features that are closely related to their expertise, while for users of the application, a series of tasks that match their needs and expectations (provided in the initial requirement collection or understanding sessions) can be preset, making sure that their feedback is relevant and targeted.

This *design and develop* stage may be conducted multiple times throughout the lifespan of an information recommendation solution in which the solution is updated to fix issues that are identified and rectified or to incorporate new features.

Operate

Overview

The methodology shifts to the *operate* stage once the information recommendation functionalities are launched. In this stage, the solution performs activities such as recommending health information to users, collecting user feedback on recommendations, and incorporating the feedback into the recommendation logic. The first entry point of the users to the solution should be an event that is related to the content of the application; for example, it can be a click on a button on a web page, an action when using a digital tool, or a click on a link included in an invitation email. Such an event triggers a series of activities to generate a list of recommendations to the user, as outlined in the following subsections.

Collect User Data on Entry

Data stored in the application, such as user account profiles, user input in digital tools, and user browsing history, contain information about the unique circumstance of a user that is needed for personalizing recommendations. When the entry-point event happens, such data are collected for subsequent algorithms.

Group Users

This is an essential step for recommending personalized information to users with different conditions. In this step, the users are grouped by the algorithm for user grouping, based on a set of predefined attributes. Members of a group could have similar demographic and medical profiles, such as condition, age, educational background, symptoms, treatments, and so on.

Recommend Information

Using the data collected on entry as input, an algorithm generates a list of recommended information according to the information recommendation logic. In the algorithm, first, user data collected on entry are checked against the rules for information recommendation; for example, if a user U has symptom S , and the rule R indicates that all users with symptom S will be recommended information I , then I will be recommended to user U . Second, recommendations that match the rules will be ranked according to previous feedback from all users in the same user group. Third and last, the information is shown to the user in the order of the rank, where information with the best feedback (eg, the highest positive feedback rate) is presented first and has a better chance to be viewed.

Track User Interaction

After the information has been recommended, users are likely to read not all but a subset of the recommendations. It is necessary to track which recommendations are read by a user so that in the later step of collecting user feedback to recommendations, questions can be asked effectively. It is assumed that a recommendation has been read by the user if the content has been exposed to the user (eg, the user clicks on a link to an article). Therefore, any interaction that indicates exposure of the information to the user is recorded. Depending on the UI or UX design, recorded interactions could include clicks on a recommendation link or button, the opening of the web page of the recommendation, and so on.

The evaluation of whether the recommendations meet users' medical needs relies on feedback from the users themselves, supported by the power of crowdsourcing. After a certain period of making the recommendations, attempts are made to collect summative feedback from users who may have read the recommendations and potentially carried out practical activities based on the recommendations.

Invite for Feedback

The collection of feedback starts with sending an invitation to the user for participation. If the user has accessed any of the recommendations, an invitation for feedback is sent. Invitations can be sent in the form of oral invitations (eg, telephone invitations or opportunistic face-to-face invitations) or written letter invitations (by post or via email), which will vary from

case to case [27]. The method of sending invitations is determined according to medical experts' suggestions to approach users with specific medical conditions appropriately and maximize the response rate.

Collect Feedback

There are a few ways in which user feedback data can be collected on the web (eg, conducting web-based surveys and allowing user ratings) [28]. Conducting a web-based survey is one of the most popular ways to collect user feedback, is easy to implement, and can meet the requirements of a web-based health information application in many cases. Questions in the survey can be asked from a UX perspective in terms of the helpfulness of the recommendations; for example, questions against a therapy recommendation could include *Did you try this therapy? Did you find the therapy easy to do? How difficult did you find fitting this therapy into your life with your other activities?* and *Did you find this therapy helped in managing your symptoms?* One of the known issues of web-based surveys is the low completion rate [29]. Some strategies to incentivize completion rates can be found in existing studies [30,31].

Incorporate

After a user's feedback is collected and digitized, first, an algorithm for analyzing feedback executes to convert the feedback data into measurable attributes. Second, an algorithm for feedback incorporation deploys these attributes into the information recommendation logic. Depending on the design of the algorithm for feedback incorporation, the outcomes of the incorporation could include an updated set of rules for information recommendation, updated ranks of recommendations, updated descriptions for each recommendation, and so on. After the incorporation process finishes, the user's journey with the information recommendation solution is completed. The updated information recommendation logic will then be applied when other users engage with the information recommendation solution.

Review and Optimize

Overview

As the information recommendation solution operates, system operation data and user engagement data accumulate. Besides using the user interaction data for improving the information recommendation logic in the *operate* stage, an in-depth review and optimization of the solution can be conducted. The purpose is to identify issues based on the analytical outcome of the accumulated operation data set and the experience gained from the continuous operation and maintenance of the solution. Whether the *review and optimize* stage needs to be carried out depends on several factors, such as the amount of analyzable data accumulated, the urgency of major optimization of the solution to address emerging requirements, and the operation status of the current information recommendation solution. Researchers and software developers need to decide when a formal *review and optimize* stage is needed. The outcome of the *review and optimize* stage should include an optimization plan, where detailed redesign and development can be carried out in the following *design and develop* stage.

Analyze Data

User engagement data such as user profile data, data of user interaction with the information recommendation solution, and user feedback as well as system operation data such as operation logs and web-based traffic data are accumulated and of statistical value to the optimization of the information recommendation solution. Depending on the sufficiency of the accumulated data, research questions such as *Do the users engage well with the solution? Is the recommendation solution effective in helping users to find the information that meet their medical needs?* and *Are the recommendations appropriate and suitable for the user to practice?* can be answered, and potential issues in the engagement process and recommendation content can be identified.

Review User Engagement UI and UX

At the *review and optimize* stage, a retrospective review can be conducted toward the user engagement UI and UX. The review can be based on 2 sources of input: first, it can be based on the researchers' experience gained while continuously operating the user engagement UI and UX. Second, it can be based on user feedback, such as volunteer user group feedback when asked to test and promote the solution. This review could identify design issues in the UI and user engagement process that cause difficulty for users in accessing the features of the solution and the health information they are recommended.

Review Information Recommendation Logic

It is difficult to provide the best configuration to elements of the information recommendation logic and achieve the optimal recommendation outcome during the *design and develop* stage. The reasons include users' composition, uncertainty in user interaction patterns with the application, and a lack of analyzable data. Thus, continuous adjustments to the configuration of algorithms and data structures are needed; for example, grouping attributes and the logic of the algorithm for user grouping, rules for information recommendation, the list of expert-verified information, and the logic for user feedback evaluation can all be fine-tuned to reflect issues identified from the data analysis. In the *review and optimize* stage, the best configuration for the information recommendation logic should be determined based on testing different configurations. It is most practical to conduct tests on different parts of the information recommendation in parallel with tests in the *operate* stage of the software to minimize impact to the existing system. To achieve this, a staging infrastructure can be set up, where a mirror copy of the solution can be created for test-related activities.

Implementation Considerations

Overview

This methodology can be adopted for the implementation of health information recommendation functionalities, either with already launched applications or when the application is still under development. In the next 2 subsections, we present implementation-related considerations of the methodology: first, components need to be developed and how these interoperate with other application components is described; and second, a 2-phased implementation strategy that aims to provide the optimal UX is described.

Software Components

The architecture design for the information recommendation solutions could vary vastly due to factors such as user requirements, the software technology stack being applied, the skill sets of developers, and governance restrictions (eg, the General Data Protection Regulation applicable in the European Union). However, when adopting the methodology, logical components for the health information recommendation

functionality should be consistent. Figure 3 shows a high-level software component diagram that implements health information recommendation functionalities in a web-based health information application. The diagram consists of 3 sections: components of a typical web-based health information application (Figure 3A), backend components of the information recommendation solution (Figure 3B), and front-end components of the information recommendation solution (Figure 3C).

Figure 3. Software component design. (A) Components of a typical web-based health information application. (B) Backend components of the information recommendation solution. (C) Front-end components of the information recommendation solution.

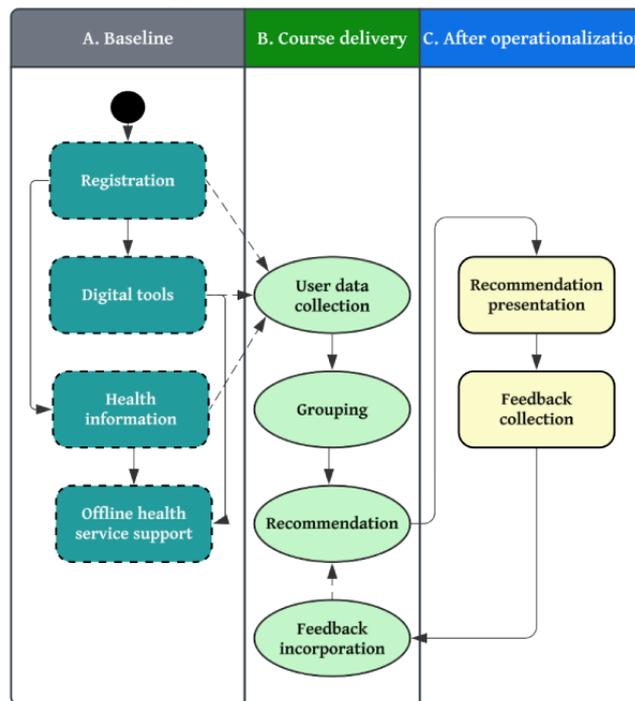

Figure 3A shows that a typical web-based health information application in the form of a website could include web pages of health information; instructions on local offline support; and, optionally, digital tools for certain informatic purposes and a registration component that is often needed by the digital tools. The 4 backend components shown in Figure 3B are needed for an information recommendation, which collects and processes all user input data, makes recommendations, and incorporates user feedback. Depending on the design of the information recommendation logic, the user input data collected could include user account data, health information browsing history, digital tool input, and user feedback on recommendations. The output of the 4 backend components includes updated information recommendation logic and a list of recommendations ranked based on user feedback. The front-end of the information recommendation solution shown in Figure 3C comprises 2 components: one for presenting recommendations and the other for collecting recommendation feedback. Depending on the design of the user engagement process, these 2 components can be either allocated on dedicated web pages or integrated into the web pages of any web-based health information application component.

The software components are designed in a loosely coupled fashion, where all functions and algorithms are independently maintained. Such a design pattern makes the adjustment of the

information recommendation logic possible, from fine-tuning to a total replacement of the recommendation model. This feature is critical to a phased implementation of the solution, as will be discussed in the next subsection. One additional advantage of such a design is that it enables the potential of the web-based health information application to become a test bed of information recommendation algorithms, where algorithms can be easily alternated to test performance.

Implementation Phases

When the information recommendation solution is first launched, the number of users is small, and feedback on recommendations is not yet provided. Here, an information recommendation model that relies heavily on crowdsourced data for recommendation evaluation could produce suboptimal recommendations, impacting the UXs with the web-based health information application. To ensure the quality of recommendations before crowdsourced data are sufficiently accumulated, an implementation strategy is applied with the following two phases: (1) an initialization phase, in which crowdsourced data are not yet sufficiently collected, and an initial version of the algorithm for recommending information is used, where the information recommendation logic does not rank the recommendations based on user feedback data; and (2) an execution phase, where crowdsourced data are sufficient, and an execution version of the algorithm for recommending

information is used, where user feedback is incorporated into the information recommendation logic for ranking recommendations based on user feedback data.

The main difference between these 2 versions of the algorithms is their logic in dealing with user feedback. Specifically, in the initial version of the algorithm, the list of recommendations is generated purely based on medical experts' input (ie, a set of predefined rules for information recommendation), whereas in the execution version, the list of recommendations is generated based on medical experts' input and further ranked based on user feedback data. Due to the loosely coupled software design, the algorithm for recommending information can be easily replaced. Researchers and data analysts can decide it is time to replace the algorithm when the amount of user feedback data is sufficient for the execution version of the algorithm to execute effectively.

Ethical Considerations

The development of the platform and analysis of EndoZone data was approved by the University of Adelaide Human Research Ethics Committee (H-2020-013 & H-2023-054). Informed consent was obtained from community members participating in the design and development phase of the EndoZone informatics platform, and all users accessing the tool after it was launched online. The extraction and analysis of de-identified EndoZone platform data for this study was in accordance with the guidelines approved by the ethics committee.

Results

Case Study: EndoZone Informatics

The methodology for enabling health information recommendation functionalities has been successfully applied in the development of the information recommendation functionalities of a co-designed endometriosis information platform called EndoZone [14]. Endometriosis is a chronic condition, where tissue similar to the lining of the uterus develops in places outside the uterus. Symptoms of endometriosis may include pain with menstruation, chronic pelvic pain, fatigue, and subfertility. Globally, it is estimated that endometriosis affects approximately 190 million women and people presumed female at birth [32]. To address the wide-ranging impact of endometriosis, the Australian government and Jean Hailes for Women's Health funded the development of EndoZone to improve knowledge, address symptoms, and provide strategies for managing endometriosis. This platform was designed for people affected by the condition as well as their supporters, such as parents, partners, teachers, and coworkers. The platform was cocreated and developed using the design thinking framework. During the cocreation process of the EndoZone platform, endometriosis community focus groups (n=36) were held to explore the key challenges and needs of the endometriosis community; in addition, a community priorities survey was conducted with 347 community member responses. On the basis of the key priorities identified, it was decided that functionalities would be developed to facilitate interaction and to support people experiencing endometriosis symptoms through the recommendation of strategies based on

their symptoms, that is, EndoZone Informatics. The design, development, and implementation of EndoZone Informatics strictly follows the health information recommendation methodology. The solution was co-designed with other components of the EndoZone platform and integrated into the platform in April 2023. The solution is currently fully implemented and operating in the execution phase. In the following subsections, we present the design, development, and implementation of EndoZone Informatics to showcase the practicality of adopting the methodology for the design and implementation of information recommendation functionalities in a web-based health information application.

Design and Develop

The design of EndoZone Informatics was part of the broader platform development process, which follows the broader co-design process of EndoZone. It was designed in consultation with 5 community representatives from endometriosis associations (patients, advocates, and supporters), clinicians (endometriosis or fertility specialist, physiotherapist or pain researcher, and endometriosis nurse), researchers, and 2 health informatics specialists. This involved a series of workshops and meetings to discuss details of the user engagement process as well as a smaller working group with clinicians to develop the initial information recommendation logic. The design was mocked up in consultation with the UI or UX designer and then integrated into the EndoZone platform. The outcome of this co-design process includes the user engagement process and the corresponding UI or UX prototype, a feedback collection method using email invitations and web-based surveys, and the information recommendation logic. Specifically, the information recommendation logic includes a list of 16 expert-verified articles for different endometriosis self-management therapies; a set of 27 rules that match symptoms to the recommendation of therapies (eg, one rule is that if the user experiences severe menstrual cramps, an article on transcutaneous electrical nerve stimulation therapy will be recommended); and algorithms for user grouping, analyzing feedback, feedback incorporation, and recommending information. After the design was ready to be reviewed, a review meeting was carried out for all stakeholders, where feedback on the design outcome was collected for adjustment. After the design outcome was adjusted and agreed upon, the solution designer and the UI or UX designer translated the outcomes to formal UI or UX design and architecture specifications for the development work to be carried out.

The develop, test, and deploy process was carried out using an agile approach, more specifically, the Scrum development process [33], which is preferred by the development team due to the existing software technology stack and developer skill sets. The development progress was regularly reported to, and closely monitored by, the digital health solution transformation experts. One issue that was encountered during this stage was some previously unforeseeable dependencies of the informatics components on several other components of the platform, which caused a 3-month delay in the release date of EndoZone Informatics. However, the development process is in general smooth.

To test EndoZone Informatics, medical and health experts participated in 2 demonstrations of the platform and tested the ready-to-launch version. In all, 9 community users participated in testing the platform’s early versions through a beta version with restricted access. Specifically, the user test was conducted after a series of tasks in which user testers were audio and video recorded while they completed the tasks and provided verbal feedback as they were using the platform. They also completed a series of questions related to their feedback on the platform (eg, what they liked, what they did not like, and suggestions for improvement), the usability of the platform, and whether they would recommend the platform to a friend or colleague. The feedback obtained from the user test was then incorporated into the further development of EndoZone Informatics features.

Operate

A user starts to engage with the EndoZone information recommendation solution from the submission of a health questionnaire named *My Endo Report*. The questionnaire contains a series of questions related to self-reported endometriosis symptoms and treatments that have been tried to manage symptoms, as well as a brief medical history. After the user has submitted the questionnaire, the backend algorithms are triggered to produce a list of recommended self-management

therapies, where the recommendations are presented as part of *My Endo Report* (Figure 4). In EndoZone, the crowdsourced input (ie, user-provided feedback on recommended therapies) is used to determine the order of the recommendations being presented: among users with similar symptoms, therapies that are rated as “more useful” are given a higher rank and shown first in the list of recommendations. The description text of each recommendation contains a ranking to highlight this order. If the user clicks on a recommended therapy, the solution assumes that the user has viewed the content and records the click event. Next, 30 days after the recommendations are made, an email is sent to the user, inviting the user to complete a follow-up survey regarding the recommendations (Figure 5). When the user accepts the invitation, a follow-up survey is generated, containing questions related only to the recommendations that the user has clicked on. For each recommended self-management strategy, the survey contains 10 questions. It asks the user about the usefulness of the strategy, including their feelings after practicing the strategy, the practicality of the strategy, the effectiveness of the strategy in improving their symptoms, and so on. Figure 6 shows an example follow-up survey for the recommendation of pelvic health physiotherapy. Once the user has submitted the follow-up survey, their engagement with the EndoZone information recommendation solution is complete.

EndoZone - Feedback Sought

Hello wenhao li,

Approximately a month ago, you completed a health report and were recommended some self-management strategies based on your reported symptoms. We want to provide the best possible recommendations to people who use EndoZone and to do this, we need to know whether the strategies were effective. The below surveys will ask you a few quick questions about the effectiveness of the recommended treatments.

1. [Follow up survey for health report completed on 13/07/2023](#)

Figure 6. A follow-up survey example.

Software Architecture

The architecture design in the EndoZone information recommendation solution strictly followed the component design shown in Figure 3 but was customized to fit the specific requirements of the application. First, based on the needs of the EndoZone information recommendation logic, the user data collection component only collects user registration data (ie, demographic profile data) and user input to the digital tool (ie,

My Endo Report submission data). Second, the recommendation presentation component is integrated into the *My Endo Report* summary page of the application as part of the *My Endo Report* outcome.

Deployment wise, based on best practice, the EndoZone information recommendation solution is designed to be cloud based. It operates on cloud-based infrastructure using Amazon Web Services. All recommendation-related components are deployed in the form of microservices using Amazon Web

Services Lambda, where each microservice contains components that are needed for a single application programming interface call. Specifically, the user data collection, grouping, and recommendation components are deployed in 1 microservice. Once the *My Endo Report* questionnaire is submitted, this microservice is called and responds with a list of recommended self-management therapies. The feedback incorporation component is deployed in another microservice. Once the follow-up survey is submitted, this microservice is called to update the information recommendation logic.

Implementation

The implementation process of the EndoZone information recommendation solution followed the 2-phased process. Compared with what is described in the *Overview* subsection in the *Methods* section, an alternative data accumulation approach was conducted in the initialization phase to accelerate the transition to the execution phase. After the platform was launched, a targeted social media campaign on Instagram and Facebook was conducted to promote initial use of the platform. During the campaign, the initial version of the algorithm for recommending information was executed based on the expert-derived set of information recommendation rules that were matched to self-management therapies and symptoms that were indicated in *My Endo Report*. In completing the report, users are contacted via various channels to self-rate how helpful each self-management therapy or strategy was to manage their symptoms using a 3-point scale (“Didn’t work,” “Helped a bit,” and “Helped a lot”).

At the time of reviewing the data, the EndoZone platform had had 57,000 visitors (Google Analytics; February 20, 2024), predominantly from Australia (n=32,000, 56.14%), the United States (n=6000, 10.53%), the United Kingdom (n=5200, 9.12%), and New Zealand (n=5000, 8.77%), of whom 5756 (10.1%) completed *My Endo Report* and submitted it through the platform. User feedback data were aggregated to count the number of reports that indicated that a particular strategy either “Helped a bit” or “Helped a lot.” This feedback was then considered to be the initial rating of therapies on which the execution version of the algorithm could rely; for example, *yoga* was rated by 682 people, of whom 404 (59.24%) rated it as either “Helped a bit” or “Helped a lot.” These feedback data were then manually incorporated, where a rating of “404/682 (59.24%)” was set as the initial rating of the therapy *yoga* for all user groups. A further analysis of the data collected through the platform is being conducted to feed into the next iteration of EndoZone Informatics.

Review and Optimize

The EndoZone information recommendation solution was integrated into the EndoZone platform in April 2023. Tests and feedback from the volunteer group have shown that the overall user engagement process can be carried out well, with a good UX. Meanwhile, based on early data accumulated, several design issues have been identified; for example, the participation rate for providing feedback is lower than expected. We suspect that the UI or UX design could be the major cause for this outcome: first, in the current design, only registered users are invited to complete the follow-up survey (unregistered users cannot be

invited because they are not asked for their email address). Currently, most users use the site anonymously, which means that most users of the platform who decided not to create an account in EndoZone are not able to experience the full recommendation functionalities and provide recommendation feedback. Second, the recommendation section is in a relatively inconspicuous position on the *My Endo Report* summary page. This may lead to reduced visibility and hence less user participation. The finding indicates that the design of web pages (UI or UX) is highly relevant to the effectiveness of the solution. It also indicates that the methodology is limited in identifying specific design defects during the initial *design and develop* stage. However, such defects can be addressed in the *review and optimize* stage, where issues that crop up during the execution of the solution are reviewed. In the context of the EndoZone platform, remedial development work has been planned in the second phase of the project from 2024 to 2026.

Furthermore, the logic for tracking user engagement with recommended therapies (ie, once the article is opened, the recommended therapy is considered to have been read) is not consistent with the industrial standard that large IT companies have applied; for example, in Google Analytics, a user is considered to have engaged with a web page if they stay on the page for >10 seconds [34]. How user engagement is tracked is not defined by the methodology and could vary from case to case. However, in the context of the EndoZone platform, the solution logic does not cause a loss of user feedback data. The impact on the UX (ie, several more survey questions are asked regarding a therapy that the user has not practiced) is limited and can be eliminated by adjusting the questions in the follow-up survey.

Discussion

Outcome

In the previous sections, we have presented a methodology that enables health information recommendation functionalities in web-based health information applications. The concept of the methodology as well as the implementation considerations, including the software component design and the 2-phased implementation process, are described in detail, based on which information recommendation solutions can be created and operationalized. The methodology has been refined and validated through its application to create EndoZone Informatics, that is, the information recommendation solution of an endometriosis information platform named EndoZone. Early data from the execution of the EndoZone Informatics solution shows that using this methodology was effective in recommending medical expert-verified information while incorporating crowdsourced input from users with similar conditions. This methodology helped users to find the information that could be of most use to them. The loosely coupled software component design enabled high flexibility in adjusting the information recommendation model, which makes the 2-phased implementation process easy to carry out.

During the application of the methodology for EndoZone Informatics, we encountered several issues. To recap, first, the dependencies of the information recommendation components

on other components of the web-based health information application caused a 3-month delay in the development progress of EndoZone Informatics. Second, the UI or UX design flaws, such as unregistered users not being able to experience the full recommendation functionalities and *underexposure* of the recommendation section in the *My Endo Report* summary page, have resulted in a lower-than-expected participation rate for providing feedback. These issues reveal a limitation of the methodology, that is, it is not able to address some specific software engineering problems. These issues also show the significance of the *review and optimize* stage, where design and development issues can be identified, and repair plans can be created.

In general, the application of the methodology for designing and implementing EndoZone Informatics is successful. It is a solid step toward enabling personalized information recommendation at scale. The solution indicates a promising approach where personalized health information recommendation can be enabled in all web-based health information applications. Compared with accessing health information via recommendations derived from commercial algorithms of search engines and social media platforms, a health information-access approach provides people with an alternative health information-ranking and -recommendation path, which ranks information based on people's medical needs; provides them with trustworthy, credible, and evidence-based recommendations; and aims for the best health outcomes.

Potential of the Methodology

The methodology is proposed to be applied in web-based health information applications targeting personalized health information recommendations for educational and knowledge-sharing purposes. As showcased by the EndoZone platform, this methodology is applicable and works well for web-based health information applications that share health information such as chronic disease self-management strategies. However, the practicality of applying the methodology in creating solutions for applications that target acute diseases is yet to be proven. Another area for further research is the practicality of applying this methodology for recommending

clinical treatments. This requires systematic study of what the impact could be if the methodology was applied for recommending clinical treatments (eg, medication use). What kind of care decisions (safety or risk of harm or relative benefits) need to be considered? What are the ethical issues involved? Answers to these questions are not yet clear.

A promising area for applying the methodology concerns creating solutions for recommending other medical and health services, such as links to local medical experts, health services, advocacy organizations, and related web-based applications [35,36]. Exploring how solutions created by applying this methodology could help in connecting web-based services to local offline services to improve the quality and scope of user support would also be of value.

Another potential application of this methodology is to generate test beds for information recommendation algorithms and their suitability for different medical scenarios. As described in the *Overview* subsection of the *Methods* section, the software component design allows all key logic components to be independently maintained and easily replaced. This feature can be leveraged for new information recommendation algorithms or models to be tested; for example, by applying different information recommendation models and monitoring user interactions under each model, the performance of different information recommendation models can be analyzed.

Conclusions

This study introduces a novel methodology that enriches web-based health applications with personalized information recommendation capabilities. Tested through the development of the EndoZone platform, our approach successfully merges expert knowledge with user insights to provide targeted health information. While we encountered developmental and design challenges, these experiences highlighted the importance of adaptability and continuous refinement. The methodology's potential extends beyond the specific case of EndoZone, offering a scalable solution for tailoring health information across various authoritative health websites, with implications for improving patient education and engagement in a digital era.

Acknowledgments

The authors are grateful for the support and expertise provided by Karl Fradley and Laura Morgan from SRA Information Technology and the team at Brainium Labs, who contributed to the development of EndoZone, which has greatly facilitated the completion of this research. EndoZone was funded by the Australian Government and Jean Hailes for Women's Health.

Abstract

Background: Type 2 diabetes (T2D) tremendously affects patient health and health care globally. Changing lifestyle behaviors can help curb the burden of T2D. However, health behavior change is a complex interplay of medical, behavioral, and psychological factors. Personalized lifestyle advice and promotion of self-management can help patients change their health behavior and improve glucose regulation. Digital tools are effective in areas of self-management and have great potential to support patient self-management due to low costs, 24/7 availability, and the option of dynamic automated feedback. To develop successful eHealth solutions, it is important to include stakeholders throughout the development and use a structured approach to guide the development team in planning, coordinating, and executing the development process.

Objective: The aim of this study is to develop an integrated, eHealth-supported, educational care pathway for patients with T2D.

Methods: The educational care pathway was developed using the first 3 phases of the Center for eHealth and Wellbeing Research roadmap: the contextual inquiry, the value specification, and the design phase. Following this roadmap, we used a scoping review about diabetes self-management education and eHealth, past experiences of eHealth practices in our hospital, focus groups with health care professionals (HCPs), and a patient panel to develop a prototype of an educational care pathway. This care pathway is called the Diabetes Box (Leiden University Medical Center) and consists of personalized education, digital educational material, self-measurements of glucose, blood pressure, activity, and sleep, and a smartphone app to bring it all together.

Results: The scoping review highlights the importance of self-management education and the potential of telemonitoring and mobile apps for blood glucose regulation in patients with T2D. Focus groups with HCPs revealed the importance of including all relevant lifestyle factors, using a tailored approach, and using digital consultations. The contextual inquiry led to a set of values that stakeholders found important to include in the educational care pathway. All values were specified in biweekly meetings with key stakeholders, and a prototype was designed. This prototype was evaluated in a patient panel that revealed an overall positive impression of the care pathway but stressed that the number of apps should be restricted to one, that there should be no delay in glucose value visualization, and that insulin use should be incorporated into the app. Both patients and HCPs stressed the importance of direct automated feedback in the Diabetes Box.

Conclusions: After developing the Diabetes Box prototype using the Center for eHealth and Wellbeing Research roadmap, all stakeholders believe that the concept of the Diabetes Box is useful and feasible and that direct automated feedback and education on stress and sleep are essential. A pilot study is planned to assess feasibility, acceptability, and usefulness in more detail.

Introduction

Background

Around 1 in 11 adults in Europe have diabetes mellitus, and the number of people with diabetes is increasing [1]. Currently, in more than 95% (n>1 million) of diabetes cases, it concerns type 2 diabetes (T2D). In people who are genetically predisposed to diabetes, adverse eating habits, excess body weight, and physical inactivity induce disruption of glucose control [2]. Hence, healthy lifestyle behaviors play a critical role in preventing and managing T2D. Indeed, quitting smoking, being more physically active, eating healthier, and losing weight when overweight can significantly reduce the risk of developing T2D [3,4]. Furthermore, in patients with recently diagnosed T2D, it was demonstrated that dietary lifestyle interventions can lead to persistent diabetes remission after 24 months in 36% (n=149) of patients [5].

Despite the obvious benefits of healthier lifestyles, adherence to healthy lifestyle behaviors in patients with T2D is poor [6-8]. This is alarming, as worse adherence obviously hampers therapeutic efficacy [9]. In Europe, glucose control is inadequate in at least half of the people with T2D. Inadequate glycemic regulation increases the risk of diabetes-related complications and mortality, and it increases medication use and health care costs [10,11]. Immediate action is needed to halt the rising incidence of T2D as well as to decrease the burden of T2D and curb health care costs [1].

A Cochrane review showed that diabetes self-management education (DSME) in people with T2D can improve glucose regulation [12]. In addition, it potentially improves blood pressure and reduces body weight and the requirement for diabetes medication. Yet, another systematic review reported that encouraging patients to play an active role in self-management, so-called patient activation or empowerment, can also improve glucose regulation [13]. Notably, mounting evidence clearly shows that the physiological response to lifestyle change is highly personal [14,15]. Moreover, it seems obvious to suppose that home monitoring of medical and behavioral parameters stimulates and improves self-management. Indeed, integrative monitoring of lifestyle behaviors and physiology using direct action-feedback loops potentially allows for the provision of informative personalized lifestyle advice [16].

Traditionally, DSME is done face-to-face, but digital tools can facilitate health behavior change and significantly improve glucose regulation in patients with T2D [17]. Effective digital tools are self-monitoring (eg, continuous glucose monitoring [CGM]) and telemonitoring by health care professionals (HCPs) [18,19]. Mobile phone apps providing automated feedback can also be effective in improving lifestyle modification and glucose regulation for people with T2D [20]. Indeed, due to low costs as compared to health care consultations and the 24/7 availability of HCPs, mobile phone apps have a lot of potential in diabetes management [21]. Currently available eHealth tools usually focus on one particular lifestyle component or relevant clinical parameter, such as CGM devices or apps that facilitate counting carbohydrates. Examples of digital tools that combine different lifestyle and biometrical parameters to improve self-management and glycemic control exist [22-24]. However, only a few digital tools exist that combine behavioral as well as biological data to provide informed, personalized lifestyle advice to people with T2D [24]. Most of the existing tools are one-size-fits-all lifestyle solutions. Personalized interventions are preferred as clinicians and patients together can choose the treatment plan that contributes most to favorable patient outcomes [25]. Here, we aimed to develop an eHealth-supported educational pathway using integrated behavioral and biological data collected by home monitoring to provide personalized lifestyle advice and promote self-management of people with T2D. Early involvement of stakeholders in the development process of eHealth tools is paramount for successful implementation in health care [26-30]. To assist in the construction of successful eHealth technologies, the Center for eHealth and Wellbeing Research (CeHReS) designed a roadmap to guide eHealth device development, implementation, and evaluation. The CeHReS roadmap consists of 5 phases and emphasizes stakeholder involvement throughout all of these phases [31]. The CeHReS roadmap was used to construct our educational program.

Objectives

Our aim is to empower patients with T2D to manage their disease by developing an integrated, eHealth-supported, blended educational pathway called the Diabetes Box (Leiden University Medical Center). In this paper, we delineate the different phases of the participatory development of the Diabetes Box using the CeHReS roadmap, and the lessons learned are shared.

Methods

Ethical Considerations

The accredited medical research ethics committee Leiden den Haag Delft (MREC registration P21.045) has reviewed the research protocol and gave its approval. The patients participating in the panel provided informed consent for their feedback and input to be used in scientific publication. Input data were deidentified. No compensation was provided for participating in the panel.

CeHReS Roadmap

The CeHReS roadmap was used to guide the development process of the Diabetes Box [31]. The CeHReS roadmap was designed to assist in planning, coordinating, and executing the development process of eHealth tools. The roadmap has a participatory dynamic and consists of 5 intertwined phases and continuous formative evaluation (Figure 1). The first 4 phases (ie, contextual inquiry, value specification, design, and operationalization) of the development process of the Diabetes Box are presented in this paper. The summative evaluation will be performed when the Diabetes Box is launched.

The contextual inquiry is meant to understand the challenges faced by the main stakeholders and how they could be solved. To this end, a literature review was performed. We followed the stages of a scoping review according to the revised Arksey and O'Malley framework [32]. We specified the research question "What diabetes self-management education strategies are being used in regular medical care?" The search strategies combined the terms "diabetes self management education," "technology/telemonitoring/glucose monitoring," and "healthcare/medical care." We searched PubMed and used Google for a broader search. One researcher (DLF) selected the studies and discussed these with a team consisting of 2 endocrinologists, a psychologist, a dietitian, and 2 diabetes nurses, all experienced in the field of DSME. Relevant studies were selected and summarized after which the team discussed the report. To elaborate further on the review of literature, previous experiences with eHealth in our center were evaluated, and important stakeholders were identified and interviewed in focus groups. Previous experiences mainly included technological and practical considerations from implementations of eHealth for patients with myocardial infarction, cardiac surgery, and COVID-19 [33-35]. The main stakeholders were

patients, medical specialists, dietitians, psychologists, and diabetes nurses. The latter 4 would later form the development team and partake in the first 2 focus groups.

During the second phase, the value specification, the values gathered in the first phase were translated into (technological) requirements. What problems should the tool solve and how should it work? Weekly meetings with the relevant stakeholders (identified during the contextual inquiry) were used to refine the values and specify the technological requirements of the Diabetes Box.

Using these requirements, prototypes of the Diabetes Box were created during a highly dynamic, iterative, and collaborative design phase. Through biweekly meetings, the development team and stakeholders collaborated closely to ideate, create, and discuss ideas. A panel of patients with T2D gave feedback on the prototype. The entire development team was present on the web during the patient panel. Two members of the team wrote a summary of the recording, after which the recording was deleted. The entire team came together to discuss the outcomes of the patient panel, extract the most important aspects, and set out to change the prototype accordingly. Throughout the development process, the development team looked back on values and knowledge from previous phases to check the integrity of the design. Furthermore, at any point, incoming information could lead to adaptations in the process. This formative evaluation was enabled by constantly involving stakeholders in evaluations and decision-making.

When the design satisfied all stakeholders, the operationalization phase began. During this phase, the Diabetes Box was put into practice. First, a plan was made to implement the newly developed technology into the context defined by the contextual inquiry. The plan was made in close cooperation with the stakeholders to ensure a good fit. Second, the technology is launched.

In the fifth and last phase, the summative evaluation, the tool will be tested in the real world. Currently, the development team is setting up a pilot study to evaluate the feasibility, acceptability, and usability in clinical practice and get an impression of the clinical effects. It is important to note that the technology is quite versatile and adaptable to suit the practical demands of stakeholders as revealed during phase 5. A summary overview of all phases in this study is presented in Figure 2.

Figure 1. Overview of the CeHRes roadmap showing the different phases and formative evaluation (adapted from van Gemert-Pijnen et al [31]). CeHReS: Center for eHealth and Wellbeing Research.

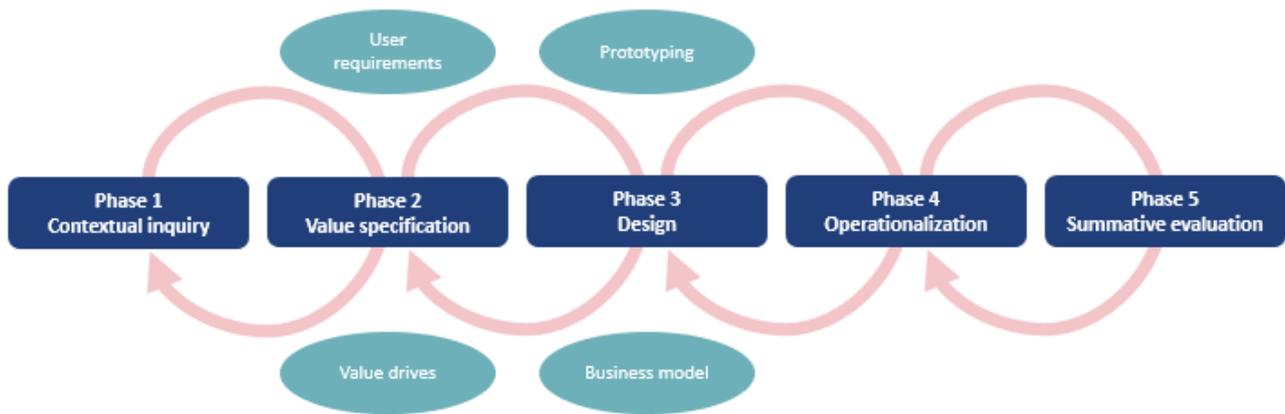

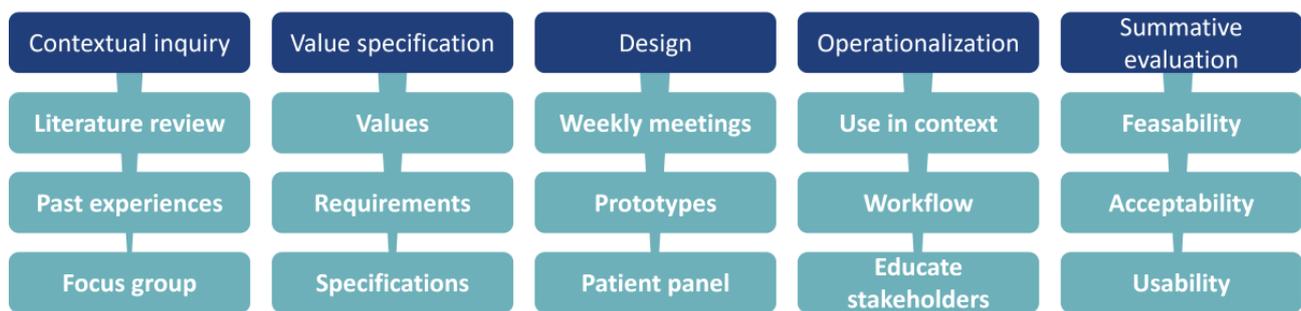

Figure 2. Overview of aspects in every phase. Note that this paper focuses on the contextual inquiry, the value specification, and the design phase [31].

Results

Phase 1: Contextual Inquiry

The contextual inquiry was meant to understand the challenges faced by the main stakeholders and how these challenges could be solved. We used a review of the literature and evaluated past experiences and focus groups with important stakeholders.

Literature Review

The information gathered from the literature review is summarized in Table 1. Studies have outlined several ways to support self-management, which can be categorized as education, monitoring, and modalities. Evidence shows that group-based education about disease pathophysiology, the influence of lifestyle (diet, exercise, stress, and sleep), self-management, and patient activation can improve glucose regulation, reduce body weight, and reduce the need for diabetes medication [4,12,17]. However, HCPs generally feel that they are insufficiently equipped to provide patients with T2D with the insights required to facilitate their health-related behavior

change [36-38]. Furthermore, studies suggest that dietician-led lifestyle intervention as compared to interventions led by other HCPs achieves greater weight reductions [39].

Studies on monitoring indicate that self-monitoring (patients monitoring their own health parameters) and telemonitoring (using information technology to monitor patients at a distance) can significantly increase glucose regulation and reduce T2D-related complications [19]. For example, CGM significantly improves glucose regulation and reinforces patient satisfaction [18,48]. In addition, even though activity tracking has ambiguous effects on glucose regulation, it appears to reduce mortality and CVD risk in patients with T2D as well as the incidence of T2D in a general population [51,52]. Furthermore, blood pressure monitoring can decrease systolic blood pressure in patients with T2D when supported by an HCP [53]. To our knowledge, weight monitoring has not been assessed as a stand-alone intervention, but focus on weight can lead to stigma in patients with T2D, potentially leading to increased emotional distress [55].

Table 1. Outcomes of literature review.

Effects	Comments
DSME^a	
<ul style="list-style-type: none"> • Self-management ↑^b • Glucose regulation ↑ [4,12,13,39] • Knowledge or insight ↑ [12] • Body weight ↓^c [12,39] • Need for medication ↓ [12] • Blood pressure ↓ [12] 	<ul style="list-style-type: none"> • The inclusion of disease pathophysiology contributes to the effect of DSME [12] • Discussing the influence of lifestyle factors (diet, exercise, sleep, and stress) in DSME is decisive for its improvements [4,12,40-46] • Empowerment and patient activation beyond mere education are important in DSME [13] • Digital components of education can be effective [17,39] • The involvement of a dietitian increases the effect on body weight [39]

As far as modalities are concerned, mobile phone apps have a lot of potential in T2D management due to low costs, 24/7 availability, and dynamic automated feedback [21]. Evidence points out that mobile phone apps providing lifestyle advice can improve glucose regulation and facilitate lifestyle modification, particularly when they are supported by

high-frequency HCP feedback [20,56,57]. Furthermore, keeping electronic dietary records effectively informs patients about the impact of food on glucose levels, but easy-to-use technology is needed [60,61]. For example, taking pictures of meals may be an adequate alternative of time-consuming, labor-intensive recording of dietary components [59].

What Experiences do we Have With Digital Tools Supporting Self-Management?

The Box

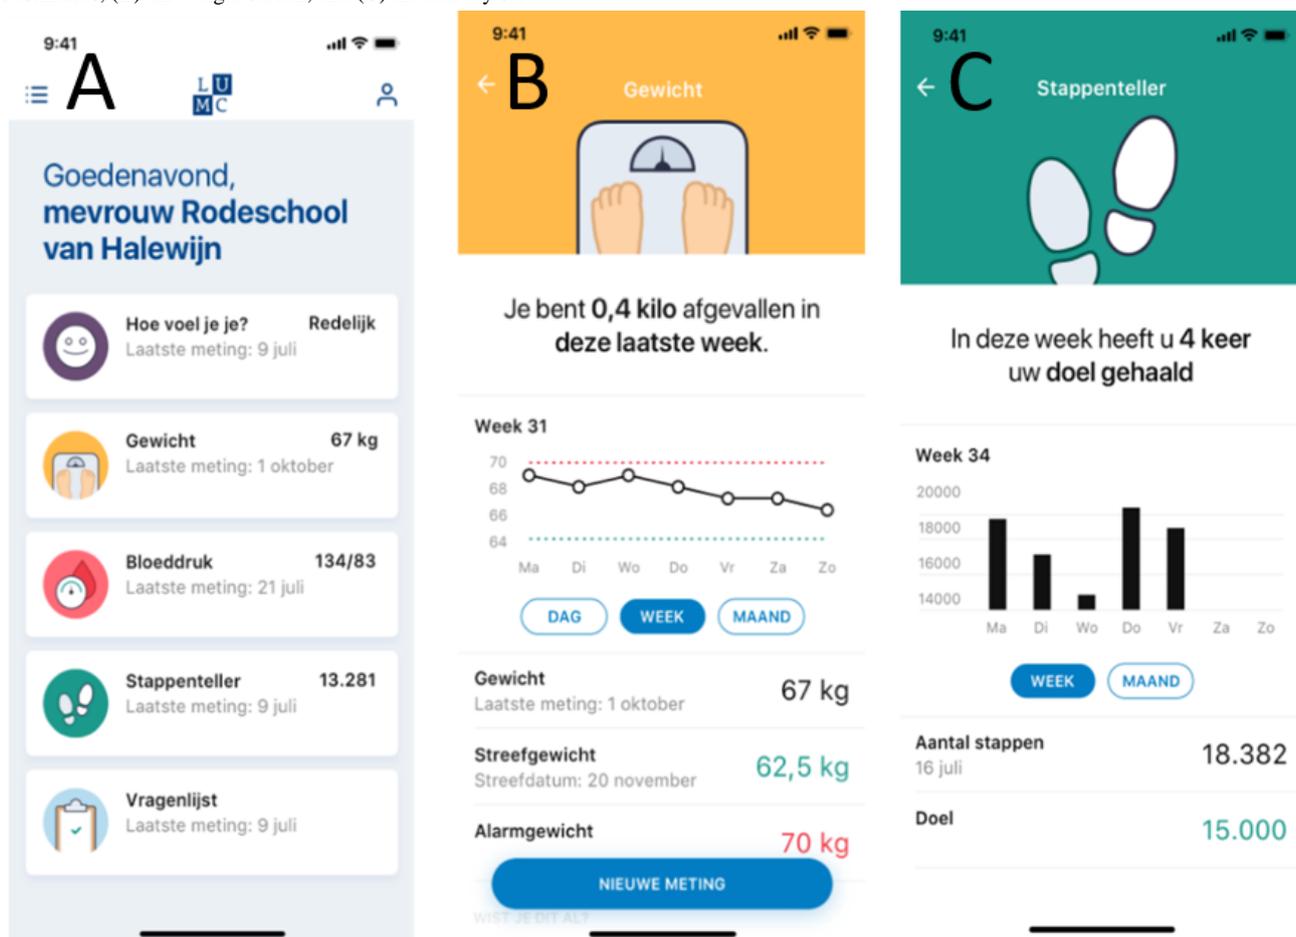

The Box (Leiden University Medical Center) comprises a set of eHealth tools that aim to improve self-management skills for a specific chronic condition. It includes devices for home monitoring of biological and behavioral parameters relevant to health (eg, glucose concentrations, physical activity, or blood pressure). The data are presented to the patient in a smartphone app called the LUMCCare app (discussed in LUMCCare App section). The data are also sent to the patients' electronic medical records in the hospital to allow evaluation by HCPs. The efficacy and safety of the Box have been examined in the follow-up care of patients with myocardial infarction. We recently reported that patient satisfaction with the Box was equal to regular medical care and that 96% (n=100) of participants appreciated that they could view their health data [62]. Furthermore, the Box has been shown to reduce hospital admissions by effectively surveying clinical symptoms and vital signs at home in patients

with COVID-19 [35]. In conclusion, the Box appears to be an effective and appreciated prototype instrument for home monitoring that can be tailored to the health care needs of different conditions.

LUMCCare App

The LUMCCare app (Leiden University Medical Center) is a smartphone app available for Android and iOS. All data collected by the devices in the Box are automatically sent to the LUMCCare app via Bluetooth. The LUMCCare app was codeveloped with people with low health literacy, ensuring a good understanding and usability also in those individuals. Currently, the app was developed in the Dutch language and can display measurements of weight, blood pressure, heart rate, electrocardiograms, steps, temperature, and oxygen saturation (Figure 3). Moreover, users can indicate their level of well-being and provide a brief explanation. HCPs can also send questionnaires to patients through the app. The vast majority of patients with myocardial infarction report intensive and consistent use and high satisfaction with the app [62].

Figure 3. Screenshots of the LUMCCare app from left to right: (A) the home screen showing general well-being, weight, blood pressure, activity, and questionnaires, (B) the weight screen, and (C) the activity screen.

Stakeholders, Current Situation, and Experiences

The main stakeholders included patients, medical specialists, dietitians, psychologists, and diabetes nurses. To evaluate and confirm the findings of our scoping review and past experiences, we organized focus groups with a professor of diabetology, a

clinical endocrinologist, a dietician, a psychologist, 2 diabetes nurses, an IT specialist, and a researcher.

According to international guidelines, people with T2D at least annually visit a physician (endocrinologist or general practitioner) and a nurse specialized in diabetes care. These HCPs should educate patients on (the role of lifestyle in) the

pathophysiology of diabetes and on the types and dosing of available medication. Based on patient needs and health parameters, they decide if the patient requires a consult with the dietician or psychologist. All international guidelines advocate lifestyle intervention as a first step in the treatment of T2D. However, health care systems generally lack the means to adequately support patients trying to change deeply engrained habits. This is made exceedingly difficult by an environment that relentlessly entices them to make unhealthy choices. All HCPs confirmed that continuous home monitoring of subcutaneous glucose concentrations has been a significant

advance in supporting and motivating patients with diabetes to enhance their own grip on disease management. The notion that home monitoring of various relevant behavioral and biological parameters and integrating the data to yield personalized feedback would enhance patient empowerment and potentially improve self-management was broadly shared. To these ends, the contents of the Box and LUMCCare app were envisioned to require specific features as further defined in the next stage of development. A summary of the current situation is provided in [Textbox 1](#).

Textbox 1. Current situation of health care for patients with type 2 diabetes (T2D) according to health care professionals (HCPs).

What is going well?

- Knowledge on diet, exercise, stress, and sleep is intermittently conveyed to patients by HCPs.
- All patients see an endocrinologist and diabetes nurse. If deemed necessary, a dietician and a psychologist are available.
- Adequate optimization of medication use.
- Close interdisciplinary collaboration between doctors, dieticians, psychologists, and diabetes nurses in the care for patients with diabetes.
- Health care can be delivered through digital means.

What can be improved?

- Patients' knowledge regarding the influence of lifestyle behaviors (diet, exercise, sleep, and stress) on glucose regulation.
- Activation of patients with T2D to improve lifestyle behaviors.
- Personalized lifestyle advice.
- Focus on personal goal setting.
- Shared decision-making regarding the timing and intensity of consultations with HCPs.
- Home monitoring of relevant parameters.
- Digital group consultations.

Phase 2: Value Specification

After a thorough exploration of the context and potential improvements, the next step was to translate the requirements of eHealth tools that were identified by the HCPs into specific technological properties. First, HCPs emphasized the need to more extensively convey the importance of lifestyle behaviors, including diet, exercise, stress, and sleep, in the control of glucose metabolism and the treatment of T2D. HCPs also stressed that the tool should tailor information and advice to the

needs and wishes of the patient and that it should be easy to use for both patients and HCPs. Moreover, it should have features that activate patients to appropriately adapt their lifestyle. Activation was listed as a separate capacity of the eHealth tool. Finally, and importantly, the capability to monitor relevant parameters at home and easy accessibility to collected data for patients and HCPs were defined as prerequisites of an effective tool. This leads to a complete list of values, tool requirements, and tool specifications ([Table 2](#)).

Table 2. User perspective, user values, tool requirements, and tool specifications of the Diabetes Box.

Values	Tool requirements	Tool specifications
Provide insight, holistic view	Provide tailored education on the relationship between specific lifestyle factors and glucose regulation	<ul style="list-style-type: none"> • Include a graph of glucose combined with relevant lifestyle factors (diet, activity, sleep, and stress). • Include education on these topics.
Activate and stimulate	Help stimulate patients to adopt healthy behaviors	<ul style="list-style-type: none"> • Include goal setting in all aspects of self-management education. • Provide direct behavior-related feedback and education.
Personalized	Tailored to the patient	<ul style="list-style-type: none"> • Provide a place where patients can monitor their own personal and combined parameters.
24/7 Availability	Rely mostly on apps and e-learning that are available 24/7	<ul style="list-style-type: none"> • Provide a digital resource that patients can use in their own time to measure glucose, diet, activity, stress, and sleep. • Provide links for access. • Resources or videos.
Integrated in health care	Integrated in health care	<ul style="list-style-type: none"> • Add Diabetes Box dashboard to the electronic medical record. • Plan education by HCPs^a in work hours.
User-friendly	Easy to use, logical, and understandable	<ul style="list-style-type: none"> • Use B1-level language throughout the tool. • Simplify user interface. • Incorporate dashboard into electronic medical record. • Align education contents with the expertise of HCPs.
Monitoring patients	Monitoring of patient parameters and making them available for patient and HCP	<ul style="list-style-type: none"> • Provide a place where patients can gain insight into personal parameters of lifestyle factors and glucose. • Provide a dashboard where HCPs can monitor combined patient parameters to provide tailored support.
Low costs	No extra costs for patients, lower costs for health care	<ul style="list-style-type: none"> • Build on existing app content. • Use group meetings. • Free for patients (insurance covered).
Service desk	Enable a patient support desk	<ul style="list-style-type: none"> • Two separate phone numbers were provided for difficulties. First, the outpatient clinic number for diabetes-related questions, and second, the Box support desk for technology-related questions.

^aHCP: health care professional.

Phase 3: Design

Overview

The Diabetes Box was developed using the participatory development method guided by the CeHReS roadmap. The design revolves around making prototypes of the Diabetes Box based on the tool specifications identified in the previous phases and gathering feedback from stakeholders. Our initial prototype was presented to HCPs and shared in a patient panel described below. After feedback from the HCPs, the Diabetes Box comprised digital self-measurement tools, an app, and DSME in the form of consultations and instructive videos (Figure 4). The tools included a continuous glucose monitor (Abbott Freestyle Libre), a sleep or activity tracker (Withings HR Steel), and a blood pressure monitor (Withings BPM Connect). The data collected were presented in the LUMCCare app. Subjective stress could also be registered, and food intake could be monitored by pictures taken of all that was consumed (Figure 5). All data were easily visualized in daily, weekly, and monthly overviews. The data of diet, activity, sleep, and subjective stress could also be plotted on the continuous glucose graph to provide

insight into the relation between lifestyle factors and glucose regulation. An expert-led educational program was developed to further promote knowledge of the relationships between various components of lifestyle and glucose control. The overarching goal of the Diabetes Box is to empower patients and facilitate self-management of their disease. The program combines knowledge from routine diabetes care provided by dietitians, psychologists, endocrinologists, and specialized nurses. All educational material was developed, aiming to promote patient self-management. Therefore, multiple behavior change techniques were included in the development of the Diabetes Box. These included information provision, goal setting, action planning, self-monitoring, feedback provision, social comparison, and motivational interviewing. In [Multimedia Appendix 1](#), we provide a list of behavior change techniques as described by Michie et al [63], including a description of the app in the Diabetes Box. There were nine 3- to 5-minute educational videos combining live feed and animations. The topics of these videos were an introduction to the Diabetes Box, the pathophysiology of diabetes, CGM, diet, exercise, sleep, stress, goal setting, and self-management. The educational

program also entailed five consultations: (1) a group consultation introducing the digital tools, (2) an individual consultation focusing on diet, (3) a group consultation regarding diet and exercise, (4) a group consultation regarding sleep and stress, and (5) an individual consultation to evaluate, conclude, and

set up future goals. Goal setting and patient activation were present in all videos and all educational consultations. The consultations lasted 45-90 minutes. Prior to each consultation, participants were asked to watch 1 or 2 videos.

Figure 4. Overview of the educational pathway for patients with T2D using the Diabetes Box.

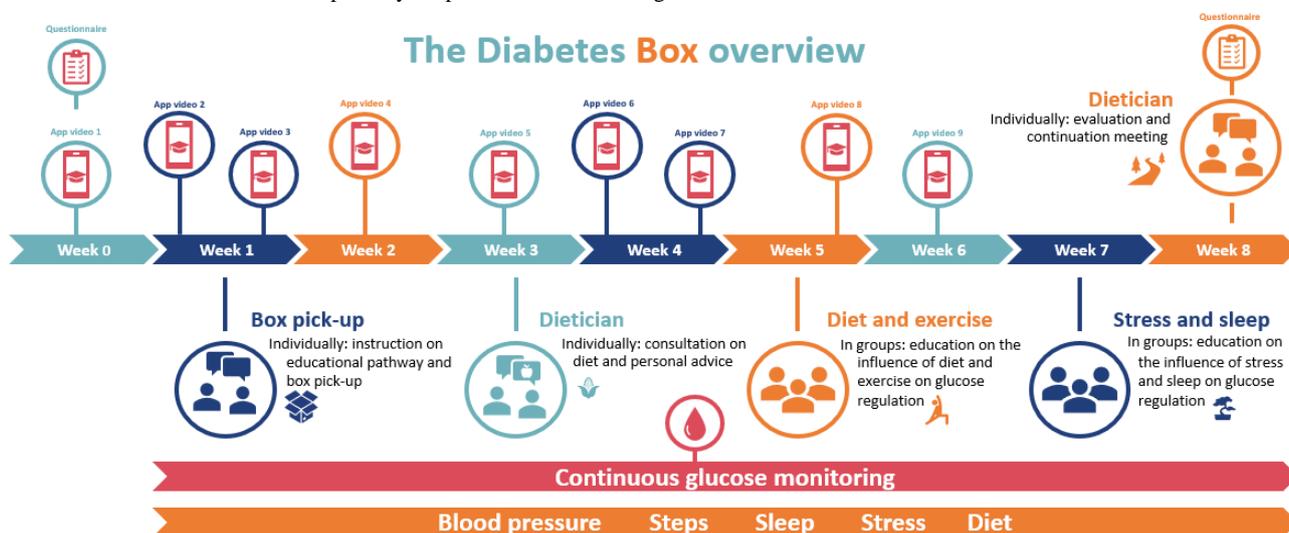

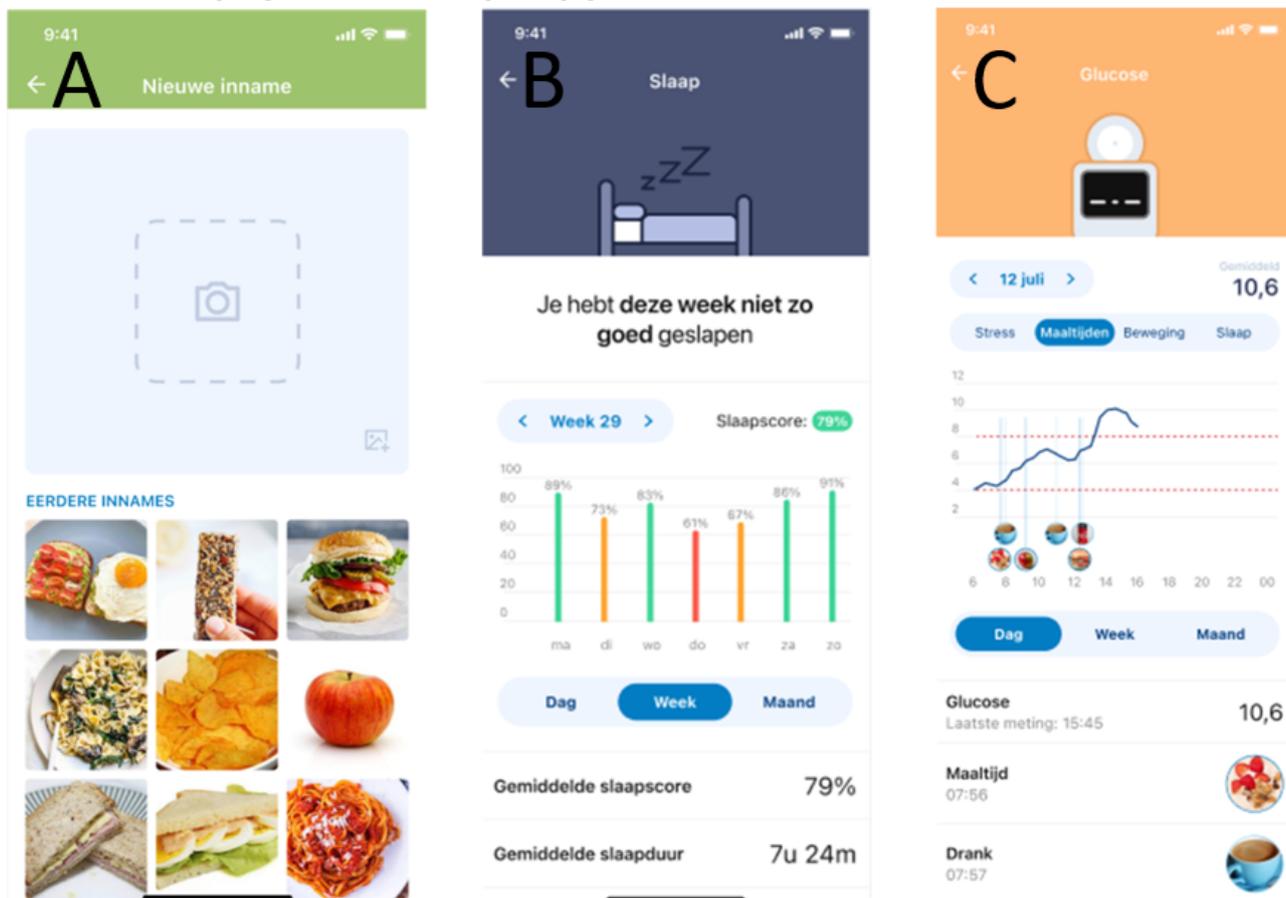

Figure 5. Screenshots of the new modalities of the LUMCCare app from left to right: (A) the screen to register a new intake, either food or drink, with a photo; (B) the sleep screen showing an average score based on estimated duration, interruptions, and regularity; and (C) the glucose screen combined with the diet screen showing the photos of intakes in the glucose graph.

Patient Panel

The prototype of the Box was shared with people with T2D to gather feedback on the preliminary design. Due to COVID-19 measures, only 4 people with diabetes were present during the session. The session took 90 minutes. The concept of the Box program was explained, 2 of the 9 educational videos were shown, the app and its functionalities were demonstrated, and people could try out the eHealth tools. The panel was asked questions covering 4 domains: general opinion, contents and clarity of the educational videos, functionality of eHealth instruments, and usability of the app. Overall, the evaluation was positive, while several potential improvements were suggested (Table 3).

Based on the feedback provided by the patient panel, multiple adaptations were made. First, a leaflet was added to the Box, explaining the flow of the program and anticipated time investment from the side of patients in more detail. Second, a web page was made, displaying the videos accompanied by instructions on when to watch which video. Third, a handout was made with detailing information about the different types of diabetes medications, their uses, and their common side effects. Fourth, as patients preferred a mix of consultation types, 2 consultations were planned online and 3 face-to-face. Fifth, the video of sleep was cut into 2 halves of 3 minutes to prevent viewers from quitting halfway through. Last, the LUMCCare was further developed to also accommodate insulin registration and other activities than steps (eg, cycling or swimming).

Table 3. Outcomes of patient panel.

Comments	Actions
General opinion	
<ul style="list-style-type: none"> Positive first impression Useful and feasible Questions about total time investment, duration of the education, and loan of the devices Advise to restrict the number of needed apps to one 	<ul style="list-style-type: none"> Informative material was made for participants of the Diabetes Box addressing the expected time investment, duration of the pathway, and the fact that participants can keep the devices. Technologically we still need 2 apps. However, 1 only needs to run on the background and does not have to be opened.
Education	
<ul style="list-style-type: none"> Positive Duration and frequency seem feasible Half preferred online (travel distance and comfort of home) and half preferred live (connection with HCP^a) Early evening is the best time Videos are appreciated (up to 3 minutes) A clear overview of videos and when to watch them is needed Advice in education has to be consistent Extra attention for diabetes medication, not all glucose levels can be related to behavior, correct use of the CGM^b 	<ul style="list-style-type: none"> Hybrid pathway, part of consultations live, part online. The video of sleep was cut into 2 parts. A web page was made with an overview of all videos explaining when to watch which. An extra handout was made about diabetes medication. Attention to explaining glucose levels was added to the information.
Devices or measurements	
<ul style="list-style-type: none"> Doable, clear, and easy to use Frequency of measurement was regarded positively Activities other than steps would be great A (3 hours) delay in showing glucose values was deemed very impractical 	<ul style="list-style-type: none"> Added activity tracking other than steps in the app. Focused on displaying real-time glucose data in the app.
LUMCCare app	
<ul style="list-style-type: none"> Positive about layout and readability Stress measurement and diet photos were deemed useful Diet photos were deemed confronting in a helpful way Incorporate insulin use in the app 	<ul style="list-style-type: none"> A functionality to register insulin use was added to the LUMCCare app.

^aHCP: health care professional.

^bCGM: continuous glucose monitoring.

Phases 4 and 5: Operationalization and Summative Evaluation

Operationalization involves the introduction of eHealth technology into practice. To test our design, we are currently planning a pilot study in 32 people with T2D to assess the feasibility, acceptability, and usability of the Box in clinical practice. Secondary objectives are evaluation of time in range and perceived learning. The study duration will be 2 months

(as the concept Box program lasts 2 months). Participants will fill out a questionnaire before and after the study, and they will be interviewed about their experience as well. Patient satisfaction, user-friendliness of Box components, added value of the program in terms of disease management, and eventual use of the help desk will be evaluated. Consultation attendance, the use of eHealth tools and apps, and eventual replacement of glucose monitors will be registered. HCPs will be asked for

their opinion regarding clinical practicalities in a structured interview, and average health care costs will be calculated.

Discussion

Principal Findings

Personalized lifestyle advice and promotion of self-management can help patients change their health behavior and improve glucose regulation. Digital tools have great potential in supporting patient self-management due to the effectiveness, low costs, 24/7 availability, and the option of dynamic automated feedback. However, reports documenting the impact of interventions incorporating multiple lifestyle modalities on glucose control are, to our knowledge, not available. Here, we developed an integrated, eHealth-supported, educational care pathway for people with T2D following the CeHReS roadmap and using a scoping review about DSME and eHealth, past experiences of eHealth practices in our hospital, focus groups with HCPs, and a patient panel. The care pathway aims to empower patients with T2D to self-manage their disease by providing them with direct feedback on their personal health behavior in relation to contemporaneous glucose levels.

HCPs and patients thought the concept of the Diabetes Box to be feasible, acceptable, and useful. The main strengths of the Diabetes Box were considered to be the integration of direct biofeedback on personal behavior, the focus on goal setting, and patient activation.

Comparison to Prior Work

The direct biofeedback regarding the impact of behavior on glucose concentrations was believed to be crucial to provide patients with insight into the relationships between their health behavior and glycemic control. A similar conclusion was drawn in an earlier study where patients with T2D were motivated to exercise while using CGM and accelerometer technology [64]. In many studies, data on lifestyle parameters were entered manually or via voice recording [22,24]. A Korean study showed input rates of diet and exercise of 24.9% and 5.3%, respectively [22]. Our study uses automatic input of steps, sleep, blood pressure, and glucose levels facilitating data gathering by participants. Diet was tracked using photographs. These photos were not analyzed for caloric content or carbohydrates but were used to provide insight into glucose-level fluctuations caused by certain food types. Beyond automated recording of behavioral and biological parameters, our app enables combining all lifestyle parameters with continuous glucose levels to create easily interpretable relations between lifestyle and glucose levels.

Regarding these lifestyle components, other interventions for people with T2D focus primarily on diet and exercise [23,24,65]. In one German study, stress management was included in the educational material, but stress or mood was not measured during the study [66]. The lifestyle components on which feedback should be provided include diet, physical activity, stress management, and sleep. Chronic stress may be a less obvious yet important disruptor of glucose control, as indicated by previous research [67,68]. Indeed, a recent meta-analysis revealed that stress reduction therapy improves glycemic control

in people with diabetes [46]. The Diabetes Box gives direct biofeedback on diet, exercise, sleep, and stress. The effect of direct biofeedback on personal behavior is further enhanced by structured and tailored education. This is important, as physiological responses to lifestyle changes are often determined by personal characteristics [14,15]. Other studies often use one-size-fits-all education or even automated SMS text messages [24,65,69]. During the educational consultations in the Diabetes Box, HCPs can inform patients regarding the effects of their personal health behavior on metabolic control. The education in the Diabetes Box was designed to be simple, patient-centered, and multimodal, which is in line with the literature on successful patient education [70,71].

In addition, most of the existing tools are used in a research setting, and the challenge is to integrate these tools into regular medical care. A recent Dutch study showed that following a 2-year multicomponent lifestyle program outside of regular medical care could reduce medication use. In this setting, 71% of insulin users could stop insulin, and 28% of participants could stop glucose-lowering medication altogether. It must be stated though that only 234 of 438 starting participants were used in the final analyses [23]. When using these tools as regular medical care, all patients with T2D will follow the program instead of a selection of the more motivated patients. Our setup is to use this tool as regular medical care for all patients with T2D. The participatory development with an entire endocrinology team working in diabetes care can improve the chance of successful implementation. We are curious if similar results will be achieved when a multicomponent lifestyle program is integrated into regular medical care.

Studies have shown that people with higher levels of lifestyle-related knowledge (eg, influence of diet on glucose levels) tend to make healthier choices to improve their glycemic control [72]. However, better education and insight do not necessarily translate into behavior change [73]. To stimulate patients to change their behavior, goal setting and activation are integrated into all components of the Diabetes Box. All videos end with an assignment to self-monitor specific behavioral and biological parameters in preparation of the next consultation, and a separate video about goal setting is included. Furthermore, the individual consultations with the dietitian revolve around diet but also cover reflection on goals set by a patient. It is difficult to empower people with insufficient diabetes-related knowledge to manage their disease [74]. Therefore, we believe it is the combination of direct feedback, structured and tailored education, and targeted patient activation that grants the Diabetes Box its great potential.

The participatory development process played a critical role in the realization of the Diabetes Box. Involving all stakeholders from the start proved very fruitful, as it clearly facilitated the creation of a program that fits all stakeholder demands. The CeHReS roadmap was very helpful as well. It provided handholds and courses of action, which make it easier to make and measure progress. In addition, the value specification generated a concrete set of wishes from the key stakeholders that could be used to fall back and make decisions.

Limitations and Strengths

Obviously, there are at least 2 issues that limit the broad-based application of the Diabetes Box for the time being. First of all, the feasibility of the program as well as its impact on metabolic control and quality of life of patients with T2D needs to be evaluated in clinical practice. As the program was primarily developed by stakeholders employed by a third-line, academic medical institution, it also needs to be tested if it works for patients under regular surveillance by primary care ($n > 1$ million, 90% of patients with T2D are treated by their general practitioners in the Netherlands). Second, although the LUMCCare app was created as a “white label” app, which means that it is relatively easy to adapt external characteristics, it was designed as part of the local (Leiden University Medical Center) infrastructure. Use by other institutions would therefore probably require modifications. We are willing to help and assist hospitals and other health care institutions that want to implement the Diabetes Box into their regular medical care for people with T2D. The challenges we foresee are training personnel and integrating the Diabetes Box into their daily workflow. The type of specialist who provides the consultations can be changed depending on what professionals are motivated and at hand. In addition, the content of the educational material can be altered to better fit the personal approach of the

professional providing the education. On a technological basis, challenges also exist. The app is white label and can be easily adapted to accommodate the look and feel of other institutions. However, the data generated in the app have to be made available for the HCPs involved. This will most commonly involve integration into the electronic medical records, which is a process that costs both time and money. In the near future, the Diabetes Box will be tested in a single-center, mixed methods, sequential explanatory pilot study including approximately 32 patients with T2D, with the primary aim to assess its feasibility, acceptability, and usability. Secondary objectives will be to evaluate its impact on the “time in range” of glucose levels and perceived learning. Subsequently, in case of promising results, the Diabetes Box will be tested for efficacy in a larger, multicenter (including primary care) intervention study.

Conclusions

We have developed a unique care pathway in close collaboration with relevant stakeholders in order to ensure a good fit. The combined effects of direct biofeedback on personal behavior, structured and tailored education, and goal setting should empower people with T2D to improve their self-management and glycemic control. A pilot study is planned to assess feasibility, acceptability, and usability in more detail.

Conflicts of Interest

None declared.

Abstract

Background: The clinical management of type 2 diabetes mellitus (T2DM) presents a significant challenge due to the constantly evolving clinical practice guidelines and growing array of drug classes available. Evidence suggests that artificial intelligence (AI)–enabled clinical decision support systems (CDSSs) have proven to be effective in assisting clinicians with informed decision-making. Despite the merits of AI-driven CDSSs, a significant research gap exists concerning the early-stage implementation and adoption of AI-enabled CDSSs in T2DM management.

Objective: This study aimed to explore the perspectives of clinicians on the use and impact of the AI-enabled Prescription Advisory (APA) tool, developed using a multi-institution diabetes registry and implemented in specialist endocrinology clinics, and the challenges to its adoption and application.

Methods: We conducted focus group discussions using a semistructured interview guide with purposively selected endocrinologists from a tertiary hospital. The focus group discussions were audio-recorded and transcribed verbatim. Data were thematically analyzed.

Results: A total of 13 clinicians participated in 4 focus group discussions. Our findings suggest that the APA tool offered several useful features to assist clinicians in effectively managing T2DM. Specifically, clinicians viewed the AI-generated medication alterations as a good knowledge resource in supporting the clinician’s decision-making on drug modifications at the point of care, particularly for patients with comorbidities. The complication risk prediction was seen as positively impacting patient care by facilitating early doctor-patient communication and initiating prompt clinical responses. However, the interpretability of the risk scores, concerns about overreliance and automation bias, and issues surrounding accountability and liability hindered the adoption of the APA tool in clinical practice.

Conclusions: Although the APA tool holds great potential as a valuable resource for improving patient care, further efforts are required to address clinicians’ concerns and improve the tool’s acceptance and applicability in relevant contexts.

KEYWORDS

clinical decision support system; artificial intelligence; endocrinology; diabetes management; human factors

Introduction

Diabetes mellitus is a chronic condition that affects millions of people worldwide. In Singapore, the prevalence of diabetes is estimated to surpass 400,000, with 1 out of 3 individuals at risk of developing the condition [1]. Uncontrolled diabetes can lead to various complications, such as neuropathy, retinopathy, and nephropathy. Diabetes is primarily associated with cardiovascular diseases, particularly ischemic heart disease and myocardial infarction, which account for most of the mortality cases in patients with diabetes [2,3].

Managing diabetes clinically poses a considerable challenge due to its complex nature. The treatment of diabetes involves achieving specific targets, such as optimal control of glycemia, blood pressure, and lipid levels, primarily relying on laboratory tests [4]. Regular review of test results and subsequent treatment adjustments are important in minimizing the risk of long-term complications and aligning with recommended targets [5]. However, the need to monitor multiple laboratory markers during clinical consultations can impose a cognitive burden. Furthermore, incomplete integration of critical patient data into the electronic medical record (EMR) can lead to errors in disease monitoring, compromising the quality of patient care [6].

Evidence suggests that clinical decision support systems (CDSSs) can assist clinicians in effectively monitoring patient data and making accurate and informed treatment decisions [7-9]. Traditionally, CDSSs have relied on medical expertise and clinical practice guidelines. However, keeping CDSS content and knowledge up-to-date is increasingly challenging due to the evolving nature of clinical practices [10]. The advent of big data and machine learning has enabled the development of artificial intelligence (AI)-powered CDSSs, capable of diagnosing conditions, suggesting evidence-based treatment options and aiding in care planning [11,12]. Research shows that AI-powered CDSSs have improved the quality of diabetes care and patient outcomes [12,13].

Despite the positive impacts of AI-driven CDSSs on health care, fewer studies have examined human factors. In addition, several critical issues surrounding AI-powered clinical tools have been brought to attention, including concerns regarding the transparency of underlying algorithms, accountability, data privacy, and limited trust and applicability [10,14]. Although these studies provide essential insights into implementing AI-based CDSSs, a significant gap exists in research concerning the early-stage implementation of an AI-enabled CDSS specifically for type 2 diabetes mellitus (T2DM). Evaluating a CDSS in the early stages of implementation is of utmost importance to optimize its benefits and mitigate potential drawbacks, as it offers vital information on use, acceptability, and the challenges pertaining to human factors in real-world clinical settings.

To support clinicians in making better treatment decisions in T2DM management, the AI-enabled Prescription Advisory (APA) tool was developed and integrated within the

endocrinology specialist clinics at the Diabetes & Metabolism Centre in Singapore General Hospital. To ensure that the tool is capable of scaling up and meeting the needs of its users, it is crucial to assess its appropriateness within the clinical context. Therefore, this study aims to explore the perspectives of clinicians regarding the use and impact of the APA tool while also identifying potential challenges associated with its adoption and application.

Methods**Overview**

This study adopted qualitative research methodology to assess the usability of the tool. For rigor and transparency, we anchored our study according to the COREQ (Consolidated Criteria for Reporting Qualitative Research) checklist [15].

Development of an AI-Enabled Diabetes CDSS

The diabetes CDSS, also known as the APA tool, was developed using data gathered from the Singapore Health Services Diabetes Registry that comprised a total of 189,520 patients with diabetes. This data set included 6,407,958 outpatient visits spanning over 5 years from 2013 to 2018 [16]. For model development, 80% of the data set was used to build therapeutic recommendations, while the remaining 20% was used to test and validate the trained models. Three distinct therapeutic recommendation models were formulated for antiglycemic, antihypertensive, and lipid-lowering treatments. These models were created by integrating both a knowledge-driven approach and a data-driven approach. The knowledge-driven approach, initially drawing inputs from clinical guidelines and expert opinions, was used to identify potential therapeutic options. Subsequently, the data-driven approach that used deep learning techniques was used to select the identified therapeutic options based on anticipated clinical outcomes. To assess the performance of model's prediction, short-term outcomes compared therapeutic options between treatments that aligned with the model's recommendations and those that did not. Confounding factors were also accounted along the way and adjusted by stratification and multivariate regression. For evaluation of long-term outcomes, the rates of model-concordant treatments were computed by multivariate logistic regression to determine whether the combined treatments exhibited a positive impact on reducing the occurrence of long-term complications and mortality.

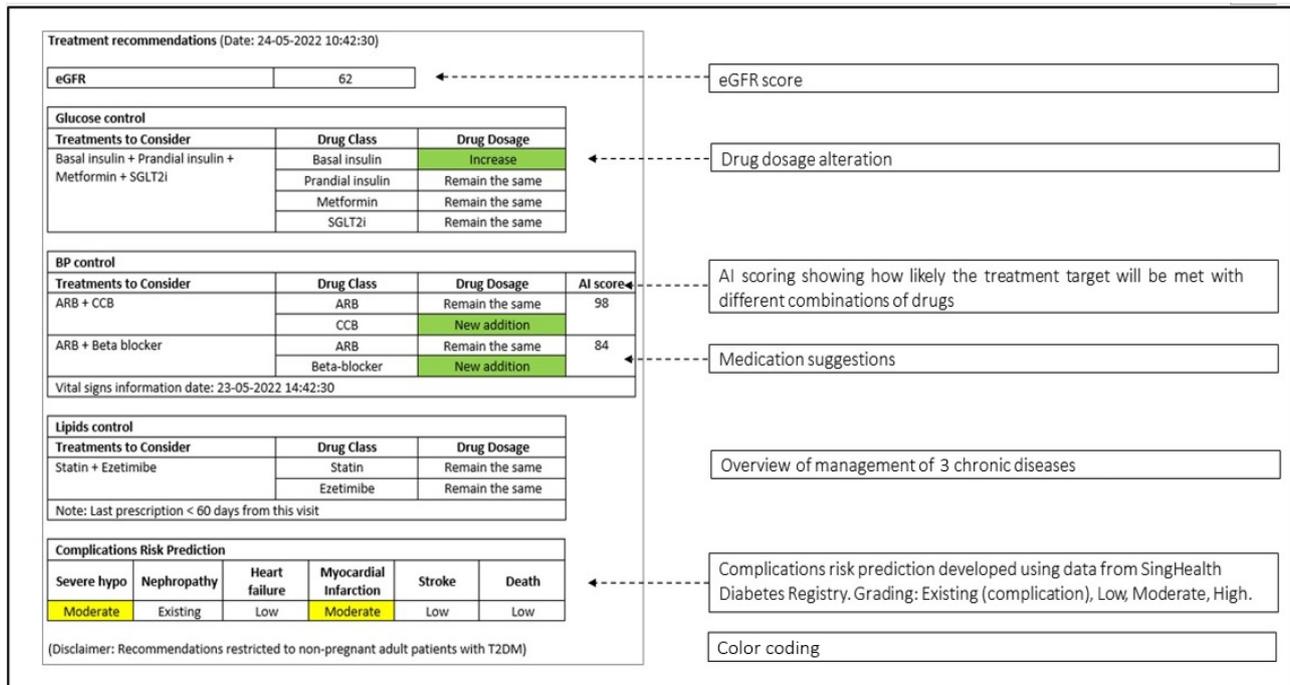

Features of the AI-Enabled Diabetes CDSS

Presently, the APA tool has been integrated into the EMR system at the Singapore General Hospital to provide tailored treatment recommendations for achieving target glucose, blood pressure, and cholesterol levels. It features 3 distinct AI components designed to improve patient outcomes and support clinical decision-making. The first component recommends drug classes based on laboratory markers such as glycated hemoglobin (HbA_{1c}), low-density lipoprotein cholesterol, and blood pressure measurements, aiding clinicians in selecting the

most appropriate drug classes to achieve glycemic, low-density lipoprotein cholesterol and blood pressure treatment targets. The second component generates an AI score that indicates the likelihood of reaching treatment targets when adopting a suggested new drug therapy. The third component generates AI-based diabetic complications risk predictions, providing

specific complication risks associated with suboptimal diabetes treatment. All outputs generated by the AI model are color-coded for enhanced visibility. Figure 1 provides a snapshot of the APA tool's outputs, illustrating how clinical results extracted from a patient's EMR are presented.

Figure 1. Outputs of APA tool. The APA tool features include laboratory markers related to diabetes care, medication prescribing recommendations, color-coding to highlight changes, and diabetic complications risk prediction. AI: artificial intelligence; APA: AI-enabled Prescription Advisory; ARB: angiotensin receptor blockers; BP: blood pressure; CCB: calcium channel blockers; eGFR: estimated glomerular filtration rate; T2DM: type 2 diabetes mellitus.

Note: The APA tool features include laboratory markers related to diabetes care, medication prescribing recommendations, color-coding to highlight changes and diabetic complications risk prediction.

Participants

Eligible participants were (1) clinicians trained in endocrinology, (2) currently employed full-time by the institution, (3) completed training in APA, and (4) used the APA for a minimum duration of 4 weeks. We purposively selected participants according to age, gender, and seniority level in the workplace to gain a range of perspectives. Participants were approached via email, and informed consent was obtained prior to enrollment into the study.

Study Procedure

Prospective participants were purposefully selected and approached by the research team to ensure their engagement in the study. Consented participants took part in a comprehensive group training session, encompassing the following key components: (1) a comprehensive overview of the tool's development and validation process, (2) exploration of the specific features and underlying knowledge rules that inform the therapeutic recommendations, (3) familiarization with the tool's output (ie, therapeutic recommendations), and (4) an interactive question and answer segment addressing general inquiries. The entirety of the training session was conducted over the course of 1 hour. Following the training, the participants

were granted immediate access to the APA tool during their clinical consultations. It was emphasized that the participants had the freedom to decide on the final treatments for their patients with T2DM, regardless of the clinical recommendations provided by the APA tool. Each participant was given a minimum of 4 weeks of exposure to the tool in the clinic setting before his or her involvement in this study. Following the 4-week period, the participants were invited to partake in a focus group discussion (FGD).

Data Collection

A semistructured FGD guide was developed by drawing upon relevant literature and leveraging the expert knowledge of the study team [17,18]. FGD was chosen to foster a dynamic and interactive environment that encouraged the exploration of shared experiences and perspectives within the professional context, thereby providing a comprehensive understanding of the collective viewpoints users had on the APA tool. To attain a variety of opinions, the participants were recruited according to their seniority (registrars, associate consultants, consultants, and senior consultants). FGDs were conducted exclusively among participants holding equivalent hierarchical positions within the workplace, with the specific intention of minimizing the potential for power differentials and fostering open and

candid dialogue. Key topics of interest included (1) participants' firsthand experiences while using the APA tool, (2) perceptions and evaluations of the various features, (3) impacts of the APA tool on clinical practice, and (4) challenges related to the adoption and application. The interview guide underwent pilot-testing multiple iterations. Consented individuals were then invited to participate in virtual FGD (2-6 participants per session according to seniority) over Zoom (Zoom Video Communications, Inc) by a facilitator (HG) trained in qualitative research methodology. Reflections were recorded after each FGD to capture and document valuable insights shared during the discussions. The duration of the FGD ranged from 50 minutes to 75 minutes.

Data Analysis

Interviews were audio-recorded following verbal consent and transcribed verbatim. Transcripts were checked for validity, and any identified errors were corrected. Two coders (SY and HG) reviewed the transcripts independently and thematically analyzed the data using NVivo (version 12; Lumivero). We used reflexive thematic analysis following each completed interview [19], contributing to the ongoing refinement and direction of the interview guide for subsequent interviews. The coding categories evolved from initial open coding to more analytical coding of the text, ultimately revealing a series of interconnected themes and patterns. The analysis and interviews continued until no new emerging themes were identified. In case of discrepancies, iterative discussions involving study team members were conducted to resolve any differences and ensure consistency in the analysis process.

Recognizing the inherent influence of the coders' subjective perspectives in the research process, the study team prioritized strategies aimed at effectively managing these preconceptions and upholding the integrity and credibility of the analysis. Specifically, we implemented the following measures: (1) the establishment of an elaborate coding protocol, meticulously designed to promote consistency and minimize potential subjective interpretations and (2) regular engagement in

peer-debriefing sessions and member checking to validate the interpretations and enhance the credibility and confirmability of our findings.

Ethical Considerations

Ethics approval was obtained from SingHealth Centralized institutional review board (2022/2329). Prior to the FGD, a proficient research coordinator (HG) engaged with each participant individually to meticulously review the participant information sheet and consent form. Particular emphasis was placed on elucidating the study's objectives, along with an extensive exploration of potential foreseeable risks and benefits. Upon satisfactory comprehension, the participants were invited to provide their informed consent by endorsing the documentation. Furthermore, they were duly informed that all collected data would undergo a stringent deidentification process to preserve anonymity. To uphold transparency and equity in the compensation process, the participants were explicitly notified beforehand that no form of compensation would be provided for their involvement in this study. It was reiterated that participation in the study was entirely voluntary.

Results

Characteristics of Participants

In total, 18 clinicians were contacted, and 13 responded positively to the invitation and participated in the FGDs. The remaining 5 clinicians declined to participate, citing time constraints and lack of interest as the reasons. The FGDs were conducted based on participants' seniority at work. Most participants were male (n=8, 61%) and aged between 31 and 50 years (n=12, 92%). The participants held various designations in their respective roles, including resident (n=3, 23%), associate consultant (n=1, 8%), consultant (n=5, 38%), and senior consultant (n=4, 31%). Notably, more than three-quarters (n=10, 77%) of the participants had no prior experience with AI-enabled CDSSs. Detailed characteristics of the study participants are shown in [Table 1](#).

Table 1. Characteristics of participants (N=13).

Characteristics	Participants, n (%)
Age (years)	
31-40	6 (46)
41-50	6 (46)
Older than 50 years	1 (8)

Senior consultant	4 (31)
Prior experience with AI^a-enabled CDSSs^b	
Yes	3 (23)
No	10 (77)

^aAI: artificial intelligence.

^bCDSS: clinical decision support system.

Our analysis yielded 2 themes and 9 subthemes that represented the participants' perspectives concerning the use and impact of the APA tool on patient care and clinical practice and the challenges to adoption and application of the APA tool. Descriptions of themes and subthemes are presented in [Textbox 1](#).

Textbox 1. Main themes and subthemes.

Use and impact of the AI-enabled Prescription Advisory (APA) tool on patient care and clinical practice

- Supporting decision-making for patients with comorbidities (artificial intelligence [AI]-powered drug class recommendations)
- Facilitating doctor-patient communication (diabetic complications risk predictions)
- Enhancing clinical confidence through cross-checking (color-coded AI-generated recommendations)
- Serving as a gatekeeper against medical negligence

Challenges concerning adoption and application of the APA tool

- Interpretability issues due to the lack of standardized guidelines on AI risk predictions
- Mistrust in the system driven by perceived lack of transparency around system development and information sourcing
- Limited applicability in a specialist setting given extensive expertise and patient care accountability of endocrinologists
- Concerns about potential harm in light of occasional contradictions between the APA tool recommendation and a clinician's professional judgment
- Frustration with technical issues associated with the tool implementation

Use and Impact of APA Tool on Patient Care and Clinical Practice

When asked about their experience with the APA tool, most participants expressed a positive impact, highlighting its potential to guide clinical decision-making as a key benefit. Specifically, the participants appreciated the AI algorithm's ability to provide drug class recommendations based on patients' laboratory markers. Notably, the tool not only simplified chronic disease management but also assisted in identifying instances of suboptimal disease control that might have otherwise gone

unnoticed during consultations. This streamlined approach proved invaluable in guiding clinicians toward effectively managing comorbidities and reducing the risk of long-term complications in patients with diabetes.

I think the most valuable part for me is the lipid control feature. Sometimes when engrossed in discussing patients' diabetes treatment plans, which is anyway their primary reasons for seeking consultation, I may overlook the assessment of their LDL-c levels. With the APA tool, a quick glance provides a clear indication of whether they are on

target or not. There isn't much extra clinical information that is required by the tool, so I am able to rely on the medication recommendations to appropriately adjust the medication for hyperlipidemia. [FGD 2, senior consultant]

Furthermore, some participants saw the AI-generated complication risk predictions as a helpful resource in “convincing patients to adhere to certain treatments or treatment plans.” By presenting visible evidence regarding the potential risks linked to noncompliance or inadequate treatment, the tool showed considerable potential in facilitating doctor-patient communication based on risk prediction.

The complications risk prediction feature stands out as particularly beneficial to me. For example, it provides an alert regarding the risk of hypoglycemia. When the risk level is classified as moderate or high, this information helped me better persuade patients to consider specific treatments or to improve their compliance with the recommended approach. [FGD 2, senior consultant]

Some participants pointed out the lack of quantitative representation for the AI-generated complication risk prediction scores. They proposed an interactive time series graph that would visually illustrate the fluctuations in risk scores over time following the adoption of the tool's recommendations. Participants believed that integrating visual aids would enhance patients' understanding of their current risk levels associated with complications and promote the benefits of adhering to treatment plans.

The ability to visually present individual risk in a quantitative way through graphical or pictorial means and illustrate the potential changes that may occur after adopting the systems' recommendations would improve information delivery. I personally believe that patients are more inclined to accept the recommendations when they see their risk in a pictorial or a graphical format. [FGD 1, associate consultant]

The color-coded AI-generated recommendations served as an additional point of reference during consultations, particularly when discrepancies emerged between the tool's recommendations and the clinician's own knowledge. This feature not only fostered critical thinking but also prompted clinicians to consider additional clinical histories that might have been overlooked initially. Overall, clinicians reported an enhanced level of confidence in their clinical decisions, thereby “improving the quality of patient care.”

So, the tool helps to reinforce my decision-making. The color-coded recommendations provide a clear visual indication, prompting me to address any discrepancies that may arise between the tool's suggestions and my own clinical plan. In this case, I delve into additional clinical histories that the tool does not have access to and elucidate the rationale behind my decisions. This process enhances my confidence and guides better decision-making during

the clinical visit, which can improve the quality of patient care. [FGD 1, consultant]

By and large, the participants perceived the APA tool as a mechanism to prevent the risk of negligence, especially in fast-paced clinical environments. Acting as a “gatekeeper for patient safety,” the APA tool effectively identified and flagged abnormal results, mitigating the risk of overlooking important tasks. The tool was regarded as a valuable partner in pursuit of delivering high-quality and safe care to patients.

I like the idea of the tool as a gatekeeper for patient safety. Making sure doctors don't forget things, reminding us to check and act on abnormal results. I think that is useful for busy clinics. [FGD 1, associate consultant]

Challenges to the Adoption and Application of APA Tool

Although participants generally acknowledged the beneficial effects of the APA tool on quality patient care and clinical practice, they equally expressed reservations about incorporating and using the tool in their own clinical settings. One major concern centered around the interpretability of the automatically generated AI score when new drugs were recommended. While participants appreciated the availability of the scoring system to inform the likelihood of achieving treatment targets based on the recommendations, they remained unsure about the interpretability of the AI score.

I think it is quite interesting that the system is able to provide different percentages of achieving optimum blood pressure when different combinations of new drugs are used. However, my question is if plan A gives a score of 48 while plan B gives a score of 45, are these recommendations still clinically relevant? I mean, of course, the situation is more direct in cases with scores such as 98 and 88, then it will make more sense to pick the plan with 98% of likelihood. [FGD 1, consultant]

A sense of mistrust in the APA system emerged, which appeared to stem from the unfamiliarity surrounding AI-based recommendations and concerns regarding transparency of the information sourcing and system development. Some participants openly expressed their hesitancy in adopting the APA tool due to the absence of essential clinical data. Without access to this information, they were not confident enough to use the tool.

When it [APA] was launched, a lot of us were not very sure how it was developed. I think part of the reason why we did not use it very much is also because we are not so familiar with how this system came about, what kind of information was used, and where the information came from. Is it also possible that critical information was not captured in the system? I can't trust totally, and [I am] not confident with what I'm seeing at the moment. [FGD 3, senior consultant]

However, participants expressed openness to embrace the tool if they were presented with additional information. They

emphasized the importance of transparent communication regarding the evidence supporting the system and the sources of information used. By gaining a clearer understanding of the logic and rules behind the recommendations, they would be more inclined to use the tool in their clinical practice.

[T]hat being said, if more information or transparent communication is given to us, I might be more inclined to use it in clinics. As I know the logic and rules behind these recommendations and where they are sourced from. [FGD 3, senior consultant]

While a minority, some clinicians exhibited strong confidence in their own clinical judgment and thus did not see the necessity to rely on the APA tool. They felt that their experience and specialist training surpassed the assistance provided by the AI-driven system. In addition, they highlighted the potential ramifications of relying on CDSS recommendations, emphasizing that the responsibility for patient outcomes ultimately rested with the clinician. Consequently, this attitude led to a reluctance to use the tool, particularly among those who believed that they possessed the requisite expertise to make well-informed decisions in patient care.

I would say that I'm as good or even better than the system. I don't feel the need to rely on it; I'll just do what I do. We are all trained endocrinologists, so we trust our judgment because that has been our bread and butter for many years. At the end of the day, we bear the responsibility for our patients, so you know, if the algorithm makes a sound decision, but something unfortunate ever happens to the patient, then it's still our own accountability on the line. [FGD 1, consultant]

These clinicians suggested the potential for the APA tool to bring benefits to the wider primary care community, particularly those who may be “less familiar with endocrinology clinical practices.” They believed that the tool could assist general practitioners in effectively managing patients with complex cases and improve patient engagement.

These recommendations would be more valuable in a primary healthcare setting, where doctors may not have extensive knowledge of clinical practices related to novel glucose-lowering medications and insulin titration, especially in complex cases. I think implementing the AP tool in such settings would greatly help doctors in improving patient engagement and care. [FGD 1, consultant]

Another important theme was related to the potential harm of the APA tool's drug recommendations on patients. Participants noted that the recommendation occasionally contradicted their own professional judgment. They cautioned against solely relying on algorithmic recommendations for clinical decision-making.

Some of the recommendations go against your clinical judgement. For example, I have two patients and the AI recommendation was to add a beta blocker to someone who doesn't have ischemic heart disease as a second line agent. That's just not something that we

would normally do. So have to exercise caution too! [FGD 1, consultant]

Finally, the participants expressed their frustration with the technical issues associated with the integration of the APA tool into the EMR system. The slow loading of clinical notes resulted in delayed clinical consultations, which added unnecessary mental burdens for some participants. Moreover, there were instances in which the clinical notes failed to load entirely, thereby affecting the quality of patient care.

One significant issue we encounter after implementing the CDSS is the considerable lag in loading clinical notes. It takes a few minutes to retrieve the clinical notes. So, by that time, I'm typically already engaged in a conversation with the patient, and we may even come up with a plan without the notes being available. In some instances, I can't even see the clinical notes at all. [FDG 4, registrar]

Discussion

Principal Findings

This qualitative study explored clinicians' perspectives on the use and impact of the APA tool, as well as challenges to its adoption and application in clinical practice. In terms of use, the APA tool offers several useful features to assist clinicians in effectively managing diabetes. As shown in the literature, patients with T2DM frequently experience multiple comorbidities, which may add complexity to pharmacotherapy management and increase the mental burden of prescribing practices [20]. Our findings suggest that the AI algorithms for drug alteration embedded in the APA tool were generally viewed as a good knowledge resource in supporting the clinician's decision-making on drug modifications at the point of care, particularly for patients with T2DM with comorbidities.

Complications arising from diabetes pose a significant burden on the public health care system [21,22]. In light of this, an important feature developed in the APA tool was the diabetic complications risk prediction that provides information on the likelihood of developing the 6 most common diabetic complications in patients with T2DM [23,24]. We found that participants viewed the risk prediction as having a positive impact on patient care by facilitating early doctor-patient communication and initiating prompt clinical responses to delay the progression of complications associated with diabetes. This finding is similar to that of other research that AI-enabled CDSSs had a positive impact on patient-provider encounters and shared decision-making [25,26]. Therefore, appropriate use of risk prediction could enable clinicians to take early proactive measures to reduce the risk of developing diabetic complications, ultimately reducing the health care costs associated with diabetes [27,28].

Despite the perceived merits of AI-generated risk scores, the absence of clear frameworks (or the scientific basis from which recommendations were derived) limited the interpretability and usability of the risk scores and subsequent follow-up actions. This has been similarly identified in the literature as a key hindrance to clinical adoption [29,30]. As knowledge is

deciphered differently based on personal experience and beliefs, the interpretation of scores could be dependent on the subjective attitudes of clinicians in decision-making [31]. Indeed, recent research indicates that the varying levels of knowledge and self-reported behavior among clinicians affect their approach in clinical practice, leading to potential noncompliance with the system recommendations [13]. Furthermore, as shown in our study, some clinicians chose to abstain from using the APA tool entirely because of their lack of trust in the quality of model inputs and parameters, as well as their concerns regarding the logic behind the AI outputs, often referred to as the “black box” situation [32,33]. To ensure a successful expansion of the APA tool within the clinical ecosystem, more effort should be directed to obtain a better comprehension of clinicians regarding the AI technology’s capabilities and the use of explainable frameworks to enhance transparency and clinician engagement [34-36].

As with the literature, clinicians in our study cautioned against being overly reliant on the APA tool, as occasional erroneous recommendations generated by the systems might prompt users to override a correct decision they have already made [26,37]. When users are subjected to automation bias, a tendency to overaccept system recommendations as a heuristic replacement of vigilant information processing [38] and medical errors ensue from following incorrect recommendations. Not only does it predispose patients to even greater harm, but it also diminishes the intention of using AI-enabled CDSSs [39]. Our results underscore the importance of collaborative intelligence, where users and AI work synergistically to enhance patient care. The human-in-the-loop concept suggests that while human oversight is active, overdependence on AI-enabled CDSSs is equally harmful. The optimal approach involves granting clinicians full control over the decision-making process while using AI to offer recommendations and inputs [40]. Clinical decisions, therefore, cannot be made without active involvement from clinicians to serve as gatekeepers, prevent negligence, and ensure patient safety. The seemingly conflicting recommendations identified in this study should be viewed as a catalyst that prompts critical thinking, and more effort should be made to confront meaningful disagreements. Also, encouraging clinicians to check on discrepancies may enhance their confidence in decision-making [41].

Finally, a significant obstacle that hindered the adoption of APA tool pertains to concerns surrounding accountability and liability, which is in line with the literature [36,42]. While ethical considerations regarding the use of AI persist, establishing well-defined clinical standards and codes of conduct for adopting APA tools can foster a culture of shared responsibility, moving away from a single form of attribution of responsibility. In addition, instead of focusing on assigning blame, it would be more constructive to acknowledge and commend clinicians’ efforts in integrating the outputs of AI-enabled CDSSs into their decision-making process, as long as the adoption of recommendations adheres to clinical standards, legal obligations, and ethical principles. This approach would motivate clinicians to embrace the most advanced medical technologies available in clinical practice, even if it means having to make a judgment call.

Collectively, the findings underscore the promising impact of adopting the APA tool within clinical settings and its potential to usher in notable enhancements in health policy. While the rapid integration of AI-based CDSSs in health care has presented promising potential for improved patient outcomes and streamlined clinical workflows, the persistent liability concerns among clinicians have created a barrier to the widespread adoption of these advanced technologies. With clinicians ultimately bearing the responsibility for any medical negligence, even after consulting with AI-enabled CDSS recommendations, there arises an urgent need for a comprehensive medicolegal framework. Such a framework must emphasize the allocation of liability among users, while also ensuring transparency in the decision-making processes of these AI tools [43]. For instance, the policy should delineate clear protocols for the documentation of AI-based recommendations, ensuring that the decision-making process is well-documented and easily accessible for medicolegal reviews. In addition, it is crucial to establish standardized protocols for the continuous evaluation and improvement of AI algorithms to minimize the risk of errors and improve the accuracy of recommendations. Creating an environment that fosters trust in AI technologies through a robust medicolegal framework will ultimately encourage clinicians to embrace these tools, leading to enhanced health care delivery and patient outcomes.

Limitations

This study provides valuable insights into the benefits and adoption challenges of an AI-based CDSS in its early stage of implementation. This study has some limitations. The study participants were limited to endocrinologists in a tertiary hospital; therefore, the generalizability of the findings to other health care settings may be limited. The sample size of the study is small, which may hinder the generation of comprehensive insights that better represent the broader context. As adoption of AI technology in clinical settings is still in its early stage, assembling a large cohort of clinicians for an in-depth analysis of AI-enabled CDSS implementation can be challenging due to the limited number of early adopters. Nevertheless, our findings shed light on the initial experiences and perceptions of a key group of clinicians, offering a foundation for future research and more extensive investigations. Our study’s sample size also aligns with the systematic review, which found that empirical studies, especially those with homogenous populations and narrowly defined objectives, typically achieve data saturation with 9-17 interviews [44]. Further research is needed to explore the use and impact of the APA tool in different clinical settings, such as primary care. As suggested by our participants, the use of the APA tool can be particularly beneficial to general practitioners who are responsible for managing a wide range of conditions and require access to a breadth of knowledge base across various specialty areas. Despite early findings on the APA tool’s use and adoption challenges, its long-term impacts on clinical and economic outcomes remain unknown. A subsequent larger evaluation is warranted to compare the APA tool with a standard of care. Finally, we did not explore the perspectives of patients with diabetes as the important end users of the APA tool.

Incorporating their perspectives may have contributed to a richer understanding.

Conclusions

AI-enabled CDSSs, such as the APA tool, has the potential to enhance clinical practice and patient care. Clinicians found certain features such as AI algorithms on medication adjustment and complication risk predictions useful in managing patients

with T2DM with comorbidities and facilitating doctor-patient communication. However, interpretability of the risk scores, concerns about overreliance and automation bias, and issues surrounding accountability and liability were commonly cited as challenges inhibiting the adoption and application of the APA tool in endocrinology clinical settings. Further work is required to address these concerns effectively to enhance the tool's acceptance and applicability in relevant contexts.

Acknowledgments

We thank all participants for their participation in this study.

Data Availability

The data that support the findings of this study are available upon reasonable request from the corresponding author. The data are not publicly available due to information that could compromise the privacy of research participants.

Authors' Contributions

SY and YMB were responsible for the conception, design, and the whole protocol of the study. SY oversaw the study. HG, PCL, HCT, MMT, DSTL, AK, CS, DC, DSS, SYTT, AJWW, CHMC, and ZW were responsible for the acquisition of study data. SY and HG were responsible for data analysis and interpretation of study data. SY and HG drafted the manuscript. All authors critiqued the output and read and approved the final manuscript.

Abstract

Background: Digitally assisted health care services and technologies are gaining popularity. They assist patients in managing their conditions, thereby reducing the burden on health care staff. Digital health care enables individuals to receive care that is more tailored to their needs and preferences. When implemented properly, it can promote equity by considering each person's opportunities and limitations in the context of health care needs, preferences, values, and capabilities.

Objective: This study aims to understand the needs, values, and preferences of individuals with chronic obstructive pulmonary disease (COPD) who are provided with a 24/7 digital health care service. Furthermore, we aim to understand the dynamics of the communities to which they belong and how these communities intersect. This will provide us with the essential knowledge to establish new methods of providing education, including the development of educational activities for health professionals to engage, train, and empower people living with COPD.

Methods: The study included 7 informants diagnosed with COPD who received 24/7 digital health care service support from a regional project in Region Zealand, Denmark. The informants were visited 4 times during 2 months, including a "Hello" visit, a day with a semistructured interview, and 2 days with field observations. The informants participated in a semistructured interview, following participant observation and an ethnographic approach. The interview content was analyzed using an inductive methodology to categorize the empirical data.

Results: Using the inductive approach, we identified 3 main categories related to the informants' needs, values, and preferences: (1) Health, (2) Value Creation, and (3) Resources. These 3 main categories were based on 9 subcategories: (1) health and barriers, (2) self-monitoring, (3) medication, (4) behavior, (5) motivation, (6) hobbies, (7) social networks, (8) health professionals, and (9) technology. These findings revealed that the informants placed value on maintaining their daily activities and preserving their sense of identity before the onset of COPD. Furthermore, they expressed a desire not to be defined by their COPD, as conversations about COPD often shifted away from the topic.

Conclusions: Digital health solutions and the health care professionals who offer them should prioritize the individuals they serve, considering their needs, values, and preferences rather than solely focusing on the medical condition. This approach ensures the highest level of daily living and empowerment for those living with long-term health conditions. The communities surrounding individuals must engage in constant interaction and collaboration. They should work together to incorporate people's needs, values, and preferences into future digital health services, thereby promoting empowerment and self-management. New educational

programs aimed at developing the digital health service competencies of registered nurses should facilitate collaboration between the 2 communities. This collaboration is essential for supporting patients with long-term health conditions in their daily activities.

Introduction

Background

In recent years, a transformation has been occurring with the increased use of digitally assisted health care services and technologies. These advancements aim to reduce the burden on the health care work force by enabling patients to better manage their own conditions [1]. Digitally based health care offers an opportunity for personalized and tailored health care services that better meet the needs of individual patients. Digitalization can also help reduce inequities if introduced thoughtfully, with an awareness of both the opportunities and barriers for individuals, considering their health care needs, preferences, values, and capabilities [1].

When health care professionals have the appropriate knowledge about these factors and are trained to address them, it can facilitate meaningful conversations and better connections with those they serve. This, in turn, can increase patient motivation and ease their access to digital services [2,3]. This necessitates educational programs for health professionals that focus on understanding their patient's needs and values, capability, person-centered services, self-management, and communities surrounding the patient. These programs should be based on evidence from empirical data obtained through interviews and observations of individuals with firsthand experience using digitally enabled health care services [4].

Digital Health Care and Chronic Obstructive Pulmonary Disease

Chronic obstructive pulmonary disease (COPD) is a leading cause of death, responsible for over 3 million deaths worldwide in 2019 [5]. In Denmark, 3355 individuals died from COPD in 2020, making it the second most common cause of death in the nation [6]. As a result of the progressive loss of pulmonary function, people with COPD experience impairments in their daily activities. These impairments can inhibit mobility, leading to a sedentary lifestyle [7]. The Global Initiative for Chronic Obstructive Lung Disease (GOLD), established in 1998, has developed a set of recommendations for managing COPD. Evidence shows that self-management improves outcomes for patients with COPD and reduces the likelihood of hospitalization [8,9]. The recommendations by GOLD also address how increased self-management can help motivate and engage people, leading to positive adaptations in their health behaviors.

Digital health monitoring is one of the most widely used tools for self-management of COPD and other long-term health conditions (LTHCs) and appears to reduce the risk of both hospitalization and acute visits [10]. In 2015, a randomized

controlled study was conducted with 100 people with COPD, with 48 randomly selected for home monitoring and 52 for usual care. The study found that people with COPD who used a home monitoring kit for 6 months had improved health-related quality of life and reduced anxiety scores compared with people who received usual care. The study also showed that people with home monitoring kits had fewer and shorter hospitalizations than those receiving usual care [11]. Furthermore, people with COPD who participate in telemedicine-based interventions feel safer, more empowered, and more in control of their own disease [11].

People with LTHCs who possess an enhanced ability to manage their condition themselves and experience a higher level of empowerment tend to have a reduced risk for hospitalization [12]. A likely explanation for this can be found in a qualitative study from 2017, which identified 3 main themes for individuals participating in a telemedicine intervention: (1) a sense of improved security and control; (2) a better understanding of their disease; and (3) the benefits of virtual conversations [13]. However, these studies do not take place within person-centered digital health communities and do not address the significance of the participants' sociodemographic characteristics. Evidence of sociodemographic characteristics is important, as research indicates that resourceful individuals benefit more from available health care, and those with an interest in technology may derive greater benefits from digital health solutions [14]. In addition, the prevalence of COPD and other chronic conditions, such as ischemic heart disease and type 2 diabetes mellitus, is higher in areas with populations characterized by lower sociodemographic status than in the average population [15,16]. This may contribute to the risk of inequity, as lower sociodemographic status often correlates with both lower levels of education and lower digital health literacy [15,17].

Educational Programs for the Digital Transformation

Another problem often overlooked concerning disadvantaged individuals living with 1 or more LTHCs is their reluctance to attend traditional educational services structured around scholastic planning. To reduce inequity, there is a need to develop new approaches to include this segment of the population, utilizing educational methods that are not scholastic or built on classical teaching methods such as classroom-based education. In response to this need, we have initiated a project where, based on an ethnographic approach involving interviews, observations, and the cocreation of educational materials, we will develop a new methodology inspired by social learning theory [18,19]. To provide guidance for the development of new educational programs and curricula tailored for digital transformation, we have examined, on an individual level, the

preferences, values, and needs of people with COPD in the context of unrestricted access to a person-centered, digitally enabled health service available 24/7. Informed by social learning theories, we have also explored the existence of communities these individuals are part of in relation to their everyday lives and their ability to identify potential sources of support.

The purpose of this study is to gather essential information about individuals living with COPD within the context of accessing support from a regular 24/7 digital health care service and the dynamics of the communities to which they belong. This information will empower us to design new methods for providing education, including the development of educational activities for health professionals. These activities will enable professionals to effectively engage, train, and empower people with COPD.

This has led us to the following research questions:

- Research question 1: What matters for people with COPD with respect to their needs, values, and preferences in the context of using a 24/7 digital health service?
- Research question 2: What is the role of the health care and social networks, respectively, and how are these a potential part of communities formed around the patient's health condition?

Methods

Design

This report is a part of a larger PhD project and constitutes the first of 4 articles. The overarching aim of this work is to obtain insights into the lives of people with COPD, supported by a 24/7 digital health service, and to use this information to develop a patient-case-based curriculum to educate health professionals on effectively engaging, enabling, and empowering individuals living with COPD.

The first study reported here was conducted from August 1, 2020, to January 31, 2021. This period coincided with the COVID-19 pandemic in Denmark before vaccinations were introduced to protect against severe cases. The study is qualitative in nature, inspired by ethnographic research methods, and includes semistructured interviews and field observations [20]. The field study involved visiting the homes of people with COPD 4 times over 2 months. The visits included a preliminary "Hello" visit, a day dedicated to a semistructured interview, and 2 days focused on field observations. This article focuses on the data and results gathered during the second visit, which involved conducting the semistructured interview.

Context

The digital health service utilized in this study is provided by an innovation project in Region Zealand, Denmark, called PreCare. This project is built on the Epital Care Model (ECM) [21,22]. The ECM, developed in 2016, offers a 24/7 digital health care service where individuals with LTHCs monitor their own health with the assistance of nurses from a response and coordination center (RCC). The ECM consists of 6 stages: citizens with unknown LTHCs, active and independent living,

virtual assisted living, virtual assisted living with support from health care professionals, outpatient care at home, and admission to a local health clinic or hospital. It serves as a template for digital health services based on patients' medical needs [22].

In total, approximately 400 participants with COPD or ischemic heart disease were enrolled in the PreCare project over a 4-year period. At any given time, there are approximately 150 participants. Each participant was provided with a tele-home monitoring kit, which included a tablet. Additionally, for participants with COPD, the kit included a spirometer, a thermometer, a pulse oximeter, and a box containing acute medicine. The participants were supported by an RCC, which was staffed with registered nurses (RNs) and an eDoctor. According to the project protocol, participants monitored their condition daily. They could always call the RCC to discuss their condition, and the RCC regularly initiated contact to ensure participants felt safe and confident. During these conversations, self-management was also supported (C Schmidt, MSc, personal communication, 2020). In the event of deterioration, the tablet would indicate a yellow or red code and send a message to the RCC. The nurses would then respond to the code and call the participant to follow-up on the reported condition. If needed, participants can take medicine from the box to treat exacerbations. In cases of further need, the nurses would contact the eDoctor [23].

Informants

The PreCare project initially provided a list of 15 participants diagnosed with COPD, each with varying degrees of severity, all of whom expressed interest in participating in the research related to the PreCare project. Subsequently, over a 4-month period, 10 of these participants were contacted by phone, selected from the top of the list. After receiving oral information about the project, 8 of these agreed to participate. However, 2 participants were not interested and the remaining 5 were not contacted as the recruitment period had exceeded. Furthermore, 1 potential informant expressed disinterest in participating after the initial meeting. The selected number of informants was determined by the limitations of the study design. The informants were invited in 3 separate periods: 3 informants were invited from August to September for the first period, 2 informants were invited from October to November for the second period, and 2 more were invited from December to January for the third period. In total, 7 informants were recruited. After obtaining oral consent via phone, further information was sent by email to 3 informants, while the other 4 did not require this. After 1 week, all 7 informants were contacted again by phone to schedule the first in-person meeting, which took place within 1-2 weeks. This study's inclusion and exclusion criteria followed the PreCare protocol [23].

Data Collection

To establish an emotional and trustworthy relationship with the informants, we scheduled a visit to their homes (the initial visit). This approach aimed to strengthen the connection between the researcher and the informants, fostering an informal and friendly atmosphere during the interview. To conduct the semistructured interview, we used an interview guide inspired by Spradley's [20] ethnographic interview techniques. The interview was

conducted in a friendly and casual approach, allowing the informants to share their experiences and discuss their everyday lives with a chronic condition as they deemed appropriate [20,24]. All interviews were conducted in the informants' homes and were audio-recorded with their consent. As a result of the informants' background, the interviews were conducted in Danish, and only quotes were later translated into English by the first author (CWS). All informants participated in the interviews; 1 participant had his spouse present during the interview.

Interview Guide

The interview guide was developed based on sociotechnical ecosystem thinking, our concept of technology readiness, and an attempt to identify how individuals belong to 1 or more communities, inspired by social learning theory ([Multimedia Appendix 1](#)) [25-28]. We conducted the interview with an open-minded approach, including "how" questions, to enable the informants to respond as they found suitable. The interview guide was structured around 6 thematic areas: daily activities, health, measurements, communities, RCC and PreCare, and literacies and digital literacies. For each of the thematic areas, we included 1 main question and underlying questions to sustain the conversation throughout the interview. For example, the theme "daily activities" included the main question: "Can you tell me how a typical day is for you?" In the theme "health," the main question was "Can you tell me how COPD has affected your life?." The 6 themes were defined by the authors and were written in Danish.

Data Analysis

The interviews were conducted, transcribed, and analyzed by the author CWS. The transcripts were analyzed using content

analysis, a method for systematically and objectively describing and quantifying phenomena. An inductive approach was used, beginning with open coding to create categories, followed by abstraction to generate main categories [29]. A 3-step content analysis was used to identify the main categories.

Analysis of Interviews

Each interview was transcribed and carefully reviewed to understand the context of the data. Subsequently, the transcripts were uploaded and coded using NVivo 12 (QSR International) [30] by CWS. Over 700 codes were identified and categorized into 66 subcategories. These subcategories were then merged to create an affinity diagram initially using paper and later repeated using NVivo. This process resulted in 9 categories, each containing 4-12 subcategories, respectively. The category "Self-Monitoring" had the fewest subcategories, while "Health Professionals and Social Network" had the most subcategories. The 9 categories were analyzed by CWS and the last author (LK) to synthesize the data into 3 main categories. CWS, who holds an MSc degree in health informatics and has been educated in qualitative methods, collaborated with LK, a professor in health service research with experience in both qualitative and quantitative analyses, for this process.

The 3 main categories identified were health, value creation, and resources ([Textbox 1](#) and [Multimedia Appendix 2](#)). The category of health consisted of 3 subcategories: health and barriers, medication, and measurements. The category of value creation was formed from hobbies, behavior, and motivation. The category of resources was merged from 3 subcategories: social networks, health professionals, and technology. In our analysis, we paid particular attention to what matters to people with COPD, supported by the theories upon which the interview guide was built.

Textbox 1. Overview of the 3 main categories and subcategories.

<p>1. Health</p> <ul style="list-style-type: none"> • Health and barriers • Self-monitoring • Medication <p>2. Value Creation</p> <ul style="list-style-type: none"> • Behavior • Motivations • Hobbies <p>3. Resources</p> <ul style="list-style-type: none"> • Social network • Health professionals • Technology

Ethical Consideration

Information regarding the study, partnerships, and data handling complies with the Helsinki Declaration and was communicated to the informants in both written and oral forms. They were

informed that their participation was voluntary and anonymous and that they could revoke their consent at any time. Furthermore, they were assured that their involvement would not prevent them from participating in the PreCare project. All consent was obtained before the interview, through the signing

of a consent form. The Danish National Center for Ethics was not required to approve the study as no biological material was used. Any data obtained from the informants were treated as personal health information and handled in accordance with Danish legislation (General Data Protection Regulation [GDPR]) and securely stored on drives. Health science questionnaire surveys and interview studies that do not involve human biological material [section 14(2) of the Danish Act on Committees] do not require reporting or approval from the Danish National Centre for Ethics [31].

Results

Characteristics of the Informants

A total of 4 men and 3 women participated in the interviews (age range 52-81 years). Two informants lived with their spouses. Despite having had COPD for an average of more than 2 years, the severity of each participant's COPD varied. Some participants continued to smoke daily despite being aware of the health risks. One male participant was unable to provide information to categorize his level of education, 2 had only completed elementary school, while 4 had completed higher education. There was no evidence of their usage of technology, such as websites and participation in online communities, in relation to their medical concerns. All informants had been included in the PreCare Project for more than 6 months.

The Three Main Categories

The main categories and subcategories identified in the content analysis provide insight into and offer a comprehensive understanding of the daily life situations and experiences of the informants living with COPD. Upon reviewing these categories, attention is drawn to both the specific consequences of a COPD diagnosis and how practical hurdles and activity levels are affected in the daily lives of the informants. These impacts are described in the interviews as limitations on activities the informants were accustomed to participating in, as well as a determination to carry out specific household duties despite a decreased energy level. The duality between "restrictions" and "experimental salvage" is evident in the category of activity but is also observed when interviews approach questions such as self-monitoring. Here, they take on different meanings, tasked with reclaiming self-discipline and control on one hand, while also being concerned that daily measurements can serve as a reminder of one's limitations, akin to "being reminded of having a chronic disease." Thus, through the interviews, it becomes apparent how the informants encounter difficulties and impediments in carrying out daily tasks due to their condition. In everyday life, this translates to tasks that were once feasible but now being difficult or impossible to complete. The distinction between "then" and "now" is frequently referenced, highlighting the contrast between the condition "before I got COPD" and "the situation as a chronic."

Health

Health and Barriers

This category describes the experience of living with COPD, detailing how it has impacted daily life and outlining the

physical and mental barriers experienced throughout the day or in general.

The informants did not express interest in delving deeper into their everyday lives with COPD. Instead, they prioritized discussing other aspects of their daily life or past experiences. They responded quickly to questions about COPD and then redirected the conversation toward other topics. This deliberate redirection indicated their reluctance to discuss their chronic illness.

Interviewer: ...Can you tell us how your diagnosis has affected your life?

M3: So, I'm crushed. One positive thing is that I had to sell my motorcycle and all my stuffs, I used to gather a lot. We had a 400 kvm house with basement and ceiling, which was filled with enamel sign, books, magazines, tech cars and bicycles...

The informant swiftly and effectively shifts his focus away from negative thoughts about COPD's interference and begins discussing his previous interest in used objects. He demonstrates a clear desire not to dwell on the negative aspects of his existence, opting instead to redirect the conversation toward something positive and reminiscent of happier times.

The limitations imposed by COPD forced the informants to forego certain daily activities, some of which could have contributed to an improved quality of life. The frequent shortness of breath and coughing prevented them from engaging in activities such as walking outside, performing household duties, or general personal care needs.

Interviewer: ...but is there other things COPD had done, that you cannot do anymore, completely?

M1: Well, I cannot go to the city and get me a cup of coffee at the street restaurant.

Interviewer: No, that's true...

M1: I'm not even sure I'd be able to go to the garbage cans anymore (coughing), but when my friend comes and the weather is good (...) he drives me in that wheelchair over there, and then we sit together and drink a cup of coffee and talk...

The informant's worry about his capacity to take out the trash underscores the profound impact that COPD has on his life, to the extent that he feels unable to leave the house without assistance. Conversations with the informant were replete with stories where social interactions played a significant role.

For some individuals, participating in a community became challenging due to shortness of breath caused by COPD. Additionally, for others, COPD had led to the complete exclusion of previous acquaintances.

M3 wife: In return, you have thought about how many of them you have helped (...), you don't really hear from them anymore, because now you can't help them anymore.

M3: Yes, there are many of those whom I have been calling, "Great that we are talking to you, we were just thinking of you, by the way we have a locker that

doesn't work". You never heard from these people again, and I have been discussing this with others, and it is true...

The informant noted that his inability to visit friends anymore, coupled with their failure to reciprocate, has made it increasingly difficult for him to maintain relationships with them. This situation has surprised him, particularly because he is no longer able to provide assistance, as reported by his wife.

Self-Monitoring

This category highlights how the informants manage and self-monitor their condition. Furthermore, it explores how the outcomes of their monitoring efforts may impact their day and their motivation to engage in activities.

In the informants' descriptions of their daily lives, the topic of self-monitoring for the PreCare project was not initially mentioned. It was only during the conversation around this subject that the activity itself was explained and, in some cases, mentioned.

M1: Yes but, it's not interesting, no(...) and then I hope in the end it can help other people too. So, I take it with pleasure, but I could still think of something more exciting things to do...

W1: Yes, but they have changes it (pause), I'm just going to write something today, I'm not in for it. It's not correct anyway (temperature)

The self-monitoring is described here as uninteresting, with 1 informant considering it a waste of time because he could find more engaging activities to do during his challenging day. The second informant emphasizes the importance of accurate measurements for individuals to actively participate in self-monitoring.

The outcomes of self-monitoring had a significant impact on the informants. The results were displayed as 1 of 3 colors—red, yellow, or green—on the tablet's display. The meaning of the color had a tangible effect on the informant's day.

Interviewer: Yes, exactly when, but then how? Because now you said that you had a red measurement yesterday was it then a difficult day when you have a red measurement?

W2: Yes, that is a stupid day, at first the mood is going down, and I am going, well yes I usually get restless, because I can't, because a day like that, I am thinking about...is it now it's going in the wrong direction...

The informant faces difficulties getting through the day when the red color appears, disrupting their daily routine. Additionally, the informant begins to question whether their COPD-related health is deteriorating or if the red color indicates a negative trend.

Conversely, the green color holds significance for the informant, particularly in contrast to the red color. Seeing a green measurement might enhance the informant's enjoyment of daily life, especially if it has been a while since they last saw a green result.

W1: It's green! (happy/excited)

W1: It haven been that for a long time....

Although there was considerable excitement surrounding the green measurement, its implications for the maintenance of the day remained unclear. However, the informant did clarify early in the conversation that she felt more motivated to venture outside into the garden on good days.

Medication

Being chronically ill entails the necessity of medication and its management which, for most of the informants, has become integrated into daily life. This category elucidates how the informants handle their medication and who supports them in managing it. The informants varied in their approaches to and understanding of medication, and the availability of help and support was crucial.

W2: Thus, those prescriptions, I also have one lying here, and this is the new medicine I got, and I don't understand it, because I should have asked about it.

W3: Yes, I have these blue folders, you probably don't know them, but those blue boxes for morning, midday, evening, and there is for (cough)...think there is for eight days, probably, that can be right? Eight days, I believe that, and I sort them every second week. I sit by the dining table, and line the whole thing up, and then I sort them.

The aforementioned examples depict 2 different scenarios of handling and understanding medicine. In the first scenario, one of the informants blames herself for not seeking information about the new medication when she first started taking it because she is unfamiliar with it. While she accepts responsibility for her medication, she still requires assistance in understanding it. By contrast, the second informant has established routines for managing her medication, and therefore, understands what she deposits into the pillbox.

As a result of errors and inconsistent care from municipal employees, the informants began to question their trust in the municipality's care team. Although the informants could receive assistance from the municipality with their prescriptions and medication management, they found that the assistance and knowledge provided by municipal employees lacked the necessary qualifications.

W2: ...but she wasn't, and then she made the mistake of repeating after the other, and I quickly notice it, and it's not, it is not calcium tablets we sit and play with.

This is a serious concern, as indicated by the informant's statement that the pills are not calcium supplements, and taking medication in incorrect amounts could have negative effects on her health. Therefore, it is vital that her medication is prescribed correctly for her condition.

When it comes to medication, there was a strong tendency among the informants to rely on the RCC nurses, especially during exacerbations. The RCC nurses use telephone communication to reach out to the informants and inquire about their health. If necessary, the nurses may advise the informants to take additional medication. The informants comply with the

nursing advice and adjust their medication accordingly because they have a high level of trust in the digital nurses.

M2: Yes, "Nærklinikken" is the ones who change it now, yes, they just say you have to take two breaths in the morning, and they do it regularly if I have felt worse for a little while. I'll just get more, double up.

M2: Yes, I feel very safe.

When it comes to medication, the informants trust the guidance of the digital nurses because they feel it is their responsibility to adjust their medication. They feel secure knowing that others are assisting them and providing direction with their medication management.

When the RNs oversee the health condition of the informants, their independence in managing their chronic disease and their understanding of their medication do not seem to improve. It appears that the RNs are still somewhat paternalistic. However, the informants do experience a sense of safety, particularly when it comes to their health and medication.

Value Creation

Behavior

This category identifies the former daily routines that had to change or be excluded from the informants' lives because of COPD. Furthermore, it highlights the new routines that should be adapted because of the weakened ability caused by their condition.

The informants must adapt their daily routines to accommodate their diminished capacity because of COPD, necessitating the establishment of new habits. Consequently, they may take fewer walks, experience reduced appetite, or sleep longer than usual. This limitation often confines the informants to their residences. When queried about their daily lives, the informants provided a range of responses. Some spoke very briefly and exhibited a negative attitude, while others believed that obtaining a comprehensive understanding of how COPD impacts daily activities was crucial.

Interviewer: ...oh if you should tell me how a typical everyday looks for you K1, what do you do on a general day?

W1: Sitting here

Interview: You sit there

W1: Yes (cough), but sometimes when I'm well, I go out in the garden.

In this case, the informant primarily spends time sitting on the same couch and does not elaborate much on her everyday activities. She finds joy in moving outside and into the garden whenever possible. Previously, she engaged in various artistic activities and housework as part of her daily routine, but these tasks are no longer feasible due to her health.

Some informants expressed that it was still important to maintain cleanliness in their own homes. While the municipality provides cleaning assistance to the majority of the informants, some individuals still prefer to handle specific tasks on their own.

W2: ...I said to her, now don't think I'm crazy but I've been standing and ironed my bedsheets for several days, then she was about to faint (...). Only the elderly irons their bedsheets. I have always done it, and I will not stop doing it as long as I can stand on my feet.

She continues to prioritize tasks such as making her bed and changing the sheets, as she has always done. Despite the challenges posed by her health, she decides to persist because these tasks hold significant importance for her. However, she acknowledges that it may take several days to complete them. By contrast, most of the informants expressed overall dissatisfaction with the cleaning assistance provided by the municipality, stating that they often had to make numerous corrections.

Another aspect they felt had changed because of their condition was the rhythm of the day. They found that getting out of bed in the morning was becoming more challenging, or they noticed that they were waking up earlier. This change could be attributed to their increased frequency of sleeping and reduced engagement in everyday activities.

M1: Yes. Well, but I wake up before Satan gets his shoes on, because I am used to doing something, and I cannot really more, so I never get really really tired (coughing), so I do not get so terrible many hours of sleep (coughing).

Here it is highlighted that the informant's daily rhythm has shifted from its previous pattern, and the indication is that their lack of sleep stems from both reduced activity and diminished tiredness. None of the informants mentioned experiencing anxiety or shortness of breath during the night, which could also contribute to a different daytime rhythm. However, the increased need for sleep during the day was frustrating, as it could result in missing out on certain activities.

Hobbies

The informants engaged in different activities in their lives that held personal value for them, and some had to alter their activities because of COPD. This category focuses on the activities that the informants currently undertake and have previously engaged in.

The activities and interests of the informants varied depending on their weekly or daily routines. However, their condition often took precedence over their interests, and the activities that were feasible differed among the informants. Additionally, there was a gender disparity, with men favoring fishing and other outdoor activities, while women tended to engage in activities such as handicrafts.

M2: So now that I have been sick, yes, I go out and fish a little, then I go and help a little with some horses.

W3: ...and then I'm knitting or doing the crosswords or trying to sew on the sewing machine (laughing).

M1: yeah, I'm trying to do the things I care about and like, unfortunately I can't paint anymore, as I cannot stand the smell of turpentine anymore, it's sad

because I've spent a lot of time painting, I don't have the energy to start writing more books. So I, I read a little, it's a bit difficult now with these glasses, but I've read a lot, and I get a lot of pleasure from it.

The different accounts provided by the informants offer insights into how interests are possible for individuals with chronic illness as well as how the condition can prevent them from pursuing activities they like/enjoy. Despite certain interests being curtailed by the condition, informants still strive to engage in activities that bring them joy and hold value for them. However, in some cases, informants found it challenging to pursue their interests because of the awareness of potential shortness of breath.

The informants expressed similar daily desires and willingness to go outside, but their walks had become shorter over time. Occasionally, they cited the weather as an excuse to stay indoors.

W2: Then the little dog and I go in and rest for an hour or half an hour, and lull a little and sleep a little. Perhaps it is something completely different. Then I get up and get ready, and then I go with my little dog and pick up the newspaper in the mailbox. We used to go for longer walks, but I don't unfortunately, I can't do it anymore.

W3: For just such a trip, so there is not much nature to go and look at from here and down to the municipal office, but just to get out and get some fresh air

The informant acknowledges here that the challenge of going on longer walks is something that annoys her, but she simply cannot manage it anymore due to shortness of breath. Despite this limitation, going for a walk can bring relief to the informants. Even though nature may not always be visually stunning, the informant finds solace in being able to get outside, especially on slightly gloomier days.

Motivation

This category underscores how the informants experienced a lack of motivation to engage in daily activities. Throughout the conversations, there was a tendency to discuss things they would love to do but lacked the competence or strength to accomplish, or they invented excuses because the tasks seemed overwhelming. These could range from simple tasks such as planting a rose to more complex endeavors such as writing a book, attending gym classes, or cooking.

W1: Not at all, and then you lose the motivation.

Interviewer: Yes, I can understand, if you have been somewhere where you think it was good, and then you come to something else that you don't think is at the same standard...

W1: but then, okay, I am not...there, but oh its hunting me, when I have to go. I will probably just get it over with, right?

The informant's desire and motivation to participate in a COPD exercise team depend on how the teacher conducts the sessions. A negative experience with teaching methods in the past has diminished the informant's motivation, making it difficult for

them to participate. It has transformed from an activity that brings joy to feeling like an obligation, something that the informant feels they must do rather than something they want to do.

Resources

Social Networks

This category explores the social networks that the informants are a part of and how they use them in their day-to-day activities.

The size of the social network varied among the informants, but the significance of social interactions was equally important to all of them. Family relationships showed considerable diversity among the informants, with some maintaining close contact with their family through daily conversations, weekly scheduled visits, or having their spouse present. By contrast, there were some informants who had limited contact with their families and spent much of their daily lives alone.

W2: I miss him very much. We lived in Fyn, and we talked over the phone several times a week. I miss my family very much, and I also miss my friends. And they all passed away...

W2: ...I talk to my daughter. So so I don't talk about..., she can say to me, I think you sound a little stalled mother, because then I'm just for the moment and then, and then we're not talking about it anymore. She knows what it is, but we don't need to.

The above description indicates that the informant is alone due to deaths in the family and social circles, and there are a significant number of people missing from her family. Interestingly, the informant does not mention at the present time that she still has 2 daughters, which she only brings up later in the interview. The informant's description of the varying family relations indicates that she is left more isolated and alone, which telephone conversations with her daughters cannot fully mitigate. The conversations surrounding the family and friends of the "lonely" informants were marked by a sense of sadness and depression over the lack of contact.

Informants with close family relations expressed how their family and close relationships maintain continuous contact with them. The conversations were even interrupted by phone calls from their families, highlighting the frequent and ongoing nature of their communication.

M2: Yeah, she is calling, or she has stopped a little, but otherwise she calls every morning, around 9 o'clock or something like, "How do we breathe today?" She says then, (laughing)

W1: Then I also have my granddaughter, I talk a lot with her, but I also take care of what I said to her, because she is a little unstable.

There are 2 different scenarios for contact described here, both indicating that the informants have contact with their families, signifying close relationships. In one instance, it is the informant's mother showing interest in their self-monitoring and health status. In the second scenario, the informant not only maintains close contact, but also plays a protective role for her grandchild, who also suffers from a diagnosis. Despite varying

family dynamics, it is evident that the informants can be divided into 2 groups: those with close family relations and those lacking such connections.

Their interest in engaging in social activities was also significant, but the informants often found themselves coming up with excuses for not participating or found it challenging to leave their homes.

W3: Yes, I haven't reached it yet, but I'm probably getting enough. There has been something on Friday, because otherwise I had set myself up for, I have otherwise gone to gym down in Vig, but.. that, which is quite far from the station off and down to Balsagård (...), of course I can go down there from time to time, but as I have it, oh for the last season there, I was not there quite many times, but it costs no matter what, they do not pull anything from because I have not been there, and that.. it annoys me a little. Then there is Red Cross that has something like this in high town.. exercise, sport is known enough, and it is every Friday morning, but there has been something here the last couple of Fridays, and I also have to just get into the rhythm that I have to go there until half 10 p.m.

As emphasized, the informant highlights that traveling a long distance to attend gymnastics is a major obstacle. Despite continuing to pay for it, this does not motivate her to attend regularly. She also mentions the challenge of incorporating it into her Friday routine and making it a regular part of her schedule.

They did not envision themselves participating in social events related to their COPD. Some of them were members of Lungeforeningen, the Danish Association for Lung Diseases. Although the Lung Association organizes various gatherings for those with COPD, none of them appeared interested in attending.

Health Professionals

The category focuses on the informants' interaction with various health professionals and how those relationships hold significance for them.

The relationship with health professionals was highly significant, as it was essential for the informants to feel secure while also being with mutual respect and seriousness. The informants interacted with various health professionals in their daily lives, and this analysis distinguished the difference between "ordinary" health professionals and PreCare nurses.

The informant's relationship with the assistance offered is crucial.

W2: After a hospitalization for yeah I don't know, let's just say a year ago. There seems to be, I can't remember who thinks that there should be a home care and dosing the medicine. And now you must not misunderstand me because I am not a racist, but there comes a little colored girl who could not really speak Danish and she was not very sweet if she had been sweet and smiling, pleasant, then it would have been

something else, but it was she not, and then she made mistakes twice after the other, and I discovered it quickly, and it is not, it isn't the tablets we sit and play with.

According to the informant, the connection with home care has been challenging because of mistakes and uncertainty. As a result of this, the informant has lost faith in the home care, which should be there to lend a helping hand and not cause her problems on a regular basis.

Unlike other health care professionals, the nurses in PreCare have succeeded in establishing a sense of security and mutual respect with the informants. The collaboration with those involved in their COPD care instills confidence in the PreCare project and the nurses among the informants.

M1: There is most of the contact through the nurses, just to start, just when I started up there was a doctor who was here, and so I have nothing bad to say about him, oh and it is also those who prescribe some medicine if I lack it, and such some things not too (slang). I think I have a good relationship with them, and are really pleased to have them, oh...and feel there is a great confidence to be with them. So, as I said earlier, I was sure I would have become a burden for the hospital if I had not known them. The society saves money, and that's not bad.

W2: But Nærklinikken has helped me, exceptionally. I'm glad I got in touch with you, you can believe. I don't know what I would have done without medical care. They do nothing.

The informant expresses happiness for the nurses and thinks that their connection is good. The following description includes several elements though. The informant mentions that their participation in PreCare makes them feel like less of a burden for the hospital and the municipality, which holds significant meaning for them. He also expresses faith in the nurses, which he had expressed several times in the conversation. Being a part of a project that highlights the superior care provided by nurses compared with general medical care has been particularly significant for the female informant.

Nurses are not only available to informants, but also offer support if an informant's condition deteriorates. When an exacerbation happens, trust means the informant has no reason to question the nurses and takes the prescribed prescription without a second thought.

M2: Yes, Nærklinikken says it, it is the ones who change it now, yes, they say you just have to have two breaths in the morning, and they do it regularly if I have had it a little bad for a while. No, then I'll just be put up, double up.

Without hesitation, the informant chooses to follow the nurses' recommendations. He has completely surrendered to the project, giving them full responsibility for his condition.

Technology

This category covers the informants' daily technology and their search for health-related information.

All informants admitted to having technology at home, although the way they used it and its purpose varied. For some, technology provides entertainment during moments of boredom in their daily lives.

W1: Yes, I'm mostly on the computer when I get bored.

Interviewer: What are you doing on the computer?

W1: I am playing games

W1: I have two different games I have discovered.

Technology was not utilized by the informants as a means to gather information about COPD. The informants felt they already possessed all the information they needed about COPD, and they were concerned that obtaining more information might increase their anxiety.

M1: It is very very rare; it is very rare. If I happen to hear that there is something new about it, then I can well find out to look it up, that it is not so exciting to read about, so

W1: I think the more you read, the more nervous you become.

The informants do not use technology to seek information about their condition. The informants did not mention being part of online groups where information could be shared during the interviews. None of the informants mentioned using social media platforms such as Facebook as a community for sharing information about their condition. They also emphasized that they generally did not share information about their condition through digital solutions.

M3: It irritates me sometimes when we sit, sometimes I cut through and say, now we don't want to talk about illness, because, oh, then such a short evening can go

The medical equipment provided by PreCare did not pose any problem for the informants to use on a daily basis. They all expressed how easy it is to use it and how it takes only a few seconds to use the technology. They appeared confident and stated that they performed the measurements every day.

M4: it's so easy, that's in order...the only thing is now just, the crazy computer goes out, or (...), I can't restart, even though I have PIN code...no matter what I do, it won't, so I wait when it comes a past...so it can restart again, the only problem...

Despite the ease, they experienced some issues with the devices. The informants encountered issues with logging in, forgot to charge the tablet, or even misused the thermometer.

Discussion

Principal Findings

This study offers valuable insights into understanding the needs, values, and preferences of individuals living with COPD as well as which communities they identify with in a digital context. Indeed, the findings highlight that while fluctuations in their health condition significantly affect the daily lives of the informants, factors such as having hobbies, old habits, and social

connections play a crucial role in their overall well-being. This underscores the importance of recognizing individuals with COPD as complete human beings beyond their medical condition.

It is interesting to note the distinction between the 2 communities the informants belong to. The community centered around the RCC represents a vital support network for them, where they feel included and have developed trust with the staff. This highlights the importance of such digital health services in providing continuous support and guidance for individuals managing chronic conditions such as COPD. Involving close relatives in the community centered around the RCC can further enhance the support system for individuals with COPD. The other community involves participation in social activities outside the context of their condition which provides informants with opportunities for social interaction, enjoyment, and connection with others beyond their health concerns. These activities offer a sense of normalcy and contribute to their overall quality of life, allowing them to engage in meaningful relationships and experiences beyond the realm of COPD management. Even though the informants may face constraints due to their condition, they still find value in participating in social activities, even if their involvement is limited.

The Needs, Values, and Preferences in the Digital Context

The informant's emphasis on maintaining their daily activities underscores the significance of preserving their sense of normalcy and independence despite their COPD symptoms. It reflects their desire to continue living fulfilling lives and not be defined solely by their health condition. Symptoms often contribute to a lower quality of life and well-being. The findings from an earlier study [32] resonate with the experiences reported by individuals with COPD in this study. Breathlessness, a common symptom of COPD, can significantly impact an individual's quality of life by limiting their ability to engage in daily activities and causing distress. This aligns with the participants' reports of reduced quality of life related to breathlessness, highlighting the importance of addressing this symptom to improve overall well-being for individuals living with COPD. While outdoor activities may be affected by COPD, the focus of the informants seems to be more on how the disease impacts their ability to engage in everyday tasks and maintain their hobbies or household chores. This also resonates well with another study including interviews of patients with COPD [7]. The study revealed that for women, being active in housekeeping was important and valued, while for men, maintaining the garden held similar significance. They also reported that people with COPD prefer activities within their home or immediate vicinity, showing little interest in engaging in social activities located far away due to their reduced physical abilities. The need to be close to a safe environment was similar for some of the informants in this study. However, some reported that they did leave their house. For example, one informant was helping with some horses, while others needed to take their dog to the dog groomer. Access to virtual support may play an important role here, as the informant could call the RN in the RCC at any time if anything were to happen.

The COPD-Related Conditions' Impact on the Identity

For the informants, it was important to avoid discussing or being associated with their COPD condition by shifting the topic during the interviews. This aligns with a previous study where people with COPD were not interested in being identified solely by their illness [33]. They found that their identity related to their condition, termed "illness identity," was affecting their roles and could potentially separate them from the social network or community. An additional contributing factor to social segregation was a sense of having a self-inflicted disease, leading to feelings of shame and guilt [33]. However, this was not evident in our data.

Most, but not all, of the informants appear to be able to cope with their diagnosis and condition. They try to continue the same kind of interactions and activities while considering their condition's restrictions. As a result, individuals experience a sense of maintaining their own identity within their communities, yet occasionally feel the sense of lacking something. This can involve engaging in distant activities, such as joining a choir.

The Two Communities of Practice

The Community of COPD Practice

In relation to the community with its formal caregivers, the informants experienced a genuine interest from the RNs in their well-being and they provided them with support in an empathic way. This experience may be attributed to the PreCare environment, with free access to RNs 24/7, where they always kept an eye on the informants. This may explain the absence of "anxiety" in the interviews with the informants. These could be attributed to the RN's *ability* to provide immediate support in response to changes in their health condition, with medication for deterioration accessible at home [32]. Anxiety, which often dominates the daily lives of individuals with COPD, is thus better managed [32]. Therefore, it is necessary for the RNs to be trained to instill confidence in individuals with COPD or other LTHCs, enabling them to feel more independent and socially active with the RCC, their equipment, and a medicine box readily available, thereby reducing anxiety and maximizing the benefits of their resources.

The informants' immediate access to the RNs in the RCC appears crucial, as it enhances their self-efficacy and confidence in how their equipment aids them in managing deterioration.

However, despite feeling secure in their use of the equipment, the informants did not appear to be influenced by their ability for self-management and did not feel more empowered, likely due to experiencing the RNs as being paternalistic. The informants were unable to fully benefit from the virtual support environment due to the influence of the RNs and instead remained in a passive role.

RNs and other clinicians will need to be aware of how they communicate to facilitate a dialog that is not experienced as paternalistic, but rather as a coaching conversation.

The Community of Social Practice

In relation to their social communities, the extent of social relationships varied among the informants. The importance of a family community aligns with the findings of Nicolson and Anderson [32], who showed that family and relatives significantly influence the quality of life for people with COPD. Nicolson and Anderson [32] identified that COPD impacted how individuals connected with relatives and perceived their ability to fulfill their roles within the family. In contrast to the study by Nicolson and Anderson [32], our findings indicate that the informants' family roles were not influenced by their COPD. They maintained their roles and continued normal interaction with their relatives and families.

Not all informants participated in social activities or were part of a local community. Those without support from friends and families experienced difficulties engaging in and finding motivation for social activities. They felt lonely when left alone in their homes, whereas those with a social network experienced loneliness to a lesser degree. This contrasts with another study [7], which found that loneliness was also a major issue for those with family support, such as spouses and friends [7]. Those who felt lonely because of their lack of participation in social activities found some comfort in the availability and contact with the RN, which to a certain extent reduced their experience of loneliness.

This underscores the necessity for RNs to possess skills in mental and social support, which should be included in the education programs for nurses.

Online resources such as patient portals and social media (eg, Facebook) can constitute a community for people with COPD. However, despite the availability of these platforms to our informants and their daily use of tablets, none of them considered these online opportunities in relation to their COPD condition. This may be due to various reasons. Some informants felt they had sufficient knowledge or were unsure how to interpret the overwhelming information on the internet. Additionally, they may have wanted to avoid exposing their diagnosis or involving others outside their close network [34]. The role of the PreCare environment and the RNs may substitute the need for a social media platform or COPD-related conversations on platforms such as Facebook.

When the informants do not participate in online communities, they may miss the opportunity to access new knowledge or learn from others with similar conditions. This lack of engagement can reduce their ability to manage their condition effectively and hinder their empowerment. Joining an online community and being actively involved can help transform newcomers into "super users" and "experts" [35]. These "online experts" can then help other members of the community, forming a virtual community of practice [25]. Thus, participants in the PreCare project may miss the opportunity to develop into experts through online activities but may instead develop this competence through participation in other communities or collaboration with the RNs.

Limitations

The study is based on 7 informants. This may be considered a limitation, as the relatively small number may result in some perspectives of people living with COPD not being expressed in the data. However, as all informants are exposed to the same PreCare environment, have the same diagnosis of COPD, and live within the same area, we find that the necessary number of participants to have enough power of information is met [36]. This is supported by the presence of common patterns among the informants and the alignment of the overall findings with the data obtained in the PreCare project. Further studies are needed to confirm our findings before they can be considered valid for scaling up and evaluating the impact of working with landscapes or communities of practice. This support aims to foster a sense of more active and independent living based on existing values.

Perspective

The findings suggest that education for RNs and other health professionals should focus on their roles as professionals while also acting as facilitators. They should avoid being paternalistic to create a space for the development of self-efficacy and self-management. A motivating factor will help develop

self-efficacy and confidence, enabling people with COPD to be more socially active and encouraging them to pursue their desires. Health professionals play a key role here, as they can provide the means to help individuals become more active, thereby increasing their well-being.

Conclusions

When using digital health solutions, people's needs, values, and preferences should be considered, focusing primarily on addressing the whole person rather than just the "illness." This approach creates the best opportunity for individuals to maintain their daily activities and feel empowered. The 2 communities the informants take part must work together and will intersect in their daily lives. They should support each other, involving the needs, values, and preferences of the individuals, and ensuring that upcoming digital health services include and embrace situated learning to enhance people's empowerment and self-management. Furthermore, new educational programs should be developed or considered to enhance the competencies of RNs who are involved in digital health services. This will provide the best opportunity for the 2 communities to collaborate and support the daily activities of people with chronic conditions.

Acknowledgments

The authors thank the PreCare Project for assisting with the recruitment of informants and the informants for participating in the study. The first author has received funding from Region Zealand. CWS, KB, and LK have been partly financed by the EU H2020 Research & Innovation Programme (grant agreement number 101016848) for the period 2021-2024.

Abstract

Background: The rapid growth of web-based medical services has highlighted the significance of smart triage systems in helping patients find the most appropriate physicians. However, traditional triage methods often rely on department recommendations and are insufficient to accurately match patients' textual questions with physicians' specialties. Therefore, there is an urgent need to develop algorithms for recommending physicians.

Objective: This study aims to develop and validate a patient-physician hybrid recommendation (PPHR) model with response metrics for better triage performance.

Methods: A total of 646,383 web-based medical consultation records from the Internet Hospital of the First Affiliated Hospital of Xiamen University were collected. Semantic features representing patients and physicians were developed to identify the set of most similar questions and semantically expand the pool of recommended physician candidates, respectively. The physicians' response rate feature was designed to improve candidate rankings. These 3 characteristics combine to create the PPHR model. Overall, 5 physicians participated in the evaluation of the efficiency of the PPHR model through multiple metrics and questionnaires as well as the performance of Sentence Bidirectional Encoder Representations from Transformers and Doc2Vec in text embedding.

Results: The PPHR model reaches the best recommendation performance when the number of recommended physicians is 14. At this point, the model has an F_1 -score of 76.25%, a proportion of high-quality services of 41.05%, and a rating of 3.90. After removing physicians' characteristics and response rates from the PPHR model, the F_1 -score decreased by 12.05%, the proportion of high-quality services fell by 10.87%, the average hit ratio dropped by 1.06%, and the rating declined by 11.43%. According to whether those 5 physicians were recommended by the PPHR model, Sentence Bidirectional Encoder Representations from Transformers achieved an average hit ratio of 88.6%, while Doc2Vec achieved an average hit ratio of 53.4%.

Conclusions: The PPHR model uses semantic features and response metrics to enable patients to accurately find the physician who best suits their needs.

Introduction

Background

Web-based medical consultation is increasingly popular as an alternative to traditional health care services because it is convenient, accessible, and affordable [1]. This type of patient-physician interaction takes place electronically, connecting both parties through text, images, and videos. Its advantages include eliminating time and space constraints and accurately documenting the medication process [2], making it more attractive to many patients than in-person medical visits. As of the end of 2022, the number of users in China's internet medical and health market reached 363 million [3]. The rapid growth of web-based medical services and the vast amount of information available have created considerable difficulties for patients in finding the physicians best suited to their needs, leading to potentially mismatched consultations [4].

At present, most existing triage procedures rely on manual recommendation from schedulers to select departments for patients. As the number of consultations increases, manual provision of advice does not guarantee the professionalism and quality of medical services [5]. In addition, schedulers are unable to provide 24-hour service, resulting in gaps in health care access and the continuity of services. At this point, a common approach might be to develop an intelligent department recommendation model. Advancements in technology, particularly in the field of machine learning, present opportunities to improve the accuracy and efficiency of patient department assignment in health care systems. For example, Mullenbach et al [6] integrated the attention mechanism and used long short-term memory to predict the patient's disease type for further triage. Li and Yu [7] used multifilter residual convolutional neural networks to investigate the issue of department recommendation. Wang et al [8] used the Bidirectional Encoder Representations from Transformers (BERT) model to study disease diagnosis and department recommendations. These approaches can potentially automate the process of assigning patients to appropriate departments, reducing the burden on schedulers and improving patient outcomes through more accurate and timely care.

However, due to the ongoing subdivision of departments, these department recommendation models still cannot accurately match medical needs with physicians' specialties. For example, obstetricians and gynecologists further specialize in subfields such as gynecology, obstetrics, reproductive endocrinology, infertility, prenatal diagnosis, and genetic counseling. This refined division not only improves the effectiveness of diagnosis and treatment but also ensures that patients receive the most cutting-edge and professional care plans. In addition, even if the diseases treated are similar or the same, different medical institutions may have different department names. These problems have placed higher demands on hospital management, requiring more precise resource allocation to adapt to increasingly specialized services. Therefore, there is an urgent need to design personalized physician recommendation models.

Personalized recommendation methods can help users manage massive amounts of information and knowledge [9] and are

crucial for providing personalized medical services that meet the patient's needs [10]. For instance, Ju and Zhang [11] integrated geographical location and patients' questions to generate personalized recommendations. Liu et al [12] proposed a physician recommendation model that considers the characteristics of patients and physicians. Lu et al [5] proposed a self-adaptive physician recommendation system that considers physician activity and patient feedback. These methods can be advantageous for both patients and web-based health care providers, as they minimize the time and effort required to find a suitable match, thus ensuring efficient delivery of health care services [13].

However, there are still some shortcomings in previous studies. Most existing studies use satisfaction as a measure of physician performance. However, the authenticity of satisfaction ratings across different platforms is not always reliable, as many users tend to habitually provide positive feedback. In terms of the evaluating indicators for recommended physicians, most studies used accuracy as a single indicator and did not consider the service quality of recommended physicians. These limitations may result in consultation mismatches, longer patient waiting times, and potentially reduced patient satisfaction. To the best of our knowledge, previous studies have not developed a triage system for recommending physicians that uses the transformer-based models, which are the cutting-edge models for natural language processing. BERT [14] is a popular transformer-based model that has been pretrained on common texts, such as Wikipedia and the Brown Corpus. BERT is a state-of-the-art model that uses an attention-based mechanism [15,16] to accurately understand the context of words, enabling unsupervised learning by linking text input and output through a decoder-encoder framework [17,18]. However, the BERT model is not suitable for semantic similarity searches or clustering, which has led to the creation of a different sentence-embedding model called the Sentence BERT (SBERT) model [19]. This modified version of the BERT model was designed to be semantically meaningful and suitable for sentence similarity tasks. It works by integrating a Siamese network and a pretrained BERT model, along with a pooling layer that generates a fixed-sized representation. The SBERT model can accurately identify whether there is a significant match between 2 sentences, making it a useful tool for data mining, information retrieval, and text matching [20].

This Study

The objective of this study was to develop a more precise algorithm that can better recommend professional and highly engaged physicians and thus improve the effective use of medical resources and the medical experience of patients by reducing the mismatches between medical needs and services. The practical benefits expected from our findings include the enhanced ability of web-based health care platforms to provide timely, relevant, and professional medical consultations that are closely tailored to each patient's unique needs. By implementing our advanced recommendation algorithm, we expect to not only identify the most appropriate specialists based on patient input but also incorporate a comprehensive evaluation of physician performance metrics. This will ensure that patients are recommended physicians who are not only experts in their

field but also highly engaged and responsive, resulting in higher-quality care.

We seek to answer these three questions: (1) how can we effectively construct features for patients and physicians to facilitate efficient physician recommendations? (2) how can we incorporate the physicians' performance metrics into recommendation strategies to increase the chance of recommending highly active physicians? and (3) how can the effectiveness of the recommendation strategy be verified considering both accuracy and service quality?

Methods

Data Collection

This research collected a total of 646,383 web-based medical consultation records from the Internet Hospital of the First Affiliated Hospital of Xiamen University between 2016 and 2023. Each record contains the textual question, deidentified codes for the physician and patient, the physician's department, and the response status and time. Response status refers to whether a consultation request has received a reply from the corresponding physicians. Response time is the duration between

submitting a request and getting a response. A total of 5 examples of the questions generated during web-based medical consultations are displayed in [Table 1](#).

These records were divided into 2 test data sets and 1 training data set. For the first test data set, the physician with the highest number of consultations was selected from each of the following departments with the most inquiries: gastroenterology, obstetrics, respiratory medicine, pediatrics, and dermatology. Their codes were 98, 141, 202, 512, and 601, respectively. A total of 400 consultation records were randomly selected from each of the aforementioned physicians. These physicians then reviewed these textual questions to determine whether they were within their expertise. Any questions that a physician is proficient in was tagged, and eventually we randomly selected 200 records for each physician from these tagged questions to compile a test data set consisting of 1000 records. For the second test data set, a sample of 10,000 consultations was randomly chosen from the total data set, excluding the consultation samples from the first test data set. The training data set consisted of the consultations remaining after the removal of the first and second test data sets. The random seed for this study was set to 2023.

Table 1. Examples of patients' consultation questions.

Sample number	Patient code	Questions	Physician code	Department	Response status ^a	Response time
1	200321	You initially diagnosed me with left varicocele and ordered a color Doppler ultrasound examination. The results showed a moderate left varicocele with reflux. I would like to inquire whether, aside from surgery, this condition can be treated through medication, injections, or other noninvasive methods?	208	Urology	True	8 h 12 min
2	306878	My child has been experiencing discomfort in the throat and recurring fevers for four days before visiting a physician, who considered it was pneumonia and started administering azithromycin. Today is the fifth day of treatment. After the first day of intravenous azithromycin, the fever subsided, but there is still occasional coughing with phlegm. I am worried about the potential for significant side effects. Should the child continue taking azithromycin?	372	Pediatrics	False	null
3	447138	I am currently on my period and have scheduled an ultrasound and mammography for this afternoon. Could you please tell me if there is a recommended waiting period before trying to conceive after a mammography?	133	Breast surgery	True	20 min
4	591872	What does the glucose tolerance test report indicate? Could you please explain it to me?	423	Obstetrics	True	9 min
5	603826	My chin is red without feeling painful or itchy, and it has been like this for over a month. I've tried Clotrimazole but no obvious effects were achieved. Could you please tell me what condition this might be and what medication I should use?	418	Dermatology	True	2 h 20 min

^aTrue: the physician has responded to the consultation request; false: the physician has not responded to the consultation request.

Data Preprocessing

Data related to patients' consultation questions were collected and presented in the form of natural language. Preprocessing of these unstructured data is crucial in machine learning framework [21] to remove unnecessary, duplicated, irrelevant, and noisy data [22]. This study involved several steps to process these consultation questions, including normalization,

tokenization, part-of-speech tagging, and stop-word removal, thereby forming a reliable corpus.

The study calculated response rates and times for all physicians as shown in equations 1 and 2, where N_R denotes the number of consultation requests that physician P_i has responded to, with "responded" indicating that the response status is confirmed as true. Meanwhile, N indicates the total number of consultation requests that physician P_i has received. Furthermore, S_T refers

to the total response time for all the consultation requests that physician P_i has responded to:

(1)

(2)

Upper and lower bounds on response times were established to minimize the impact of extremely high and low values on the experiment. Response times >95% were capped at 8 hours and 6 minutes, while those below the fifth percentile were raised to 9 minutes.

Feature Extraction

Feature extraction is the process of converting raw input data into a meaningful set of features [23] that can be understood by

machine learning classifiers. In the feature extraction stage, 2 unique features for both patients and physicians were introduced.

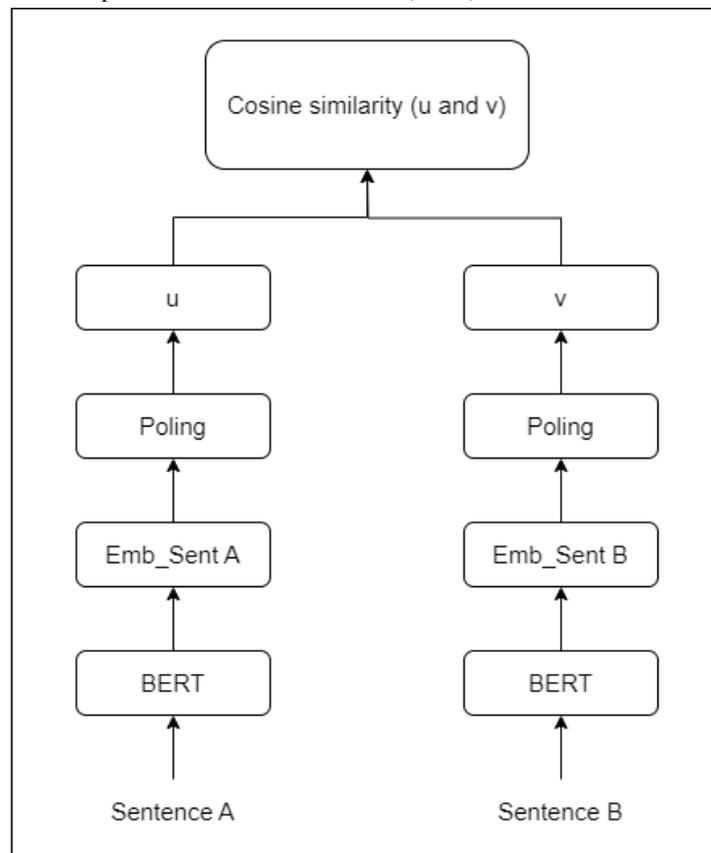

Patients' Feature Modeling

This study used the pretrained SBERT model known as "distiluse-base-multilingual-cased" to convert all consultation questions into semantic representations and then calculate sentence embeddings for further analysis. As shown in Figure 1 [19], the SBERT model processed sentences A and B through BERT pooling to generate their respective embeddings, u and v . The similarity between these embeddings is then calculated using the cosine similarity method, which effectively measures how similar sentences are. The cosine similarity is expressed by equation 3, where u and v represent 2 vectors:

(3)

Figure 1. Sentence Bidirectional Encoder Representations from Transformers (BERT) architecture.

Physicians' Feature Modeling

Term frequency-inverse document frequency (TF-IDF) model [24,25] is a commonly used method in text mining and information retrieval because it can capture the importance of words and has the potential to extract features from multiple texts. The formula of this algorithm is shown in equation 4:

(4)

where $TF(t,d)$ represents the frequency of a specific keyword t in document d , while $IDF(t)$ signifies the inverse document frequency. According to this formula, the higher the $TF-IDF(t,d)$ value, the more significant the feature is in the document.

This study used the TF-IDF model to extract crucial information from a collection of patients' consultation questions aggregated by physician codes, selecting the top 20 with the highest TF-IDF weights. This extracted information was then fed into an SBERT model to compute cosine similarity among physicians.

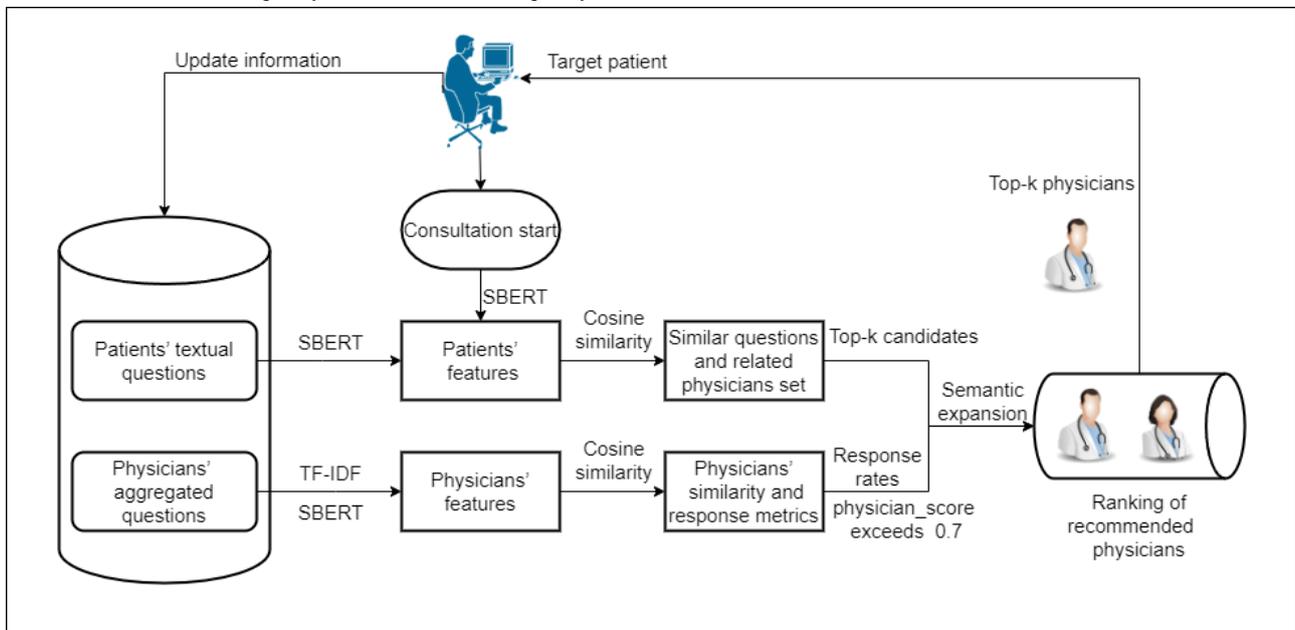

Recommendation

Overview

A patient-physician hybrid recommendation (PPHR) model with response metrics was developed by combining features of both patients and physicians. This model also considers the

physician’s response rate in the recommendation strategy. The PPHR model, which is a type of top-*k* recommendation system, is designed to provide patients with a list of the top-*k* physicians who are most likely to meet their medical needs, as illustrated in Figure 2.

Figure 2. The architecture of the patient-physician hybrid recommendation model. SBERT: Sentence Bidirectional Encoder Representations from Transformers; TF-IDF: term frequency–inverse document frequency.

Step 1: Generate a Candidate Set Using the Patient Feature–Based Model

The patient feature–based (PFB) model was developed to identify sets of the most similar questions. When a new consultation starts, the consultation questions will be processed using SBERT to generate the corresponding embeddings. The patients’ features were used to construct a similarity matrix among questions using cosine similarity. Then, consultation questions that are similar to the new consultation will be identified by comparing the patients’ features. The physicians who are associated with these similar questions are considered potential candidates. The similarity score, known as the *init_score*, serves as the baseline for making recommendations. The top-*k* physicians are selected as candidates from the set of similar questions, where *k* is an adjustable hyperparameter in this model.

Step 2: Expand the Candidate Set Based on the Patient-Physician Hybrid Model

As patients’ textual questions are unprofessional, setting a similarity threshold based solely on the patient characteristics may limit the recommendation results. The patient-physician hybrid (PPH) model ensures that all potential physician recommendations are considered. This model is formed by combining the physicians’ features with the PFB model to semantically expand the scope of candidates. It does this by creating an index called the *expand_score*, which is derived from the physicians’ features. This index reflects the degree of similarity among physicians and helps determine which

physicians have the necessary expertise and qualifications to provide the right care for a given patient. This approach can adjust biases in the system that may arise from recommending physicians based solely on similarities to patients’ questions. The PPH model is shown in equation 5:

$$\text{physician_score}_i = \text{init_score}_i \times \text{expand_score}_i \quad (5)$$

If the *physician_score* exceeds 0.7, it will be used to semantically expand the range of candidates. When the physician is not derived from the PPH model, the *expand_score* is assumed to be 1.

Step 3: Optimize the Ranking of the Candidate Set by Incorporating the Response Rate

The response rate can serve as an indicator to measure the efficacy of physicians’ performance. An increase in the response rate suggests that physicians are more willing to treat patients. This can be viewed as a positive feedback loop, as higher response rates lead to more motivated physicians. Therefore, it is crucial to consider the physicians’ activity level along with the similarity index, as this can skew the recommendation results toward more active physicians, increasing the chance that inquiries will be answered and thus improving patient satisfaction. The final PPHR model is displayed in equation 6. The top-*k* physicians are selected for recommendation based on the scores, where *n* represents the number of times physician *D_i* is recommended:

(6)

Evaluation

The proposed PPHR model's effectiveness was evaluated using the following metrics: hit ratio, precision, recall, F_1 -score, and high-quality service proportion. In the first test data set, a recommendation was considered correct when the selected physician was among the top- k recommended physicians. The hit ratio refers to the proportion of correct recommendations to the total number of recommendations. In the second test data set, a recommendation was regarded as accurate if the recommended physician's maximum physician_score is >0.7 . Precision refers to the proportion of correctly recommended physicians to the total number of recommended physicians. By contrast, recall is the ratio of correctly recommended physicians to the number of physicians who should have been retrieved in the sample. The F_1 -score is a valuable metric for assessing the recommendation algorithm's effectiveness, as it merges precision and recall to yield the best results. A higher F_1 -score signifies a more efficient algorithm. Precision, recall, and F_1 -score were calculated using the formulas described in equations 7 to 9, where TP is a true positive, FP is a false positive, and FN is a false negative:

(7)

(8)

(9)

A quick response time is a critical element for high user satisfaction, allowing the system to promptly provide services that meet patient expectations. If a physician responds quickly, the patient will perceive the quality of the physician's service to be better than that of a physician who takes a longer time to respond. Therefore, the proportion of physicians who respond quickly among all recommended physicians, known as the high-quality service proportion, is a significant measure of evaluation. The calculation for high-quality service proportion is determined by the formula shown in equation 10:

(10)

The term N_f represents the number of physicians whose response time is faster than the average response time, while N denotes the number of recommended physicians.

Baseline Experiments

For the PFB model, the purpose of baseline experiments was to determine whether excluding physicians' features from the PPHR model would degrade performance. A total of 3 steps were taken to assess its performance compared to the PPHR

model. First, the hit ratio and ranking of the selected physician in the recommendation set were calculated in the first test data set. Second, the precision, recall, and F_1 -score of the recommendation results were computed in the second test data set, and the consultation questions that were recommended to the selected physician (codes 98, 141, 202, 512, and 601) were collected. Finally, a questionnaire for assessing the rationality of the recommendations was administered by randomly selecting 200 consultation questions (100 for each model) for each physician from those consultation questions. The questionnaire included an evaluation of the relevance of each selected physician with the consultation questions. The survey question was as follows: "Based on your area of expertise, how would you rate the match between you and consultation question?" The questionnaire used a Likert 5-point scale [26] for measurement, with scores ranging from 1 (very inappropriate) to 5 (very appropriate). The Mann-Whitney U test [27] was used to determine whether there was a statistical difference in the physicians' perceptions of how well the consultation questions from these 2 models matched their area of expertise.

For the PPH model, the proportion of high-quality services in the recommendation results was calculated to assess whether eliminating the response rate in the PPHR model will reduce service quality.

Doc2Vec [28] was used to create text embeddings for all patients' consultation questions to reconstruct the PPHR model. The performances of Doc2Vec against SBERT were evaluated in the first test data set to determine the effectiveness of transfer learning without contextual modeling. The model's performance is measured by the hit ratio and the ranking of the selected physician within the set of recommendations.

Ethical Considerations

This study complied with all relevant ethical regulations. All the available data sets have been deidentified and anonymized. The First Affiliated Hospital of Xiamen University Ethics Committee approved this study (approval number SL-2021KY044-01), and no informed consent was necessary.

Results

Data Set Summary

Among the 646,383 consultation records, there were 193,675 patients and 858 physicians across 44 departments. According to Table 2, which provides a summary at the record level, 32.95% ($n=212,983$) of the records were created by male patients, while female patients accounted for 67.05% ($n=433,400$) of the records. The predominant age group among patients was 20 to 39 years, representing 54.6% ($n=352,907$) of the total number of consultations. Patients most frequently consult senior physicians, who account for 62.65% ($n=404,958$) of all consultations. Most consultations were initiated between 12 and 17 hours, accounting for 37.04% ($n=239,401$) of the total, while the bulk of responses were received between 18 and 23 hours, accounting for 40.94% ($n=208,417$). The average response time of the physicians was 3 hours and 40 minutes, with an average response rate of 65.2% ($n=421,441$).

Table 2. Summary of the characteristics of the collected data records (N=646,383).

Characteristic	Value, n (%)
Gender	
Male	212,983 (32.95)
Female	433,400 (67.05)
Intersex	0 (0)
Age group (y)	
<20	118,484 (18.33)
20-39	352,907 (54.6)
40-59	125,957 (19.49)
>60	49,035 (7.58)
Physician's professional title	
Junior	10,766 (1.67)
Intermediate	45,892 (7.1)
Subsenior	184,767 (28.58)
Senior	404,958 (62.65)
Consulted created moment (h)	
0-5	15,686 (2.43)
6-11	195,297 (30.21)
12-17	239,401 (37.04)
18-23	195,999 (30.32)
Consultation responded moment (h)	
0-5	13,394 (2.61)

Case Analysis

This study recommends the following question, as shown in sample 4 in [Table 1](#): "What does the glucose tolerance test report indicate? Could you please explain it to me?" This was done to verify the feasibility of the PPHR model. Questions similar to the target patient's question and related candidate physicians are displayed in [Table 3](#).

The physicians who were similar to the candidate physicians were identified and included in the recommendation strategy along with response indicators. The codes and scores of the

recommended physicians of the PPHR model are displayed in [Table 4](#).

To evaluate the precision of the recommended results, we compared the diagnoses for the consultation question within the recommended results. For example, physician 141's diagnosis includes "gestational diabetes" and "glucose tolerance," while physician 164's diagnosis includes "glucose tolerance" and "diabetes." This information matches the consultation question of sample 4, suggesting that the recommended results are likely accurate.

Table 3. Top-10 most similar questions to the target patient's question and related physicians.

Question code	Cosine similarity	Physician code
394946	0.9766	178
559249	0.9765	423
317643	0.9618	141

Evaluating the Effectiveness and Service Quality

Figure 3 shows a comparison of the PPHR model with the PFB and PPH models in terms of various indexes. The x-axis represents the number of recommended physicians (K), with values ranging from 2 to 20 and increasing in increments of 2. The PPHR and PFB models exhibit comparable performance when K is <10. However, as K increases to ≥ 10 , the PPHR model demonstrates a marked improvement over the PFB model. The PPHR model achieves its highest F_1 -score when K is 14, indicating optimal performance at this level. At this stage, the model has a precision of 71.26%, a recall of 82.02%, and an F_1 -score of 76.25%. Compared to the PFB model, the precision has increased by 15.43%, the recall has increased by 9.10%,

and the F_1 -score has increased by 12.05%. The results presented in Table 4 indicate that although there are minor fluctuations in the rankings of the selected physicians of the PPHR model, its hit ratio has increased by 2.19% compared to the PFB model. These indicate that incorporating physicians' features into the recommendation strategy can improve the effectiveness of the recommendation system.

Regardless of the value of K, the PPHR model provides better h_{qos_prop} than the PPH model. When K is set to 14, the high-quality service ratio of the PPHR model is 41.05%. This is an improvement of 10.87% over the PPH model. This suggests that incorporating the response rate into the recommendation strategy can enhance service quality.

Figure 3. Comparison of our proposed patient-physician hybrid recommendation (PPHR) model with the patient feature-based (PFB) model and patient-physician hybrid (PPH) model in terms of various indexes, including precision (blue), recall (green), F1-score (red), and hqos_prop (orange).

Evaluating the Performance of Text Embedding

The results displayed in Table 5 compare the SBERT model with the Doc2Vec model in terms of text embedding, with K set to 14. The ranking indicates the position of the selected physician within the recommendation set, while the hit ratio

represents the percentage of successful recommendations. The SBERT model surpasses the Doc2Vec model by 65.92% in hit ratio, and the rankings of the selected physicians improved by 1.57. These findings suggest that using the SBERT model to create text embeddings could improve the performance of the recommendation system.

Table 5. Performance comparisons were conducted using different models for the selected physicians.

Physician code	Hit ratio			Ranking		
	Doc2Vec-PPHR ^a	SBERT ^b -PPHR	SBERT-PFB ^c	Doc2Vec-PPHR	SBERT-PPHR	SBERT-PFB
98	0.485	0.850	0.820	4.55	3.19	3.04
141	0.555	0.915	0.890	3.99	2.36	2.47
202	0.430	0.800	0.780	4.93	3.47	3.33
512	0.505	0.940	0.925	5.95	3.37	2.73
601	0.695	0.925	0.920	2.78	1.97	1.90
Combined, mean (SD)	0.534 (0.101)	0.886 (0.059)	0.867 (0.064)	4.44 (1.172)	2.87 (0.668)	2.69 (0.549)

^aPPHR: patient-physician hybrid recommendation.

^bSBERT: Sentence Bidirectional Encoder Representations from Transformers.

^cPFB: patient feature-based.

Rationality Evaluation

As can be seen in Table 6, for each physician, the PPHR model consistently received higher ratings than the PFB model. The average rating of the PPHR model is 3.90, which is 11.43%

higher than that of the PFB model. The P values indicate that the differences in ratings between these 2 models are statistically significant, indicating that the PPHR model is capable of recommending better-performing physicians compared to the PFB model.

Table 6. Rationality evaluations of patient-physician hybrid recommendation (PPHR) model and patient feature-based (PFB) model for selected physicians.

Physician code	Rating		<i>P</i> value
	PPHR	PFB	
98	3.89	3.48	.01
141	4.00	3.57	.02
202	3.79	3.33	.02
512	3.83	3.54	.049
601	3.98	3.56	.03
Combined, mean (SD)	3.90 (0.09)	3.50 (0.10)	— ^a

^aNot applicable.

Discussion

Principal Findings

In this study, we developed an innovative physician triage algorithm named the PPHR model. This model improves the accuracy of matching patients' textual questions with physicians' specialties and optimizes the ranking of candidates according to the physicians' service performance. Consequently, the PPHR model may help increase both the efficiency and the quality of web-based medical services by recommending active physicians with the most appropriate specialties.

Challenges and Solutions for Web-Based Triage Systems

Triage service is a preliminary service in medical diagnosis [29], serving as the first point of contact for patients in health care. It is crucial for improving the efficiency and precision of medical services. In offline outpatient clinics, patients' choices are limited due to the physicians' fixed schedules, especially if the appointment times cannot be changed. Therefore, triage is usually performed at the department level [30]. In contrast, web-based consultation services typically do not adhere to a fixed schedule, and all physicians can provide services on the web, so patients have a wider range of choices. However, the current triage systems have inherited the offline departmental recommendation form, which provides limited assistance to patients. In addition, due to the ongoing division of departments, the naming conventions of these departments have become confusing, resulting in possible overlap in disease areas that physicians specialize in across various departments. Furthermore, with the development of regional medical platforms [31], physicians from different regions and multiple hospitals may share the same web-based consultation platform, which complicates the supply of medical services. Therefore, it is imperative to develop a new type of physician recommendation system.

The construction of a triage system must first consider the matching of the physicians' specialties with the patients' medical needs, which is a prerequisite for the effective operation of web-based medical services [32]. The triage system needs to accurately create user profiles for physicians and patients, analyzing their characteristics, and achieve precise matching. Traditional triage systems typically use the profiles of

professional-level physicians. These profiles mainly include the names of diseases and medical fields that physicians specialize in, which can be difficult to match with patients' textual questions. Patients often ask their physicians questions using nonprofessional, colloquial descriptions of symptoms rather than precise disease names. Therefore, using professional descriptions to create physician profiles does not semantically match well with patients' questions. Some studies have attempted to extract physicians' features using textual questions from patients [5,11,12]. Our study draws on this approach, using natural language processing technology to build physician characteristics based on a large corpus of patient inquiries, thus constructing the profiles from the patient's perspective and aligning more closely with patient needs.

In addition to expertise, the quality of service provided by physicians is equally important in ensuring effective web-based diagnosis and treatment. In web-based services, the quality of service is particularly reflected in the response time and rate, as well as the thoroughness of the content provided. Formally, response time and rate are obvious and accessible indicators. Previous research did not consider these indicators when developing triage systems. Therefore, we have included the consideration of the response rate in the scoring calculation of our model's ranking. As there is a correlation between response rate and time, our results showed that this approach also significantly improved the recommended physicians' response time.

Feasibility and Potential Extensions of the Proposed Model

The most significant difference between web-based and offline medical consultations is the limited availability of data. When physicians cannot physically examine patients, the dialogue generated during the consultation becomes the primary source of usable information. Due to potential incompatibilities and lack of data sharing between web-based and offline systems [26], patients' medical histories are often missing on most web-based consultation platforms, making it more challenging to extract patient characteristics. In terms of the quality of medical services, patients' satisfaction with physicians is an indicator that can be referenced. However, the authenticity of satisfaction ratings on different platforms is not always reliable, as many users tend to habitually give positive feedback. Therefore, whether satisfaction ratings should be included in

the model remains to be studied and verified. The PPHR model was designed to use minimal information to match physicians with patients. Despite the limited number of variables included, the advantage is that the algorithm is portable across different platforms, offering greater versatility and suitability for widespread adoption. Subsequently, different platforms can modify the model to suit their specific circumstances, including by incorporating past medical histories and satisfaction ratings. They can also adjust various hyperparameters within this framework, such as adjusting the weight of the response rates or setting a different number of recommendations to meet the needs of different platforms. In addition, the user interface can display information that the model used or disregarded, providing additional support for patient decision-making. Considering that some physicians may not be familiar with web-based platforms, it is also feasible to show indicators of their offline services. For instance, it is important to consider whether a physician has a sufficient number of in-person appointments and the level of satisfaction expressed by patients regarding those services. If a physician's expertise is a good match for a specific type of consultation and they have outstanding offline reviews, despite not being highly active on the web, patients could consider switching to offline consultations during clinic hours.

Real-World Application Challenges

Implementing the PPHR model in a real-world scenario presents a number of challenges. First and foremost, ethical issues related to privacy, consent, and confidentiality are major concerns. It is of the utmost importance that patients' medical histories and personal information are handled with the utmost care, in accordance with the patients' consent and in compliance with local and international laws. The PPHR model training process includes the pseudonymization or anonymization of data by removing or replacing personally identifiable information, as well as the use of SBERT for text vectorization, which transforms textual data into numerical vectors that represent the semantic meaning of the text but do not contain explicitly identifiable information, preventing the extraction of personal information directly from the vectors to protect individual privacy. It is also important to consider data confidentiality. Encrypting data at rest and in transit protects against unauthorized access. Using strong encryption standards, such as Advanced Encryption Standard for data at rest and Transport Layer Security for data in transit, can ensure that even if data are intercepted or accessed, they remain unreadable and secure. It is imperative to implement strong authentication mechanisms to verify the identity of users accessing the system; use multifactor authentication to add an extra layer of security; and implement role-based access control to ensure that users can access only the data relevant to their role, maintaining the principle of least privilege.

Integration with existing health care IT systems is another challenge. Many health care providers use legacy systems that may not be immediately compatible with newer models, such as PPHR. This requires the development of interfaces or middleware that can seamlessly connect the model to various health care IT infrastructures without disrupting existing workflows.

In addition, patient and physician acceptance is an integral part of the implementation process. Many users may be skeptical or resistant to changing traditional consultation methods. Educating both physicians and patients about the benefits of the PPHR model, such as increased efficiency; better physician-patient matching; and, ultimately, improved health care outcomes, is critical to facilitating adoption.

Evolving Text Feature Extraction

Text embedding is a fundamental method for text feature extraction, where Doc2Vec is an effective means of implementing text embedding [33]. However, with the advent of transformer-based models, previous text embedding methods are gradually being replaced by SBERT in the industrial service sector. First, Doc2Vec provides a static embedding for each word, best used for tasks that can benefit from representations without the need for understanding word-context relationships [34]. SBERT provides dynamic contextual embeddings that allow for a deeper understanding of the meaning of words in context. It also has the ability to transfer knowledge and analyze subwords [35], which are essential for more complex language comprehension tasks.

Second, the computational efficiency of SBERT compared to traditional methods such as Doc2Vec is primarily influenced by its transformer architecture. Transformers take advantage of parallel processing, which significantly speeds up the training phase. However, they also tend to be resource-intensive, primarily due to the need for larger memory footprints to handle the contextual embeddings and underlying mechanisms. For the PPHR model, this means that there could be increased computational requirements, especially when processing a large corpus of patient queries or generating physician profiles.

Third, when considering the scalability of SBERT within the PPHR model for widespread use, several strategies can help mitigate potential challenges. Horizontal scaling, or adding more machines to spread the load, is a straightforward approach but can increase costs. More efficient strategies include the use of cloud-based services that offer dynamic scaling options to accommodate fluctuating demand without the need for constant, high-capacity infrastructure. Another key consideration is optimizing input sequences. By limiting the length of textual input without losing critical information, the PPHR model can reduce the processing required for each query, making the system more responsive. In addition, caching frequently accessed embeddings and using batch processing for embedding generation can significantly reduce the overall computational load.

It also indicates that as technology progresses, the underlying technical components of models must be regularly updated and refined to enhance the system's overall efficiency. This is a real-world challenge that any web-based medical triage system in operation will encounter.

Limitations and Future Directions

There are some limitations and further solutions. First, it is important to collect data from multiple sources. This study was limited to 1 hospital, which casts doubt on whether the findings are relevant in different contexts. To overcome this limitation,

subsequent research should aim to collect information from various sources to evaluate the efficiency of the proposed algorithm. Second, there were some irrelevant contents in our data sets, for example, questions such as “Doctor, will you be available tomorrow? Where can I find you?” These business process-related questions are often mixed with medical questions describing symptoms and represent noises in the data set [36]. Even though preprocessing methods may reduce these noises, manual involvement might still be necessary to enhance the data quality. Third, a common limitation of deep neural networks [37] is the lack of a natural method to explain their predictive results, which makes it difficult to understand why specific samples are predicted to be similar. Models based on transformers make it very challenging to identify when unfair biases or spurious correlations might drive predictions. Therefore, we have introduced the involvement of physicians. If physicians could provide more information based on order details, such as scores based on the perspectives of professional suitability and willingness to accept orders, it might effectively improve the final performance of the model. Fourth, it is critical to regularly update the physicians’ professional information because this information changes over time. Relying on outdated data can result in less-than-ideal recommendations. To ensure that physicians’ profiles are up to date, a time range feature can be implemented. This feature automatically deletes data beyond the specified time range and periodically updates the model with only the latest data. This approach can improve the chances of making accurate recommendations for active physicians and

reduce the chances of those still in training or changing areas of expertise. Fifth, obtaining valid feedback from patients and physicians is essential to validating the model’s benefits to patients in real-world settings on a larger scale. For instance, surveys can be conducted on patients’ use of the system, whether patients have adopted the system’s recommendations, and patients’ feedback on whether the system has been helpful. Observing changes in metrics such as the number of consultations for the same condition before and after using the system, comparing their outcomes, and examining the health economic effects of the system are also important. Finally, we were unfortunately only able to obtain textual data to develop the PPHR model. However, the triage system framework proposed in this paper has the potential to incorporate various types of data beyond text. It is possible to integrate multimodal information, such as text, images, audio, and video, using vector embedding techniques to create new vector features. On the basis of this, calculating similarities could potentially achieve more precise matching.

Conclusions

This paper presents a PPHR model with response metrics that uses natural language processing techniques to tackle web-based medical triage tasks. The system filters out relevant physicians, aiding patients in finding the physicians who best suit their actual medical requirements. This approach has significant practical value and can be incorporated into various health website systems to enhance the quality of physician recommendations.

Abstract

Background: Maternal and child health outcomes are positively influenced by early intervention, and digital health (DH) tools provide the potential for a low-cost and scalable solution such as informational platforms or digital tracking tools. Despite the wide availability of DH tools out there for women from before to after pregnancy, user engagement remains low.

Objective: This study aims to explore the factors that shape women's DH adoption and sustained use across the maternal journey from preconception to postbirth, to improve user engagement with DH tools.

Methods: One-hour semistructured qualitative interviews were conducted with 44 women from before to after pregnancy (age range 21-40 years) about their experiences with DH. This study is part of a larger study on women's maternal experiences with health care and DH and focuses on the factors that affected women's DH adoption and sustained use. Interviews were audio recorded, transcribed verbatim, and analyzed using inductive thematic analysis.

Results: Five main themes and 10 subthemes were identified that affected women's adoption and sustained use of DH tools. These included themes on their preexisting attitudes to DH, perceived ease of use, perceived usefulness, perceived credibility, and perceived value of the tool.

Conclusions: The themes that emerged were fully or partially mapped according to the Unified Theory of Acceptance and Use of Technology 2 model. The applicability of the model and the need to consider specific cultural nuances in the Asian context (such as the importance of trust and social influence) are discussed. The interaction of the 5 themes with DH adoption and sustained

use are explored with different themes being relevant at various points of the DH adoption journey. The insights gained serve to inform future DH design and implementation of tools for women to optimize their DH engagement and the benefits they derive from it.

Trial Registration: ClinicalTrials.gov NCT05099900; <https://clinicaltrials.gov/study/NCT05099900>

Introduction

The lifelong health of an individual can be linked to periods even before conception and birth, as maternal health and behaviors have been shown to influence child health [1]. Many countries including Singapore, have worked on improving the quality of maternal health care [2]. In recent years, the challenges in maternal health have shifted from lowering maternal and infant mortality rates to managing complicated health outcomes such as obesity in women before, during, and after pregnancy [2]. Unhealthy weight in women can have implications for both mothers (eg, attempts at conception, pregnancy-related complications, and mental health disorders) and their children (eg, increased risks of childhood obesity and developmental problems later in life) [1,2]. These are known as the “twin metabolic and mental health challenges” as characterized in the S-PRESTO and GUSTO mother-offspring cohort studies in Singapore [3,4]. Evidently, managing maternal health outcomes has both direct and indirect consequences on maternal and child health [1-4]. As such, early intervention in maternal health decisions, as early as preconception, has the potential to positively influence maternal and child health outcomes [2].

A multitude of digital health (DH) tools have been developed to improve multiple maternal and child outcomes [5-14]. DH tools can take the form of digital platforms, such as smartphones, websites, forums, social media, and wearables, which also enable tracking of health data [6,15]. Due to their accessibility and the potential for low-cost implementation at scale, DH tools have the capacity to easily disseminate information and interventions for behavioral change to a large audience [15]. For maternal and birth outcomes, DH tools have been applied in numerous ways to improve and manage several conditions beyond obesity. These included fertility education apps [10], tracking of symptoms and complications through a continuum from before to after pregnancy [5,7], improving the delivery of pregnancy and antenatal care [6,11,14], early labor support apps [13], and promoting postpartum health screening via DH platforms [12]. These have been widely implemented in many geographies, from European to African countries [7,10,16-18]. Accelerated by the recent COVID lockdowns [19], DH tools present an opportunity to satisfy the health care, informational, and support needs of women throughout their journey from preconception to postbirth.

To realize the potential of DH tools, attention needs to be given to their adoption and retention by the users. User engagement with the DH tool is vital in maximizing the potential benefits

derived from it [18,20]. The degree of user engagement determines the depth, breadth, and length of tool use [9,21]. Studies investigating the engagement of DH tools among pregnant women report a lack of user engagement. One study examining the uptake of digital antenatal care services by pregnant mothers found poor adoption of DH due to a lack of awareness and cost barriers [16]. Other studies found that despite incentives to motivate engagement, women struggled to sustain long-term use [18]. These findings have been observed across diverse settings, ranging from high-income countries like Germany to low-income countries like Uganda. Evidently, user engagement is affected by differences in women’s accessibility to and knowledge of the DH tools [17], emphasizing the need to actively identify reasons driving unequal adoption of DH tools [22]. The needs of women evolve as they progress through their reproductive stages and thus require varying interventions at different time points [23,24]. This calls for more research to understand the factors that affect the adoption and sustained use of DH tools by women to supplement current research on the perspectives of clinicians [25]. Insights gained from women through their experiences can serve to better inform DH innovators, from the early design and development process to the implementation phase.

As such, this study seeks to explore and understand the factors that influence women in their adoption and sustained use of DH tools before, during, and after pregnancy. This study provides a continuation of research from a previous study by Lee et al [26], using the same pool of data obtained from performing 44 interviews with women across preconception to postbirth phases but focusing on responses specific to technology adoption. While Lee et al [26] primarily focused on key elements in DH interventions that promote healthy behavior change in women from before to after pregnancy, this study identified 5 main themes that support DH uptake and sustained use. The translational insights derived from this study aim to inform the future design and implementation of DH tools for women across preconception to postbirth, to create a positive impact on behavioral and health outcomes in both mother and child.

Methods

Ethical Considerations

The study procedures were approved by the National Healthcare Group Domain Specific Review Board (reference 2021/00034). Informed consent was obtained from participants by providing the consent form during initial contact and prior to the interview session. Additionally, the researcher explained the consent form

fully before participants consented. Participation was voluntary and participants could withdraw at any point of the study. There were no direct risks involved for participants and any data collected were deidentified, encrypted, and stored in accordance with the institution's data management policies. Participants were reimbursed SG \$30 (US \$23.06) for their time spent on the study.

Recruitment

This study recruited women who were trying to conceive, were pregnant at the time of contact, or had a child aged 0 to 2 years through purposive sampling from the National University Hospital and the community in Singapore (ClinicalTrials.gov Identifier: NCT05099900). Study advertisements were distributed around National University Hospital, public places (eg, bus stops, housing estates, and learning institutions), and social media platforms (eg, Telegram and Facebook). The research team provided an overview of the study to potential participants who responded to the advertisement via email, phone call, or messaging. The team screened interested participants based on the following inclusion criteria: (1) English fluency; (2) aged 21 to 45 years; and (3) actively trying to conceive or currently in first to third trimester of pregnancy or have a child aged 0 to 2 years. Participants were not eligible for the study if they met the following exclusion criteria: (1) evidence or diagnosis of cognitive impairment; (2) current diagnosis of psychiatric disorder; (3) significant hearing impairment; (4) women requiring or who had any form of assisted conception; and (5) inability to complete the study at the judgment of the clinician investigators. The research team established communication with eligible participants to schedule the interview sessions. Recruitment took place over a period of 9 months (from November 2021 to July 2022) and ended when data saturation was achieved for each group (ie, preconception, during pregnancy, and postbirth). No participants declined to participate or dropped out after consenting to the study.

Data Collection

This study adopted a qualitative approach to explore women's experiences from preconception to postbirth, including their DH experiences and expectations. Prior to the interview session, participants completed a web-based questionnaire ([Multimedia Appendix 1](#)) regarding their demographics and technology use patterns. Before commencing the interview, participants were informed about study goals and researchers' interest in the research topic. All participants provided informed consent to the audio recording of the interview for the research team's transcription purposes. A 60- to 90-minute semistructured interview was conducted either in-person or virtually via Zoom, depending on participants' preference. Open-ended questions were used to facilitate discussion surrounding participants' experiences with their preconception, pregnancy, or postbirth journey, and their use or expectations of DH to support their journey. Both the questionnaires and interview guide have been detailed in Lee et al [26]. Guiding topics for the interview are presented in [Multimedia Appendix 1](#) [26]. This manuscript is focused on the DH segment of the interview, specifically exploring women's experiences with DH and current expectations of how DH could support their maternal journey.

Given that this manuscript presented a different focus on technology adoption from Lee et al [26], responses included in this work are different and were not reused between the manuscripts. All interviews were conducted in English with at least 2 researchers present. The interviewing team comprised of VVL, SV, WYN, NYL, and QYL—all female and trained in qualitative research.

Following the interview session, participants completed another web-based questionnaire ([Multimedia Appendix 1](#)) regarding their pregnancy concerns and DH expectations. All participants were reimbursed for their time. No repeat interviews were carried out and transcripts were not returned to participants. Reflective notes were taken after the interview to consider additional guiding prompts for future interviews.

All data collected, including signed consent forms, interview recordings, and questionnaire data, were deidentified, encrypted, and stored in a secure database.

Data Analysis

For the questionnaire, descriptive analyses were conducted using SPSS (IBM Corp). Pairwise deletion was employed to handle missing data in the questionnaire responses. For the interviews, audio recordings were transcribed verbatim. Inductive thematic analysis was conducted to identify emerging and recurring themes. First, transcripts were randomly assigned to the 5 interviewing researchers to conduct primary coding to descriptively label the data. All generated primary codes were then compared and discussed among all researchers to resolve any discrepancies. Thereafter, secondary coding, where labeled data were grouped into categories, was conducted independently for each group (preconception, pregnancy, and postbirth) using Microsoft Excel. As the categories that emerged from secondary coding were similar across all 3 groups, the categories were analyzed into broader, overarching themes. The final set of codes and broader themes was concluded for the study data after discussions and iterations by all researchers. No feedback was provided by participants on the findings.

Results

Participant Characteristics

The cohort used in this study was previously described in Lee et al [26], where detailed demographic characteristics were provided ([Multimedia Appendix 1](#)). A total of 44 participants (age range 21–40 years; mean age 31.6, SD 4.0 years) completed the study. Participants across preconception (13/44, 29.5%), pregnancy (16/44, 36.4%), and postbirth (15/44, 34.1%) phases were recruited. Participants were Chinese (33/44, 75%), Malay (4/44, 9.1%), Indian (4/44, 9.1%), and other (3/44, 6.8%) ethnicities. In terms of education, there was an equal distribution of participants who had 15 years of education or less (22/44, 50%) and those who had more than 15 years of education (22/44, 50%). Socioeconomic status (SES) varied, with participants categorized as low SES (9/44, 20.5%), middle SES (13/44, 29.5%), and high SES (22/44, 50%). Family size ranged widely, with participants having had no children (17/44, 38.6%), 1 child (16/44, 36.4%), and 2 or more children (11/44, 25%) at the point of the study. All participants spoke fluent English.

The technology use patterns and expectations obtained from the questionnaire responses are shown in Table 1. One participant from the postbirth group was entirely excluded from the table due to nonresponse to the questionnaire. Two participants (one from the pregnancy and one from the postbirth group) had missing data due to incomplete questionnaire responses. Women indicated preferred online sources of information and information topics. For instance, Google and child development-related information were commonly perceived as a useful information source and topic respectively. Most women could accept using DH tools that required weekly

logging of information, and receiving feedback based on data logged was also rated by women as a feature that they were likely to use DH tools for. Participants across the 3 phases also used a variety of DH apps, including apps for physical health, mental health, fertility, pregnancy, and child-related care, which has been detailed in Lee et al [26]. While the tables presented in Lee et al [26] focused on categories of apps being used, Table 1 shows specific technology use patterns and aspects of DH tools participants would like to see. Multimedia Appendix 1 provides a breakdown of the categories of mobile phone application use across the 3 phases.

Table 1. Technology use patterns and expectations of study participants from questionnaire responses.

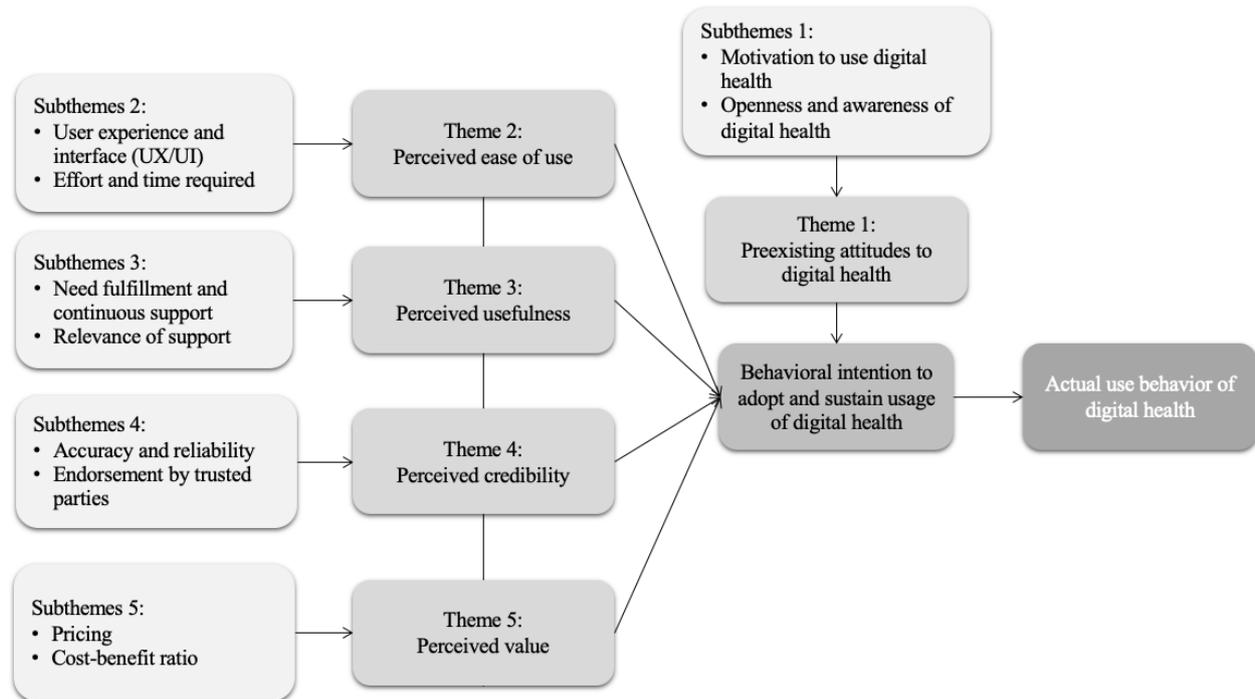

Technology use and category	Preconception (n=13)	Pregnancy (n=16)	Postbirth (n=15)
Useful online sources of information (n=42), n (%)

Interview Data

A total of 5 themes and 10 subthemes were identified as factors that motivate or hinder women's behavioral intention toward adoption and sustained use of DH tools (Figure 1).

Figure 1. Factors influencing women's behavioral intention to adopt and sustain use of digital health tools.

Theme 1: Preexisting Attitudes Toward DH

Existing attitudes are defined as women's motivation to use DH tools, as well as their openness and awareness of DH tools.

Motivation to Use DH

Prior experiences and understanding of DH shaped women's current motivations to adopt DH tools. Women expressed having low motivation due to previous unpleasant experiences with DH tracking tools whereby tracking lifestyle metrics such as diet, physical activity, and water intake felt like a chore. Some women disengaged because they lacked the motivation to enter data manually, while others found it stressful to adhere to the requirement of regular data entry.

Last time I used to track my water intake, but got a bit lazy...because [you've] got to key in manually so I stopped that. [Participant 5, preconception]

Previously I was tracking my diet but it got too troublesome. [Participant 18, postbirth]

After like one, two months, I start to get very stressed in order to meet this routine [and] having to comply to the app, I think that would be more stressful to me...Do a food diary, nope that's [going to] be more stressful... [Participant 41, preconception]

Such poor motivation was also attributed to poor understanding of the impact of lifestyle factors on maternal and child health, and how tracking lifestyle metrics might be useful.

I don't really know how sleep can impact, [so] I wouldn't really track sleep. [Participant 33, preconception]

So like of course [diet tracking is] good to have but I don't have [the] confidence I will use it. I also don't

know what [features of diet tracking are] good.
[Participant 18, postbirth]

Openness and Awareness of DH

Women were generally open to using DH tools to manage their pregnancy journey if they were aware of such tools, provided that the tool met their need for it to be easy to use, require little time, and provide health monitoring benefits.

But of course, if there's an app that can help me monitor my health better, I might be willing to try it.
[Participant 34, preconception]

I think if it was too complex to use, or if the app made me spend too much time on it, then I might not want to be so hooked on my digital device, especially if I have young kids. [Participant 23, postbirth]

Women also suggested that outreach efforts to increase knowledge and awareness of a DH tool and its benefits might also encourage the adoption of the tool.

I think that if they come and engage me...like do you know that this app allows you to do this and do that. I'm like "okay!" [Participant 12, preconception]

Theme 2: Perceived Ease of Use

Based on the interviews, DH tools' perceived ease of use was contingent upon factors such as user experience and interface of the digital platform, as well as how much effort and time were required from the user in their use of the DH tool.

User Experience and Interface (UX/UI)

Women's intention to continue the use of a tool after initial adoption was highly dependent on the user experience and interface of the DH tool. Unappealing interfaces that were challenging to navigate, slow loading times, or discomfort in

user experiences were major sources of frustration that led to disengagement with a digital tool.

Just [that] the outlook was not very appealing...maybe the colour, the outlook, the way it is placed, not very user friendly. It's a bit confusing on how to use it. [Participant 31, during pregnancy]

For me like the UX is important also, the ease of use and the features and functionalities of the app. [Participant 4, during pregnancy]

When I needed to track those information [for my baby], I downloaded a few apps to try.

If its' hard to use, or the interface is not so...erm I don't feel comfortable, I'll just straightaway delete. Until I find one that's comfortable, then I just stick to it. [Participant 1, postbirth]

Hardware and software issues of a DH tool such as the extent of battery consumption, data use, storage space, and data syncing problems lowered the likelihood of adoption and sustained use. Women were also highly likely to delete an app if they experienced frequent technical glitches.

[I used to use] HealthHub, but I'm not using [it] now because the syncing has some issues. [Participant 37, preconception]

Too much data, memory space, [and also] it will be good if [it] doesn't drain too much battery. I think Fitbit drains quite a bit [of battery life]. [Participant 5, preconception]

What would stop me [is] if it's always buggy and always hanging, and then like half the time you can't get the app to work, then obviously I would just delete it. [Participant 38, postbirth]

Level of Effort and Time Required

The perceived ease of use was influenced by the level of effort and time required on the part of the user. Women identified several barriers that prevented continued use of a DH tool, including data entry that required too much time and effort, especially postbirth when women were busy caring for their children. DH tools with a steep learning curve and long onboarding time in the initial stage of use were also the reasons that led women to disengage from digital tools.

But after a while I stopped [tracking my diet] because I feel that it was a bit troublesome to have to key in what I eat, then find the exact food and portion size that I ate. I mean, although that did help me to manage my diet, but it was troublesome for me to use in the long run. [Participant 18, postbirth]

So in the beginning I use [an app for breathing exercises] more, but I think when [my child] came, well I had no time to do that anymore [Participant 8, postbirth]

When you first [begin to use] an app, [you] probably need to load quite a bit of information in there. So if that first stage [takes] me a little longer to actually set it all up, I might just give up in the end. [Participant 34, preconception]

Theme 3: Perceived Usefulness

Another crucial determinant in women's adoption and ongoing use of DH tools was perceived usefulness, which was shaped by the extent of need fulfillment and continuous support provided, as well as the relevance of support.

Need Fulfillment and Continuous Support

It was important to women that DH tools fulfilled their unmet needs and delivered comprehensive support. The idea of providing an all-in-one solution was especially appealing, due to issues like app fatigue as women found it tedious to manage several apps for different health-related functions, or having to filter through overwhelming amounts of information on the internet. Having an all-in-one support tool was pointed to as an enabler of better access to quality information and increased ease in tracking health and lifestyle metrics.

I would say the only thing that would make [the DH tool] superior would be the fact that it has everything I need. So I can just delete my Flo app, I don't even have to do my Google search anymore. I mean [I can] reduce my Google search at least. [Participant 35, preconception]

Yea, as in I think that would be helpful because sometimes along the way in the journey then you have questions, and you don't pre-empt the questions way before, so if the, the app covers the whole span then you can obviously uh, look through it at the different stages that you're at in your journey [Participant 26, postbirth]

Furthermore, it was critical that DH tools delivered complementary support to the current continuum of care provided by the health care system. This was especially prominent for women in the pregnancy and postbirth phases, as many of their needs included touch points with the health care system, such as understanding their pregnancy trimesters or their child's development through doctor consultations or health booklets. Offering complementary support emerged as a feature to increase the likelihood of DH adoption. For example, scheduling appointments and integrating DH records of the child were mentioned as useful tools.

If I can use this app as like an all-in-one [tool], [including] scheduling appointments [or] even uploading my ultrasound photos...And you can download the digital copy of [the ultrasound scan], instead of having just the physical [copy], which you might lose or it might degrade over time. These ultrasound scans are quite precious to like the family during the pregnancy [because] that is [the] only time where you can like see the baby. [Participant 4, during pregnancy]

Relevance of Support

Women highlighted the importance of the relevance of support provided by DH tools. They valued being able to receive tailored information based on their individual needs and preferences. This included information that was relevant to women's current phase in the pregnancy journey, topics of interest, or areas of child development in which they had concerns at that time.

What would stop me from using the app is if I'm not interested to know about that particular topic or maybe I don't see that my child has any issues at all in that aspect, then I wouldn't bother to check. [Participant 26, postbirth]

The desired feedback from tracking maternal indicators was envisioned as being aware of women's conditions and sensitive to their emotional well-being, ensuring that it would not induce additional stress.

It really depends on the circumstances. Let's say I'm producing a lot of breast milk [and] I'm keying it into the app, then I wouldn't mind seeing it. But let's say I'm a mother who doesn't produce enough [breastmilk] and I'm keying it into the app. Then, I look at it and I start to feel depressed. Then, I probably would not enter it again. [Participant 33, preconception]

The relevance of support was particularly important as women were often overwhelmed by the sheer amount of information available through technology. Often, such "knowledge burden" (participant 30) became unhelpful and a source of anxiety, as women needed to have sufficient mental capacity to filter through information and determine what was useful and appropriate for their circumstances.

Maybe you read too much and then you give yourself anxiety. Let's say [the information states] you cannot eat [too much of this], then you'll [wonder if you're] eating too much. So sometimes, in a way it's more like [a] knowledge burden. Yeah but you need to know how to filter. [Participant 30, preconception]

Theme 4: Perceived Credibility

The extent to which DH tools were deemed credible was described to have a notable impact on their adoption and long-term use. Accuracy and reliability of information and support, along with endorsement by trusted parties through social networks, played a role in shaping the perceived credibility of a DH tool.

Accuracy and Reliability

Women indicated the need to perceive the information and support provided as accurate and reliable. Women brought up challenges in navigating conflicting information from online sources, their social networks, and health care professionals. They suggested that it was essential for DH tools to provide accurate information that aligned with clinical recommendations from health care professionals. Perceived reliability of information was also influenced by the source of information, as women expressed greater trust in the advice provided by medical professionals.

Sometimes [information] can be contradicting so I'm not sure which source to trust. [Participant 9, during pregnancy]

Let's just say they have a moderator, a medical professional [in the online forum], that would answer questions here and there, that could be a game changer. Because then, I would look out for this badge

– okay this [medical professional] says this. So, that would be an edge over a sea of apps. [Participant 14, during pregnancy]

But I was hoping [for information about] medication [that you take] before pregnancy or after pregnancy, or medication [you take] while you are pregnant, breastfeeding and stuff. But sometimes, [information] is inaccurate. Let's say there's some medication, [like] Panadol [that] you can't take while breastfeeding, but the doctor [says] you can take while you are breastfeeding...Trust the doctor or trust the app? [Participant 42, postbirth]

Endorsement by Trusted Parties

Women were more inclined to use DH tools recommended by trusted networks. Most women agreed that gaining awareness about DH tools from their clinicians or health care providers was important in influencing their decision to adopt them.

Definitely if a healthcare provider recommended it. So a lot of the things I have on my phone are to do with [physiotherapy] and all that, they've all come from the [physiotherapist], the lactation consultant, birth class teacher. [Participant 7, during pregnancy]

Social networks that women were already situated in also had a strong influence on their decision-making. Recommendations via word-of-mouth from friends, female communities on online support groups or forums, and key influencers on social media platforms were persuasive in encouraging the adoption of DH tools. Additionally, it was important that these trusted parties were situated in the local context. Another commonly brought-up factor that influenced women's choice of DH tools was the sharing of experiences, such as how other women or mothers overcame their struggles with the support of DH tools. Such positive reviews were perceived as credible information that affirmed DH tools' ability to provide adequate and effective support to help women manage similar challenges.

Asian Parent [online platform with parenting-related content] was recommended because I know of friends who used it. So, I think word of mouth is always more powerful. [Participant 14, during pregnancy]

Recommendations from friends or mummies. If I was on the internet, and it popped up, [saying that]this is the number 1[app]. Not trending app but in your area, maybe, within Asia or within Singapore, this is the app most mummies are using. [Participant 7, during pregnancy]

Women also considered satisfaction ratings and reviews by other users on the internet or application download platforms when deciding which DH tools to adopt.

If it's on Play store, they have reviews and stars, so I kind of read those first. I mean some of them have issues like after an update, it just [does not] work anymore, then I just don't download [those apps]. But I generally go for those that are generally highly ranked. If they are highly ranked, but their latest reviews are actually quite bad, then I don't really [download those too]. Then if I do have one in mind

already, I kind of go and Google for that specifically to see what are the reviews. [Participant 34, preconception]

Theme 5: Perceived Value

The pricing of a DH tool, together with the balance of costs and benefits, played a pivotal role in shaping the perceived value of the tool.

Pricing

Women raised concerns regarding DH tools that required payment as there was a plethora of free applications and information on the internet. Specifically, DH tools that required an upfront fee were a strong deterrence to adoption as women preferred to experience the tool to understand its utility before deciding on the financial commitment.

[I think] what would stop [me from using an app would be] the pricing. So, I'm not too sure how much I would be willing to pay for such an app, because like [I said], everything can be found on the Internet. [Participant 5, preconception]

I think if it's paid, like straight-up a paid app, and I am not sure what the features are, that might prohibit me from paying for it or downloading it. [Participant 4, during pregnancy]

Instead, women were more open to using DH tools that were free but had paid features embedded within the tool, as they were able to make more informed purchase decisions based on its value.

But if it's like Flo, [which is] free to download and then there is paid features that I feel like might be helpful, then I might consider paying for it. So, price might be a challenge. [Participant 4, during pregnancy]

Cost-Benefit Ratio

Women emphasized that their willingness to bear the expenses of DH tools is dependent on whether the cost is supported by its perceived benefits. One feature that women were willing to pay a premium for included teleconsultation features with health care professionals and receiving medical advice.

If it's just to calculate my ovulation, I don't think [I will pay for an app]. But if it's an app that has [in-built] chatbots, where I am able to consult doctors or fertility experts on any subject, then yes, I will [pay for the app]. [Participant 39, preconception]

Other factors, such as perceived usefulness and perceived credibility would increase the perceived value of DH tools. Benefits such as continuous support from preconception to postbirth, including long-term support for their child's health and development, and personalization were brought up to outweigh price considerations. The ability of the DH tool to provide an all-in-one comprehensive platform—integrating health records and incorporating functions of other health apps to reduce app fatigue—was pointed out to further enhance the tool's value.

[I would pay for the app] if it's going to override [other apps] like Health Hub. Otherwise, it would kind of defeat the purpose if I'm on this app to track my baby's progression, [but] at the same time I have to track my baby's health records on Health Hub. [Participant 41, preconception]

In addition, the cost of DH tools needed to be justified by its credibility, through evidence-based information and support.

It depends on the [expanse] of the app. So if it follows me until the baby is two years old, then the amount that I would pay would be [different from] if it allows me to follow through to 8 years instead. [Participant, 41, preconception]

To garner a premium subscription rate, the app must really be personalized, or must really have sufficient evidence, [so] that it's worth the subscription fee. [Participant 5, preconception]

Discussion

Principal Findings

Our study identified the major themes that influenced women's adoption of DH tools from before, during, to after pregnancy. Depending on the stages they were in, women applied different considerations of those themes. For instance, the level of time and effort required to engage in DH tools was more salient to women as they were unlikely to devote time out of their busy schedules preconception, or out of their priorities to caring for their newborn postbirth. By accounting for the varying challenges faced by women in different stages, DH tool developers can improve user engagement with the tool and sustain use over time.

Unified Theory of Acceptance and Use of Technology (UTAUT) 2 Model

The 5 main themes and 10 subthemes discussed were mapped based on existing literature on IT use, specifically the Unified Theory of Acceptance and Use of Technology 2 (UTAUT 2) model. UTAUT 2 consists of 7 factors identified to contribute to the acceptance of technological tools: performance expectancy, effort expectancy, social influence, facilitating conditions, hedonic motivation, price value, and habit [27]. UTAUT 2 has its roots in the UTAUT model, which was formed by empirically comparing 8 other models and deriving the primary factors affecting technology use [27]. UTAUT 2 expands UTAUT with factors focused on behavioral intention to use the technology [27].

The themes of perceived usefulness and perceived ease of use identified in our study can be mapped to performance expectancy and effort expectancy respectively in UTAUT 2. The quality of information women received and the extent to which they believed the information fulfilled their needs determined their perceived usefulness of the DH tool and was therefore likely to influence their intention to adopt it. As women progress through different stages, their informational needs would change accordingly (eg, different information relevant to specific trimesters across pregnancy) [23,24]. Having a DH tool that caters to information and features specific to a

particular stage in time would naturally improve engagement [26]. The predictability of informational needs from before to after pregnancy can offer a guide to DH developers in providing relevant content to women, thus improving their perceived usefulness of the DH tool. Additionally, enhanced antenatal education for women on improving long-term health outcomes would serve as motivation for higher quality information [16], thus highlighting the importance of perceived usefulness in the use of DH tools. Likewise, for effort expectancy, their experiences and the resources required of them in terms of time and effort would determine their perceived ease of use of the tool.

Under the theme of perceived credibility, there were two subthemes that emerged as follows: (1) the endorsement by trusted parties and (2) the accuracy and reliability of information. The subtheme of endorsement by trusted parties can be likened to the factor of social influence under the UTAUT 2 model. In addition to social influence being a key factor for the adoption of DH tools (as in UTAUT 2), the trust it invokes and the way it is marketed also influenced women's intentions to adopt it. Interestingly, while the UTAUT 2 model predicts the significance of the social influence factor when tool use is mandated [27], in our study, endorsement by trusted parties was highlighted where the use of DH tools by women was not mandatory. The subtheme on the perceived quality of information is not directly linked to any of the factors in UTAUT 2. It is plausible that women in our study who looked for information online were exposed to information that was not verified or reliably accurate [28]. This contrasted with other available trusted sources and may have led to the emergence of this specific subtheme. Overall, while perceived credibility is not a factor in UTAUT 2 in its entirety, current literature shows the rising importance of perceived credibility as a predictor of intention, over factors such as DH literacy in DH tool adoption [22,28]. The theme of perceived credibility and its relationship with social influence prompts further research into the significance of social influence and its nuances for technology adoption specific to a particular deployment context. In one example, public health care is a widely provided good in Singapore, and Singapore residents express trust in public health care and government services. As such, based on our study, promotion, and endorsement by government or public health care professionals may support the perceived credibility of the DH tool and in turn, promote adoption of the tool [29].

Another theme that emerged was perceived value, similar to the factor of price value on the UTAUT 2. Perceived value focuses on the subjective value that women assign to the DH tool, rather than the absolute price value of it as defined in UTAUT 2. Women revealed that they often performed a subjective cost-benefit analysis before deriving the absolute price value they were willing to pay for the DH tool. In addition to considering the pricing of the tool, women would weigh costs against the subjective benefits they derive from the tool. When pricing the tool, it is important to understand what women take into consideration to estimate their willingness to pay in any given tool deployment context. In Singapore, as public health care programs are subsidized or provided for free, women also

tend to expect the prices of tools to be subsidized, or free-of-charge [30,31].

Another theme that emerged in our study, women's preexisting attitudes toward DH, can be reflected by the UTAUT 2 factor of facilitating conditions, stipulating that women's attitudes and their prior experiences would influence their perception of the new tool. Women in the preconception, pregnancy, and postbirth groups collectively used over 34 different DH apps for a variety of functions such as physical health monitoring; government and public health-related; mental health; and fertility-, pregnancy-, and child-related health (Multimedia Appendix 1). This indicates that women are experienced with DH use, which is aligned with the growing prevalence of DH use by women in Singapore [32]. Women who have had negative experiences with app use may hesitate when faced with another similar app again [33]. Analogically, positive experiences may reinforce positive attitudes toward a new DH tool.

Out of the 5 themes from our study, 2 themes can be fully (ie, perceived ease of use and perceived usefulness) and 3 themes can be partially (ie, perceived credibility, perceived value, and preexisting attitudes to DH) mapped to the factors listed in UTAUT 2 [27]. In addition, the model has to be contextualized to the deployment environment, and the differences between the themes that emerged in our study and the factors of UTAUT 2 warrant further research. Additionally, there were 2 other factors in the UTAUT 2 model that did not emerge as themes in our study: hedonic motivation and habit. It is possible that while habitual use may determine DH use, women could end up switching between DH tools catering to different needs too often to form a habit. Women may also perceive the use of DH tools to be limited to their reproductive journey and hence may not form a habit as opposed to DH tools for long-term health [34]. It is also possible that while those factors were at play, the participants' lack of awareness or expressiveness did not allow us to capture these factors with the deployed methodology. This area warrants further research. Nevertheless, UTAUT 2 shows high potential as a model used to understand women's DH engagement during their reproductive journey.

Adoption Intention and Sustained Use

The behavioral intention to use a DH tool has been previously shown to vary across the user journey, from the initial adoption to continued use [35]. It was the case for women in our study as well. The 5 identified themes exert different influences on their decision-making at different timepoints in their journey. Themes such as preexisting attitudes toward DH, perceived credibility, and perceived value are more pertinent in influencing adoption intention. For instance, in the early adoption stages, women's motivation to adopt a DH tool was more significantly influenced by their preexisting attitudes toward DH, shaped by previous unpleasant experiences or lack of understanding of DH tools. Women also sought recommendations from their surroundings to form the perceived credibility of the DH tool in determining if they would want to adopt it. Similarly, the UTAUT 2 model on technology adoption identified social influence to be pertinent to women, especially in the early stages of adoption [27]. This was confirmed by our study where women mentioned that recommendations about DH tools from their

trusted social networks would have enhanced their early adoption of the DH tool. Additionally, the theme of perceived value has been shown to factor into user intention [36], where women preferred free-to-use apps with only a small minority willing to pay for the tool.

Themes such as perceived usefulness and perceived ease of use are relevant to both early adoption and sustained use of the DH tools. In terms of early adoption, the perceived usefulness and perceived ease of use have been shown to influence the intention to use [35]. The ability of the tool to meet women's needs in specific phases and transition across phases (eg, from pregnancy to postbirth), and a smooth experience using the tool emerged as desired factors that motivated sustained use in the long run. Additionally, women in our study highlighted the expected effort required for the DH tool as a determinant of its long-term use. This could be due to the changing needs and bandwidths of women over different phases of motherhood, which affect their capacity to manage the expected effort in sustained use of a DH tool, which calls for individualized requirements and informational needs [23,24]. As women navigate each phase, this would necessitate adapting to new features of the tools and resources required of them. The relatively rapid and predictable timing of the transition from one phase to the next is inherently useful and can be harnessed to sustain engagement from one phase to the next. Interestingly, prior studies suggest that effort expectancy is not a predictor of continuous use [35], and such discrepancy would require further research.

There are many studies examining the difference between the early adoption and sustained use of information systems [35,37]. There is a gap, however, in the understanding of these 2 elements for DH tools adoption by women from before to after pregnancy. In this study, we propose how the 5 discovered themes interact with these 2 elements and note the role of the deployment context in the realization of these elements.

Future Directions

This study works as a foundational inquiry into understanding women's needs and expectations, in line with the principles of co-design [38]. The potential next step could include the generation of the content-strategy-design guide—a deep dive into the specific components of the tools, such as content, appearance, workflow, and integration with the system and the existing user journey [39]. By eliciting themes that are the most salient to women in their reproductive journey, these insights can serve to inform DH tool developers in designing ways to improve engagement with a DH tool. Such a strategy has been used before, where qualitative methodology was employed to co-design a DH tool for women in pregnancy [30]. Table 2 summarizes the insights and recommendations that emerged from our study. Along with technology expectations in Table 1, this could provide specific guidance in designing frequency of use, sources of information, and the preferred information topics at each phase from preconception to postbirth.

Table 2. List of recommendations based on women's identified challenges and motivators in the adoption and sustained use of digital health tools.

Theme and subtheme	Recommendation
Perceived ease of use	
User experience and interface (UX/UI)	Consistent updating and maintenance of apps
Level of effort and time required	Adjusting the use of the app to user's availability
Perceived usefulness	
Need fulfillment and continuous support	All in one tool allowing women to use it consistently from preconception to postbirth, covering multiple functions
Perceived credibility	
Endorsement by trusted parties	Encouraging adoption by getting trusted endorsements from fellow mothers and health care providers (gynae, etc)
Perceived value	
Pricing	Accounting for localized context where users expect free-to-use apps

Limitations

As 79.5% (35/44) of our participants were of middle to high SES, the results of our study may have limited generalizability, especially stemming from their prior familiarity with technology. Additionally, the recruitment criteria included English fluency. Further research can investigate the perceptions of lower SES groups and non-English speakers to examine the validity of the identified factors affecting sustained adoption. Last, women who had used or were using assisted conception were excluded, similarly to women who had current diagnoses of psychiatric disorders. These women might face vastly different struggles and considerations to the population we examined which could potentially be supported by various DH tools as well. This calls

for future research to examine the applicability of our findings to these populations of women from before to after pregnancy.

Conclusion

The study examined the factors affecting sustained adoption of DH tools for women from before to after pregnancy and mapped them according to the UTAUT 2 model. Our study shows that the UTAUT 2 model can broadly reflect the adoption of DH tools in women from before to after pregnancy. Specific considerations of the cultural implications are needed in its application to the context of Singapore, a highly tech-pervasive Asian society, which is different from the European and African contexts where prior DH adoption studies have been conducted. Additionally, understanding the interactions of the themes with

early adoption and sustained use could support DH design in ensuring both uptake and long-term use. There are various considerations to be noted in the design of DH tools for women's preconception to postbirth to promote engagement, and tool design should be a regular iterative process to continuously improve the ability of the tool to meet women's needs.

Authors' Contributions

VVL, SV, DSQO, LLS, YSL, SYC, AB, and DH conceived the study. VVL, SV, and DSQO were involved in protocol development and gaining ethical approval. VVL, SV, WYN, NYL, and QYL were involved in participant recruitment, data collection, and data analysis. WYN and NYL wrote the first draft of the manuscript. All authors reviewed and edited the manuscript and approved the final version of the manuscript.

Conflicts of Interest

AB and DH are coinventors or previously filed pending patents on artificial intelligence-based therapy development. DH is a shareholder of KYAN Therapeutics, which has licensed intellectual property pertaining to AI-based drug development. SC reports grants from Société Des Produits Nestlé S.A. outside the submitted work and is a coinventor on patent filings by Nestlé S.A. relating to maternal supplements. SC has received reimbursement from the Expert Group on Inositol in Basic and Clinical Research (EGOI; a not-for-profit academic organization) and Nestlé Nutrition Institute for speaking at conferences. All other authors declare no financial or nonfinancial competing interests.

Multimedia Appendix 1

Annexes of pre- and postinterview questionnaires, interview framework, demographic data, and mobile application usage data of participants.

Abstract

Background: As a reaction to the global demographic increase in older adults (aged 60+ years), policy makers call for initiatives to enable healthy aging. This includes a focus on person-centered care and access to long-term care for older adults, such as developing different services and digital health technologies. This can enable patients to engage in their health and reduce the burden on the health care systems and health care professionals. The European Union project Smart Inclusive Living Environments (SMILE) focuses on well-being and aging in place using new digital health technologies. The novelty of the SMILE project is the use of a cocreative approach focused on the needs and preferences of older adults with chronic obstructive pulmonary disease (COPD) in technology development, to enhance access, adaptation, and usability and to reduce stigma.

Objective: The study aimed to describe the perspective, needs, and preferences of older adults living with COPD in the context of the design and development of a conversational agent.

Methods: This study carried out a data-driven thematic analysis of interview data from 11 cocreation workshops with 33 older adults living with COPD.

Results: The three particular features that the workshop participants wanted to implement in a new technology were (1) a “my health” function, to use technology to manage and learn more about their condition; (2) a “daily activities” function, including an overview and information about social and physical activities in their local area; and (3) a “sleep” function, to manage circadian rhythm and enhance sleep quality, for example, through online video guides. In total, 2 overarching themes were identified for the 3 functions: measurements, which were actively discussed and received mixed interest among the participants, and health literacy, due to an overall interest in learning more about their condition in relation to everyday life.

Conclusions: The future design of digital health technology must embrace the complexities of the everyday life of an older adult living with COPD and cater to their needs and preferences. Measurements should be optional and personalized, and digital solutions should be used as a supplement to health care professionals, not as substitute.

Introduction

Background

Global policy makers have demanded maintained action and initiatives to enable healthy aging in all parts of the world. The United Nations and the World Health Organization (WHO) describe healthy aging as “developing and maintaining the functional ability that enables well-being in older age” [1]. The proportion of older adults will double from 1 billion to 2.1 billion between 2019 and 2050 globally [1]. As a reaction to this demographic change, areas of action suggested in the *UN Decade of Healthy Ageing: Plan of Action 2021-2030* include person-centered care and access to long-term care for older adults, such as developing different services including assistive technologies [1].

Cocreating Technology With Older Adults

The European Union Horizon 2020 project Smart Inclusive Living Environments (SMILE), a collaborative project among Denmark, Norway, Canada, the Netherlands, and Greece, draws on practical situations that older adults face in daily life to create smart living environments (SLEs) with novel eHealth solutions. The project intends to assist older adults with chronic obstructive pulmonary disease (COPD) to maintain their independence in the comfort of their own homes. The project emphasizes the involvement of older adults by identifying their needs and preferences and by involving them in co-designing and testing a new technological solution [2]. The technological solution that is cocreated with end users in the SMILE project is a conversational agent (CA), designed to facilitate daily communication online through a weblink that can be accessed on a smartphone, tablet, or computer.

In SMILE, qualitative cocreation workshops are used to enhance the practical involvement of older adults in the development of technology. This highlights one of the novelties in the SMILE project, as earlier cocreation or participatory design processes have not succeeded in facilitating active participation in all phases of a design process, from the initial needs identification to the final evaluation phase [2]. The aim of the cocreation workshops is to provide a secure environment where participants can share their daily experiences and thoughts about their health conditions, preferences, needs, and daily activities. These workshops also serve as exploratory sessions for both the participants and the researchers in facilitating the generation of ideas for future technology design and development [3].

The Living Labs

The SMILE project uses the concept of “living labs” to study the use and impact of new digital technology on older adults’ daily lives. A “living lab” is a user-centered, open ecosystem that enables the integration of research and innovation processes into real-life communities and settings [4]. Using living labs has the advantage of being independent of existing economic models and policies, making it possible to challenge existing societal structures by providing suitable arenas for testing new ideas [5].

The Danish SMILE living lab “PreCare,” was launched in 2018 and operates in a collaboration between the Odsherred

municipality and Region Zealand. PreCare offers digital and outward-bound homecare treatments to older adults living with COPD and has approximately 150 older adults enrolled. PreCare works in dynamics between innovation, development, implementation, operation, and analysis based on an action research-based “plan-do-study-act cycle” [6] and is therefore in constant development. The Norwegian SMILE living lab is located in Gudbrandsdalen, a rural valley consisting of 12 municipalities. In Norway, the number of people over the age of 80 years will almost double in rural areas by 2040 [7,8], posing significant challenges in the context of demographic aging. In rural Norway, the long distances between people, workplaces, public services, care services, and institutions are challenging for older adults who age in place, especially those who have chronic conditions [9]. In SMILE, these challenges are used to collaborate closely with older adults with COPD, engaging them as co-designers and using qualitative methods to explore their lived experiences and needs [10].

Interprofessional Collaboration

With the SMILE project’s intent, interprofessional collaboration is promoted, and existing structures and roles among patients, health care professionals, and informal caregivers are challenged [11]. Older adults, their social network, and health care professionals must be capable and willing to use these new technologies for the “smart inclusive living environment” to fully work.

Traditionally, health care professionals provide care to patients, with minimal involvement of the patients. This has gradually changed to an increased collaboration among health care professionals, patients, and informal caregivers. In the WHO’s global strategy on integrated and people-centered health services (2016-2026), people, patients, and communities are placed at the center of health services. The strategy emphasizes that the care should be organized around the health needs and expectations of people and communities rather than a specific disease. People have individual preferences, needs, and abilities, and therefore should not be understood as patients defined by their disease [12]. Therefore, innovative initiatives toward more patient-oriented activities in health care are needed, such as the co-design of new digital solutions as carried out in the SMILE project, as well as the development of new digital solutions to support both patients, citizens, and formal and informal caregivers.

Methods

Overview

The empirical data presented and analyzed in this study were collected through 11 cocreational workshop sessions in Denmark and Norway with people living with COPD. The analysis was thematic and privileged the participants’ descriptions and perspectives that were related to their reasons and relevance criteria for the design and use of the CA.

Aim

The aim is to describe the perspective, needs, and preferences of older adults living with COPD in the context of the design and development of a CA.

Participants, Recruitment, and Eligibility

A total of 33 older adults living with COPD participated in the SMILE cocreation workshops. In Denmark, 21 participated, and in Norway, 12 participated. Participants were recruited through health care partners as a part of their enrolment in the SMILE living labs. Access to the participants was established through the registered nurses at each living lab, and participants were then contacted through email or phone by the researchers. Participants were eligible to participate if they were aged 65 years or older, lived with COPD, and were able to fill in the Readiness and Enablement Index for Health Technology (READHY) instrument and take an active part in the cocreational design workshops and evaluation. Oral and written consent was obtained from all participants before the workshops (Multimedia appendix 1).

The saturation or information power of the sample size in this study was addressed based on the 5 items impacting information power in qualitative research presented by Malterud et al [13]. These included the following: (1) the study aim is specific and therefore can hold fewer participants, with its focus on identifying needs and preferences and with the purpose of cocreating a technology, through an iterative process; (2) the sample specificity is relevant to the study aim and is limited to older adults with COPD, but has variations regarding technology readiness; (3) theoretical frameworks included READHY and concepts presented by Yock et al [14] to cocreate technology with end users; (4) the dialogue with the participants was clear and followed a semistructured interview guide, which often requires fewer participants; and (5) the strategy for the analysis is an in-depth analysis of themes and narratives, for example, not a cross-case analysis where more participants often would be needed [13]. Based on these, saturation for this study was achieved.

Ethical Considerations

Informed consent was obtained from all humans participating in this study. Data obtained from participants was handled according to General Data Protection Regulation (GDPR). Our research has followed the declaration of Helsinki's ethical principles for medical research involving human participants. In Denmark, health science questionnaire surveys and interview studies that do not involve human biological material (section 14(2) of the Danish Act on Committees) do not require reporting or approval from the Danish National Centre for Ethics [15]. In Norway, the field studies were approved by the data protection officer at Innlandet Hospital Trust (journal 14832226).

Data Collection

Cocreation Workshops

The empirical data were gathered through 11 cocreation workshops: 5 in Denmark and 6 in Norway. Each workshop had a duration of 2 hours, and between 2 and 5 participants were present at each workshop. The CA was developed through 3 design iterations and the workshops were conducted before each iteration, meaning that there were 3 phases of the workshops. Each workshop phase had different purposes, which corresponded to the development of the CA.

The purpose of the first phase of the workshops was to elaborate on early ideas, to present and discuss 9 possible functions, and to narrow these down to 3 or 4 prioritized functions based on input from the participants. In total, 4 prioritized functions were identified in the first phase of the workshops, which were (1) physical activity, (2) clinical condition, (3) social activity, and (4) sleep. These 4 functions were then implemented in a CA mock-up. After each workshop, a summary report was written and provided to the technology developers, to inform the development of the CA based on input from the participants.

The purpose of the second phase of the workshops was to present the CA mock-up to the participants and gather input that could be used to develop the CA prototype version 1. The mock-up presented to the participants was built in Botpress [16] and consisted of a basic chatbot with predetermined dialogues that concentrated on the 4 functions identified as relevant by the participants during the first phase of the workshops. The functions and mock-up were discussed with the workshop participants. This phase resulted in changing the features, that is, social activity and physical activity were merged into one feature called "daily activity." There were changes to the interface and the conversation strings, and an onboarding feature that teaches users how to interact with the CA was included.

The third phase of the workshops was used to elaborate on the participants' perceptions of the content and functions of the CA prototype version 1. The prototype contained an onboarding feature and three main functions: (1) my health, (2) daily activity, and (3) sleep, which were developed based on input from the participants from phase 2. Findings from the third phase were used to develop the CA prototype version 2.

All workshops were audiotaped. Before data from the workshops were analyzed, sound recordings from the cocreation workshops were transcribed verbatim in the native languages at each living lab site [17]. In analyzing the transcriptions, relevant parts presented in this study were translated into English. EKW carried out the transcription and translation of the Danish material, and JMB carried out the transcription and translation of the Norwegian material. All translations privilege clarity of meaning over the verbatim transcripts.

Thematic Analysis

This study conducted a thematic analysis of the data from 11 cocreation workshops. The thematic analysis was inspired by Braun and Clarke [18]; concepts of data-driven analysis; and a realist approach to give voice to the data and the realities, meanings, and experiences presented in the data. As a part of the workshops, the themes "my health," "daily activity," and "sleep" were established, which corresponded to the most desired functions among the participants to implement in the CA. The analysis focused on identifying and reporting themes and patterns within these 3 functions. This was not based on coding or specific prevalence of the themes identified but through addressing overarching themes of relevance for the 3 most desired functions addressed by the participants [18]. Finally, the thematic analytical approach was inspired by Borgnakke [19], to strengthen the innovative and thematical analytical approach, inspired by practice-oriented research methods.

All researchers took an active part in processing the data, enhancing the process of addressing possible blind spots, and understanding several ways to see the data [20]. In this process, the researchers also acknowledge their active role in the identification, selection, and presentation of themes and patterns from the data in this study [18].

The thematic analytic approach corresponds to the interest in strengthening the relationship between technology development and the participant's needs and preferences, as well as in cocreating digital health technology that can support older adults' healthy aging and everyday life. By starting technology development from the participant's preferences and needs, focusing on meaning-making rather than on adopting a consensus-driven approach, the thematic analysis can help sharpen the sense of themes, problems, and dilemmas seen from the older adult's perspective, reasons, and relevance criteria. With this analysis, the aim was to capture the relevant themes and layers based on the participants' thematizations and problematizations and thus increase insight into everyday use situations and challenges.

The transcribed and translated data have not been presented to the participants, and member checking of the analysis has not been conducted [21]. However, due to the iterative approach in the cocreation workshop process, the findings were addressed and validated through the 3 ongoing workshop phases.

Results

Overview

In this section, results from the thematic analysis of data from 11 cocreation workshops are presented. The purpose of the analysis was to acquire knowledge and insight into older adults' own experiences and formulations on important topics and dilemmas connected to their everyday lives in the development of the CA. The results are summarized according to the 3 embedded functions in the CA: "my health," which addresses the user's health condition; "daily activity," which informs about both physical and social activities; and "sleep," which addresses circadian rhythm.

My Health

My health was one of the top-rated functions from the beginning of the cocreational process. The participants argued that their health is the most important thing they have. One of the first things addressed by some of the participants was that they want to learn more about their health condition, that is, they want to increase their health literacy. Examples included general information about COPD, for example, "when were you diagnosed with COPD?" "What are the different levels of COPD?" and other commonly asked questions that could be provided to them through the CA. Doing inhalations correctly was also highlighted as an important aspect of their daily life with COPD. Therefore, participants suggested that the CA could contain guides, written or video, on how to do inhale measurements.

An important thing [in relation to my health] is inhalation-technique...it is critical that a patient inhales correctly and is measured on whether you get

it down where it needs to be...you can look up some videos on YouTube, they can show it...if there was a video link to a nurse and the citizen had a whistle at home. Then I am sure that it could happen on a video that the person sat and breathed, and the nurse instructed. [M1]

An important aspect of the CA development and the function "my health" was that the participants raised concerns about the technology replacing their contact with health care professionals. A lot of the participants were positive toward new technologies in general, and over half of them already used different types of technologies in their everyday life including smartwatches, smartphones, and in-home measuring tools for their condition, for example, technologies provided to them by PreCare. But if a technology was implemented to replace their contact with health care professionals, they were not interested in it.

Well, I absolutely don't agree that technology is a good thing [if the idea is to replace human visits], because my daughter works in healthcare, and she said they're developing things now so they can call you and have this setup where they can check if you have a fever and see everything. What about the poor old folks at home who are isolated? Maybe the home care personnel are the only person they see? [M2]

I was also offered when I came into PreCare that I could have a conversation on that tablet, right, then I said I wouldn't agree to that. If I'm going to have a conversation, it has to be face-to-face...but I may be old-fashioned. [F2]

The participants mostly trust information from health care professionals. However, they were open to reading health-related information through the CA but required that this information refers to a trusted site, such as *medicin.dk* or *sundhed.dk* in Denmark and *Folkehelseinstituttet* or *Helsenorge* in Norway.

The participants had different needs and interests about the extent and frequency of monitoring their condition. Some participants were interested in measuring a few health data, for example, blood pressure and oxygen saturation, and some were interested in measuring more. Moreover, some participants were interested in measuring their condition daily, and some preferred measuring whenever they felt like it.

I do measurements as much as I can remember to do it...and I feel good about that. [M2]

I do measurements every day. [F2]

I do my saturation measurements at about 10 or 12...then I can see if the measures are not bad...or think why I am feeling the way I am, oh yes, I can see that on the measurements. That is actually a good indicator for me... [M2]

Arguments for wanting to measure their condition daily included getting a feeling of insight into their condition and a general feeling of being aware of their current health state. Arguments against daily measurements included being reminded about their condition and having to identify with it daily. This shows the conflicting feelings and needs when being a patient who receives

treatment by the health care system and a person living everyday life with a chronic condition.

I feel a bit ambivalent about it because it annoys me so much that I have to measure my condition every day because then I become aware of it and sometimes, I can't quite get it to hit the numbers I want to. I try again and then it gets even worse and then I get irritated and stop. [F2]

The different preferences in terms of usage led to a discussion on how to personalize the CA. The participants suggested a “my profile” function that can help personalize the CA and add or remove measurement units as wanted. This function could also hold data such as height, weight, and information on current medicine intake, etc, that can be entered if relevant.

The participants also suggested the option of sharing their data stored in the CA with health care professionals and informal caregivers. This statement was however not shared by all participants; some found it very relevant, to be able to share data with family or their general practitioner, and some found more value in the data being private, as they did not want to worry or burden their loved ones.

In sum, the “my health” function is highly relevant to several workshop participants, as they state that “our health is the most important thing we have.” The relevance of the function is highlighted in the participant’s wish for more information and knowledge about their condition, guides to do proper in-home measurements daily and comprehensive measurements of different parameters, and the possibility of sharing this data with health care professionals and informal caregivers. However, not all participants shared this view fully, and nuances were identified. Some participants did not wish to measure daily, some wished to measure selected parameters, and others did not want to share their data with others. Therefore, the need for personalization of the app in a “my profile” function was identified.

Daily Activity

The daily activity function was created as a merge of the 2 top-rated functions—physical activity and social activity—based on ongoing input from the workshop participants. In a brainstorming session, participants suggested that the “daily activity” function should be able to suggest social activities in the local area; motivate them to be active, for example, through text or voice reminders; be able to monitor their activity, for example, through step count; and have an incorporated walking community feature, as some participants found it motivating to walk with others.

I have a “walking-friend”...and we walk together once a week, that could be a thing? Maybe that could be a part of this [the technology]. [M1]

It [the technology] could for example suggest you contact your walking friend. [M2]

Some participants also suggested incorporating knowledge or management of lung capacity in this function, both to learn about how much physical activity they can do in a day and for how long based on their individual condition to feel safe when

going outside, as well as inspire easy physical exercises and activities at home.

For the social activities, participants proposed receiving suggestions of social activities in the local area; receiving reminders about activities, for example, pop-up reminders or through a calendar function; or inspiring them to attend social communities for example, “COPD friends,” knitting clubs, and lung choirs.

It's about knowing what is happening in the local area. I started in a knitting club, and I can't knit, and I am probably 20 years younger than the other people there, but I have fun, then I just draw or do pearls. It's the social aspect, and just getting out of the house. [F1]

Participants suggested merging physical and social activities, among others, because the participants had different needs and preferences related to physical activity. Some participants had a high activity level and associated physical activity with exercising in a gym. They wanted reminders on planned workout sessions, motivational messages, and inspiration for different exercises; wanted to use sensors, wearables, or smartphones to track their progress; and suggested features such as “my goals” and “my progress.”

It's a bit funny when you now have the option [to count steps] I catch myself getting annoyed when I've forgotten my phone when I've gone places, then you don't know how much you've walked. [F1]

You somehow get happy when it says “you did it”...that means something. [F2]

The other group of participants had a lower activity level and associated physical activity with taking out the trash or cleaning the house. This group was also open for activity tracking and goal setting, but also highlighted adding breathing exercises for people who use oxygen supply.

The function could be called daily activity, because doing the dishes or something else, everything counts, anything that gets you out of the couch....it is an exercise just going to the bathroom, at least for me it is, everything counts, so you don't feel like you are not doing anything at all. [F2]

The participants also emphasized that physical and social activities for them are often connected, since just getting out of the house or going for a walk with someone covered both functions. Also, some participants struggled to see how the CA could add value when it measured the same things that they already did on their smartphones, for example, step count. Therefore, the social activity function was appealing to a lot of participants, as they did not have a lot of experience in using technology to find social activities. The daily activity function should ideally according to the participants be able to suggest social activities, both online and physical, for example, cinema, theatre, concerts, lung choir, etc. This would motivate and inspire them to do new things and preserve or boost their social life. A calendar function was suggested to help them keep track of upcoming activities, including social activities, daily

household activities, physical activities, doctors' appointments, medicine, etc.

In sum, both social and physical activities are important to several of the workshop participants. The participants had different needs in relation to physical activities, as some had a high activity level and some had a lower activity level according to their condition and personal wishes. Participants were open to receiving motivational SMS text messages, but this should be optional; thus, the need for personalization of the CA is still relevant for this function. The participants highlight that physical and social activities, for them, are widely connected and therefore wanted input on social activities and gatherings in the neighborhood. The social activity element adds value to the function, as some participants already measured their steps daily through other technologies but were not familiar with using technology to initiate social activities.

Sleep

The sleep function was well discussed from the beginning of the workshop phases. Some participants did not think that the function was relevant, and others claimed sleep quality to be very important. For the thematic analytical framework, it is important not to stop at this finding. The technology development depends both on the findings of the different opinions and on the specific reasons given by the participants. Those who found it important that "sleep" was included in the CA development justified it with a meaningful aspect, which was "if you don't sleep well, your whole next day is ruined."

It [sleep] is important for how you feel during the day, that you sleep well. Personally, I often sleep like hell, and then the day after is ruined. Then you can't get anything done the next day... [M1]

But what this simple justification refers to is, in the perspective of everyday life, a large and complex problem. If the series of weekdays is ruined by poor sleep, then the seriousness and magnitude of the reason are understood. Participants asked for ideas and help to fall asleep, as this was often a struggle. When it comes to measuring sleep, participants had mixed opinions; some stressed that they did not need technology to tell them that they had a poor night's sleep, and others already used a wearable such as Fitbit (Google) to track their circadian rhythm. Something that was further stressed by this discussion was that the measurements should not be forced; they should be based on need and interest, and not mandatory day-to-day measurements.

I know how much I sleep and whether I've slept, I don't need that. [F1]

I think it is probably very different...because there are many who have a little bad sleep, so if they could find out why you have it then you can do something about it, because it means a lot for the whole day, if you have had a bad night, you have a bad day too. [F2]

Meanwhile, some participants said that they have gotten the right medication and therefore sleep was not something they worry about. Another participant highlighted that if he wakes up during the night, this is not an issue for him as he is retired

and can just sleep in if he wants to. Another participant says that this feature could be useful—only if the CA could tell him when he needs to consult a professional for help solving problems related to sleep, instead of him trying to solve it himself.

Together, these descriptions are illustrative of the heterogeneity of needs in relation to sleep. This may indicate that the sleep feature may need a longer co-design process to be able to catch all nuances that evolve as the participants learn about what the technology may do for them. Specifically, the following features were suggested for the sleep function: advice on how to fall asleep, advice on when to consult a medical professional, reminders to wake up and get oxygen, information on how to get better sleep quality, information on the impact of different medicines on sleep, and ideas for calming breathing exercises.

By starting with the older adults' reasons and preferences, the thematic analysis sharpens the sense of proportion. Next, the practical suggestions linked to the technical aids or informative COPD-related details allow themselves to be placed with greater precision in relation to the older adults' perception of technological measures as desirable or not, or useful or useless in everyday use.

Importantly, measurements of sleep were raised several times in conjunction with discussions about this feature. These discussions highlighted that the participants had mixed feelings toward measurements. All participants imagined that such measurements could be useful, but that it must also be optional.

Discussion

Principal Findings

In this section, the principal findings based on the 3 themes—my health, daily activity, and sleep—are summarized and discussed in relation to the overarching identified themes, measurements, and health literacy.

The workshop participants expressed strong interest in the "my health" function; some asked for comprehensive information and knowledge about their health guides to proper in-home measurements, highlighting the interest in increasing health literacy, which was identified as an overarching theme, and the ability to share data with health care professionals and informal caregivers. Measurements were also identified as an overarching theme, and it received mixed input; the participants had different preferences regarding the frequency and capacity of measurements. Therefore, personalization of the CA is necessary, which can be achieved through a "my profile" function enabling individualized setup.

Participants emphasized the importance of social and physical activities within the "daily activity" function. Different needs were identified, as some had a high activity level and others had a low activity level due to their condition. Personalized motivational messages were welcomed optionally. The participants highlighted that physical and social activities for them are widely connected; therefore, social activities and gatherings in the local area to get them out of the house were requested. Social activities added increased value to the function,

as some participants already tracked their steps daily through other technologies.

Participants had a mixed interest in the “sleep” function. They argued that if you do not sleep well, your whole day is ruined. Some participants also wanted information on how to fall asleep easier, sleep patterns, and tips for better sleep. Measuring sleep was debated, with some finding it useful and others invasive if not optional.

Measurements

SMILE focuses on older adults’ needs and preferences in undertaking a cocreational approach to technology development. The older adults in the project are participants in developing the CA, patients with chronic conditions, citizens in a community, and users of the CA. As identified in the workshops, not all participants want to be reminded that they are patients every day, for example, through daily measurements, and a lot of emphasis was placed on the importance of social activities being a part of the CA. However, with the implementation of new health technologies, the borders between private homes and the health care system are torn down, including technologies entering citizens’ homes, enabling daily measurements.

Measurements are a cross-cutting theme and a common focal point for the SMILE project’s technology development and for the workshop participants’ decision on technological aids. Daily measurements seem to be an important feature that can optimize and aid participants through, for example, novel health technologies, such as smartwatches. However, daily measurements did receive mixed interest. The workshop participants highlighted that being measured every day, as a person living with COPD, is for some valuable and others harmful. Regardless of this, measurements must be seen in conjunction with other themes, such as physical activity. Some participants already measured their physical activity through Fitbit or on their smartphone (eg, step count).

Moreover, the participants who already monitored their steps daily doubted how the CA could bring them further value. The participants also emphasized that measurement must be easy to do and ideally automatically, as with smartwatches. Participants were open in using one solution, such as the CA, to do daily measurements; if it could collect all the measures, they found valuable as they did not have to measure everything twice.

Based on this, it can be emphasized that measurement must be needs based. Not all participants are interested in measuring several parameters every day. For some participants, the motivation to measure is that they feel ill. During those periods, they feel the need to monitor themselves. Others are motivated to do measurements to follow their condition daily. Regardless, it is important to emphasize that the main attitude of the workshop participants toward the CA was formulated almost as a statement: whatever may be offered to them by technological aids, they do not want it to become a substitute for their face-to-face contact with health care professionals.

Health Literacy

The long-term aim of the development and implementation of the CA is that it can be used by citizens in their own homes,

regardless of health conditions and independently of social and professional networks. Studies have addressed how digital solutions and a focus on more hybrid care models have the possibility of relieving the global burden on health care systems and health care staff [22]. However, these digital solutions need to be perceived as valuable by several actors in the specific health care setting and need to be used “correctly” to prevent adding an extra burden on the staff and to enable widespread adoption among patients [23].

As illustrated in the analysis, the participants are interested in learning more about their health, tracking their physical activities, and getting advice and techniques to improve their sleep. In addition, they are interested in reflecting on their life situation as older adults living with COPD, from an everyday perspective.

At the same time, the thematization possibilities can be seen in relation to the development of professional education, which includes both health skills and digital literacy and deals with cocreational technology development. Theoretical approaches and concepts, such as Negt’s [24] conceptualizations of identity and technological competence, are relevant and can be put into the perspective of the themes and issues raised by the workshop participants. Negt’s statements that “identity competence relates to a lifelong learning process” and that “identity is not determined once and for all” resonate in relation to the results from the first phase of the workshops. In relation to the focus of SMILE and the workshop participants, this means that the orientation and perspective of the participants are challenged, partly by what Negt [24] describes as a reality test between “the well-ordered society” and “the marginalized environments, groups” and partly by the development of health literacy as a, didactically speaking, lifelong interaction among case, knowledge, and experience. Concerning technological competence, the challenges refer both to the development of an ability to distinguish between technologies and to the understanding of technology as a social project. In SMILE auspices, it also refers to the dilemma between the technology development system and patient orientation, with the latter guided by human needs, closer to the participant’s everyday life and experiences.

To clarify the technological user value, there is an implicit demand that older adults with COPD have some degree of both health literacy and digital literacy. Correspondingly, it requires a similar and explicit demand that health professionals have digital literacy, not only in terms of individual competence but in terms of collaborative and patient-oriented competence across professions. Ethnographic studies close to health care practice show examples of patient-oriented interprofessional cooperation as well as how interprofessional competence development can support the bridging between the hospital context and the home context [20,21].

Against this background, the results show that participants in the SMILE workshops prefer not to replace their interaction with health care professionals with technology but are open to using it as an additional tool in care. Thus, if the CA is able to inform the users about health-related topics, it needs to be from trusted sources. The participants emphasize that health care

professionals must be active contributors to address health challenges alongside technology.

Conclusions

Future development of digital health services should encompass the complexities of everyday life among older adults to enhance usability, adoption, and successful use. Participants in the SMILE workshops are interested in reflecting on their life situation as older adults with COPD from an everyday perspective. Participants are open to using new technology, the

CA, to learn about their health, monitor physical activity, and discover social activities in their local area. The CA should not only focus on the “patient” and the condition but also acknowledge the complexities of everyday life as an older adult living with COPD. This means grasping the different needs and preferences of individuals, regardless of their condition, in designing technology is important. Daily measurements should be optional, and digital solutions should be used as a supplement, not a replacement for in-person interaction with health care professionals.

Acknowledgments

The authors thank European Union Horizon 2020 and Smart Inclusive Living Environment (SMILE) for making this work possible. They also thank PreCare, Sykehuset Innlandet Trust, and the municipalities in the Norwegian living lab in Gudbrandsdalen for helping with the recruitment of participants, and above all, they thank the participants for their contribution to this study. This research was funded by the European Union’s Horizon 2020 Research and Innovation Program under grant 101016848.

Abstract

Background: Sepsis is a common cause of serious illness and death. Sepsis management remains challenging and suboptimal. To support rapid sepsis diagnosis and treatment, screening tools have been embedded into hospital digital systems to appear as digital alerts. The implementation of digital alerts to improve the management of sepsis and deterioration is a complex intervention that has to fit with team workflow and the views and practices of hospital staff. Despite the importance of human decision-making and behavior in optimal implementation, there are limited qualitative studies that explore the views and experiences of health care professionals regarding digital alerts as sepsis or deterioration computerized clinician decision support systems (CCDSSs).

Objective: This study aims to explore the views and experiences of health care professionals on the use of sepsis or deterioration CCDSSs and to identify barriers and facilitators to their implementation and use in National Health Service (NHS) hospitals.

Methods: We conducted a qualitative, multisite study with unstructured observations and semistructured interviews with health care professionals from emergency departments, outreach teams, and intensive or acute units in 3 NHS hospital trusts in England. Data from both interviews and observations were analyzed together inductively using thematic analysis.

Results: A total of 22 health care professionals were interviewed, and 12 observation sessions were undertaken. A total of four themes regarding digital alerts were identified: (1) support decision-making as nested in electronic health records, but never substitute professionals' knowledge and experience; (2) remind to take action according to the context, such as the hospital unit

and the job role; (3) improve the alerts and their introduction, by making them more accessible, easy to use, not intrusive, more accurate, as well as integrated across the whole health care system; and (4) contextual factors affecting views and use of alerts in the NHS trusts. Digital alerts are more optimally used in general hospital units with a lower senior decision maker:patient ratio and by health care professionals with experience of a similar technology. Better use of the alerts was associated with quality improvement initiatives and continuous sepsis training. The trusts' features, such as the presence of a 24/7 emergency outreach team, good technological resources, and staffing and teamwork, favored a more optimal use.

Conclusions: Trust implementation of sepsis or deterioration CCDSSs requires support on multiple levels and at all phases of the intervention, starting from a prego-live analysis addressing organizational needs and readiness. Advancements toward minimally disruptive and smart digital alerts as sepsis or deterioration CCDSSs, which are more accurate and specific but at the same time scalable and accessible, require policy changes and investments in multidisciplinary research.

Introduction

Background

Sepsis is an uncontrollable response of the body to an infection, whereby the immune system starts attacking its own tissues and organs leading to organ dysfunction [1]. Sepsis is a common cause of serious illness and death. There are an estimated 918,000 hospital admissions with suspected sepsis, up to 250,000 cases of sepsis, and 48,500 deaths associated with sepsis in the United Kingdom each year [2]. Similarly, high levels of sepsis are reported internationally [3,4], with 11 million sepsis-related deaths calculated for 2017, representing approximately 20% of all deaths globally [5,6]. Sepsis is recognized by the World Health Organization as a global health priority [7].

Sepsis symptomatology can look like that of other conditions, potentially delaying and misleading diagnosis and treatment. As such, sepsis demands prompt intervention to avert poor outcomes [8]. Evidence has shown that timely, appropriately targeted, intravenous antibiotics are effective in improving outcomes for patients with sepsis [9-11]. On the basis of this evidence, hospitals in the United Kingdom have been set targets to rapidly diagnose and administer intravenous antibiotics [12,13]. Other countries have introduced national guidance for sepsis [14]; and the International Surviving Sepsis Campaign updated guidelines for the management of sepsis in 2021. These latter guidelines recommend the adoption of performance and quality improvement initiatives and of protocols and screening tools to improve and accelerate the identification and treatment of sepsis in hospitals [8,15], although these processes remain challenging and suboptimal [16,17].

Prior Work

Interlocking with the complexity of sepsis and the clinical intervention required [1], factors linked to the professional profile and the work environment affect the timely management of sepsis in secondary care. Previous qualitative research with health care professionals (HCPs) has highlighted limits in professionals' capacity to identify sepsis, difficulties in hand over of patients, and errors in communication [18-22]. Time pressures, the intense workload, and the complex clinical

environment are all barriers which need to be overcome; simultaneously, well-coordinated multidisciplinary work and effective leadership are necessary to combine smoothly for effective sepsis management [2,18,20,21].

To support rapid sepsis diagnosis and treatment, screening tools have been proposed. These include the quick sepsis-related organ failure assessment [qSOFA; 1]; systemic inflammatory response syndrome (SIRS) criteria [23,24]; and in the United Kingdom, the national early warning score (NEWS) in 2012 [25,26], updated in 2017 as NEWS2 [12,27]. More recently, machine learning algorithms for early recognition of sepsis have been developed, performing better when compared with the aforementioned sepsis scoring tools [28,29].

With the expansion of electronic health records (EHRs) across the UK National Health Service (NHS), screening tools for sepsis have been embedded into hospital digital systems (DSs) as digital alerts. These digital tools are also known as computerized clinical decision support systems (CCDSSs) and are meant to enhance clinical decision with both targeted and general information [30], but there are also considerable concerns about alert fatigue [31]. There are different ways in which digital alerts, including sepsis or deterioration CCDSSs, interface with users. A total of 3 categories have been identified [32]. Hard-stop intrusive alerts pop up and either prevent users from taking any action or allow them to proceed only with the override of a third party, such as a senior decision maker. Soft-stop intrusive alerts allow the user to proceed after entering a response, often from a multiple-choice box. Nonintrusive, passive alerts do not pop up or interrupt the user workflow or require any interaction on the part of the user. Sometimes these are in-line, for example, an alert appearing in a row of an electronic patient list.

Previous evidence on the effect of digital alerts as sepsis or deterioration CCDSSs (henceforth, sepsis digital alert) on care quality and patient outcomes offered mixed results [33]. Work in NHS trusts in England demonstrated that the introduction of digital sepsis screening tools with their accompanying alerts was associated with an increase in timely treatment and reduction in risk of mortality in 2 trusts [34,35]. Some studies, mainly conducted in the United States, have demonstrated an

increase in patients receiving timely intravenous antibiotics [36,37] and a decrease in in-hospital mortality [38-40] and length of stay [36,41,42], but others have not found any impact either on mortality [37,41,43,44] or hospital length of stay [39].

Sepsis digital alerts, which are embedded into the hospital EHRs DS, fit into the highly complex workflow of the management of sepsis, as any other CCDSSs. Qualitative literature exploring HCPs' views and experiences with sepsis digital alerts is scarce. A recent study [45] found that HCPs' perceptions of a hypothetical sepsis digital alert are linked to the level of trust professionals had in the alert; HCPs' trust was enhanced both by their previous experience with similar alerts and by being engaged in implementation and training initiatives about the sepsis digital alert. In another US-based study, physicians in a pediatric emergency department (ED) were interviewed about reasons for accepting or rejecting a sepsis electronic best practice alert: two-thirds of participants considered nonpatient factors relevant specific to the ED environment, individualized practice patterns, the digital tool design, and education [46].

Goal of This Study

The emerging evidence of the contribution of sepsis digital alerts is promising but still limited; there are no validated digital tools available to NHS trusts, with scarce evidence as to which tool to use and their effect on patient outcomes. In addition, the introduction of sepsis digital alerts is often accompanied by treatment plans, under the aegis of antimicrobial stewardship, and by implementation and quality improvement initiatives and education and training for HCPs; while these have been shown to yield positive results [34,47,48], little is known on how these actions affect the implementation and impact of the alerts.

This study aimed to explore the views and experiences of HCPs on the use of sepsis digital alerts and to identify barriers and facilitators to the implementation and use of sepsis digital alerts in NHS hospitals.

Methods

Study Design

This is a qualitative, multisite study with semistructured interviews with HCPs and unstructured observations of HCPs working in hospitals. It is nested within a broader program of research seeking to evaluate the impact of sepsis digital alerts on patient outcomes and staff activity in NHS hospitals, the Digital Alerting for Sepsis (DiAIS) study.

Sample and Settings

A combination of purposive and convenience sampling was used. A total of 3 NHS trusts were selected as sites for this qualitative study from the 6 hospitals involved in the DiAIS study. The 3 sites were chosen with consideration of diversity in the EHRs DS and in the sepsis digital alerts, previous evidence on the evaluation of sepsis digital alerts [34], and implementation and quality improvement initiatives. Trusts' coinvestigators were asked to identify and invite potential participants for interviews from their trusts. Participants were sampled to include a variety of job roles and a range of hospital units (EDs, outreach emergency response teams, and acute and

intensive care units [ICUs]). In 2 sites (1 and 2), observations were conducted, and coinvestigators supported the research team to this end providing initial liaising with relevant colleagues in ED and the outreach team.

Data Collection

All data were collected between November 2022 and July 2023 by RL and AJ Borek. Most semistructured interviews with HCPs were conducted remotely using videoconferencing software (Microsoft Teams); the remaining were conducted in person at the participant's place of work. The topic guide was developed from the study objectives with input from the wider research team and the study patient and public involvement representative (Multimedia Appendix 1). Questions asked HCPs about their experiences of identifying and managing patients with sepsis and about their views and experiences of using sepsis digital alerts. Where relevant, HCPs were asked about their experience of developing and implementing sepsis digital alerts. Interviews lasted between 30 and 75 (mean 52) minutes, were audio recorded, and were professionally transcribed verbatim and pseudonymized.

Unstructured observations [49] sought to observe clinical practice to see how sepsis digital alerts fitted into the workflows of HCPs in different roles. We sought to assess what impact they had on clinical decision-making and to identify whether sepsis digital alerts were used differently by HCPs in different roles. A total of two types of observation were done: (1) observations of practice in EDs, with occasional informal conversations, and (2) one-to-one shadowing of an HCP in outreach teams, with more frequent dialogue. Either the HCP who expressed interest in being shadowed or the ED head or manager consented in writing before the observations. The observations lasted between 2 and 4 hours. Paper-and-pencil notes taken during the observations were anonymized and typed up.

Data Analysis

Data analysis began concurrently during data collection and was supported by NVivo (version 12; QSR International). Data from both interviews and observations were analyzed together inductively using thematic analysis [50,51]. Similarities and differences between transcripts were assessed using a constant comparison approach [52]. A codebook was developed to code the whole data set, across the 3 sites. Codes were compared with one another to create categories, grouping similar codes together. All categories were clearly named to ensure that only related data were included in that category. However, some codes and categories remained site specific to allow for comparisons between sites. Regular core team (RL, AJ Borek, and STC) meetings accompanied data collection and analysis phases to deliberate on the codebook and the data analysis and to follow an iterative approach, which is documented in a number of Microsoft Word documents with annotations and comments for auditing purposes. We referred to the 8 quality criteria for qualitative research to ensure rigor and trustworthiness of our process [53].

Ethical Considerations

The wider program of research, the DiAIS study, of which this study is a part, was reviewed and approved by the UK NHS Health Research Authority (Project ID—288,328). This qualitative work stream was further separately reviewed and approved by the Research Governance, Ethics and Assurance Team of the University of Oxford and the UK NHS Health Research Authority of England and Wales (Project ID 313699-22/PR/1020). The research teams of each trust reviewed and approved the study at the site level. Full verbal or written consent was obtained from all participants included in this study. Data were pseudonymized. Participants were offered a voucher to thank them for their time. The monetary value of the voucher was £20; US \$25.

Results

Overview

We interviewed 22 HCPs: 8 (36%) from site 1, and 7 (32%) from each of the other 2 sites (Table 1). In site 1 and 2, a total of 12 observation sessions were also undertaken: 5 (42%) in the EDs and 7 (58%) sessions involved shadowing professionals, 3 (25%) of whom completed an interview. We identified 3 themes about HCPs' views and use of their sepsis digital alerts and a fourth theme capturing the complexity of how the hospital environment affected sepsis digital alerts' use across the 3 sites. The first 3 themes feed into the fourth theme, which allows a comparison between the 3 NHS trusts involved in this study. The presentation of the results was structured in this way as each section is seen as building on the previous one and supporting the following one.

Table 1. Characteristics of interview participants (N=22).

Theme 1: Alerts Nested Within EHRs Support Decision-Making

All participants liked that sepsis digital alerts were nested within the DS of the EHRs shared across a trust. Having patient data all in 1 place, including clinical history, patients' trends during their hospital stay, preconditions, comorbidities, test results, and various digital alerts or scores, was described as useful to more quickly and safely build a picture of the patients who are

flagged by the sepsis digital alert. This was regarded as enabling better decision-making and quality care:

We've been electronic in ICU for a long time but, of course, the interaction has been difficult because of the wards being paper-based and now having everything available everywhere is incredibly helpful. So, the cutting out of searching for information, it makes things much more efficient and I think as a result, much safer. [ICU consultant, site 1]

All participants underlined that the sepsis digital alert in the patients' EHRs were supporting, and by no means substituting, clinical decision-makers, whose knowledge and experience were of paramount importance in sepsis identification and management. Sepsis digital alerts were seen as "a piece of the puzzle" (outreach team nurse, site 3), neither intended for, nor leading to, the formulation of a diagnosis or clinical decision in isolation:

I think it's another objective piece of the puzzle that will support junior members to ask for more help because they cannot ignore it, which is helpful I think, when they are wondering how to identify that someone is unwell. [Outreach team nurse, site 3]

I will go and look in the obs chart for the patient to figure out what obs would have triggered the alerts and if there's congruence. So, does the presentation and the obs match the sepsis digital alert?...The more senior you get the more nuance you're looking for. [ED consultant, site 3]

Some participants placed greater emphasis on the teamwork support function of the sepsis digital alert. They valued that they could access information related to clinical observations and the actions of their colleagues, reach out to them if needed, and factor these data into their own decisions. Other participants emphasized the monitoring support function of the sepsis digital alert; having a quick synopsis of the condition of all the patients in a hospital unit allowed better patient prioritization and management of workload:

Nowadays, I am not looking at six patients, which I can go you, you, you, you, you. I'm looking at 60 and how do I look at those patients? I can't. How do I look at them? I look at them electronically and you know, the digital system and the alert enabled me, despite not flawlessly, to build a really good impression about what the acuity is and where the danger is within my department. [ED consultant, site 1]

At the operational level, participants described how sepsis digital alerts are embedded within a complex, multimodal way of working, which includes beepers, mobile phones, and landline phones for communications between hospital units' team and with the laboratories; paper notes in absence of available computers to quickly annotate patients' observations before uploading them onto the DS; and face-to-face interactions, including for very urgent escalations:

The triage nurse is quite far from us...So, if they're very worried and they can't get through on our phone, then they come and find us in person and walk to us and ask for advice. Usually, because they're also quite busy, they usually try to ring us and just make us aware of the patient on the screen and they just say, please can you prescribe paracetamol, antibiotics, and request patient review. Then I can do it over the phone. In A&E, we don't really hold beepers. Beepers are more for the ward team. [ED consultant, site 3]

Theme 2: Alerts Are Reminders That Lead to Context-Dependent Actions

Participants viewed sepsis digital alerts as useful to remind and prompt HCPs of a number of actions, from reviewing a patient's information in the EHRs to visiting them in person. In general, participants reported that sepsis digital alerts' utility decreased with increasing staff training and experience with sepsis cases, and with the higher senior HCP:patient ratio of certain units, such as acute or intensive care. More junior HCPs said that sepsis digital alerts afforded them with greater confidence to further investigate and interpret why sepsis digital alerts triggered, which could lead them to follow the sepsis protocol and to escalate to senior decision-makers:

Thinking back [to] being a junior, one of the big lessons is learning to recognise a critically sick patient, and that takes experience, so having some hard parameters to hang your hat on is really helpful, because I think we all remember you know running to get help when actually things were fine. [ICU consultant, site 1]

For senior participants who "have a greater cognitive load" (acute medical unit nurse, site 3), the sepsis digital alerts were described as reminders to avoid missing actions for patients in their department:

I think the alert itself is really helpful, I think particularly for when you're looking through a patient list, the whiteboard of patients, to have the visual prompt there of somebody that may be way down the list in view of time to be seen, waiting to be seen, but if they've got that alert on the system then generally a senior registrar will pick those patients out and review their case and potentially start the right treatment before the patient is fully assessed, so I think the prompt certainly helps with that identification. [AMU nurse, site 3]

HCPs' specialty and experience, and hospital units hosting different patient cohorts—with varying conditions, treatments, and lengths of stay—were seen to play a role in the use and views of sepsis digital alerts. Thus, some participants commented that they found sepsis digital alerts unspecific and oversensitive, which potentially could lead to overtriaging, overreferring, and, more rarely, overtreating patients:

In a major trauma ward the alert could be triggering because, I don't know, they've got local pressure...It doesn't necessarily mean they've got sepsis, it's very injury-related. Those nurses might find it a little bit frustrating because they will be like, I don't need to go and give antibiotics straight away, with the sepsis six treatment, because it is irrelevant for this quota of patients. [AMU nurse, site 3]

Nevertheless, participants highlighted that this also had the positive implication of increasing inter- and intrateam communication, and reducing the risk of missing patients:

The threshold for which EHR alerts are generated is very, very low so there's different criteria that could match together to generate that alert and, therefore,

we do get a degree of inappropriate patient alerts and referrals. But equally it's much better to because if we screen those patients, it's better that we have more rather than missing some...with less sensitive criteria. [Outreach team nurse, site 2]

Theme 3: Improving Alerts and Their Introduction

Most participants expressed the importance of sepsis digital alerts being easy to use and accessible; some participants underlined that a user-friendly sepsis digital alert was important so that new staff could be trained more easily and quickly in its correct use. Other participants felt that ergonomic sepsis digital alerts were more likely to facilitate HCPs' work and teamwork and to be acknowledged. Conversely, complicated interfaces and pop-up sepsis digital alerts were seen to interrupt HCPs' work, requiring several steps and with the risk of confusing, desensitizing, and irritating users. In result, sepsis digital alerts were reported to be overridden and ignored. By contrast, some participants warned against the alerts being used in excess and deskilling hands-on practice because HCPs, especially those more junior, may "become so fixated on the number that they forget the core part of some of their nursing skills" (outreach team nurse, site 1).

Thinking about potential improvements of sepsis digital alerts, participants suggested adding a checklist of what a colleague has or has not done, or key pieces of information regarding the patient that could be sent in an SMS text message when referring a patient. Participants also suggested quick training that could be accessed via a smartphone:

Currently to learn about sepsis, it requires you to log off the computer, to watch a video, to sit in front of a computer that you can only use with a plug, then it's one of the barriers, but if you have a QR code, that anyone can access—because everyone got a smartphone at the moment—with a quick reference guide to what you need to do, but also some information about sepsis and also some training videos, what you've got to do, that will really help. [AMU nurse, site 3]

In this respect, several participants, especially from the outreach teams, envisioned sepsis digital alerts embedded into portable devices so that HCPs could be reached when they are on the move. Other features of more advanced sepsis digital alerts that participants suggested included alerts being adjusted to the patient, factoring in their baseline parameters, comorbidities, and previous conditions or addressing relevant HCPs team; and alerts processing more information regarding the patient, transparently showing why they triggered and allowing for greater interaction with users:

What needs to happen is that when results come back and they're horribly abnormal, the doctor or the nurse looking after the patient is alerted to that fact without them having to log into a computer...without having to remember the patient's name and hospital number and then clicking through a load of tabs to find what the blood test is. Wouldn't it be nice if there was some way that a person could be alerted directly that this

particular patient has a particular problem? [ICU consultant, site 1]

Many participants wished to have a sepsis digital alert embedded in a DS shared beyond the trust and across the community, ambulance service, and primary care. Participants felt that a widely integrated sepsis digital alert would reduce ED waiting, triaging, and handover times:

If there was a system whereby we could link up our different services and have those observations pulled through so that those patients that don't get the alert when they have a set of normal obs in hospital, still have some other way of being flagged on the system that actually this concerning presentation was the case an hour ago in the community. [AMU senior nurse, site 2]

Finally, participants found the implementation optimization and quality improvement initiatives around the sepsis digital alert useful and emphasized the need for ongoing training and education on sepsis identification and management. In all 3 trusts, at piloting and rollout, the sepsis digital alerts were iteratively adjusted based on staff feedback and regular training around sepsis. However, as some participants highlighted, several other "human factors" should be targeted by broader training aiming to change the organizational culture:

The predominant obstacle's definitely human factors so where you get cultural norms within a ward and certain clinical areas...there's just that kind of like, "Oh, we take care of our patients really well and they would never get sepsis" kind of attitude. There are clinical areas that we go to and there seems to be like a resistance [to] intervention from a specialist team because it's like, "Oh, well, if it was that, then we would have noticed"...it's that kind of assumption that they would know if the patient was going to deteriorate, which actually when you look at the evidence is not the case. [Outreach team nurse, site 2]

Theme 4: Contextual Factors Affecting Views and Uses of Alerts in the Trusts

This fourth theme brings together and present the first 3 themes against 4 sets of factors that affect the views and uses of sepsis digital alerts. Some of these factors differently combine in the context of each of the 3 trusts, allowing comparative reflections. The following quote encapsulates several of these factors constituting the complexity of the hospital environment:

It's all human factor stuff. So, yes, we've got the digital alert, yes people know it might be sepsis, but what gets in the way is people. The context in which they're working, their environment, the business of the ward, the acute conditions of the other patients, the demands on them. It swings both ways, if people are really not busy, not that that ever happens, but then people tend to do less. Then when they're really, really busy things also get missed and they get a bit swamped. [Outreach team nurse, site 1]

The first set is that of the factors pertaining to individual HCPs. As reported in theme 2, HCPs' seniority and clinical specialty affect the use of sepsis digital alerts. On occasion, personal circumstances (eg, childcare duties and other nonprofessional commitments) can play a role in their decision-making.

The second set of factors relate to the hospital unit or department; these will have HCPs with specific training and specialty caring for certain types of patients, and this influences the use of sepsis digital alerts in these patient populations. For example, in intensive units, such as ED resuscitation and ICU, sepsis cases are seen more frequently, and more senior staff look after more severely ill patients so observations are taken more frequently. Participants reported that these aspects make the sepsis digital alert less relevant.

The third set is that of the factors pertaining to the trust. The workload:staffing ratio, along with the presence of senior decision-makers per patient, are specific to the hospital unit but also dependent on the overall management and resources of the trust. Several participants, from sites 2 and 3, raised the issue of delayed actioning of the sepsis digital alert due to heavy workload, and to the retrospective uploading of patients' observations or clinical actions performed, resulting in lower performance toward meeting targets (eg, antibiotics within 1 h) at time of auditing:

The nursing notes said "IV access obtained. Antibiotics given" and then an hour or so later you see at 13:30pm antibiotic prescribed. 13:31pm antibiotic given. It all just seems a little bit like that's all been done after the fact. So sometimes you just have to infer that it sounds like they were really on top of this, and they just left the documentation, rightly, till the end, but we can usually tell, and you can see that gap between prescription and administration, that's often the bit that tips it over the 60 minutes. [Outreach team consultant, site 2]

As highlighted in theme 3, the trust plays a role by investing in staff education or training about sepsis per se and sepsis digital alerts, in the implementation of quality improvement and in technological equipment, spanning from the number of computers available to introducing useful and accessible software programs.

The fourth set of factors is that of the digital tool itself, its features, and functionalities, which correlate with optimal use of sepsis digital alerts, as theme 3 encapsulated. Some aspects inherent to the sepsis digital alert are closely related to other factors, such as how ergonomic and accessible an alert is, which are linked to both trust and individual factors.

The 4 sets of factors differently combine in each of the trusts included in this study. Reading these in conjunction with the characteristics of each trust (Table 2) allows some comparative results, to which the unstructured observations have proved particularly enlightening.

In site 1, the DS was more recently introduced, with ED as the leading unit in the implementation; it is a straightforward system with hardly any intrusive alerts, but with a number of linkable phone apps and functions, such as the DS chat. The sepsis digital

alert is a patient deterioration, nonsepsis specific, and passive alert. A nurse-led outreach team operates 24/7. The combination of these elements results in a perceived easiness-to-use of the DS and usefulness of the deterioration digital alert. Results indicate that the deterioration digital alert is acknowledged by HCPs and ignites the intended behaviors (eg, review, escalate, investigate, and visit). This positive pattern appears to occur even in the apparent absence of a major focus from the Trust on sepsis per se. Of note is that these same elements are related to, for some participants in site 1, an excessive reliance and use of the deterioration digital alert as a patient referral trigger; this means that the deterioration digital alert has been perceived to raise the number of patients' referrals, sometimes unnecessarily.

In site 2, the sepsis digital alert is nested within a DS considered "clunky" (ED consultant, site 2) by some participants; some professionals expressed the opinion that digital alerts were too numerous and could cause them an "alert fatigue" (outreach team nurse, ED nurse, ICU consultant, and acute medical unit nurse). Sepsis has been a priority on the trust's agenda, including via the development of an ad hoc algorithm for the sepsis digital alert, the establishment of an outreach team dedicated to sepsis, and several collateral initiatives related to sepsis management and antibiotic prescribing.

Nevertheless, some ED professionals reported that, within the framework of a very busy workflow and workload, there were team communication issues in the department, which meant that the sepsis digital alert could not always be acknowledged and acted upon timely

The pandemic and staff changes in the outreach team for sepsis meant that they felt that their role was not always known in ED; this might also be because at the time of this study, the 2 nurses in this team had been in their role for 8 or 9 months only. The team for sepsis was infrequently in person in the ED or onward, reporting occasional feelings of being negatively perceived as wanting to interfere with the work of colleagues. Some site 2 ED participants wished they had a 24/7 outreach team for more support with emergencies to alleviate workload which was perceived as untenable. The planned expansion of the outreach team for sepsis, with more staff and aiming to be operative 24/7, is a promising response on behalf of this trust to the heavy workload of professionals in ED and trust-wise.

Site 3 presents yet another different configuration of elements. Over the decade of DS use, lessons have been learned about the counterproductive effects of having too many soft-stop and pop-up alerts, and these have been actively reduced. The rollout of the sepsis digital alert was accompanied by, and optimized via, weekly flat-hierarchy, multidisciplinary meetings on sepsis awareness and optimized based on how the sepsis digital alert should work and look like. Site-3 participants involved in those meetings found them informative and useful. This initiative, together with the trust's ongoing investment in sepsis education and training in the DS and the sepsis digital alert, appeared to support better use of the digital tool. This was the case even though the sepsis digital alert being nested within the same DS as site 2 and also described as not user-friendly. In site 3, however, the sepsis digital alert dialogue box is different, with tailored interface to the HCP role (whether a prescriber or a

nonprescriber is logged-in). An aspect that was reported as needing improvement was the Situation-Background-Assessment-Recommendation form, which was often done ex post as paperwork, and therefore, did not fulfill its full potential in speeding up referrals. Finally, the support of a nurse-led, 24/7 outreach team was an extra resource for staff and the NEWS2 score was fruitfully used in combination with the sepsis digital alert.

Table 2. Main characteristics of National Health Service trusts' research sites.

Characteristics	Site 1	Site 2	Site 3
The EHRs^a DS^b			
When DS introduced	DS was introduced in 2019	DS was introduced in 2015	DS (same as site 2) was progressively introduced from 2013
DS interface and access	DS interface user-friendly and the same across the site and job roles	DS interface not straightforward, with numerous tabs and colours; DS is different in intensive care	DS interface not straightforward, with numerous tabs and colours; different DS login for nurses and doctors
Digital alerts in the DS	Other alerts in use, mainly passive ones (eg, for ED ^c triaging)	Other soft-stop digital alerts, as well as passive ones (eg, for ED triaging)	Other soft-stop digital alerts, as well as passive ones (eg, for ED triaging)
Additional functions of the DS	DS has several functions, used as a phone app and linked to tablets for patients' observations	Use of DS's additional functions was not found	Other software and applications are in use, eg, on sepsis management and antibiotics administration
The sepsis or deterioration digital alert			
When sepsis digital alerts introduced	Alerts was introduced in 2019	Alerts was introduced in 2016	Alerts' was introduced in phases from 2016
Features of the sepsis digital alert	Sepsis digital alert is NEWS2 ^d (sepsis is suspected with a score of 5+ and a confirmed or suspected infection)	Sepsis digital alert is based on in-house adaptation of sepsis red flag screening tool	Sepsis digital alert is built in the DS, based on St John Sepsis Algorithm; alert informed by a binary alarm: (1) for potential sepsis and (2) for potential severe sepsis
Sepsis digital alert's functioning	Passive icon that changes color according to the score	Alert is both soft-stop and passive; prescribers and nonprescribers can respond differently	Alert is both soft-stop and passive; prescribers and nonprescribers can respond differently
Sepsis digital alert's interface	On the wards, alert embedded in EHR and does not pop up; in ED, alert appears on the digital list of patients	On the wards, the alert box pops up when an EHR is opened and closed; in ED, the alert is also a passive, colorful icon on patients' digital dashboard	On the wards, the alert box pops up when an EHR is opened and closed; in ED, the alert is also a passive, colorful icon on patients' digital dashboard
Trust actions on sepsis, the DS and the sepsis digital alerts			
Trust's position	Deterioration and acuity are the priority	Sepsis was among the trust's priorities up until COVID-19; there were several initiatives for sepsis awareness raising and education (eg, sites' performance competitions, videos and information on the intranet, sepsis trolleys, and champions)	Sepsis was among the trust's priorities up until COVID-19; there were several initiatives for sepsis awareness raising and education (eg, sites' performance competitions, videos and information on the intranet, sepsis trolleys, and champions)
Sepsis digital alerts' roll out	ED led on alerts' implementation	ED led on alerts' implementation	Weekly flat-hierarchy, multidisciplinary meetings on sepsis awareness and alert's optimization
Approach to digital alerts	Keep a minimal number of soft-stop digital alerts	Digital alerts were reported as too numerous	Keep a minimal number of soft-stop digital alerts
Trust's deterioration or sepsis team	NEWS2-based, nurse-led, 24/7 outreach team	Sepsis team for awareness and training, and to support hospital units following sepsis digital alerts; active during office hours.	NEWS2-based, nurse-led, 24/7 outreach team

^bDS: digital system.

^cED: emergency department.

^dNEWS2: National early warning score 2.

Discussion

Principal Findings

Participants generally viewed sepsis digital alerts positively but emphasized that they cannot substitute the HCP's knowledge and experience in the identification and management of sepsis. Sepsis digital alerts are only a piece of the puzzle in a patient's presentation, as well as in the complex, multimodal, and multidisciplinary clinical practice. Participants considered them as useful, context-specific reminders prompting HCPs to take a range of actions, from reviewing to escalating a patient.

Participants identified features of better sepsis digital alerts, such as accessibility and user-friendliness. More sophisticated sepsis digital alerts should be more specific; be patient based; target HCP teams; be portable and remotely accessible; and integrate community, ambulance, and primary care with secondary care to accelerate ED triaging.

Factors pertaining to the individual HCP, the hospital unit, the trust, and the digital tool itself differently combine and were seen to affect the use of sepsis digital alerts in the 3 trusts in this study. The combination of these 4 sets of factors leading to the more optimal use of a sepsis digital alert include a general, non-ICU with a lower senior decision maker:patient ratio; HCP's previous experience with the sepsis digital alert; presence of a 24/7 emergency outreach team; sepsis digital alert's quality improvement initiatives and continuous sepsis training; strong technological resources in the trust; good staffing and teamwork; digital tool's ease-of-use; and digital tools that are not numerous and intrusive.

Strengths and Limitations

We included 3 NHS hospital trusts in this study to explore differences in relation to the EHRs DS and the sepsis digital alert, the implementation optimization strategies, and the approach and training in relation to sepsis. The study set out to involve ED, outreach or sepsis teams, and ICU professionals in different roles and career stage; as a result, we obtained a varied sample. The multisite design and the varied professional profiles afforded meaningful comparisons across job roles, units, and trusts toward a more nuanced identification of factors affecting the use of the sepsis digital alerts. Observations provided insights on how the sepsis digital alert fitted with workflows that were richer than the self-reported descriptions of sepsis digital alert in the interviews. Finally, 2 researchers (RL and AJ Borek) with different disciplinary backgrounds conducted interviews and observations in 1 of the sites. This added rigor to the process of data collection and analysis.

All 3 sites in this study are large, high-resourced, and urban university hospitals; research in trusts with different characteristics and contexts (eg, smaller district hospitals and hospitals in lower-resources settings) could convey different results. HCPs from other hospital wards and units may have different experiences and provide a contrasting example to further understand how sepsis digital alerts are viewed and used but was beyond the resources available for this study. Due to research team capacity and time constraints dictated by the project timeline, we could not include all the 3 trusts for the

observations. Finally, the study recruitment strategy resulted in sampling and nonresponse biases which contributed to the fact that certain professional categories, such as junior doctors, were absent. Although we made efforts to recruit junior doctors, none volunteered to participate. This was influenced by the high workload and limited time and capacity as the study was conducted at the time of junior doctor strikes. The absence of junior doctors is a remarkable limitation as sepsis digital alerts, as this study has also found, may be more useful for less senior health professionals.

Comparison With Prior Work

The introduction of sepsis digital alerts rests on the evidence of the challenges to optimally identify and manage sepsis in hospitals, in particular in EDs, where HCPs have been found to need more confidence and time to assess and escalate septic patients [18,21]. Our study found that sepsis digital alerts support HCPs in identifying and making quicker decisions about deteriorating patients, which might be particularly important and helpful to new and less experienced HCPs in ED and in the general wards. The sepsis digital alert is an additional element that HCPs factor in their practice; it is not a substitute for their judgment. Similarly, a US study found that participants were more inclined to accept the machine learning-based system for sepsis if they perceived the tool as a partner, supporting their autonomy and workflow, and not a surrogate of their clinical judgment [54]. For this same reason, another work involving hospital leaders found that participant tended to distrust more machine learning than rule-based sepsis CCDSSs [55]. The literature on CCDSS implementation supports this finding: a study across 4 Italian hospitals concluded that the perception that an advanced CCDSS could reduce HCPs autonomy was the most significant barrier to implementation [56].

Users' attitudes and perceptions about the ease of use and usefulness have been at the center of established technology acceptance theories [57,58]. Trust in the sepsis digital alert and its uptake were found to be affected by individual factors, such as previous experience with the DS, as 2 recent systematic reviews on the implementation of a CCDSS [59] and of an EHRs DS have corroborated [60]. Although our participants did not directly discuss trust in the sepsis digital alert, its importance can be inferred from other aspects they raised, especially when thinking about better sepsis digital alerts. Participants would welcome more sophisticated and reliable sepsis digital alerts, which would be more accurate and transparent, as previous work observed [61,62]. At the same time, our study revealed that perceived usefulness in the sepsis digital alert depended on the HCPs' professional experience and specialty training. More senior and emergency HCPs as well as intensivists tended to take less advantage from the sepsis digital alert. Similarly, previous work has demonstrated that HCPs can disregard the evidence underpinning CCDSSs for fear that their critical reasoning and, again, their professional autonomy are challenged [56]; but also, because the evidence embedded in the digital tool may be seen as jeopardizing hierarchical, power relations based on medical specialty and seniority [63].

Concomitantly, features and functionalities of the digital tool appear to influence the use of the sepsis digital alert [45,46]. A

study highlighted that easy-to-use tablet applications as part of the DS for sepsis were important mediators facilitating implementation [62]. We also found that accessible, mobile phone apps and functions, such as the chat of the EHRs DS in site 1, appear to support better use of the sepsis digital alert. The usability of the digital tool has been a focal aspect in theories of ergonomics and human-technology interaction [64,65]. Work on the uptake of CCDSSs found that scarcity of available computers, unfriendly user interface, and excessive number of intrusive alerts lead to disengagement and fatigue [31,56,64,66]. Our study corroborates the importance of factors inherent to the design of the sepsis digital alert and the EHRs DS; both sites 1 and 3 made the deliberate choice of keeping minimal or reducing soft-stop digital alerts.

Previous work has shown the importance of functional teamworking; this should be based on high standards of coordination and communication to ensure the smooth journey of the septic patient and improve clinical outcomes [20,61]. Our results indicate the sepsis digital alert contributes to prompter patients' referral, escalation, and treatment. However, participants felt that lack in communication among staff could hamper the proper use of the sepsis digital alert, as some participants in site 2 raised. This resonates with the findings of the aforementioned study in the pediatric ED where professionals' acknowledgment of the sepsis digital alert was based on factors specific to the ED environment [46]. Significantly, another study found that a discontinuous flow of communication and teamwork among clinicians was a barrier to the integration of a machine learning sepsis early warning system in ED [62].

Organizational factors were identified as a significant obstacle to recognizing and responding to patients with sepsis in ED [21]. Significantly, our study corroborated how trust-level factors, such as good level of staffing, staff training and involvement in the sepsis digital alert' optimization, and appropriate technological resources, linked with more optimal use of these CCDSSs. In line with our results, other work concluded that organizational factors affected HCPs' trust in the sepsis digital alert; this connection was facilitated by engagement and education activities fostering sepsis digital alerts' understanding and acceptance [45,46,55,62]. The importance of the context in affecting individual HCPs' decisions and practices related to CCDSSs has been demonstrated in studies using the normalization process theory [67-69]. Accordingly, organizational and practice theories applied to the introduction of technology in the complex health care environment maintain that implementation processes are connected with the interaction between the technology, on the one hand, and HCPs' practices, teamwork relationships, organization's policies and priorities, on the other hand [70-72]. The uniqueness of the hospital context makes it difficult to compare the effectiveness of a sepsis digital alerts in isolation.

This study highlights that the introduction of sepsis digital alerts necessitates a multilevel approach [56,72] that includes understanding and actions at 4 sets of factors: the HCP, the hospital unit or department, the hospital, and the digital tool. Multilevel approaches to innovations, including digital ones as in this study, have been captured by several process frameworks

developed in implementation science. Comprehensive innovation process frameworks have provided research logic models factoring in several determinants which we found in our work. These determinants spanned from the intervention characteristics, the inner and outer settings—such as leadership, networks, and communication—and learning climate, to the characteristics of individuals and the process [73-75]. Other tools also embedded a plethora of factors to be considered when assessing intervention scalability [76]; factors worth analyzing to assess scaling readiness include the strategic or political context, the intervention costs and benefits, delivery setting, and workforce [76]. Other work has concentrated on specific factors of the scale and spread journey, such as the types of innovations [77], specific context and processes, such as the NHS innovation pathways and its accelerators [78]; the importance of the context [79]; of patient and public involvement [80]; and of innovation intermediaries [81]. The necessity of adopting a multipronged, evolving strategy which goes beyond mechanistic logics of change have been promoted [82,83]. This same approach has emerged as mandatory from our retrospective, descriptive qualitative study based on the views and uses of sepsis digital alerts already in place in 3 hospital trusts in England.

Implications

An a priori analysis of the organizational environment to assess the hospital readiness and unique feasibility for the introduction of the sepsis digital alert is recommended. Mapping areas demanding change in the trust and planning resources and actions for their improvement mitigate the risk that sepsis or deterioration CCDSSs fail to offer the intended benefits [72]. In addition to more structural factors, such as resources, staffing, sepsis training, and a successful leadership-teamwork dynamic, it is also advisable that organizational cultural factors are factored in. Cultural factors that trusts should consider assessing include the trust's prioritization of sepsis or of deterioration and acuity, staff retention trends and sociodemographic profile, attitudes and readiness toward technological innovations, and the more impalpable norms regulating hierarchies and power among staff.

Hospital trusts should aim to plan ongoing implementation optimization initiatives in the pilot and rollout phases [55]. These initiatives should be flat-hierarchical and multidisciplinary so that HCPs with different job roles and training, based in different hospital units, can voice their unique perspective and support needs they expect to be met by the sepsis digital alert [84,85]. The trust should ensure the continuous involvement of information technology developers [86], and that staff feedback is appropriately collected and analyzed so that it materializes into context-based modifications of the tool. The engagement of staff should go hand-in-hand with education and training to aim at the maximization of behavior changes toward improved patient care. These activities should be reinforced by the establishment of champions and other strategic communication and educational campaigns, whereby staff can easily and remotely access information about the sepsis digital alert. It would be useful if trusts established dedicated advisory groups monitoring and managing all the actions necessary for a more successful post go-live [86].

Design, content, and technical aspects can act as barriers or facilitators to changing the clinical behavior toward better patient care in technology-based interventions [87]. Further multidisciplinary research should inform the development of sepsis digital alerts which are easy to use but at the same time are more sophisticated, able to target specific HCPs and hospital units, and simultaneously become more patient-specific, transparent, and interactive [88]. Sepsis digital alerts should also be more effectively linked to guidance on sepsis protocols, escalation practice, and antibiotics prescribing. Researchers and developers should work in conjunction with HCPs and policy makers to refine technology-based behavior change techniques that *effectively* support HCPs' decision-making, care practice, and improve patients' outcomes as a result.

Conclusions

Current sepsis digital alerts nested within the EHRs are introduced to support the identification and management of sepsis or deterioration and improve patient outcomes. These sepsis or deterioration CCDSSs fulfill their purpose but not entirely and not equally in all hospitals; an organic, multilevel framework to enhance tailored implementation of sepsis digital

alerts is needed, along with the simultaneous validation of their effect on patient outcomes. No technological innovation in the health care setting can be a solo driver of change, and sepsis digital alerts are not magic wands able to dissipate issues that instead become important barriers to their optimal use in the rollout phase. Sepsis digital alerts implemented in trusts with good levels of staffing, resources, and functional teamwork are likely to be taken up more optimally and become good partners for HCPs. Equally, where the roll out of sepsis digital alerts is accompanied by multidisciplinary quality optimization initiatives, and by training, education, and other sepsis awareness actions that continually engage staff, HCPs are more likely to accept and embed the sepsis digital alert in their practice. Trust implementation of sepsis digital alert requires changes on multiple levels and at all phases of the intervention, starting from a prego-live analysis assessing and addressing organizational needs and readiness. Advancements toward minimally disruptive and smart sepsis digital alerts, which are more accurate and specific, but at the same time scalable and accessible, have to see policy changes and investments in multidisciplinary research agendas.

Acknowledgments

This study has received funding from the National Institute for Health and Care Research (NIHR), Programme Health and Social Care Delivery Research, Research Call: HSDR Digital Technologies to Improve Health and Care (award number NIHR129082). AJ Borek and STC have received support from the NIHR Health Protection Research Unit in Healthcare Associated Infections and Antimicrobial Resistance (NIHR200915) at the University of Oxford in partnership with the UK Health Security Agency (UKHSA). The views expressed here are those of the authors and not necessarily those of the NIHR or the institutions of affiliations of the authors. The authors would like to acknowledge the work and contribution of the wider study team, the Digital Alerting for Sepsis team, as well as of the staff of the three NHS trust sites where the study was conducted. The important contribution of the late P Ghazal to this work is also acknowledged. P Ghazal was a champion of thinking creatively, and speaking to improve care for patients.

Authors' Contributions

CEC, KH, P Goodman, and STC contributed to conception and design. RL, AJ Borek, JW, AJ Brent, AK, RD, and STC contributed to data acquisition. RL, AJ Borek, KH, JW, AJ Brent, AK, GC, SP, AG, BG, P Ghazal, and STC contributed to the analysis and interpretation of data. RL drafted the article and all authors revised it critically for important intellectual content. All authors granted approval for the final version of the manuscript to be published.

Abstract

Background: Chronic low back pain (CLBP) is a major economic and social problem worldwide. Despite the variety of recommended treatments, long-term self-management of this condition is complex and requires the development of innovative interventions. Mobile health (mHealth) technologies hold great promise for the management of chronic pain, particularly to support physical activity. However, their implementation is challenged by a lack of user compliance and limited engagement, which may be due to insufficient consideration of the needs of potential users during development.

Objective: This study aims to explore the needs of people with CLBP and health care professionals regarding mHealth technologies to support self-managed physical activity, and to delineate design recommendations based on identified needs.

Methods: A participatory study was conducted using a 3-phase, user-centered design approach: needs investigation with a group of experts in a workshop (phase 1), needs exploration with end users in focus groups (phase 2), and validation of needs using Delphi questionnaires followed by the development of a set of recommendations (phase 3).

Results: A total of 121 people with CLBP, expert patients, health care professionals, rehabilitation researchers, and biomechanical engineers participated in this study. The results indicated how technology could help people with CLBP overcome their difficulties with managing physical activity. Specific needs were formulated concerning device objectives, expected strategies, functionalities, technical features, conditions of use, and potential facilitators and barriers to use. These needs were validated by consensus from the potential end users and translated into design recommendations.

Conclusions: This study provides design recommendations for the development of an mHealth device specifically adapted for people with CLBP.

KEYWORDS

chronic low back pain; needs; self-management; physical activity; mobile health; mHealth; user-centered design

Introduction

Background

Chronic low back pain (CLBP) is a major public health concern worldwide because of its economic and social consequences [1,2]. It is the leading cause of disability and work absenteeism, and its prevalence is still increasing [3,4]. Management of daily symptoms and activity are major challenges for people with this condition [5-7].

Self-management strategies and maintaining an active lifestyle have been consistently recommended for people with CLBP [8-12]. Self-management can be defined as the ongoing and dynamic ability to handle symptoms, such as pain, physical and psychological consequences, and lifestyle adjustments [13,14]. Self-management programs include educational and psychosocial interventions; maintaining an active lifestyle is a core component of these programs. People with CLBP are encouraged to engage in regular physical activity and to adopt healthy behaviors to manage their symptoms [14]. Although self-management and physical activity-based interventions improve pain [15] and reduce disability [16,17] in the long term, as well as promote the development of self-management skills [18,19], the effect of such interventions are small to moderate. Moreover, it is difficult to support self-management in clinical practice because of constraints in time, service organization, and follow-up [20]. Therefore, there is a need to identify innovative interventions to promote sustainable self-managed physical activity in people with CLBP.

Recent advances in technology like mobile health (mHealth) may offer new opportunities to support self-managed physical activity and pain in people with CLBP. mHealth is defined as a “medical and public health practice supported by mobile devices, such as mobile phones, patient monitoring devices, personal digital assistants, and other wireless devices” [21]. It can help people change their health behaviors [22] and help people with CLBP pursue specific physical activity goals while receiving continuous feedback on their physical performance [23,24]. It could be used to help them manage their condition and maintain an active lifestyle [25,26]. From the point of view of health care professionals, mHealth technology can provide individualized interventions with real-time feedback, support their coaching role [27], and support the development of behavior change [28,29].

Although mHealth technologies are promising, their content and the context in which they are offered need to be explored further. Many mobile apps are available to support people with CLBP in self-management, mainly providing exercise recommendations or information about the mechanisms of CLBP. These apps score poorly on the Mobile Application Rating Scale (a scale to assess app quality), and do not mention the theoretical approaches on which they are based [30-32]. Sometimes these mobile apps are combined with a physical

activity tracker; however, they have shown limited effectiveness in disability and pain management in people with CLBP [33,34]. For example, several studies using the Fitbit device found nonsignificant results for pain [35,36] and disability [37]. This lack of an effect could relate to the fact that the target population for the tool is healthy individuals. Devices, such as the Fitbit were developed primarily to help young people improve their physical condition and they do not specifically consider people with CLBP and their context. They do not appear to be suitable for supporting health care professionals or people with CLBP who may benefit from increasing their participation in unstructured physical activity, like walking, and reducing sedentary lifestyle habits [38-41]. Moreover, studies of rehabilitation programs that integrated mobile technology found mixed results because of participants' lack of adherence to the wearable technology [35,36].

It is now widely recognized that user-centered design (UCD) approaches are needed to facilitate the development, acceptability, and implementation of mHealth technologies [42-45]. In the field of CLBP, such designs are seldom used and rarely rigorously applied [46], particularly in the initial stages of device design [47].

This Study

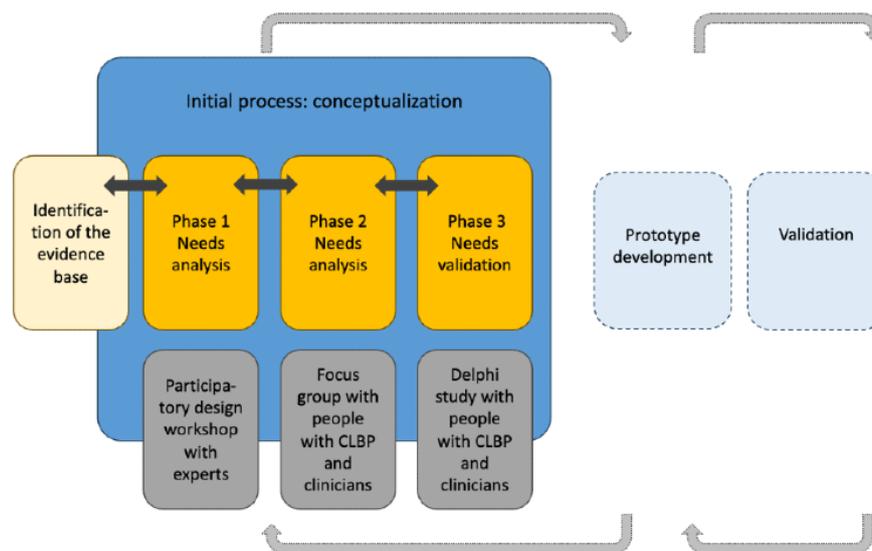

The main aim of this study was to explore the needs of people with CLBP and health care professionals regarding the use of mHealth technologies to support self-managed physical activity and pain. The specific aims were to (1) investigate how technology could help people with CLBP overcome the difficulties of managing their own physical activity with an expert group, (2) explore the needs, experiences, and preferences of people with CLBP and health care professionals regarding technology to support self-managed physical activity, and (3) validate the identified needs and develop a set of mHealth technology design recommendations.

Methods

Design

A participatory study was conducted using a UCD approach. UCD is an iterative process that focuses on users and their contexts in all stages of development design [44,48,49]. This study focused only on the initial process of the approach to investigate the needs of people with CLBP and to guide future prototype designs (Figure 1) [50-52]. The study was conducted in France and Switzerland and involved three successive data collection phases: (1) needs investigation with a group of experts, (2) needs exploration with people with CLBP and health care professionals, and (3) validation of the needs identified and development of recommendations. It was conducted after a preliminary literature review that aimed to identify existing evidence on mHealth devices used to support self-managed physical activity in people with CLBP.

Figure 1. Illustration of the 3 phases of data collection based on the initial process of a user-centered approach. CLBP: chronic low back pain.

Ethical Considerations

The study was approved by the research ethics committee of the University of Lyon (CER-UDL 2022-10-13-003). The Cantonal Ethics Committee of Swissethics stipulated that this research was outside their jurisdiction and did not require ethics approval (Req-2022-00733).

Data Collection

Phase 1: Needs Investigation With an Expert Group

Overview

The first phase investigated how technologies could support people with CLBP in overcoming difficulties with physical activity and pain self-management. A web-based participatory design workshop involving an expert group was set up for this purpose [50].

Sample

The expert group consisted of patients who were experts, clinicians with expertise in low back pain management, rehabilitation researchers, and biomechanical engineers in the rehabilitation field. Inclusion criteria for patients who were experts in self-management of their disease acquired over several years, and experience with several treatment modalities, including participation in at least 1 multidisciplinary rehabilitation program. Clinicians, rehabilitation researchers, and biomechanical engineers were required to have at least 5 years of experience in their respective fields.

Recruitment

The expert group was recruited through the investigators' clinical networks. Potential experts were contacted via email and telephone by the research team who explained the workshop to them, invited them to participate, and obtained their consent.

Data Collection

Data were collected during a 3-hour web-based participatory design workshop via teleconference in October 2022, moderated

by 2 members of the research team (AD-B and MB). The workshop was organized into a preliminary activity followed by 3 phases. Before the workshop began, each participant received a summary of the existing evidence on mHealth devices used to support self-managed physical activity and pain in people with CLBP. In the first part of the workshop, the demographic characteristics of the participants were collected using a short questionnaire. Each of the 4 expert subgroups (patients who were experts, clinicians, rehabilitation researchers, and biomechanical engineers) was asked to reflect on the difficulties and factors limiting self-managed physical activity and pain in people with CLBP. In the second part, 2 subgroups were formed with different expert representatives (each subgroup consisted of at least 1 patient who was an expert, 1 clinician, 1 rehabilitation researcher, and 1 biomechanical engineer) to encourage discussion and the generation of several ideas on how technology could help people with CLBP overcome the difficulties identified. Each subgroup explored potential solutions to address the difficulties identified for a described persona. All exchanges with the group were recorded and transcribed.

Phase 2: Needs Exploration With End Users

Overview

The second phase explored the needs, experiences, and preferences of people with CLBP and health care professionals for using technology to support self-managed physical activity and pain. Two series of focus groups were run for this purpose [51]. The first explored end-user experiences and needs relating to physical activity and pain self-management. The second focused on potential technological solutions to meet the identified needs.

Sample

A sample of people with CLBP and a sample of health care professionals were recruited. Inclusion criteria for people with CLBP were a clinical diagnosis of CLBP and participation in ongoing rehabilitation within a multidisciplinary program.

Inclusion criteria for health care professionals were more than 2 years of experience caring for people with CLBP and participation in a multidisciplinary rehabilitation program for CLBP.

Recruitment

Recruitment was done in collaboration with 2 rehabilitation centers, one in Switzerland and the other in France. Health care professionals involved in the care of people with CLBP at both rehabilitation centers were informed of the study via an email from the research team with information about the study attached. People with CLBP were informed about the study by their health care professionals and received written information about the study. All people with CLBP and health care professionals willing to participate were contacted by the research team who provided further information and collected signed informed consent for participation. All participants included in phase 2 were different from those in phase 1 to explore diverse perspectives.

Data Collection

The 2 sets of focus groups were conducted separately for people with CLBP and health care professionals at the rehabilitation centers in Switzerland and France, with 4 to 8 participants as recommended by Kitzinger et al [51]. Each participant attended 2 focus groups held 2 weeks apart between January and February 2023. In the first series of focus groups, participants shared their experiences and needs regarding self-managed physical activity and pain in relation to the issues outlined by the expert group. In the second series of focus groups, participants discussed the potential technological solutions to meet the identified needs, in detail. A total of 8 focus groups were conducted by the research team. Participants were asked about their past experiences with health care technologies and their potential future needs for using technology. The potential facilitators and barriers to using technology to support self-managed physical activity and pain were also discussed. Two members of the research team moderated all the focus groups using a standardized interview guide developed by the research team (MB, JJD, or AD-B). An interview guide was developed for people with CLBP and health care professionals, asking the same questions but rephrased specifically for each group. Each focus group lasted approximately 1 hour 30 minutes and was recorded and transcribed. Participant's demographic characteristics were collected using a short questionnaire before the focus groups, and all data were coded to ensure anonymity.

Phase 3: Needs Validation

Overview

The third phase involved validating the identified needs and delineating a set of design recommendations for mHealth technologies. For this, a two-round Delphi questionnaire approach was used [52]. The first round assessed the needs expressed by participants during the previous consultation phases, and the second round consisted of evaluating the responses that did not reach a consensus based on the suggestions from the first round.

Sample

People with CLBP and health care professionals were selected. The inclusion criterion for people with CLBP was having already completed or in the process of completing a multidisciplinary rehabilitation program. The inclusion criterion for health care professionals was more than 2 years' experience caring for people with CLBP.

Recruitment

Participants were recruited through poster advertising, social media, and word of mouth, in Switzerland and France. Participants from phase 2 were invited to join phase 3, allowing them to evaluate all the needs identified in the earlier phases, not just those discussed in their focus groups. All recruitment materials directed interested individuals to a web-based survey (LimeSurvey) to determine their eligibility, register their characteristics, and provide informed consent.

Data Collection

The Delphi questionnaire was developed from all the themes identified from the results of the 2 previous phases of the study. Two researchers (MB and AD-B) selected each statement for the questionnaire. The research team then validated the statements according to the elements discussed during the previous 2 study phases. Before completing this questionnaire, the research team provided participants with a standardized summary of the methodology and the preliminary results of the first 2 phases. All participants completed a short sociodemographic questionnaire. Each participant was asked to rate their level of agreement with each statement on a 4-point bidirectional scale: strongly disagree (1), disagree (2), agree (3), or strongly agree (4). If participants "disagreed" or "strongly disagreed," they were invited to propose a new suggestion corresponding to their own opinion in open text boxes. The first round of questionnaires remained open for 4 weeks. Consensus was considered achieved if 90% of the participants agreed or strongly agreed with a statement. The second-round questionnaire was based on suggestions for statements for which there was no consensus in the first round. The second round was open for 12 weeks and only people who had already responded to the first round were invited to respond to the second round. This third phase lasted 16 weeks, from June to September 2023.

Data Analysis

Descriptive statistics were used to characterize the participants in the 3 phases, using frequencies and percentages. In phase 1, participant discussions were recorded and transcribed verbatim for analysis using an inductive thematic analysis [53,54]. First, 2 researchers (MB and AD-B) independently read the transcripts to familiarize themselves with the content. Second, they separately coded the data using NVivo (version 20, Lumivero) to create an initial codebook. After the initial coding, the codebook was discussed between the 2 researchers, and segments of the content with similar meaning were assigned to the same code. Third, the coded transcripts were used to refine the concepts of the initial codebook and combine the codes into key themes. When new codes or themes emerged, the codebook was revised, and the previous transcripts were recoded. Any

discrepancies between the researchers were resolved by discussion, and any necessary adjustments were made. This thematic analysis was then conducted again to reach a consensus. Finally, the content of the themes and subthemes of the coding scheme was discussed with the entire research group.

In phase 2, the data analysis procedure from phase 1 was repeated using recorded material from all the focus groups [53,54] and the field notes written by the moderator in charge of describing the group interactions. The final version of the codebook from phase 1 was reused and revised by 2 researchers for use in phase 2 (MB and AD-B). All themes were validated by the entire research group.

In phase 3, the level of expert consensus was calculated for each item after each round [55]. Consensus was considered achieved when 90% of the participants agreed or strongly agreed with a statement. All suggestions were reviewed by 2 researchers (MB and AD-B), and the data were coded using the same codebook used for phases 1 and 2.

Results

Overview

A total of 121 participants were involved in the study. Of the 121 participants, 9 experts took part in the first phase, including

4 subgroups of 2 to 3 experts in the first part of the workshop and 2 subgroups of 4 to 5 experts in the second part of the workshop (one of the subgroups was composed of 1 patient who was an expert, 1 clinician, 1 rehabilitation researcher, and 1 biomechanical engineer while the other was composed of 1 patient who was an expert, 2 clinicians, 1 rehabilitation researcher, and 1 biomechanical engineer). Of 26 participants who took part in the second phase, 11 people with CLBP and 15 health care professionals (including 4 and 7 participants, respectively, for the 2 sets of focus groups with people with CLBP, and 7 and 8 participants, respectively, for the 2 sets of focus groups with health care professionals). Of 86 participants who took part in the third phase, 45 people with CLBP and 41 health care professionals. About 63% (7/11) of the participants with CLBP and 46% (7/15) of health care professionals from phase 2, participated in phase 3. The demographic characteristics of the participants are presented in [Table 1](#) and more details about the participants are available in [Multimedia Appendix 1](#).

More than 12 hours of participatory design workshop data, focus group data, and suggestions from 2 questionnaires were coded into 5 themes that are described in more detail below: (1) difficulties experienced by people with CLBP in relation to self-managed physical activity and pain, (2) device concept (aim and strategies), (3) device content, (4) condition of use, and (5) facilitators and barriers to use.

Table 1. Characteristics of the participants in each phase of the study.

^aCLBP: chronic low back pain.

^bNot applicable.

Difficulties Encountered by People With CLBP in Relation to Self-Managed Physical Activity

The difficulties faced by people with CLBP in relation to self-managed physical activity and pain were specifically explored in phase 1 by the expert group composed of patients who were experts, clinicians, rehabilitation researchers, and biomechanical engineers. All participants were asked to discuss these difficulties to reach a consensus on the problems faced

by people with CLBP. These difficulties were then iteratively addressed by people with CLBP and health care professionals in phases 2 and 3. These difficulties are presented in Table 2. The more prevalent ones included pain, personal beliefs, difficulty pacing physical activity, and a lack of sustained, individualized, long-term support from health care professionals. Only these prevalent difficulties were used as the basis for the assessment of the needs of people with CLBP and health care professionals, as they were shared by both groups.

Table 2. Difficulties and factors limiting self-managed physical activity and pain in people with chronic low back pain (CLBP) identified by the different groups of participants in the different phases.

^fDifficulty mentioned by the group.

Device Concept

The needs of people with CLBP and health care professionals regarding the device concept are described in Tables 3 and 4 and illustrated with verbatim. All participants highlighted the

importance of having a device that would not only help increase physical activity level of people with CLBP but also better pace it. They insisted on the need for this device to also help people with CLBP with long-term pain management. To achieve these objectives, they suggested the device should support the

following behavior change strategies: goal setting, delivery, and social support. self-monitoring, feedback, positive reinforcement, reward

Table 3. Needs relating to device concept, especially objectives of the device, identified by experts, people with chronic low back pain (CLBP), and health care professionals.

Needs identified	Quotes (translated from French into English)
Help to pace physical activity	<ul style="list-style-type: none"> • “[The device should] allow self-pacing.” [Person with CLBP; phase 2] • “I want it to be regular...even if performance increases progressively, the fact that it’s regular is precisely to maintain the benefits for the back in the long term.” [Person with CLBP; phase 2]
Support long-term self-management of pain and not only physical activity	<ul style="list-style-type: none"> • “That it’s not just a device to improve physical activity, but also symptom management, pain management.” [Ieg^a; phase 1] • “The device must really improve the patient’s well-being.” [Ieg; phase 1]

^aIeg: interdisciplinary expert group.

Table 4. Needs relating to device concept, especially expected behavior change strategies supported by the device, identified by experts, people with chronic low back pain (CLBP), and health care professionals.

Needs identified	Quotes (translated from French into English)
Goal setting	<ul style="list-style-type: none"> • “What seemed important was that this device already allowed a certain degree of individualization, for example, based on patient goals.” [Ieg^a; phase 1] • “There must be clear goals. Without clear objectives, we’ll just keep going. We’ll get the story we want.” [Person with CLBP; phase 2]
Self-monitoring	<ul style="list-style-type: none"> • “The system should allow the patient to monitor their progress.” [Ieg; phase 1] • “To move forward, you need to know what’s happened recently. How can you know if you don’t have any data? Yes, it’s been the same for 6 months, but the same, better, less? Well, I don’t know. I can’t remember.” [Person with CLBP; phase 2]
Feedback and coaching advice sent by the device	<ul style="list-style-type: none"> • “We could also imagine motivational alerts if you’ve walked a little less or have been a little less active in the last few days. Not in a negative way, but in a positive way.” [Ieg; phase 1] • “To have that on the smartphone to say, ‘Ah today you basically did what you needed to do.’ Or at the end of the day ‘you haven’t done all your steps’ or ‘you’re missing some targeted exercises’ and that would be magic.” [Person with CLBP; phase 2]
Positive reinforcement	<ul style="list-style-type: none"> • “It’s important that the words are kind and positive. You don’t want to hear, ‘Are you in pain?’” [Person with CLBP; phase 2] • “I think it’s better to take into account positive emotions and parameters than to point out negative parameters such as stress!” [Hp^b; phase 3]
Reward delivery	<ul style="list-style-type: none"> • “We wondered if something a little bit like a game could also stimulate activity...if the device could collect points or have something to help motivate to do exercises.” [Ieg; phase 1] • “You took longer, you did more’ suits me well, I’ve won stars, I’ve changed levels, super, I’m super happy. I mean, it’s working really well for me.” [Person with CLBP; phase 2]
Education	<ul style="list-style-type: none"> • “We know that when it comes to pain; simply put, the more you know, the less pain there is. So I don’t know if a questionnaire that picks up things that have been covered in a program...to see if people still remember them, are able to remember them.” [Hp; phase 2] • “To maintain our level of knowledge. All knowledge, in the end, we tend to go back to the representations we had in the past.” [Hp; phase 2]
Social support through testimonials	<ul style="list-style-type: none"> • “Maybe if you can have patient testimonials, examples of people who have found solutions or things that are difficult and then they’ve been able to solve them. Maybe that can be motivating.” [Ieg; phase 1] • “People with low back pain sometimes suffer from negative images, and to see that others have been successful, in quotes, I think can motivate them, even if it’s anonymous.” [Hp; phase 2]

^aIeg: interdisciplinary expert group.

^bHp: health care professional.

Device Content

The needs of people with CLBP and health care professionals regarding device content are described in Tables 5 and 6 and

illustrated with verbatim. Participants expressed the need for a device that would allow people with CLBP to automatically track the following data: number of steps, heart rate, activity versus rest time, intensity of the activity, stress, and sleep. They

emphasized the need for the collection of additional data recorded by the user, such as an activity diary, well-being, pleasure, satisfaction, comfort, medications taken, pain, sleep, and stress. They insisted that the user should specifically select automatically-collected and self-reported data. Participants also wanted the device to be able to send notifications to help people with CLBP manage their physical activity and pain. They

highlighted the usefulness of receiving regular activity reports and of being able to access specific resources, such as physical exercises, relaxation exercises, and questionnaires to refresh knowledge about pain. They suggested the use of a wristband combined with a digital app that is easy to use, discreet, comfortable, waterproof, and robust.

Table 5. Needs relating to device content, especially functionalities, identified by experts, people with chronic low back pain (CLBP), and health care professionals.

Needs identified	Quotes (translated from French into English)
Automatically and effortlessly collect the user's activity data: steps, heart rate, active-resting time, intensity of activity, stress, and sleep	<ul style="list-style-type: none"> • "I think, on the contrary, to be able to objectively go back to your daily activities and then read, 'Oh well, yes, actually I'm doing a lot more than I feel I'm doing' or 'I'm doing a lot less than I feel I'm doing,' that's important." [Hp^a; phase 2]
Recording of data entered by the user: activity diary, well-being, pleasure, satisfaction, comfort, medication taken, pain, stress, and sleep	<ul style="list-style-type: none"> • "To be able to quantify pain." [Person with CLBP; phase 2] • "All measures, obviously pleasure activities." [Hp; phase 2] • "I am not in favor of focusing on pain, but on the positive management of pain, what is the point of quantifying it for the sake of quantifying it, the nocebo vocabulary is still used too much, and everything is still based too much on negative criteria." [Hp; phase 3, round 2]
Notifications, alerts, and messages tailored to the user	<ul style="list-style-type: none"> • "If we think about artificial intelligence, we can imagine that the application will gradually be able to personalize advice based on the data collected." [Ieg^b; phase 1] • "It could say: 'You're too stressed, do what's necessary to reduce it.'" [Person with CLBP; phase 2]
Reports: history accessible over a variable period (day, week, and month)	<ul style="list-style-type: none"> • "Have a PDF report of what we do at the end." [Person with CLBP; phase 2] • "The device captures all this data and then we make a summary to get an overview over several days, weeks, or even months." [Hp; phase 2]
Information transfer: provision of personalized physical exercises, provision of relaxation exercises, and provision of pain reminder questionnaires	<ul style="list-style-type: none"> • "I think with targeted exercises, but clearly individually, because we all do, we all have different activities." [Person with CLBP; phase 2] • "I've used a lot of digital tools, meditation tools, instant meditation support tools. It's been a great help." [Person with CLBP; phase 2] • "We tend to go back to the representations we had in the past. Questionnaire reminders." [Hp; phase 2]
Personalization: initial settings for automatically-collected data and data entered by the user, setting an activity goal	<ul style="list-style-type: none"> • "It's important to be able to personalize all the elements that the patient sees in a visual format or personalize them according to what they want to see." [Ieg; phase 1] • "Adapt the measured data." [Ieg; phase 1] • "Any personalization, tracking, and visualization options are welcome. The important thing is to give patients the freedom to choose what they want to track and share." [Person with CLBP; phase 3]

^aHp: health care professional.

^bIeg: interdisciplinary expert group.

Table 6. Needs relating to device content, especially characteristics, identified by experts, people with chronic low back pain (CLBP), and health care professionals.

Needs identified	Quotes (translated from French into English)
Support: wristband combined with a digital app on a smartphone	<ul style="list-style-type: none"> • "Just a wristband can be more discreet, with just one sensor. And then on your phone you'll see what you want to see." [Person with CLBP; phase 2]
Ease of use	<ul style="list-style-type: none"> • "For me, the keyword in all of this is simplicity. In all that it can mean in terms of tools, in terms of use, in terms of presentation. I really mean simplicity in the broadest sense." [Ieg^a; phase 1] • "Something that's hyper user friendly, because otherwise it's not worth it." [Person with CLBP; phase 2]
Esthetics: discreet, comfortable, attractive, different colors, waterproof, and robust	<ul style="list-style-type: none"> • "In terms of comfort, something that's light, that's flexible." [Person with CLBP; phase 2] • "It must also be an attractive object." [Hp^b; phase 2] • "The device would have to be waterproof because swimming is good for my pain and it would be a shame to lose my physical activity data. Also, if you're going to wear it 24 hours a day, it needs to recharge quickly." [Person with CLBP; phase 3]

^aIeg: interdisciplinary expert group.

^bHp: health care professional.

Conditions of Use

The needs of people with CLBP and health care professionals regarding the conditions of use are described in [Table 7](#) and illustrated with verbatim. Participants indicated that this device may be used either 24 hours per day or only during the day, depending on the user's preference. They wanted it to be provided by a health care professional as part of a rehabilitation program, and they wanted health care professional supervision

for its use. They wanted to be able to consult the data collected in real time, but some health care professionals expressed concern about misinterpretation and suggested that the data should initially be only available in the presence of a therapist. All participants insisted on the importance of long-term follow-up by a health care professional to check the use of the device and to help adjust the goals (either face-to-face or by videoconference).

Table 7. Needs relating to conditions of use identified by experts, people with chronic low back pain (CLBP), and health care professionals.

Conditions of use	Needs identified	Quotes (translated from French into English)
Frequency of use of the device	Can be used continuously all day, or night and day (according to the user's needs)	<ul style="list-style-type: none"> • "It has to be worn 24/7." [Person with CLBP; phase 2] • "I'd say all day, 24 hours a day." [Hp^a; phase 2] • "Be careful about wearing 24/7—to be determined according to the objectives and the patient—I think wearing it all the time is difficult over time too." [Hp; phase 3]
Conditions for providing the device	By a health professional, as part of a rehabilitation program, after educational therapy	<ul style="list-style-type: none"> • "The devices are not that easy to use, so it's also part of the therapist's role to teach how to use them, or even provide tutorials." [Ieg^b; phase 1] • "Something that will be implemented during therapeutic education workshops when we're doing nondrug tools." [Hp; phase 2]
Conditions for consulting the data for the user	In real time or when the user is a novice: possibly accompanied by a health care professional the first few times	<ul style="list-style-type: none"> • "You go to the app, you look when you feel like it." [Person with CLBP; phase 2] • "That they (patients) have access to information a posteriori, that they don't have access to information in real time, that is, that the watch or eventually the device. The application will record the data, but it won't be visible. It will only be visible after x amount of time." [Hp; phase 2] • "Real time also has its advantages. It can be motivating, depending on the parameters. There's the whole biofeedback side, which has proven to be very useful in certain situations." [Hp; phase 2]
Follow-up conditions related to device use	Follow-up session with a health care professional after a period of device use, possibly by videoconference	<ul style="list-style-type: none"> • "And maybe the digital tool and, at some point, a human relay that comes back on time that we can readjust." [Person with CLBP; phase 2] • "That's when I tell myself that teleconsultation makes sense, even in a group. At the end of a program or afterward, when you've really got an appointment." [Hp; phase 2] • "To have a regular appointment with a professional to take stock." [Person with CLBP; phase 3] • "For it to be beneficial, you'd have to have a regular review with a health professional, readjust the objectives." [Person with CLBP; phase 3]

^aHp: health care professional.

^bIeg: interdisciplinary expert group.

Facilitators and Barriers to Device Use

The facilitators and barriers to the use of a device mentioned by the participants in all the study phases are described in [Table 8](#). The facilitators mentioned corresponded to the functionalities and features considered necessary for the content of the device.

The potential barriers were related to concerns about the validity of the data collected, the storage and confidentiality of that data, the need to recharge the device, the additional availability of health care professionals to provide and monitor the device, and the risk of adverse effects associated with the use of the device.

Table 8. Facilitators and barriers to the use of a device identified by people with chronic low back pain (CLBP) and health care professionals in phases 2 and 3.

Facilitators and barriers	Quotes (translated from French into English)
Facilitators	
Personalization	<ul style="list-style-type: none"> • Provided in Table 5
Ease of use	<ul style="list-style-type: none"> • Provided in Table 6
Esthetic	<ul style="list-style-type: none"> • Provided in Table 6
Conditions of use	<ul style="list-style-type: none"> • Provided in Table 7
Barriers	
Validity of automatic data collection	<ul style="list-style-type: none"> • “(The device) is not ready for sleep yet.” [Person with CLBP; phase 3] • “In addition, the measurement accuracy of these objects is still very random.” [Hp^a; phase 2] • “Heart rate is a very interesting variable, but the measuring devices are often unreliable.” [Hp; phase 3]
Data storage and security	<ul style="list-style-type: none"> • “I’m not so much a fan of data in the cloud. I’m not a big fan of data that just magically disappears.” [Person with CLBP; phase 2] • “To have this tool that measures all our activities for weeks on end? Well, there are things that are a little bit in the realm of privacy that will also be measured.” [Person with CLBP; phase 2]
Instrument: setting up and reloading the device	<ul style="list-style-type: none"> • “The debate is about the battery and recharging.” [Person with CLBP; phase 2] • “The only drawback, like any electronic device, is that it needs to be recharged, which creates a time lapse where the data is not, cannot be collected automatically and subjectively by the device.” [Hp; phase 2]
Conditions for making the device available and monitoring its use	<ul style="list-style-type: none"> • “In the feasibility of the current programs. We’d need more time to integrate such a tool, because if we have to add things. If we have to add another tool to integrate. On top of what we’re already asked to do. Of course, that means extra time.” [Hp; phase 2]
Adverse reactions linked to the use of the device: misinterpretation, guilt	<ul style="list-style-type: none"> • “They make cause-and-effect relationships that are very random. And these objects also have a very random precision of measurement, so sometimes they come to conclusions that are completely off the mark, and sometimes, in my opinion, in some cases, I’m not saying for all, but it can be counterproductive.” [Hp; phase 2] • “Wearing a connected bracelet 24 hours a day can be stimulating for some profiles, but it can also be guilt-inducing for others.” [Hp; phase 3]

^aHp: health care professional.

Needs Validation

The needs of people with CLBP and health care professionals regarding device concept and content and the conditions of use were confirmed in 2 rounds of Delphi questionnaires with 86 and 61 participants, respectively (Tables 9 and 10). Twenty-eight needs were selected from those identified in the previous 2 study phases. A lot of attention was given to the variables that could be collected or recorded by the device, as much of the discussion in phases 1 and 2 focused on these aspects. In the first round,

consensus was reached on 13 (46%) of the 28 needs (the 13 validated needs are italicized in Table 9). In the second round, the 15 needs for which there was no consensus were modified based on the suggestions made in the first round of consultation: 11 (73%) of the 15 needs were reformulated, and 3 (20%) of the 15 needs were merged into a single need (changes in needs are italicized in Table 10). In the second round, consensus was reached on 11 (91%) of the 12 needs. Out of 25 needs in total, a consensus was reached on 24 (96%) needs.

Table 9. Degree of consensus on the items proposed in the Delphi questionnaire for each participant group (round 1).

Items: "The device should make it possible to"	All, (N=86; %)	People with CLBP ^a (n=45; %)	Hp ^b (n=41; %)
<i>Achieve a personalized physical activity goal^c (Cc^d)</i>	99	98	100

Synthesis of Design Recommendations

The needs validated by the participants were synthesized as design recommendations using the Behavioral Intervention Technology model and are illustrated in [Figure 2](#). This is based on the illustration of the MyFitnessPal mHealth app by Mohr et al [56] and describes the expected functionalities and technical features of the device. The numbers shown illustrate the

conditions of use and the expected workflow: (1) first, the automatic data collected by the device can be selected, then (2) the data collected by the user can also be selected. From this, (3) an activity objective can be defined, (4) and the user can follow changes in the values of variables collected or recorded, referring, if he or she wishes, to the physical or relaxation exercises proposed. (5) Reception of regular notifications and alarms can be set.

Figure 2. Illustration of design recommendations for a mobile health device that specifically meets the identified needs of people with chronic low back pain and health care professionals to support self-managed physical activity.

Discussion

Principal Findings

This study explored the needs of people with CLBP and health care professionals regarding the use of mHealth technology to support self-managed physical activity and pain. It elucidated how people with CLBP believed the adoption of an mHealth device could mitigate their difficulties in managing physical activity in relation to their pain, beliefs, difficulties in pacing physical activity, and the need for long-term individualized support.

The results of this study show that participants (people with CLBP and health care professionals) expressed interest in using an mHealth system to help people with CLBP manage their physical activity and pain over the long term. They wanted a device that would allow them to set personalized activity goals, monitor their activity, receive feedback on their performance, receive positive reinforcement, possibly receive rewards, learn information, and receive social support. These results provide a more precise definition of the needs identified by Merolli et al [46], who highlighted the usefulness of developing a technological solution to support the self-management of CLBP with tracking, notifications, feedback, provision of educational resources, and exercises. These results, collected using a rigorous process, accurately describe the expectations of end users in terms of the characteristics of a potential device.

Special attention was paid to the functionalities and variables recorded by the device. This is a fundamental step in the development of effective technology [57]. People with CLBP and health care professionals described the need to set realistic activity goals and to track them using an mHealth device, while also having complementary tools to help them manage their pain daily (eg, a physical activity exercise bank and relaxation exercises). They strongly emphasized that physical activity

should be monitored using self-selected variables, stating that the need was not always to increase physical activity level, but rather to better pace it daily through achievable goals. Several participants with CLBP highlighted their tendency to overdo activity, debunking the assumption that physical activity levels in people with CLBP are often lower than in healthy people [58-60].

Overall, people with CLBP and health care professionals expressed similar needs in terms of an mHealth device. They strongly emphasized that the settings should be personalized, and the device should be easy to use. However, the opinions of these groups differed regarding the variables that should be collected and the components that should be provided by the device. Health care professionals believed the focus should not be on the assessment of negative variables, such as pain, whereas people with CLBP wanted to collect this type of variable. Health care professionals suggested that a “challenge” module should be included, with a system to collect points or badges, to encourage users to interact with the device. The opinions of the people with CLBP were more divided about such a module, with some very interested in this type of reward and others completely opposed to it because they were afraid of being involved in competitive challenges. The gamification of mHealth is attracting increasing interest as a means of encouraging changes in physical activity behavior, although current evidence on the effectiveness of this type of device is still limited [61,62].

The potential disadvantages and adverse effects associated with the use of a device to self-manage physical activity were discussed in detail during the 3 phases of the study. On the one hand, the effects of such a device on the development of new behaviors and lifestyles may be directly linked to its maintenance. For example, behavior change is less likely to occur if the device monitor is lost, broken, not charged, or forgotten. In contrast, if the device is used consistently and integrated into an intervention aimed at maintaining new

behaviors, new habits could emerge in the medium term [63,64]. In addition, some health care professionals were concerned that people with CLBP could misinterpret the data collected by the device, and that this could induce feelings of guilt. Indeed, some health care professionals were against users being able to consult their data in real time, whereas people with CLBP saw this as an obvious possibility. The ability of the mHealth device to provide feedback to the user is considered important for encouraging behavioral change [61,65]. Health care professionals also mentioned the additional time required to teach their patients to use the device. In addition, both health care professionals and people with CLBP expressed concern about the validity of automatically-collected data, its security, and the individual's privacy.

The discussions went well beyond the functionality of the device. The results highlighted the importance of developing an intervention around the mHealth device to help people with CLBP manage their activity and pain, rather than simply relying on the mHealth device. Human support was stated as an essential component of long-term care for people with CLBP. These results confirmed the findings of Svendsen et al [66] that technology alone was not enough to encourage people to engage in self-management. All participants were very clear about the conditions in which the device should be made available, that is, its implementation should be supported by a health care professional, and education should be provided on the importance of physical activity, its role in pain management, and the operation of the device. Education is important to increase the effectiveness of device use because people's beliefs determine their behavior [67]. These findings go beyond those of the pilot study by Ellingson et al [68], which showed the promising effects of a device-based intervention combined with minimal human support for people with CLBP; because they specified the expected characteristics of human support, in particular, the context in which the device should be offered, how it should be supported by health care professionals, and the frequency at which health care professional support should be provided.

After validating the needs of people with CLBP and health care professionals regarding mHealth devices, we developed design recommendations using the Behavioral Intervention Technology model (Figure 2) [56]. This model helped to structure the needs identified during the 3 phases of the study and to link them to the behavior change strategies that could be integrated within a new intervention encompassing the use of an mHealth device. These design recommendations should now be further developed in the light of behavior change theories and taxonomies currently published in the literature (eg, Michie's taxonomy) [14,69,70]. Future research should also seek to discuss and refine the prototype development phase with end users. Indeed, after this

initial conceptualization phase, this synthesis could be revisited at a later stage to continue the prototype development phase, still using a user-centered approach.

Limitations

This study was based on the experiences of experts and potential end users. It first identified the needs of 9 experts in phase 1, followed by 26 people with CLBP and health care professionals in phase 2, and then validated these needs with a large number of participants (86 in the first round and 62 in the second round). Despite the sample size, the first limitation concerns the population studied, and its impact on the representativeness and transferability of the results. The participants with CLBP and the health care professionals were all involved in multidisciplinary rehabilitation; therefore, the results may not be generalizable to other settings. This choice was made to have a comparable, homogeneous sample, but the needs and experiences of people with CLBP who do not have access to multidisciplinary rehabilitation (ie, only physiotherapy sessions) may be different.

The Delphi method used in phase 3 may have been subject to some bias. Although the needs for device design were developed during phases 1 and 2, not all the elements that emerged in the first 2 phases were specifically examined during phase 3. The elements selected by the research team for the Delphi questionnaire are those that have been the subject of significant debate among the participants in the previous phases. Thus, in phase 3, particular attention was paid to the variables collected by the device, the content, and the condition of use. This process may have left out elements that would have been also important to present in the Delphi questionnaire. In addition, participants involved in phase 2 were invited to take part in phase 3, which might have introduced bias because of their previous involvement in defining the needs. This involvement may have resulted in an overestimation of the consensus level achieved in the 2 rounds of Delphi questionnaires.

Conclusions

This study used a UCD approach to explore the needs of people with CLBP and health care professionals regarding the use of a device to support self-managed physical activity. It identified potential users' expectations regarding the device's objectives, behavior-change strategies supported by the device, the device's functionalities, its technical features, and facilitators and barriers that may influence its implementation in a clinical context. The results were used to delineate design recommendations for the development of an mHealth device specifically for people with CLBP and health care professionals. These recommendations will be used in the future to prototype innovative devices that could be offered by health care professionals to people with CLBP in a follow-up rehabilitation context.

Acknowledgments

This study was supported by the University of Applied Sciences and Arts Western Switzerland (Haute école spécialisée de Suisse occidentale, HES-SO). It was also supported by the Claude Bernard Lyon 1 University and Ezus association. The authors thank Emmanuelle Chaléat-Valayer, Stéphane Genevay, and Damiano Salvi for their help in recruiting participants.

Abstract

Background: People with Achilles tendinopathy (AT) experience persistent pain that can limit engagement with daily occupations and negatively impact mental health. Current therapeutic exercise approaches vary in success, with many people experiencing reinjury, leading to a cycle of chronic tendinopathy often lasting years. High-magnitude precision loading may help people exit this feedback cycle, but applying these principles clinically is challenging.

Objective: This user-centered design case study aims to provide an overview on how the PhysViz (a prototype for a novel remote rehabilitation intervention for AT management) was developed and evaluated following the development phase of the Framework for Accelerated and Systematic Technology-Based Intervention Development and Evaluation Research (FASTER).

Methods: The development process engaged a multidisciplinary team comprising people with AT experiences, clinicians, and engineers. It followed the 5 stages within the FASTER development phase: empathize, define, ideate, prototype, and test. The PhysViz development and evaluation were informed by needs assessments, surveys, literature reviews, validation studies, case studies, roundtable discussions, and usability testing (some of which have been published previously). The FASTER systematically guided the integration of evidence-based features and behavior change theory.

Results: By using the FASTER and ensuring that the PhysViz system was underpinned by diverse stakeholder needs, this work resulted in the development of a working prototype for both the PhysViz physical exercise tool and the accompanying PhysViz software package (mobile app and web application). A variety of study designs informed user-desired features that were integrated into the PhysViz prototype, including real-time biofeedback in the form of precision load monitoring, customizable exercise programs, and pain tracking. In addition, clinicians can visualize client data longitudinally and make changes to client exercise prescriptions remotely based on objective data. The identified areas for improvement, such as upgrading the user interface and user experience and expanding clinical applications, provide valuable insights for future PhysViz iterations. Further research is warranted to assess the long-term efficacy and feasibility of the PhysViz in diverse clinical settings and its potential to improve AT symptoms.

Conclusions: Being one of the first technology development initiatives guided by the FASTER, this study exemplifies a systematic and multidisciplinary approach to creating a remote rehabilitation intervention. By incorporating stakeholder feedback and evidence-based features, the PhysViz addresses key challenges in AT rehabilitation, offering a novel solution for precision

loading and therapeutic exercise engagement. Positive feedback from users and clinicians underscores the potential impact of the PhysViz in improving AT management outcomes. The PhysViz serves as a model for technology-based intervention development, with potential implications for other tendinopathies and remote rehabilitation strategies.

Introduction

Background

Achilles tendinopathy (AT)—a chronic condition characterized by ongoing pain in the Achilles tendon and loss of function related to mechanical loading [1]—may limit participation in daily activities while negatively impacting mental health and reducing quality of life [2]. Although therapeutic exercise is the cornerstone of nonsurgical AT management [3-5], success varies [6-9], and rates of reinjury are high (eg, up to 27% in elite athletes) [10]. Tendinopathy may be recalcitrant to treatment [11,12] due, in part, to inappropriate treatment selection, inadequate dosing of therapeutic exercises, or psychosocial or contextual factors that are barriers to therapeutic exercise adherence [13,14]. Taken together, these facts highlight the need for research to optimize exercise-based AT treatment protocols and methods to personalize and deliver these protocols to promote adherence to therapeutic exercise and improve clinical outcomes.

Therapeutic exercise using high-magnitude loading (ie, >70% of maximal voluntary contraction [MVC]) can elicit positive adaptation in healthy tendons [15,16]. The extent to which these findings transfer to tendinopathic tendons remains largely unknown [17]. An individualized dose of 70% MVC exercise is higher than what is typically used in AT rehabilitation [6,18-20], and clinicians such as physical therapists (PTs) may struggle to achieve both this load magnitude and precision in the clinic. Although a 70% MVC prescription may be achieved clinically by basing an exercise load on a patient's 1-repetition maximum, remote monitoring systems may improve access to adjustable high-magnitude precision loading and promote exercise adherence.

Remote monitoring systems can improve access to care, reduce the need for in-person follow-up and associated costs, and increase patient engagement with self-monitoring and built-in opportunities for clinician feedback [21,22]. As pain behavior is 1 method clinicians use to moderate AT exercise programs [6,18-20] (eg, instructions to not exceed a certain rating on a 10-point numerical pain rating scale during therapeutic exercises), home-based precision exercise dosing incorporating biofeedback and remote clinician monitoring could provide patients reassurance that their pain is acceptable and that they are operating in the correct loading range.

Existing dosing feedback systems are not yet practical or scalable due to prohibitive costs, space requirements (ie, isokinetic dynamometers), functional limitations (eg, positioning using handheld dynamometry as well as appropriate biofeedback and user interface [UI] and user experience [UX]) [23,24], and

a lack of tailoring for home use by nonprofessionals. Given these limitations, and within the scope of AT rehabilitation, the development of a new system to facilitate precision dose-based therapeutic exercise is warranted. Knowing that the magnitude and precision of loading are important factors for inducing positive tendon adaptation [15,16], a home-based exercise-dosing system incorporating biofeedback and remote monitoring could potentially improve outcomes for those with AT. This paper provides a high-level overview of the development of 1 such system using the Framework for Accelerated and Systematic Technology-Based Intervention Development and Evaluation Research (FASTER) [25].

Prior Work

The concept for a home-based training system to enable high-magnitude loading of the triceps surae (ie, the gastrocnemius, soleus, and plantaris muscles, which act through the Achilles tendon to plantarflex the foot) comes from researchers at the Institute of Sport Sciences at the Humboldt University of Berlin [26]. In 2020, the Tendon Injury Prevention and Rehabilitation Group at the University of British Columbia consulted with the Humboldt group and obtained permission to adapt the Humboldt researchers' idea for the development of an AT remote rehabilitation system, called the 'PhysViz'.

The PhysViz comprises a physical exercise tool incorporating a Bluetooth-enabled load sensor and the PhysViz software package consisting of a patient-facing mobile phone app and clinician-facing web application. The purpose of the PhysViz is to facilitate high-magnitude loading of the Achilles tendon, collect loading data, provide real-time biofeedback during loading to promote exercise engagement, centralize all patient data for review, and enable the remote modification of a patient's exercise prescription by an overseeing clinician. The goal of the system is to enhance AT rehabilitation through high-load precision exercise-dosing approaches and empower active participation of patients in their rehabilitation through the dissemination of actionable information to both patients and clinicians.

The Goal of This Study

Designing a new system to facilitate precision dose-based therapeutic exercise in an evidence-based and user-informed manner is challenging. Traditional design often prioritizes time to market, potentially at the expense of rigor [27]. Rigorous, evidence-based, user-centric development takes time; however, such a time delay may lead to technologies becoming obsolete, implementation conditions changing, or new interventions emerging [25]. Unfortunately, a significant portion of medical research funding (up to 80%) ends up as "research waste," failing to make a notable impact on public health [28]. In

addition, 50% of clinical innovations never reach widespread clinical adoption [29], and the translation of research-based solutions into clinical practice can take upwards of 17 years [30]. As such, technology-based clinical interventions must strategically develop solutions and generate supporting evidence in a timely manner [25]. This work aims to describe the approach taken to develop the PhysViz, which features user-centric development and theoretical underpinning. This manuscript not only presents the systematic approach taken in developing the PhysViz system but also highlights both previously published findings (primarily in the empathize stage within the FASTER development phase) and new findings (primarily in the prototype and test stages).

Methods

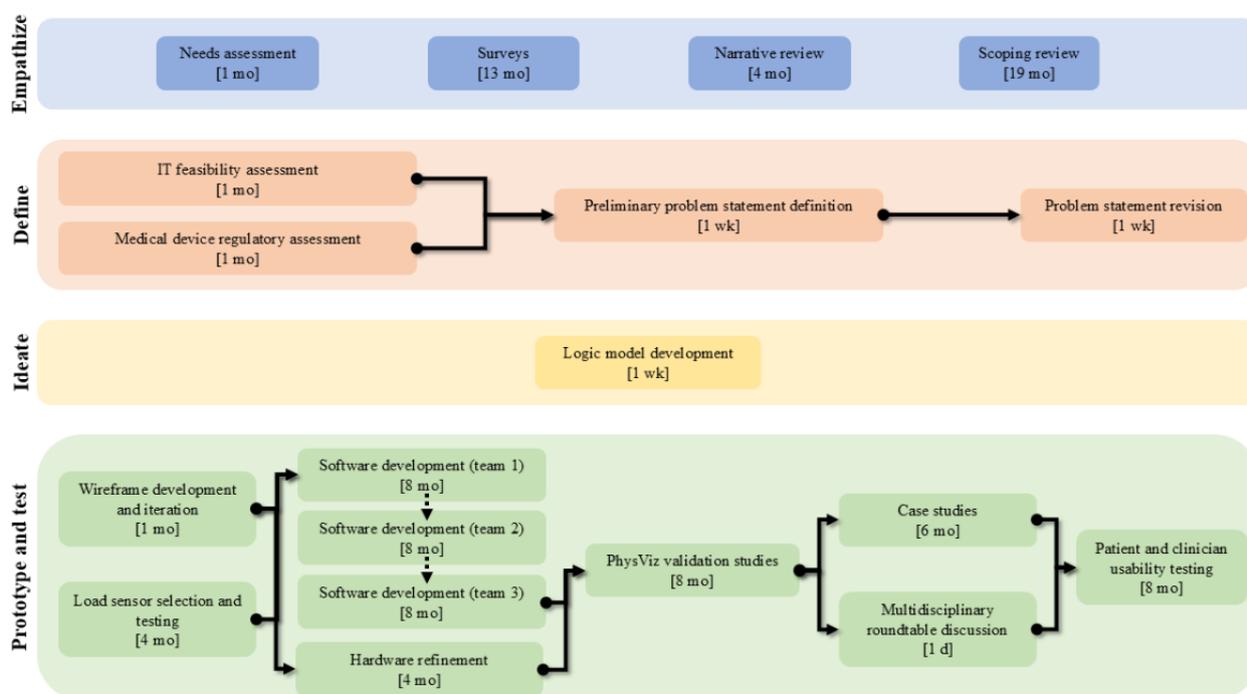

Design Approach

To promote the timely and strategic generation of supporting evidence, the PhysViz development is guided by the FASTER [25]. The FASTER includes 3 phases: development, progressive usability and feasibility evaluation, and scaled evaluation and implementation. This work is situated within the development phase, which aims to engage with end users and use transdisciplinary thinking (eg, engineering design and clinical experience) to generate actionable evidence appropriate for the

efficient design and implementation of technology-based interventions. Specifically, within this phase, the FASTER underscores the importance of empathizing with users to understand their needs, preferences, and experiences while also using established design theories to generate ideas, develop prototypes, test them, and iterate. The FASTER development phase can be further broken down into 5 stages derived from Stanford Design Thinking: empathize, define, ideate, prototype, and test [31].

This work describes 1 of the first case studies applying the FASTER for the development of a remote rehabilitation system. An overview of the design approach and timeline is presented in Figure 1. By integrating previously published studies with new research, this manuscript offers a comprehensive perspective on the PhysViz development process guided by the FASTER. It is important to note that this manuscript offers a broad overview of how various research studies contributed to the PhysViz design through the FASTER development phase. It does not provide a detailed account of the methods and results of each individual study involved in the PhysViz development. To ensure transparency and facilitate replication of the development process, studies that have not been previously published in peer-reviewed journals have been deposited on the Open Science Framework website [32-34].

Figure 1. PhysViz development timeline according to the development phase of the Framework for Accelerated and Systematic Technology-Based Intervention Development and Evaluation Research. The arrows denote the progression of tasks. When arrows are not present, this denotes tasks completed concurrently. Development broadly progressed from the empathize stage to the prototype and test stages.

Stages of the FASTER Development Phase

Empathize

Within the FASTER empathize stage, researchers should determine end-user needs and preferences while also examining the broader context to define the research problem in detail [25]. As such, this stage consists of a needs assessment and surveys

to garner information on end-user needs, while also including both narrative and scoping reviews to gain a broader understanding of exercise-based AT rehabilitation.

Needs Assessment

To assess end-user needs for the patient-facing Phys Viz mobile app, our research team completed a needs assessment featuring

clinicians, engineers, patient partners, and researchers. Due to the transdisciplinary nature of developing a software tool for home-based use by patients, it was vital to get multiple perspectives to establish the initial direction of the app development. Specifically, the research team was asked the following in reference to the PhysViz app: (1) what features they must see; (2) what features they would like to see; (3) what information they would like tracked; (4) what they would like the UI to look like; (5) whether they expected to see an overview or summary dashboard, and if so, what information they would like displayed there; (6) what type of security protection they expected to see; and (7) whether they had any other comments or relevant information pertaining to the development. All suggestions were collated and presented back to the research team for communal ranking before starting the development process.

Surveys

As described in Merry et al [35], to further identify end-user needs and preferences within the specific implementation context, we conducted 2 surveys to identify perceived barriers and facilitators to participating in and prescribing exercise-based therapies for AT among people with AT and PTs, respectively. While the PT survey assessed both clinical practice patterns and barriers and facilitators to developing, prescribing, and monitoring exercise-based treatments for AT, the survey of people with AT expanded upon the barriers and facilitators pertaining to engagement and adherence to exercise-based rehabilitation for AT through a series of questions using the capability, opportunity, motivation, and behavior (COM-B) model [36,37]. According to the COM-B model, for a behavior to occur, an individual must have sufficient *capability* (physical and psychological), *opportunity* (social and physical), and *motivation* (automatic and reflective). In addition, we asked participants what potential app features are desirable in the context of AT rehabilitation.

Narrative and Scoping Reviews

As described in Merry et al [17], we completed a narrative review to provide an overview of the broader AT context by (1) synthesizing the principles of tendon remodeling under resistance exercise-induced loading among both healthy and pathological tendons and (2) commenting on the biomechanical principles of Achilles tendon loading that may impact a therapeutic exercise prescription for AT. This work not only served to identify research gaps and potential future use cases for the PhysViz, but it was also undertaken to inform aspects of the PhysViz development based on prior evidence.

As described in Merry et al [32,38] and in parallel to the narrative review, we conducted a scoping review to synthesize how current resistance exercise-based AT interventions are being designed and implemented clinically. Given that therapeutic exercise is considered a primary clinical management strategy for AT [3,4], this review sought to understand what aspects of therapeutic exercise may be common across the clinical research evidence (in contrast to the largely mechanistic evidence encompassed in the narrative review) and how these aspects could potentially be built into the PhysViz design [32,38].

Define

In the define stage, information from the empathize stage is used to specify the problem in detail, including its location, the potential users and stakeholders involved, and any other pertinent details. Using both the contextual and research evidence identified in the empathize stage, we defined a preliminary problem statement. The problem statement was then refined after a medical device regulatory assessment and an IT feasibility assessment.

Ideate

The ideate stage then focuses on the generation of ideas and the exploration of possible solutions to the problem. Specifically, we developed a logic model for the PhysViz based on the therapeutic exercise treatment principles (both mechanistic and clinical) identified in the empathize stage coupled with the barriers and facilitators to participating in and prescribing therapeutic exercise for AT identified using the COM-B model. The purpose of developing the logic model was to link potential PhysViz features to desirable behavioral and treatment outcomes a priori; in this way, features could be strategically developed based on evidence and proposed treatment pathways rather than on personal opinions or “it sounded like a good idea at the time” logic.

Prototype and Test

Overview

The prototype stage describes the creation of low-fidelity prototypes using select ideas from the ideate stage to help the team members visualize and communicate their ideas. Select prototypes are then advanced to the test stage where feedback from end users and stakeholders is garnered to evaluate the feasibility of the design solution. The prototype and test stages are critical for ensuring that the team’s design solution is feasible and meets the needs of the end users. The iterative nature of these stages allows for continual improvements and adjustments, ultimately leading to the timely development of a more appropriate and user-friendly final product.

Using the logic models as a feature guide, we developed a series of wireframe designs for the PhysViz patient-facing mobile app and clinician-facing web application. The wireframes were then presented to the research team for review and iteration before beginning the software development. We completed the development of the PhysViz software consisting of both a mobile app and a web application in collaboration with 3 teams of senior computer engineering students from the University of British Columbia. Each team, consisting of 4 to 5 students, completed 8 months of development before passing the development to the next team. Building upon the initial design developed by the Humboldt group [26] and given the incorporation of a Bluetooth-enabled load sensor in the PhysViz design, the first PhysViz physical exercise tool was tested by the research team to assess viability and potential modifications based on learnings from the empathize stage.

Load Sensor Selection and Testing

As described in Merry et al [39], a fundamental aspect of the PhysViz design was the inclusion of a Bluetooth-enabled load

sensor enabling mobile phone connectivity with the physical exercise tool. To start, we searched for an appropriate load sensor to meet the following criteria: (1) the product must be Bluetooth ready, (2) both tensile and compressive sensors were considered, (3) there were no restrictions on price, and (4) high-load tensile load sensors (eg, crane scales) were not considered. We reviewed 11 load sensors and selected 2 for more rigorous testing based on relevant technical specifications. Advanced testing consisted of comparing each load cell's output against a gold standard mechanical testing machine to assess validity and reliability [39]. After the completion of this study, a single load sensor was selected for inclusion in the physical exercise tool.

PhysViz Validation

In conjunction with work undertaken by Pratt et al [40], with an initial prototype of the PhysViz system complete and before using it for AT rehabilitation purposes, it was important to determine whether the system could consistently and accurately measure *in vivo* muscle strength compared to computerized dynamometry, which is the gold standard for assessing muscle function; for example, if a particular exercise prescription was meant to be based on an individual's MVC, was the MVC recorded using the PhysViz valid and reliable, thus promoting safe use among individuals who were symptomatic? We completed a validation study with healthy individuals to establish the efficacy of the PhysViz as a potential home-based exercise tool [40].

In conjunction with work undertaken by Schreiber et al [33], given the fundamental roles of precision load management and objective feedback (via the app) in the PhysViz system, it was also important to quantify whether real-time biofeedback has the potential to enhance the execution of AT rehabilitation exercises; for example, if an exercise program prescribed isometric plantar flexion exercises at 70% of an individual's MVC, would the biofeedback provided by the PhysViz to the individual improve their ability to execute the exercises at the prescribed load? We completed a cross-sectional study with healthy individuals to study the effect of biofeedback within this context [33].

Case Studies

Having completed basic validation of the PhysViz system, we conducted three 12-week case studies among people with current AT symptoms under the oversight of a clinician-scientist. Case studies began with an introductory session where we gave each participant basic instructions on how to use the PhysViz. We then tested the participant's plantarflexion MVC using the PhysViz, which informed the first therapeutic exercise dose intensity (70% of MVC). We asked each participant to exercise 2 to 3 times a week using the "exercise mode" of the PhysViz, which guides users through a therapeutic exercise session using audiovisual biofeedback. The research clinician checked in with participants approximately every 3 weeks and adjusted the therapeutic exercise dose based on participant tolerability. At the end of the 12 weeks, we held a semistructured debrief interview with each participant to discuss intervention acceptability, ergonomics, UI design, and comfort.

Multidisciplinary Roundtable Discussion

In parallel to the case studies, we assembled a stakeholder group for an open discussion to (1) refine the design through communal knowledge with a focus on proposals for improvement (customization and flexibility) and utility, (2) consider potential feature additions identified during the survey, and (3) comment on potential use cases beyond AT. The stakeholder group consisted of the research team in addition to external clinician-scientists, practicing clinicians (PTs, occupational therapists, and physicians), people with lived AT experiences, engineers, and insurers or regulators.

Patient and Clinician Usability Testing

As described in Merry et al [34], to obtain further user feedback on the PhysViz prototype, we completed a cross-sectional usability study including both people with AT and PTs. We used semistructured 1-on-1 interviews with embedded usability testing featuring a concurrent think-aloud method [41] to inform iteration on the PhysViz system in conjunction with the case studies and roundtable discussion. Combined results from the usability testing and concurrent think-aloud findings were used to create a list of potential design alterations based on common usability issues and end-user suggestions for improvement. The proposed modifications were then evaluated independently by 2 researchers (KM and MMM) using the affordability, practicability, effectiveness, acceptability, side effects and safety, and equity (APEASE) criteria [42]. Interrater agreement was assessed using Cohen's κ and prevalence-adjusted bias-adjusted κ . Values between 0.61 and 0.80 indicate substantial agreement, and values exceeding 0.80 indicate almost perfect agreement [43,44]. A critical appraisal of each proposed modification using the APEASE criteria facilitated the inclusion of only those modifications deemed most feasible for potential implementation in the second version of the PhysViz system.

Ethical Considerations

Ethics approval for this study was obtained from the University of British Columbia Clinical Research Ethics Board (approval number: H21-02879). Participants provided informed consent to participate in the study before taking part.

Results

Empathize

Needs Assessment

Five members of the research team completed the needs assessment, which led to establishing an initial direction for the PhysViz software development. Common "must-see" features included load monitoring and biofeedback, a customizable exercise program, app availability for both iOS and Android devices, and the ability to sync data between the mobile app and the web application. Some examples of "would be nice" features included instructions for participants (eg, video demonstrations or animations), reminders or notifications, a program calendar, and 2-way interaction capabilities between the patient and clinician. A desirable UI was defined by participants as simple and minimalistic, with an emphasis on ease of use for users of different ages and digital literacy levels.

User safety (people with AT) was noted as particularly important with a need to avoid placing any patient in a potentially harmful position by trying to complete therapeutic exercises exceeding recommended intensities.

Surveys

The survey results, which are published elsewhere [35], led to the following features being prioritized within the initial conceptualization of the PhysViz: exercise demonstrations, education on AT and treatment strategies, guided exercise sessions (ie, automatically counts sets, repetitions, and rest periods), and pop-up reminders for completing the exercise program.

Narrative and Scoping Reviews

The narrative review results, which are published elsewhere [17], highlighted the importance of high-load tolerability with the PhysViz design. The long sitting position was identified as advantageous to allow for ankle dorsiflexion and knee extension within the PhysViz design.

The findings from the scoping review, which are published elsewhere [38], emphasized the importance of modifiable exercise programs (both in terms of adjustable resistance and exercise volume) and the incorporation of techniques that allow for improved tracking of treatment fidelity and adherence within the PhysViz design.

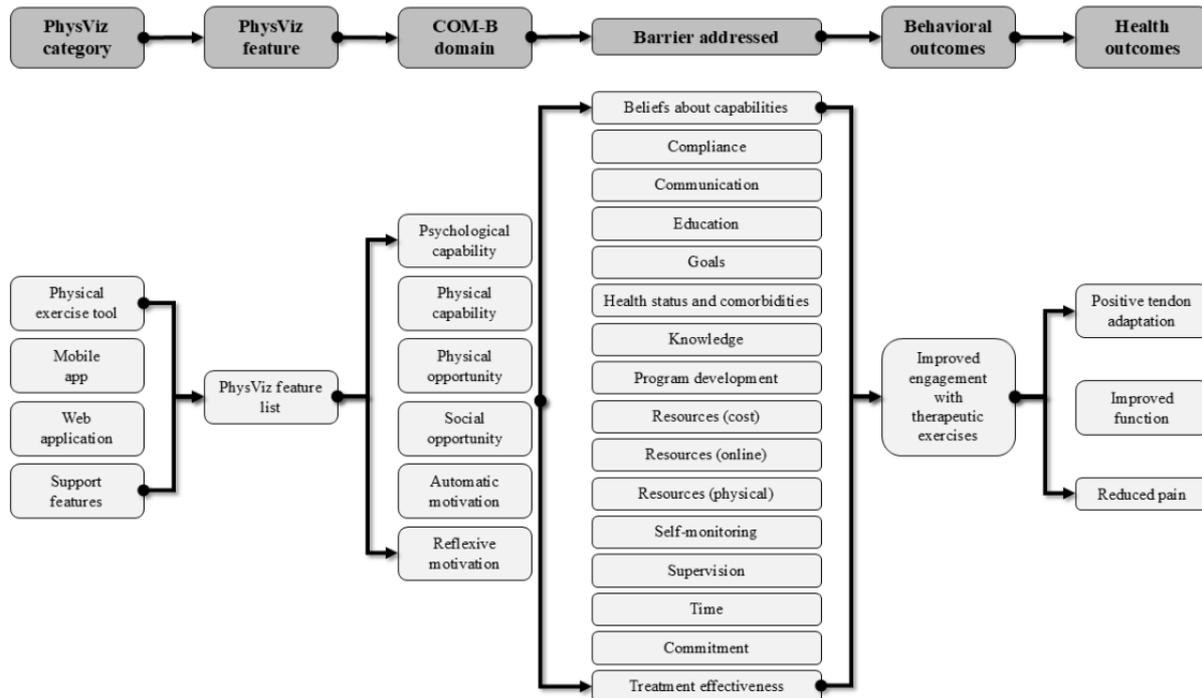

Define

Primary users of the PhysViz system are expected to be people with AT and PTs or other clinicians (eg, occupational therapists and physicians) who oversee and guide AT management. Secondary users will include clinical practice regulators, health care insurers, software engineers, and researchers. The initial problem statement was as follows: “People with chronic AT need a better way to deliver heavy loads to the Achilles tendon because not everyone has access to exercise equipment, and sufficient loading intensity appears to be important for tendon rehabilitation.” After regulatory and feasibility assessments, the problem statement was revised as follows: “People with chronic AT want to get back to their sports and daily occupations quickly but often struggle to adhere to therapeutic exercise programs and load the tendon heavily enough. Emerging exercise technologies have the potential to empower users, providing autonomy and objective feedback, thereby facilitating a quicker return to their activities.”

Ideate

We used findings from the empathize stage to inform the development of a logic model to address the revised problem statement and guide the initial development of the PhysViz system by linking potential evidence-based features with behavioral and treatment outcomes. Figure 2 presents a general logic model, while detailed logic models are presented in Multimedia Appendix 1.

Figure 2. PhysViz development general logic model. COM-B: capability, opportunity, motivation, and behavior.

Prototype and Test

Overview

On the basis of findings from the preceding stages and the operationalization of these findings in the logic model, we developed wireframe designs for both the PhysViz mobile app

and web application (Figure 3 and Figure 4, respectively). The wireframe designs evolved based on circulation and iteration among the research team and were ultimately developed into working software packages for testing. In addition to the custom mobile app and web application, the physical exercise tool rounds out the PhysViz system architecture (Figure 5).

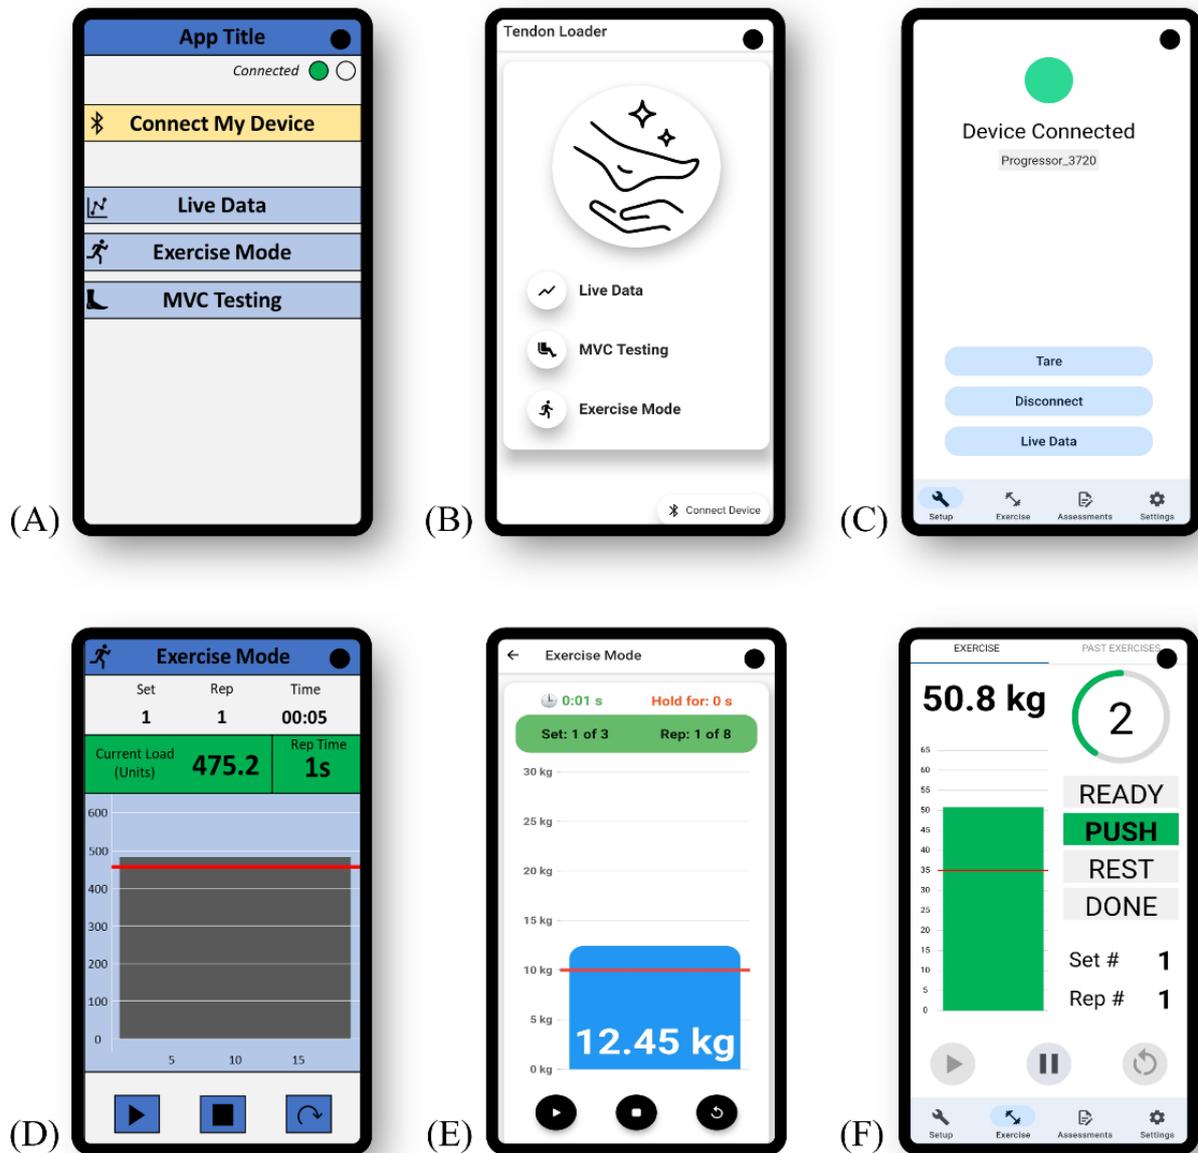

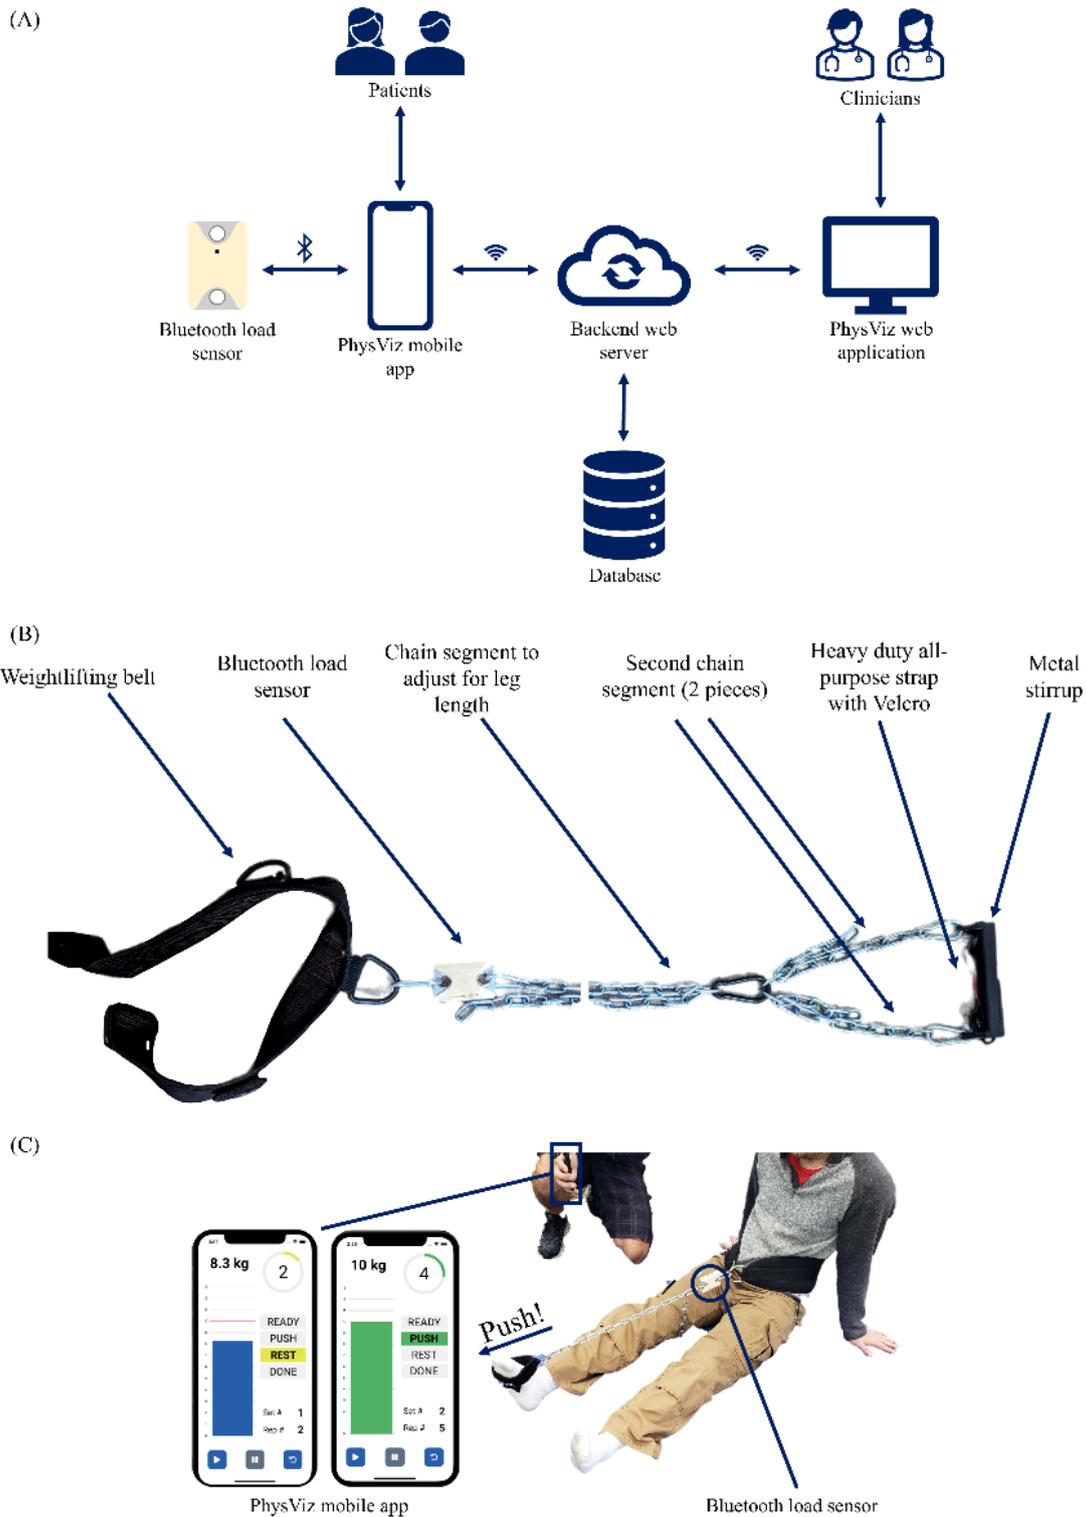

Figure 4. PhysViz web application sample exercise page. (A) Initial wireframe. (B) First prototype. (C) Current prototype.

Figure 5. (A) System architecture diagram. (B) Current iteration of the PhysViz physical exercise tool. (C) Demonstration of intended system use with participant plantarflexing into the stirrup and imparting a load through the Achilles tendon. Participant simultaneously receives real-time biofeedback from the PhysViz mobile app.

Load Sensor Selection and Testing

We selected the Progressor load sensor (Tindeg) for inclusion in the PhysViz system due to its superior performance across its measurement range compared with the Activ5 load sensor (Activbody). Complete findings are provided in the study by Merry et al [39].

PhysViz Validation

The findings indicate that the PhysViz is a valid and reliable tool for isometric plantar flexor MVC measurement; complete findings are provided in the study by Pratt et al [40]. In addition, according to the findings presented in the study by Schreiber et al [33], PhysViz biofeedback was found to enhance the execution of AT therapeutic exercises by lessening the

percentage difference between recorded and prescribed load across a brief exercise protocol (ie, 2 sets of 10 five-second repetitions) compared to a nonbiofeedback condition.

Case Studies

Over the 12 weeks, participant 1, a male individual aged 35 years experiencing unilateral AT for 5 months, completed 27 therapeutic exercise sessions using the PhysViz. In this time, participant 1's plantarflexion MVC on his affected side increased by 29% despite his pain score remaining unchanged.

Due to an additional sports-related injury impacting the affected side, participant 2, a male individual aged 40 years experiencing unilateral AT for 6 years, elected to discontinue the case study after 6 weeks. Over these 6 weeks, participant 2 completed 7 exercise sessions with the PhysViz. Only a single MVC test was recorded, precluding any inquiry into strength increases.

Participant 3, a female individual aged 57 years experiencing bilateral AT for 1 year, completed 8 exercise sessions with the PhysViz over the 12 weeks and increased her plantarflexion MVC by 20%. Participant 3's pain score and self-reported pain tolerability was variable, with no clear trend.

Overall, information from the interviews showed that the PhysViz system was well received by all 3 participants. Specifically, the participants identified that compared to standard treatment options (ie, heel drops or calf raises), the real-time biofeedback was particularly useful because it promoted engagement in the rehabilitation process through the visualization of load intensity and the pacing of repetitions. Nevertheless, all 3 participants noted lower extremity pain while using the system, particularly in the knee, calf, and Achilles tendon. Despite reporting that the pain was tolerable, they expressed a desire to refine the positioning to mitigate the pain and improve overall comfort during use. Finally, the participants generally felt that the UI of the mobile app was adequate and accessible, although simplistic in comparison to other apps. If the plan is to disseminate the system beyond a research-based audience, the participants suggested improving the UI and adding additional features to bolster the somewhat rudimentary UX (eg, brief animations, reminders to complete exercises, and an in-app calendar showing completed and upcoming exercise sessions).

Multidisciplinary Roundtable Discussion

Of the 18 people invited to the discussion, 10 (56%) attended, including the research team members, external clinician-scientists, practicing clinicians (PTs and occupational therapists), people with lived AT experiences, and engineers. Overall, the group identified the main value proposition of the PhysViz system as being able to deliver high-magnitude loading precisely, either in the clinic or at home. Given the importance of loading intensity when managing AT, the invitees suggested that the PhysViz offered a useful alternative for patients who may not have time to go to the gym or lack access to the gym equipment often required to deliver the high loads needed to rehabilitate the tendon. Furthermore, the group identified that both PTs and individuals with AT stood to benefit from using the PhysViz: PTs can individualize and monitor care better when they have objective measurements such as those provided

by the PhysViz; and individuals with AT are more likely to adhere to, and subsequently benefit from, treatment when they are able to see objective progress.

The group did identify that the design of the PhysViz physical exercise tool could be improved; in particular, the group sought to reduce the system complexity to make it accessible for more potential users. Specifically, the invitees reiterated the importance of modifying the design while maintaining flexibility in the system such that it can still be individualized to suit an array of patient needs (eg, body size, flexibility, and preexisting injuries). Depending on the revised design of the physical exercise tool, the invitees also suggested that the PhysViz could be used to help manage other lower limb tendinopathies (eg, patellar tendinopathy) and could be used as a general dynamometer to help augment care.

Patient and Clinician Usability Testing

According to the findings presented in the study by Merry et al [34], 15 people with AT and 4 PTs participated in the usability testing study. During the usability testing across the 8 tasks completed with the physical exercise tool and mobile app, people with AT encountered an average of 12 (SD 3) total usability issues. Most of the issues (102/183, 55.7%) were "severity 2—minor problems" according to the scale developed by Nielsen [45] and were most commonly issues associated with the "meaning of labels" (47/183, 25.7%), the "understanding of system instructions/error messages" (37/183, 20.2%), and the "visibility of system status" (31/183, 16.9%) according to the coding scheme postulated by Kushniruk and Patel [46]. During the clinician usability testing of the 3 tasks completed using the web application, PTs encountered an average of 3 (SD 3) total usability issues. Most of the issues (7/13, 54%) were "severity 2—minor problems" and were most commonly issues associated with the "meaning of labels" (8/13, 62%) and "navigation" (3/13, 23%).

During the debrief, 73% (11/15) of the people with AT stated that the PhysViz system was worth improving, with an additional 20% (3/15) stating that it is worth improving, provided research demonstrates its efficacy. Most of the participants with AT (13/15, 87%) stated that they would be willing to use a system such as the PhysViz during their AT rehabilitation. When asked to rate how helpful the PhysViz would be in supporting them to achieve their AT rehabilitation goals on a scale ranging from 0=*not helpful at all* to 10=*extremely helpful*, the system received a mean score of 7.2 (SD 1.2). By contrast, 50% (2/4) of the clinician participants stated that the PhysViz system was worth improving, with the other 50% (2/4) suggesting that it might be worth improving, provided changes were made to accommodate other musculoskeletal conditions besides AT.

Using the APEASE criteria, 25 proposed modifications were considered, and of these, 16 (64%) were deemed feasible for implementation in the next version of the PhysViz system (ie, having met all APEASE criteria). Cohen's κ and prevalence-adjusted bias-adjusted κ values describing interrater agreement of the proposed PhysViz modifications were 0.39 (fair agreement) and 0.83 (almost perfect agreement), respectively.

Discussion

Principal Findings

Overview

This paper reports the formative development of the PhysViz, a novel remote rehabilitation system for people with AT using the FASTER. In addition to addressing the rationale and stakeholder needs underpinning the PhysViz, this project led to working prototypes of both the PhysViz physical exercise tool and the PhysViz software package that was tested by the potential end users (ie, both people with AT and PTs). Taken together, we think the development process outlined in this work represents a meaningful addition to the digital health landscape by providing a case study in systematic technology-based intervention development.

PhysViz development was framed within the development stage of the FASTER [25]. By comprehensively reviewing the literature and by engaging stakeholders through cross-sectional surveys and usability testing studies, this work leverages prior research knowledge, clinical insights and practice strategies, and patient-identified needs to improve the chances of intervention efficacy and uptake.

Empathize

The needs assessment, survey results [35], narrative review [17], and scoping review [38] collectively revealed critical insights into user expectations and preferences. Significantly, information was woven together from (1) research team members, (2) external stakeholders to whom we appealed directly, and (3) previous research, to inform system development in a robust way; for example, users expressed a demand for a versatile app compatible with both iOS and Android devices, with data-syncing capabilities for remote clinician monitoring. The emphasis on a simple and minimalistic UI aligns with the goal of inclusivity across different age groups and digital literacy levels. The incorporation of high-load tolerability and the use of the long sitting position in the design addressed specific biomechanical considerations highlighted in the narrative and scoping reviews.

Define and Ideate

The problem statement identified in the define stage highlighted the challenge of enabling individuals with AT to return to their activities quickly, emphasizing the importance of autonomy and objective feedback. The importance of autonomy and objective feedback identified aligns with past research [47], which found that personalized feedback can improve patient outcomes. This led to the formulation of a logic model, linking evidence-based features with behavioral and treatment outcomes. Taken together, both stages allowed the research team to critically reflect on the value proposition of the PhysViz system from the perspective of multiple end users, where it may fit along the treatment pathway, and how it may integrate into existing clinical workflows. Furthermore, mapping how different PhysViz system categories (eg, physical exercise tool and mobile app) could potentially address current treatment barriers helped mitigate potential design pitfalls such as unnecessary complexity and redundancy. Mapping also helped to delineate what features

were needed in the PhysViz technologies (ie, physical exercise tool, mobile app, and web application) and what could be considered intervention support features (eg, the exercise protocol completed using the PhysViz, user training, and support for use).

Prototype and Test

Overview

Complexity was gradually built into the PhysViz system over months of development with the computer engineering student teams; varying levels of prototype fidelity were used to mock-up potential features and prove concepts in a timely manner. The resulting PhysViz system prototype and more specifically the UI and UX were then holistically evaluated toward the end of the prototype and test stages. Several features built into the PhysViz system prototype emerged directly from gaps in the literature and current standard care practices.

PhysViz UI and UX

The UI and UX of the PhysViz, tailored to address gaps and preferences identified in the emphasize stage, mirror recommendations from past literature that advocate for simplicity and intuitive design [48,49]. The needs assessment results underscored the importance of a simple and minimalistic UI, with a focus on ease of use for users across various age groups and digital literacy levels. Informed by the needs assessment and by the literature [45,50-53], we strategically designed the app and web portal with the goal of having simple screens and buttons as well as a predictable structure.

Moreover, the scoping review highlighted a significant gap in reporting related to adherence, compliance, and fidelity to prescribed exercises in AT interventions [38]. This poor reporting of adherence, compliance, and fidelity is also reflected in the existing literature [54,55], highlighting a need for improved monitoring systems. The UI and UX of the PhysViz addresses this gap by incorporating features for automated tracking of exercise sessions (ie, there is no “save/upload data” button present; the system does this automatically), accompanied by intuitive visual cues and real-time biofeedback in the form of repetition timing and load intensity monitoring. The various forms of exercise cueing and data visualization aim to empower users to increase their adherence, fostering a more engaging and motivating rehabilitation experience. The case studies underscored participants’ positive experiences with the PhysViz UI and UX, particularly appreciating aspects such as the color change effect when “target load” intensity was reached, as well as the pacing of repetitions. These results are further supported by previous literature, which highlights the utility of biofeedback to enhance user engagement and adherence [56,57].

During usability testing, most of the usability issues encountered by people with AT related to the “meaning of labels” (47/183, 25.7%), “understanding of system instructions” (37/183, 20.2%), and “visibility of system status” (31/183, 16.9%) [34]. When assessing the web application, most of the usability issues PTs faced were associated with the “meaning of labels” (8/13, 62%) and “navigation” (3/13, 23%). Usability testing results such as these will help inform further UI and UX iteration to improve

the PhysViz by specifically identifying problematic features or areas according to end users.

In the case studies, participants generally perceived the UI of the mobile app as adequate and accessible, although they acknowledged its simplicity compared to other apps. Notably, suggestions emerged for enhancing the UI, particularly if the goal is to extend the reach of the PhysViz system beyond a research-based audience. Recommendations included incorporating brief animations, reminders for completing exercises, and an in-app calendar displaying completed and upcoming exercise sessions, aligning with behavior change literature [58,59]. These suggestions, if implemented, could address the reported simplicity of the UI and enhance the overall UX, making the PhysViz more accessible to a wider audience.

Biofeedback

Biofeedback emerged as a promising feature with the potential to address several gaps in existing treatment strategies. The need for precision loading, a key consideration highlighted in the narrative review [17], is directly addressed through real-time biofeedback in the form of load intensity monitoring, allowing users to achieve and maintain high-magnitude loading with greater accuracy. The results from the validation studies substantiate this claim, demonstrating that the PhysViz system is a valid and reliable tool for isometric plantar flexor MVC measurement and that biofeedback is a useful feature for promoting the accurate execution of exercise parameters such as load intensity [33,40]. Given the lack of reporting on exercise fidelity identified in the scoping review, biofeedback and the automated tracking of exercise sessions incorporated in the PhysViz may enhance program fidelity for individuals with AT while also facilitating transparent and automated reporting for clinicians.

The importance of transparent reporting was also identified in the surveys, which revealed a perceived lack of patient compliance among PTs [35]. Biofeedback has the potential to bridge this gap by supplying both people with AT and clinicians with objective, measurable data, fostering a collaborative approach to rehabilitation and improving overall treatment compliance. In the case studies, participants commended the real-time biofeedback provided by the PhysViz, citing its utility in promoting engagement through the visualization of load intensity and the pacing of repetitions. Moreover, insights from the multidisciplinary roundtable discussion, including perspectives from clinicians and individuals with AT, underscored the value proposition of the PhysViz in delivering high-magnitude loading precisely, thus enhancing its potential to address compliance challenges. Usability testing further supported the positive impact of biofeedback, with individuals expressing willingness to use the PhysViz during their rehabilitation, highlighting its potential to improve overall treatment compliance [34].

This multifaceted evidence stemming from both sets of end users surveyed [35] and existing literature [17,38] highlights the potential for precision loading and the need for improved therapeutic exercise engagement among people with AT. The findings were substantiated during the prototype and test stages of this work, including the validation studies [33,40], case

studies, roundtable discussions, and usability testing [34]. Together, this body of evidence supports the notion that the biofeedback offered by the PhysViz serves as a valuable instrument for strengthening collaborative rehabilitation initiatives and promoting increased fidelity and, potentially, engagement with therapeutic exercises for AT rehabilitation.

Comparison to Previous Work

This work aligns with and builds upon existing literature regarding telehealth development, particularly within the context of human-centered design for health care interventions. Emerging research suggests that integrating human-centered design into telehealth research results in more usable, acceptable, and effective health care interventions [60,61]; however, there is significant underreporting and a lack of guidance in the development of sustainable health care apps [62], and much of the telehealth app research focuses more on laboratory and field evaluations than on the design and development phases [63].

Our work addresses these gaps by emphasizing the early stages of the development process, specifically the empathize and define stages within the FASTER, where thorough needs assessments and stakeholder engagement initiatives were conducted. This approach allowed us to prioritize end-user needs and design features that are both practical and meaningful for the target population. By focusing on the development phase, we ensured that the PhysViz system was not only functional but also aligned with the preferences and constraints of potential end users. In addition, our iterative development process, which included usability testing and multidisciplinary discussions, contributed to creating a more sustainable telehealth solution that can adapt to the evolving needs of its end users. This proactive approach contrasts with much of the existing telehealth research, which often underrepresents the importance of early-stage design and development in favor of later-stage evaluations [63].

A recent review of telehealth app development highlighted that lengthy development times and the use of limited qualitative research methods are often cited as constraints associated with the long-term efficacy of the apps [63]. Telehealth app development frequently uses interviews and focus groups [63], and while these methods are effective for gathering direct feedback from end users, they have been criticized for their limited ability to elicit tacit knowledge [64]. While our work did use these methods, we also relied on multiple smaller-scale and time-efficient studies, using diverse methods to capture both explicit insights (through the surveys and multidisciplinary roundtable discussion) and tacit knowledge (through case studies and usability testing). This mixed methods approach not only allowed us to gather comprehensive data on end-user needs and preferences but also facilitated the iterative refinement of the PhysViz system, ensuring that it was both user centered and responsive to the complexities of real-world use. By integrating feedback from a variety of stakeholders—patients, clinicians, and engineers—we were able to design a telerehabilitation solution that is more likely to be effective, sustainable, and widely accepted in clinical practice. This approach highlights the importance of combining traditional qualitative methods

with more agile techniques to enhance the development and adoption of telehealth technologies.

While telehealth apps are often developed with the inclusion of end users, this engagement tends to be limited to a single user group such as patients or clinicians [65]. By contrast, our work involved multiple end-user groups throughout the development process, including people with AT as well as clinicians and stakeholders responsible for the implementation and dissemination of the PhysViz. This comprehensive approach allowed for a more holistic understanding of the diverse needs, preferences, and challenges associated with both the use and the integration of the system. By engaging these varied perspectives, we were able to design a more adaptable and user-friendly telehealth solution that not only meets the therapeutic needs of patients but also aligns with the practical and logistical requirements of clinicians and health care systems. This multistakeholder engagement is critical in ensuring that the resulting technology is effective, sustainable, and capable of being seamlessly integrated into routine clinical practice.

Strengths and Implications

This work represents one of the first uses of the FASTER development phase in developing a remote rehabilitation intervention (including a physical exercise tool, a mobile app, and a web application). The collaborative and multidisciplinary nature of this work is a strength, particularly in integrating perspectives from people with the condition of interest and clinician partners throughout the timely and rigorous development of the PhysViz system prototype. Involving a diverse team, including those with lived experiences, has not only enriched the development process but also ensured that the resulting intervention is attuned to the real-world needs and preferences of end users. This inclusive approach enhances the credibility and applicability of the system and serves as a model for future technology-based rehabilitation development efforts.

Another notable strength lies in the diversity of study types used. Tailoring study designs to suit development needs is a core feature of the FASTER, which suggests a variety of methods for informing and evaluating the proposed intervention. By incorporating narrative and scoping reviews, case studies, and both qualitative and quantitative data, this research amalgamation effectively addresses the limitations inherent in a single-study approach. This comprehensive methodological approach allows for a more nuanced understanding of the intervention's usability according to end users and potential effectiveness in managing AT through the mobilization of high-magnitude precision loading. It also contributes to a more holistic assessment of the PhysViz system, capturing a range of perspectives and insights that might be overlooked in a single-study design.

Furthermore, the systematic identification of theory-based techniques, such as the integration of the COM-B model, adds a layer of robustness to the intervention development process. By aligning the PhysViz system with behavior change theory, we enhance our understanding of the underlying mechanisms and pave the way for more targeted and potentially effective interventions. This methodological rigor ensures that the developed intervention is technologically sound and theoretically

grounded, increasing its potential for successful implementation in real-world rehabilitation settings.

Future Directions

The positive reception from users and clinicians underscores the potential impact of the PhysViz system; however, the identified areas for improvement, such as improving consistency and intuitive navigation, should guide future iterations. More specifically, mobile app clarity can be improved by adding a designated "Home" button within the app UI to anchor users, adding an in-app back button, and avoiding potentially confusing words such as "tare." Further efforts seem necessary to enhance the UI and UX of the biofeedback interface to present users with crucial information while preventing information overload. Furthermore, the potential extension of the PhysViz to manage other tendinopathies and its use as a general purpose dynamometer offer exciting possibilities for broader clinical applications. Future research should explore these potential applications and assess the feasibility and effectiveness of the PhysViz in diverse clinical and home-based settings.

Limitations

This study has several limitations. First, the PhysViz development detailed in this work constitutes only 1 cycle through the FASTER development phase; further iterations of the system are recommended before proceeding to FASTER phase 2 (progressive usability and feasibility evaluation). In addition, because the FASTER provides little guidance regarding when it is appropriate to move between phases, some research and development discretion is needed. Second, long-term exposure to the PhysViz system by end users (people with AT or clinicians) was limited. Three people with AT completed case studies, although the use of the system during these studies was relatively low, limiting the comprehensiveness of feedback. Moreover, the lack of any long-duration (ie, >1 session) testing by the clinicians makes it challenging to comment on their opinions of the PhysViz within the context of their working environment. Although the clinicians were asked how they might integrate the PhysViz into their practice, the study did not specifically explore potential logistical or legal challenges they might face, which presents an area for future research. Third, working with the computer engineering student teams helped control costs when completing development and provided students with experiential learning opportunities; however, because of the course structure, coupled with other commitments, the students were limited in their development capacity. Furthermore, we did not have a software developer actively working on the project. As a result, development iterations took a significant amount of time to implement, limiting the rapid prototyping and feedback cycle typical of engineering design. We tried to circumvent this by using wireframe models and other low-resolution strategies where possible.

Conclusions

This paper describes the development process of the novel PhysViz system, an exercise-based remote rehabilitation system for AT management. This is one of the first studies to describe using the FASTER for technology-based intervention

development; by following the FASTER development phase guidelines, the PhysViz incorporates past evidence, end-user needs and opinions, and behavior change science. Our goal is that the PhysViz will be used to improve the current knowledge of appropriate therapeutic exercise dosing for tendinopathic tissue rehabilitation as well as improve the pain, functional

status, and activity of people with chronic AT. Future iterations of the PhysViz may be adapted for other home-based treatment strategies that provide user autonomy with remote clinical supervision, thereby decreasing in-clinic time and associated costs.

Acknowledgments

The authors would like to first acknowledge the researchers at the Institute of Sport Sciences at the Humboldt University of Berlin—specifically Univ-Prof Dr Adamantios Arampatzis, Dr Sebastian Bohm, Prof Kirsten Legerlotz, and colleagues in the Department of Training and Movement Sciences—for inspiring this technology and graciously letting the authors adapt their idea. The authors would also like to thank members of the research team who have assisted at various stages of the PhysViz development process: Vivian Chung, Rob Morgan, and Kip Squier. This work was supported by the WorkSafeBC research program (RS2020-TG05), the Natural Sciences and Engineering Research Council of Canada (PGSD3-559905-2021), and by a Natural Sciences and Engineering Research Council of Canada Discovery Grant (AWD-007759). CN is supported by a Michael Smith Foundation for Health Research Health Professional-Investigator Award (HPI-2020- 0719). JLW is supported by a Michael Smith Foundation for Health Research Scholar Award (SCH-2020- 0403) and an Arthritis Society STAR Career Development Award (STAR-19-0493).

Abstract

Background: The COVID-19 pandemic contributed to an increase in teleconsultation adoption in the Polish primary health care system. It is expected that in the long run, teleconsultations will successfully replace a significant part of face-to-face visits. Therefore, a significant challenge facing primary health care facilities (PHCs) is the acceptance of teleconsultations by their users, especially physicians.

Objective: This study aimed to explore physicians' acceptance of teleconsultations during the COVID-19 pandemic in Poland.

Methods: A representative survey was conducted among 361 physicians of PHCs across Poland in 2021. For the purposes of the study, we developed a modified Technology Acceptance Model (TAM) model. Based on the modified TAM, we analyzed the impact of perceived usefulness (PU), perceived ease of use (PEU), and intention to use teleconsultation (INT) on physicians' satisfaction (SAT) and quality of work (Q). The psychometric properties of the research instrument were examined using exploratory factor analysis. Finally, structural equation modeling was used for data analysis.

Results: The results indicated a generally high level of PU (mean 3.85-4.36, SD 0.87-1.18), PEU (mean 3.81-4.60, SD 0.60-1.42), INT (mean 3.87-4.22, SD 0.89-1.12), and SAT (mean 3.55-4.13, SD 0.88-1.16); the lowest rated dimension in TAM was Q (mean 3.28-3.73, SD 1.06-1.26). The most important independent variable was PU. The influence of PU on INT (estimate=0.63, critical ratio [CR]=15.84, $P<.001$) and of PU on SAT (estimate=0.44, CR=9.53, $P<.001$) was strong. INT was also a key factor influencing SAT (estimate=0.4, CR=8.57, $P<.001$). A weaker relationship was noted in the effect of PEU on INT (estimate=0.17, CR=4.31, $P<.001$). In turn, Q was positively influenced by INT (estimate=0.179, CR=3.64, $P<.001$), PU (estimate=0.246, CR=4.79, $P<.001$), PEU (estimate=0.18, CR=4.93, $P<.001$), and SAT (estimate=0.357, CR=6.97, $P<.001$). All paths between the constructs (PU, PEU, INT, SAT, and Q) were statistically significant, which highlights the multifaceted nature of the adoption of teleconsultations among physicians.

Conclusions: Our findings provide strong empirical support for the hypothesized relationships in TAM. The findings suggest that the PU and PEU of teleconsultation have a significant impact on the intention of physicians to adopt teleconsultation. This results in an improvement in the satisfaction of Polish physicians with the use of teleconsultation and an increase in Q. The study contributes to both theory and practice by identifying important prognostic factors affecting physicians' acceptance of teleconsultation systems.

Introduction

Background

Telemedicine is an IT-based method that has the potential to support and enhance physicians' patient care [1]. Telemedicine is defined as a tool using information and communication technology (ICT) that is used to support and promote remote care, health-related professional education, and public health administration [2]. One of the basic forms of telemedicine is teleconsultations. Medical consultations have been provided remotely (teleconsultations), by telephone, or by instant messaging for many years, but the COVID-19 pandemic has forced widespread use of this form of communication with patients. Teleconsultations have reduced the high costs of medical services and the queues of patients in clinics [3]. In Poland, the need for teleconsultations began at the beginning of the pandemic. Most physicians had to adapt to the requirements of COVID-19 rules and regulations. Even though the need for teleconsultations has already been officially abolished, telemedicine is still the future of medicine. Not all advice has to be given to patients on-site in a clinic. In the face of a decreasing number of physicians, an aging society, and an increased demand for health care, telemedicine seems to be a solution that will solve the problems of personnel shortage. However, the use of telemedicine tools requires the medical staff to be proficient in using them and to accept and support such solutions.

The aim of our study was to examine the physicians' satisfaction (SAT) and quality of work (Q) in conditions of teleconsultations during the COVID-19 pandemic in Poland. For the purposes of the study, we developed a modified Technology Acceptance Model (TAM) and tested it in primary health care facilities (PHCs) in Poland. This model allowed us to analyze the impact of perceived usefulness (PU), perceived ease of use (PEU), and intention to use teleconsultation (INT) on SAT and Q. In our study, we focused primarily on teleconsultations, consisting of telephone and video conversations between physicians and patients [2]. Teleconsultations are the basic form of telemedicine in Poland, and during the COVID-19 pandemic, they were the only form of PHC in the country [4].

The first part of this paper analyzes the literature focusing on TAM in relation to the research hypotheses. The second part contains a description of the research methodology used in this study, with emphasis on the validation of the research tool developed for measuring the modified elements of TAM. The following section presents the results regarding the analyzed constructs of the model and the results of structural equation modeling (SEM). The last part of the paper contains the discussion, conclusions and practical implications.

Literature Review

Until March 2020, the use of telemedicine was negligible and mainly concerned patients in rural areas. In 2019, teleconsultations accounted for as much as 8% of all medical visits in the United States [5]. The situation has changed significantly after the outbreak of the COVID-19 pandemic, especially in the case of emergency visits. In the United States, there was a 683% increase in teleconsultations between March

2 and April 14, 2020 [5]. Researchers agree that the COVID-19 pandemic has changed the way we think about telemedicine. First and foremost, it popularized this way of providing medical services. However, its primary advantage is to protect both patients and physicians from the risk of virus infection [6,7]. In the long term, researchers believe that telemedicine can successfully replace a significant portion of face-to-face (F2F) visits; however, it will not eliminate them completely [4,8,9].

Telemedicine is not a new concept. Decades ago, pioneering projects emerged to test the concept of telemedicine or evaluate its applicability. However, most of these telemedicine projects failed to meet expectations. The failure was blamed on an underdeveloped and mostly primitive IT infrastructure, immature technology, and ineffective use [1]. The failure of first-generation telemedicine projects prompted an in-depth analysis and rigorous assessment of the technological, social, cultural, and organizational dimensions surrounding their introduction.

Resistance from users of new technologies in the medical community is as natural as possible, even if users are aware of the benefits this technology brings with it [10]. Therefore, an essential organizational challenge facing health care organizations considering or planning to provide telemedicine-enabled health care services is technology acceptance by users [1]. The problem regarding acceptance of technology has been discussed for a long time [11], and many models have been developed to assess users' attitudes toward new solutions [12-15]. Acceptance of ICT by physicians providing health care has also been assessed [16-18].

TAM is the most popular model in the literature for testing the acceptance of technology [19]. Van Schaik et al [20] used TAM to assess the attitudes of physiotherapists toward new medical technologies. Chau and Hu [21] studied the acceptance of telemedicine technologies by physicians. Holden and Karsh [22] extensively reviewed the literature on TAM applications and related models for ICT acceptance by health care professionals and, more specifically, health care information systems. They noted that in health care, there is a need for a complete approach to technology acceptance testing than for other professionals from companies or ICT organizations [22]. We chose to use TAM in our study because it is general, parsimonious, and ICT specific. It is designed to provide an explanation and prediction of the acceptance of a wide range of ICTs by a diverse population of users in different organizational contexts. In addition, the model has a well-researched and validated list of psychometric measurements, and this makes its use operationally attractive. Finally, TAM is the dominant model for studying user acceptance of technology, and over the years, it has accumulated satisfactory empirical support for its overall explanatory power and assumed individual causal relationships [1,2]. Over the past few decades, many researchers have proven that TAM enriched with certain other constructs is better suited to research and explain the acceptance of new information technologies by users [23].

TAM analyzes the influence of various factors on the intention to use new technology, among which the main role is played

by PU and PEU [24]. PU is defined as the extent to which the user's work performance is expected to improve through the use of new technology [2,25]. Similarly, Davis [11] defined PU as an individual's perceptions regarding the outcome of the experience with technology. In the area of health care, Kissi et al [26] defined PU as "physicians' belief regarding the benefits of telemedicine services that they improve access to medical care, the flow of medical records and patients' health."

PEU, in contrast, is the degree to which using new technology is expected to be effortless [2,25,27]. In the area of health care, PEU describes how physicians perceive telemedicine services in terms of their ease of use and learning [26].

TAM suggests that actual technology usage is determined by individuals' INT [2]. INT is understood as a motivation encouraging the system's user to use the system continuously, and in the case of physicians, it concerns their motivation to use telemedicine services, including, above all, teleconsultations [26]. INT is affected by PU, PEU, and users' attitudes toward technology [2,19]. Lin et al [28] used an integrated approach with the key elements from TAM and assessed the technology acceptance by health professionals of what they called "personal digital assistance (PDA)." The main variables from TAM (PU and self-efficacy) determined INT [28]. Similar conclusions were reached by Zayyad and Toycan [29], Chau and Hu [30], Tubaishat [31], and Vitari and Ologeanu-Taddei [32]. Thus, our first research hypotheses were proposed as follows:

- Hypothesis (H)1: PU has a direct effect on INT.
- H2: PEU has a direct effect on INT.

The results of Lin et al [28] showed that the traditional variables of TAM can be effectively integrated with variables from other theoretical approaches, which may help better understand the acceptance of new technologies by health care professionals [33]. There are relatively fewer TAM tests and modifications in the health care sector. Therefore, it is worth making such attempts to broaden the knowledge about new factors affecting physicians' acceptance of technologies. In our research, we decided to include 2 new constructs: SAT and Q. SAT explains how satisfied users are with using a particular service [19]; Q explains how physicians assess the value and worth of their work with the use of teleconsultations. The addition of these constructs was a consequence of both literature reviews and interviews with physicians (pilot survey). Bhattacharjee and Premkumar [10,34-36] noted that in the use phase of technology (postacceptance), PU is positively associated with user SAT. Alsohime et al [37] also confirmed the effect of PU on SAT, noting the significant impact of training courses before the implementation of new technology. Petter and Fruhling [38] confirmed that the SAT that users have with the information system positively affects their INT. As a consequence, we presented the subsequent hypotheses:

- H3: PU has a direct effect on SAT.
- H4: INT has a direct effect on SAT.

In our previous studies examining technology acceptance in Polish PHC facilities, we developed a conceptual framework defining the impact of PU and PEU on the need for teleconsultation adoption and examined the influence of selected

behavioral factors on these constructs [2]. In this paper, we enriched these previous studies by analyzing the impact of PU and PEU as independent variables on SAT and Q. In our analysis, we additionally considered INT as a mediating variable in the model. This is the first study that extends TAM to include an analysis of SAT and Q in the teleconsultation condition.

Padilha et al [39] surveyed students and nurses' ease, usefulness, and intention to use a Massive Open Online Course. Findings confirmed the significant impact of PU, PEU, and INT on the current and future Q the groups studied [39]. Similar conclusions were reached by Saputra et al [40] and Chirchir et al [41]. Souza et al [42] proposed a process model for the evaluation of the Q of clinical decision support systems following the ISO/IEC 25022 and ISO/IEC 25010 standards, part of which was to identify the effect of SAT on Q. Given these considerations, we proposed the following hypotheses:

- H5: PU has a direct effect on Q.
- H6: PEU has a direct effect on Q.
- H7: INT has a direct effect on Q.
- H8: SAT has a direct effect on Q.

Although according to the research conducted so far, TAM is a reliable model for examining technology acceptance in PHC facilities, we can always try to supplement it with new research constructs [2]. TAM, in our study, was supplemented with 2 constructs, SAT and Q, which will contribute to the health care literature.

The Polish health care system is based on an insurance model. PHC physicians in Poland must be health insurance physicians who have a contract with the National Health Fund (NHF) to provide health care services. The functioning of PHCs in Poland is based on the right of patients to personally choose a preferred physician. The selected physicians receive an annual capitation fee for each registered patient [43]. PHC facilities in Poland function as both state-owned and private facilities. Both sign contracts to provide services that are free to the patient and paid for by the NHF. Each facility is managed according to its own rules. Private facilities have more flexibility in making decisions and in hiring and paying employees. Public facilities are subject to top-down regulations governing their operations. As private facilities provide fee-based services, in addition to free services, they have more resources to pay salaries and run their operations.

Methods

Data Collection

In this cross-sectional study, the survey followed a multimodal approach, integrating computer-assisted web interviewing (CAWI), computer-assisted telephone interviewing (CATI), and paper-and-pencil interviewing (PAPI) techniques across a statistically representative sample of 371 PHC facilities. This number was derived from a total of 5503 outpatient PHC facilities in Poland, calculated to be representative at a 95% CI level, with a 50% response distribution and a 5% margin of error, for the aforementioned assumptions, and the minimum survey sample size was 359 [44-47]. The survey sample was randomly selected from the BISNODE database, which includes

comprehensive information on all Polish PHC facilities. Of 5503 outpatient facilities in Poland, 371 (6.7%) were successfully surveyed, with each representing 1 physician providing remote medical advice. The survey process entailed replacing nonparticipating facilities with other randomly chosen facilities, ensuring the integrity and representativeness of the sample. Quality control measures were rigorously followed, with a certified polling company overseeing the survey execution. Instances of schematic responses and unusually short survey durations led to the exclusion and replacement of certain responses, resulting in a final analytical sample of 361 (97.3%) records. Before filling the questionnaire, the physicians were informed that the questionnaire is aimed at PHC physicians and concerns the evaluation of their satisfaction with the use of the teleconsultation system for the provision of patient care.

The sample was limited to 1 PHC physician from each randomly selected facility in Poland. This approach was adopted for several reasons. Conducting a survey that included multiple physicians from each facility would have significantly increased the scale and complexity of the study. Given resource constraints, such as funding, time, and personnel, it was more feasible to limit the number of participants, while still achieving a representative sample. The aim was to obtain a broad overview of the acceptance and satisfaction with teleconsultation across a wide range of PHC facilities in Poland. By selecting 1 physician from each facility, we ensured a diverse and statistically representative sample of the entire population of PHC facilities, which may not have been possible with a more concentrated sample from fewer facilities. The study was primarily designed to assess the impact of system-level factors (eg, PU and PUE) on the acceptance of telemedicine. Although individual characteristics, such as age and gender, are important, the primary focus was on broader systemic issues that could be generalized across the population. Conducting an extensive survey during the COVID-19 pandemic posed unique challenges, including limited access to PHC facilities and the need to minimize contact. The study design did not include a detailed examination of individual physician factors and their impact on the acceptance of telemedicine, and the approach was strategically chosen to balance comprehensiveness, feasibility, and the overarching research objectives.

Survey Instrument and Measures

The survey instrument contained 2 groups of statements and questions: statements about analyzed latent factors and general questions about age and gender of the respondent, legal status of the PHC facility, voluntariness of providing remote advice, and ways in which the respondent provided remote advice. The questionnaire included 48 statements and questions, but only the statements used in the modified TAM are presented in [Multimedia Appendix 1](#). A 5-point Likert scale was used in this study: 1 (I do not agree), 2 (I do not agree somewhat), 3 (I neither agree nor disagree), 4 (I agree somewhat), and 5 (I agree).

SEM in this study was adapted from the original TAM, which identifies PU and PEU as the principal determinants of technology use and acceptance. The PU variable measures the degree to which physicians believe that teleconsultations

improve their work efficiency and patient care. It encompasses aspects such as enhanced health care delivery, better documentation, and cost-effective monitoring. PU in this context is gauged through 6 survey statements (PU1-PU6), which assess various dimensions of utility that teleconsultations provide in the health care setting [11,48-51]. PEU variables are defined as the extent to which physicians believe that teleconsultations are effortless to learn and implement. The variables relate to the ease of use of the teleconsultation system and the use of medical data. This construct is evaluated via 7 survey statements (PEU1-PEU7), focusing on the usability and accessibility of the teleconsultation system [2,25,27]. INT, similar to that in TAM, used as a mediating variable, represents the likelihood of physicians continuing to use teleconsultations in the future. It is measured through 5 survey statements (INT1-INT5), focusing on the perceived long-term utility and effectiveness of teleconsultations in patient diagnosis and care [11,12,41]. Q, used as an independent variable, refers to the perceived enhancement in work value and worth due to teleconsultations and is gauged through 3 survey statements (Q1-Q3). It assesses whether teleconsultations uphold the standard of traditional visits and enable comprehensive patient care [22]. The SAT variable measures the overall contentment of physicians with teleconsultations. It includes aspects such as convenience compared to traditional visits and comfort in providing remote advice [11,52] and is assessed through 4 survey statements (SAT1-SAT4) [12,13,53,54].

Exploratory Factor Analysis

The study required validating the structure and dynamics within the adapted TAM, because the original model was extended to encompass SAT and Q. The evaluation of the survey statements for inclusion in the factors measuring the assessed dimensions was based on exploratory factor analysis (EFA). EFA was used to select the final variables for the structural model. For each dimension, EFA was separately carried out to assess the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy. The value of this index should be >0.7 [55]. For all dimensions, this condition was fulfilled, but the KMO value of the PEU dimension was <0.7 . The EFA results for each dimension are presented in [Table 1](#).

In addition, the ability of each dimension to be represented by individual survey statements was assessed using Bartlett's test of sphericity. For each dimension, the chi-square value was significant, and in each case, $P < .001$. Based on EFA, the PEU dimension was finally divided into 2 separate factors: PEU_1 and PEU_2. Questions PEU1, PEU2, PEU3, and PEU4 were about the technical ease of use of the system (PEU_1), and questions PEU5, PEU6, and PEU7 were about the ease of use of the system from the point of view of handling medical data (PEU_2). Reliability analysis was conducted for all dimensions of the validity of using the adopted statements to measure each factor. Cronbach coefficients were determined for each factor, with acceptable values falling within the range of 0.7-0.95 [56]. The constructs were confirmed to possess suitable psychometric properties, enabling their effective use in SEM analysis. For the PEU dimension, reliability analysis did not give a clear answer as to which statement should be removed to improve the Cronbach and KMO coefficient values. The use of survey

statements to measure the PEU dimension requires confirmation in the structural model. The EFA results for the PEU dimension are presented in Table 2, and component factor loadings are presented in Table 3.

Based on imputed factors, a structural model was prepared, where the effects of PU, PEU_1, and PEU_2 on INT, SAT, and Q were studied. Figure 1 shows the final tested model with only significant dependencies.

Figure 1. Structural model depicting the factors affecting SAT with teleconsultation and Q. Research hypotheses H1-H8 for direct paths. H: hypothesis; INT: intention to use teleconsultation; PEU: perceived ease of use; PU: perceived usefulness; Q: quality of work; SAT: satisfaction.

In the original TAM, the actual use of technology is the independent model variable. In this study, physicians were required to conduct teleconsultations, so INT and SAT variables were treated as mediators affecting the dependent variable, Q. Because of this, the effect of PU, PEU1, and PEU_2 variables

on Q was also studied indirectly. The research hypotheses H9-H14 regarding indirect effects were proposed as follows:

- H9: PU has an indirect effect on Q through INT.
- H10: PU has an indirect effect on SAT through INT.

- H11: PU has an indirect effect on Q through INT and SAT.
- H12: PEU_2 has an indirect effect on Q through INT.
- H13: PEU_2 has an indirect effect on SAT through INT.
- H14: PEU_2 has an indirect effect on Q through INT and SAT.

Ethical Considerations

The survey instrument was approved by the Ethics Committee of the Warsaw University of Technology that issued the Certificate of Ethics Approval (certificate dated January 15, 2021). As a result of the contact, 587 physicians provided consent to participate in the study, of which, despite consent, in 216 (36.8%) PHC facilities, the complete set of surveys could not be completed. Respondents were informed about the purpose

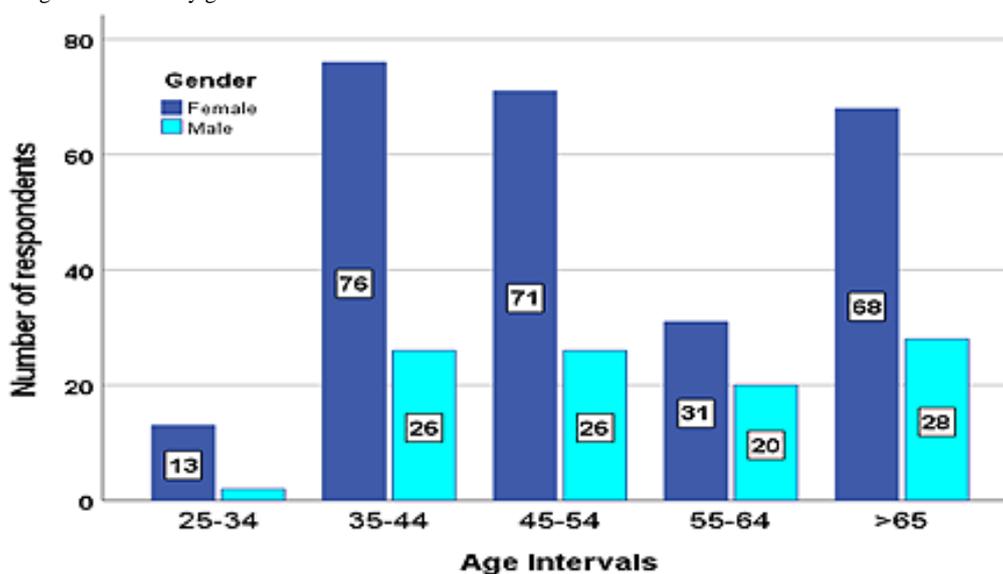

of the research before starting the survey. They could withdraw from completing the survey at any time. Study data were anonymous and deidentified. No compensation from respondents was taken for the research.

Results

Participant Characteristics

Of the 361 physicians, 199 (55.1%) were in the 35-54-year age group, 94 (26%) were of retirement age and over 65 years old, 260 (72%) were women, and only 101 (28%) were men. The age distribution of the surveyed physicians is presented in Figure 2.

Figure 2. Physicians' age distribution by gender.

Evaluation of the Level of TAM Dimensions

The research considered the dimensions originally defined in TAM (PU, PEU, and INT) [11]. Two dimensions were added to the model: SAT and Q.

The PU variable assesses physicians' perceptions of the utility and benefits of teleconsultation services. The mean scores for PU1-PU6 ranged from 3.85 to 4.36 (SD 0.87-1.18), indicating a generally high level of agreement among physicians that teleconsultations are beneficial to their work. The highest mean score was for PU1 (4.36, SD 0.94), suggesting that the physicians particularly valued teleconsultations during challenging times, such as pandemics. The SDs, ranging from 0.87 (mean 4.24) for PU4 to 1.18 (mean 3.85) for PU3, implied some variability in how the physicians perceived the usefulness of different aspects of teleconsultations. The higher deviation in PU3 indicated more varied opinions about the efficiency enhancement brought by teleconsultations. The skewness for all PU statements was negative, ranging from -0.81 to -1.73, suggesting a tendency among the physicians to agree that teleconsultations are useful in their work. The most pronounced skewness was observed in PU1, indicating strong agreement about the difficulty of work during a pandemic without teleconsultations. The kurtosis values ranged from -0.38 for PU5 to 2.77 for PU1, indicating varied distribution patterns.

The higher kurtosis in PU1 reflected a more peaked distribution, suggesting more consistent agreement among physicians regarding its statement. The data suggested that physicians perceive teleconsultations as a valuable tool in their professional practice. The high mean scores across all PU items reflected positive perceptions of the teleconsultation system's usefulness, particularly in aiding work during a pandemic (PU1). The variation in SDs pointed to some differences in individual opinions about the specific benefits of teleconsultations, such as work efficiency and time-saving aspects. The negative skewness across all items highlighted a general agreement on the usefulness of teleconsultations, with a stronger consensus in areas such as coping with pandemic challenges. The kurtosis values, particularly for PU1, indicated that most responses were concentrated around higher ratings, showing strong agreement in specific areas of usefulness. The PU variable demonstrated that physicians generally regard teleconsultations as a beneficial tool in their practice, particularly under challenging conditions, such as a pandemic. Although there was overall agreement on their utility, the variation in perceptions across different aspects suggests areas where experiences and expectations of teleconsultations may differ among individual physicians.

The PEU variable examines physicians' perceptions of the ease and effortlessness associated with using teleconsultation systems. The mean scores for PEU1-PEU7 ranged from 3.81

to 4.60 (SD 0.60-1.42), respectively, and indicated a generally high level of agreement among the physicians that teleconsultation systems are user friendly and easy to use. The highest mean score was for PEU7 (4.60, SD 0.60), suggesting that using external systems during teleconsultations was perceived as particularly straightforward by most of the physicians. The SDs, ranging from 0.60 (mean 4.60) for PEU7 to 1.42 (mean 3.81) for PEU2, suggested a variation in the perceptions of ease of use, with the greatest variation in responses relating to the intellectual effort required (PEU2). The skewness for all PEU statements was negative, ranging from -0.99 to -1.99. This indicated a tendency among the physicians to rate the ease of use of teleconsultation systems highly, with a pronounced leaning toward agreement for most statements, particularly PEU7. The kurtosis values for the PEU variables were varied, with some (eg, PEU7) indicating a highly peaked distribution (7.13), which suggests that responses were more consistently clustered around the higher end of the scale. Overall, the data indicated that physicians find teleconsultation systems relatively easy to use. The high mean scores across all PEU items reflected a positive perception of the teleconsultation system's usability. The variation in SDs, especially the higher deviation for PEU2, suggested that although using the teleconsultation system is generally perceived as easy to use, there are aspects, such as the intellectual effort required, where opinions vary more widely. The pronounced negative skewness, especially for items such as PEU7, underlined a strong agreement in the ease of integrating and using external systems, which might be due to prior familiarity and necessity in clinical practice. The high kurtosis value for PEU7 pointed to a strong consensus among the respondents about the ease of this particular aspect of teleconsultation systems. The physicians generally found teleconsultation systems to be user friendly, with some areas, such as integration with external systems, being particularly well received. Around 253-325 (70.1%-90%) respondents rated the questions in the PEU group positively. However, there was notable variability in perceptions regarding the intellectual effort required, suggesting areas for potential improvement or further training.

The INT variable reflects physicians' intentions and willingness to continue using teleconsultation services in the future. The mean scores for INT1, INT3, INT4, and INT5 were 4.22 (SD 0.89), 3.99 (SD 1.01), 3.87 (SD 1.12), and 4.06 (SD 0.94), respectively. These scores, being close to or above 4 on a 5-point scale, suggested a generally positive inclination among the physicians toward the continued use of teleconsultations. The SDs for INT1, INT3, INT4, and INT5 indicated a moderate level of variation in responses. This variation signified that although there is a general trend of positive intention, individual physicians' perspectives on the future use of teleconsultations vary. The skewness values for these variables ranged from -0.97 to -1.20, which are negative. This negative skewness indicated a tendency among respondents to agree with the statements related to INT, suggesting that a larger proportion of physicians are inclined to continue using these services. The kurtosis values for INT1 (1.26), INT3 (0.46), INT4 (0.22), and INT5 (0.79) showed a relatively normal to slightly peaked distribution. This indicated a consistent pattern in physicians' responses, with a tendency toward agreement on the future use of

teleconsultations. The data indicated a positive attitude among physicians toward continuing the use of teleconsultations. The inclination to add video consultations to telephone conversations and to use teleconsultations for patient diagnosis and collaboration with other physicians was evident. The moderate spread in responses, however, pointed to some differences in enthusiasm or confidence about teleconsultations among individual physicians. These differences could be attributed to factors such as personal experience, familiarity with technology, or specific demands of their medical practice. Around 253-289 (70.1%-80%) of respondents intend to use teleconsulting in the future.

The Q variable was rated by physicians as the lowest level of all dimensions. The mean scores ranged from 3.28 (SD 1.26) to 3.73 (SD 1.06). The spread of responses was not even. The mean scores for Q1, Q2, and Q3 were 3.73 (SD 1.06), 3.43 (SD 1.19), and 3.28 (SD 1.26), respectively. These scores indicated a moderate level of agreement among physicians regarding Q, with some variability in the perception of different aspects of Q. The SDs for Q1-Q3 suggested a significant spread in responses. This indicated a varied perception of Q among the physicians, reflecting diverse experiences and expectations regarding teleconsultations. The skewness values for Q1 (-0.82), Q2 (-0.55), and Q3 (-0.27) were negative, implying a tendency for responses to lean toward agreeing with the statements about Q, although this tendency was less pronounced compared to other variables, such as SAT or PU. The kurtosis values for Q1 (-0.01), Q2 (-0.82), and Q3 (-1.18) suggested a relatively flat distribution, particularly for Q2 and Q3. This flatness indicated that the responses were more evenly spread across the scale, reflecting a wide range of opinions on the quality of work. The data suggested that although there is a general trend of moderate satisfaction with Q, there is considerable variation in how physicians perceive this Q. This variability could be influenced by different factors, such as the type of teleconsultation services used, the technological infrastructure in place, and the specific needs of the patient population being served. The more even distribution of responses, especially for Q2 and Q3, indicated that opinions on Q are diverse. This diversity might reflect the complexity of evaluating health care quality in a remote setting, where factors such as patient interaction, diagnostic accuracy, and treatment effectiveness play a crucial role. Only 199 (55.1%) respondents felt that teleconsultations are suitable for holistic patient care, 130 (36%) felt that remote consultations do not allow for comprehensive care, 108 (29.9%) felt that the Q by both methods is not the same, and 224 (62%) believed that the Q using remote visits is similar to that of visits in the clinic. Most physicians (n=260, 72%) agreed with the statement that teleconsultations improve Q.

The SAT variable offers valuable insights into physicians' contentment and approval levels regarding the use of teleconsultations. Physicians positively rated statements regarding SAT. The mean scores for the 4 statements of the SAT variable (SAT1, SAT2, SAT3, and SAT4) were 3.55 (SD 1.16), 4.13 (SD 0.88), 4.00 (SD 0.99), and 3.91 (SD 1.01), respectively. These scores, hovering around or above 4 on a 5-point scale, indicated a general trend of SAT among physicians with teleconsultation services. The SDs for

SAT1-SAT4 suggested a moderate level of variation in responses. This indicated that although there is an overall sense of SAT, there are differences in individual experiences and perceptions regarding teleconsultation services. The skewness values for these variables ranged from -0.62 to -1.14 , which are negative. This negative skewness implied a leaning toward higher SAT ratings among the respondents, indicating that more physicians agree with the positive aspects of teleconsultations. The kurtosis values for SAT1 (-0.52), SAT2 (1.51), SAT3 (0.82), and SAT4 (0.78) suggested a mixed distribution pattern. Although SAT1 indicated a relatively normal distribution, SAT2 showed a more peaked distribution, suggesting more consistent high ratings among physicians. The data suggested that

physicians are generally satisfied with teleconsultation services, as indicated by the mean scores leaning toward the higher end of the scale. The moderate variation in responses indicated differing levels of SAT, which may be influenced by individual experiences, technological proficiency, or specific needs in their practice. The skewness toward higher SAT ratings suggested that a larger proportion of physicians find teleconsultations to be a convenient and effective medium for providing health care services.

Descriptive statistics of all model variables are presented in Table 4, and distributions of the responses are presented in Table 5.

Table 4. Descriptive statistics of model variables.

	Mean (SD)	Variance	Skewness	Kurtosis
PU1 ^a	4.36 (0.94)	0.87	-1.73	2.77

Structural Equation Modeling

Based on the factors extracted in EFA, a structural model was developed (Figure 3). The model demonstrated excellent fit with the data, as indicated by indices such as the chi-square-to-degrees-of-freedom index: PCMIN/DF=0.91 (<5 is acceptable), comparative fit index (CFI)=1 (>0.9 is acceptable), goodness-of-fit index (GFI)=0.99 (>0.9 is acceptable), and root mean square error of approximation (RMSEA)=0 (<0.08 is acceptable). These values suggested that our model is robust and accurately represents the observed data.

In assessing the relationships between key constructs in our teleconsultation acceptance model, we used maximum likelihood estimates to derive regression weights (Table 6). Our analysis revealed significant relationships between the constructs, as

evidenced by the *P* values and critical ratios (CRs) in the regression weights. The influence of PU on INT was strong (estimate=0.63, CR=15.84, *P*<.001), suggesting that physicians' PU of teleconsultations significantly predicts their INT. PEU_2 also positively influenced INT (estimate=0.17, CR=4.31, *P*<.001), albeit to a lesser extent than PU. Both PU (estimate=0.44, CR=9.53, *P*<.001) and INT (estimate=0.4, CR=8.57, *P*<.001) significantly predicted SAT, indicating that PU and INT are crucial determinants of SAT with teleconsultations. Q was positively influenced by INT (estimate=0.179, CR=3.64, *P*<.001), PU (estimate=0.246, CR=4.79, *P*<.001), PEU_1 (estimate=0.18, CR=4.93, *P*<.001), and SAT (estimate=0.357, CR=6.97, *P*<.001), highlighting a multifaceted impact on Q. Since on each path of the model, the values of the regression parameters had *P*<.05, it can be said

that at a significance level of =.05, all the direct dependencies of the model are significant, and hence, H1-H8 are supported.

Standardized regression weights underscore the relative strength of these relationships in standardized format, which is particularly useful for comparing the effects across different predictors within our model. A significant positive covariance was observed between PU and PEU_1 (estimate=0.37, CR=6.52, $P<.001$) and between PU and PEU_2 (estimate=0.28, CR=5.05, $P<.001$), suggesting that PU and PEU are interrelated constructs. However, no significant correlation was found between PEU_1 and PEU_2 (estimate=0, $P=.99$), indicating these aspects of

PEU may independently influence the model. The squared multiple correlations for INT (0.48), SAT (0.58), and Q (0.6) indicate a substantial proportion of variance in these endogenous variables, explained by their respective predictors.

Our findings provide strong empirical support for the hypothesized relationships within TAM. The significant paths between constructs such as PU, PEU, INT, SAT, and Q highlight the multifaceted nature of teleconsultation acceptance among physicians.

These results underscore the importance of both PU and PEU in influencing INT and SAT, which, in turn, impact Q.

Figure 3. Structural model presenting standardized estimates. BI: measurement error; INT: intention to use teleconsultation; PEU: perceived ease of use; PU: perceived usefulness; Q: quality of work; SAT: satisfaction.

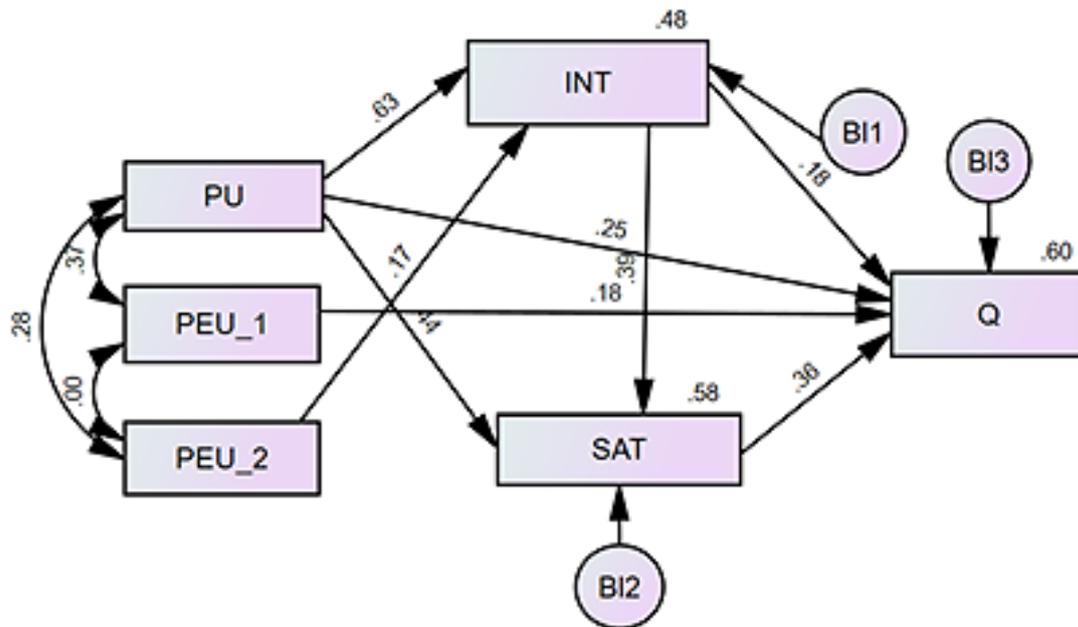

Table 6. Standardized regression weights of direct model paths.

Model paths	Estimate	P value
PU ^a →INT ^b	0.626	<.001
PEU ^c _2→INT	0.17	<.001
PU→SAT ^d	0.439	<.001
INT→SAT	0.395	<.001
INT→Q ^e	0.179	<.001
PU→Q	0.246	<.001
PEU_1→Q	0.176	<.001
SAT→Q	0.357	<.001

^aPU: perceived usefulness.

^bINT: intention to use teleconsultation.

^cPEU: perceived ease of use.

^dSAT: satisfaction.

^eQ: quality of work.

Mediation Analysis

In addition to the analysis of the model's direct paths, a mediation analysis was conducted. The values of regression factors for indirect model paths were determined (Table 7). The mediating effects within the structural model for the teleconsultation research provide insights into the indirect pathways through which independent variables influence dependent variables. PU had a substantial indirect effect on SAT through INT, with an estimate of 0.25 ($P < .001$). This suggests that the PU of teleconsultation systems significantly influences SAT, mediated by INT. Additionally, PU indirectly affected Q through both INT (estimate=0.112, $P < .002$) and SAT (estimate=0.16, $P < .001$). These paths indicate that PU leads to higher Q, as it influences INT and SAT with it. PEU_2 indirectly influenced SAT via INT, with an estimate of 0.07 ($P < .001$). This effect signifies that the PEU contributes to SAT through INT. For Q, PEU_2 had an indirect effect through the mediation of INT (estimate=0.03, $P < .001$) and SAT (estimate=0.02, $P < .001$). These findings imply that PEU of teleconsultations not only impacts INT but also enhances the Q delivered through SAT. The path from INT to Q mediated by SAT was significant, with an estimate of 0.14 ($P < .001$), indicating that INT contributes to Q, as mediated by SAT levels. The bootstrap 95% CIs for these indirect effects reinforced their significance, as they did not include 0, and the P values were well below the .001 threshold, indicating robustness in these mediating relationships. The mediating effects elucidate the important role

of INT and SAT with teleconsultation services in enhancing the PU and PEU.

Our findings from the SEM analysis corroborate several key hypotheses concerning direct, indirect, and mediating effects within the teleconsultation context. In accordance with H1, PU exhibited a significant direct effect on INT. Supporting H2, PU was also found to directly affect Q. In line with H3, a direct effect of PU on SAT was substantiated. PEU_1's direct effect on Q affirmed H4, demonstrating the technical influence of PEU on Q. PEU_2 was confirmed to directly impact INT, lending credence to H5. H6, positing a direct effect of INT on SAT, was also validated. Similarly, H7 was supported, with INT having a direct influence on Q. SAT was found to directly affect Q, confirming H8. The indirect influence of PU on Q through INT, posited in H9, was also substantiated. PU was found to indirectly affect SAT through INT, supporting H10. Moreover, the hypothesized indirect effect of PU on Q via the mediating roles of INT and SAT, as stated in H11, was validated. PEU_2's indirect impact on Q through INT, as hypothesized in H12, was confirmed. The indirect effect of PEU_2 on SAT via INT, detailed in H13, was likewise corroborated (Table 8).

Since on each path of the model, the values of the regression parameters had $P < .05$, it can be said that at a significance level of $= .05$, all the indirect dependencies of the model are significant, and hence, H9-H14 are supported.

Table 7. Standardized regression weights of indirect model paths.

Indirect model paths	Estimate	P value	Significance
PU ^a →INT ^b →SAT ^c	0.247	<.001	Significant
PU→INT→SAT→Q ^d	0.088	<.001	Significant
PU→INT→Q	0.112	<.002	Significant
PU→SAT→Q	0.157	<.001	Significant
PEU ^e _2→INT→SAT	0.067	<.001	Significant
PEU_2→INT→SAT→Q	0.024	<.001	Significant
PEU_2→INT→Q	0.03	<.001	Significant
INT→SAT→Q	0.141	<.001	Significant

^aPU: perceived usefulness.

^bINT: intention to use teleconsultation.

^cSAT: satisfaction.

^dQ: quality of work.

^ePEU: perceived ease of use.

Table 8. Corroboration of hypotheses concerning direct, indirect, and mediating effects.

Hypothesis (H)	Description	Supported (yes/no)
H1	PU ^a has a direct effect on INT ^b .	Yes
H2	PEU ^c has a direct effect on INT.	Yes
H3	PU has a direct effect on SAT ^d .	Yes
H4	INT has a direct effect on SAT.	Yes

^dSAT: satisfaction.

^eQ: quality of work.

Discussion

Principal Findings

This study evaluated Polish physicians' acceptance of teleconsultations during the COVID-19 pandemic in Poland. Most of the physicians positively assessed the PU of teleconsultations. The majority of physicians believed that their work during the COVID-19 pandemic would have been difficult without teleconsultations (88%) and that teleconsultations turned out to be a useful system enabling medical care (87%). The least number of physicians said that teleconsultations save time (61%) and improve performance (72%). Physicians are willing to use new technologies if they do not require additional time and effort, which is in line with other studies [25]. Similar results regarding the usefulness of teleconsultations during a pandemic and the ease of using them were obtained in a cross-sectional study conducted in 2020 in one of the Romanian counties using a questionnaire that assessed, among other things, the perception of teleconsultations by physicians. The study showed a positive perception of telemedicine by Romanian physicians. However, the researchers also highlighted the cons of teleconsultations, such as the time-consuming process, fear of making medical errors remotely, and communication difficulties on the part of patients [57]. The time-consuming nature of teleconsultations has also been confirmed in Great Britain; British physicians reported on time-consuming daily phone calls, emails, and complex electronic medical record protocols [58].

The PEU was also highly rated (average above 4). Most of the surveyed physicians (97%) declared that they know how to

connect to external systems during teleconsultations. Using teleconsultations was understandable for most of the respondents (96%), and most of them (94%) could easily prepare all necessary documents (prescriptions, sick leave, referrals for tests, etc) during the teleconsultations. Our results confirm those of other studies according to which the teleconsultations are simple and support physicians' responsibility in their work and medical decisions [30,59].

Polish physicians also positively assessed the future of teleconsultations and declared their intent to this form of work with patients (83%) and other physicians to agree on the diagnosis (73%). According to the majority of respondents (79%), remote monitoring of patients' health would improve the performance of teleconsultations. In the future, they (75%) would also willingly use video visits to facilitate contact and diagnosis of patients. Similar findings were obtained in a Romanian study, in which physicians concluded that telemedicine should be used continuously, not just during the COVID-19 pandemic. Most physicians (91.1%) considered it necessary to provide care using telemedicine after the pandemic [57]. In addition, in Brazil, most physicians want to continue remote care and demand regulations on the use of telemedicine that would allow the extension of remote services [60].

Teleconsultation became popular during the COVID-19 pandemic, and now, there are expectations that it will become a permanent part of the health care system [61]. The development and integration of ICT in health care delivery have great potential for patients, providers, and payers in future health care systems [62].

Polish physicians positively assessed SAT and felt comfortable giving the system a high SAT score. The mean value of responses for all statements regarding SAT was approximately 4. Only the statement regarding the identity of remote and traditional visits was rated lower. Only 62% of physicians believed that both forms of medical consultations are equivalent, and the average for this dimension was 3.55. This is probably due to the influence of teleconsultations on Q, which Polish physicians assessed as the lowest of all the dimensions of TAM. The average response ranged from 3.28 to 3.73. Only 55.1% of respondents stated that teleconsultation is suitable for holistic patient care, and 36% stated that teleconsultation does not allow for comprehensive care. The literature also emphasizes that teleconsultations will never replace F2F meetings. The large-scale and urgent introduction of teleconsultation into our practice is likely to be redefined in the post-COVID-19 era [7]. Another opinion is that teleconsultation is not inferior to personal visits to the office in terms of the preferences and satisfaction of patients and physicians. It should, therefore, be an effective complement to F2F office visits as a mechanism for segregation and long-term continuity of care [63].

Comparison With Previous Studies

This is the first such study conducted on SAT and Q in PHCs. SAT and Q have already been studied in other medical specialties (eg, urology, dermatology, psychiatry, and oncology). In a study conducted among dermatologists, almost all categories regarding SAT with remote dermatological teleconsultations were rated at about 9 on a 0-10 scale [64]. Schubert et al [65] assessed SAT with teleconsultations in psychiatry, which turned out to be at a high level. Providers were satisfied with telepsychiatry, and both believed that telepsychiatry provides patients with better access to care. Urological teleconsultation introduced quickly during the COVID-19 closure has achieved a high level of satisfaction among both patients and physicians [7]. Physicians are interested in using telemedicine tools that increase improved access to health and differentiate their clinical practice [66]. Telemedicine benefits all physicians' patients by increasing access to health care services and remotely managing elderly people with chronic conditions [67]. Therefore, the findings of our research are in accordance with other studies documenting the openness of physicians to the use of teleconsultations in providing health services to patients [68].

However, teleconsultations have limitations regarding the uncertainty caused by the inability to physically check the patient's health condition, and this is something physicians should be aware of [69]. Studies so far show that almost two-thirds of physicians report uncertainty about the correctness of a diagnosis made with telemedicine, and only one-fourth have confidence in making remote decisions [57]. Teleconsultations will never fully replace a personal visit, due to the inability to check the physical symptoms of the disease and the lack of nonverbal signals expressing trust and empathy during remote contact.

SEM results substantiate the significant influence of PU on INT, SAT with this technology, and Q. A possible reason for this may be the availability and effectiveness of teleconsultation, the time saving in this system, and Q. Thus, a positive effect

from PU will result in better SAT with teleconsultations and INT. This result is in line with other studies conducted in the field of telemedicine [30,70-73].

The medical PEU from the point of view of handling medical data (PEU_2) has a minor but significant impact on INT. Notably, the technical PEU_1 has a significant impact on Q. The easier it is to use teleconsultation, the better physicians are at assessing Q. The less effort users put in to handle medical data, the more positive their INT to use the system. This is in line with other studies, showing that the acceptance of telemedicine is greater when it provides faster health care, cost savings, better documentation, and time savings [52]. However, a study conducted in the United States found that the role of the influence of PEU on INT is insignificant. The study focused on pediatricians' INT to use of online health apps. The reason for this could be the longer contact of physicians with telemedicine technology [64]. Another explanation is that for highly competent physicians, the effect of PEU on INT is of little importance [74].

PU and PEU are considered the main determinants that directly explain the intent to use ("accept") a new technology [75]. In this study, we, therefore, confirmed the hypotheses that the constructs described in the traditional TAM are appropriate for measuring the intent of physicians to use teleconsultations.

INT emerged as a factor influencing SAT and Q and a pivotal mediator linking PU with both SAT and Q, thus underscoring the importance of intentions in the acceptance and effective use of telemedicine. This finding is in harmony with the existing literature that emphasizes the mediating role of INT in the context of technology acceptance [26]. When physicians believe that using teleconsultation will be effortless and useful, their attitude and INT will improve. This system, with less effort, encourages physicians to use teleconsultations and improves SAT and Q [31,70,76,77]. Therefore, the condition for the implementation of telemedicine technologies should be ensuring its understanding by health care providers in order to gain their acceptance and ensure the use of these technologies in the future [78]. SAT also turned out to be a significant mediator between PU, PEU, and Q. Our research, therefore, showed that the main elements of TAM viewed as PU and PEU have a significant impact on INT, which has been confirmed in other studies [30,70-73,79-82].

The model reaffirms the significant direct and indirect roles of PU and PEU in shaping INT, SAT, and Q. These findings contribute to the extant literature on teleconsultation acceptance and underscore the nuanced factors that influence the acceptance and satisfaction of teleconsultation services among physicians.

Implications

When planning a new teleconsultation system, PHC facilities should be able to predict whether the new system will be acceptable and satisfactory for medical staff, investigate the reasons why the planned system may not be fully acceptable, and then take action to increase the system's acceptance. The results of this study show that the PU of a system is a key determinant of medical professionals' INT. Therefore, before introducing a new system to PHC facilities, managers of these

facilities can increase the acceptance of the system by involving medical personnel in the implementation process, assessing the medical personnel's perception of the system (PU and PEU) and taking appropriate actions based on this assessment. Training should also be provided to medical staff to highlight the effectiveness and usefulness of teleconsultation in PHCs. Information and training sessions should primarily focus on how teleconsultation can help improve the quality of PHCs.

Intention as an intermediary variable has a significant and positive impact on users' SAT with teleconsultation and its Q. To increase the expected results in the Q of teleconsultations, the teleconsultation system should be useful for health checking, improving the quality of life, and increasing the capacity for self-care. To increase PEU, the teleconsultation system should be clear, understandable, easy to learn, easy to implement, and easy to perform health checks with. To increase the perceived utility, the teleconsultation system should positively influence the treatment plan, provide more comprehensive care services, and efficiently diagnose and efficiently plan and precisely monitor the patient's condition. The system should make physicians willing to use it to increase their INT. All this will contribute to greater SAT of physicians with their work and better quality of care [83].

This study is a contribution to the field of teleconsultation acceptance research. The modified TAM and its psychometric properties verified in this study can be used as a research framework to understand the acceptance of teleconsultation, especially in the population of PHC workers. The model can also be used for future TAM research in a variety of contexts in identifying, explaining, and predicting the intention of PHC professionals to use teleconsultation. Therefore, it is highly recommended to replicate this study in different environments to generalize the results across domains.

Limitations

In the discussion of research findings, it is crucial to acknowledge the limitations of this study to provide a comprehensive understanding of its context and implications. Although the study offers valuable insights into the factors influencing the acceptance and SAT of medical professionals with teleconsultation systems, several limitations must be considered.

The study was conducted across a specific number of PHC facilities in Poland. Although efforts were made to ensure a representative sample of PHC facilities, the findings might not fully encapsulate the diverse range of experiences and perceptions of all medical professionals nationwide. Regional variations, different health care settings, and varying levels of teleconsultation acceptance could influence SAT and acceptance levels.

The cross-sectional nature of the survey limits our ability to infer causality or changes over time. Longitudinal studies would be required to understand how perceptions and SAT with teleconsultation evolve as users gain more experience and as the technology itself advances.

The reliance on self-reported data can introduce biases, such as social desirability or recall bias. Participants' responses might not accurately reflect their true experiences or feelings toward teleconsultation.

Although the study focused on PU and PEU, other factors could influence SAT and INT. These might include individual technological proficiency, prior experiences with teleconsultation, or organizational support, which were not extensively explored in this study.

The study primarily addressed teleconsultation in PHC settings. The findings might not be generalizable to other forms of teleconsultation or to specialists' use of teleconsultation, where different factors could be more influential. The study also did not deeply explore the technological and operational constraints that might impact the effectiveness and user SAT with teleconsultation systems, such as system reliability, user interface design, and integration with existing health information systems.

The study was conducted during a period potentially influenced by the COVID-19 pandemic, which might have affected attitudes toward teleconsultation. The urgency and necessity of teleconsultation during the pandemic might not reflect standard operational conditions.

By addressing these limitations, future research can build upon the findings to develop a more nuanced understanding of the factors influencing the successful implementation and adoption of teleconsultation systems in various health care settings. In the forthcoming models, we also intend to include constructs such as compatibility, self-efficacy, social norms, perceived behavioral control [25,84], social interaction, invasiveness, and relevance [85].

Conclusion

After the outbreak of the COVID-19 pandemic, there was a dynamic development of teleconsultations in PHCs in Poland. Therefore, we conducted satisfaction surveys of Polish physicians based on a modified TAM, which we extended with new constructs, including physicians' SAT and Q, considering INT as a mediating variable. The tool developed for this model was verified in terms of psychometric properties. Therefore, it has the potential to be used in both research and practice, especially to assess the SAT and Q of PHC physicians who use teleconsultations in Poland.

The findings highlight significant relationships between PEU, PU, INT, and physicians' SAT with teleconsultation and their Q. The study showed that the PEU and PU of teleconsultations are predictive determinants of the acceptance of teleconsultation, which in turn influences physicians' SAT and Q.

Identification of the most important factors influencing physicians' SAT and Q can provide important information to managers of PHC facilities and help them make the right decisions. This study provides information for the strategies of PHCs and policy makers to accept and encourage the use of teleconsultations in Poland.

Abstract

Background: Wearable devices (WDs) have evolved beyond simple fitness trackers to sophisticated health monitors capable of measuring vital signs, such as heart rate and blood oxygen levels. Their application in health care, particularly medication management, is an emerging field poised to significantly enhance patient adherence to treatment regimens. Despite their widespread use and increasing incorporation into clinical trials, a comprehensive review of WDs in terms of medication adherence has not been conducted.

Objective: This study aimed to conduct a comprehensive scoping review to evaluate the impact of WDs on medication adherence across a variety of diseases, summarizing key research findings, outcomes, and challenges encountered.

Methods: Adhering to PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines, a structured search was conducted across MEDLINE, Web of Science, and Embase databases, covering the literature from January 1, 2010, to September 30, 2022. The search strategy was based on terms related to WDs and medication adherence, specifically focusing on empirical studies to ensure the inclusion of original research findings. Studies were selected based on their relevance to medication adherence, usage of WDs in detecting medication-taking actions, and their role in integrated medication management systems.

Results: We screened 657 articles and identified 18 articles. The identified studies demonstrated the diverse applications of WDs in enhancing medication adherence across diseases such as Parkinson disease, diabetes, and cardiovascular conditions. The geographical distribution and publication years of these studies indicate a growing interest in this research area. The studies were divided into three types: (1) studies reporting a correlation between data from WDs or their usage and medication adherence or drug usage as outcomes, (2) studies using WDs to detect the act of medication-taking itself, and (3) studies proposing an integrated medication management system that uses WDs in managing medication.

Conclusions: WDs are increasingly being recognized for their potential to enhance medication management and adherence. This review underscores the need for further empirical research to validate the effectiveness of WDs in real-life settings and explore their use in predicting adherence based on activity rhythms and activities. Despite technological advancements, challenges remain regarding the integration of WDs into routine clinical practice. Future research should focus on leveraging the comprehensive data provided by WDs to develop personalized medication management strategies that can improve patient outcomes.

KEYWORDS

medication adherence; scoping review; database search; integrated medication management; drug; pharmacy; pharmacology; pharmacotherapy; pharmaceuticals; medication; adherence; wearable; synthesis; review methods; digital health

Introduction

The term “medication adherence” refers to the extent to which patients correctly follow their medication regimens [1-4]. Medication adherence is influenced by lifestyle habits and the potential for using wearable devices (WDs) that record daily activities as activity data has been broadly considered [5-8].

WDs are currently equipped with various types of sensors [9-12]. Beyond standard heart rate or gyro sensors for activity

and sleep tracking, some devices can measure or estimate blood pressure, blood glucose levels, blood oxygen levels, and various biomarkers [13-20]. Along with their widespread use, there has been an increasing trend in the use of these devices in health care. According to ClinicalTrials.gov, the number of clinical trials using WDs as outcome measures in drug-related interventions increased from 5, between January 1, 2016, and December 31, 2016, to 21 by 2021, marking a more than fourfold increase [21]. Due to their ability to provide long-term continuous monitoring with minimal burden on patients, there

are reports of WDs being used not only in clinical trials but also in managing chronic diseases such as obesity, diabetes, and Parkinson disease, as well as in detecting conditions like COVID-19, cardiovascular diseases, and managing the side effects of chemotherapy [22-28].

In recent years, efforts have been made to use WDs to manage patient medication adherence. Medication management with WDs encompasses a wide range of approaches, including detecting medication-taking actions using motion sensors, using the device as an interface for information notifications, and analyzing various data recorded on the WDs to assess how accurately patients take their medications [29-31].

On the other hand, in the field of medication adherence, there has been a wide range of research methodologies and a lack of focus on specific disease areas, resulting in the absence of a review that provides research guidelines for the field. Therefore, this study seeks to conduct a comprehensive scoping review of WD applications across a spectrum of diseases, aiming to summarize key research findings, outcomes, and challenges encountered in medication management and adherence.

Methods

Databases and Search Strategy

The investigation was conducted in strict adherence to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines (Checklist 1) [32]. Overall, 3 major databases were searched: MEDLINE (through PubMed), Web of Science Core Collection (through Web of Science), and Embase (through ProQuest Dialog). Terms related to WDs and adherence were established separately for the search. These terms were appropriately divided into Medical Subject Headings (MeSH) terms and free words. For instance, in the MEDLINE search, the MeSH terms “wearable electronic devices” and “patient compliance” were used. Notably, under “patient compliance,” the inclusion of “medication adherence” was confirmed (Table 1). The search period was limited from January 1, 2010, to September 30, 2022. When filters were available, literature types such as reviews and editorial materials were excluded from the search.

Table . Search detail (MEDLINE).

^aMeSH: Medical Subject Headings.

Database searches were conducted from November 2022 until December 2023. The search, removal of duplicates, and initial screening were performed by a single author (HI). Screening of potentially compatible references was independently performed by 2 authors (HI and HK). In case of any disagreements, the last author (SH) provided advice. The search process is shown in detail in [Multimedia Appendix 1](#). Management of the literature and removal of duplicates were performed using Zotero (version 6.0.30; open-source software of the Corporation for Digital Scholarship).

Inclusion and Exclusion Criteria for Papers

In this survey, no strict criteria were set for the research design or outcomes so as to encompass a broad range of studies that could potentially relate to the subject. However, each included study met at least one of the following conditions, which were also used to classify the study types in the Results section: (1) studies reporting a correlation between data from WDs or their usage and medication adherence or drug usage as outcomes, (2) studies using WDs to detect the act of medication-taking itself,

and (3) studies proposing an integrated medication management system that uses WDs to manage medication. For condition 3, studies were only included if they clearly demonstrated the contribution of WDs to medication management, at least through notifications or other functions; studies that simply used WDs to obtain patient vitals or biometric information were excluded. Additionally, studies that conducted these types of investigations as a sub-analysis were also considered for inclusion in this review, even if it was not their main objective.

Organizing the Results

Owing to the relatively small number of existing studies in this field, there is a wide variation in research methodologies, making it challenging to integrate the results into specific metrics. Therefore, in the Results section, we present which of the 3 study types outlined in the “Inclusion and Exclusion Criteria for Papers” section is satisfied by each selected paper. Furthermore, we provide insights into each study’s approach in the Discussion section. This scoping review aimed to provide an overview of the research field and not to analyze the

effectiveness of interventions. Therefore, we did not critically assess the methodological quality of the included studies.

Results

A flow diagram of the selection procedure is shown in Figure 1. Following the literature search and screening, we ultimately obtained 18 references. A summary of the literature is presented in Table 2.

Figure 1. Flow diagram of study selection.

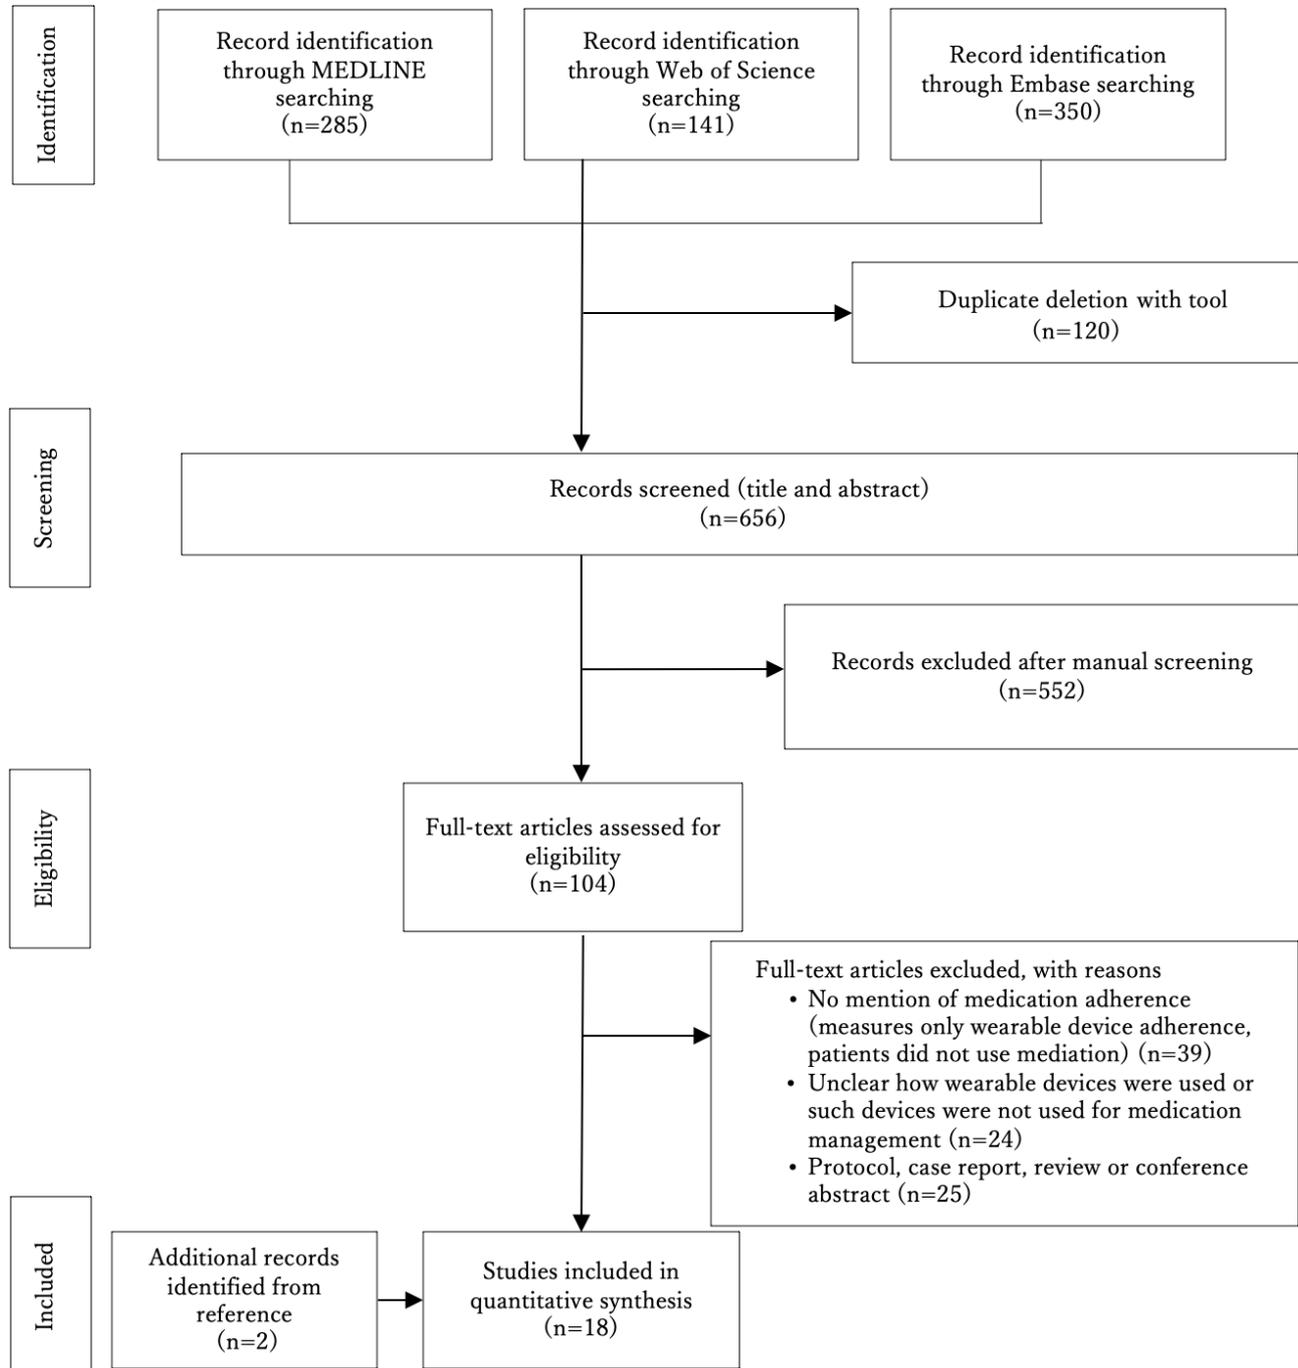

Table . Summary of search results.

Author (published year)	Target population	Findings	Type of wearable device	Sample size, n	Usage of wearable devices	Country	Study type
Agurto et al (2021) [33]	Parkinson disease	It was possible to quantitatively determine the patient medication condition (on/off) due to the speed, acceleration, and symmetry of body movement.	Band (feet, wrist, lumbar, and sternum)	33	Record of acceleration	United States	1, 2
Quisel et al (2019) [31]	Hypertension, diabetes, and dyslipidemia	There is a significant relationship between medication adherence and activity tracking in individuals with chronic illness. Those who use activity tracking have higher medication adherence than those who do not use activity tracking.	Wristband	791 - 10,499	Activity tracking (step count, sleep time)	United States	1
Zhang et al (2020) [34]	Hypertension	Wearable device nonusers have higher medication use scores ($P < .001$) On the other hand, medication use has a negative effect on adherence to the device use (no significant difference).	Wristband	317	Blood pressure monitoring	China	1
Zhang et al (2020) [35]	Hypertension	Wearable device nonusers have higher medication use scores ($P = .003$).	Wristband	212	Blood pressure monitoring	China	1

Author (published year)	Target population	Findings	Type of wearable device	Sample size, n	Usage of wearable devices	Country	Study type
Cochran et al (2021) [36]	Patients with serious mental illness (major depressive disorder, schizophrenia, bipolar 1 disorder)	Higher values of both the previous day's activity rhythm score and activity intensity score characteristics tended to be associated with higher next-day intake rates. Patients with mean activity rhythm scores greater than the patient-level median had higher overall intake rates than those with lower activity rhythm scores ($P=.004$).	Adhesive patch	113	Detection of medication intake, activity tracking (step counts, heart rates)	N/A ^a	1
Belknap et al (2013) [37]	Tuberculosis	The positive detection rate of medication behavior was 95% (95% CI 93.5 - 96.2), and the specificity was 99.7% (95% CI 99.2 - 99.9).	Adhesive patch	30	Detection of medication intake	United States	2
Browne et al (2019) [38]	Tuberculosis	The positive detection accuracy (percentage of correctly identified medications) of wirelessly observed therapy (WOT) was 99.3% (95% CI 98.1 - 100). WOT medication adherence was noninferior to directly observed therapy (DOT) (WOT 95.6% vs DOT 92.7%; $P=.31$).	Adhesive patch	61	Detection of medication intake	United States	2, 3
Lee et al (2021) [39]	General patient (who commonly takes medication)	The medication behavior recognition by the developed model showed an accuracy of 92.7%, a precision of 0.909, and a recall of 0.949.	Wristband (camera attached)	89	Detection of medication intake	South Korea	2

Author (published year)	Target population	Findings	Type of wearable device	Sample size, n	Usage of wearable devices	Country	Study type
Kalantarian et al (2016) [40]	General population ^b	The constructed model was able to accurately classify chewable, saliva swallow, medicine capsules, conversation, and drinking water, with an average accuracy and recall of 90.17% and 88.9%, respectively.	Necklace	N/A ^a (135 instances)	Detection of medication swallow using sensors	N/A	2
Fozoonmayeh et al (2020) [29]	General patient	F_1 -scores for the classification of medication activities (tablets, liquid agents) and nonmedication activities (sending SMS text messages, walking, writing, opening, and drinking bottle water) are up to 0.983.	Wristband	24	Tracking acceleration, heart rate, and atmosphere pressure	N/A	2
Spaulding et al (2019) [41]	After acute myocardial infarction	With the integration of the Corrie app and Apple Watch, the participants could be reminded to take drugs and track them directly on their wearable devices.	Wristband	60	Medication record, reminder (notification) ^c	United States	1, 3
da Silva et al (2019) [30]	Hypertension	Sending automatic reminders to patients via commercially available smartphones and smart TVs has reduced the number of missed medication doses and improved treatment compliance.	Wristband	N/A	Reminder (notification)	N/A	3
Levine et al (2019) [42]	Kidney or pancreas or liver transplant recipient (immunosuppressant user)	The use of mobile medical apps in this study did not indicate an increase in medication compliance.	Wristband	108	Reminder (notification)	United States	3

Author (published year)	Target population	Findings	Type of wearable device	Sample size, n	Usage of wearable devices	Country	Study type
DiCarlo et al (2016) [43]	Hypertension	Positive detection accuracy (percentage of correctly identified medications) was 98% (95% CI 96.4-99.1).	Adhesive patch	37	Detection of medication intake	United Kingdom	2, 3
Noble et al (2016) [44]	Hypertension	Wearable device data revealed inappropriate drug use. Of 15 additional patients surveyed, 87% indicated that the device helped improve compliance.	Adhesive patch	54 (15 commercial pharmacies and 39 patients)	Detection of medication intake, activity tracking (rest, activity, and exercise)	United Kingdom	2, 3
Cochran et al (2022) [45]	Schizophrenia	When categorizing engagement with the system as moderate and high engagement, based on medication adherence and device adherence as indicators, the average medication adherence rates were 0.62 for the moderate group and 0.87 for the high engagement group.	Adhesive patch	277	Detection of medication intake, activity tracking (rest, activity, and exercise)	United States	2, 3
Profit et al (2014) [46]	Patients with serious mental illness (major depressive disorder, schizophrenia, bipolar 1 disorder)	In the ingestion detection test, the detection rate of the ingestion sensor by the wearable sensor was 96.6%.	Adhesive patch	29	Detection of medication intake, Activity tracking (rest, activity, and exercise)	N/A	2, 3
Daar et al (2020) [47]	HIV	The system demonstrated its capability to collect real-time ingestion data and automatically send reminder SMS text messages to HIV patients undergoing ARV ^d treatment.	Skin patch (adhesive)	15	Detection of medication	United States	2, 3

^aN/A: not available.

^bAlthough they were not patients, the study was conducted to simulate actual drug-taking behavior.

^cThe document only stated that “Medication adherence is also measured from the smartphone and smartwatch app usage data” and did not provide any details; however, we confirmed the functionality from an external site that provides an overview of the application.

^dARV: antiretroviral.

Among the selected literature, 2 (11.1%) papers were published before 2014, 8 (44.4%) papers between 2015 and 2019, and 8 (44.4%) papers between 2020 and 2022. Regarding the geographical distribution of the studies, North America

accounted for 8 (44.4%, all from the United States) papers, Europe for 2 (11.1%, both from the United Kingdom) papers, and the Asia-Pacific region for 3 (16.7%, including 2 from China and one from South Korea) papers. However, 5 (27.8%) studies did not specify the study region. In terms of sample size, 6 (33.3%) papers had a sample size of 50 or fewer, 4 (22.2%) papers had between 51 and 100 participants, 2 (11.1%) papers had between 101 and 200 participants, 4 (22.2%) papers had over 200 participants, and 2 (11.1%) papers did not specify the sample size. Additionally, 3 (16.7%) papers did not specify a particular disease as their research subjects, whereas 15 (83.3%) papers focused on specific diseases. Among these, 4 papers addressed neuropsychiatric disorders, 6 (33.3%) addressed lifestyle-related diseases and 3 (16.7%) focused on infectious diseases.

We categorized each study into the following three study types: (1) studies reporting the relationship between WD data or device usage and medication adherence or drug usage as an outcome, (2) studies detecting medication-taking behavior directly using WDs, and (3) studies proposing integrated medication management systems where WDs are used. Below are examples of the study classifications.

Study Type 1: Studies Reporting a Correlation Between Data From WDs or Their Usage and Medication Adherence or Drug Usage as Outcomes

Quisel et al [31] demonstrated that using WDs improved medication adherence among patients with hypertension, diabetes, and hyperlipidemia. Additionally, Cochran et al [36] showed a correlation between activity rhythm scores derived from WD data and medication adherence rates.

Studies classified under study type 1 investigate the relationship between medication adherence outcomes and the use or data of WDs, directly highlighting methodologies to clarify the involvement of WDs in medication adherence. These studies suggest the potential impact of WD use on adherence in real-world settings, as well as the relationship between WD-recorded data and medication adherence.

The studies suggest both positive and negative relationships between WD usage and medication adherence. However, the studies indicating a negative impact on adherence involved new WD distributions at the start of the research, not based on spontaneous usage. While one study suggests high adherence among a large cohort of spontaneous WD users, additional verification with other databases is needed. Studies using WD data reported that features derived from the data were correlated with medication adherence, suggesting the potential to estimate adherence from WD data.

Study Type 2: Studies Using WDs to Detect the Act of Medication-Taking

Browne et al [38] demonstrated that a system combining ingestible sensors and WDs could detect medication-taking behavior with high accuracy. Kalantarian et al [40] developed a method using a necklace-type WD to detect medication-taking behavior through throat movements, achieving an accuracy of 90.17%.

Studies under study type 2 focus on detecting medication-taking behavior itself using WDs. Various methods for detecting medication-taking behavior, such as movement, video, and positional relationships with the medication, have been proposed and verified as practical attempts to contribute to the understanding of medication adherence.

Nearly all studies show that medication-taking behavior can be detected with high accuracy, often exceeding 90%. This is a necessary factor for real-world applicability. However, many of the devices used were proprietary, with only one study using a commercially available WD.

Study Type 3: Studies Proposing an Integrated Medication Management System That Uses WDs to Manage Medication Adherence

Spaulding et al [41] demonstrated that a system combining a smartphone app and WD improved medication adherence in patients post-acute myocardial infarction. This system promoted regular medication intake through reminder functions, contributing to reduced readmission rates.

Studies under study type 3 do not focus solely on WDs but propose systems that manage medication adherence using IoT technology, with WDs serving as one of the interfaces. These studies discuss the development, specific usage, and verification results of medication adherence management systems using WDs, considering real-world applicability.

The studies indicate that WDs are useful interfaces for recording patient adherence. However, most studies used WDs primarily for notification or recording functions, without leveraging the multiple sensors embedded in WDs.

Discussion

Initially, we describe studies that report WD data or associations with device use as an outcome of medication adherence or use (primarily those belonging to study type 1).

Agurto et al [33] investigated the impact of medication on physical activity levels in Parkinson disease patients. By objectively monitoring physical activity, they demonstrated that WDs can distinguish between medicated and non-medicated states. Parkinson disease, characterized by rapid and marked changes in physical activity following dopaminergic medication such as levodopa, is one area where WDs have been actively used [48-50]. However, this study is unique in that it extends the use of wearables to discern medication states.

Quisel et al [31] suggested that higher activity tracking and intensity using WDs are correlated with better medication adherence. Quisel et al [31] and Cochran et al [36] are among the few that have investigated the relationship between activity intensity and adherence. Quisel et al analyzed insurance databases using the proportion of days covered as an adherence measure. However, the proportion of days covered, by only calculating the prescribed days for medication, fails to confirm actual intake, thereby missing instances of nonadherence even when medication is prescribed [51,52]. Another limitation was the exclusion of medication purchases under different insurance plans that were not recorded in the database [31]. These

limitations are difficult to overcome in database-based studies, and conducting validation using a different database is necessary to strengthen the results.

Cochran et al [36] scored individuals' activity rhythms or patterns using WD data to analyze their correlation with medication adherence. Although adherence to chronic diseases is expected to be closely related to lifestyle, no studies have objectively measured lifestyle rhythms and analyzed their correlation with medication. The Cochran study showed that more consistent activity rhythms predict better adherence. However, the study's limitations include the use of only 7 days of data and unclear thresholds for activity rhythm categorization, suggesting that further validation is needed for broader application.

Zhang et al conducted 2 parallel studies in 2020 at the same location but with different inclusion criteria: one encompassing all participants and the other focusing on individuals aged over 60 [34,35]. Notably, these studies contrasted with those of Quisel et al, indicating higher medication use scores among individuals not using WDs. However, these studies distributed new devices for the survey, differing from the group that wore the devices voluntarily [31]. Additionally, they focused primarily on device adherence, with medication usage as a secondary inquiry, without mentioning wearable-driven medication management systems. Additionally, this study defined a composite compliance score related to hypertension and reported a positive relationship between the composite compliance score, blood pressure values, and device usage. However, it also reported a negative relationship between medication use and these indicators. It is unlikely that there is a negative correlation between medication use and blood pressure values or hypertension indicators, suggesting the possibility of overlooking important factors such as age.

In type 1 studies, the nature of the target population differs, and the results are contradictory, making it difficult to draw consistent conclusions about the relationship between WD usage and medication adherence at this point. Among populations that regularly use WDs, a positive relationship between the amount of data recorded by the device and medication adherence has been suggested in relatively large samples. Considering the results from populations where WDs were distributed, it is possible that the temperament of those who use WDs reflects their medication adherence, indicating that WD usage itself may not be a factor that improves medication adherence. On the other hand, if appropriate behavioral features are derived from WD data, it may be possible to capture an individual's medication adherence status.

Next, we discussed studies that detected medication-taking behaviors (study type 2). Although the types of data and devices used in these studies vary, all have achieved high accuracy in detection, suggesting that the technical feasibility of medication detection has already been established or is achievable. Some studies have developed both hardware and software independently, while others have only developed software independently. Using custom hardware allows for the collection of more data and the creation of more accurate predictive models tailored to patient outcomes and conditions. However, the costs

of development and the lower recognition of these devices could hinder their widespread adoption in the general market.

Noble et al, Belknap et al, Browne et al, DiCarlo et al, Cochran et al, Profit et al, and Daar et al used patch-type devices [37,38,43-47]. These devices detect medication intake using sensors attached to the medication that transmit a signal to a patch worn on the body. Unlike smart pill bottles or detection methods based on arm movements, these patches offer a highly robust method for measuring medication adherence. Among the 7 studies using patch-type devices, 4 specifically reported on the accuracy of medication detection, each achieving an accuracy rate exceeding 95% [37,38,43,46]. This method is highly beneficial for diseases such as tuberculosis and schizophrenia, where continuous medication is crucial; however, the need for a sensor and transmitter for each medication makes it potentially expensive, necessitating a cost-effectiveness analysis for chronic diseases such as hypertension, where immediate adherence is not critical.

Kalantarian et al [40] specifically targeted the action of swallowing to detect medication intake, using a novel approach focused on throat movements. This unique study, which focused on throat movements, recorded a high accuracy of 90.17%. This also suggests that combining this method with smart pill bottles could further improve the accuracy. However, this throat-movement-detecting device, which is not commonly used, may face practical barriers because of its appearance and comfort.

Fozoonmayeh et al [29,39] and Lee et al [39,39] conducted studies to detect medication-taking behavior through arm movements using widely available wristband devices. Fozoonmayeh et al [29] used a commercial smartwatch, which could lower the clinical application barrier owing to its price and availability. Recognizing medication-taking behavior based solely on arm movements is challenging because of similarities with other actions, such as drinking water. However, the F_1 -score in this study was 0.983, indicating a highly effective model. Conversely, Lee et al [39] attempted to enhance accuracy by equipping the device with a camera and combining motion detection with image recognition. Although the model's accuracy was lower at 92.7% compared to that of Fozoonmayeh et al [29], image recognition might be necessary to accommodate a variety of medication forms beyond the pills.

Finally, we describe a study proposing an integrated medication management system that uses WDs as part of the system (study type 3). Overall, research in this study supports comprehensive medication management by providing user-friendly interfaces. The primary functions are notifications and reminders, indicating that the role of WDs in medication management is limited. On the other hand, Spaulding et al [41] made it possible to record medication intake directly from a WD display, indicating its role in logging medication. WDs, which provide the most immediate interface for software and systems, have the potential to enhance the efficiency of disease-management systems by expanding their functionality.

These medication management systems are predominantly software-based, and many studies have used commercially

available devices [53-55]. However, research such as that by Daar et al [47] involves developing custom devices. Although commercially available devices offer the advantages of being affordable and easily accessible, they have predetermined specifications and data capabilities that may not accommodate all the necessary metrics for certain diseases [11,56]. For instance, Kalantarian et al [40] used a unique necklace-type device to detect the swallowing motion, a form not commonly found in the market. Furthermore, many biochemical markers cannot be measured using commercially available devices, suggesting the need for developing custom devices to realize specific disease management strategies.

Limitations

The limitations of this study include (1) restriction to original articles written in English and published in scientific journals and (2) room for improvement in the categorization of the studies (study type). The field of medication adherence management using WDs is relatively new, and projects in this area are expected to start with small-scale validations. Such studies are not always written in English or published in international journals. During our survey, we screened numerous abstracts from relevant conference presentations and non-English literature that appeared pertinent. However, obtaining complete access to these sources is often challenging, making their inclusion in reviews impractical.

Additionally, the diverse nature of studies on adherence management using WDs led to the categorization of some overlapping research types. Although this can be helpful in understanding the characteristics of the research, it is often duplicative and not a clear-cut classification. While we believe that this classification has minimal impact on the interpretation of the results in this review, defining clearer research directions as the field evolves could potentially facilitate a better understanding of prior studies.

Future Directions

Further research is needed in various regions to understand the relationship between WD usage and medication adherence. On the other hand, the individual data from WDs can objectively capture patient behavior and create features related to adherence, such as daily rhythms and body movements influenced by medication. Currently, there are no reported medication management systems that fully use the various sensors and data WDs possess. However, in the future, by combining the detection of medication-taking actions, it is expected that WD data can be used to estimate individual medication adherence with high accuracy. Exploring better features that can be applied in real-world settings is crucial.

In the studies classified under study type 1 or 2, few have reached the point where they can be used by the general public as commercial products. As mentioned earlier, these studies face many gaps, including the need for basic theory validation, the development of consumer-oriented devices, and cost-effectiveness analysis. Addressing these research gaps with the aim of clinical application is expected to promote the use of WDs and improve medication adherence and patient health outcomes.

Conclusions

Medication management using WDs is currently being implemented based on empirical research, primarily as a simple interface for patient notifications. Technically, the detection of medication-taking behavior has achieved high accuracy, necessitating real-life empirical studies to further leverage this technology. Notably, it has been suggested that specific medication-taking behaviors and daily activity rhythms are related to medication adherence [36]. These findings imply that WDs can predict patients' medication adherence through daily activities and not merely by recognizing isolated medication-taking events. Exploring behavioral data from WDs in future research to clarify the relationship between patient lifestyles and medication practices promises to greatly expand the use of WDs in managing medication adherence.

Acknowledgments

This study was supported by the Japan Science and Technology Agency's Support for Pioneering Research Initiated by the Next Generation (SPRING) program (grant JPMJSP2123).

Authors' Contributions

HI and SH designed this study. HI and HK were responsible for setting the search terms and configuring the search queries, while SH conducted the final review of the search strategy. Screening and integration of results were conducted by HI and HK under the guidance of SI and SH and were reviewed by SI and SH. The integration of results was conducted by HI and HK. HI drafted and completed the manuscript. SH supervised the study. All authors have reviewed and approved the final manuscript.

Abstract

Background: Robotic technologies present challenges to health care professionals and are therefore rarely used. Barriers such as lack of controllability and adaptability and complex control functions affect the human-robot relationship. In addition to educational opportunities, the possibility of individual adaptation can improve the usability and practical implementation of robotics. Previous work has focused on developments from a technology-centered perspective and has included user interests too late in the process.

Objective: This study addresses the following research question: What cocreative research approaches are used in the field of nursing robotics to improve the usability, intended use, and goal-directed application of robotic developments for nurses and to support the nursing process?

Methods: This scoping review provides an overview of the topic and the research activities taking place within it. Five databases and the reference lists of the identified publications were searched for studies without further restrictions. Studies were included if they developed and evaluated interaction and control platforms for robotic systems in health care in a cocreative way with end users.

Results: The search resulted in 419 hits, of which 3 publications were included. All publications were feasibility or user studies that were mainly carried out in the European Union. The 3 interaction and control platforms presented were all prototypes and not commercially available. In addition to those in need of care, all studies also included family carers and health care professionals.

Conclusions: Robotic interaction and control platforms in health care are rarely, if ever, developed and evaluated with feasibility or user studies that include prototypes and end users. While the involvement of end users is crucial, this review emphasizes that all stakeholders, including health care professionals, should participate in the development process to ensure a holistic understanding of application needs and a focus on user experiences and practical health care needs. It is emphasized that the active involvement of end users in the development process is critical to effectively meeting the needs of the target group.

KEYWORDS

human-robot interaction; cocreation; robotics; user-centered design; health care

Introduction

The narrative of the digital transformation of health care confronts health care professionals with the challenge of using robotic systems. The challenge is to adapt the technologies to the different and individual needs of patients. Standardized robotic functions, such as those designed for industrial robots, regularly reach the limits of their usability in care situations [1].

For a human-robot relationship to be highly usable, it must be meaningful and effective to the user. The medical journalist Nicole Janke [2] suggests that the main barriers to the use of robotics in health care are the lack of controllability, the lack

of adaptability, and the complexity of control functions for changing users, contexts of use, and suitability for the user. The current inflexibility is one of the reasons for the rather low penetration of already available robotic systems in everyday life and, especially, in care. On the one hand, their use will be improved if health care professionals are introduced to the applications in a structured way through tailor-made teaching programs [3]. On the other hand, functionality will be increased if members of these nontechnical professions are given the opportunity to make certain adjustments to individual care situations themselves, thus improving situation-specific usability.

Implementation science is currently shifting from linear and safe development in controlled laboratory environments to more iterative, participatory, and complex models where interventions are developed and evaluated directly in the later field of application [4,5]. Participatory design approaches such as cocreation or design-based research [6] can be a solution to achieve usability and user acceptance. Cocreation is a collaborative approach that involves end users and relevant stakeholders in all phases of a project, from needs analysis and problem definition to the evaluation of prototypes and the final phase of a project [7].

Previous work has addressed cocreative research in technological development from a more general, theoretical perspective, in the context of raising awareness among target groups and identifying needs from a technology-centered perspective. Reference to user interests often occurs only in the testing phase of a finished technology [8-10]. Involving end users as early as possible in the development process can be seen as a way to increase acceptance and have a positive impact not only on patient satisfaction but also on the quality of care [11,12]. In addition, cocreation can increase the success of implementations of evidence-based interventions and policies through equal and deep involvement of end users [13,14]. As a result, social determinants and contextual factors responsible for the feasibility and acceptability of interventions are influenced at the earliest stage of the development cycle [15].

Currently, there are no established methods that address the adaptation of the cocreative development process to the health care or nursing context to address challenges such as collaboration or power structures [8]. To our knowledge, there also have been no systematic reviews focusing on robotic interaction and control platforms in health care. Therefore, this study addresses the following research question: What cocreative

research approaches are used in the field of nursing robotics to improve the usability, intended use, and goal-directed application of robotic developments for nurses and to support the nursing process? The following subquestions can be formulated: (1) How is the cocreative process of robotic technology development designed in the context of nursing? (2) How can changes in usability, intended use, and goal-directed application be measured over the course of the development process?

Methods

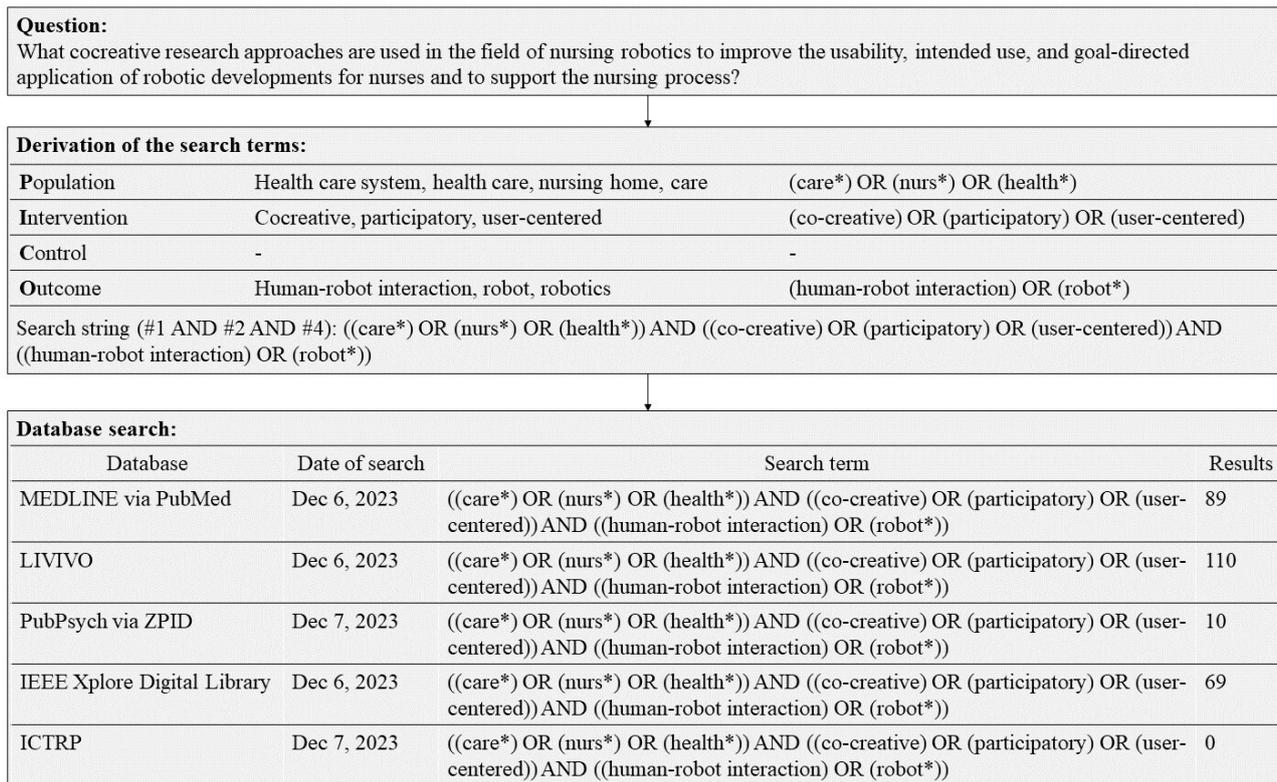

A scoping review was carried out to provide an overview of the research field, outlining the extent and nature of research activity, mapping approaches and key concepts, and identifying research gaps [16]. The content and structure of the report are based on the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement [17].

Search Strategy

A systematic search was conducted of MEDLINE (via PubMed), LIVIVO, PubPsych (via ZPID), and IEEE Xplore Digital Library (via the IEEE website). Trial registrations were searched via the International Clinical Trials Registry Platform (ICTRP). The search terms were derived using the population, intervention, control, outcome (PICO) scheme. [Figure 1](#) illustrates the derivation of the search terms and the database search.

The reference lists of the publications identified by the search were scanned for additional relevant publications. Only publications that reported on robotic interaction and control platforms and described a cocreative development process were included.

Figure 1. Derivation of the search terms and the database search. ICTRP: International Clinical Trials Registry Platform.

Study Selection

The criteria for the selection of publications are described in [Textbox 1](#). According to the question of this scoping review, robotic interaction and control systems that were developed in a nursing context with end users (nurses) and evaluated in practice were included.

The term *robotic system* used in this paper is based on the ISO 8373:2012 definition. According to this, a robot performs useful tasks autonomously, in the sense that it is able to perform these tasks on the basis of its sensor data without human intervention.

Despite the great progress in robotics, it remains a challenge to synthesize a variety of interaction scenarios (eg, speech, image, text, or movement) in a natural way. Research in human-robot interaction includes both multimodal input signals from humans to robots and multimodal output signals from robots to humans [18]. The aim is to improve the user experience, reduce annoying processes, and promote adoption. The latest research approaches in the field of care also need to be considered in order to translate advances in robotics into practice by developing a natural and adaptive style of interaction [19].

The relevance of a robotic intervention to health care is determined by its structure and services. For example, health services can be provided in the outpatient setting by general practitioners or specialists in nonmedical professions, in the inpatient setting, and as rehabilitation services. In addition to the treatment of diseases, prevention and health promotion are also a focus of the health care system [20,21].

As the end users are explicitly defined as nurses, robotic interventions that are more established in the medical context (eg, surgery) and are subject to different frameworks were excluded. The preliminary research identified a great deal of development of robotic systems and application scenarios for nursing care. However, as the purely technical consideration of application has not yet led to comprehensive implementation, new research approaches such as participation should be brought into focus. Even pure evaluations in cocreative design cannot do justice to the problem and were therefore excluded from this scoping review. The language of publication was not restricted to avoid further reducing the search results of relevant publications.

Textbox 1. Inclusion and exclusion criteria of the search.

Inclusion criteria

- Robotic systems, defined according to ISO 8373:2012
- Health care
- Intervention: interaction and control platform for robots
- Outcome: cocreative development and evaluation

Exclusion criteria

- Cocreative assessment only
- Development of robotic systems
- Intended use: medical procedures

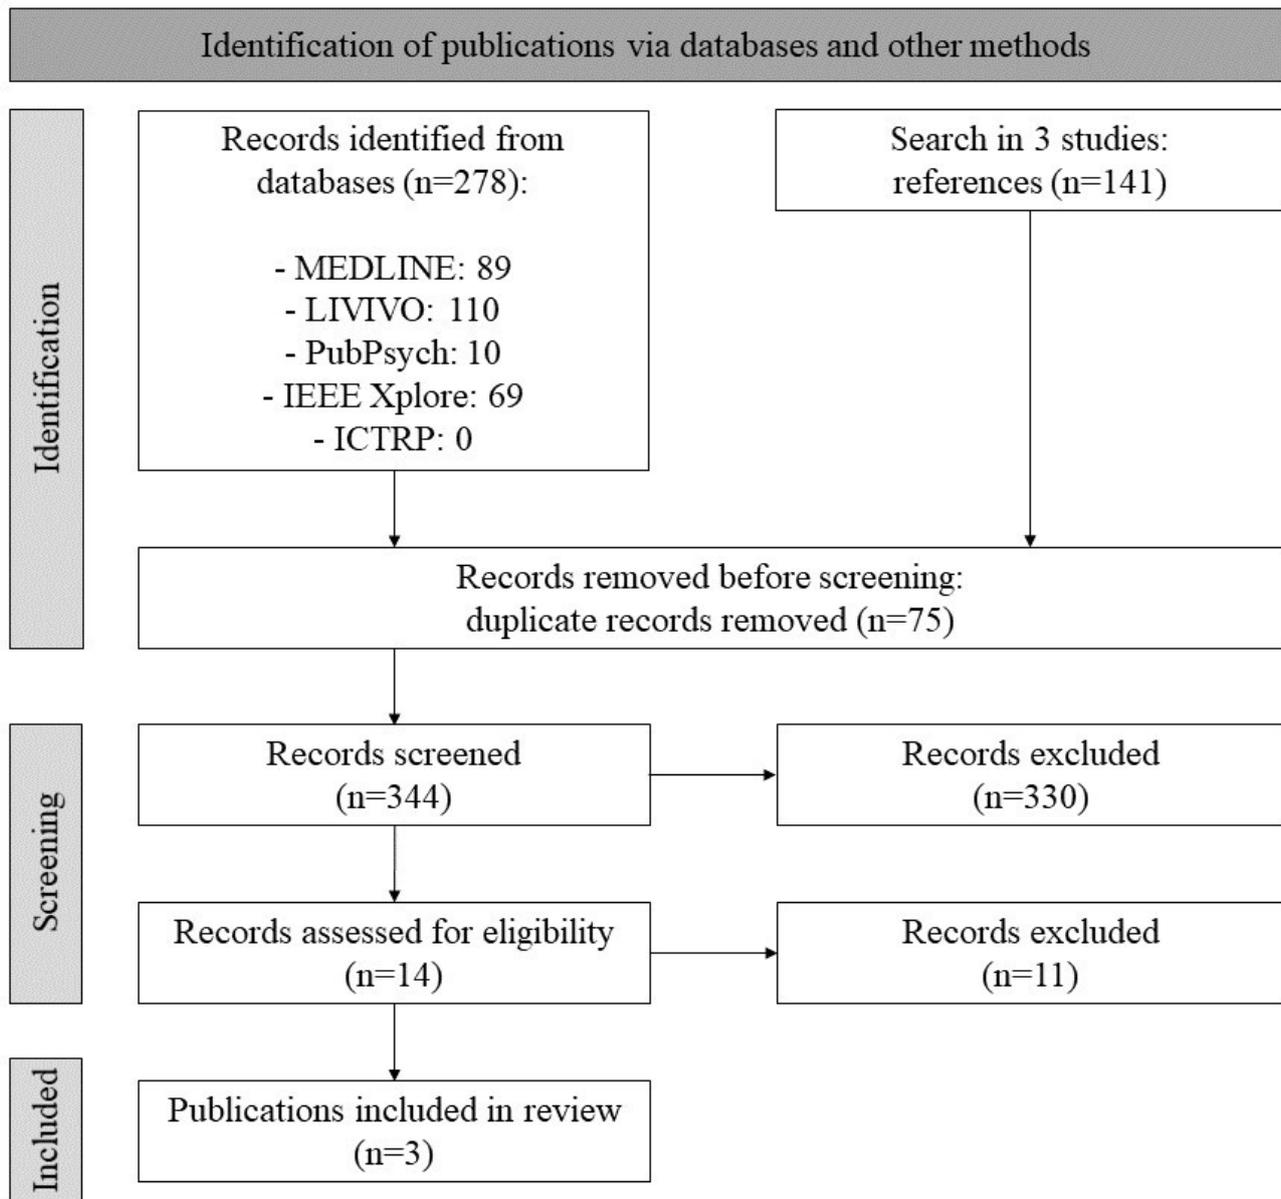

Collection and Analysis of Data

The characteristics of the included studies are summarized and assessed in [Multimedia Appendix 1 \[22-24\]](#). The summary and preparation of the data can be described as “data-driven thematic analysis,” in which prominent and recurring themes in the literature are identified, summarized under thematic headings, and subsumed into a higher-order theoretical structure through induction and interpretation [25,26].

Results

Research and Study Selection

The databases were searched manually by PM in December 2023. There were a total of 419 hits, from which 75 duplicates were removed. The remaining 344 hits were reduced to 14 full texts after title and abstract screening. After checking the full texts for eligibility, 3 studies were included. The screening process was repeated with the references of the 3 included studies. However, no further relevant sources could be identified, so 3 studies were finally included ([Figure 2](#)). Uncertainties regarding inclusion were discussed with PJ. The bibliographic data of the included publications and the full table of extracted data can be found in [Multimedia Appendix 1 \[22-24\]](#).

Figure 2. Flowchart of the study selection. ICTRP: International Clinical Trials Registry Platform.

Characteristics of the Included Studies

All publications included were in English. The studies were conducted in 6 countries; 4 of these countries were in the European Union (EU-28), which was represented by 2 publications [22,23]. Both studies were multinational and were partly conducted in Switzerland and Germany. The third included study was conducted in New Zealand [24].

All included publications were feasibility or user studies [22-24]. All had a cocreative study design. This involves users and stakeholders in the development of the robotic interaction and control platform.

One publication did not provide information about ethics committee approval and did not mention that informed consent was obtained from participants or their carers [23].

Characteristics of the Study Participants

In addition to involving end users, cocreative development approaches also require consideration of relevant stakeholders

who may interact with the end product and have a legitimate interest in its design. Health care is not an individual service provided by a single professional group, but requires interdisciplinary cooperation between different professions. In the spirit of a stakeholder analysis, the participants in the included publications are identified below.

The 3 included studies reported a total of 299 participants (Table 1), with additional carers including informal carers in one study and both formal and informal carers in another study. In one publication, the term *carer* could not be assigned to formal or informal care. In addition, one study included family members, facility managers, general practitioners, pharmacists, sociologists, geriatricians, psychologists, and computer specialists. One study involved professional teleassistants in a service center. The studies were designed in such a way that the researchers involved the carers in a cocreative way in the development of application scenarios and interaction concepts. People older than 65 years were included in 2 studies, while in 1 study the average age of the participants was only reported

as 80.5 years. Children and adolescents were not reported. One study did not report the health status of the participants. The other 2 reported on people with mild to moderate cognitive

impairment. One study defined intact hearing and vision as inclusion criteria (Table 1).

Table . Characteristics of the included participants (n=299). The studies included a mean of 99.67 (SD 100.5; range 16-241) participants.

Characteristics of the Robotic Interaction and Control Platforms

The 3 studies reported on different robotic interaction and control platforms (Textbox 2). All were developed as prototypes and were not commercially available. One study was particularly noteworthy for claiming that the platform that was developed worked for all available service robots. It took into account the dynamic autonomy of the robot and the different digital skills of the target groups. Machine learning could be used to individualize the robot and extend its range of functions [23].

The capabilities and functions of the robotic systems are retrospectively summarized in 4 themes derived from the studies after review (Table 2). Carrying or manipulating objects was described in 1 case. For example, a water bottle was picked up and brought to the user [23]. Reminder functions were described in 2 studies, including for taking medication or for upcoming appointments [22,24]. Monitoring of people was described in 2 studies, including recording of well-being and sleep quality

or emergency detection and assessment [22,24]. Communication with third parties via text, audio, or video was described in all scenarios.

Two studies developed an interaction concept consisting of differentiated user interfaces with an adapted range of functions for different end users (people in need of care, carers, and health care professionals) [22,23]. The user interfaces for health care professionals were described as web-based applications in all publications.

Interaction via screens of different sizes using touch gestures was described in all 3 studies. A combination of audio output and written visualization was also chosen as output in all 3 studies. In 2 studies, facial or audio recognition of the target person was used to start the interaction [22,24]. The following requirements were defined for the user interface: a flat menu structures with step-by-step interactions [23]; no foreign or technical language [23]; large and high-contrast colors, buttons, and fonts [22-24]; and the possibility to adjust the volume [22,24].

Textbox 2. Brief description of the robotic interaction and control platforms.

<p>GUARDIAN platform [22]</p> <ul style="list-style-type: none"> • Senior App: enables direct feedback to caregivers from the interaction • Caregiver App: provides the ability to remotely monitor the older person’s well-being and activities • Misty II: serves as a stress sensor for older people <p>Interaction and control platform for the Care-O-bot 3 [23]</p> <ul style="list-style-type: none"> • Care-O-bot 3: development platform • User Interface for Local Elderly User (UI-LOC): enables autonomous activities • User Interface for Remote Caregivers (UI-CG): enables semiautonomous navigation, scene-based autonomous manipulation without predefined action sequences, and training of objects and action sequences • User Interface for Professional Teleassistants (UI-PRO): enables semiautonomous telemanipulation, object training, error handling, and emergency management <p>Robogen [24]</p> <ul style="list-style-type: none"> • Web-based application to support the medication process in home care

Cocreative Study Design

Margaritini and colleagues [22] divided the cocreation process into 2 phases. In the first, 3-month phase, people with care needs and their carers (formal and informal) used an initial version of the platform. The aim of this phase was to evaluate the response of older people to the use of this new technology. As a result, technical change requests from older people were identified in order to improve the overall experience with the platform and, in particular, the usability of the graphical interface. At the beginning of the study, participants were introduced to the platform by the research team (consisting of psychologists, biomedical engineers, and physiotherapists) and helped to set it up. Monthly evaluation visits were then carried out to collect quantitative and qualitative data. The second phase followed the same participation pattern. The platform was also tested over a period of 3 months.

Mast and colleagues [23] refer to user-centered design in their research approach. A total of 6 user studies were conducted at different stages of the project. Again, 2 main phases can be identified. In the first phase (preparatory studies), mainly user studies and analytical studies were carried out. A needs analysis was carried out with older people and care staff using a mixed methods design. The focus was on the requirements for robotic systems and their integration into the daily life of end users, as

well as on the technical requirements. Iterative design was the second phase. After the technical development, the existing prototypes were evaluated with older people, informal carers, and professional teleassistants. For this purpose, a usability study was carried out to evaluate the different user interfaces with representatives of the target group. The results were then used to revise the platform.

The third study, by Tiwari and colleagues [24], had 3 iterative cycles. The first cycle, which defined the framework concepts, involved developing an understanding of the underlying process that the platform was intended to map. This was done by observing nurses at work and then evaluating the information collected. In addition, interviews were conducted with people in need of care, relatives, facility management, nursing staff, doctors, and pharmacists. In the second cycle (the design of the application), prototypes of the application were discussed with computer scientists, sociologists, geriatricians, psychologists, nurses, and doctors. In the final phase of testing and refinement, a usability study was carried out with people in need of care.

The evaluation methods used by the studies (Table 3) collected both quantitative and qualitative data on requirements for robotic interventions, interactions and controls, usability, ease of use, and acceptance, using established methods such as focus groups, think-aloud, and questionnaires. Observational data were collected using video, photographs, and transcripts. Interviews

were conducted without information about the use of guidelines. Recordings of the user interfaces of the robotic systems were also used for evaluation. Carers, health professionals, and experts were involved in the evaluation in addition to older people. All publications reported on established evaluation tools.

The interventions were reviewed for their characteristics. Three studies were conducted in the participants' home environment [22-24]. In 1 study, the interaction between the participants and

the robotic systems followed a schedule set by the researchers [24]. In the other 2 studies, participants were free to interact with the system [22,23].

The duration of the intervention, in terms of participants' exposure to the robotic system or use per person, was reported in all publications. One study reported 2 intervention cycles of 3 months each [22]. The other 2 studies reported durations of 1 hour [23] and 2 hours [24].

Outcomes

The results of the tests were not described in detail in the trials. One publication merely presented the study protocol for its development [22]. The other 2 studies focused on the presentation of the platforms and the incorporation of the results into development; as subprojects of larger studies, only selected results were presented [23,24]. Technical aspects such as feasibility, usability, suitability, functionality, and specific requests for future features were recorded as outcomes. The user perspective was considered in all 3 studies, with usefulness and interaction with the robot being of interest. Two studies described the preceding requirements analysis, which specified

functions and requirements that were crucial for acceptance by the target group [23,24]. An evaluation of the cocreative collaboration between the participants was not mentioned in any of the publications.

Discussion

This scoping review on the state of the art in cocreative development of robotic interaction and control platforms in health care shows that only a few publications have dealt with the interaction and control of robots by end users in a cocreative way. The studies have all been feasibility or user studies of prototypes with target groups including people in need of care,

carers, or health care professionals. Only technical aspects such as usability or functionality were described. None of them evaluated the cocreative study design.

The identified studies all focused on home care. This takes into account the expected increasing shortage of skilled care workers. In order to reduce the workload of carers and at the same time enable people to live self-determined and independent lives for as long as possible, their own home is the ideal place [27-29]. There are no research reports on residential care.

The applicability of robotic systems in health care requires interaction and control mechanisms that can be easily adapted to the individual preferences of health care professionals without the need for engineers or programmers. In addition, this interaction and control should be based on familiar concepts such as touch-based screen inputs or audio commands. The aim should be to use robotic interventions to create ethically justifiable and socially acceptable added value that primarily supports and relieves health care professionals in their activities and accompanies those in need of care in their daily lives with dignity. The aim should not be simply to compensate for system deficits and staff shortages [30].

In the development process of such interaction and control platforms, it is important to distance oneself from purely technical solutions and instead rely on the active participation of the end users in order to reduce ethical concerns and avoid developments that do not meet the needs of the target group. All 3 studies included in this review considered the application needs and requirements of the end users in terms of “user-centered design.” To this end, a needs analysis was first carried out to understand the underlying processes and requirements of the platform. The focus was on the user interface, that is, the controls and existing technical functions. After technical implementation in the form of prototyping, these were discussed with the end users. Improvements were then made to the platform based on the data collected, and the platform was evaluated again with the target group. In this way, it was possible to design a user-oriented end application that, although not commercially available, at least addressed the acceptance problem as a possible cause of the low penetration of robotics in health care [31].

The available studies have also shown that the involvement of potential end users alone is not sufficient. All stakeholders need to be involved in order to obtain a holistic picture of the intended application. In addition to care recipients and their carers (formal and informal), implementation often has an impact on other professions, such as doctors or therapists. All legitimate stakeholders should therefore be considered and involved in the technical development.

The approach of the included studies represents a change of perspective from a purely technical consideration of functions

and control elements to an orientation toward the experiences and needs of end users and practical care. The underlying development process is oriented toward users and their everyday lives as well as the care process, as required by Roland Berger GmbH [32]. The generalization of the care process into standardized procedures is a challenging and complex scenario for robotic interventions due to the human component, that is, the interests of the end user. When aspects such as individualized interactions are added, it becomes impossible for technical developers to meet the requirements and needs of the target group without the involvement of health care professionals in the development process [33,34]. Health care professionals are an important part of the research. With their understanding of diseases and their impact on the lives of those in need of care, as well as their own research expertise, they are asked as potential end users to influence technical developments toward their needs and requirements for interaction and control [35]. The generally skeptical attitude of health care professionals toward technical applications [33,34] explains why the results of this review identified only a few publications on this question, which also referred exclusively to prototypes.

The literature suggests that technical feasibility studies in cocreative design have used both quantitative and qualitative research methods. Quantitative analyses were mainly used to objectively measure the success of the study, while qualitative methods were used selectively and for a specific topic (eg, needs analysis or evaluation of prototypes). The studies did not discuss evaluation of the methodology or presentation of results and processes. Therefore, no comparison with other development concepts is possible. It remains questionable how the stakeholders involved perceived the collaboration and whether the eventual acceptance of the platforms was higher than with previously developed platforms. An evaluation of the attitudes of the health care professionals involved in the studies toward technological interventions could provide additional valuable insights for the implementation of technologies in health care.

The scoping review method used here is only intended to provide an overview of the research field. It does not consider the effectiveness of the studies or derive recommendations for clinical practice [36]. So far, only feasibility studies of robotic interaction and control platforms are available. A systematic assessment of the included studies using a critical appraisal tool was not carried out. This was not part of the research interest.

The operationalization of the research question and the development of the search terms are justified and can be used as a starting point for further literature searches. The process is transparent and fully documented (Figure 1). Due to the resources available in the project, only one reviewer was involved in the selection and assessment of the studies. Despite the care taken, bias cannot be excluded.

Abstract

Background: The safety of telemedicine in general and telephone triage (teletriage) safety in particular have been a focus of concern since the 1970s. Today, telehealth, now subsuming teletriage, has a basic structure and process intended to promote safety. However, inadequate telehealth systems may also compromise patient safety. The COVID-19 pandemic accelerated rapid but uneven telehealth growth, both technologically and professionally. Within 5-10 years, the field will likely be more technologically advanced; however, these advances may still outpace professional standards. The need for an evidence-based system is crucial and urgent.

Objective: Our aim was to explore ways that developed teletriage systems produce safe outcomes by examining key system components and questioning long-held assumptions.

Methods: We examined safety by performing a narrative review of the literature using key terms concerning patient safety in teletriage. In addition, we conducted system analysis of 2 typical formal systems, physician led and nurse led, in Israel and the United States, respectively, and evaluated those systems' respective approaches to safety. Additionally, we conducted in-depth interviews with representative physicians and 1 nurse using a qualitative approach.

Results: The review of literature indicated that research on various aspects of telehealth and teletriage safety is still sparse and of variable quality, producing conflicting and inconsistent results. Researchers, possibly unfamiliar with this complicated field, use an array of poorly defined terms and appear to design studies based on unfounded assumptions. The interviews with health care professionals demonstrated several challenges encountered during teletriage, mainly making diagnosis from a distance, treating unfamiliar patients, a stressful atmosphere, working alone, and technological difficulties. However, they reported using several measures that help them make accurate diagnoses and reasonable decisions, thus keeping patient safety, such as using their expertise and intuition, using structured protocols, and considering nonmedical factors and patient preferences (shared decision-making).

Conclusions: Remote encounters about acute, worrisome symptoms are time sensitive, requiring decision-making under conditions of uncertainty and urgency. Patient safety and safe professional practice are extremely important in the field of teletriage, which has a high potential for error. This underregulated subspecialty lacks adequate development and substantive research on system safety. Research may commingle terminology and widely different, ill-defined groups of decision makers with wide variation in decision-making skills, clinical training, experience, and job qualifications, thereby confounding results. The rapid pace of telehealth's technological growth creates urgency in identifying safe systems to guide developers and clinicians about needed improvements.

KEYWORDS

telephone triage; teletriage; telehealth; telemedicine; safety; system error; human error; triage; outcome; patient safety

Introduction

Definitions and Terminology

Telemedicine refers to the electronic transmission of medical data from one source to another to promote clinical health. A wide range of services and applications, including 2-way video, email, smartphones, and other communications technology, are included in telemedicine. With the aid of these technologies, patients and caregivers who are geographically separated can communicate and receive treatment, consultation, follow-up, counseling, and health education, as well as engage in medical intervention, monitoring, and remote hospitalization [1,2]. The biggest benefits of telemedicine, aside from cost savings, are expanding patient access to treatment, expanding the availability of medical services, and improving clinicians' efficacy [3].

The delivery and facilitation of health and health-related services, such as medical care, provider and patient education, health information services, and self-care, using telecommunications and digital communication technology is known as *telehealth*.

Although telehealth and telemedicine are frequently used synonymously, the term "telehealth" is used as an umbrella term to refer to all aspects and activities of health care and the health care system that are carried out via telecommunications technology, as opposed to the more specific term "telemedicine," which only refers to the practice of medicine remotely [4,5].

Triage is the process of classifying and prioritizing symptoms. Based on quality, and in the context of health services, triage refers to the process of ranking patients according to their need for care. Using triage services can lower health care costs by preventing patients from making needless and expensive trips to emergency departments (EDs) and by assisting them with self-care and informal care while the doctor is away [6,7].

Telephone triage (assessment and triage of symptoms by telephone) predates telehealth by about 50 years. In the past 5-10 years, the broad industry of telehealth has subsumed telephone triage, which has quickly evolved into *teletriage* to include a wide range of high-tech features (video, biotelemetry, and patient wearables) to enhance remote, brief, but urgent encounters [6,8].

Teletriage is an unscheduled, brief (2-10 minutes), urgent encounter (by telephone only) initiated by patients seeking an estimate of symptom urgency and triage by a clinician to get an urgent on-site evaluation and definitive diagnosis [6,8].

Televisits (via video technology) are now a common substitute for a face-to-face medical appointment and may be 20-30 minutes in length.

Definitions and terms related to telehealth and teletriage are included in [Multimedia Appendix 1](#).

Teletriage: History and Characteristics

Wheeler et al [8] defined teletriage as the complex process of remotely assessing acute, worrisome symptoms to estimate their urgency and to render clinical advice and triage for further evaluation and diagnosis, as appropriate. The goal is to ensure the safe, timely, and appropriate disposition of patient symptoms remotely. This service is accomplished with remote encounters by telephone or real-time video (including biotelemetry). A disposition is a directive from clinician to patient about when and where to be further evaluated and treated. It may also include a risk estimation statement, such as "your symptoms sound urgent," to both inform and motivate patients to comply with the medical advice [8].

Historically, the need for teletriage became an issue when health maintenance organizations (HMOs) realized that they could be more cost-effective by conserving on-site appointments for the sickest patients, which is a form of triage and a way to control access [9].

The overarching goal of medical care (systems and processes) is to use valid, reliable components and experienced trained clinicians to produce safe outcomes. Since the 1970s, clinicians have informally performed teletriage in ambulatory care settings ranging from urgent care and EDs, physician offices, clinics, and student health centers to disease management and ambulatory surgery. Beginning in the midnineties, teletriage and the telehealth industry began developing early systems [10].

One description of teletriage [10] is that it is a time-sensitive, complex, human-technology hybrid process of remote medical decision-making. Currently and in the future, a range of technologies will provide a range of information. On the continuum of care, teletriage can now be acknowledged as the entry point to clinical care. It legitimately qualifies as "prehospital care."

By discussing treatment alternatives and the need for care, teletriage aims to identify the most appropriate degree of care that is needed. These alternatives could involve self-care or informal care, normal or emergency doctor visits, prompt referral to the ED or emergency clinics, or ambulance dispatch, depending on the data collected during evaluations. To support self-care and informal care, teletriage services may also entail providing information and help for difficult medical decisions, as well as managing symptoms. In a variety of medical facilities, nurses or doctors conduct teletriage [11,12].

The teletriage system, which is primarily run by nurses, determines the level of medical urgency and the type of health care that is needed when patients are contacted by telephone. This system is crucial for delivering affordable, effective, and secure health care [13].

The decision-making process is difficult and stressful in the emergency teletriage scenario because decisions must be made quickly and are dependent on nonvisible, unreliable, and incomplete information and nonvisible indicators. Additionally, patients' capacities for clear symptom communication differ,

particularly when young patients are involved. The lack of precise criteria for making the decision further increases the difficulty of the decision-making process [14,15].

Over the past few years, numerous Western nations and sizable corporations have started to offer primary health care services after regular business hours. In 2020, the COVID-19 pandemic accelerated telehealth growth exponentially. Almost overnight, telehealth rapidly became an established, essential service [16].

Currently, many US health plans provide advice lines. These services are advertised as a benefit of patients' health plans. Advice lines offer clinicians' advice for patients who have concerns about acute or worrisome symptoms who are calling from home. A telephone call to an after-hours advice line is typically the patients' first attempt to gain access—a medical consultation for a symptom that patients interpret as urgent. However, standards are still lacking for clinical decision makers, their experience, qualifications, clinical training, and practice [8,17,18].

Once considered embryonic, telehealth now appears to be in an adolescent phase. It is rapidly and erratically growing, and technology is outpacing clinical standards. Telehealth appears to be undergoing an identity crisis [9].

Opposing forces—technology, cost containment, and safe clinical practice—now struggle to claim control of the field, one so new that regulation cannot keep pace. There are inherent

risks in the clinical task—remote, rapid, clinical decision-making using software that serves technological interests but may not serve clinical safety [18].

In the United States, these forces are quite evident, as health care needs to save money may be at odds with patients' needs for access. Furthermore, health care institutions may attempt to limit patients' use of ED, urgent care, office, and clinic services to be cost-effective or to use less costly (and less qualified) staff in the telehealth process, thereby reducing safety [10,19].

In the United States, evidence-based electronic guidelines have not yet emerged. No telehealth-based professional organization yet exists. Some agencies have developed regulations, including the Utilization Review Accreditation Commission (URAC) [20], the American Academy of Ambulatory Care Nursing [21], the American College of Emergency Physicians (ACEP) [22], the American Nurses Association (ANA) [23], the Emergency Nurses Association [24], and the North American Nursing Diagnosis Association (NANDA) [25]. Inadequately designed technology can lead to unintended consequences, while field testing may not be adequate [26,27]. The ACEP [22] has developed descriptions and broad classifications of emergent to acute symptom patterns for on-site triage. There is a need for a similar classification for telerriage.

Clearly, we are in early days in telehealth research, with the need to define meaningful measures for safe outcomes (Table 1).

Table 1. Safe outcomes.

Outcome	Description
AR ^a	A timely, safe disposition: right place, right time, for the right reason. ARs are considered safe.
OR ^b	A referral deemed (retrospectively) by some to be unnecessary at the time and place initially recommended. ORs are likely safe but not cost-effective.
UR ^c	A referral to a lower level of care than is safe or timely, often resulting in a delay in care. URs have the potential to cause or result in patient harm [8].

^aAR: appropriate referral.

^bOR: overreferral.

^cUR: underreferral.

Controversies have emerged in relation to referrals (outcomes). Both appropriate referrals (ARs) and overreferrals (ORs) are considered safe, but ORs are not cost-effective—a less desirable outcome. Some experts suspect that doctors of medicine (MDs) are reluctant to define safety or to criticize other MDs'/researchers' work.

Without a consensus on safe outcomes that are evidence based, it will be difficult for the industry to make meaningful progress toward the goal of safety. Research on meaningful safe outcomes is needed. We chose to discuss telerriage safety for several reasons: patient safety and safe practice are important topics, and telerriage has a high potential for error.

Telerriage involves making medical decisions under conditions of uncertainty and urgency. Telerriage has also conflicting goals: the institutions' need to control costs (especially in the United States), while also ensuring patient access to care in a safe,

timely manner. Furthermore, this underregulated subspecialty lacks adequate research on system safety.

Our review and analysis present a glimpse of current safety through analyzing 2 developed representative systems in 2 countries: Israel (Clalit Health Services) and the United States (Redwood Healthcare Plan [RHP]). We examined each system to learn how developed each system is and to explore the elements that might influence safe practice and patient outcomes.

This might be the first study to review and compare 2 formal telerriage systems. Both authors have performed triage in formal systems and taught and consulted in telehealth for a combined 50 years. Telerriage was the focus of this study. We focused on urgent, time-sensitive calls from patients or their families regarding acute or worrisome symptoms. We believe the telehealth industry and telemedicine can benefit from our findings.

Methods

Study Design

This study included 2 parts:

- A narrative review of the literature: studies describing nurses' and physicians' teletriage systems from the United States and Israel
- Qualitative assessment, including interviews with several physicians (Israel) and 1 nurse (the United States)

Part 1: Narrative Review

Both key authors of this paper have practiced in the field of telehealth; thus, they have a reality-based perspective on the subspecialty.

We restricted our review to system features (structure, process, and outcomes) to provide a more orderly review in this variable and broad field. In this narrative review, we discussed the various facets of and challenges in teletriage, with special focus on the United States and Israel, which serve as representatives for teletriage for nurses and physicians, respectively.

Search Terms

Using the following key search terms, we searched PubMed, Medline, and Google Scholar for papers relevant to this review: Telephone Triage AND Teletriage AND Telehealth AND Telemedicine AND Telecare (and Tele-Triage); + Safety, + Systems, + Physician-led, + Nurse-led. + System Error, + Human Error.

Selection Criteria

It was essential that we study developed systems, because even today, US telehealth practice is still typically unregulated—variously devoid of complete or evidence-based components, such as guidelines, formal documentation, qualified staff, clinical training, and standards—in many office, clinic, ED, and ambulatory care settings.

For our critical analysis, we focused on the best examples of current practice: large, formal clinical call centers or HMOs. These services in the United States provide 24–7 clinical call coverage.

We narrowed our review of the literature to studies that focused either directly or generally on teletriage safety. See [Multimedia Appendix 2](#) for criteria for selecting papers. Only English language publications that were published in scholarly journals or organizations between 1970 and 2023 were included. All types of papers were considered, including original papers, reports of randomized clinical trials, observational studies, and editorials or essays by key opinion leaders.

A summary of early research (1977 to the 1990s) focused mostly on the physician practice of teletriage. A recent review (the 1990s to 2022) summarized and critiqued teletriage safety research.

Part 2: Qualitative Assessment

Using a qualitative approach, we conducted interviews with 15 representative physicians who worked in a pediatric teletriage

service (Clalit Health Services) in Israel. In addition, we interviewed 1 nurse who worked in a nurse teletriage service in the United States.

To obtain their subjective perspectives on maintaining patient safety in this setting, the physicians were asked about factors that may have impacted their reaching a “correct” diagnosis and deciding on reasonable and appropriate treatment.

To gather detailed and accurate information that would accurately reflect the participants' subjective experiences, we used a semistructured qualitative study (SSQS) technique in this study. Participants' replies were evaluated and analyzed thematically when themes were found.

The use of open-ended questions, which gave the study its qualitative quality, allowed participants to candidly discuss the challenges they encounter in teletriage settings and the strategies they use to ensure patient safety.

The research complied with the Standards for Qualitative Research (SRQR) items [28]. We examined the responses using qualitative content analysis, which is a systematic procedure for collecting and analyzing qualitative data. Using a consistent set of codes to group texts with comparable content and creating themes and subcategories within themes from participant replies, this technique aims to “answer questions such as what, why, and how, and the common patterns in the data are searched for” [29].

Ethical Considerations

Informed consent was obtained from the physicians and nurse participating in the qualitative section of the study. All necessary approvals for this study were obtained from the Ethics Committees of Clalit Health Services and the University of Haifa (approval numbers 0031-16COM2 and 458/16, respectively).

Results

Telemedicine and Teletriage Growth Surge During the COVID-19 Pandemic

Telemedicine, or the use of digital and remote medical technologies to connect patients and caregivers, has become the hottest and most talked-about area of technology, thanks to the COVID-19 pandemic. The influence of the pandemic on the area of telemedicine worldwide is best summarized by the *New York Times* headline “10 Years of Change in One Week: Telemedicine on Fast Track” dated April 20, 2020.

COVID-19 plagued the world for most of 2020, posing a serious threat to public health. Although many health organizations were primarily focused on combating the immediate effects of COVID-19, maintaining basic and vital therapeutic services was equally important. Initial responses in many nations included clinic closures and the suspension of all noncritical medical services [30,31].

Telemedicine provides ongoing medical care, while maintaining strict social distancing. To reduce their exposure to others and still obtain medical care, patients at risk may benefit from staying at home. As a result, it is not surprising that health care

systems worldwide are turning to telemedicine, which has led to an exponential surge in its use as opposed to a previously slow uptake of the novel practice [32,33]. Thus, because of the COVID-19 pandemic, teletriage services have been implemented more frequently [34].

The benefits of teletriage during the COVID-19 pandemic have been described in recent studies; these studies show that this technique removes face-to-face contact, lowers the danger of exposure for medical personnel and other patients, and conserves scarce resources. Results suggest that more investigation is needed to ascertain how teletriage affects clinical outcomes, expenditures, and the use of follow-up care [35,36].

Although the COVID-19 pandemic has fueled the awareness and growth of technology and televisits, which are a convenience and infection control, the COVID-19 period has not made teletriage systems safer. It has made technology proliferate explosively.

Teletriage: First Point of Access to Care

Patients call advice lines for a reason. They want to know whether their symptoms are urgent. Clinical decision makers assess the symptoms, estimate the urgency, triage the symptoms, and advise when, where, and why the patient should be seen. Teletriage is designed specifically for this purpose—estimating symptom urgency and triage to ensure timely access to care. On the continuum of care, teletriage can now be acknowledged as the entry point to clinical care. It legitimately qualifies as “prehospital care” [8].

The primary function of teletriage is the assessment and management of symptoms by telephone, which also calls for expert judgment, clinical evaluation, and proactive information gathering from the patient [6,37].

According to researchers, nurses estimate and rule out symptom urgency to determine a disposition by using pattern recognition. “Telephonic medical diagnosis of patients’ problems” is what telephone medicine, as practiced by doctors, is defined as [15,38].

Teletriage System Safety

The task in teletriage is to safely assess symptoms, estimate the urgency, and triage the symptoms presented remotely and then advise a disposition (time and place) for them to be further evaluated. The goal is to “make good decisions under conditions of uncertainty and urgency” to avoid the risk of delay in care, diagnosis, or treatment. Compared to in-person consultations, teletriage is a complex activity that entails certain inherent dangers because there is no visual contact and no nonverbal communication [39-41].

While performing teletriage, nurses must rely on audio signals rather than visual ones, although patients can speak about their symptoms using different terms. The ability of clinicians to communicate effectively is crucial, but there are also several other abilities that must be present, including the ability to recognize verbal cues, concentrate on obtaining a focused history, and understand the importance of having proper documentation [14,42,43].

Other characteristics of after-hours care that could pose risks include a high patient call volume, a variety of clinical conditions presented, the likelihood of urgent conditions being present, unknown patients, knowledge gaps regarding patients’ medical histories, and the potential for information transfer discontinuity. Concerns have been raised because teletriage might compromise patient safety [44-48].

Regarding the reliability and safety of teletriage services, several recent studies have produced contradictory findings. Some studies were pessimistic, reporting that patient safety is frequently jeopardized by teletriage decisions [49]; service providers do not always forward the case to the on-call physician, when necessary [50]; and only a small number of diagnostic and therapeutic choices made during teletriage consultations offer the same level of health care as in-person conversations [51]. Inadequate visual cues that help doctors identify patients in acute condition were indicated as patient safety hazards in a study using teletriage [40].

However, more reassuring findings have been reported by other studies on the safety of teletriage systems. For instance, Blank et al [52] reviewed studies in which telephone counsel was contrasted with professional advice that is thought to be acceptable in that circumstance (ie, the “gold standard” of professional advice). The accuracy/appropriateness rate was 44%-98% in this review, with a median of 75%. Most decisions were appropriate according to a different study [14].

Concerning teletriage system effectiveness, the evidence also points to a variety of outcomes. According to certain studies, teletriage interventions, particularly for parents of small children and for older patients with chronic diseases, significantly reduce the number of emergency visits and readmissions [53,54]. Additionally, patients have stated that teletriage services have gained their trust and satisfaction. One study, however, found that a significant portion of patients who were directed to the ED using teletriage may have been treated elsewhere [55].

Based on a summary of several systematic reviews, when considered as a whole, the available research does not offer conclusive answers to queries concerning the standard of care delivered, the equity of access, costs, or outcomes in teletriage settings [18].

Growth alone in a new subspecialty will not guarantee safety. Developing a safe system is essential to any subspecialty, especially teletriage and telehealth. Defining the new subspecialty is one of the first challenges and sets the stage for transparency and, later, safety [14].

Even with the use of video and other technologies, remote symptom assessment is a uniquely risky task. Fraught with uncertainty, and many unknowns, teletriage is extremely time driven and time sensitive. A delay in care can be lethal if a required follow-up evaluation and treatment are not performed in a timely manner. In addition, teletriage is still in an underdeveloped state and lacks a reliable system. Finally, nurses and physicians perform this decision-making task under surprisingly difficult conditions [14,43-46].

Human factors in teletriage that challenge and possibly impair clinicians’ decision-making process are detailed in [Textbox 1](#).

Textbox 1. Telehealth risks (human factors).

- Inability to see patients (technology dependent)
- Ability to see but not to touch or gather patient vital signs (technology dependent)
- Extreme brevity of patient encounters (5-15 minutes)
- Incomplete or inaccurate information provided by patients
- Extensive sensory deprivation (endured by clinicians; technology dependent)
- Physical and cognitive demands imposed by high call volumes
- Potential for decision fatigue due to call volume and repetitive nature of the task [26,56]
- Clinicians often not knowing the patient, their education level, or their likelihood of compliance with advice
- A lack of structure (standardization of process and structure)
- Institutional pressures on clinicians to act as a gatekeeper rather than an access facilitator
- User-unfriendly electronic and paper guidelines

One way to avoid the risk of delays in care is to create a system. The Donabedian model [57-59] provides a framework for examining and evaluating health service quality. According to Donabedian [57-59], information about the quality of care can be drawn from 3 categories: structure, process, and outcomes.

Like other subspecialties, teletriage requires certain components to support safety. These components include standards (policies and procedures); sufficient numbers of qualified, experienced clinicians; specialized clinical training in medical decision-making; evidence-based, transparent, user-friendly guidelines; and electronic medical records (EMRs), audiotapes, or written documentation.

System Components: Evidence of a Duty to Care

Not surprisingly, in malpractice cases (when an error has occurred and a patient has been injured or has died), expert witnesses for the plaintiff always request tangible evidence of the system [9]:

- Guidelines used in the call (paper or electronic, eg, computerized decision support system [CDSS])
- Qualified experienced clinicians: résumés of nurses who managed the call, adequate numbers of clinicians
- Standards or policies and procedures, including job descriptions and qualifications
- Call center standards
- Actual call documentation: EMRs, paper form, or transcription of audiotaped calls
- Clinical teletriage training program materials

System Error

System error is thought to be the worst form of medical error [26]. Determining the effect of safety requires an examination of the problem of system error, defined as a failure of systems, processes, or conditions that are intended to prevent errors from occurring and that might lead people to make mistakes [60].

The Institute of Medicine (IOM) [60] has broadly defined system error as the “wrong match of plan” or the “failure to use any plan” to prevent error. For example, IOM research shows that the after-hours time, when no system in place, is especially risky in the United States [60]. In telehealth, complete systems

(process or structure) are a first step toward reducing system error. Complete does not imply evidence-based or quality systems, however [8].

Malpractice in Teletriage

When a patient is harmed through unsafe telepractice, a malpractice case ensues. The plaintiff’s expert witnesses request evidence of care for that event: all documents that provide evidence of an adequate system, as described before. Institutions that can produce evidence of care are more able to demonstrate fulfillment of the duty of due care.

Physician teletriage malpractice may be related to the lack of a basic, complete teletriage system [16,49,61-65]. Nurse teletriage malpractice may be related to both the lack of a complete system or practicing in a complete system made up of faulty components [6,8,44,66-68].

What Are Meaningful Outcome Measures?

“We don’t look for patterns of our recurrent mistakes, or devise and refine potential solutions for them. But we could, and that is the ultimate point” [69].

We know what error and near misses look like. However, we have not yet clearly defined what constitutes safe practice and outcomes. Many researchers define telehealth safety variably, based on medical consensus on a study-by-study basis. Research continues to focus on nonessential elements of the process or structure (ie, communications, type of practitioner, patient compliance, and satisfaction).

The unfortunate outcomes described in malpractice [70-73] serve as fragments of the larger picture—system error, the essential and underrecognized problem.

Historically, medicine and nursing adhere to the key obligation “First, do no harm.” Nonmaleficence, which is derived from the maxim, is one of the principal precepts of bioethics—a fundamental principle worldwide.

Currently, professional organizations, such as the ANA [23] and the American Medical Association (AMA), typically set standards to guide medical decision-making, ethical practice, and patient safety. Formal systems—evidence-based structures

and methods and guidelines—support clinicians' safe practice and promote safe outcomes. Such system components are evolving slowly.

Safety Studies on US Teletriage

Research on the safety of teletriage systems, whether practiced by registered nurses (RNs) or MDs, is scarce [54].

Safety Research in the United States

Early studies examining the system structure and process provide a basis to inform research on system error. Although safety is often a topic of telehealth research, to the best of our knowledge, system error is still underresearched.

It is likely that the proprietary nature of telehealth technologies interferes with research on system safety. Telehealth trends make it difficult to achieve system transparency. The field urgently needs evidence-based CDSSs, EMRs, and other new technologies, such as features that provide feedback on outcomes to clinicians for the purpose of learning from their mistakes or successes.

In addition, CDSS, computerized decision-making system (CDMS) and EMR components, so fundamental to the clinical decision-making process, make it essential that these technologies be demonstrably and verifiably safe and effective. Questions remain about the safety of guideline technologies [74].

Early Research (1977-1990)

Early studies on teletriage focused on physician practice. Predictably, key demographic groups of frequent calls included infants and children, the elderly, and women. Topics also included categories of symptomatic calls and urgent situations: the sudden, rapid death of children, calls to the ED and poison centers, postpartum concerns, suicidal callers, and cases resulting in malpractice [9].

The first studies on remote telephone encounters often focused on problems that plagued physicians: strategies for reducing inappropriate after-hours calls, follow-up postdischarge calls, characteristics and perceptions of after-hours callers and high users ("frequent flyers"), call patterns, and dissatisfaction in pediatric practice. In general, US physicians were dissatisfied with the task of teletriage [9].

Research by Perrin and Goodman [75] marked the beginning of a change in how teletriage was practiced in the United States. The study compared the teletriage practices of pediatric nurse practitioners (PNPs) with those of pediatricians. Researchers found that PNPs are as safe and proficient as physicians, although PNPs take slightly more time to manage calls.

Research in 1990-2000

Research later focused on nurses' safety: communication, close calls, malpractice claims, access, chest pain, the influence of after-hours calls, and clinical and nonclinical decision makers. Later, the first teletriage training manual for nurses was published [9]. Lephrohon and Patel [14] showed how nurses practicing teletriage made decisions, describing pattern recognition and estimation of urgency as key decision-making strategies.

Research in 2000-2023

In the 2000s, rudimentary systems emerged [8]. Research highlighted the field's disorganization and lack of professional development [76]. Patient safety research was inconsistent and of variable quality, often commingling widely different clinical and nonclinical decision makers, intermingling terminology, and making unquestioned assumptions. Evidence-based studies were sparse.

A recently published systematic review [77] assessed the effectiveness of teletriage as one of these technologies during the COVID-19 pandemic. Studies investigating teletriage's effect on patient safety, clinical outcomes, and patient satisfaction were included. The authors concluded that teletriage interventions reduce unnecessary visits, improve clinical outcomes, reduce mortality and injuries, increase patient satisfaction, reduce health care provider workload, improve access to primary care consultation, and increase patient safety and satisfaction.

In [Multimedia Appendix 3](#), we describe a developed teletriage center in the United States and include an interview with a qualified nurse working in this call center. Throughout the interview, she describes her personal feelings and reflections. [Table 2](#) describes the required education, key system components, decision-making strategies, and goals of both Israeli physicians and US nurses.

Table 2. Decision maker comparison: Israeli MDs^a and US RNs^{b,c}

Decision maker	Minimum qualifications	System components	Decision-making strategies	Task objectives
Physician (autonomous, licensed clinician)	Doctorate level: 7 years of science-based clinical education and training + pediatrics specialty training for 4.5 years	Documentation: <ul style="list-style-type: none"> Regulation: state medical board clinical training, guidelines 	<ul style="list-style-type: none"> Diagnosis Clinical judgment Critical thinking 	<ul style="list-style-type: none"> Make a medical diagnosis. Identify and verify emergencies and urgencies.
Licensed nurse (autonomous, licensed clinician supported by a medically developed CDSS ^d)	Associate of arts (AA)/bachelor of science (BS)/master of science (MS)/doctor of nursing practice (DNP): 2-7 years science-based clinical education and training	<ul style="list-style-type: none"> ≥3 components Guidelines: CDSS Documentation: EMRs^e/audio-taping, clinical teletriage training Practice standards: American Academy of Ambulatory Care Nursing (AAACN) Call center standards: URAC^f Regulation: Board of Registered Nursing 	<ul style="list-style-type: none"> Pattern recognition Clinical judgment Contextual information Nursing process Critical thinking 	<ul style="list-style-type: none"> Identify and verify emergencies and urgencies. Estimate symptom urgency. Rule out symptom urgency. Interpret patient responses.

Telemedicine and Teletriage in Israel

In Israel, most of the health care and social assistance is public, including health care, welfare, child support, and old age and disability benefits. The national mandatory statutory health insurance system used in Israel is based on the Bismarck model. Both designated and ordinary taxes are used to pay for it. All citizens are required to join 1 of the 4 health plans (also known as mutualities or sick funds). The health plans provide both insurance for their members and a public basket of services, either through operating their own services or entering into contracts with service providers [78-80]. All 4 health plans are fully computerized, and all doctors and most other health care providers use EMRs that either are directly linked to the central medical record of the health plan through the internet or comprise its whole internal system. Between all community services, there is practically complete clinical data sharing. Highly developed decision support systems help with these.

Each health plan has highly advanced personal health records that allow members to access their own medical data online. These data entail prescription drug purchases and visits to the doctor, as well as imaging, laboratory, and other diagnostic test findings. Most of this is presently available online and via a smartphone in at least 2 of the health plans. Based on medical data and protocols created by the health plans, these plans currently provide proactive warnings and reminders for their members. The doctors at Maccabi, the second-largest health plan, can view their computerized medical information using a smartphone [78].

In Israel, physicians typically provide for all telehealth services, referred to as telemedicine. The physician practice of medicine or telemedicine is a range of remote high-tech remote

encounters. The Ministry of Health (MOH) in Israel has regulations that apply to telemedicine services. Telemedicine standards were released in 2012 and have since been revised, as necessary, for different medical specialties. The MOH [79] provided an update in 2019 that details requirements for providing medical care remotely.

Although the worldwide pandemic has significantly accelerated what appears to be the next digital medical revolution, Israel has long recognized the enormous potential of telemedicine and has made it a national priority by allocating significant resources, establishing pertinent regulations, and promoting partnerships between health organizations, research institutions, start-up businesses, and independent researchers.

“Digital Health as an Engine of Growth” is a national priority program that Israel declared in March 2018. By using the information and communication technologies that are readily available to the entire Israeli population, the Israeli MOH [80] has stated that it is its mission to “bring about a leap in the health system that will enable it to become sustainable, advanced, innovative, renewed, and constantly improving.” In other words, the opportunity to further implement and expand a variety of telemedicine solutions is created by the worldwide acceleration of technology development and the digital revolution. The realization of the significance of digital health for the efficiency of the health care system and the requirement to offer strategic, systemic, and all-encompassing solutions for the foreseeable future are embodied in this national priority program [80].

Israel benefits greatly from a mix of human resources, a sizable number of businesses engaged in the development of digital medicine, and a sizable investment in research and development (R&D). It is a leader in communications and cyber innovation,

which is essential to the creation of cutting-edge digital medicine that will be used worldwide.

The conditions for the successful implementation of telemedicine in Israel are encouraging: the population has individual identification numbers, digital medical records are stored in sizable databases, all people have access to medical insurance, the standard of medicine is high, and communication technologies are of high quality and are widely available throughout the country [81].

In Israel, all health plans operate telemedicine services in one form or another. For administrative requirements with the clinic and the attending personal physician, they all permit online services. With each of them, the attending physician can also be reached via telephone or video call during clinic hours and sometimes even after hours.

Additionally, several of the health plans offer online pediatric and family services that primarily act as medical triage after working hours, throughout the evenings, nights, and weekends. The patients can use telephone or video calls and occasionally even submit images during the online consultations [82,83].

Some health plans have also begun using the TytoCare test device, which enables online physical assessment. During a digital visit, the equipment checks the patient's heart rate, respiration, temperature, ears, throat, and skin lesions using a variety of medical devices. A few Israeli hospitals have already begun to offer telemedicine consultations, particularly for presurgery evaluations, follow-up care, genetic and dietitian consultations, and even remote rehabilitation.

The quality of the telemedicine service provided and its safety are now the 2 most important factors to consider. Some telemedicine promotion initiatives during the pandemic seem to be predicated on the idea that a sizable part of outpatient visits may be effectively managed remotely, and patients can be prioritized for telemedicine services without endangering their safety or the standard of care [84].

An Israeli study [85] emphasized the growth in telemedicine usage during the first COVID-19 lockdown in Israel, as well as the anticipated partial fall in usage following the pandemic's end. As of May 2020, most Israeli pediatricians recommended that once the pandemic has passed, they return to in-person consultations and base their therapeutic judgments on frontal data rather than on data obtained through telemedicine contacts [85].

There are not many studies on the safety of telemedicine or teletriage services conducted in Israel. Haimi et al [84] examined the level of safety of a pediatric telemedicine service, paying particular attention to the accuracy of the diagnoses and the reasonability of judgments made by the online doctors. This service serves as a time-sensitive teletriage of spontaneous calls from parents about acute, worrisome symptoms of their children that require triage (symptom sorting). The study showed high levels of diagnosis accuracy (98.5%) and decision reasonableness (92%).

In addition to the literature review, using a qualitative study, we interviewed 15 physicians who had worked at the Clalit

Pediatricians Online Service (a teletriage service) over the past 5 years [82-84,86]. Using a semistructured interview protocol form, we questioned the physicians about the difficulties and obstacles they face in the teletriage setting that may affect their capability in maintaining patient safety. In addition, they were asked about their perceptions of their capacity to uphold patient safety in this teletriage environment and, in particular, regarding elements that impacted their capacity to make reasonable decisions, determine the best course of action, and diagnose accurately, while upholding patient safety.

The physicians described several difficulties they face in the teletriage setting that may impact their ability to maintain patient safety [84]. The main factor was the difficulty to make a diagnosis from a distance due to the physician's inability to perform a physical examination in the telemedicine setting. Additional factors were treating unfamiliar patients, working alone, working under stressful conditions, having technological difficulties, and having a moral conflict between their desire to please and provide parents with good service on the one hand and the wish to maintain good medical practices on the other. While describing the challenges they face the teletriage setting, the physicians described various techniques and tools that they use to ensure patient safety.

Using a thematic analysis, we used the participants' replies to determine themes. These themes were compared with the original transcriptions to determine whether they accurately reflected the original data, guaranteeing a constant flow. The following themes were gleaned from the interviews with the 15 physicians:

- Use of intuition: Many physicians claimed to have used their intuition during the diagnostic process and frequently in relation to parents.

You learn to rely on your intuition ... whether you feel that the parents understand what you are saying, or that in this case, your instructions won't help.

There is adversity, especially regarding certain decisions—I am sometimes hesitant about what to do, since I'm alone, especially at nights, and have to rely a lot on my intuition.

- Expertise: Most medical professionals believe that their clinical expertise in pediatrics in general and in telemedicine in particular aids in their diagnostic and decision-making processes. The more experience a medical professional has in telemedicine, the more confident they feel.

During my first few days at work, I was afraid I would miss things or that there would be problems. After a while, however, I began to work with more confidence and less stress.

There are some difficult aspects. At first, I felt insecure, but over time I gained experience (even the ability to diagnose better than the face-to-face doctor)! Like diagnosing a child with diabetic ketoacidosis ...

- Using protocols: Many physicians said they use protocols and rules of thumb when making decisions. Most also use the protocols that are generated for special circumstances.

They believed this assisted them in maintaining patient safety. They were also conscious of potential biases in their thinking.

I use protocols. For example, head injuries among babies under the age of six months, or a high fever among babies younger than one month old. These make it easier to make a decision.

I use some rules of thumb. For instance, if a young boy is able to jump around, then he does not have appendicitis.

- Making shared decisions with parents: A few medical professionals reported talking to the parents of their patients about their opinions on the diagnostic process and potential treatment options.

I used to share my decision-making process with the parents. If there were several options, I would let the parents decide. In such a case, I depend on them.

I usually share, but I do not consult. I give my opinion and explain it, and only then do I wait for feedback.

- Using nonmedical factors: Most of the physicians agreed that they consider nonmedical considerations, in addition to medical factors when making decisions. Their opinions of the parents, particularly their level of comprehension, anxiety level, health literacy level, and the assurance that the parents will act appropriately if the child's illness worsens, are the most important considerations. The family's ability to access medical care was another crucial nonmedical element.

In addition to medical factors, the parents' tone of voice and level of stress may affect my decision, even if it seems to be a simple diagnosis ... Language is also a factor. For example, new immigrants do not

always understand me, and I am therefore more prone to sending them to the ED ...

Aside from the medical condition, the patient's place of residency is also important. Living far from a medical care facility is a factor; and I will be more likely to consider an ED referral. In such cases, I also ask more questions about the availability of the doctor nearby.

You have to trust the parents' information and rely on them to follow the instructions correctly. If I feel that the chances of me being understood are poor (due to a lack of understanding or oversophistication on the part of the parents), I will refer them to the ED more easily.

- Additional techniques: The physicians schedule video conversations with the parents in cases of diagnostic doubt, ask them to send digital images, or schedule a follow-up call a few hours later.

If I needed additional information, I would arrange a video call or a follow-up call at a later time. Rarely would I consult with a senior physician.

Despite the difficulty making the decision, pictures and videos often compensate for the lack of a physical examination ... In one case, I managed to correctly diagnose a child with intussusception!

Despite the difficulties and obstacles mentioned by online doctors [79], many of the physicians surveyed in this study reported having generally positive experiences with their telephone assessments and feeling confident in their ability to conduct thorough assessments and reach the right treatment decisions.

The key conclusions, with examples and comparisons between the 2 systems, are shown in [Table 3](#).

Table 3. Key conclusions derived from the findings.

Key topics	Findings
Specialized clinical training for teletriage tasks	
RHP ^a	The RHP does not provide formal specialized teletriage training for nurses. However, it requires formal training for its electronic algorithms. Physicians present lectures on various specialties for the nurses.
Clalit Health Services	Teletriage training for pediatricians is not available. The authors believe training would aid pediatricians in making safer decisions during online consultations.
Conclusion for both systems	Judging from the interviews with nurses and physicians, it appears that both systems' clinical training is not adequate and formal training would be beneficial. Clinical training for any new subspecialty is an essential safety measure. Research has shown that clinical preparation has the potential to build confidence, improve performance, and reduce error, while improving morale [70-72,75,82,83].
Electronic algorithms and protocols	
RHP	With rare exception, the RHP requires nurses to follow and heavily rely on electronic algorithms in decision making. This raises the question of whether the RHP's electronic algorithms function more as a CDMS ^b than as a CDSS ^c [73]. The nurse interviewed (Ms Finley) stated that the overreliance on algorithms discourages nurses' critical thinking and dampens her initiative to perform a more thorough preliminary symptom assessment and to promote interpersonal interactions.
Clalit Health Services	The Clalit system provides several written protocols for certain clinical scenarios, and physicians are encouraged but not required to use them. In our qualitative interviews, many physicians said they used protocols and rules of thumb when making decisions.
Conclusion for both systems	For both nurses and physicians, guidelines are a key decision support tool. In addition, guideline quality (validity and reliability) requires evidence-based research—long overdue in this risk-prone field.
Documentation	
RHP	The RHP system provides 2 methods for call documentation, an audiotape recording and an electronic paper trail—a record of the patient-clinician encounter derived from a given guideline. However, the documentation output is limited to a patient's yes/no responses to the algorithmic questions. The result is an anonymized history with few details or context specific to a given patient [26]. Finley stated that physicians who later evaluate patients on-site do not have a good sense of why the patients were advised to be seen urgently. The RHP later developed a new policy allowing nurses to use a free-text area to document a brief symptom history using standard questions to elicit more specific details and context. Quality assurance is further bolstered by audiotaping all calls for follow-up review.
Clalit Health Services	The Clalit system requires physicians to document calls, completed in the child's medical file. As a result, the personal physician can view the online consultation during business hours. However, the language used in the documentation is completely up to the individual physician.
Conclusion for both systems	The RHP "paper trail" appears safer and more complete. However, the documented output appears to introduce confusion into on-site follow-up encounters. Clalit Health Services' lack of standardized language requirement may interfere with communication and continuity of care—a professional principle. Both systems are inadequate and increase miscommunication—one of the most common, recurrent error in this field.
Clinical call center standards (policies and procedures): clinicians' knowledge and experience	
RHP	According to Finley's interview, the RHP appears to have no job requirements or job descriptions and according to its policy may hire inexperienced nurse graduates. New nursing graduates are a poor match for the medical decision-making task, which according to many experts, requires a minimum 5-year bedside experience.
Clalit Health Services	The Clalit system hires only certified pediatricians, even though their level of experience as pediatricians in general and as online physicians may vary greatly.
Conclusion for both systems	Experience is critical in decision-making. Both groups could benefit from improved standards for required experience and job qualifications.
Clinical call center standards (policies and procedures): call length (teletriage meeting duration)	
RHP	Although it is the customary role of management to develop call center policies and procedures (standards), at the RHP, staff nurses have developed a minimal number of standards. One is a maximum call length, while another is a closing reminder to callers to call back if symptoms worsen or change.
Clalit Health Services	The Clalit system does not place any constraints on session length. However, since physicians are paid "per consultation," it may be an incentive to process calls quickly, although using the best medical decision.

Key topics	Findings
Clinical call center standards (policies and procedures): patient outcome feedback	
RHP	RHP nurses operate in a vacuum regarding patient outcomes (follow-up diagnosis). Outcomes provide feedback and are a measure of patient safety. Feedback about one's decisions is essential to improved practice and one of the strongest risk management measures available [87]. The rationale for not providing feedback to nurses is based on the Health Insurance Portability and Accountability Act (HIPAA). This federal law does not prevent US physicians' access to patient outcomes, however.
Clalit Health Services	Clalit physicians have complete access to the outcomes of their calls. Learning of their mistakes or successes may improve their practice and safety.
Conclusion for both systems	Ignorance about outcomes of one's decisions has never been shown to improve practice. Feedback mechanisms, known as planned error recovery, not only allow practitioners to learn the final diagnosis and thus improve their practice but also may improve guideline design and quality.

Discussion

Principal Findings

This narrative review and analysis presented a glimpse into current teletriage safety by analyzing 2 established and representative systems in 2 countries: Israel and the United States. We examined each system to learn how developed each is, perform a comparative analysis of both systems' safety, and explore the elements that might influence safe practice and patient outcomes.

In the initial stage, we carried out a thorough analysis of papers pertaining to patient safety in teletriage scenarios. Current research yields conflicting results regarding the dependability and security of teletriage systems. Although some critics claim that teletriage decisions frequently endanger patient safety [40,49-51], other research claims that using teletriage systems results in better safety outcomes [14,52].

We also analyzed a clinical call center of a large national US HMO based on the responses of a representative advice nurse to an interview (Multimedia Appendix 3), highlighting areas of risk that may contribute to system error [17]. We found that this representative system is still underdeveloped and lacks certain risk management elements. We based our conclusions on the interview, recent research, legal and risk management requirements related to the duty of due care, medical and nursing traditions, and existing subspecialty structures and processes.

In addition, we performed a qualitative study in which we interviewed 15 Israeli physicians working in a pediatric teletriage service in Israel, asking them about factors that affect their ability to maintain patient safety, while providing an accurate diagnosis, making appropriate decisions, and choosing the best course of action [83]. The physicians discussed the challenges they encounter in the telemedicine/teletriage context and the many strategies they use to arrive at the best diagnosis and course of care, protecting patient safety. These strategies include using their experience and intuition, using protocols generated for special clinical scenarios, making shared decisions with the patients (or their parents in the case of children), applying nonmedical criteria to aid in decision-making in situations where the medical data are ambiguous, and using

more sophisticated tools (eg, video chats) when additional details are required. Many of the physicians surveyed in this study reported having generally positive experiences with their telephone assessments and feeling confident in their ability to conduct thorough assessments and make the best treatment decisions, despite the challenges and blockages described [82].

This study may be the first to examine and compare 2 official telehealth systems. For a combined 45-50 years, the 2 authors have performed triage in formal systems, taught, and provided consultation in the field of telehealth.

Teletriage, as stressed in this research, is the process of evaluating and prioritizing symptoms using telecommunication technologies. The main goal of teletriage is to assess and manage symptoms by telephone, which necessitates the use of professional judgment, clinical assessment, and proactive patient information gathering. The purpose of teletriage is to determine whether the needed on-site evaluation should take place and, if so, the venue and time. Teletriage involves clinical decision-making under remote and uncertain conditions. An overarching goal of teletriage safety is to avoid delays in care or diagnosis, which can cause patient harm.

Clinicians typically estimate the urgency of acute symptoms remotely and advise a disposition (triage level) for further medical diagnosis and treatment, as appropriate. The growth of teletriage services has accelerated due to the COVID-19 outbreak.

All types of health care delivery must consider safety, but with teletriage, this is both more crucial and challenging because acute symptoms may be time sensitive. Delay in care and diagnosis can result in harm to patients. Since there is no visible contact or nonverbal communication during teletriage, it is a more complicated activity than in-person consultations and it has certain inherent risks. The rapid pace of telehealth's growth creates urgency in identifying safe systems to guide developers and clinicians about needed improvement. Establishing a system is a key strategy to reduce the possibility of delay in care and diagnosis.

In the United States and internationally, one way to be cost-effective is to use the least paid person who can *safely* do

the job—an RN. Internationally, nurses have traditionally performed this task since the late 1980s. Early studies found that nurses are a safe substitute for physicians [14,73]. Thus, although physicians initially performed this task, they later delegated it to nurses.

Health care institutions historically provide standard features to support nurses and to enhance safety (subspecialty clinical training, standards, and documentation). In the case of teletriage, guidelines are typically written by physicians, similar to standing orders. These components provide a structure and process for this subspecialty and underpin safe practice.

An evolving subspecialty, even after 50 years, teletriage appears misunderstood and neglected. System error is thought to be a result of the absence or inadequacy of systems. In malpractice cases, expert witnesses for the patient or their family request evidence of the duty of due care. Typically, this evidence comprises documents: call documentation, guidelines used, clinical training materials, policies, and procedures (standards), including written job descriptions and qualifications.

Clearly, this analysis must acknowledge that contexts of the institutions described here differ in terms of respective health care systems and decision makers' clinical qualifications. The US health care system, and teletriage in particular, is plagued by disparate, competing forces: institutional cost containment, the need for professional standards, and diverging technological goals—the emphasis of speed over safety. This scenario requires better risk management.

Israel has universal health care, which appears to act differently. Physicians' depth and breadth of education and clinical training are superior to those of nurses. The US health care system compensates for this difference by providing more structure in the form of guidelines—typically developed collaboratively by physicians and software engineers. Physicians are not actual users of the guidelines that nurses are required to use.

Another variable is that of the populations served. Clalit pediatricians serve the needs of a diverse but still circumscribed pediatric population, whereas RHP nurses serve a broad, diverse population in terms of age range, symptom presentation, and diversity. This is a large order for nurses to manage and calls for a robust structure and process.

Finally, both RHP and Clalit systems share a common problem: incomplete systems of variable quality. The Clalit system's safety appears to rely on physician decision-making expertise, where standards, guidelines, and training are not that strong. The RHP may appear more complete. Safety may hinge on physician-developed electronic guidelines. Standards and training appear piecemeal or added as an afterthought. Without a meaningful, evidence-based structure and process in teletriage, quality (including safety) is at risk [18,58]. If establishing a system is a strategy to reduce possible error, then both systems could benefit from similar improvements.

Even if expert-level physicians require a less robust system, it appears that both physicians and nurses could benefit from specialized clinical training. In addition, consistent feedback regarding patient outcomes, known as planned error recovery—an essential error reduction strategy—promotes a

method to self-check or to double-check another person's work [87].

Teletriage electronic algorithms must be evidence based. These guidelines are typically collaboratively developed by physicians and software developers. Nurses are required to use them, whereas physicians rarely use such tools.

Our narrative review and in-person interviews with physicians and a nurse about their experiences working in teletriage settings yielded several key findings, including the absence of specific formal training for the medical personnel working in teletriage; problematic protocols in particular clinical scenarios that, although not always available for all scenarios, are of low quality and do not allow for flexibility and agility, when needed; problematic documentation (mainly in nurse teletriage); inadequate experience and knowledge of the personnel who must make decisions in the face of uncertainty and urgency; limitations on the duration of calls or compensation based on the number of calls (which incentivizes personnel to conclude sessions promptly); and unsuitable feedback mechanisms that prevent personnel from understanding what transpired with patients and from learning from errors.

Drawing from our individual findings, the essential elements of teletriage are:

- Specialized clinical training for teletriage tasks
- Electronic algorithms and protocols
- Documentation
- Clinical call center standards: clinicians' knowledge and experience, call length (teletriage meeting duration), patient outcome feedback

Limitations

As with any narrative evaluation, selection bias cannot be completely ignored, even if this narrative analysis of the current literature was quite extensive and comprehensive and included a qualitative assessment of physicians and a nurse working in a teletriage setting.

Conclusion

Like other subspecialties, teletriage necessitates several elements to support safety, including qualified, experienced clinicians in sufficient numbers; specialized clinical training in medical decision-making; evidence-based, open, and approachable guidelines; and EMRs, audiotapes or written documentation, and standards (policies and procedures).

Fostering teletriage patient safety can be accomplished by taking the following general steps to improve MD and nurse practice in both Israel's and the United States' clinical call systems:

- Adequate training: Providers must receive adequate training to properly monitor and provide telehealth services. This includes knowledge of the systems being used, as well as familiarity with medical terminology and protocol.
- Regulation of telecommunication devices and systems: Providers must be aware of the regulations and requirements for the telecommunication devices and systems they use. This includes ensuring that the equipment is in good

- working order and adheres to all safety and security regulations.
- Appropriate patient population: Telehealth services should only be used to treat patients who are stable and not at risk for an immediate life-threatening event. This will help ensure patient safety and avoid unwanted outcomes.
 - Careful monitoring: In appropriate consultations, when needed, providers must carefully monitor patients and document any changes in their condition. This will help ensure that any changes or issues are addressed quickly and appropriately. Typically, nurses do not perform this task; in Israel, this is the role of the physician, for example, by using devices such as TytoCare.
 - Quality assurance: Quality assurance protocols must be in place to ensure the accuracy and effectiveness of providers' services. This includes regularly reviewing documentation and providing feedback on any services deemed inadequate.
- Follow-up care: Providers must ensure that any patient receiving telehealth services receives follow-up care. This can include referrals to specialists or any other services needed to address any health concerns. Typically, nurses do not perform this task; in Israel, this is the role of the physician.
 - Evidence-based studies of systems and safety: Misguided researchers unfamiliar with the triage task have produced confusing, misleading studies. Research that nibbles around the edges of the problem (patient or clinician satisfaction, clinician stress levels and attitudes, nonclinician practice) fails to address the core problem—system error. The telehealth industry requires long-overdue evidence-based outcome studies that meaningfully demonstrate the structures and processes that inform and strengthen safety.

Acknowledgments

We would like to express our gratitude to the physicians and the one nurse who took part in the interviews. We received no funding for this study.

Data Availability

All data analyzed during this study are included in this published paper and its supplementary information files. Additional data sets generated during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

MH was involved in the conceptualization of the study, methodology, investigation, data curation, interviewing the physicians, analysis, and writing the paper. SQW was involved in data curation, methodology, formal analysis, interviewing the nurse, and writing the paper.

Abstract

Background: Digitization is vital for data management, especially in health care. However, problems still hinder health care stakeholders in their daily work while collecting, processing, and providing health data or information. Data are missing, incorrect, cannot be collected, or information is inadequately presented. These problems can be seen as data or information problems. A proven way to elicit requirements for (software) systems is by using creative frameworks (eg, user-centered design, design thinking, lean UX [user experience], or service design) or creative methods (eg, mind mapping, storyboarding, 6 thinking hats, or interaction room). However, to what extent they are used to solve data or information-related problems in health care is unclear.

Objective: The primary objective of this scoping review is to investigate the use of creative frameworks in addressing data and information problems in health care.

Methods: Following JBI guidelines and the PRISMA-ScR framework, this paper analyzes selected papers, answering whether creative frameworks addressed health care data or information problems. Focusing on data problems (elicitation or collection, processing) and information problems (provision or visualization), the review examined German and English papers published between 2018 and 2022 using keywords related to “data,” “design,” and “user-centered.” The database SCOPUS was used.

Results: Of the 898 query results, only 23 papers described a data or information problem and a creative method to solve it. These were included in the follow-up analysis and divided into different problem categories: data collection (n=7), data processing (n=1), information visualization (n=11), and mixed problems meaning data and information problem present (n=4). The analysis showed that most identified problems fall into the information visualization category. This could indicate that creative frameworks are particularly suitable for solving information or visualization problems and less for other, more abstract areas such as data problems. The results also showed that most researchers applied a creative framework after they knew what specific (data or information) problem they had (n=21). Only a minority chose a creative framework to identify a problem and realize it was a data or information problem (n=2). In response to these findings, the paper discusses the need for a new approach that addresses health care data and information challenges by promoting collaboration, iterative feedback, and user-centered development.

Conclusions: Although the potential of creative frameworks is undisputed, applying these in solving data and information problems is a minority. To harness this potential, a suitable method needs to be developed to support health care system stakeholders. This method could be the User-Centered Data Approach.

Introduction

Background

Despite advancing digitization in the health care sector, problems still hinder health care stakeholders in their daily work while collecting, processing, and providing health data or information. These problems can be seen as data or information problems.

This scoping review aims to review if creative frameworks were used to solve data or information problems in health care.

Figure 1. Data Information Knowledge and Wisdom Hierarchy (DIKW).

Data are defined as “facts and statistics collected for reference or analysis [and] the quantities, characters, or symbols on which a computer performs operations” [2]. Data gain value when analyzed and structured into information, which is crucial for extracting insights and making informed decisions. The word information is defined by [3] as “notice, news or advice communicated by word or writing.” Claude Shannon, the father of modern information theory, quantifies information as a measure of uncertainty or surprise in a message, introducing the concept of entropy as in [4].

Over the past decades, replacing “information” with “data” has become common. The word data now includes entities and meaning [5]. However, this can cause misunderstandings, so it is important to consider the specific discipline’s framework [6].

In general, data can be categorized as structured, unstructured, or semistructured. Structured data are organized and formatted in a predefined manner, with each element assigned a specific type, often found in databases or spreadsheets (eg, CSV and XML) [7]. In health care, this type of data includes electronic health records (patient demographic information, diagnosis codes, and medication lists) [8].

Unstructured data lacks a predefined structure, including text, images, audio, video, and social media posts, making it harder to process automatically [9,10]. In health care, this data can be descriptions or medical history, mainly text in free written form. Semistructured data combine elements of both, with some organizational structure but not a rigid schema (eg, JSON files,

A secondary objective was to understand how these creative frameworks were applied in detail to understand their possible impact on solving data and information problems.

Definition of Data and Information

The correlation between data and information can be visualized with the information pyramid [1], whereas data are necessary to get information that leads to further possible knowledge and wisdom (Figure 1).

XML documents with optional tags, or a combination of checkboxes and descriptions).

The Importance of Data and Information in Health Care

Medical decision-making is one area that benefits crucially from leveraging data and information. Health care providers can gain valuable insights into patients’ diseases or treatment outcomes [11]. Also, it can improve the patient’s health status or satisfaction (cf. [12,13]). It can also significantly influence the quality of patient care and patient safety. By continuously analyzing, for example, clinical data and patient feedback, it is possible to identify areas needing improvement [14]. Another aspect is positively adjusting operational activities by analyzing patient flow, operational processes, and workflows [15].

Data and Information Problems in Health Care

Despite the importance of data and information, health care professionals and practitioners must often make highly calculated and accurate decisions with limited information, resources, and knowledge [16-20]. That puts a more significant burden on the staff and prevents them from harnessing the potential value of data and information. These problems can be seen as data and information problems.

A data problem is present when the necessary data for further processing, analysis, and provision are unavailable or cannot be collected (sufficiently). That can involve anomalies, discrepancies, or limitations within the data itself or difficulties

related to data processing, integration, quality assurance, or ethical considerations.

An information problem can arise when the information is not provided sufficiently or is unrepresentative. This points to a challenge when seeking, evaluating, synthesizing, or using information sources and can encompass difficulties related to information scarcity, retrieval, relevance assessment, credibility assessment, information organization, or ethical considerations.

It is important to stress that (regardless of these definitions) the complexity of these problems constantly changes depending on the context and the target group. Due to that, a “one-fits-all” concept or solution is unrealistic.

Creative Frameworks in Software Development in Health Care

Diverse approaches are used in various fields to stimulate innovative thinking, generate novel ideas, and foster problem-solving. Some of these well-known creative approaches are design thinking, user-centered design (UCD) or human-centered design (HCD), lean UX [user experience], lean startup, and service design. These creative approaches are frameworks that provide a structured approach or guidelines that define the overall context, principles, and objectives for fostering creativity. They often offer an overarching perspective and may encompass multiple creative methods.

In contrast, an individual creative method refers to a specific technique or tool. They are typically more focused compared to frameworks. Creative methods include mind mapping, storyboarding, 6 thinking hats, and scamper or interaction room.

In the context of health care, the approaches design thinking, UCD, and HCD are often successfully used to develop user-centered software or hardware to support health care professionals’ daily practice [21-24]. This may be due in no small part to the fact that specifically human-centered design is anchored in ISO (International Organization for Standardization) standards, which aim to ensure consistency, quality, safety, efficiency, and interoperability in different disciplines.

An example is ISO 9241, focusing on the Ergonomics of human-system interaction. In the ISO 9241:2019, Part 210 focuses on a human-centered design for interactive systems. The HCD process is divided into different activities and sub-activities and focuses on their responsibilities for human-centered quality in software development [25].

Creative Frameworks and Data or Information Problems in Health Care

Data and information problems can vary significantly in their complexity—from anomalies or limitations in the data to information overload. Depending on the context, further complex combinations of problems can arise and pose challenges for all relevant target groups.

Many of these problems cannot be solved by one discipline alone. Interdisciplinary and human-centered exchange is necessary to find the best possible solution.

Creative frameworks are ideal here; they provide a structure and help find creative, human-centered solutions in an interdisciplinary team.

An initial keyword search [26] conducted by the authors showed that data and information problems in health care were partially solved by using creative frameworks. A total of 100 papers were screened for two acceptance criteria: (1) data or information problem present and (2) a creative framework used to solve it. The screening resulted in 4 papers that met the criteria. However, these results were not representative (small sampling size, incomplete data), so it was impossible to deduce the extent to which creative frameworks are disseminated and applied in detail in the context of data and information problems and whether this output is just a coincidence. After all, no other publication was found that deals with this focus, which led to conducting a scoping review to obtain further information.

Methods

Overview

In this work, a scoping review was conducted to determine if creative frameworks were used to solve data or information problems in health care. A secondary objective was to understand how creative frameworks were applied in detail to understand their possible impact on solving data and information problems.

The scoping review was conducted using the guidelines of the Joanna Briggs Institute (JBI) [27] and the PRISMA-ScR (Preferred Reporting Items for Systematic Analyses and Meta-Analyses extension for Scoping Reviews); see [Figures 2 and 3](#). It provides researchers with a preferred reporting item and a checklist, as in [28]. Papers meeting the criteria for inclusion were chosen with a developed decision flow diagram (see [Figure 2](#)).

Figure 2. Overview of the decision flow diagram with the different scenarios.

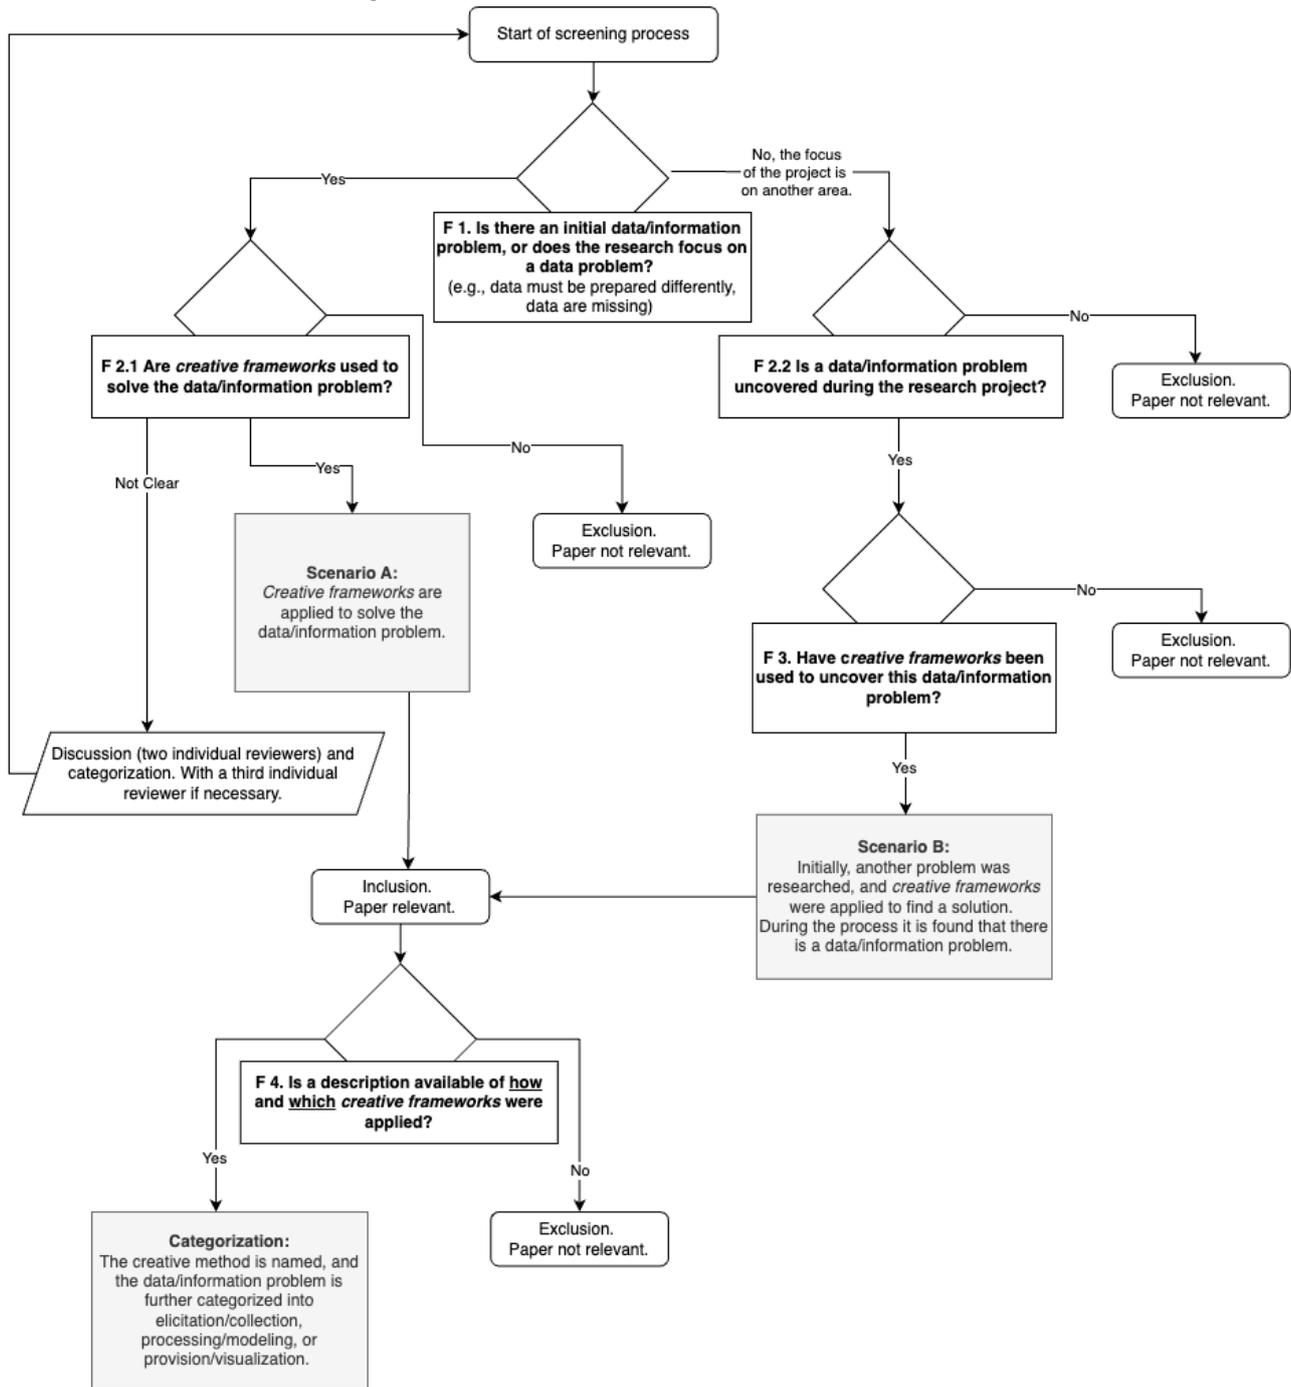

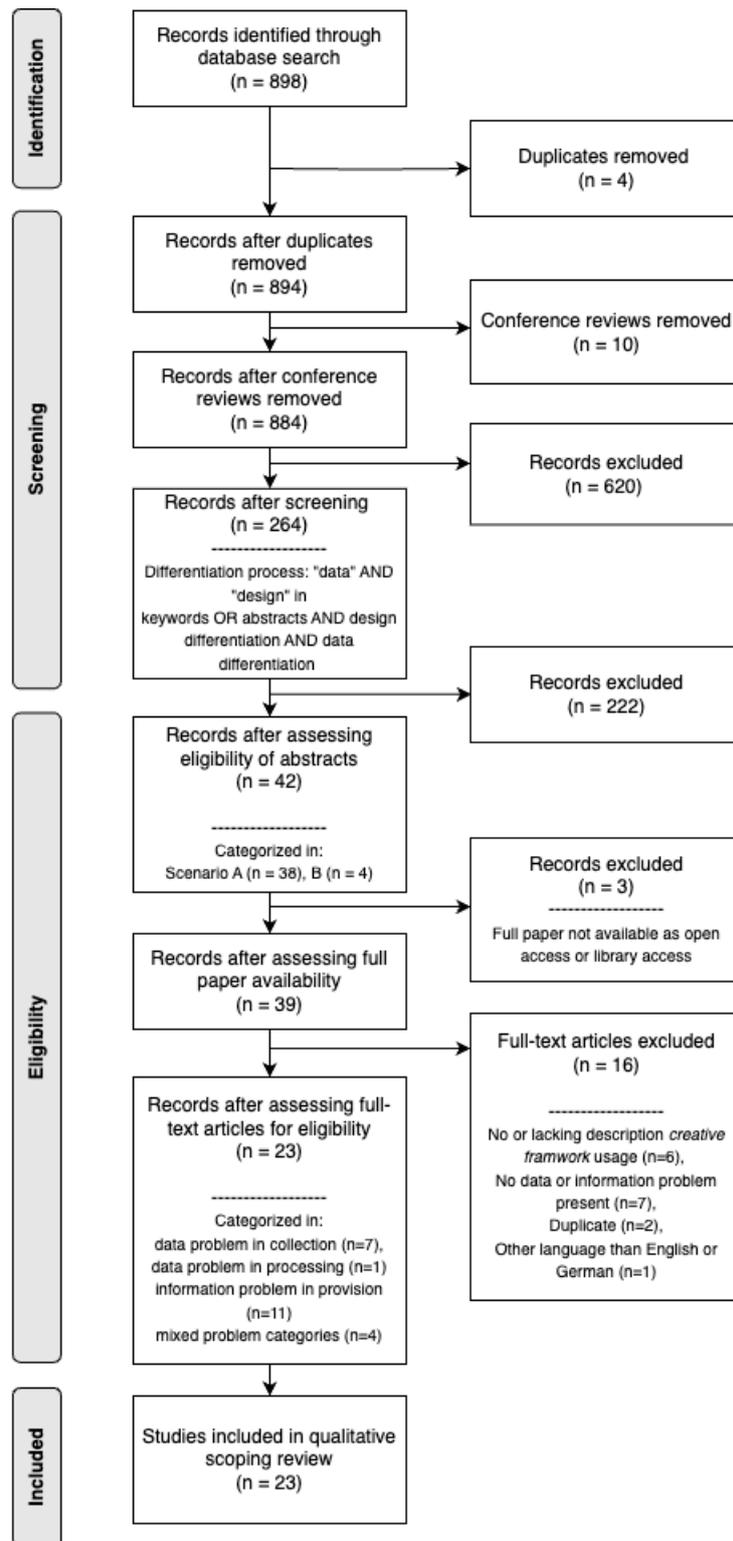

Figure 3. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram, including the different rounds and scenario decisions conducted.

Research Question

The following research question was explored: Have creative frameworks been used in solving “data or information problems” in medicine or health care, for example, the collection, processing, or provision of data?

Search Strategy

SCOPUS, ACM, and IEEE libraries were initially considered suitable because they are known for their extensive coverage of academic literature (journals, conference proceedings, reports), particularly in computer science. Additionally, the published papers are peer reviewed, and they provide advanced search features.

During initial keyword testing, it was found that the libraries ACM and IEEE are unsuitable for this scoping review as they have either keyword or content group limitations. Due to the number of different keyword spellings (see Tables I and II) and the need for a parallel search in the document title, abstract, and keywords, SCOPUS was chosen.

Studies published in German and English from 2018 to 2022 were included. The search was performed on July 6, 2022.

Search String and Source Selection

The main search strings were »data« AND »design« in the categories of Computer Science, Medicine, Nursing, and Health Professions. Due to the more common definition of data, which refers to a data-based definition of information as mentioned in the Introduction, the keyword information was not included. However, further analysis of the query results will interpret the word data and distinguish between data and information.

Concerning the selection of creative frameworks, the authors decided to focus on UCD, HCD, and design thinking because they have already proven successful in software development. Additional keywords like service design, lean UX, and lean startup were tested for relevance. Service design returned a significant query result with approximately 200 papers; thus, it was included in the search string. Lean UX and lean startup delivered only a handful, and the keywords were referenced neither in the title nor abstract nor keywords, so these 2 creative frameworks were excluded from the search string.

The remaining 4 keywords for creative frameworks were searched using the title, abstracts, and authors' keywords. As these main keywords are insufficient to differentiate when and how creative frameworks have been used (collection, processing, provision or visualization), further subkeywords were defined. That was primarily due to different spelling and general writing options for UCD and HCD, as seen in [Multimedia Appendix 1](#). The overall number of keywords and substrings was 32 (including main and differentiation keywords). Definitions of the keywords are listed in a separate appendix.

All retrieved papers were matched against a decision flow diagram (see [Figure 2](#)). This step was included to guarantee that all perspectives and approaches to using creative frameworks in data and information problem-solving were included. Therefore, the papers were further categorized in this diagram with different implementation scenarios of creative frameworks (creative frameworks used yes/no, data or information problem solving with creative frameworks yes/no).

Study or Source of Evidence Selection

All identified papers were collected within an EndNote database and shared with all reviewers after the search. The differentiation of the paper focused on screening the document title, abstract, and keywords. This step was conducted individually with smart groups by each reviewer. In EndNote, smart groups can be populated automatically by predetermined criteria. It can be described as "Search in this group in the title, abstract, keywords for keywords X, Y, Z."

Duplicates and conference reviews were removed within the screening process.

Potentially relevant sources were retrieved in full while checking the eligibility. Any disagreements between the reviewers at each stage of the selection process were resolved through discussion or with an additional reviewer.

The search results and study inclusion process are presented in the PRISMA-ScR flow diagram, as shown in [Figure 3](#).

Results

Overview

The literature search retrieved 898 items from SCOPUS. After the removal of duplicates (n=4) and conference reviews (n=10), titles, abstracts, and keywords of 884 papers were screened according to the inclusion and exclusion criteria (description scenarios see [Table 1](#) and decision flow diagram see [Figure 2](#)).

The overall process can be viewed with the PRISMA ScR flow diagram (see [Figure 3](#)). Afterward, further research results are presented.

Table 1. Description of 2 defined scenarios of the decision flow diagram.

Scenarios	Descriptions
Scenario A	<ul style="list-style-type: none"> • Creative frameworks are applied directly to solve a data or information problem. • A data problem was evident at the beginning of the study, and a creative method was used to solve a data or information problem. That means the awareness of the data problem was high, and choosing creative frameworks to solve the problem was a conscious decision.
Scenario B	<ul style="list-style-type: none"> • Creative frameworks are applied indirectly to solve a data or information problem. • That means the awareness of a data or information problem came later in the research process, and a creative method was conducted first.

Findings

A total of 42 abstracts and articles were assessed for eligibility, and 39 papers could be retrieved as full texts. Two reviewers screened the remaining 39 full papers individually and categorized them into data problems (elicitation or collection,

processing), information problems (provision/visualization), and mixed problems (data and information problems).

During this process, 23 papers were included (see [Table 2](#)), and 16 were excluded (see [Table 3](#)). Any disagreements between the 2 reviewers were discussed, and a third reviewer was consulted in cases of doubt. A detailed overview of the

categorization of all 39 papers can be found in [Multimedia Appendix 2](#).

Table 2. Summary of available full-text papers included.

Problem category	Number of papers
Data elicitation or collection	7
Data processing or modeling	1
Data, information provision, or visualization	11
Mixed problems (data and information problem present)	4
Total amount of papers included	23

Table 3. Summary of available full-text papers excluded.

Duplicate	2
Other languages used than English or German	1
No data or information problems described	7
Insufficient or missing description of the creative framework	6
Total amount of papers excluded	16

Key Finding 1—General Minority

At the beginning of the scoping review, 898 papers were identified. In the end, 23 papers met all inclusion criteria. With these papers, the research question, “Have creative frameworks (UCD, HCD, design thinking, or service design) been used in solving ‘data/information problems’, for example, in the collection, processing, and/or provision of data?” can be answered with yes but it is a minority. Only 23 papers used creative frameworks to solve data and information problems in health care.

At this point, the question arises as to why. Is the application of creative frameworks in this context insufficient, or was the focus on solving specific data and information problems with creative frameworks not given? Or are there other factors contributing to this, like the lack of insufficient description and exclusion (see Key Finding 2)? Since creative frameworks have proven successful in developing health care software and hardware in the health care sector, transferring these frameworks and techniques to solve data and information problems does not seem so far-fetched.

Key Finding 2—Lacking Descriptions of Problem Statements and Method Description

From all query results, 264 had the keywords »data« AND »design« AND 1 design differentiation (e.g., design thinking) AND 1 data differentiation (e.g., data collection).

To better understand what, how, and why the creative frameworks were applied, the papers (n=264) were further screened for 1. data/information problem present and 2. Creative framework used. In the first step of this activity, the reviewers focused on the title, abstract, and keywords and searched for a problem statement and the mention of a creative framework (that goes beyond mentioning it in the keywords). If a problem was mentioned, it was checked to see whether it was a data or information problem.

It is important to stress that the word “problem” does not mean that every paper needs to focus on a major or new problem and try to find a solution. In some cases, the problem may be rather “small” and very specific, for example, the UI design no longer works for the target group and needs to be adapted. In other cases, the problem is more general and indicates, for example, a lack of sufficient data for further research. In total, 222 papers had to be excluded because they did not contain a problem statement that referred to a data or information problem or because no creative framework was mentioned. In these cases, it is difficult to completely understand the authors’ thoughts and decision-making process. Further clarification with the authors could help, but it is beyond the scope of this review.

From the remaining 39 papers that were checked for eligibility (full paper read), only 23 could be included (see [Multimedia Appendix 3](#) for further details). In many contributions, the data or information problem was not described in detail (n=7) and only briefly mentioned in the abstract. The description of how creative frameworks were applied was insufficient or missing in 6 papers. That could point to the fact that the authors did not feel a more detailed description was necessary or that they maybe had difficulty applying the creative framework. Further details are provided in [Multimedia Appendix 4](#) showing 6 examples of included (n=2) and excluded (n=3) papers.

Key Finding 3—Initial Clarity About Problems Needed

During the screening and development of the decision framework for inclusion criteria, it was found that there might be different types of awareness when and how a creative framework is used to solve a problem. Either “We have a data or information problem, and we use creative frameworks to solve it” or “We have a problem, and we use creative frameworks to solve the problem or we use it to find out more about it. As a result, we found a data or information problem.”

Most papers (n=21) identified a data or information problem first (see Scenario A) and later decided to apply creative framework to solve it. In only 2 cases (n=2) did the researchers

address a different type of problem and identified a data or information problem by applying a creative framework (referring to Scenario B). This might point to the fact that the problem must be apparent first before deciding to use a creative framework to solve it.

Key Finding 4—Creative Frameworks Most Applied in Case of Information Problems

Most of the included papers (n=11) dealt with an information problem, and 8 dealt with a data problem. Some papers (n=4) dealt with a combination of data and information problems and were categorized as mixed problems (problem in data collection, data processing and information provision n=1, problem in data collection and data processing n=2, and problem in data collection and data provision n=1).

That could indicate that creative frameworks are particularly suitable for solving provision or visualization problems and less for other, more abstract areas such as data problems. Also, combining several creative frameworks to solve a data/information problem leads to a preferred visual (data) output.

However, the remaining 8 papers show that it is possible to use a creative frameworks for a more abstract problem. This could mean that creative frameworks have not yet been identified as suitable.

Key Finding 5—UCD is Most Frequently Used as a Creative Method

In the process of testing keywords for relevance, UCD, HCD, and design thinking were considered the most relevant as they have already proven to be successful in software and hardware development. After testing additional keywords such as service design, lean UX, and lean startup for relevance, only service design yielded a significant number of query results, approximately 200 papers. Therefore, it was incorporated into the search string. However, lean UX and lean startup produced only a handful of results, and these keywords were not referenced in the papers' title, abstract, or keywords. Consequently, these 2 creative frameworks were excluded from the search string.

Most of the final papers used only UCD to solve the problem at hand (n=16); the other remaining papers used either design thinking (n=2), HCD (n=1), other creative frameworks such as Rapid Contextual Framework (n=1), Design Science (n=1), or Design Study Methodology (n=2). Only a few papers used more than one creative method (n=2). That indicates that UCD is, compared to design thinking, HCD, or service design, the most common, best-known, or best-understood method to apply in health care settings.

Concerning the papers that used UCD (n=16), they can be divided into data collection problem (n=5), data processing problem (n=1), information problem (n=7), mixed data, and information problem (n=2).

This indicates that UCD is specifically used and probably suited for data collection problems and information problems. It is unclear if it is less suitable for data processing problems, as we

do not know if it could be successfully applied or if researchers might know of the possibility of doing so.

Key Finding 6—no Unified Spelling

As shown at the beginning of Tables I and II (in [Multimedia Appendix 1](#)), many keywords (n=32) were used for this qualitative scoping review. Different spellings had to be considered, especially for the keyword »user-centered design« and further differentiations. That prolonged the overall process of the scoping review as it had to be continuously checked that all differentiations were included during the screening and eligibility process. Overall, this made it challenging to proceed efficiently and effectively. It is still possible that relevant papers might not be part of this work because not all relevant keywords and their spelling variants have been included.

Closing the Gap: A New Approach Is Needed

The results of the initial literature research and scoping review demonstrate that creative frameworks have been used to address challenges in health care, such as information overload or data collection hindrances. However, this specific approach tends to be a minority.

Having identified an application gap, we propose a new idea—a Human-Centered Data Approach. With this, we aim to propose a structured way to minimize data and information problems in the health care setting.

The main goal is to analyze and integrate the users' data and information needs and include these already at the earliest stage of development possible. This could influence the quality and quantity of data and the user's overall value.

First, because the user's awareness of data and information increases: "What are data or information, what importance do they have for me, and what information do I need?" Second, it is more likely that the applicability and understandability of the data and information for the user will increase.

It could also be possible to categorize data quality, quantity, or value according to stakeholders. A guideline could be part of the new approach to optimizing the data and, hence, information and include the user throughout the development process, for example, concepts or solutions.

Furthermore, developing this new approach within an interdisciplinary team is also essential. Different perspectives are needed to develop this new approach and conduct it correctly. Furthermore, to interpret potentials and risks that come with user-centered data (from the perspective of ethics: with more data value to the user, a loss could have even more severe (personal) consequences). Therefore, computer science, design, ethics, society stakeholders, and policy disciplines would be mandatory.

A sound basis for the approach could be to use an already existing and successful method, like HCD, UCD, or design thinking, and apply it to the context of data and information problems. That shall be done with an interdisciplinary team. The presentation of this will be part of the following publication.

Discussion

Overall, this scoping review aimed to review if creative frameworks were used to solve data or information problems in health care. A secondary objective was to understand how these creative frameworks were applied in detail to understand their possible impact on solving data and information problems.

Identifying a relatively small number of papers (23 out of 898) that meet the inclusion criteria raises intriguing questions about applying creative frameworks in health care problem-solving. This small number may be due to the combination of data/information problems and creative frameworks, but this might also be because many papers had to be excluded due to a lack of clear data-/information problem description and method application (n=222), which were inclusion criteria. Authors may need to recognize the significance of providing detailed accounts of problem definitions and applying creative techniques to facilitate knowledge dissemination and the reproducibility of research outcomes.

Nevertheless, while it is established that methods using creative methods such as UCD, HCD, or design thinking have been successful in health care software and hardware development, their limited use in addressing data and information problems suggests that there may be barriers or unexplored opportunities. That prompts us to consider whether health care has yet to fully harness creative frameworks' potential in data-related challenges.

Most papers dealing with information problems (11 out of 23) hint at the suitability of creative frameworks for solving information provision and visualization challenges. This observation suggests that creative frameworks might be particularly suitable for addressing issues that require a visual representation of data. However, based on the findings, it is impossible to conclude that one specific creative framework is best suited for a specific problem. To do so, a higher number of results is needed.

Despite this, the presence of papers that tackle more abstract data problems (8 out of 23) shows that creative frameworks are not confined to information provision but can also be applied effectively to other complex data-related issues. This contrariness highlights the need for a more comprehensive understanding of when and how to apply creative frameworks across various health care contexts.

The differentiation between scenarios where researchers identify a data/information problem first or use creative frameworks to uncover such problems underscores the importance of problem clarity in adopting creative frameworks. Most cases (21 out of 23) had clarity about their problem statement in the beginning. However, cases where creative frameworks reveal hidden data or information problems (2 out of 23), indicate that creative frameworks can also be employed as exploratory tools to uncover latent issues. This nuanced perspective emphasizes the versatility of creative frameworks in health care research.

UCD, as the most used creative method (in 16 out of 23 papers), may suggest that it is the most familiar and widely accepted approach in health care settings. Its preference might also be

attributed to its established reputation and applicability in health care contexts due to its references to ISO standards.

Another issue was the inconsistent spelling and terminology of UCD and HCD in the literature, which raises a practical concern for researchers conducting qualitative scoping reviews. The diversity in keywords and spellings could hinder the retrieval of relevant papers and add complexity to the literature search process. That emphasizes the importance of standardization in terminology and the need for researchers to employ comprehensive search strategies encompassing multiple spellings and variations to examine the available literature thoroughly.

With this work, we wanted to research if creative frameworks have been used to solve data or information problems in health care. We believe we have found an answer to this: yes, but it is a minority. We also wanted to highlight the need for a new approach to use the potential of creative frameworks to solve these problems. Additionally, we want to highlight that interdisciplinary discussion and evaluation, which includes the target group(s) in the earliest and all steps, is necessary to gain valuable data and information.

Limitations

Concerning the scoping review, the selection of full papers for inclusion in this study depends on the authors' ability to provide a clear problem statement and a precise presentation of their methodology. It is possible that some of the excluded papers may have conducted research that could align with the acceptance criteria but failed to meet these criteria during the screening process due to their lack of description.

Furthermore, studies with significant findings are more likely to be published, while those with null or negative results may not be accessible, leading to an incomplete picture. Also, studies that SCOPUS does not index are not part of this review but can still hold valuable results.

Additionally, it is important to stress that selecting studies and extracting data in scoping reviews involves some subjectivity. Researchers must make judgment calls about study inclusion and data extraction, which can introduce bias and influence the overall outcome.

In fast-evolving fields like computer science, it is possible that this research does not cover all the relevant research despite the vast time span, as the overall screening process takes a longer time and is resource-intensive.

Lastly, the review heavily depends on available literature. Three articles could not be screened for eligibility because they were neither available as open access nor through online academic libraries.

Conclusions

In conclusion, this scoping review offers valuable insights into using creative frameworks in health care research. The findings underscore the potential benefits of applying creative frameworks to address data and information problems while highlighting the need for greater clarity in problem definition,

a more comprehensive exploration of creative methodologies, and improved reporting practices.

As health care evolves, embracing creative problem-solving approaches may prove instrumental in tackling complex data and information challenges.

We believe that the adaptation or further development of UCD to the context of data and information problems could positively influence tackling data and information challenges. Ultimately,

a new approach could initiate interdisciplinary dialogue, allowing researchers, practitioners, and stakeholders to reshape health care data management and improve patient care, informed decision-making, and the overall efficiency of health care systems.

Nevertheless, at this point, it is yet unclear if this will succeed or not. However, it could help to foster interdisciplinary discussion at the earliest development stage of software or hardware solutions.

Abstract

Background: More than 18 million cancer survivors are living in the United States. The effects of cancer and its treatments can have cognitive, psychological, physical, and social consequences that many survivors find incredibly disabling. Posttreatment support is often unavailable or underused, especially for survivors living with disabilities. This leaves them to deal with new obstacles and struggles on their own, oftentimes feeling lost during this transition. Mobile health (mHealth) interventions have been shown to effectively aid cancer survivors in dealing with many of the aftereffects of cancer and its treatments; these interventions hold immense potential for survivors living with disabilities. We developed a prototype for WeCanManage, an mHealth-delivered self-management intervention to empower cancer survivors living with disabilities through problem-solving, mindfulness, and self-advocacy training.

Objective: Our study conducted a heuristic evaluation of the WeCanManage high-fidelity prototype and assessed its usability among cancer survivors with known disabilities.

Methods: We evaluated the prototype using Nielsen's 10 principles of heuristic evaluation with 22 human-computer interaction university students. On the basis of the heuristic evaluation findings, we modified the prototype and conducted usability testing on 10 cancer survivors with a variety of known disabilities, examining effectiveness, efficiency, usability, and satisfaction, including a completion of the modified System Usability Scale (SUS).

Results: The findings from the heuristic evaluation were mostly favorable, highlighting the need for a help guide, addressing accessibility concerns, and enhancing the navigation experience. After usability testing, the average SUS score was 81, indicating a good-excellent design. The participants in the usability testing sample expressed positive reactions toward the app's design, educational content and videos, and the available means of connecting with others. They identified areas for improvement, such as improving accessibility, simplifying navigation within the community forums, and providing a more convenient method to access the help guide.

Conclusions: Overall, usability testing showed positive results for the design of WeCanManage. The course content and features helped participants feel heard, understood, and less alone.

Introduction

Background

There are an estimated 18.1 million cancer survivors in the United States, and the number is projected to increase to 22.5 million by 2032 [1]. Approximately 40% of cancer survivors experience long-term physical, cognitive, psychological, and social consequences of cancer and its treatment, which can lead to significant disability [2]. These effects can include physical challenges, including but not limited to pain, fatigue, decreased functional mobility, limb loss, lymphedema, speech and swallowing difficulties, emotional challenges (as cancer survivors may experience anxiety or depression), and cognitive challenges (such as “chemo brain”) [3-5]. These aftereffects can lead to activity limitations and participation restrictions, which according to contemporary frameworks and legal definitions may be considered as disabilities [6,7]. Yet, even with significant functional impairments, not all cancer survivors self-identify as disabled [8,9]. Regardless of the terminology used, the aftereffects of cancer and their related functional impacts can have a significant negative impact on well-being and health-related quality of life [10]. Survivorship plans and rehabilitation programs, which play a crucial role in restoring survivors’ physical and emotional well-being, are frequently underused by cancer survivors [11]. This can be due to obstacles like time, financial constraints, and transportation issues [12], which hinder their accessibility. Mobile health (mHealth) apps can help make rehabilitation services accessible and put them in the hands of those who need them.

mHealth Apps

Mobile technologies—smartphones, tablets, and smartwatches—are increasingly ubiquitous in today’s society and can be used almost anywhere [13]. The Pew Research Center reports that 85% of American adults own smartphones, and the ownership is relatively consistent across genders; racial groups; and urban, suburban, and rural users [14]. This leads to an increase in the development of mHealth apps. The COVID-19 pandemic has led to mHealth strategies becoming even more important in cancer care. According to the recommendations of Curigliano et al [15], patients with cancer should be offered mHealth strategies to support symptom management and adoption of healthy behaviors. The number of mHealth apps has increased throughout the years, with around 325,000 apps available in 2017 [16]. Charbonneau et al [17] identified 123 mHealth apps for cancer survivors available in the 2 most important marketplaces (ie, Apple iTunes and Google Play). Typical areas of usage in cancer are disease management support (eg, symptom monitoring, management of side effects, medication reminder and dosing, and access to health information), support of healthy behavior (eg, healthy diet and increased physical activity), or the connection with other patients (eg, social support through peers) [18-20].

Evaluating the Usability of mHealth Apps

It is important to gather qualitative and quantitative data on mHealth apps to determine how satisfied users would be with the product at hand. According to one scoping review, of 133 different eHealth articles that conducted usability testing, 105 used questionnaires, 57 used task completion, 45 used “think aloud,” 37 conducted interviews, 18 performed heuristic evaluation, and 13 used focus groups [21]. The System Usability Scale (SUS) was the most frequently used questionnaire with a total of 44 studies. A combination of methods was used in 88 of the studies. Further, cancer was tied as the second most frequently evaluated health condition (n=10), with only mental health being evaluated more often (n=12).

Usability testing is a common effective method for evaluating the usability of mHealth apps. Studies have shown that usability testing is an effective method for examining mHealth apps for diabetes [22,23], depression [22,24], and youth at risk for developing psychosis [25], as well as managing pain [26], heart failure [27], and cancer symptoms [28]. Common questionnaires often included variations on the Mobile Application Rating Scale [25,27] or the SUS [22,24,26]. Additional techniques often employed in usability testing include measuring time per task [26] and using think aloud techniques [29]. In addition to evaluating fully implemented mobile apps, studies have conducted usability testing on prototypes of mHealth apps for supporting mental health [30], chronic kidney disease [29], fall risk detection system for older users [31], HIV [32], and cancer survivors [33-35]. Many studies have conducted heuristic evaluation before usability testing on an mHealth prototype to fix usability issues before bringing it to users [28,29,32,33]. While Nielsen’s 10-point usability heuristics [36] are geared toward computer-based applications, most of these are also applicable in mobile app design. The SUS questionnaire was also commonly used in usability testing studies for examining mHealth prototypes [29,31,37].

WeCanManage App

We designed a high-fidelity prototype for WeCanManage, an evidence-informed mHealth self-management intervention, aimed at empowering individuals with tools to effectively manage cancer as a chronic condition. Users are asked to log into the app daily for 5-10 minutes to complete mobile microlearning modules of self-management content. The intervention content is based on extensive literature review and formative interviews with cancer survivors with known disabilities (n=30) and supportive cancer care professionals including social workers, psychologists, occupational and physical therapists, and a physiatrist specializing in cancer rehabilitation (n=5) [9]. A team of survivor scientists, people with lived experiences of cancer and disability, further informed intervention content and focus. Intervention content is presented sequentially as information is scaffolded on itself to promote depth of learning, retention, and application. The content is divided into 4 broad sections: WeCanRelate (fosters a sense of

validating and normalizing the survivorship experience), WeCanAdapt (teaches goal direction self-management strategies), WeCanBe (emphasizes mindfulness-based practices), and WeCanSpeakUp (addresses self-advocacy and disability rights). In addition to the instructional content, WeCanManage provides users with 3 circles of support, including one-on-one connections with other users (Connect to Peers [C2P]), community forums (to discuss intervention content and shared experiences with the entire user community), and a library with evidence-informed educational content [38]. We conducted a thorough evaluation of the usability of the high-fidelity prototype for cancer survivors with disabilities, employing both heuristic evaluation and usability testing to assess its effectiveness in addressing the unique needs and challenges of this user group.

Methods

WeCanManage High-Fidelity Prototype

The high-fidelity prototype was created on Marvel [39], a web-based collaborative design platform that provides tools for creating wireframes, designs, and prototypes of interactive applications. We aimed to design WeCanManage specifically for smartphone usage. The prototype of WeCanManage allows users to navigate between the Home, Journey (Courses), C2P, Community (Community Forum), and Library (see Figure 1).

The Course section provides cancer survivors with an educational intervention that works with them on dealing with the long-term effects of their newly acquired disabilities through problem-solving, mindfulness, and self-advocacy. The content is designed to be a 4-week program where the user unlocks a series of microlessons divided into 4 modules (WeCanRelate, WeCanAdapt, WeCanBreathe, and WeCanSpeakUp), which

educate users with different methods to deal with the effects of postcancer treatment in their daily life. To prioritize user control and accessibility, the course content is conveyed through mobile microlearning modules, presented in different formats such as readable text, clickable text-based cards, and audio (Figure 2).

At the end of many of the daily sessions, there are interactive engagement activities, such as reflections that feed into the Community Forum and knowledge checks (see Figure 3). The engagement activities are designed to support consolidation of knowledge and application of course content to the user's lived experiences.

The Community and C2P sections offer users a chance to engage with others, fostering networking opportunities and creating a support system with individuals undergoing similar experiences. C2P facilitates connections with others, allowing users to filter by categories like cancer type and disability, while Community features discussion forums for each of the 4 course sections and an open discussion forum. Lastly, the Library section contains additional evidence-informed resources such as articles and factsheets. The various sections of the prototypes were initially created as a low-fidelity prototype through an iterative co-design approach involving both the design teams and cancer survivors, who served as representatives of our targeted audience [40].

Because of its prototype nature, users could navigate all links, but functionalities such as real-time chat with other users and composing reflections or community posts were not operational. To overcome this, we incorporated simulated features in the prototype, triggering them automatically on user interaction. After creating the high-fidelity prototype, we evaluated it through 2 distinct methods: heuristic evaluation and usability testing.

Figure 1. Screenshots of the WeCanManage prototype: (A) Home, (B) Journey, (C) Connect to Peers (C2P), (D) Community, and (E) Library.

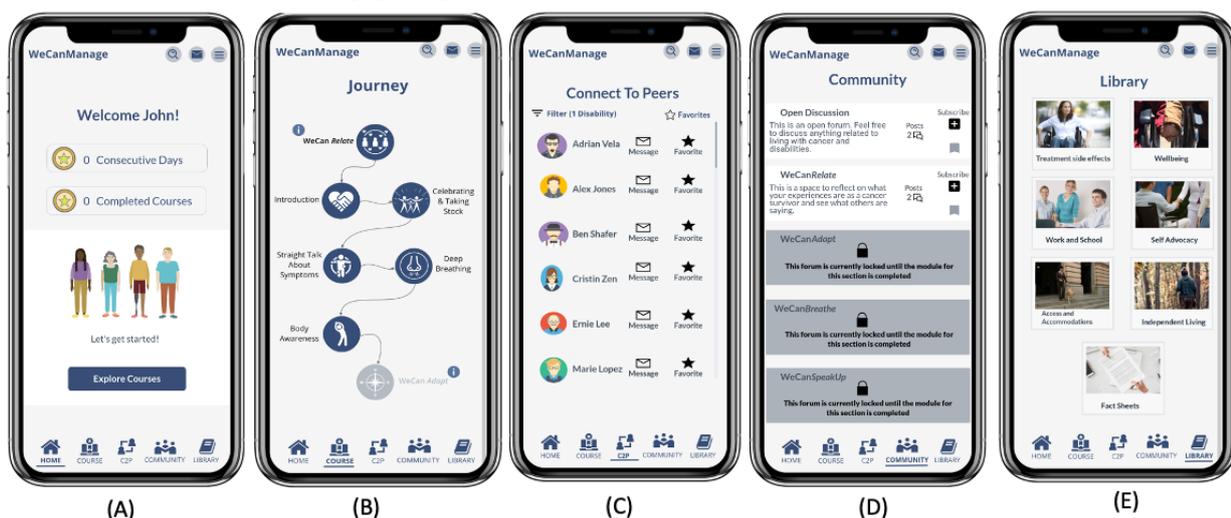

Figure 2. Screenshots before heuristic evaluation: (A) card view and (B) learning format after clicking on the Formats icon.

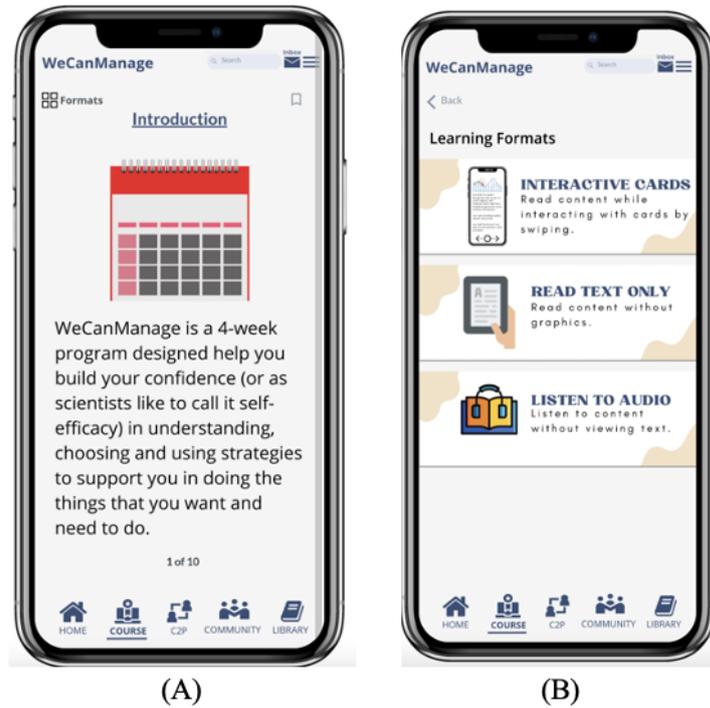

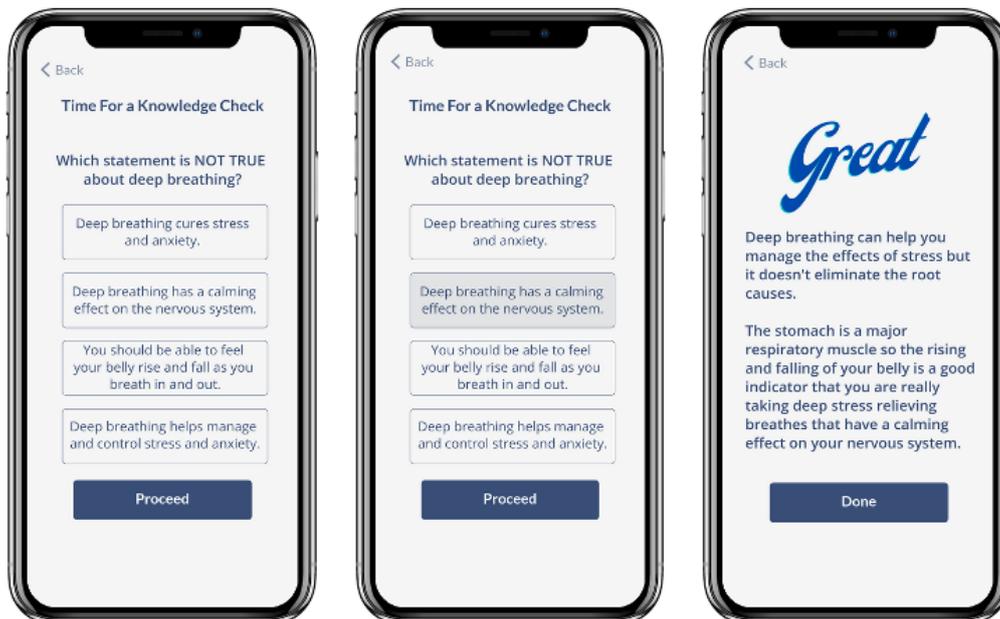

Figure 3. Sample of a knowledge check.

Methodology for Heuristic Evaluation

Nielsen’s 10 principles of heuristic evaluation [36] were used for the initial testing of the prototype (Textbox 1). The prototype was given to 22 undergraduate students at a Midwestern university taking a human-computer interaction course in the Spring of 2022 who were trained in conducting heuristic evaluation. No supplemental demographic data were gathered. They were given the WeCanManage prototype during a class period of 1 hour 15 minutes. During the session, students were split into 6 groups, and each group was given 5 tasks to complete using the prototype. We created 3 sets of 5 tasks, and therefore

every 2 groups completed the same tasks. The tasks included going through the introduction course module, switching to text and video fields, and filtering the users by a specific disability through the C2P page. Students logged in to classroom computers and accessed Maze, an online testing platform used to monitor assessment details [41], recorded the path taken by students to complete tasks, and presented questions about their experience to help track their progress. At the end of the session, the groups documented violations of the 10 heuristic principles and rated their usability severity on a 0-4 scale, where 0 is not a usability problem and 4 is a usability catastrophe. Furthermore, the student evaluators filled out a questionnaire through Maze

providing feedback and thoughts on the prototype's design. The questionnaire covered their likes and dislikes of the design, their

impressions of course modules, and the ease of changing the format of the content.

Textbox 1. Ten principles of heuristic evaluation from Nielsen [36].

1. Visibility of system status
2. Match between system and the real world
3. User control and freedom
4. Consistency and standards
5. Error prevention
6. Recognition rather than recall
7. Flexibility and efficiency of use
8. Aesthetic and minimalist design
9. Help users recognize, diagnose, and recover from errors
10. Help and documentation

Methodology for Usability Testing

We modified the prototype based on the feedback from heuristic evaluation and conducted usability testing over Zoom. We used purposive sampling with targeted outreach through cancer survivorship networks, including both clinical and community. To be eligible for participation, individuals had to meet the following inclusion criteria: be 18 years or older; have a history of breast cancer, head and neck cancer, or sarcoma; have completed active treatment; self-identify as a person with a disability; and possess the ability to understand and communicate in English. Participants received a gift card for their time. Sessions lasted approximately 90 minutes. Sessions were recorded and participants shared their screens for data collection. Participants were told to connect to Zoom on a computer or laptop device. Usability testing occurred between September 2022 and February 2023. As we encountered minor issues with the Maze platform during the heuristic evaluation, including audio malfunctions, we transitioned to Ballpark, an extension of Marvel that facilitated usability testing of the prototype. Participants were given 8 tasks to complete (see [Textbox 2](#)). They were told that they were on day 6 of the 4-week period. Consequently, they could access content from sessions 1-6, while subsequent sessions remained locked to replicate the user's sequential navigation experience, with new content being unlocked on a daily basis. The first 6 tasks were based on the course sessions and navigating through each course by reading the content cards and doing related engagement activities. Task 2 required participants to switch the viewing mode using the accessibility features (eye symbol) to the text-only mode, while task 6 involved watching a 1 minute 20 second-long mindfulness video, instead of the default card format. The final 2 tasks (tasks 7 and 8) focused on navigating the Community Forum and C2P sections. After each task, participants rated their satisfaction level and the time taken to complete each task using a 7-point Likert scale. On finishing all 8 tasks, participants had the opportunity to freely explore

the app using a "think aloud" approach to express their thoughts and experiences.

To evaluate usability, participants completed the modified SUS, a reliable and valid 10-item questionnaire that assesses usability [42,43]. While the SUS has been around since 1986, it has been shown to be effective in evaluating the usability of recent health apps [44]. To calculate SUS scores, 1 is subtracted from the raw score of the odd-numbered items (those items phrased in a positive way), and the raw score of the even-numbered items (those items phrased in a negative way) is subtracted from 5. The total scores are then multiplied by 2.5 to derive the "standardized SUS score," which ranges from 0 to 100. A SUS score of 68 is considered average usability [45], while a score above 80.3 is deemed an A grade, placing it in the top 10% of scores [46] and corresponding to a narrative rating of good-excellent [47]. In addition, we included open-ended questions to gather feedback on participants' preferences and areas for improvement regarding the app. Examples of these questions include "How easy or difficult was it to see all the content on the screen?" and "What did you think of the design of the course modules?"

To assess the effectiveness of the app design, following a similar approach to Adler et al [48], we evaluated task completion by having 2 independent coders review each recording and code whether the participants

- Completed the task quickly on their own (C)
- Completed the task on their own though it took a little longer (L)
- Needed help to complete the task (H)

The coders achieved an agreement percentage of 87.5%. Any discrepancies were resolved through discussion. To assess efficiency, we analyzed the number of misclicks (clicks outside of clickable areas in the prototype) and the time taken to complete each task.

Textbox 2. Eight tasks given to usability testing participants.

Course

1. Go to the Course and click on the WeCanRelate session. Read through all of the cards.
2. Go to the Course and click on the Introduction session. Switch to Text view to read all the cards at once using the eye symbol on the bottom left of the first screen of the module.
3. Go to the Course and click on the Celebrating & Taking Stock session. Read through all the cards and then go to the reflection. Start “typing” your reflection and post it. Do you see your post accurately reflected?
4. Go to the Course and click on the Straight Talk About Symptoms session. Read through the cards and follow the link to the library and the Understanding the Cancer Rehabilitation Team Fact Sheet.
5. Go to the Course and click on the Deep Breathing session. Read through the content and complete the knowledge check. Did you get the correct answer?
6. Go to the Course and click on the Body Awareness session and go through to the end of the module by watching the video.

Community

1. Go to the Community Forum. Create a new post in the Open Discussion forum. Enter a title, select the community tag, enter text, and post your response.

Connect to Peers

1. Find the Connect to Peers (C2P) option and filter to narrow the search to people who are deaf or hard of hearing.

Ethics Approval

We obtained institutional review board approval from the participating universities in the project (University of Illinois Chicago #2020-1067, Northeastern Illinois University #79, and Northwestern University #NUUIC21CC03).

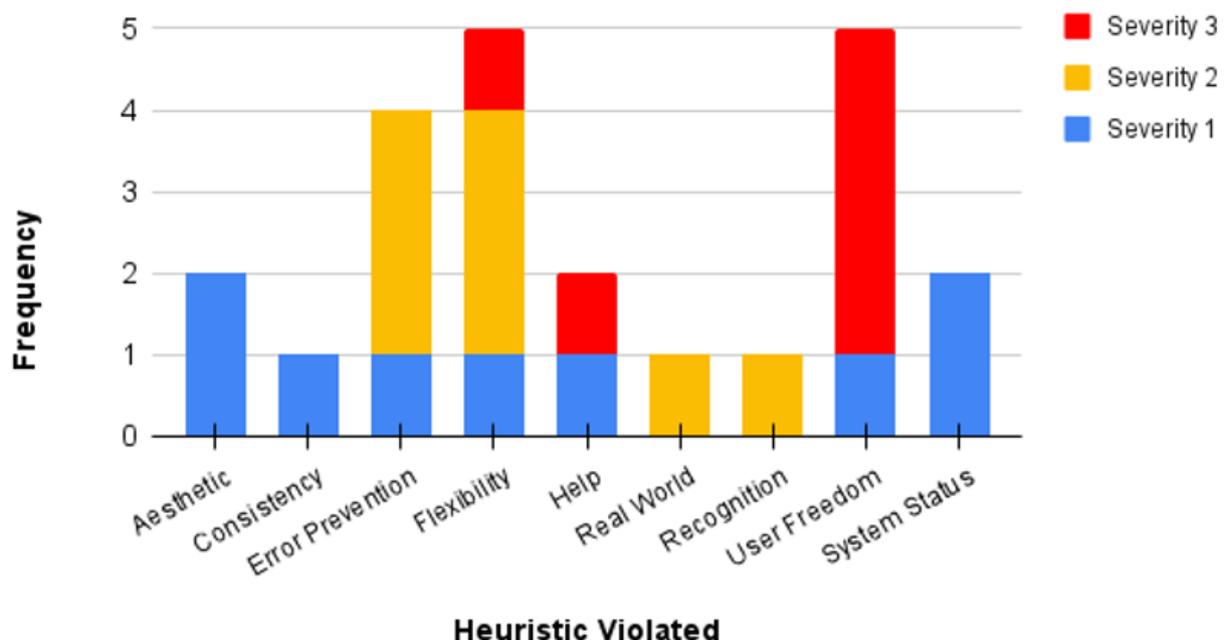

Results

Results of Heuristic Evaluation

We conducted an analysis of the identified heuristic violations and their severity. The highest severity rating recorded was a 3, as illustrated in Figure 4. The most frequent heuristic violations were related to flexibility, user control, and freedom,

followed by error prevention. The issues identified were primarily navigation problems within the prototype, missing back buttons, and font size being too small. Suggestions for improvement were also raised, such as adding an FAQ page, a way to contact the creators or administrators, and including a walk-through or how-to page. Student evaluators expressed appreciation for the images and content, the knowledge check feature, the color scheme, and the layout. They found the app easy to read and navigate. The dislikes expressed included the absence of a help guide and nonfunctional back buttons. Additionally, some groups reported having difficulty finding the format button to switch the mode of learning to text-only or audio.

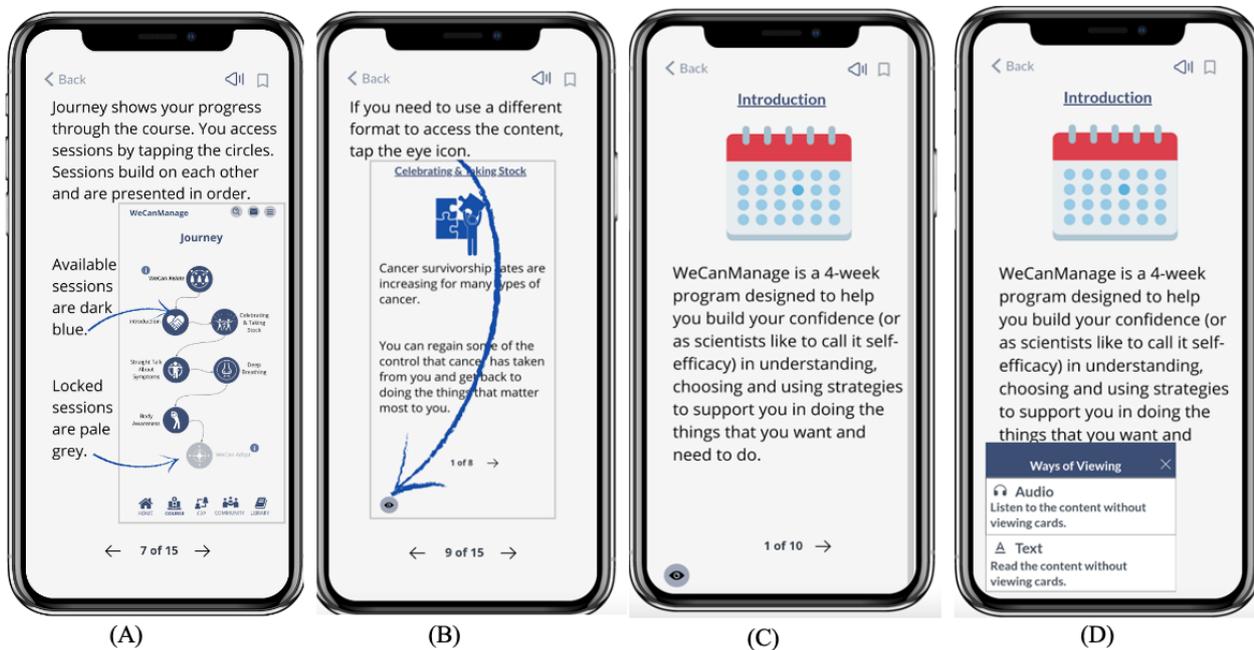

Figure 4. Graph displaying the frequency and severity of heuristic violations.

Modifications Based on Heuristic Evaluation

Drawing from the findings of the heuristic evaluation, we enhanced the prototype by introducing a help guide (Figure 5A and B) and seamlessly integrating it into the first course session. (C,D) Updates to the accessibility format and switching from card view to audio or text views.

Figure 5. Updated prototype screens after heuristic evaluation. (A,B) Help guide incorporated into the first course session. (C,D) Updates to the accessibility format and switching from card view to audio or text views.

Results of Usability Testing

We had 10 cancer survivors with disabilities (9 female, 1 male; 9 White or Caucasian, 1 Black or African American) who completed usability testing. The average age of the participants was 59 years. Usability scores show that participants had an overall positive reception to the design of the prototype. We had an average SUS score of 81; our prototype's usability is therefore considered good to excellent with a grade of an A and in the top 10%.

We assessed participants' satisfaction levels and the time taken to complete each task. The average scores for these 2 measurements are presented in Table 1. Generally, participants exhibited high satisfaction rates; however, lower numbers were observed for task 2 (finding the eye icon to change the accessibility format), task 7 (creating a post in the Community Forum), and task 8 (using the filter in C2P).

In addition, we evaluated the effectiveness of the app design by categorizing participants' task completion into 3 groups: completed quickly (C), completed with a little more time (L), or required assistance to complete the task (H). Overall, most participants completed their tasks without any issues, with only 17 of 80 cases (21%) needing help to complete them (see Figure 6). During task 1, a slight learning curve was observed as some participants had difficulty locating the correct module, leading to the need for assistance in completing the task. However, this issue was not prevalent in subsequent tasks. Task 2 revealed that some participants encountered challenges while switching

We also revised the method for switching accessibility format features (Figure 5C and D). Furthermore, we increased the font size on multiple screens and improved navigation by implementing additional back buttons for a smoother user experience.

the card format to text view using the eye symbol, as they had trouble locating the button. In task 4, some participants faced difficulties clicking on the correct resource within the Library as directed in the learning module. For tasks 7 and 8, several participants struggled to navigate both the Community and C2P sections because certain text and icons were too small or unclear in their function, leading to confusion on what to do.

Likewise, while analyzing efficiency based on the number of misclicks per task, tasks 7 and 8 exhibited notably higher misclick rates (Table 2). The table also presents the actual time taken per task, with task 1 showing higher time than the other tasks. As mentioned earlier, task 1 had a learning curve, but it also involved reading the most cards (15 cards) as we integrated the help guide into the first course session. Therefore, this finding is expected given the additional content to review in task 1.

The prototype's help guide received a positive response, with 8 of 10 participants (80%) rating it as very helpful or extremely helpful. Similarly, 8 of 10 participants (80%) reported finding the eye symbol (to change the course format) easily. In response to open-ended questions, participants expressed their likes and dislikes of the prototype and its design. Many participants shared positive opinions on the design and content of the modules, finding them helpful and insightful. The video located within one of the modules received positive feedback, with some expressing a desire for additional videos. The purpose of the Community section was well liked as participants enjoyed

having a place to freely express themselves with other cancer survivors and appreciated the opportunity for users to support each other. The Library resources were found to be informative and useful, covering a wide range of topics.

Our findings were overwhelmingly positive, supported by quotes from participants (some written and some oral):

I want to see the whole thing work! I know that this is a prototype, but I want to see more!

Great app, it would have been very helpful to me when I was just out [of] treatment.

Even though I'm not very comfortable with technology, and that might be because of my age, ... I don't think that this would be difficult for me. I think there'd be a real fast learning curve. I felt good and positive when I realized I had learned something, and I could just click on it now without having to think about it.

I do like the app. I like that I know I'm not alone feeling this way.

These participant quotes reflect their enthusiasm and positive experiences with the app, highlighting its potential benefits and ease of use.

On the basis of our session observations and participants' feedback on areas for improvement, we identified several issues:

- Accessibility concerns, including small font sizes and icons, particularly with the navigation arrows on cards, the top navigation bar, and the eye icon.
- Some participants experienced confusion while navigating the Community page when creating new posts.
- Difficulty in locating and using the filter option within the C2P page.
- Participants expressed a desire for an easy way to return to the help guide.
- Feedback indicated a preference for changing the robotic voices used in the audio format for the modules. The prototype used Google US English from voicegenerator.io, but the intention is to have a real person's voice in future implementations.

Addressing these areas for improvement can further enhance the app's usability and user experience.

Table 1. Average satisfaction per task and time per task (out of 7).

Task	Average task satisfaction	Average time satisfaction
1	6.5	6.4
2	5.7	5.9
3	6.6	6.5
4	6.5	6.2
5	6.7	6.3
6	6.8	6.6
7	5.2	5.5
8	5.8	5.7

Figure 6. Graph displaying the frequency of H (required assistance to complete the task), C (completed quickly), and L (completed with a little more time) ratings given to participants as they completed a task.

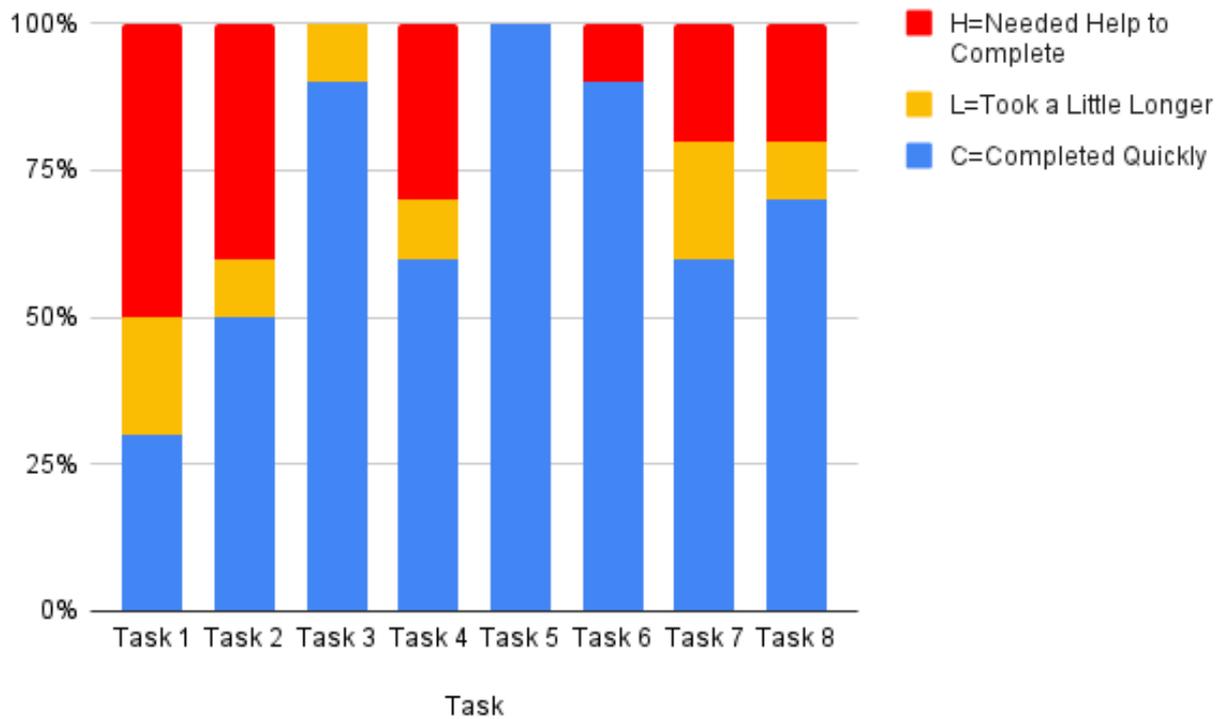

Table 2. Percentage of misclicks and time per task.

Task	Misclicks (%)	Time (minutes)
1	8	3:28
2	4.75	2:28
3	3.30	2:19
4	5.64	2:13
5	0.83	2:15
6	0	1:57
7	19.24	1:34
8	16.38	0:44

Modifications Based on Usability Testing

On the basis of the findings from usability testing, we made several modifications to the prototype. To enhance usability, we increased the sizes of navigation icons, the eye icon, arrows within cards, and the top navigation bar. Throughout the application, we enlarged or bolded fonts for easier reading, including the “create new post” button in the Community section. We redesigned the layout of the Community Forum,

increasing text and margins to achieve a cleaner and more concise design. Additionally, we revamped the subscribe button to reduce confusion (see Figures 7 and 8). To improve accessibility, we enlarged the C2P filter. Finally, we added a convenient way to return to the help guide by including it in the hamburger menu icon on the main page. These changes aim to enhance user experience and address the identified issues during usability testing.

Figure 7. Modifications made to the Community before and after usability testing.

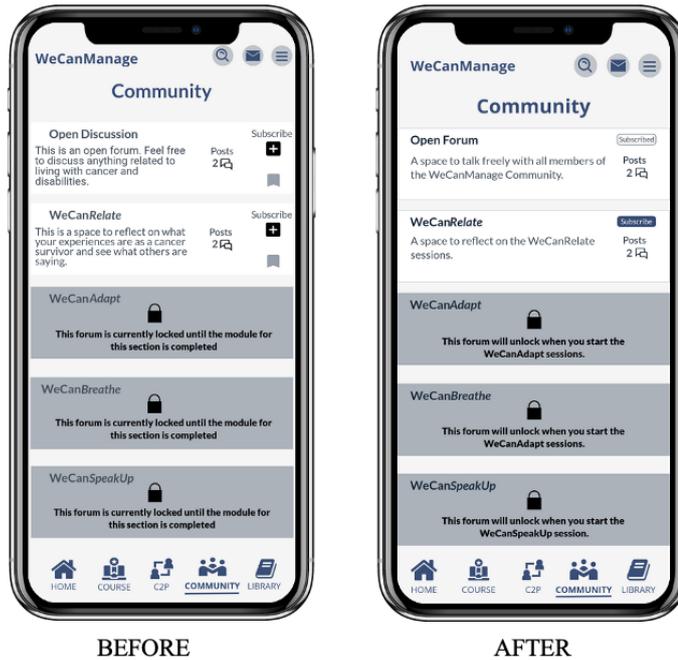

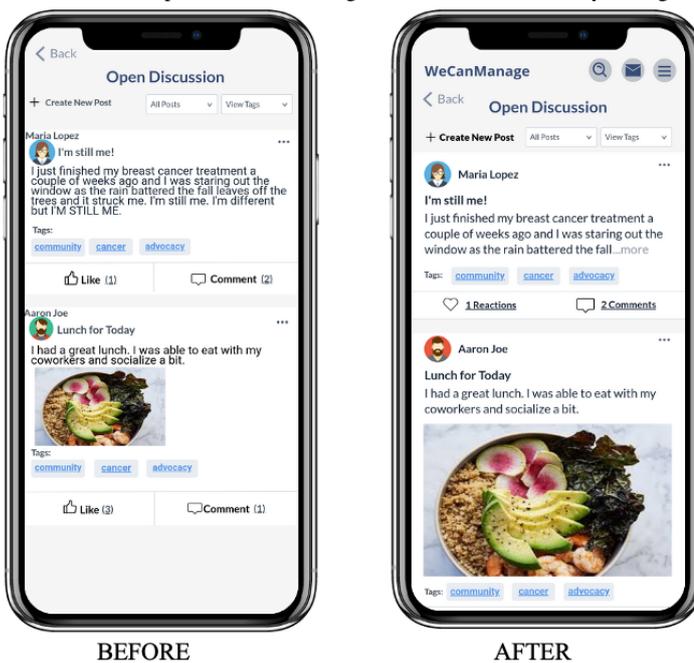

Figure 8. Modifications made to the Open Discussion design before and after usability testing .

Discussion

Principal Findings

Cancer and its treatments can lead to long-term disabilities, significantly impacting a survivor’s overall quality of life [10]. Unfortunately, postcancer treatment resources are often limited, further exacerbating the challenges faced by survivors [49,50]. To address this, we developed a high-fidelity prototype for an mHealth app called WeCanManage, aimed at empowering

cancer survivors with disabilities to effectively self-manage the long-term effects of cancer treatment. Through conducting the heuristic evaluation, valuable improvements were made, including the incorporation of a helpful guide and the enhancement of accessibility formatting options, ultimately enhancing the overall user experience of the app.

In usability testing, we engaged cancer survivors with disabilities, using multiple methods such as task completion, think aloud strategies, SUS, perceived task satisfaction, and

open-ended questions. These methods have been extensively used to evaluate various applications, with the SUS being one of the commonly used questionnaires [21]. The results of usability testing were overwhelmingly positive, with cancer survivors expressing appreciation for the app's content, features, and design. The prototype achieved an impressive SUS score of 81, ranking it in the top 10% of scores and earning an A grade. Moreover, participants reported high satisfaction levels and efficiency, with average scores of 6.2 and 6.1 (out of 7), respectively. Conducting usability testing enabled us to thoroughly assess the app's overall effectiveness, efficiency, satisfaction, and usability. We were able to identify areas for improvement, particularly in terms of accessibility. The insights gained from this testing process have allowed us to refine and enhance the app, ensuring a positive user experience for cancer survivors with disabilities.

In a study by Fuller-Tyszkiewicz et al [24], end users rated an mHealth prototype higher in usability and reported a more positive experience than clinical experts. Interestingly, users did not share the same concerns about the amount and layout of content presented as the experts had anticipated [24]. This discrepancy underscores the significance of testing potential users to tailor the app to their specific needs and preferences. While expert opinions (whether clinical or in design) are valuable, evaluating an app on actual users is ideal.

Implications for Designers and Researchers

One of our primary findings is the importance of accessibility when designing applications for cancer survivors. Our app was specifically designed for cancer survivors with disabilities, and as such, we incorporated customized options to switch the learning style. Users could choose between clicking through content cards and accessing audio or text-only views. This flexibility proved to be helpful, particularly for participants with cognitive issues like "chemo brain," who found it easier to navigate the audio versions of the course sessions. However, during testing, we identified other accessibility concerns related to font sizes and icons. Some users found them too small to see, click on, and navigate effectively. Addressing these issues is essential to ensure an inclusive and user-friendly experience for all app users.

The importance of having a help feature was revealed during heuristic evaluation, and through usability testing, we learned that users expressed a desire for a convenient way to return to the help guide. In response to this feedback, we have now incorporated the option to access the help guide directly from our main menu.

One comment expressed by many of our participants was how lonely the experience of a cancer survivor is. Consistent with findings from other studies that highlight the significance of social features in mHealth apps [51], participants expressed their appreciation for the Community Forum and C2P sections. These features provide a valuable opportunity for them to connect with others facing similar situations, fostering a sense of community and support. Additionally, participants reported that reading the content in the course sessions made them realize that their experiences were shared by others, helping them feel less isolated and reassured that they were not alone in their

journey. When asked what they liked about the app, one participant wrote the following: "The information, reliable and trustworthy, ... and the realization that I am not alone."

Limitations

Our aim was to achieve a minimum of 12 participants for usability testing, as SUS results are ideally derived from 12 or more participants [52,53]. However, we encountered challenges in recruitment because of technical difficulties, such as some participants lacking access to a laptop or facing issues with Zoom and screen sharing, leading to incomplete usability testing. Additionally, recruitment was hindered by our specific inclusion criteria, which focused on individuals who identified as having a disability. These challenges impacted our ability to reach the desired number of participants for the usability testing phase. Nevertheless, it is worth noting that according to Nielsen [54], 5 participants are typically adequate for identifying usability problems. Thus, we can reasonably infer that our processes have successfully identified the majority of issues, providing a level of confidence in the validity of our findings despite the lower number of participants in the usability testing phase. Additionally, it is worth mentioning that several studies evaluating mHealth prototypes have used the SUS with fewer than 12 participants [29,31,37]. We encountered instances where some participants experienced lingering effects of cancer and its treatment, but they did not self-identify as having a disability, resulting in their exclusion from usability testing. This finding has important implications for the implementation and adoption of WeCanManage, ensuring that cancer survivors experiencing disabling aftereffects can fully benefit from the tool and appreciate its relevance and value in their daily lives and experiences.

Furthermore, as this was a prototype, not all features were fully implemented (eg, the ability to create a post on the forum or direct message a user was mimicked), which may have caused some participants to encounter difficulties in the Community section of the prototype. In addition, during usability testing, participants expressed concerns regarding text and icon sizes. It is important to note that the testing was conducted over Zoom using computers (not mobile devices), and the prototype's size (matching that of a phone) might have posed challenges during interaction, which may not be representative of the real application's experience. Finally, it is worth noting that the age of participants and their level of comfort with technology might have influenced their overall experience [55]. Nevertheless, because these individuals constitute our target user base, it remains essential for us to maintain the app's usability and accessibility to meet their needs.

Conclusions

When creating an mHealth app, it is crucial to evaluate it with the target users in mind, in our case, cancer survivors with disabilities. Usability testing allowed us to identify the design's strengths and areas requiring improvement. The WeCanManage prototype achieved a SUS score of 81, placing it in the top 10% of scores. Our future work will involve feasibility testing of an implemented web-based mobile app of WeCanManage. This will enable us to further refine the application and ensure that

it meets the needs and preferences of our target users, enhancing its overall usability and impact.

Abstract

Background: As Japan is the world's fastest-aging society with a declining population, it is challenging to secure human resources for care providers. Therefore, the Japanese government is promoting digital transformation and the use of nursing care equipment, including nonwearable devices that monitor heart and respiratory rates. However, the feasibility of monitoring heart and respiratory rates with nonwearable devices and the consistency of the rates measured have not been reported.

Objective: In this study, we focused on a sheet-type nonwearable device (Safety Sheep Sensor) introduced in many nursing homes. We evaluated the feasibility of monitoring heart rate (HR) and respiratory rate (RR) continuously using nonwearable devices and the consistency of the HR and RR measured.

Methods: A sheet-type nonwearable device that measured HR and RR every minute through body vibrations was placed under the mattress of each participant. The participants in study 1 were healthy individuals aged 20 - 60 years (n=21), while those in study 2 were older adults living in multidwelling houses and required nursing care (n=20). The HR was measured using standard methods by the nurse and using the wearable device (Silmee Bar-type Lite sensor), and RR was measured by the nurse. The primary outcome was the mean difference in HR and RR between nonwearable devices and standard methods.

Results: The mean difference in HR was -0.32 (SD 3.12) in study 1 and 0.04 (SD: 3.98) in study 2; both the differences were within the predefined accepted discrepancies (<5 beats/min). The mean difference in RR was -0.98 (SD 3.01) in study 1 and -0.49 (SD 2.40) in study 2; both the differences were within the predefined accepted discrepancies (3 breaths/min).

Conclusions: HR and RR measurements obtained using the nonwearable devices and the standard method were similar. Continuous monitoring of vital signs using nonwearable devices can aid in the early detection of abnormal conditions in older people.

KEYWORDS

heart rate; older adults; respiratory rate; nonwearable devices; vital signs

Introduction

The vital signs of older adults change with age [1,2], making it necessary to monitor them at their residences and in nursing homes [3,4]. Continuous monitoring of their heart rate (HR) and respiratory rate (RR) to obtain essential data and immediate assessment of any abnormality by medical personnel have proven successful in reducing hospitalization and mortality rates [5]. However, measuring vital signs once or twice daily for older people living at home and in nursing homes is unrealistic [6]. Moreover, the impact of COVID-19 necessitated remote monitoring of vital signs with fewer visits from medical staff to prevent infections [7].

Therefore, continuous vital sign monitoring devices that can be used without affecting daily activities must be developed.

Wearable devices (WDs), including wrist-worn devices [8], ViSi Mobile (Sotera Wireless, Carlsbad, CA) [9], and health patches (VitalConnect, San Jose, CA) [9], can monitor vital signs without interfering with daily activities. Measuring vital signs continuously with a WD may improve patient comfort and safety [10-12] and reduce nurse workload [10] by reducing the number of nurse-conducted measurements. However, redness and itching are common among older adults using WDs [9] because their skin is particularly fragile and WDs come in direct contact with the skin [13]. Therefore, developing and introducing nonwearable devices (NWDs) for monitoring older patients continuously is desirable [14].

NWDs, which measure vital signs without direct patient contact, reduce older adults' feeling of restraint and awareness of being monitored as well as the workload associated with vital sign assessments for care providers. NWDs such as highly sensitive fiber optic mattress [11,15] and office chairs [16] are being researched and developed. Verification of its use in magnetic resonance imaging as well as in medical and nursing care settings is underway [17] and has attracted widespread attention.

As Japan is the world's fastest-aging society with a declining population [18], it is challenging to secure human resources for care providers [19]. Therefore, the Japanese government is promoting digital transformation and the use of nursing care equipment, including NWDs. Many nursing homes have purchased and introduced NWDs since 2015 when the government started providing assistance payment for such devices as policy guidance [20,21]. Sheet-type NWDs, such as Safety Sheep sensors α (NJI Co., Ltd., Fukushima, Japan), NEMURI SCAN (Paramount Bed Co., Ltd., Tokyo, Japan), and Mimamoleaf (Techno Horizon Co., Ltd., Nagoya, Japan), have been developed and introduced in Japan. We focused on Safety Sheep sensors α , which is a monitoring device that has been introduced in many nursing homes [22], including 3319 nursing homes in Japan as of December 2022. This NWD includes a highly sensitive pressure sensor placed under a mattress and does not come in contact with the individual's skin. It detects body vibrations and calculates the individual's status (lying on bed/moving on bed/getting out of bed), HR, and RR every minute. These data are displayed on a monitor at nursing homes. Care providers check these data and, if they are abnormal, can take immediate action and provide appropriate care.

However, the data from NWDs, including sheet-type NWDs, cannot be used by nursing homes as longitudinal data to evaluate changes in individuals accurately and provide appropriate care [23] because the consistency of the HR and RR measured by such instruments has not been evaluated yet [24]. Moreover, based on the accumulated data, it may be possible to detect deteriorating conditions during end-of-life care and unplanned hospital visits at an early stage, concentrate care on high-risk targets, and improve the quality of care using fewer personnel. Therefore, this study aimed to evaluate the feasibility of continuous HR and RR monitoring and consistency of the rates measured using the NWD.

Methods

Setting and Participants

This was a prospective, observational, and pilot feasibility study. Two studies were conducted to evaluate the feasibility of continuous HR and RR monitoring, and the consistency of the HRs and RRs was measured using an NWD (Safety Sheep sensors α). In this study, the study power was calculated based on a previous study [9], and a sample size of 20 was estimated to obtain sufficient data for analysis.

Study 1: Healthy Participants

Study 1 included 22 healthy participants aged 20 - 60 years who were working at a company. The authors recruited participants from June 1 to June 30, 2022. Participants were

excluded if they had been diagnosed with heart or respiratory disease. To maintain the privacy of the participants, their vital signs were measured in a private room in company A. The NWD was placed under the mattress after preparing a bed. Each participant came to the room at separate designated times for measurements.

Study 2: Older Adults Who Needed Nursing Care

Study 2 included 26 older adults aged ≥ 65 years who were living in multidwelling houses managed by a company and required nursing care. Each multidwelling house had a care worker who was available for 24 hours daily. Thus, older adults who required nursing care could immediately receive nursing care from their care workers. Managers working in multidwelling houses recruited older adults for this study from July 1 to October 30, 2022. Participants diagnosed with cardiac or respiratory disease or those with implanted medical electronic devices, such as pacemakers, were excluded. Each participant was visited at appointed dates and times, and their HR and RR were measured in their rooms.

Data Collection

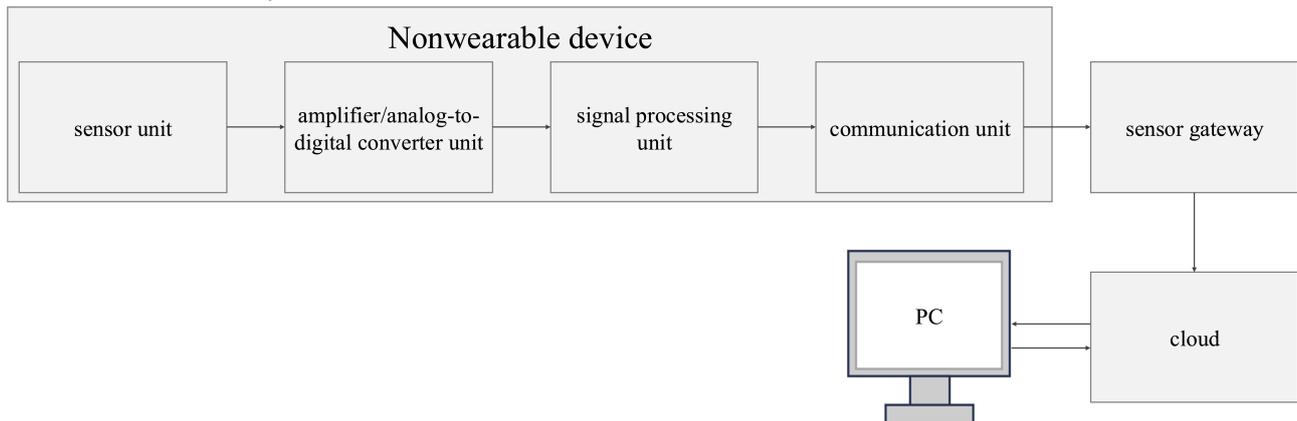

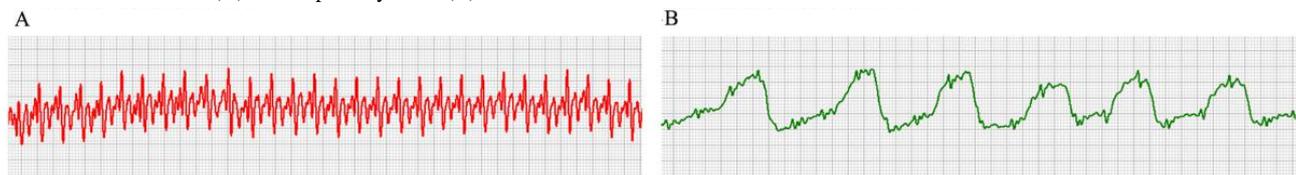

In this study, data were collected by 2 nurses: one measured the HR and RR, while the other recorded them. They waited for the participant to visit the private room at company A in study 1 but visited the participant's room themselves in study 2. First, the nurses explained the purpose and methods of this study to the participants. Second, the participants lay on a bed with the NWD in place. Third, the nurse who took the measurements attached a WD to the participants' chests and asked them to rest for 5 minutes. The same nurse then measured the RR over 1 minute and reported five sets of measurements to the recording nurse. The recording nurse documented the start time of the measurement and the number of RRs. After a 1-minute break, the HR was measured using the same method. After completing the measurements, the participants were informed that the procedure was complete, and the WD was removed. Finally, the participants were checked for skin abnormalities.

Measurement

Nonwearable Device

The Safety Sheep sensor α (width 800 mm; height 17 mm; depth 150 mm) was used as the NWD (Figure 1) [25]. In the multidwelling house, this NWD was placed in all the residents' beds. The NWD comprises a sensor unit, amplifier/analog-to-digital converter unit, signal processing unit, and communication unit (Figure 2). The HR and RR are determined from heartbeat- and respiration-derived vibration waves transmitted through the device, respectively.

First, in the sensor unit, 6 piezoelectric elements capable of detecting minute vibrations are placed at 10-cm intervals. The vibrations generated by the participants mainly included those derived from heartbeat, respiration, and body movements. The vibration data acquired at the sensor section are converted into digital data at the amplifier/analog-to-digital converter unit. Subsequently, in the signal processing unit, HR and RR are determined from the digitally converted data (Figure 3).

Figure 2. Nonwearable device system.**Figure 3.** Heartbeat wave (A) and respiratory wave (B).

Heartbeats have relatively high-frequency components and occur at periodic intervals; after passing through a high-pass filter, characteristics derived from heartbeats are extracted, and HR is detected from the intervals between the extracted characteristics. The frequency components of respiration mainly have low-frequency components and occur at relatively regular intervals; after passing through the low-pass filter, the same process used to detect HR is used to detect RR. The frequency components of body movement are mainly low-frequency components, like respiration, but often do not repeat cyclically, and the amplitude is much larger than that of respiration. Very large signals are generated simultaneously on several piezoelectric elements, distinguishing them from respiration. The determined HR and RR are sent via the communication unit and Raspberry Pi to the cloud. Care workers at the nursing homes can access the cloud server using a web application on their personal computers and view the data with a browser (Figure 2).

Measurement of Vital Signs by Nurses

In this study, the standard method used to measure HR and RR was performed by nurses as previously described [9,10,26]. Briefly, 2 nurses with 20 years of experience measured the HR and RR of all participants. The nurse measured the HR by touching the participant's radial artery for 1 minute, and the RR by visually observing the thoracic movement for 1 minute. The nurse avoided touching the mattress while taking the measurements to eliminate interference.

Electrocardiograms and respiratory effort belts are other standard methods for measuring HR and RR; however, they are difficult to use in nursing homes staffed with only a few medical professionals [27,28]. Moreover, these contact devices have many electrodes and are not recommended for use in nonhospital settings as they cause physical restraint and discomfort in older adults [28]. Therefore, in this study, the standard method was

used to ensure the safety of older adults and avoid causing discomfort.

Wearable Device

A Silmee Bar-type Lite sensor (TDK Co., Tokyo, Japan; width 64 mm; height 96 mm; depth 28 mm) was used as the WD to measure the HR of participants. This device could simultaneously measure electrocardiogram signals, pulse wave, acceleration, and skin temperature and was set to 125 Hz for the electrocardiograph and offline mode. This device was attached to the participants' chests at 3 cm below the collarbone using a special gel pad, and their electrocardiogram signals were measured. The HR was calculated per minute based on the time between heartbeats, which is the device output from an electrocardiogram.

HR cannot be measured visually but is preferably measured at the location of the heart. Therefore, we measured the HR both by using the WD and by manually palpating the participant's radial artery as mentioned in the previous section.

Collection of Basic Information

In study 1, the following items representing basic participant information were self-reported: sex, age, height, weight, respiratory diseases, and heart diseases. In study 2, the following data were collected from care workers in multidwelling houses: sex, age, height, weight, level of care needed, and diagnosis of dementia. Older adults who required nursing care were classified based on their care needs as levels 1 - 5. Each municipality has certified care needs according to the level of nursing care required [29,30]. Care need level 1 requires relatively low assistance, while care need level 5 requires extensive assistance with personal care.

Data Analysis

The primary outcome was the mean difference between the HR and RR measured using the NWD and those measured by the nurses and the WD. We defined $HR < 5$ beats/min and $RR < 3$

breaths/min as the accepted mean difference before starting the study. We also defined the maximum error not leading to a change in care or observation as the criterion based on previous studies [9,31].

HR and RR data from the NWD were each compared with measurements taken by the nurses and WD at the same time point. The measured data were compared at each time point, and measurement errors were calculated. Subsequently, Bland-Altman plots were created to assess the agreement between the data measured using the NWD and those measured using the WD [32,33]. This method has been widely used in comparative studies [32,34]. We calculated the mean difference and 95% limits of agreement (LoAs) between the NWD data and manually measured data. Python (version 3.8.1; Python Software Foundation) and R statistical software (version 3.6.3; R Foundation for Statistical Research) were used for analysis. All statistical tests were 2-sided, and statistical significance was set at $P < .05$.

Ethical Considerations

This study was conducted in accordance with the principles of the Declaration of Helsinki and approved by the Human Study Ethics Committee of the authors' affiliated university (approval number: M2021-374).

The participants were informed about the study aims and procedure, both verbally and in writing, and consented to participate by signing a consent form. For older adults with

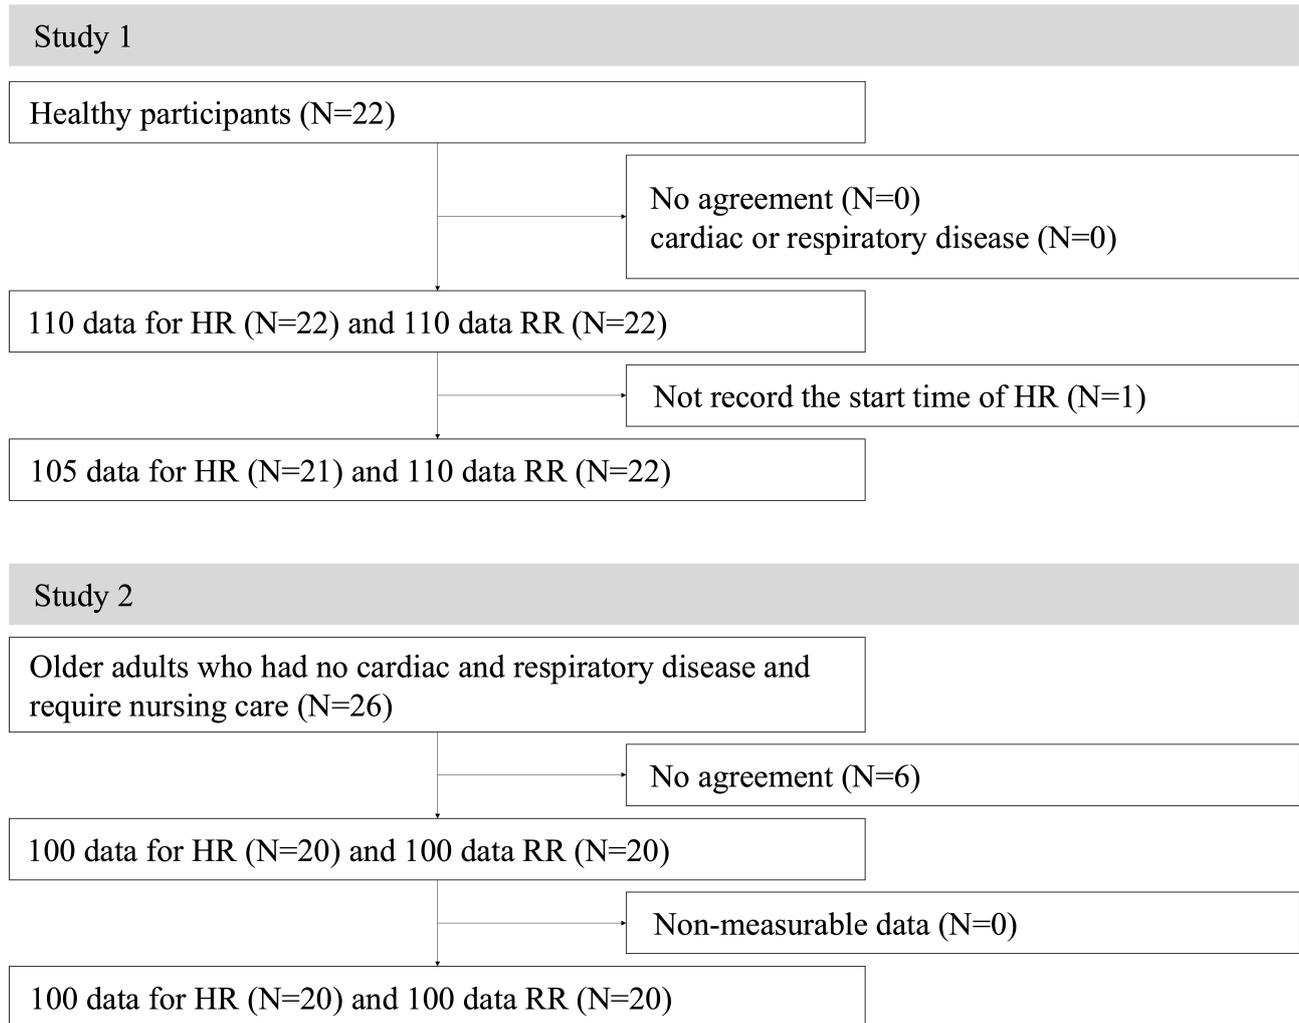

difficulty communicating due to dementia or other cognitive impairments, their relatives were contacted, and their proxy consent was obtained. All participants (and their family members, when needed) were informed that participation in the study was voluntary and that they could withdraw at any point. Moreover, we explained that the participants would not be disadvantaged by not participating in the study, discontinuing participation, or withdrawing their cooperation. To protect privacy and confidentiality, the data collection nurse assigned each participant an identification number, and the list linking names and identification numbers was kept by the nurse. The researchers did not have access to this list, ensuring that the data remained anonymized.

HR measurement using the WD required direct contact with the skin; therefore, we attempted to protect the skin by applying a protectant (PureBarrer; Granmate Co., Chiba, Japan) before attaching the device. After the measurements, a release agent (3M Cavilon Remover; 3M, Maplewood, MN) was used for careful removal. No compensation was provided to participants for their involvement in this study.

Results

Demographics

A total of 22 healthy individuals participated in study 1 (Figure 4). The study population included 11 (50%) male participants and 11 (50%) female participants with a mean age of 47 (IQR 32.5 - 57) years (Table 1).

Figure 4. Flow diagram depicting the inclusion and exclusion of study participants.**Table .** Participants' characteristics for studies 1 and 2. Data are presented as median (IQR) or n (%).

	Value
Study 1 (n=21)	
Male sex, n (%)	11 (50)
Age (years), median (IQR)	47 (32.5 - 57.0)
Body mass index (BMI; kg/m ²), median (IQR)	22.2 (20.6 - 23.9)
Study 2 (n=20)	
Male sex, n (%)	3 (15)
Age (years), median (IQR)	87.5 (85.0 - 90.5)
BMI (kg/m ²), median (IQR)	22.1 (20.1 - 23.6)
Respiratory disease, n (%)	0 (0)
Care need level 1, n (%)	7 (35)
Care need level 2, n (%)	6 (30)
Care need level 3, n (%)	6 (30)
Care need level 4, n (%)	0 (0)
Care need level 5, n (%)	1 (5)
Dementia, n (%)	12 (60)

In study 2, 26 older adults requiring nursing care were selected, of whom 20 participated (Figure 4). Three older adults did not consent, and 3 could not obtain consent from their families. The study population included 3 (15%) male participants and 17 (85%) female participants with a mean age of 87.5 (IQR 85 - 90.5) years (Table 1). Among the participants, 7 (35%) needed care level 1, 6 (30%) needed care level 2, 6 (30%) needed care level 3, and 1 (5%) needed care level 5. None of the participants dropped out during the study periods in studies 1 or 2.

Technical Feasibility

In study 1, 110 HR data points (22 participants) and 110 RR data points (22 participants) were measured. The start time of HR measurement was not recorded for 1 participant owing to human error. Therefore, the NWD, WD, and nurse measurements for this participant could not be merged. We excluded the HR data of the participant (5 data points) and included 105 data points for HR (21 participants) and 110 data points for RR (22 participants).

In study 2, 100 data points each for HR (20 participants) and RR (20 participants) were measured. There were no missing

data; therefore, 100 data points each were included for the HR (20 participants) and RR (20 participants).

Heart Rate

The mean differences measured by the NWD, nurses, and WD are shown in Table 2. The mean HR in study 1 measured by the NWD was 66.57 (SD 8.45) beats/min, the nurse measured 66.25 (SD 8.05) beats/min, and the WD recorded 66.57 (SD 8.45) beats/min. The mean HRs in study 2 measured by the NWD, nurse, and WD were 64.22 (SD 6.13), 64.18 (SD 7.20), and 65.21 (SD 7.84) beats/min, respectively.

The Bland-Altman plots are shown in Figure 5 and Table 3. The mean, differences, and LoAs (1.96 SD) were plotted. The y-axis in Figure 5 indicates the measurement differences and LoAs. First, the differences between NWD and nurses for 95% were within the LoAs; however, wide LoAs were observed (study 1 [lower LoA to upper LoA]: -6.86 to 4.90; study 2: -7.72 to 7.80). Second, the differences between NWD and WD for 95% were within the LoAs; however, wide LoAs were observed (study 1: -3.42 to 4.02; study 2: -7.20 to 9.26).

The differences in the HR measurements are presented in Table 4. Approximately 90% of the measurement differences were within 5 measurements in studies 1 and 2.

Respiratory Rate

The mean differences measured by NWD, nurses, and WD are shown in Table 2. The mean RR in study 1 measured by the NWD was 13.54 (SD 3.31) breaths/min, and by the nurse was 12.55 (SD 3.27) breaths/min. The mean RR in study 2 measured by NWD was 16.14 (SD 2.89) breaths/min and by the nurse was 15.65 (SD 3.22) breaths/min.

The Bland-Altman plots are shown in Figure 5 and Table 3. The mean differences and LoAs (SD 1.96) were plotted. The y-axis in Figure 5 indicates the measurement differences and LoAs. The differences between the data obtained from the NWD and nurses for 95% were within the LoAs. However, wide LoAs were observed (study 1 [lower LoA to upper LoA]: -6.41 to 5.76; study 2: -5.17 to 4.19).

The differences in RR measurements are presented in Table 4. Approximately 90% of the measurement differences were within 5 measurements in studies 1 and 2.

Discussion

This study evaluated the feasibility of monitoring HR and RR continuously using an NWD placed under the participant's mattress and measured the consistency of the rates. The consistency of the HR and RR measured was proved by the finding that the mean differences in HR and RR calculated using the NWD in healthy participants and older adults who required nursing care were within the predetermined and accepted cutoffs. Moreover, none of the participants dropped out of the study or complained of physical abnormalities. Therefore, continuous

monitoring of vital signs using NWDs is feasible at residences and in nursing homes.

First, no participants dropped out or complained in this study. Although a WD can provide accurate measurements, skin redness and itching have been reported due to skin contact with the device [9]; in contrast, our study participants did not report such skin-related issues. Moreover, if participants are aware that they are being monitored, their RR may tend to be lower than normal [35]. NWDs provide a nonintrusive alternative that allows for continuous monitoring in bed without skin contact or irritation [36]. In this study, an NWD yielded HR and RR values that were close to normal values because the patients were not uncomfortable and were less likely to notice that they were being monitored.

Second, we showed the correlation of HR measured using the NWD. The mean difference in HR measured using the NWD was within the predetermined acceptable range (study 1: -0.32 and 0.33 [nurse and WD, respectively] and study 2: 0.04 and 1.03 [nurse and WD, respectively]). In addition, the HRs measured with the NWD and WD were similar in this study. The mean differences in HR measured using other WDs are reportedly -0.20 (SD 5.54) [9], -1.1 (SD 3.8) [31], and 1.8 (SD 1.8) [37], close to those observed in this study. The device used in these previous studies was a wireless WD with electrodes attached to the anterior chest [9,31]. Although there are differences in measurement methods (ie, direct vs indirect contact with the skin), measurement positions (anterior chest vs posterior back), and device systems (electrical signals of the heart vs waves from body vibrations), the consistency in HR measurements suggests that both NWDs and WDs achieve

similar accuracy. WDs can monitor an older adult's activity continuously without much discomfort [36]. Both NWDs and WDs are noninvasive and can be easily integrated into the daily lives of older adults [38]. Therefore, it is important to select the appropriate device based on the specific needs and condition of the patient.

Third, we showed the correlation of RR measured by the NWD. The mean difference in the RR measured using the NWD was within the predetermined acceptable range (study 1: -0.98 ; study 2: -0.49). The mean differences in RR measured using other WDs are -2.3 (SD 6.8) [23] and 1.19 (SD 3.43) [9], similar to that in this study. We observed that the NWD could measure RR almost as well as the nurses, with a low measurement error (<5 breaths/min). However, a large difference of 17 breaths/min was seen in the measurement error (5 and 22 breaths/min for the nurse and NWD, respectively), consistent with a previous study by Weenk et al [9], who reported a difference of 26 breaths/min. In the present and previous studies, nurses assessed RR by visually observing the chest [9]. The reproducibility of the method is limited by high interobserver variability [39], and a large difference was expected in this study. In addition, the number of events related to the reliability of bradycardic and tachycardic respiration was low in this study. Therefore, their reliability could not be evaluated. The reasons for this include the short measurement time per participant, exclusion of participants with cardiac or respiratory disease, and starting the measurement after the participants had rested for 5 minutes. In the future, it is necessary to conduct long-term measurements, such as overnight measurements, to evaluate events related to the reliability of bradycardic and tachycardic respiration in older adults.

The strength of our study is that we evaluated the consistency of HR and RR measured using an NWD that has already been introduced in many facilities in Japan, and suggested the possibility of improving the nursing home environment. We believe that monitoring the HR and RR of older adults safely and unobtrusively when they are in bed may help in detecting sudden changes and providing suitable care without frequent visits. NWDs reduce the number of vital sign measurements and rounds and the burden on care providers, nurses, and care workers, allowing them to concentrate on care [40]. Given the

declining population and limited number of health care workers, devices with consistent HR and RR will help optimize the patient's environment. Therefore, we believe that NWDs can be applied in various facilities.

This study had some limitations. First, the participants were healthy or older adults without cardiac or respiratory disease. Therefore, the consistency in participants with cardiac and respiratory diseases should be examined further. Second, the measurement times for HR and RR in this study were short (5 minutes). When the NWD was installed at the residences and nursing homes, participants were continuously monitored while they were in bed. The disadvantages of continuous measurements, such as those taken overnight, were not considered. Third, the criterion measurement is lacking. In this study, nurse-based measurement was selected as the criterion for HR and RR as described in many studies [9,18,26]. Contact devices, such as electrocardiography, have also been used [8,9]. However, they are known to cause skin issues, such as peeling of the stratum corneum and red spots [41,42]. In this study, older adults (whose skin is typically more fragile) were recruited [13]. Therefore, we decided to use nurse-based measurement to prevent any discomfort and adverse events among the study participants. Ideally, HR and RR should have been measured using both methods. Despite these limitations, the consistency of HR and RR measured using the NWD suggests that this method may be useful for monitoring vital signs at residences and in nursing homes.

This study evaluated the feasibility and consistency of measuring HR and RR using an NWD placed under the mattress. The mean differences in HR and RR measured by the NWD were both within the predefined accepted discrepancies. No physical abnormalities were noted during the measurements. Therefore, we suggest using these devices at residences and in nursing homes. Safe monitoring of vital signs using NWDs is expected in the future for the early detection of abnormal conditions without inconveniencing older adults, care workers, and nurses. We believe that NWDs promote medical digital transformation, which will enable care providers to observe conditions accurately and provide appropriate care through the data obtained from such devices.

Acknowledgments

We would like to thank all the participants in this study. We would also like to thank Ms Kazumi Sato, Ms Kaori Sato, and other staff of NJI Co., Ltd. for their cooperation. This study was supported by the Japan Society for the Promotion of Science Grants-in-Aid for Scientific Research (grant 21H04849 to SF) and NJI Corporation (grant 21AB100084 to SF).

Data Availability

Data from this study are available by contacting our research team.

Authors' Contributions

KI, AM, MNW, and SF contributed to the research idea, study design, and organization of the study. KI contributed to data management and statistical analysis. KI, AM, MNW, and SF contributed to the interpretation. KI, AM, MNW, and SF contributed to data acquisition. Each author has reviewed, discussed, and agreed to their individual contributions ahead of submission.

Conflicts of Interest

SF and MNW received grant support from NJI Co., Ltd., which developed the Safety Sheep Sensor.

Abstract

Background: The exponential growth in computing power and the increasing digitization of information have substantially advanced the machine learning (ML) research field. However, ML algorithms are often considered “black boxes,” and this fosters distrust. In medical domains, in which mistakes can result in fatal outcomes, practitioners may be especially reluctant to trust ML algorithms.

Objective: The aim of this study is to explore the effect of user-interface design features on intensivists' trust in an ML-based clinical decision support system.

Methods: A total of 47 physicians from critical care specialties were presented with 3 patient cases of bacteremia in the setting of an ML-based simulation system. Three conditions of the simulation were tested according to combinations of information relevancy and interactivity. Participants' trust in the system was assessed by their agreement with the system's prediction and a postexperiment questionnaire. Linear regression models were applied to measure the effects.

Results: Participants' agreement with the system's prediction did not differ according to the experimental conditions. However, in the postexperiment questionnaire, higher information relevancy ratings and interactivity ratings were associated with higher perceived trust in the system ($P < .001$ for both). The explicit visual presentation of the features of the ML algorithm on the user interface resulted in lower trust among the participants ($P = .05$).

Conclusions: Information relevancy and interactivity features should be considered in the design of the user interface of ML-based clinical decision support systems to enhance intensivists' trust. This study sheds light on the connection between information relevancy, interactivity, and trust in human-ML interaction, specifically in the intensive care unit environment.

Introduction

Overview

In the intensive care unit (ICU), intensivists make an extremely high number of decisions. For example, McKenzie et al [1] found that approximately 100 decisions are made every morning round. According to Ward et al [2], despite the continual increase in the number of ICUs, the number of intensivists remains about the same, resulting in an extremely high

workload. The high rate of decision-making together with the continuous overload prompts the need for decision support tools.

Although machine learning (ML) algorithms and systems serving the medical community are continually increasing, their adoption into routine health care practice is not guaranteed [3]. One reason is the complexity of the algorithms, which often leads to clinicians' lack of trust in such systems [4]. A multidisciplinary approach may enhance trust, by considering the human factor, the technological aspect, and the interaction between them [5]. This study examined 2 human-automation

interaction features that emphasize the importance of the human factor in the design of ML-based clinical decision support systems (CDSSs).

Clinical Decision Support Systems

To date, many CDSSs are categorized as “expert systems”—systems that try to imitate the way an ideal physician would think. These systems generate conclusions based on sets of rules [6]. In contrast, ML algorithms approach problems in the opposite way—they generate rules from historical data [6,7]. ML algorithms are currently being developed in almost every field of medicine and, in many instances, are already providing equal or even greater accuracy than physicians (eg, [8-10]). However, though ML CDSSs can enhance the quality of care, the adoption of such systems in all medical fields, and specifically in critical care, remains low [11].

In contrast to expert systems, ML algorithms are complex, and understanding and explaining the reasoning underlying them is often impossible [12]. Thus, ML algorithms are frequently considered black box algorithms. This fosters physicians’ distrust and skepticism of ML systems [13] and has been suggested as a major cause of the low rates of adoption and acceptance of these systems within the medical community [14]. Wrong decisions made by intensivists can result in severe and even fatal outcomes. Thus, they may be reluctant to share their decision-making responsibilities with black box CDSSs that they do not understand [11].

Interpretable ML

As ML algorithms are developed to serve humans, human interaction with them must be considered. One approach to move from a “black box” to a “clear box” [15] lies in the growing field of interpretable ML [16-19]. Miller [20] offered an approach that combines artificial intelligence, social science, and human-computer interaction (HCI). He referred to “human-agent interaction” as the intersection of these 3 domains, including it as part of the interpretable ML field. Impressive work has been performed on interpretable ML in the HCI community (eg, [21-24]). Unfortunately, the ML community and the HCI community do not always work together [25]. This results in poor usability of many interpretable ML algorithms [20], yet opens an opportunity for HCI and

interaction design researchers to seek means of enhancing trust in ML CDSSs [26].

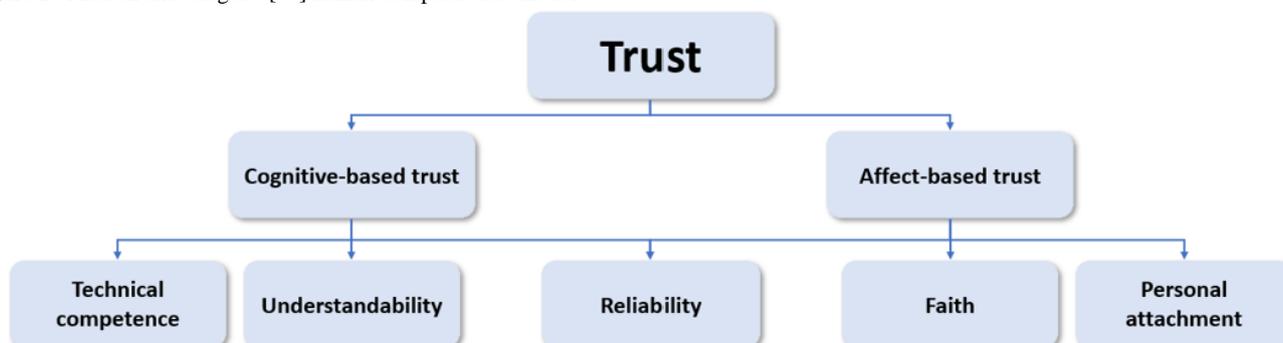

Human-Automation Trust

Parasuraman and Riley [27] defined automation as a technology that executes “a function that was previously carried out by a human.” This wide definition covers all kinds of machines, computers, and applications of artificial intelligence. Human-automation trust is a well-studied subject (eg, [28-34]). In the context of human social interactions, trust can be defined as “the willingness to be vulnerable to the actions of another person” [35]. Research has shown that humans perceive computers as social actors and may interact with them as they would with each other [36-38]. The interaction between humans and automated systems, or, in the context of this study, intensivists and black box algorithms, has also been shown to be substantially influenced by trust [31].

Although human-automation trust is being researched by many disciplines, no dominant model or approach has been determined for its measure. However, a well-accepted conclusion is that trust is not a standalone construct, but rather multidimensional [32]. In this study, we used the definition of Lee and See [29] for human-automation trust “an attitude that an agent will help achieve an individual’s goals in a situation characterized by uncertainty and vulnerability.” This definition corresponds well with the interaction between intensivists and ML CDSSs, even though the ICU environment is characterized by high levels of both uncertainty and vulnerability.

According to Madsen and Gregor [30], human-computer trust is comprised of 2 main dimensions—cognition-based trust (CBT) and affect-based trust (ABT). CBT is based on the user’s intellectual perceptions of the system’s characteristics, while ABT is based on the user’s emotional responses to the system. The 2 dimensions can be further subdivided. CBT is comprised of the understandability of the system and the technical competence of the system, whereas ABT is comprised of faith, personal attachment, and reliability. Madsen and Gregor [30] note that reliability was also found to influence CBT, although its influence on ABT is stronger. The researchers suggested a questionnaire for measuring trust, which we implemented in this study (Figure 1).

Figure 1. Madsen and Gregor’s [30] human-computer trust model.

Aim

The primary aim of this study was to investigate the influence of elements of the user interface (UI) design on intensivists’

trust in ML-based CDSSs (“black-box”-based algorithms). From the many UI elements that can be modified, the 2 that were chosen and compared are information relevancy and interface interactivity.

The literature is abundant regarding information relevancy, interactivity, and trust, as well as the influence of the 2 former factors on the latter. However, to the best of our knowledge, no research has assessed connections between information relevancy, interactivity, and trust in the context of human-ML interaction, specifically in the context of the ICU environment.

Hypothesis 1: Information Relevancy

Information relevancy concerns the degree to which users perceive that the information content of a system meets their needs [39]. This factor was found to positively influence user satisfaction with websites [39,40] and users' trust in health infomediaries [41]. Relevant information has been found to be an attribute that is more crucial for users than usability and convenient use of the system [42]. Considering the above, our hypothesis is as follows:

- *Higher levels of information relevancy will lead to higher levels of trust in the system.* [H1]

Hypothesis 2: Interface Interactivity

Interactivity can be defined in various ways. For this study, we used a common definition by Steuer [43]—"the extent to which users can participate in modifying the format and content of a mediated environment in real time." Interactivity is considered to strongly influence users' experiences during the interaction [44] and is key to the success of e-commerce websites [45-47]. Interactivity was found to increase users' trust in websites in general and specifically in e-commerce, mobile commerce [48,49], and brand loyalty [44]. Although most of the literature on interactivity has focused on e-commerce trust and intentions to use websites, we expected greater interface interactivity to positively influence the interaction between ML CDSSs and intensivists, and to enhance their trust. Considering the above, our hypothesis is as follows:

- *Higher levels of interface interactivity will lead to higher levels of trust in the system.* [H2]

Methods

Overview

To test the hypotheses, a laboratory experiment with 3 conditions was designed. This enabled testing the effects of

Table . The experimental conditions.

	Noninteractive	Interactive
Nonrelevant information	1	^a
Relevant information	2	3

^aNot tested.

Apparatus and Stimuli

A total of 3 UIs that represent 3 medical conditions were designed using Axure RP software (version 9.1; Axure Software Solutions, Inc). The interfaces were imitating an ML bacteremia prediction system. The system, which at the time of the study was still in its development stage, provides prediction and a list

information relevancy and interactivity on intensivists' trust in a simulated ML-based bacteremia prediction system. Bacteremia is a common phenomenon in ICUs, that clinicians need to identify and respond to [50]. Thus, a decision support system that assists clinicians in identifying this condition can serve as a good reference for generalizing and deriving implications for the UI design of many ML-based CDSSs. Each experimental condition was characterized by a different set of UI. The effects were measured with both a behavioral measure (the participants' decisions that were captured by the simulation software) and a postexperiment questionnaire that captured their perceived understanding of the system.

Participants

The participants were 47 physicians (female: n=14; male: n=33) from critical care specialties of 5 tertiary hospitals in Israel. They were recruited through a convenience sample of on-duty physicians and were free to withdraw from the study at any time. The experiment was conducted for 1 month, between the first and second COVID-19 lockdowns in Israel. All the participants were compensated with a gift card (US \$15) and there were no exclusion criteria except for being a critical care physician.

Ethical Considerations

This research complied with the American Psychological Association Code of Ethics and was approved by the institutional review board at Ben-Gurion University of the Negev (21-12-19). Informed consent was obtained from each participant.

Experimental Design

To test the hypotheses, a 2 × 2 (relevant/nonrelevant × interactive/noninteractive) between-subjects fractional factorial experiment was designed. The experiment included 3 conditions (as shown in Table 1). The 15 - 16 participants were randomly assigned to 1 of the 3 conditions; the duration of their performance was not limited. A total of 3 clinical cases of patients who were hospitalized in an ICU with medical conditions implying bacteremia onset were extracted. The presentations of these cases were designed by 3 experienced intensivists to provide accurate context.

of the main features that were significant for the prediction algorithm. The right section of all the interfaces presented similar time-series charts. The charts included trends over time for the 10 clinical measures that are most related to bacteremia prediction. The information that was presented in the left section was manipulated to match the 3 conditions. An example of an interface (condition 2) is shown in Figures 2-4.

Figure 2. The right section shows the time-series chart, and the left section shows the patient's current clinical measures. HR: heart rate; ICU: intensive care unit; MAP: mean arterial pressure; RR: respiratory rate; WBC: white blood cell count.

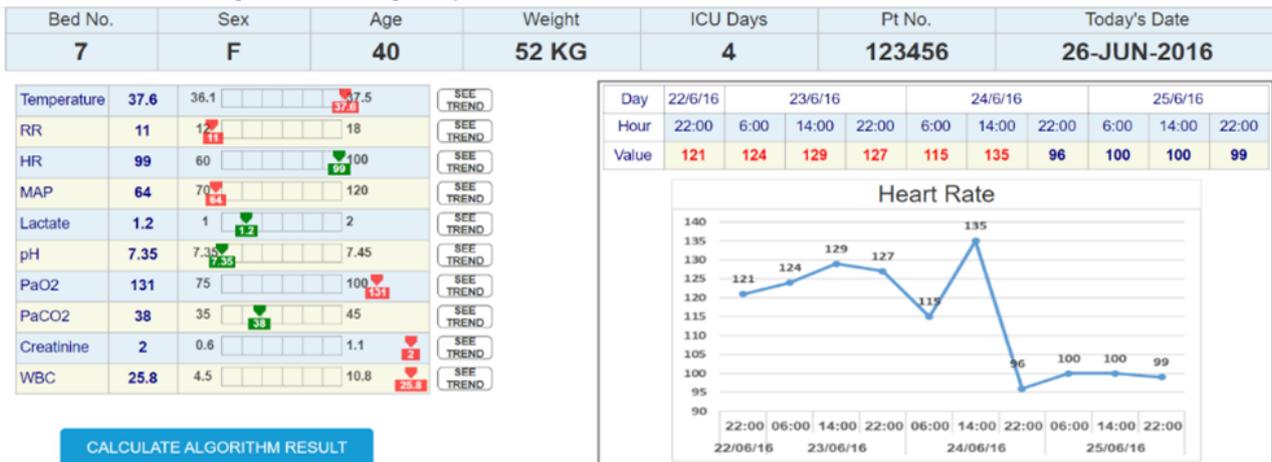

Figure 3. The bacteremia prediction system calculates the result. HR: heart rate; ICU: intensive care unit; MAP: mean arterial pressure; RR: respiratory rate; WBC: white blood cell count.

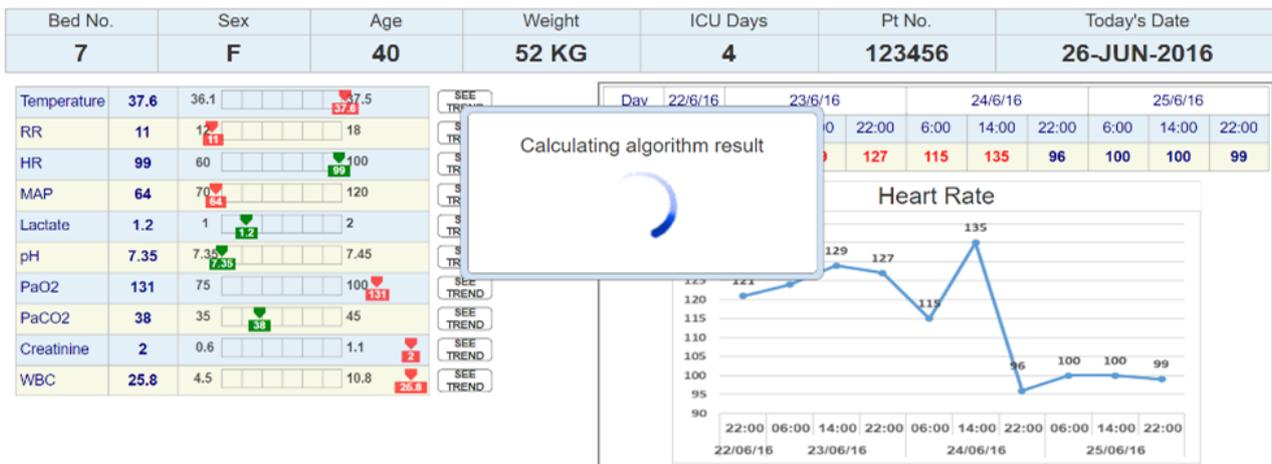

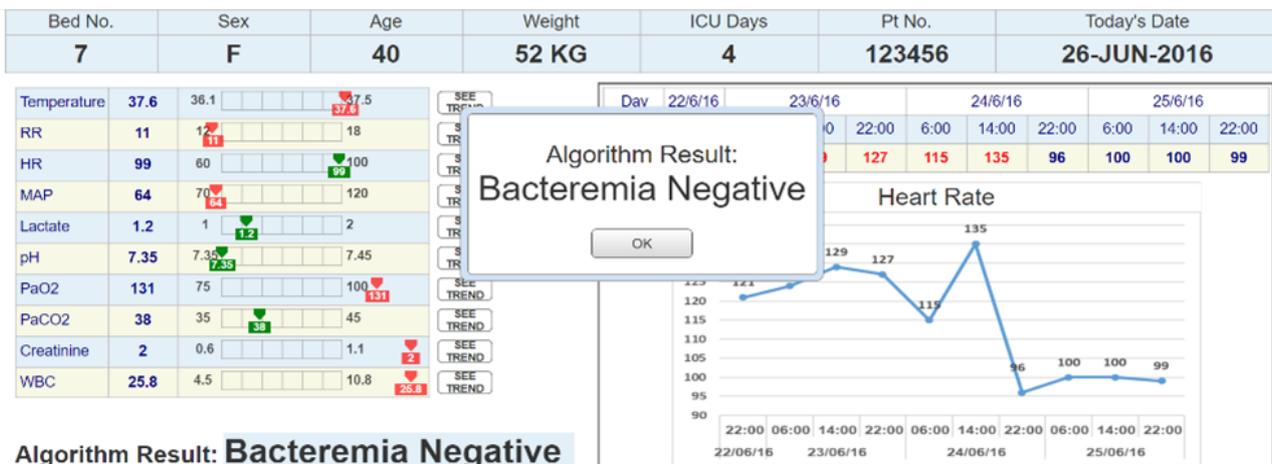

Figure 4. The bacteremia prediction system presents its prediction. HR: heart rate; ICU: intensive care unit; MAP: mean arterial pressure; RR: respiratory rate; WBC: white blood cell count.

Algorithm Result: **Bacteremia Negative**

The information relevancy level was set by the type of clinical measurements that were presented in a table in the left section of the chart. For the relevant information conditions, the information presented in the table comprised the current values

of the same clinical measures that clinicians usually use to assess a patient's condition. In addition, the normal range of each measure was presented. In the nonrelevant information condition, the information presented in the table comprised the

values of the 10 features that were ranked as most important by the bacteremia ML prediction algorithm for making the prediction. Although these features were most significant for the prediction algorithm, they were not usually used by clinicians and, therefore, were considered nonrelevant (see Figure 5).

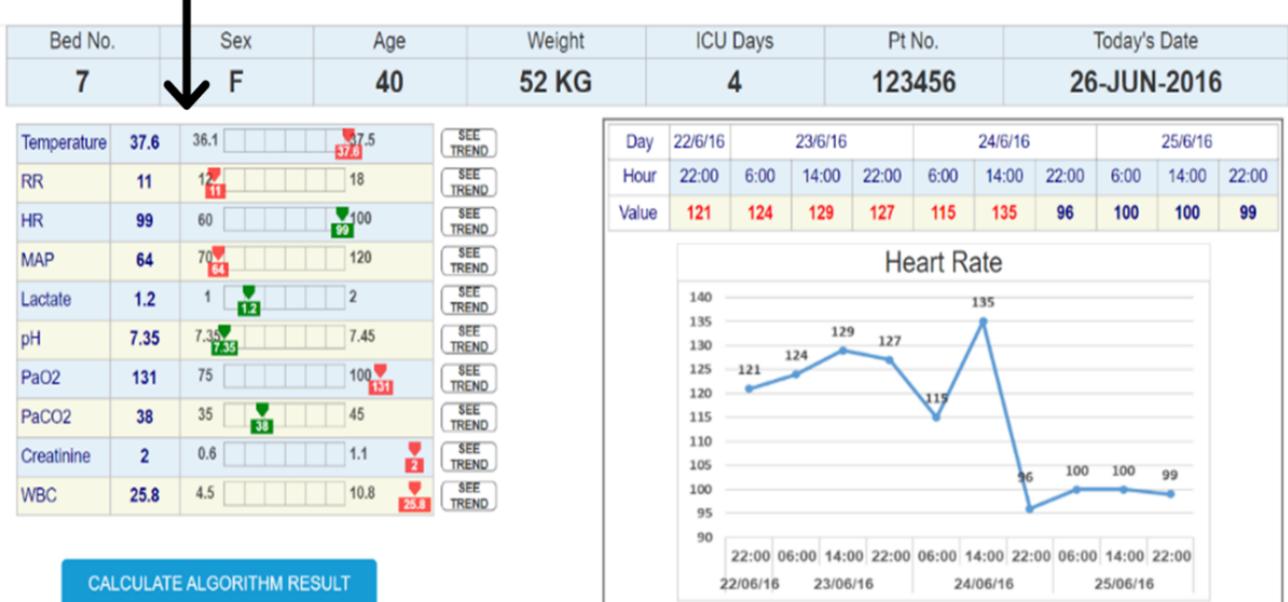

The interface interaction level was set by the type of interaction that the participants were assigned with the UI. In the interactive condition, the participants were required to enter values of the patient's current clinical measures (the values provided in the written clinical case) before they could explore the other charts and information. Entering and copying values to and from the

patient record is a common task clinicians apply in a subset of the IT systems in the ICU. In the noninteractive conditions, the information about the patients appeared right away, and the participants could only explore the information and ask the system for its prediction (see Figure 6).

The fourth combination, nonrelevant information and interactivity, was not tested, as in the nonrelevant information condition, the information that was presented was of the features of the algorithm. Thus, including the algorithm features in the clinical case and entering them into the UI would seem unrealistic.

Figure 5. The relevant and nonrelevant conditions. The top frame shows the relevant information condition with the patient's current clinical measures; the bottom frame shows the nonrelevant information condition with the values of the algorithm's most important features. ArtBPD: arterial line blood pressure; HR: heart rate; ICU: intensive care unit; MAP: mean arterial pressure; PEEP: positive end-expiratory pressure; P/F ratio: PaO₂/FIO₂: oxygen arterial pressure to percentage of inspired oxygen ratio; RR: respiratory rate; WBC: white blood cell count.

Relevant information - Patient's current clinical measures

Nonrelevant information – The algorithm's most important features

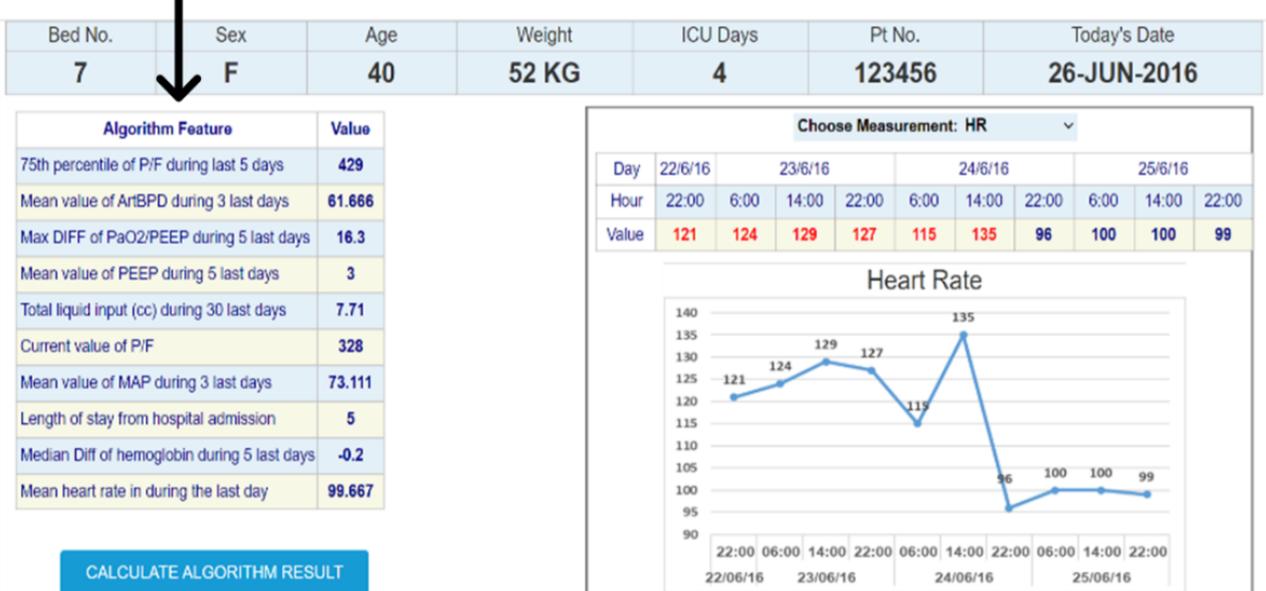

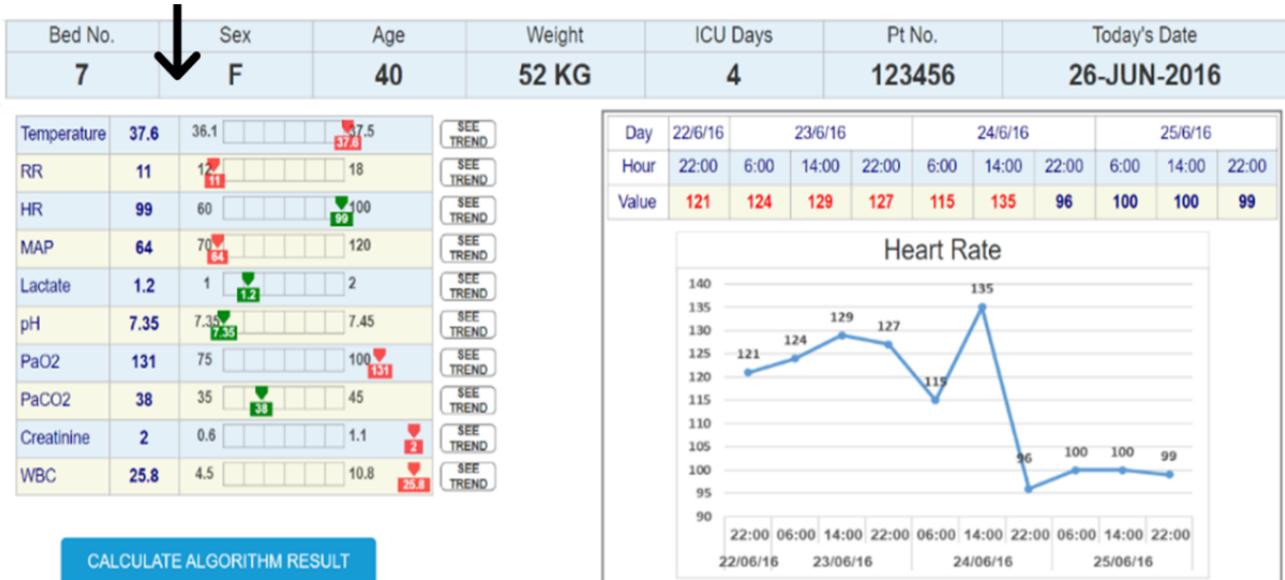

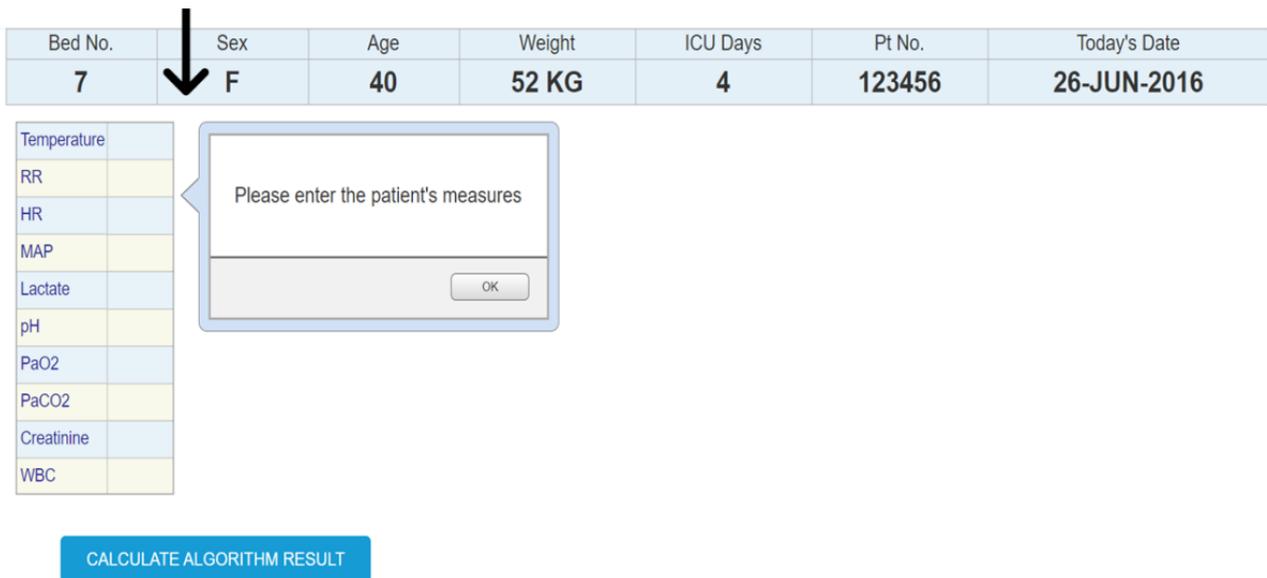

Figure 6. The interactive and noninteractive conditions. The top frame shows the noninteractive condition. The bottom frame shows the interactive condition, in which participants had to actively engage with the UI and provide the patient's current clinical measures, before they could explore the other charts and information. HR: heart rate; ICU: intensive care unit; MAP: mean arterial pressure; RR: respiratory rate; UI: user interface; WBC: white blood cell count.

Noninteractive UI - Information appears right away

Interactive UI – The user must enter patient measures

Procedure

The participants were introduced to the purpose of the study and received an explanation about the ML bacteremia prediction system. They were then introduced to the simulation software, with the UI fitting the condition they were assigned. The participants were asked to first read the clinical case, and only then to explore the UI. After exploring the UI, they could click on the “calculate algorithm result” button to receive the algorithm’s prediction. The predictions that were presented to the participants were accurate. Participants in the interactive condition had to enter the values of the patient’s current clinical measures before the system calculated the algorithm result. All the participants were asked to handle the information as though

they were taking the described patient under their care, and the information provided was all that was available to them.

After the algorithm presented its prediction, the participants could continue to explore the UI and the information presented, and then answer whether they agreed with the algorithm’s prediction or not. After answering this question, they proceeded to the same procedure with two additional clinical cases. To avoid order bias, counterbalancing was used. The number of times participants agreed with the system’s prediction represents their reaction to the system.

Postexperiment Questionnaires

After completing the 3 clinical cases, the participants answered 2 demographic questions about their experience and gender and 3 questionnaires about their trust in the system, the interactivity

of the system, and the information relevancy of the system. The postexperiment questionnaires measured perceived understanding of the system. These consisted of the AIMQ (AIM quality) questionnaire [51] to measure information relevancy, 7 items from an interactivity questionnaire [44] that assessed interactivity, and 14 items from a questionnaire that assessed trust [30]. The latter questionnaire associated the CBT subdimensions of understandability, technical competence, and reliability from the human-computer trust questionnaire. All the questionnaires used a 7-point Likert scale (1=low and

7=high). See Table 2 for the entire list of the variables. To control for possible variance, the gender and years of experience of the participants were recorded. These analyses were performed because studies have shown a significant impact of gender [5,28,52] and years of experience [29,53] on the interaction of humans with automation, and a consequent influence on the development of human-automation trust. The questionnaire questions are presented in Multimedia Appendix 1.

Table . The experiment variables.

Construct	Scale	How it was measured
Years of experience	Continuous	Demographics
Gender	Nominal	Demographics
UI ^a level of information relevancy	Binary	By design
UI level of interactivity	Binary	By design
Information relevancy rating	Discrete (1-7)	AIMQ ^b questionnaire [51]
Interactivity rating	Discrete (1-7)	McMillan and Hwang [44]
Understandability	Discrete (1-7)	HCT ^c ; Medsen and Gregor [30]
Technical competence	Discrete (1-7)	HCT; Medsen and Gregor [30]
Reliability	Discrete (1-7)	HCT; Medsen and Gregor [30]
Cognitive-based trust	Discrete (1-7)	HCT; Medsen and Gregor [30]
Agreement with the system	Discrete (0 - 3)	Simulation software

^aUI: user interface.

^bAIMQ: AIM quality.

^cHCT: human-computer trust.

Data Analysis

To measure the participants' immediate reaction to the system, the participants were grouped by the number of times they agreed with the system's prediction. This information was compared with their information relevancy rating. Due to the different group sizes, the Welch test was used to conduct the comparisons.

A linear regression model was used to assess the influence of several variables on trust as a single construct (cognitive-based trust). Although the 2 study hypotheses aimed to identify the main effects of information relevancy and interactivity on trust, variables 1 - 6 (years of experience, gender, UI level of information relevancy, UI level of interactivity, information relevancy rating, and interactivity rating) were included in the model to control for possible variance. Interactions were assessed on gender and years of experience with all the other variables.

Three linear regression models were used to assess the effect of CBT subdimensions. Variables 1 - 6 were included in the

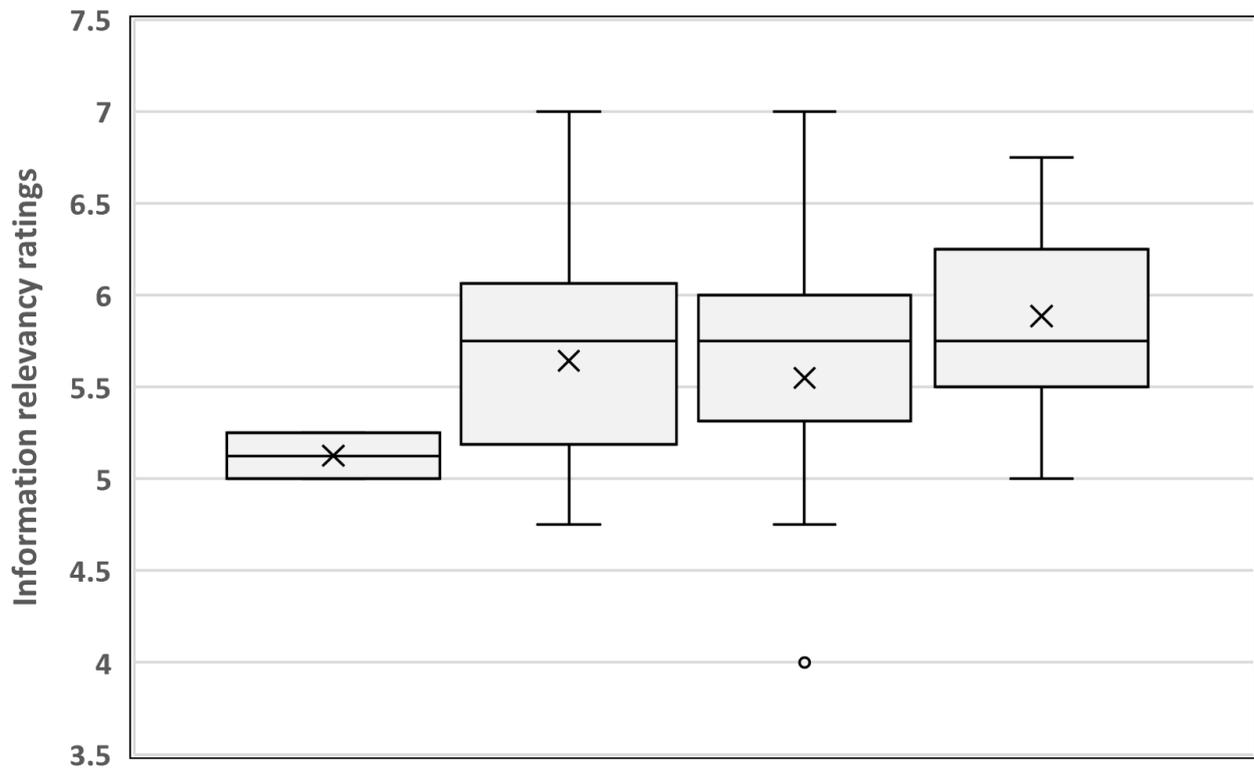

models to control possible variance. Interactions were assessed on gender and years of experience with all the other variables.

Results

Participants' Agreement With the System's Prediction

The conditions of the experiments (variables 3 and 4; Table 2) were not found to be associated with the participants' trust in the system. However, participants' responses to the postexperiment questionnaires reveal significant findings. Overall, the higher the participants rated information relevancy, the more frequently they agreed with the system's prediction. Information relevancy was rated significantly higher among those who agreed 3 times with the system's prediction compared to those who did not agree at all ($t_{11}=-3.924$, 2-tailed; $P=.05$). No other comparisons between the groups were significant (see Figure 7). Participants' agreement with the system's prediction did not differ according to their experience, gender, or the interactivity ratings of the system.

Figure 7. Box plot of the information relevancy ratings and the number of times participants agreed with the system’s prediction. A significant difference was found between participants who agreed with all the system’s prediction and participants who did not agree at all.

Trust as a Single Construct

The significant main effect for the UI level of information relevancy revealed that relevant information resulted in higher perceived trust ($\beta=2.684; P=.05$). Higher information relevancy ratings ($\beta=.824; P<.001$) and higher interactivity ratings ($\beta=.613; P<.001$) were associated with higher perceived trust in the system. A significant interaction between UI level of interactivity and years of experience ($\beta=-.056; P=.05$) revealed lower trust ratings among experienced participants with higher

interactivity ratings. The adjusted R^2 of the regression model was 0.5296.

CBT Subdimensions

A significant main effect was observed for the UI level of information relevancy and technical competence ($\beta=4.5; P<.001$). In addition, across all the models, significant main effects for information relevancy ratings and interactivity ratings were observed. The statistical measures are summarized in [Table 3](#). No other significant main or interaction effects were observed across the subdimensions.

Table . Statistics for the subdimensions of the cognition-based trust (CBT) dimension.

CBT subdimension	$\beta_{\text{information relevancy ratings}}$	$P_{\text{information relevancy ratings}}$	$\beta_{\text{interactivity ratings}}$	$P_{\text{interactivity ratings}}$
Technical competence	1.18	<.001	.6	<.001
Understandability	.4	<.001	.53	<.001
Reliability	.72	<.001	.53	<.001

Discussion

Principal Findings

Trust is difficult to measure. Participants’ agreement with the system’s prediction did not differ according to the experimental conditions. However, in the postexperiment questionnaire, higher information relevancy ratings and interactivity ratings were associated with higher perceived trust in the system, and the explicit visual presentation of the features of the ML algorithm on the user interface resulted in lower trust by the participants.

Information Relevancy

The results of our experiment revealed that information relevancy plays an important role in operators’ trust in ML-based systems. Two different, but complementary questions were addressed and they are (1) to what extent does relevant information enhance intensivists’ trust in ML-based CDSSs? and (2) what type of information do intensivists consider to be relevant? The answer to the first question is derived directly from the results—perceived relevant information is important and affects various aspects of the operators’ trust in the system. This finding supports the first hypothesis and corroborates

studies from diverse domains, which found that information relevancy substantially influences users' trust in technological systems [41,54,55].

Regarding the second question, discerning the type of information that intensivists consider relevant is more complicated. As hypothesized, providing detailed information about the algorithm's features decreased the participants' trust in the system. A possible explanation for the decreased trust is that the participants found the detailed information about the ML algorithm confusing and irrelevant. Accordingly, the information about the ML algorithm may have supported the participants' belief that they were dealing with a black box algorithm, and this, in turn, may have fostered distrust of the system [13].

Across all the CBT subdimensions assessed (understandability, technical competence, and reliability), the greater the relevancy of the information presented in the UI, according to the participants, the higher their trust. This concurs with the analysis of trust as a standalone construct and thus supports the first hypothesis.

The understandability and reliability ratings were not found to differ significantly between the information relevancy conditions. This suggests that the presentation of ML features did not significantly decrease the participants' ratings of understandability and reliability. However, ratings of technical competence did differ between the information relevancy conditions. This could indicate a stronger effect on trust, in the technical competence subdimension, compared to understandability and reliability.

Interactivity

The participants' trust ratings were not found to differ significantly between conditions. However, trust ratings increased as participants' perception of UI interactivity increased. This finding supports the second hypothesis and is in line with a meta-analysis by Yang and Shen [56], which concluded that perceived interactivity was much more effective than objective interactivity.

Two possibilities arise to explain the gap between participants' perceptions of the interactivity and the actual UI level of interactivity. First, within the 2 interactivity levels, the objective gap between the different conditions may not have been strong enough. The less interactive condition also forced 2-way communication between the participants and the UI. Possibly, the initial user engagement did not add enough interactivity to render a noticeable difference. Alternatively, the participants may not have perceived increased interactivity. Second, although entering and copying values to and from the patient record is a common task clinicians must apply in a subset of the IT systems in the ICU, participants may have considered that manually entering the patient's clinical measures was dull or redundant. This could have reduced participants' opinion of the system and led to lower trust ratings.

Although more interactive perceptions of the UI were associated with higher trust ratings, it is arguable whether extreme levels of interactivity are always preferable. Kalet et al [57] investigated the influence of different interactivity levels in a

computer-assisted instruction system on medical students' performances. They found that a mid-range UI level of interactivity maximized improvements in the performance of clinical skills. Yang and Shen [56] found that extremely high levels of website interactivity were less effective than moderate levels. However, pinpointing the exact amount of moderate interactivity, universally or specifically for a domain, is challenging. Furthermore, treating interactivity as a continuous variable and fitting it into a linear regression model could lead to measurement and interpretation errors. According to Yang and Shen [56], interactivity should be considered as a curvilinear variable, with the peak at the center of the curve and not at the edges. When fitting a linear regression model to an interactivity variable, the latter is considered linear, but this is not always the case. This approach may fail to capture the real influence of different levels of interactivity.

Across the 3 CBT dimensions examined (understandability, technical competence, and reliability), the more interactive the UI, according to the participants' perception, the higher their trust. This was precisely the situation when trust was analyzed as a standalone construct. Otherwise, the interactivity levels examined were not found to differ between the CBT dimensions. Notably, a linear regression model was set for each subdimension. Although the results showed that the more interactive the UI, the higher the ratings for each subdimension, moderate levels of interactivity may have had a greater effect on those subdimensions.

Finally, the literature is scant regarding correlations between experience and interactivity, and additional research is needed to elaborate on the significant negative interaction across years of experience and interactivity ratings.

Limitations and Future Research

Some limitations of this study represent opportunities for future research. First, the study design, limited resources, and the period the study was conducted (between the first and second waves of the COVID-19 pandemic) posed limitations on participant recruitment. The limited sample size dictated a design with only 2 levels of each variable. Future research should explore advanced and more realistic UI interactions and different information types. Second, although Madsen and Gregor's [30] approach was used to analyze trust, the ABT dimensions were not explored. Such investigation is needed to obtain a wider view of the relations between trust and its subdimensions, both cognitive-based and affect-based. Third, due to time limitations, the study did not evaluate participants' attitudes and changes in trust in the system over time. Finally, the study was performed in a simulation environment, using a specific interface design, and using case studies rather than real-time data from patients. Investigating clinician collaboration with a variety of interface designs, within real-world information systems used in diverse health care settings could yield a deeper understanding of future interface design.

Conclusions

Developing ML algorithms is only the first step toward improving medical treatment. To increase acceptance and trust of ML-based CDSSs, and expand their use, a broader and more

multidisciplinary approach (eg, user-centered design) should be taken. This approach needs to be specifically evaluated in the health care work environment, considering its unique challenges and professional personnel. A better understanding of means to increase intensivists' trust in ML-based CDSSs may open new opportunities for user-centered design and improved decision-making processes in the ICU.

Human factor studies, like this one, highlight the importance of understanding the effect of specific UI features when designing ML-based CDSS and other "artificial intelligence" systems. This study focused on the effects of 2 UI features related to intensivists' trust in ML-based CDSSs. We demonstrated that the level of relevancy of the information that is presented in the UI and the interactivity level of the UI can

play major roles when designing ML-based CDSSs. However, to enhance trust in these systems, more UI features should be investigated.

A wide point of view on trust should be maintained. In this study, trust as a standalone construct was influenced significantly by the different information relevancy levels in the tested conditions. Of the CBT subdimensions, only technical competence was influenced in the same way. These findings emphasize the need to analyze trust from different perspectives. For the research community and system designers, this may promote a broad understanding of means to enhance and foster trust in ML-based CDSSs, as well as in other "artificial intelligence" systems.

Abstract

Background: Assistive technologies (ATs) have the potential to promote the quality of life and independent living of older adults and, further, to relieve the burden of formal and informal caregivers and relatives. Technological developments over the last decades have led to a boost of available ATs. However, evidence on the benefits and satisfaction with ATs in real-world applications remains scarce.

Objective: This prospective, real-world, pilot study tested the perceived benefit and satisfaction with different ATs in the real-world environment.

Methods: Community-dwelling adults aged ≥ 65 and their relatives tested a tablet computer with a simplified interface or a smartwatch with programmable emergency contacts for 8 weeks in their everyday life. Perceived benefits and satisfaction with ATs were assessed by all older adults and their relatives using different assessment tools before and after the intervention. Outcome measures included the Technology Usage Inventory, Quebec User Evaluation of Satisfaction with Assistive Technology 2.0, and Canadian Occupational Performance Measure.

Results: A total of 17 older adults (tablet computer: $n=8$, 47% and smartwatch: $n=9$, 53%) and 16 relatives (tablet computer: $n=7$, 44% and smartwatch: $n=9$, 56%) were included in the study. The number of participants that were frail (according to the Clinical Frailty Scale) and received care was higher in the smartwatch group than in the tablet computer group. Older adults of the smartwatch group reported higher technology acceptance (Technology Usage Inventory) and satisfaction (Quebec User Evaluation of Satisfaction with Assistive Technology 2.0) scores than those of the tablet computer group, although the differences were not significant (all $P>.05$). In the tablet computer group, relatives had significantly higher ratings on the item *intention to use* than older adults ($t_{12,3}=3.3$, $P=.006$). Identified everyday issues with the Canadian Occupational Performance Measure included contact/communication and entertainment/information for the tablet computer, safety and getting help in emergency situations for the smartwatch, and the usability of the AT for both devices. While the performance ($t_8=3.5$, $P=.008$) and satisfaction ($t_8=3.2$, $P=.01$) in these domains significantly improved in the smartwatch group, changes in the tablet computer group were inconsistent (all $P>.05$).

Conclusions: This study highlights the remaining obstacles for the widespread and effective application of ATs in the everyday life of older adults and their relatives. While the results do not provide evidence for a positive effect regarding communication deficits, perceived benefits could be shown for the area of safety. Future research and technical developments need to consider not only the preferences, problems, and goals of older adults but also their relatives and caregivers to improve the acceptability and effectiveness of ATs.

(JMIR Hum Factors 2024;11:e53811) doi:[10.2196/53811](https://doi.org/10.2196/53811)

KEYWORDS

assistive technology; older adults; caregiver; benefits; usability; gerontechnology

Introduction

In their global disability action plan from 2015, the World Health Organization (WHO) defined assistive technologies (ATs) as “any item, piece of equipment or product, whether it is acquired commercially, modified or customized, that is used to increase, maintain or improve the functional capabilities of individuals with disability” [1]. For older adults, ATs can positively impact not only functionality but also autonomy, safety, and communication. In particular, ATs might support older adults who wish to remain in their own homes instead of depending on institutional care. In addition, the application of ATs has become a valid option in relieving the formal and informal caregivers of older adults [2].

In recent years, the field of ATs has evolved to include a wide range of devices for different audiences, varying in complexity and price. Examples include mobile health applications [3], wearable devices [4,5], robotic systems [6], virtual reality applications [7], or sensory aids [8]. ATs are used for various purposes such as personal disease management [3], managing fall risks [9], ensuring correct medication [10,11], and preventing social isolation [12,13]. Clearly, there is an abundance of available ATs assisting with age-related challenges. Yet, the effectiveness of ATs for older adults remains inconclusive [3,9,12,14]. Nevertheless, studies investigating the benefits and usability of ATs for older adults in the real-world environment are still lacking [15-17]. A focus on multimorbid and frail populations is of special interest, as one would expect that this cohort might especially benefit from the use of ATs. In addition, the use of ATs by older frail and nonfrail adults often depends on and includes relatives and caregivers who significantly contribute to the (successful) application of ATs. Additionally, this group itself might benefit from the application of ATs through a reduction of care burden [18]. Thus, studies testing the effectiveness of ATs should also consider the effects on caregivers and relatives.

Older adults are less likely than younger adults to use technology, and this depends on a number of factors including sociodemographic factors, attitudinal variables, and cognitive abilities [19]. However, despite the assumption that older adults are afraid and reluctant to use ATs, recent evidence indicates that they are relatively open to the idea of using technologies in their everyday life, independent of their age and subjective health status [20,21]. The factors that influence the intention of older adults to use digital technologies are complex and include environmental, psychological, and social determinants [22]. Among the most important ranked criteria for the selection and use of ATs by older adults are the promotion of independence, affordability, ease of use, and ethical company policies [23]. Thus, the use and effectiveness of ATs ultimately depend on the alignment of the technological developments and user needs.

Recently, emergency buttons or watches and wearable devices with GPS tracking or fall detection for older adults have gained special interest. However, few studies exist investigating the benefit of these devices for older adults. Most existing research focuses on wearables worn for disease monitoring or activity tracking [24]. A recent study with an emergency button (worn

as a wristband or necklace) that was connected to the landline did not show any improvement for health-related quality of life and other outcome measures [5]. Focusing on the issues of loneliness and lack of social interaction, software systems for (tablet) computers designed specifically for older adults are entering the market. The systems feature large icons and simple menus. Functionalities include video calls, access to the news, photo albums, or games. However, the benefit of such ATs remains unclear. While 1 study reported a significant improvement of loneliness, social support, and well-being among community-dwelling older adults living alone using a special computer system [13], a large systematic review and meta-analysis of similar interventions found no benefits on psychological outcomes in people with cognitive impairment and dementia [7].

This prospective, real-world, pilot study aims to assess the individual benefits and satisfaction gained from an emergency smartwatch and a senior tablet computer by community-dwelling older adults and their relatives in the real-world environment. The products were selected based on the results of a product competition for companies.

Methods

Study Population

Since the use of ATs often requires or supports the contact and interaction with relatives, this study considered 2 participant groups: older adults and their relatives or a close friend (hereinafter referred to as relatives). The inclusion criteria for older adults were (1) aged ≥ 65 years; (2) residence in the area of Ulm (distance ≤ 50 km); (3) an independent or assistive living situation; (4) the ability to speak and read German; and (5) the ability to consent to the study participation (adults with dementia were excluded). In addition, older adults had to have intact vision and hearing (normal or corrected). The relatives had to (1) be a family member or someone close to the adult; (2) speak and read German; (3) give consent to study participation; and (4) have a smartphone, tablet computer, or PC with internet connection. Participants were recruited in Southern Germany using convenience (via analogous and digital recruitment methods such as flyers, social media, and clinic staff) and snowball sampling (asking participants for other potential participants). As this was an exploratory study, no sample size calculation was conducted. The aim was to recruit between 6 to 10 participants per selected device. This number was defined based on feasibility. For 4 different ATs with 5 available devices each, 2 rounds of the study with 40 participants can be performed within 4 months.

Ethical Considerations

Ethical approval was obtained from Ulm University Ethical Committee (Nr. 230/21, 05.07.2021). Before entering the study, individuals received detailed information about the study and provided written informed consent to participate. Data analyses were performed on pseudonymized data. No financial remuneration was provided for participation.

Selection of the ATs

Initially, 4 different AT were chosen for this interventional study. The ATs were selected from the 2020 product competition “Daheim Dank Digital” (at home thanks to digitalization) [25] aimed at startups and established companies in German-speaking countries (Germany, Austria, and Switzerland). Companies were asked to apply with ATs that could compensate age-related deficits and impairments described in 5 predefined use cases. The use cases were designed together with experts from different areas of expertise and focused on (1) nocturnal restlessness and fall risk; (2) loneliness, hearing and vision impairment, and forgetfulness; (3) inactivity and listlessness in daily routine; (4) urinary incontinence and reduced fluid and food intake; and (5) limited mobility, weakness, and loneliness.

A total of 9 companies presented their products, and a scientific jury evaluated the devices based on availability; readiness for use; and impact in at least 1 of the categories of communication, security, or autonomy. These categories were specified as target areas in the overall project. A total of 4 products were selected for this user study based on their availability. The identified devices focused on safety (an intelligent bed exit alarm from the company NevisQ and a smartwatch with an emergency button from the company CareIOT GmbH) and communication (the Media4Care tablet computer from Media4Care GmbH and the Eldertech app, which supports communication and coordination of care within a family, from Eldertech GmbH). At the time of the study, all products were commercially available and had a CE certificate.

Study Design

We performed a prospective, real-world, pilot study of 4 different ATs with community-dwelling adults aged ≥ 65 years and their relatives. Together with the participants, the

investigators decided which product was the most suitable for the older adult. Based on their individual needs, a decision was made for 1 of the targeted areas: communication or safety. Unfortunately, no candidates were identified for the evaluation of the bed exit alarm and the app; therefore, the selection was limited to the tablet computer and the emergency smartwatch. Both devices were used in their versions that were current as of August 2021. Details on the main functionalities of these 2 devices are listed in [Table 1](#). Further technical information on the 2 products can be found in [Multimedia Appendix 1](#).

In an introductory assessment session, all participants and their relatives were informed of the study procedure, goals, and possible risks and consented to participate. Baseline data were captured in a subsequent meeting at the participant’s home or in the study center (SM and BK). Participants were given the selected AT and a short introduction to the device. Participants then tested the AT in their daily life over a period of 8 weeks. In case problems with the use of the AT arose, participants were asked to first seek help in the manual, on the web, or via the company hotline before contacting the study center. This was done to reproduce a real-life setting as accurately as possible.

During the study period, the study team called the participants after 1, 2, 4, and 6 weeks to inquire about the use of the product; help solve possible issues; and remind participants to document errors, problems, and the frequency of use. After the test period of 8 weeks, the participants and their relatives were assessed a second time. This meeting took place at the participant’s home or in the study center. The relatives performed an independent assessment of the AT based on their user experience gathered during the testing period (assisting or interacting with older adults). Thus, the relatives’ ratings represent their own perception of the AT rather than the perception of the usefulness of the AT for the older adult.

Table 1. Main functionalities of the 2 assistive technologies tested in the study.

Device	Main functionalities and features
Smartwatch	<ul style="list-style-type: none"> • Emergency button, including the notification of contacts via phone and mail • GPS tracking • Analysis of movement profile and automatic notification of contact persons in case of deviations from the norm
Tablet computer	<ul style="list-style-type: none"> • Video calls • Messenger service • Entertainment (games, news, podcasts, radio, and music) • Photo album • Touchscreen

The questionnaires were paper based and filled out by 1 of the investigators (SM or BK) during the interview sessions before and after the intervention. Older adults and their relative were interviewed in separate sessions to reduce the interview duration and to avoid interaction, except when older adults required support from the relative. Interviews were performed face-to-face with all older adults. Interviews with relatives were also performed by phone.

Data Collection

At baseline, sociodemographic data were collected including sex, age, living situation (alone, together with partner, or with someone else), education (<10 y or ≥ 10 y), level of care (administratively assigned level of care measuring a person’s care need and determining their claim for additional support), self-perceived health status (excellent, very good, good, fair, or poor), and self-perceived age. Additionally, information on interest in technology was collected (high, medium, or low).

To assess older adults' ability to perform instrumental activities of daily living (IADL), the Lawton scale was used [26]. The corrected IADL score was calculated taking into account the possibility that the activities have never been performed [27]. To capture additional information about the participants' social situation, the Lubben Social Network Scale-6 was used [28]. With the Clinical Frailty Scale (CFS), frailty and fitness of the older adults (scale from 1="very fit" to 9="terminally ill") were assessed [29]. In addition, both older adults and relatives had to rate their life satisfaction (scale from 0 to 10, with higher values indicating higher life satisfaction).

Frequency of Use

Older adults were asked to document their use frequency of the technology in each of the 8 intervention weeks. The frequency of use was reported on a 5-point scale, that is, it captured whether the technology was used on 7, 5 - 6, 3 - 4, 1 - 2, or 0 days per week.

Technology Usage Inventory

The Technology Usage Inventory (TUI) was administered to the older adults and their relatives to assess the influence of psychological factors on the use and acceptance of technology [30]. The items *curiosity* and *technology anxiety* were asked before the intervention, whereas the items *interest*, *usability*, *usefulness*, *skepticism*, and *accessibility* were asked after the intervention. Answers were given on a 7-point Likert scale (1="strongly disagree" and 7="strongly agree"). In addition, the *intention to use* the AT was asked on a visual analog scale (0="agree" and 10="disagree") after the intervention. For orientation purposes, the item *intention to use* has been reversed in the *Results* section of this paper.

Quebec User Evaluation of Satisfaction With Assistive Technology 2.0

Satisfaction with the technology was evaluated after the intervention using the German version of the Quebec User Evaluation of Satisfaction with Assistive Technology (QUEST) 2.0 [31]. Of the original 12 items of the QUEST 2.0, only the 8 items relating to an AT device (domain device) were considered. Each question was scored on a 5-point scale (1="not satisfied at all" and 5="very satisfied"). The questionnaire was completed by both the older adults and their relative. Additionally, they were asked to choose the 3 items with the highest relevance for them. Overall satisfaction was calculated as the mean score across all answered items. The QUEST 2.0 has been shown to be a valid and reliable assessment for a population of assistive device users [32].

Canadian Occupational Performance Measure

The Canadian Occupational Performance Measure (COPM) is a semiquantitative, client-centered instrument that was used to investigate the perceived satisfaction with the performance of the AT in the specified problem areas of the older adults and their relatives [33]. For this purpose, everyday issues of personal importance related to the use of the AT were determined together with an occupational therapist during the interview before the intervention. For each participant, up to 5 everyday issues were identified, and for each of these issues, the older adults and their relatives had to rate their perceived level of

performance and satisfaction on a scale from 1 to 10, with higher scores indicating higher performance or satisfaction. Ratings for the defined issues were then summed and divided by the number of issues to obtain a performance score and a satisfaction score. After testing the AT, the older adults and their relatives repeated the rating on the previously defined everyday issues of personal importance.

Data Analysis and Statistics

For all outcome measures, descriptive statistics were calculated and included the mean (SD). The focus of the analysis was on the outcomes that assessed the usability aspects of the ATs, that is, the TUI and QUEST 2.0. In addition, exploratory statistical inference testing was performed to assess the effects of the ATs on the specified everyday issues of the older adults and their relatives (COPM). The assumption of a normal distribution was tested by the Kolmogorov-Smirnov test of normality. Subsequently, 2-tailed *t* tests were used to compare intervention groups using the Welch *t* tests (life satisfaction, TUI, and QUEST 2.0) and preintervention and postintervention data using paired *t* tests (COPM). Uncorrected *P* values are presented in the *Results* section. However, to control the false discovery rate, we used the correction of the *P* values via the Benjamini-Hochberg procedure [34]. If this correction changed the outcome of the statistical test, this is reported in the *Results* section. In addition, effect sizes were calculated using Cohen *d*. The statistical significance was set at $P < .05$ for all tests. Statistical analyses were performed using RStudio (RStudio Team).

Results

Participants

The study was performed from August 2021 to April 2022. A total of 44 older adults were screened for inclusion in the study. From this sample, 18 older adults and their relatives met the inclusion criteria and were enrolled in this study. There was 1 dropout who stopped study participation due to dissatisfaction with the technology. A total of 17 older adults (tablet computer: $n=8$, 47% and smartwatch: $n=9$, 53%) and 16 relatives (tablet computer: $n=7$, 44% and smartwatch: $n=9$, 56%) completed the study and were included in the final data analysis. In the tablet computer group, there were 2 cases where the same relative belonged to 2 older adults, and there was 1 case where 2 relatives belonged to the same older adult.

The sociodemographic characteristics of the older adults and their relatives are shown in Tables 2 and 3, respectively. Older adults in both groups were aged >80 years on average but reported a younger self-perceived age. Even though participants in the smartwatch group were older on average, they felt younger than those in the tablet computer group. Data on self-perceived health status, level of care, corrected IADL, and frailty indicated that older adults in the smartwatch group were more dependent and slightly frailer than those in the tablet computer group. A total of 4 participants, all in the smartwatch group, perceived their own health to be poor or fair. However, older adults of the smartwatch group were socially more engaged than those of the tablet computer group. While most older adults (tablet computer: 7/8, 88% and smartwatch: 6/9, 67%) and all relatives indicated

at least a medium level of technology interest, one-third (3/9, 33%) of participants in the smartwatch group reported a low level of technology interest. Relatives in the smartwatch group

had a higher mean age and included more male persons than the relatives in the tablet computer group.

Table . Sociodemographic characteristics of older adults. Data are presented as frequency and percentage or as mean (SD).

Characteristics	Tablet computer (n=8)	Smartwatch (n=9)

Frequency of Use

The frequency of use of the tablet computer and smartwatch in everyday life was heterogeneous across the study period. In the tablet computer group, 5 older adults reported varying use frequencies, which ranged between not using the technology at all (0× per week) and regularly using the technology (7× per week). Two participants of the tablet computer group stopped using the technology after the first week of the intervention. In the smartwatch group, 6 older adults used the technology consistently across all 8 intervention weeks (mostly 7× per week). In the smartwatch group, 2 participants stopped using the technology after the first 1 to 3 weeks. A total of 2 older adults (1 in each group) did not document their frequency of use.

Life Satisfaction

The mean life satisfaction of older adults changed nonsignificantly from 7.9 (SD 3.3) to 7.3 (SD 3.1) in the tablet computer group ($t_7=1.1$, $P=.31$, $d=0.29$) and from 7.2 (SD 2.1) to 8.1 (SD 1.9) in the smartwatch group ($t_8=1.1$, $P=.29$, $d=0.44$). Similarly, the mean life satisfaction of relatives changed nonsignificantly from 8.9 (SD 0.9) to 8.0 (SD 2.1) in the tablet computer group ($t_6=1.5$, $P=.17$, $d=0.53$) and from 7.7 (SD 1.4) to 8.1 (SD 0.7) in the smartwatch group ($t_6=0.9$, $P=.41$, $d=0.39$). In the smartwatch group, 2 participants only provided the preintervention (n=1) or postintervention (n=1) value and were not considered in the statistical analysis.

Technology Acceptance

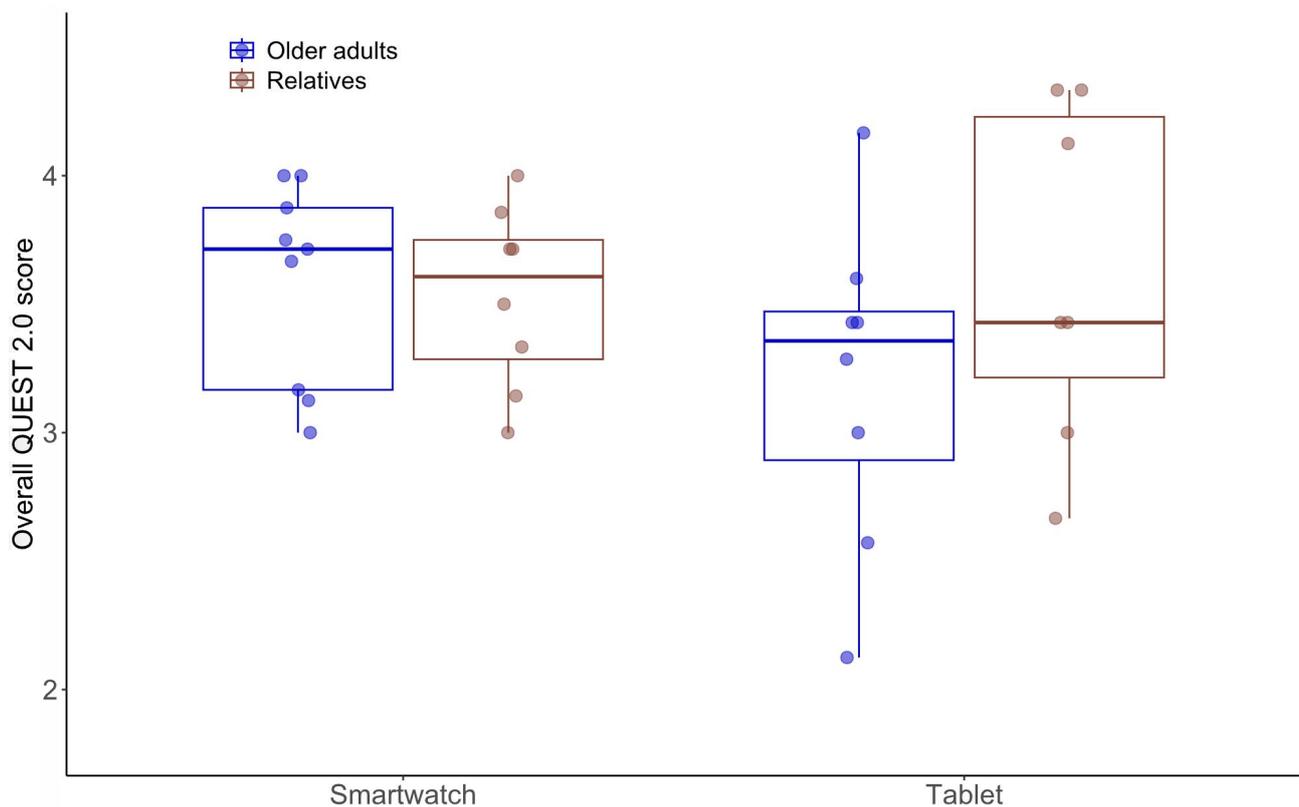

Prior to the intervention, mean ratings for technology acceptance of older adults and their relatives ranged between 5.8 and 6.5 points for *fearfulness* and between 4.4 and 5.1 points for *curiosity* in the tablet computer and smartwatch group, respectively. For both items, the differences between the tablet computer and smartwatch groups were not significant (older adults: *fearfulness* $P=.11$ and *curiosity* $P=.77$; relatives: *fearfulness* $P=.43$ and *curiosity* $P=.36$). After the intervention, ratings from the older adults and their relatives of the tablet

computer and smartwatch groups were similar for the items *interest*, *accessibility*, *usability*, and *skepticism* (older adults: *interest* $P=.90$, *accessibility* $P=.64$, *usability* $P=.26$, and *skepticism* $P=.67$; relatives: *interest* $P=.65$, *accessibility* $P=.78$, *usability* $P=.64$, and *skepticism* $P=.39$). This was different for the items *usefulness* and *intention to use*. TUI scores on the item *usefulness* were higher in the smartwatch group (older adults: mean 5.0, SD 1.0; relatives: mean 5.4, SD 1.4) than in the tablet computer group (older adults: mean 3.8, SD 1.5; relatives: mean 4.2, SD 1.6), although this did not reach statistical significance (older adults: $t_{12.3}=1.9$, $P=.07$, $d=0.98$; relatives: $t_{12.1}=1.6$, $P=.14$, $d=0.83$). TUI scores on the item *intention to use* were significantly higher in the smartwatch group (mean 6.1, SD 3.4) than in the tablet computer group (mean 2.7, SD 2.2; $t_{13.6}=2.4$, $P=.03$, $d=1.14$) in older adults (note that after correction for multiple comparisons, the P value exceeded .05). Although ratings on *intention to use* from the relatives were also higher in the smartwatch group (mean 7.8, SD 2.7) than in the tablet computer group (mean 5.9, SD 1.5), the differences were not significant ($t_{11.0}=1.7$, $P=.11$, $d=0.86$). Interestingly, in the tablet computer group, relatives' ratings on the item *intention to use* (mean 5.9, SD 1.5) were on average twice as high as those of older adults (mean 2.6, SD 2.2; $t_{12.3}=3.3$, $P=.006$, $d=1.66$). In contrast, the relatives' and older adults' ratings on the item *intention to use* were similar in the smartwatch group (older adults: mean 6.1, SD 3.4; relatives: mean 7.8, SD 2.7; $t_{14.8}=1.1$, $P=.28$, $d=0.54$). Descriptive data on all items of the TUI can be found in [Multimedia Appendix 2](#).

Satisfaction With the Technology

The overall satisfaction score of the QUEST 2.0 across all items was similar for the older adults and relatives of both groups ([Figure 1](#)). The mean satisfaction score of older adults was 3.2 (SD 0.6) in the tablet computer group and 3.6 (SD 0.4) in the smartwatch group ($t_{11.4}=1.5$, $P=.16$, $d=0.75$). Similarly, the mean satisfaction across all items rated by the relatives was 3.6 (SD 0.7) in the tablet computer group and 3.5 (SD 0.4) in the smartwatch group ($t_{8.6}=0.3$, $P=.77$, $d=0.16$).

Figure 1. QUEST 2.0 score (scale from 1 to 5) of older adults and their relatives for the tablet computer and smartwatch groups. Higher values represent higher satisfaction. Dots represent data from individual participants. QUEST: Quebec User Evaluation of Satisfaction with Assistive Technology.

The 3 most relevant rated items for both AT groups were *safety and reliability* (n=4), *ease of use* (n=7), and *effectiveness* (n=7). Thus, these items were analyzed separately (Table 4). This analysis suggested that older adults of the smartwatch groups rated all 3 items better than older adults of the tablet computer group. Likewise, the relatives of the smartwatch group rated the items *safety and reliability* and *effectiveness* better than those of the tablet computer group. This was different for the

item *ease of use*. This item was rated better by the relatives of the tablet computer group than those of the smartwatch group. In addition, item ratings of relatives were better than those of older adults in the tablet computer group. However, none of the abovementioned comparisons yielded significant test results (older adults: *safety and reliability* $P=.06$, *ease of use* $P=.57$, and *effectiveness* $P=.40$; relatives: *safety and reliability* $P=.21$, *ease of use* $P=.40$, and *effectiveness* $P=.21$).

Table . Results (mean and SD) of selected QUEST^a 2.0 items (scale from 1 to 5) for the tablet computer and smartwatch groups. Higher values represent higher satisfaction.

QUEST 2.0 items	Tablet computer		Smartwatch	
	Older adults (n=8)	Relatives (n=7)	Older adults (n=9)	Relatives (n=9)
Safety and reliability, mean (SD)	2.8 (1.0)	3.2 (1.5)	3.7 (0.7)	3.5 (1.2)
Ease of use, mean (SD)	3.1 (1.4)	3.9 (1.2)	3.9 (0.8)	3.5 (1.2)
Effectiveness, mean (SD)	3.1 (1.4)	3.2 (1.5)	3.6 (1.5)	3.9 (1.6)

^aQUEST: Quebec User Evaluation of Satisfaction with Assistive Technology.

Self-Perceived Performance and Satisfaction

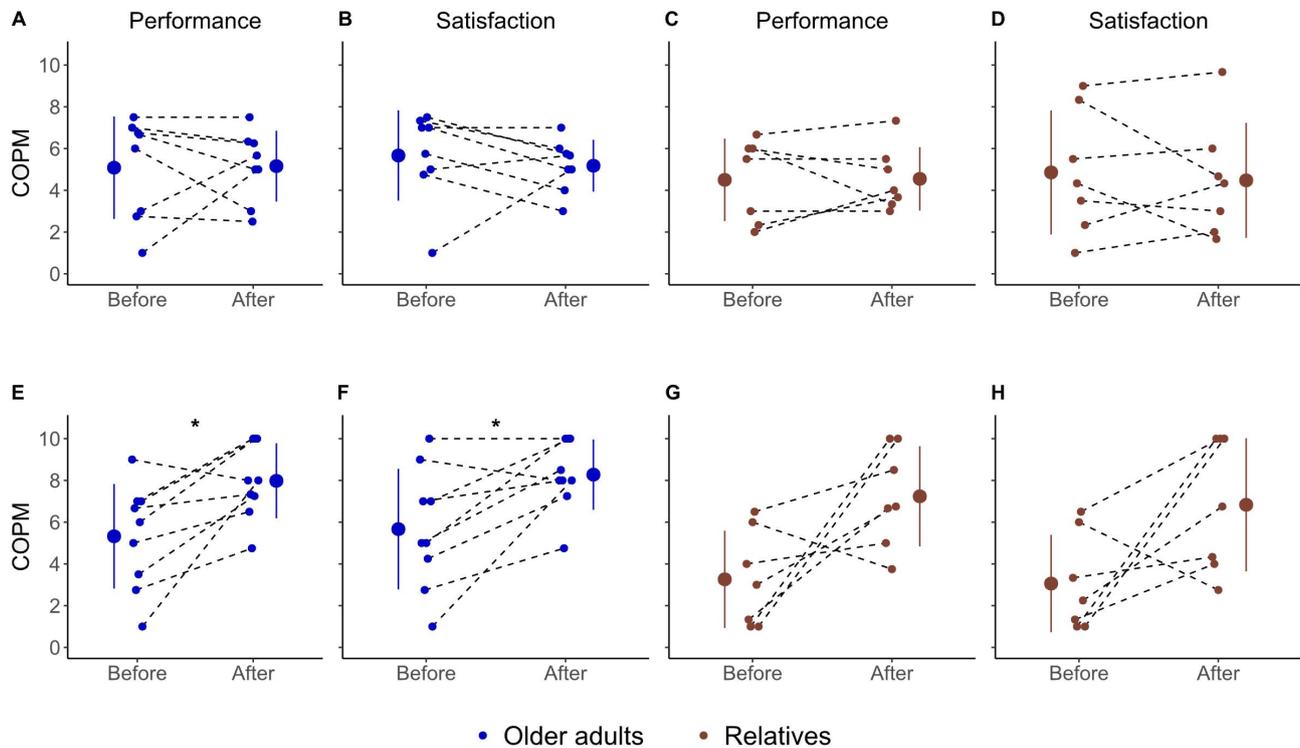

The most frequently reported everyday issues identified in the COPM were contact/communication with relatives (tablet computer group), entertainment/information on news (tablet computer group), perception of safety (smartwatch group), getting help in emergency situations (smartwatch group), and usability of the AT (both groups). The number of specified issues ranged between 1 and 4.

In the tablet computer group, the older adults and their relatives reported diverse scores for self-perceived performance and satisfaction, with both improved and reduced scores. Statistical analysis showed that self-perceived performance (older adults: $t_7=0.09$, $P=.93$, $d=0.03$; relatives: $t_6=0.08$, $P=.94$, $d=0.03$) and satisfaction (older adults: $t_7=0.6$, $P=.54$, $d=0.23$; relatives: $t_6=0.5$, $P=.64$, $d=0.18$) did not significantly change in the tablet computer group during the intervention (Figure 2A-D). This was different in the smartwatch group. All but 1 older adult and 1 relative reported improved performance and satisfaction in

the defined issues. Statistical analysis showed that self-perceived performance ($t_8=3.5$, $P=.008$, $d=1.17$) and satisfaction ($t_8=3.2$, $P=.01$, $d=1.06$) significantly increased in the older adults of the smartwatch group (Figure 2E-F). In the relatives of the

smartwatch group, self-perceived performance ($t_6=2.5$, $P=.04$, $d=0.96$) and satisfaction ($t_6=2.3$, $P=.06$, $d=0.87$) increased, although this result was not statistically significant (after multiple comparison correction; Figure 2G-H).

Figure 2. COPM score (scale from 0 to 10) of older adults and their relatives for the (A-D) tablet computer and (E-H) smartwatch groups. Higher values represent higher self-perceived performance and satisfaction. Small dots represent data from individual participants. Bigger dots and error bars represent mean and SD. Asterisks (*) indicate significant differences after correction for multiple comparisons. COPM: Canadian Occupational Performance Measure.

Discussion

Principal Findings

This prospective, real-world, pilot study analyzed the perceived benefit and satisfaction with 2 types of AT for older adults and their relatives addressing different user needs (communication related vs safety related). The devices were (1) a tablet computer with a video call function and entertainment content for older adults and (2) a smartwatch with an emergency button and GPS tracking. Both older adults and their relatives in the smartwatch group consistently reported improved outcomes in the domains of life satisfaction and self-perceived performance and positive ratings for technology acceptance and satisfaction. Several participants emphasized feeling more secure when going out while wearing the device. In contrast, experiences with the tablet computer were more diverse, with several participants reporting poorer technology acceptance, satisfaction, and self-perceived performance.

Wearables with sensor-based risk assessment or fall detection and GPS locating can contribute to reducing older adults' fear of going outside and thus preserve participation in the community, autonomy, and mobility [35-37]. However, issues with device aesthetics, reliability, and ease of use can negatively impact device acceptance [35,38,39]. Most available studies that focus on the accuracy of device measurements are conducted within a laboratory setting. Contrary to our study,

the main sensor location in existing studies is the waist or lower back [36,37]. However, it has been shown that a sensor location at the wrist (eg, watch or wristband) is an important feature for better acceptance of the device [40]. Another study found the highest satisfaction for a pendant worn on a key chain or around the neck [35]. Both forms have the advantage of being familiar or comfortable—aspects that are essential for technology adoption as stated by Fischer et al [41]. Although many emergency smartwatches for older adults have entered the market in recent years, only a few intervention studies with devices similar to the smartwatch tested here exist. Thus, the benefit and results for older adults and their caregivers remain inconclusive [38,42]. Future interventional studies in a real-world setting that take into account the wearers' wishes and focus on reliability, familiarity, and ease of use are needed.

Tablet computers for older adults are designed to improve participation, provide social support, and reduce loneliness or anxiety. Based on the existing research, the effectiveness of these systems remains inconclusive [5,13,43]. In our study, older adults in the tablet computer group reported on average reduced life satisfaction after the 8-week test period and worse scores for safety and reliability when compared to the smartwatch group. Several participants reported technical failures. Some of the issues mentioned included video calls that did not work, difficulties in receiving pictures from relatives, and defective charging. Considering the high value put on device

reliability, these problems are part of the explanation for the negative results of the tablet computer. Additionally, the device is operated via a touchscreen, a technology older adults are mostly unfamiliar with. Consistently, the item ease of use was rated higher by the relatives in the tablet computer group, who belong to a generation already familiar with the use of a touchscreen [43].

Participants received no training prior to using the ATs in their daily lives. This procedure was chosen to create a situation that is as realistic as possible. In most cases, older adults purchasing ATs need to rely on the assistance of their relatives or the company support hotline [35]. In both groups, there were 2 participants who stopped using the ATs after the first few weeks of the intervention period, potentially due to a lack of adequate preparation or lack of support. Indeed, previous research indicates that older adults wish to receive additional training of the technology items they use in the home [44]. Thus, it might be necessary to incorporate training, particularly for more innovative ATs with reduced familiarity and potentially challenging features [38].

This study included 3 older adults characterized as vulnerable or prefrail (CFS score=4) and 4 with some level of frailty (CFS score>4). Physical frailty is a “medical syndrome with multiple causes and contributors that is characterized by diminished strength, endurance, and reduced physiologic function that increases an individual’s vulnerability for developing increased dependency and/or death.” (p. 4) [45]. Frail older adults face specific challenges when it comes to using and deriving benefits from ATs [46]. However, this subgroup is frequently underrepresented in intervention studies, thereby impeding a comprehensive understanding of their requirements [47]. In this study, all vulnerable or frail older adults reported a high likelihood for intention to use the ATs, indicating that this population is overall open to using ATs in their daily lives. Additionally, vulnerable or frail older adults had an average technology satisfaction score of 3.5 (SD 0.5), that is, their satisfaction was between “more or less satisfied” and “quite satisfied.”

As clearly deduced from the introductory WHO definition [1], the term AT is a very broad umbrella term, and it covers an extremely heterogeneous group of products. Each product targets users with specific needs and specific goals. Measuring such diversity is challenging within scientific research. The COPM is unique in the sense that it allows the analysis and quantification of individual user needs and specific AT aims. Thus, it can be adapted to different settings, targets, domains, and participants—irrespective of their age, sex, or other attributes. The tool has been used in other studies investigating the effectiveness of ATs [48,49]. The TUI and QUEST 2.0, however, include predefined items or questions that are not developed specifically for older adults. A recent study suggests that independence, affordability, ease of use, and ethics are the most important AT evaluation criteria for older adults [23]. It

is possible that these domains are not adequately represented by the TUI and QUEST 2.0. Assessments focusing on older adults or specifically adapted to the needs and wishes of this group might be better suited in future studies.

Limitations

The 2 ATs studied target different domains (communication vs safety). Thus, the comparability and generalizability of results are limited. However, the used of the COPM allowed an item-specific evaluation according to its properties to help resolve the identified issues. Although the overall interest in the study was high, only 17 older adults and 16 relatives were included in this study. Thus, the statistical power of the study was relatively low, and further studies with larger samples are required to draw robust conclusions. Having the participation of a relative as a prerequisite for enrollment was one of the biggest obstacles for recruitment as they often declined to participate due to time restrictions. However, as many ATs require or support the interaction with relatives, we consider it important to investigate both perspectives, that of the older adults and that of the relatives. A large systematic review on ATs for older adults with dementia analyzed 571 studies and found that most investigations of clinical effectiveness were conducted with small sample sizes of <20 participants [50]. Conducting real-life intervention studies on the effectiveness of ATs requires a significant amount of effort and time. Combined with difficult recruitment among the population aged ≥65 years, this explains the low sample sizes. Unfortunately, we did not find any older adults–caregiver dyads who were willing to test the smart bed rail or the care planning app and able to participate in the study assessments. Both products are possibly of interest for frail older adults with a higher risk for fall or need for care. These individuals might be too sick to participate in a study such as this, live in some form of assisted living facilities or nursing homes, and be more difficult to reach. Older adults with no interest in technology did not participate in the study, causing a certain sample bias. The study was conducted with the device versions (including the software) that were current as of August 2021. The reproduction of the study using newer device versions could potentially change the results.

Conclusion

This prospective, real-world, pilot study confirmed the potential of ATs to support older adults and their relatives, especially for safety-related issues, but also highlighted the remaining obstacles for widespread use. Frail older adults and their relatives, who would potentially benefit the most from ATs, are especially difficult to reach. Thus, future research and technical developments of ATs should take into account the preferences, problems, and goals of older adults. In addition, this study highlights that individualized measures such as the COPM are necessary to identify the needs and assess the user benefits of the ATs in real-world applications.

Acknowledgments

This study was supported through funds from the German Federal Ministry of Education and Research for the project Future City 2030 (grant 13ZS0054A). The devices that were tested were graciously provided by the manufacturers for the duration of the study. Neither the funding party nor the manufacturers influenced the study design, data collection, analysis, interpretation, or the writing of the manuscript. The authors would also like to thank Sybille Beck for her support in performing the interviews during the study.

Authors' Contributions

MD, DD, SM, BK, and MLF conceived and designed the research. BK and SM were responsible for recruitment and data collection. BK, PW, MLF, and FMV analyzed the data. PW and MLF drafted the paper. All authors edited and revised the manuscript. All authors approved the final version of manuscript.

Abstract

Background: Viscoelastic hemostatic assays, such as rotational thromboelastometry (ROTEM) or thromboelastography, enable prompt diagnosis and accelerate targeted treatment. However, the complex interpretation of the results remains challenging. Visual Clot—a situation awareness-based visualization technology—was developed to assist clinicians in interpreting viscoelastic tests.

Objective: Following a previous high-fidelity simulation study, we analyzed users' perceptions of the technology, to identify its strengths and limitations from clinicians' perspectives.

Methods: This is a mixed qualitative-quantitative study consisting of interviews and a survey. After solving coagulation scenarios using Visual Clot in high-fidelity simulations, we interviewed anesthesia personnel about the perceived advantages and disadvantages of the new tool. We used a template approach to identify dominant themes in interview responses. From these themes, we defined 5 statements, which were then rated on Likert scales in a questionnaire.

Results: We interviewed 77 participants and 23 completed the survey. We identified 9 frequently mentioned topics by analyzing the interview responses. The most common themes were “positive design features,” “intuitive and easy to learn,” and “lack of a quantitative component.” In the survey, 21 respondents agreed that Visual Clot is easy to learn and 16 respondents stated that a combination of Visual Clot and ROTEM would help them manage complex hemostatic situations.

Conclusions: A group of anesthesia care providers found Visual Clot well-designed, intuitive, and easy to learn. Participants highlighted its usefulness in emergencies, especially for clinicians inexperienced in coagulation management. However, the lack of quantitative information is an area for improvement.

Introduction

Rapid hemostatic assessment is essential to targeted coagulation management in acute bleeding [1]. Increasingly used viscoelastic hemostatic assays, such as rotational thromboelastometry

(ROTEM) or thromboelastography, enable faster insights into coagulation dysfunction than conventional laboratory tests. Standard coagulation assays are not optimal for managing acute hemorrhages that require rapid therapeutic action, as it often takes more than an hour to obtain the results [2,3]. European

and North American transfusion recommendations underline the advantages of viscoelastic hemostatic assays for managing trauma and severe perioperative bleeding, including the reduced need for transfusions, fewer perioperative complications, shorter hospitalization, and lower overall treatment costs [1,4,5]. Its usefulness has been demonstrated in many operative areas such as obstetrics [6,7], pediatric surgery [8], transplantation [9], cardiac surgery [10,11], neurosurgery [12], and burn surgery [13,14]. Viscoelastic hemostatic tests are also paramount in the diagnostic and treatment adjustment of hematological disorders, such as inherited afibrinogenemia, hemophilia, or multiple myeloma [15-18]. However, despite these technologies' widespread use and considerable advantages, their results' interpretation remains challenging and requires well-trained clinical personnel [19-21]. Visual Clot—a situation awareness-based visualization technology—was developed to support health care professionals in interpreting viscoelastic test results by reducing the complexity of their presentation. Based on raw ROTEM data, the results are displayed in real time as a 3D animated model of a blood clot to represent various elements of hemostasis, including platelets, plasmatic factors, and fibrin. It can also effectively illustrate the influence of heparin and hyperfibrinolysis [22] ([Multimedia Appendix 1](#)). In a high-fidelity simulation study, anesthesiologists using Visual Clot were 2.2 times more likely to articulate the correct therapeutic approach. In addition, these anesthesiologists had a lower median time to administer the first appropriate targeted coagulation product. Overall, physicians presented with the results of viscoelastic testing using Visual Clot were approximately 56% more likely to provide accurate therapeutic interventions. In the same study, physicians were 3.5 times more likely to feel confident in their decisions when working with Visual Clot compared to traditional ROTEM results [23]. In the first computer-based study analyzing user perceptions of Visual Clot, participants described the technology as well-designed, easy to learn, and intuitive [24]. The guiding principles of the Visual Clot technology that result in enhanced situation awareness include Endsley's user-centered design principles [25], Wittgenstein's philosophy as articulated in *Tractatus Logico-Philosophicus* [26], and insights from the National Aeronautics and Space Administration (NASA) publication "On Organization of Information: Approach and Early Work" by Degani et al [27]. Endsley's principles emphasize the use of direct visual representations of data to enhance situational awareness, a central principle in Visual Clot's data visualization. Wittgenstein's theory emphasizes the importance of logical representations that meaningfully correspond to the reality they are intended to represent. Visual Clot follows this principle by visually representing elements such as fibrin, platelets, plasmatic factors, hyperfibrinolysis, and bleeding. Following NASA's approach, Visual Clot strives to achieve the highest level of "order and wholeness" by consolidating all essential data into a single display. The primary goal of Visual Clot technology is to provide the care provider with situational information quickly

and with minimal cognitive load. In this study, we aimed to capture and analyze perceptions of anesthesia personnel working with Visual Clot in a high-fidelity simulation to identify the strengths and recognize the potential for future improvements.

Methods

Ethical Considerations

The Cantonal Ethics Committee of the Canton of Zurich reviewed the study protocol and issued a declaration of no objection (Business Management System for Ethics Committees Number Req-2021-01112). Furthermore, each participant gave informed consent to use his or her data for research purposes. Participation was voluntary and without financial compensation.

Study Design

We conducted a researcher-initiated single-center mixed qualitative-quantitative study at the University Hospital Zurich, Institute of Anesthesiology, Switzerland. Study participants were anesthesia personnel, including staff anesthesiologists, residents, and nurses. After participating in a high-fidelity simulation study of perioperative bleeding scenarios, where they worked with Visual Clot and ROTEM, we interviewed participants on their perceptions of Visual Clot technology.

As a second step, the same participants received an email invitation to participate in a survey a few weeks later. They rated statements we generated from identified and frequently mentioned themes in interview responses on a Likert scale.

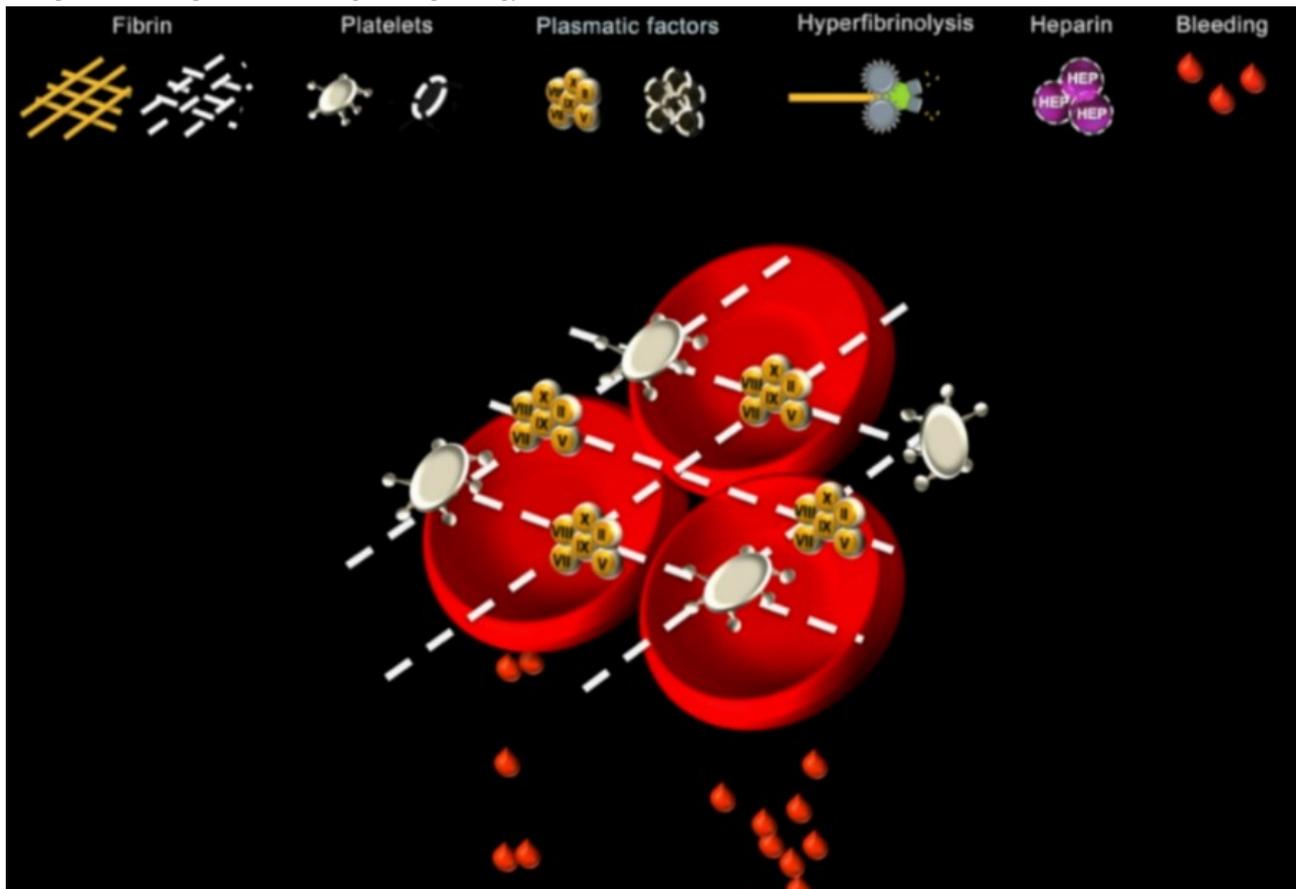

Previous High-Fidelity Simulation Study

In the high-fidelity simulation study [23], anesthesia teams, composed of a staff anesthesiologist, a resident, and an anesthesia nurse, participated in high-fidelity perioperative bleeding scenarios using either Visual Clot or ROTEM. The primary outcome of the study was correct targeted coagulation therapy. Secondary outcomes were time to targeted coagulation therapy, confidence, and workload.

ROTEM is the standard of care for managing acute hemorrhage in the study center, so all participants were familiar with the technology before participating [20]. Some participants had taken part in previous Visual Clot studies and, therefore, were already familiar with the technology [22,24].

Nevertheless, before the simulations began, we gave a 10-minute presentation that reviewed ROTEM and introduced Visual Clot. [Multimedia Appendix 1](#) provides an instructional video of Visual Clot. Participants were invited to ask questions freely before starting work in the simulation environment. Each team solved 1 of 4 different perioperative bleeding scenarios, which were randomly allocated. We ended the scenarios when all necessary therapeutic measures were derived or, at the latest, after 15 minutes. [Figure 1](#) illustrates an example of a Visual Clot printout used in the simulation study.

Figure 1. A Visual Clot result presentation showing a fibrin deficiency. The fibrin in the clot is shown as a dashed line, indicating its absence. The blood drops indicate the presence of a coagulation pathology.

Participant Interviews

After the simulations, we encouraged the participants to freely verbalize their thoughts in a distraction-free environment while the data collectors made field notes. The only suggestion to the participants before the interviews was to verbalize their positive and negative opinions of Visual Clot. The participants could define final adjustments in the collected answers at the end of the interviews.

Survey

In the second step, we formulated 5 statements to summarize the insights gathered during the interviews. The statements were submitted for evaluation on a 5-point Likert scale graded from “strongly agree” to “strongly disagree.” An email invitation was sent to all interviewed participants.

Outcomes and Statistical Analyses

Part I: Participant Interviews

Collected interview responses were translated from original German to English using a translation system DeepL (DeepL

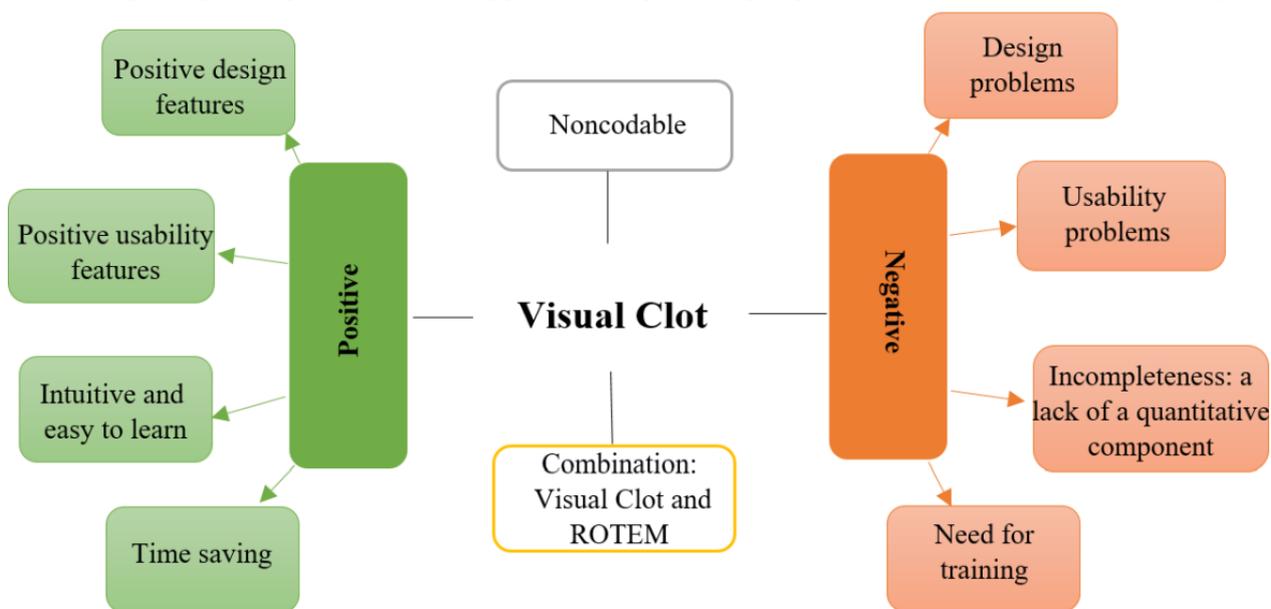

GmbH). [Multimedia Appendix 2](#) provides the complete translated field notes.

The most commonly used terms in positive and negative responses were identified using the word count function. Word groups with the same root were united, excluding the frequently used filler words such as “to,” “and,” or “the” ([Table 1](#)). Using a template approach [28] we identified the major themes that dominated participants’ answers. As a result, we generated a coding tree ([Figure 2](#)). According to the coding template, we assigned statements to the themes. A total of 3 of the study authors, all anesthesiology residents GG, GS, and SA, rated the interview statements separately from each other using the coding tree ([Figure 2](#)). If the 3 investigators disagreed after multiple data coding, the final decision was taken in a joint discussion. Interrater reliability was calculated to investigate the consistency of the coding tree’s application.

Table 1. The most commonly used positive and negative terms to describe Visual Clot.

Positive terms		Negative terms	
Terms	Frequency, n	Terms	Frequency, n
Easy or easier	28	Missing	13
Good	16	Quantitative or quantification	11
Fast or faster	13	Information	9
See a problem	12	Values	8
Interpret quickly	11	Time	8
Simple	9	Fibrinogen	6
Understand	9	Numbers	6
Visual	8	Hyperfibrinolysis	6
Interpretation	7	Less	5
Intuitive	7	Confusing	4
At a glance	7	Flashing	4
Overview	7	Simplified	3

Figure 2. A coding tree representing the themes describing positive and negative user perceptions. ROTEM: rotational thromboelastometry.

Part II: Survey

The literature states that quantitative data can help generalize and confirm specific observations found in qualitative research [29-32]. For the subsequent survey, we defined 5 statements based on the previously identified themes. The same group of interviewed anesthesiologists was asked to rate them on 5-point Likert scales in a questionnaire created using Google Forms (Alphabet Inc). Participants were informed that the survey takes only a few minutes to complete, participation is voluntary, and no compensation is offered. The translated announcement of the survey invitation is displayed in [Multimedia Appendix 3](#). The data collection was finished 3 weeks after the questionnaire was sent.

Statistical Analysis

The interview data analysis and figures were made using Microsoft Word and Excel (Microsoft Corp). We present the number of statements and their percentage distribution in the identified themes.

To define the interrater reliability of the coding template, we calculated Fleiss' Kappa using R (version 4.0.5; R Foundation for Statistical Computing). We calculated every statement's median and IQR for the survey analysis. We used the Wilcoxon signed rank test to determine the difference between the median and neutral answers. Statistical significance was indicated as $P < .05$.

Results

Study and Participant Characteristics

Detailed information on the study and participants is provided

Table 2. Study and participant characteristics.

Characteristics	Values
Study characteristics	
Total number of interviewed participants, n	77
Total number of participants completed the survey, n	23
Participant characteristics	
Interview participants	
Staff physicians, n (%)	8 (10.4)
Residents, n (%)	35 (45.5)
Anesthesiology nurses, n (%)	34 (44.2)
Anesthesia experience in years, median (IQR)	8 (3-10)
Number of ROTEM ^a interpretations per year, median (IQR)	26 (5-41)
Survey participants	
Staff physicians, n (%)	7 (30.4)
Residents, n (%)	8 (34.8)
Anesthesiology nurses, n (%)	8 (34.8)

Part I: Qualitative Analysis of Interview Answers

Word Count Analysis

The most frequently used words and word combinations used to describe the advantages of Visual Clot were: easier or easy (26/77, 33.8%), interpret or interpretation (23.4%, 18/77 participants), quick or quickly (19.5%, 15/77 participants), visual, visualize, visualized, or visualization (19.5%, 15/77 participants), good (16.9%, 13/77 participants), faster or fast (15.6%, 12/77 participants). In the group of statements describing the limitations of Visual Clot, the words and word groups most frequently used were: ROTEM (23.4%, 18/77 participants), missing (information or values or numbers; 16.9%, 13/77 participants), quantitative or quantification (16.9%, 13/77

in [Table 2](#). Residents and nurses were the dominant participants in the interviews. The most experienced participant had 33 years of experience in anesthesia. The least experienced had less than 1 year. Residents and nurses also dominated the survey.

participants). [Table 1](#) visually represents the most commonly used words in positive and negative perceptions.

Coding Tree

[Figure 2](#) shows the generated coding tree, including 2 main domains and 9 themes. The interrater reliability of the tree raters was 0.856 (95% CI 0.831-0.880), indicating almost perfect agreement [33].

Statements Describing Visual Clot

[Table 3](#) demonstrates examples of statements assigned to particular subtopics with participant counts and percentages.

A total of 4 comments were defined as positive but not assigned to any themes. There was 1 such statement in the negative group. A total of 19 comments were not assigned to any theme and were described as noncodable.

Table 3. Statements examples assigned to particular domain and subtopics with participant count and percentages.

Major domain and subtopics	Examples
Positive statements describing Visual Clot (179/319, 56.1%)	
Positive design features (63/295, 21.4%)	<ul style="list-style-type: none"> “Very simplified” (Participant 13). “Visual presentation” (Participant 21). “Tells figuratively what to do” (Participant 26).
Positive usability features (30/295, 10.2%)	<ul style="list-style-type: none"> “It can be perfectly integrated in the clinic” (Participant 24). “A good tool to get an overview” (Participant 32). “You can see at-a-glance what is missing” (Participant 70).
Intuitive and easy to learn (61/295, 20.7%)	<ul style="list-style-type: none"> “Directly applicable and does not require long training” (Participant 5). “Very intuitive” (Participant 75). “Easy to understand” (Participant 76).
Time saving (21/295, 7.1%)	<ul style="list-style-type: none"> “2-3 seconds to a quick overview” (Participant 22). “Immediate detection of the problem” (Participant 5). “Quick to interpret” (Participant 27).
Negative statements describing Visual Clot (113/319, 35.4%)	
Design problems (23/295, 7.8%)	<ul style="list-style-type: none"> “Confusing, blinking” (Participant 57). “Quality of hyperfibrinolysis difficult to demonstrate” (Participant 22). “Not everything you see is relevant” (Participant 24).
Usability problems (12/295, 4.1%)	<ul style="list-style-type: none"> “Quantity of change is not visible” (Participant 2). “You have to know the pictures first” (Participant 30). “No prioritization possible” (Participant 76).
Incompleteness: a lack of a quantitative component (62/295, 21.0%)	<ul style="list-style-type: none"> “Also values that are in normal range—is it close to the limit or not?” (Participant 54). “No graduation ‘all or nothing’” (Participant 60). “Exact quantification not possible” (Participant 4).
Need for training (15/295, 5.1%)	<ul style="list-style-type: none"> “Not yet established” (Participant 29). “Needs to get used to it” (Participant 45). “Needs habituation (not used by default yet)” (Participant 50).
Combination: Visual Clot and ROTEM^a (8/295, 2.7%)	
	<ul style="list-style-type: none"> “Would be nice to have it together with ROTEM” (Participant 50). “Ideal solution if could be combined with ROTEM” (Participant 49). “Combination of both necessary” (Participant 74).

^aROTEM: rotational thromboelastometry.

Positive Statements Describing Visual Clot

Positive Design Features

Most comments were made on this topic, emphasizing that a “pictorially summarized” (participant 2) and “visually appealing” (participant 3) data presentation allows one to see “the relevant ROTEM information at-a-glance” (participant 9). Such a design supports health care professionals in making clinical decisions. It is essential in emergencies because the actual coagulation status is immediately visible (participant 14) and it is instantly apparent which hemostasis components are missing (participant 12).

Positive Usability Features

Visual Clot is “a good tool for broad application,” stated participant 72. It enables “pre-interpretation of the complex information” (participant 3) and focuses “on the essential”

(participant 65). The benefits of the Visual Clot in urgent situations were also highlighted: the technology is “very good for emergencies,” stated participant 13.

Intuitive and Easy to Learn

As in the previous study [24], the Visual Clot was also described here as intuitive and easy to learn. “Very intuitive, short time needed to understand it,”—pointed out participant 6. It was underlined that visualizations provided by the Visual Clot are “quickly recognizable even by untrained persons or with little knowledge of coagulation” (participant 13).

Time Saving

The Visual Clot provides an “overview at-a-glance,” as participant 76 said. “I immediately saw what was missing,” stated participant 16. These features lead to quicker diagnosis—“focus is faster on the problem”—as participant 46 said, and thus to faster initiation of treatment.

Negative Statements Describing Visual Clot

Design Problems

Several ideas that could potentially enhance Visual Clot's design were identified. Participant 47 pointed out that the presentation of platelets and fibrinogen are similar, and thus it is difficult to distinguish. Participant 48 also agreed: "I did not notice that platelets were missing because it was white and dashed like fibrinogen." Some participants found that the Visual Clot is too dynamic—too much movement on the screen, which can lead to distraction and make the interpretation of the results difficult "Even if coagulation status is fine, everything is moving, and you can poorly differentiate what is missing" (participant 53), "moves too much, even if everything is fine—distraction" (participant 55).

Usability Problems

Visual Clot is "confusing at the beginning"—stated participant 31 and added that it is "difficult to use without routine." Visual Clot provides "too much information at once,"—participant 53 pointed out.

Incompleteness: Lack of a Quantitative Component

The central Visual Clot aspect criticized was the technology's incompleteness in terms of lacking a quantitative component.

Several participants stated that the Visual Clot is "not precise" (participant 1), which can be explained in the words of participants 53 and 9, respectively, who said that in the Visual Clot "quantitative is missing" and that one "can get more information with the ROTEM."

Need for Training

The main point identified in the participants' opinions on this topic was the lack of experience working with this technology and that it is a very new tool not yet established in clinical practice.

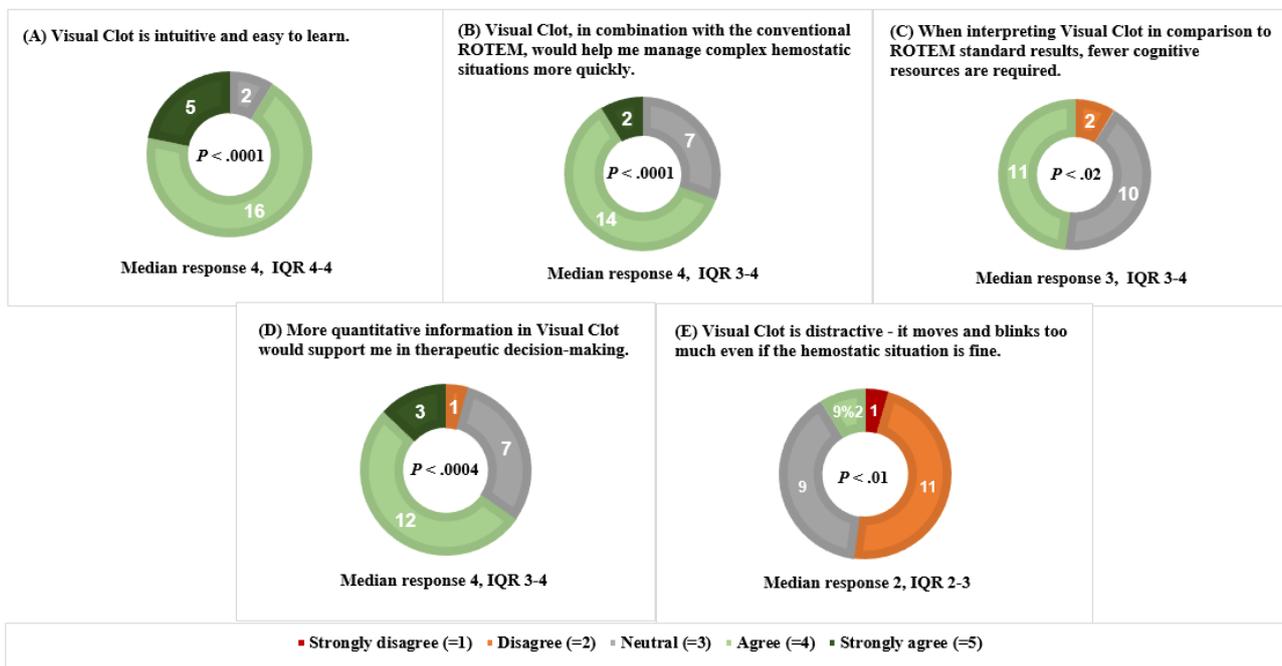

Combination of Visual Clot and ROTEM

Several participants said they could benefit from combining the Visual Clot and ROTEM when interpreting coagulation assays. "A combination of Visual Clot and ROTEM would be perfect," pointed out participant 19, while participant 74 said, "a combination of both is necessary." There was no difference in positive and negative statements based on participants' specialty or level of experience.

Part II: Analysis of Statements Assessed in the Survey

Figure 3 shows the detailed evaluation of the statements rated in the survey.

Figure 3. Pie charts presenting survey results with the number of participants who chose a particular category (N=23). ROTEM: rotational thromboelastometry.

All sample medians differed statistically significantly from neutral ($P < .05$). The number of participants in the quantitative part of the evaluation differs from the qualitative part because not all participants completed the questionnaire. The results are presented as medians and IQR. P values are provided to indicate a statistically significant difference between the median of the sample and the neutral value.

Discussion

Principal Findings

This mixed qualitative-quantitative study analyzed the perceptions of anesthesiology personnel regarding Visual Clot—a new situation-awareness and user-oriented visualization technology for viscoelastic hemostatic resuscitation—after the high-fidelity simulation study. User perceptions enable us to identify the positive aspects of the technology and reveal the potential for improvement in the future. After computer-based

studies, this is the first time that Visual Clot has been evaluated in a high-fidelity simulation study, a validated process for testing a noncertified product in an environment that closely resembles clinical reality [34,35].

The principal findings demonstrate that the design features of Visual Clot have received the most positive comments. As in the previous computer-based Visual Clot study [24], the participants of this high-fidelity simulation study emphasized that the way this technology is designed provides a good overview of the clotting situation and is an additional help in the decision-making process during acute bleeding situations. Further, Visual Clot was described as intuitive and easy to learn. Participants repeatedly mentioned that the results of Visual Clot are quickly recognizable and understandable even by inexperienced clinicians. The main criticism concerned the lack of quantitative information.

Previous Visual Clot studies [22-24,36,37] underline the benefits of additional visualization technology, simplifying standard ROTEM data interpretation [20]. Anesthesia providers using Visual Clot in a high-fidelity simulation study were more likely to correctly administer targeted coagulation therapy and to give the first targeted coagulation product faster. In addition, participants demonstrated greater decision-making confidence with Visual Clot [23]. Moreover, the correctness of the clinical decisions was independent of previous rotational thromboelastometry knowledge and experience.

The superior participants' performance when working with Visual Clot may be explained by its design supporting the strengths of human sensory perception. The Visual Clot was developed to assist care providers in managing highly complex coagulation situations, presenting the data in an awareness-oriented interface design. The main aim of this design is to convey the information as quickly as possible and with the lowest cognitive effort [25].

Principles of situation awareness-oriented and user-centered design enables effective data management and a comprehensive understanding of what is happening and thus help to stay situationally aware. This concept is essential in many domains, including medicine, where managing complex and dynamic situations is fundamental [38,39].

Its definition breaks down into three separate phases (1) the perception of environmental elements in the current situation within a volume of time and space, (2) understanding their meaning, and (3) their projection in the near future. Based on this, the Visual Clot data are visually represented, preprocessed, and simplified. The results of coagulation parameters are divided into 3 categories: too low, normal, or too high. Such information presentation increases diagnostic confidence, but numeric indicators are needed for precise data analysis and targeted treatment initiation. As previously indicated, the lack of quantitative information is reflected in user responses. It also explains the participants' considerations that combining Visual Clot and ROTEM would be helpful in clinical decision-making.

Some other technologies based on situation awareness and user-centered design principles include Philips Visual Patient Avatar (Philips) [40], AlertWatch (AlertWatch Inc), Dynamic

Lung Panel and PulmoSight (Hamilton Medical AG), HemoSight and Physiology Screen (Mindray Medical International Limited), and Alarm Status Visualizer (Masimo Corp) [41,42].

This study showed user perceptions regarding the new situation awareness-based, user-oriented technology for thromboelastometry data presentation—Visual Clot. It makes us aware of the user's needs and could help us simplify information processing and decision-making in the future. An integral facet of advancing the technological framework informed by the results of this study lies in the prospect of merging quantitative data into the Visual Clot platform and presenting this merged information in a consolidated interface. This concerted integration promises to align both quantitative and qualitative data to provide a more complete and accurate representation of prevailing conditions. This integration can be achieved in a variety of ways, including the direct overlay of numerical values onto the Visual Clot visualization, or the parallel juxtaposition of a complementary graphical representation alongside the numerical data set.

Strengths and Limitations

This study has several strengths and limitations. The interview part of the study has the typical limitations of qualitative research. The findings of qualitative analysis cannot be extrapolated to larger populations with the same certainty as quantitative results because the findings are on the subjective basis and not tested for statistical significance [43]. However, the quantitative survey helped to provide greater insight into the importance of the main themes identified. Moreover, the interviewed participants were selected according to their availability in the clinical praxis and not randomly.

Furthermore, the number of participants in the survey was lower than in the interviews because not all participants in the simulation study completed the survey. Finally, it is a single-center study performed in a university hospital with high care standards in Europe. User perceptions may vary across diverse clinical settings in different parts of the world.

Conclusions

After previous studies investigating user perceptions of Visual Clot in computer-based simulation studies, this is the first study to analyze the user perceptions of Visual Clot in a high-fidelity simulation—the intermediate step between computer-based simulation studies in a laboratory and real-life use. In this study, Visual Clot appeared to be a well-accepted additional tool supporting health care professionals working with ROTEM. Based on participants' perceptions, user-centered and situation awareness-oriented design, as shown in Visual Clot, can simplify the presentation of complex information and thus make critical decision-making quicker and more efficient. The benefits of this technology have been particularly highlighted in emergencies and even for care providers with little experience in coagulation management. Participants described Visual Clot as intuitive and easy to learn. The lack of a quantitative component has been identified as a significant limitation. These findings highlight the advantages of Visual Clot and its potential

for improvement may help further develop this and other situation awareness-based technologies.

Acknowledgments

The authors are thankful to the study participants for their time and effort. The Institute of Anesthesiology of the University Hospital of Zurich, Zurich, Switzerland and the University of Zurich, Zurich, Switzerland funded this study.

Abstract

Background: Sleep apnea is a significant public health disorder in Finland, with a prevalence of 3.7%. Continuous positive airway pressure (CPAP) therapy is the first-line treatment for moderate or severe sleep apnea. From November 18, 2019, all patients who started their CPAP therapy at Oulu University Hospital were attached to a sleep apnea digital care pathway (SA-DCP) and were instructed on its use. Some patients still did not use the SA-DCP although they had started their CPAP therapy.

Objective: We aimed to study health care professionals' (HCPs') perspectives on the SA-DCP and its usefulness for their work; whether the main targets of SA-DCP can be reached: shortening the initial guiding sessions of CPAP therapy, reducing patient calls and contact with HCPs, and improving patients' adherence to CPAP therapy; and patients' perspectives on the SA-DCP and its usefulness to them.

Methods: Overall, 6 HCPs were interviewed in May and June 2021. The survey for SA-DCP users (58/91, 64%) and SA-DCP nonusers (33/91, 36%) was conducted in 2 phases: from May to August 2021 and January to June 2022. CPAP device remote monitoring data were collected from SA-DCP users (80/170, 47.1%) and SA-DCP nonusers (90/170, 52.9%) in May 2021. The registered phone call data were collected during 2019, 2020, and 2021. Feedback on the SA-DCP was collected from 446 patients between February and March 2022.

Results: According to HCPs, introducing the SA-DCP had not yet significantly improved their workload and work practices, but it had brought more flexibility in some communication situations. A larger proportion of SA-DCP users familiarized themselves with prior information about CPAP therapy before the initial guiding session than nonusers (43/58, 74% vs 16/33, 49%; $P=.02$). Some patients still had not received prior information about CPAP therapy; therefore, most of the sessions were carried out according to their needs. According to the patient survey and remote monitoring data of CPAP devices, adherence to CPAP therapy was high for both SA-DCP users and nonusers. The number of patients' phone calls to HCPs did not decrease during the study. SA-DCP users perceived their abilities to use information and communications technology to be better than nonusers (mean 4.2, SD 0.8 vs mean 3.2, SD 1.2; $P<.001$).

Conclusions: According to this study, not all the goals set for the introduction of the SA-DCP have been achieved. Despite using the SA-DCP, some patients still wanted to communicate with HCPs by phone. The most significant factors explaining the nonuse of the SA-DCP were lower digital literacy and older age of the patients. In the future, more attention should be paid to these user groups when designing and introducing upcoming digital care pathways.

Introduction

Background

Sleep apnea is a significant public health disorder in Finland, with a prevalence of 3.7%. The prevalence of sleep apnea worldwide has been increasing in relation to the obesity pandemic [1]. Untreated sleep apnea increases cardiovascular diseases, accidents, likelihood of taking sick leave, and premature mortality [2]. The clinical severity of sleep apnea is defined based on 3 components: daytime sleepiness owing to sleep apnea, the apnea-hypopnea index (AHI), and arterial blood oxygen saturation [2]. Continuous positive airway pressure (CPAP) therapy is the first-line treatment for moderate or severe sleep apnea in addition to conservative therapy (ie, weight loss, avoidance of sleep-disturbing substances, and lifestyle issues) [2]. CPAP therapy is a safe and efficient treatment for sleep apnea, relieving both daytime and nighttime symptoms and improving traffic safety [3,4]. In Finland, the need for CPAP treatment and the number of outpatient visits in both specialized and primary care have increased considerably because of the increased number of patients with sleep apnea [5].

The digitalization of health care has been seen as a potential option for offering treatment to patients regardless of time and place and involving them in their own care [6,7]. In addition, digitalization has the potential to make health care systems more efficient [8]. Despite its potential to improve health care services, digitalization does not automatically guarantee better services [9]. It has been noted as a problem, for example, that digital services are not necessarily aligned with clinician and patient preferences [9]. The challenge is that, in some cases, they complement rather than substitute the current services, and care processes are not always redesigned to achieve the best benefits from digital services [9-12]. Citizens' willingness and ability to use electronic services is also an obstacle to realizing the benefits of health care digitalization [13,14]. Because data breaches cause potentially catastrophic consequences, information security concerns have weakened patients' adoption of digital health services [15,16]. The challenges of the technical implementation of digital services, such as missing functionalities and lack of interoperability with existing information systems, have weakened the willingness of health care professionals (HCPs) to use them [10].

Factors promoting the adoption of digital health services are their perceived benefits for patients and patients' previous positive experiences with electronic services [13,15]. Previous studies showed that digital health interventions can improve patients' adherence to their care [17,18]. For example, Aardoom et al [18] showed that adherence to CPAP therapy in patients with sleep apnea can be improved with digital interventions in the initial months of treatment. Adherence to the use of the digital health service has also been found in some studies to positively affect outcomes [19,20]. Good digital literacy promotes the use of digital health services; studies have found

young people have better digital literacy than older age groups [13,21]. As the user base of digital health care services can be very broad, and users can have functional limitations owing to age or illness, the ease of use of these services is important in promoting their use [15,22].

Finland's first phase of health care digitalization involved the digitalizing of HCPs' tools, such as electronic patient records; e-prescribing and digitalization have progressed well [23]. Currently, Finnish citizens are increasingly offered digital health care services and products [22,24]. Several countries, including Finland, have introduced new health technology assessment methods to ensure that digital health provides evidence-based benefits [16,22,25]. Digital care pathways (DCPs) are an example of digital health care services, and today, there are >300 DCPs in use in Finnish specialized care units [26]. One of the main goals of DCPs is to complement or replace traditional health care appointment visits [26]. In addition, DCPs aim to support and help in the self-treatment of long-term illnesses, monitoring, and adaptation to the illness, as well as enable patients to prepare for various health care procedures beforehand [26]. Several DCPs have been studied in Finland from the perspective of HCPs, organizations, and patients [7,10,13,27-31]. One of these DCPs is the sleep apnea DCP (SA-DCP), which was introduced at Oulu University Hospital (OUH) on November 18, 2019 [32]. All patients who start their CPAP therapy in OUH will be attached to the SA-DCP, that is, their patient data will be recorded in it, and they will be instructed on how to log in and use it [32]. When a patient starts on the SA-DCP, they register as an SA-DCP user through strong identification by accepting the terms of use and privacy statement and entering his or her contact information [33].

Objectives

In OUH, the CPAP therapy for patients with sleep apnea begins with an initial guiding session where patients are instructed on using their CPAP device. SA-DCP contains information and instructions about CPAP therapy; therefore, it would be desirable for patients to familiarize themselves with that information in advance [32]. In this way, the initial guiding session of CPAP therapy could be shortened because the basic information about CPAP therapy would not need to be reviewed again during the sessions. The SA-DCP contains reliable information about sleep apnea, its treatment, and CPAP therapy [32]. With the introduction of SA-DCP, it would be desirable to reduce patients' phone calls and other contacts with HCPs when information can be found in the SA-DCP. The SA-DCP also includes electronic messaging between patients and HCPs, which could reduce such calls [32]. The major aim of the SA-DCP is to increase patients' adherence to CPAP therapy. However, there is still a challenge in that some patients with sleep apnea do not log in and use it.

The main aims of the study are as follows:

1. To investigate HCPs' perspectives on the SA-DCP and its usefulness for their work
2. To determine whether the main targets of SA-DCP can be reached: shortening the initial guiding sessions of CPAP therapy, reducing patient calls and contact with HCP, and increasing patients' adherence to CPAP therapy.
3. To examine patients' perspectives on the SA-DCP and its usefulness.

Methods

Study Participants and Data Collection

The study population included HCPs at the OUH and patients who had started their CPAP therapy at the OUH. The patient population consisted of 2 groups. *SA-DCP users* were patients who had registered with the SA-DCP. *SA-DCP nonusers* referred to patients who had not registered with the SA-DCP.

Interviews of HCPs

HCPs of the OUH were contacted via email. Overall, 6 HCPs participated in the interviews from May to June 2021. Of these, 4 (67%) HCPs worked with patients, 1 (17%) was a supervisor, and 1 (17%) connected patients with sleep apnea to the SA-DCP and booked their appointments. The interviews were conducted remotely using a structured questionnaire. The HCPs provided voluntary informed consent for the interview by submitting a signed document. The interviews were then recorded and transcribed.

Survey for Patients With Sleep Apnea

The first part of material collection was conducted between May and August 2021. With the help of OUH HCPs, the survey, along with an invitation to participate and information about it, was sent to SA-DCP nonusers by mail. Respondents could send their responses by prepaid mail or electronically using Webropol Ltd's Webropol survey tool. SA-DPC users were informed about the study through the SA-DCP. They provided their consent and answered the survey using the SA-DCP questionnaire.

The second part of material collection was conducted between January and June 2022. Both SA-DCP users and SA-DCP nonusers were informed about the study with the annual device delivery in an assistive equipment center (AEC). They could send their responses by prepaid mail or answer electronically using Webropol Ltd's Webropol survey tool.

The patients' survey included multiple choice questions, 5-item Likert-type questions (with choices ranging from strongly disagree to strongly agree), and open-ended questions. In total, 33 SA-DCP nonusers and 58 SA-DCP users responded to the survey.

Remote Monitoring Data of CPAP Devices

Information about patients' adherence to CPAP therapy was collected from the remote monitoring data of CPAP devices. The HCP of OUH carried out the material collection manually in May 2021 in connection with 1-year controls of CPAP therapy. The collected information was anonymized and provided to the researchers. In total, CPAP remote monitoring

data were collected from 90 SA-DCP nonusers and 80 SA-DCP users.

Registered Data of Phone Calls

The information about the number of patients' phone calls per year to an AEC was collected from Aurora Innovation Ltd's TeleQ program. The registered phone call data were collected during 2019, 2020, and 2021.

SA-DCP Customer Feedback Survey

Patients using the SA-DCP had the opportunity to provide customer feedback using the SA-DCP survey tool. The patients provided informed consent through the SA-DCP that their customer feedback could also be used for research purposes. The customer feedback did not contain any personal information. Feedback on the SA-DCP from 446 patients between February 18 and March 24, 2022, was included in this study.

Statistical Methods

Patients' survey data were analyzed using SPSS software (version 28.0; IBM Corp). Descriptive statistics were applied to calculate the mean and SD for continuous data and frequency and percentage for categorical data. Baseline differences between the groups were explored using a 2-tailed independent sample *t* test for continuous variables and chi-square test for categorical variables. A *P* value <.05 was considered statistically significant for all analyses.

Qualitative Analysis

Qualitative methods were used in this study to analyze the open-ended questions in patient surveys and interviews with HCPs. The collected material was first analyzed using an inductive content analysis method to obtain a comprehensive understanding [34]. Initially, the HCPs' and patients' responses to the open-ended questions were open coded. Subsequently, the analyzed data were grouped into subcategories, and then similar findings were combined into the main categories to enable the final analysis. Finally, the textual data were analyzed using the quantification method [35].

Ethical Considerations

The study followed the guidelines of the Finnish Advisory Board on Research Integrity [36]. According to Finnish Law (488/1999), this study was exempted from review by the institutional review board (ethics committee of Northern Ostrobothnia Hospital District). The respondents were informed of the study. All participants voluntarily participated in the study and provided their informed consent. The results were processed such that no participants were identifiable in the results or quotations of this study. Sensitive personal information was not collected. The data were processed and stored in a secure environment according to the procedures of the University of Oulu.

Results

The Number of New CPAP Therapies, SA-DCP Users, and Phone Calls in the Years Studied

The number of new CPAP therapies in OUH between 2019 and 2021 is presented in Table 1. The percentage of SA-DCP users

has increased annually, but there are still patients who do not use the SA-DCP (Table 1). The number of phone calls per year to an AEC is presented in Table 1.

Table 1. New continuous positive airway pressure (CPAP) therapies, patients attached to the sleep apnea digital care pathway (SA-DCP), phone calls to an assistive equipment center (AEC) per year, and percentage of SA-DCP users.

	Year		
	2019	2020	2021
The number of new CPAP therapies	1172	1645	1160
The number of patients attached to the SA-DCP	292 ^a	1645	1160
The number of SA-DCP users	130	1006	935
Percentage of SA-DCP users	44.5	61.2	80.6
The number of phone calls per year to an AEC	2784	4068	4020

^aThe SA-DCP was introduced from November 18, 2019, onward.

HCPs' Perspectives on the SA-DCP and its Usefulness for Their Work

On the basis of the interviews with HCPs, the main themes, facilitators, and barriers related to using the SA-DCP are presented in Textbox 1. According to the interviewed HCPs, they were unable to identify significant changes in their workload and working practices following the introduction of the SA-DCP. Only one responder perceived that his workload had slightly increased because the SA-DCP did not support integration with electronic patient record; therefore, patient data had to be transferred manually from one program to another

(Textbox 1). However, HCPs reported that in some situations, the SA-DCP brought more flexibility to their work practices regarding patient communication (Textbox 1). For example, it enabled them to respond to patients' DCP messages during nonurgent work times, not only preremoved times. HCPs also reported that the initial guiding session of CPAP therapy went more smoothly for SA-DCP users who had familiarized themselves with the information about CPAP therapy through the SA-DCP (Textbox 1). The interviewed HCPs hoped that patients would make more use of the SA-DCP and its possibilities so its benefits would be better used.

Textbox 1. Themes and perceived barriers and facilitators regarding implementation of the sleep apnea digital care pathway (SA-DCP) according to health care professionals (HCPs).

Use rate of SA-DCP

- Barriers
 - SA-DCP's use rate had been lower than HCPs assumed it would be.
 - Some patients still thought that the only proper contact was personal contact with HCPs.
 - Patients' previous experiences with the need to log in to several digital health care services reduced their motivation to use them.
- Facilitators
 - Reminder text messages about logging into the SA-DCP have been sent to patients since June 2020.

Initial guiding session of continuous positive airway pressure (CPAP) therapy

- Barriers
 - Some SA-DCP users and nonusers still had not familiarized themselves with the prior information about CPAP therapy in advance.
- Facilitators
 - The guidance went more smoothly for SA-DCP users who familiarized themselves with the prior information about CPAP therapy.
 - From the patients' perspective, the instructional videos available in the SA-DCP were perceived as useful and clear.

Patients' communication practices with HCP

- Barriers
 - There were still a lot of phone calls.
 - HCPs also had to be reminded that they should not always call patients in connection with treatment controls but send a message via the SA-DCP.
- Facilitators
 - The SA-DCP gives patients more flexibility to contact HCPs regardless of time and place. For example, the patient may be in a location where they cannot answer the HCP's phone call.
 - HCPs may instruct the patient during a phone call to watch SA-DCP's educational video to get a better understanding of the matter.

Patients' adherence to CPAP therapy

- Barriers
 - There was no clear indication that patients' adherence to CPAP therapy was higher with the introduction of the SA-DCP.
- Facilitators
 - Reports obtained from CPAP devices had increased some patients' adherence to CPAP therapy.

Integration of SA-DCP into existing information and communications technology systems

- Barriers
 - The SA-DCP had to be used in a different web browser than electronic patient record (EPR).
 - Remote monitoring of CPAP devices requires a separate program, and remote monitoring data cannot be viewed via the SA-DCP.
 - Attaching patients to the SA-DCP is laborious and must be done manually by copying patient information from the EPR.
 - Data had to be copied manually from SA-DCP's messages into patients' care plans.

Workload and work practices of HCPs

- Barriers
 - HCPs' workloads did not change with the introduction of the SA-DCP.
- Facilitators

- The SA-DCP brought more flexibility to HCPs' work practices regarding communication with patients.
- The SA-DCP was a good way to deliver the necessary contact information to patients and thereby instruct them to reserve time for the necessary procedures by themselves.

The professionals also brought up ideas for the development of SA-DCP. They hoped that SA-DCP's integration with other information and communications technology (ICT) systems would be improved. One factor that caused a large workload for professionals was arranging appointment times for patients. The time reserved for the patient may not always suit him or her, necessitating a discussion about a more suitable time. If the patient could book appointments through the SA-DCP, it would greatly reduce the professionals' working hours. Two respondents mentioned that in the future, an initial guiding session of CPAP therapy could also be carried out remotely, but this would require that patients for whom this would be suitable should be identified in advance. The professionals hoped that all surveys and measurements made by the patients related to their treatment would be available in an electronic format. The hope was also that the SA-DCP's calendar would automatically remind patients, for example, to renew equipment, giving them more responsibility for managing their own affairs. One respondent wished that instructional videos could be directly linked to SA-DCP's messages so that patients would not have to search for them.

The HCP interviewees perceived digital services in health care as a positive thing. According to them, the services should be easy to use, and the real end users of the services should be included in their development. One respondent believed that patients will use digital health care services more frequently in the future, but such systems are always initially met with resistance. The respondent mentioned that at first, patients in

Finland were against e-prescribing and the Patient Data Repository of Kanta Services, but today, such services are commonplace, and people use them smoothly.

Comparison of Characteristics Between SA-DCP Users and SA-DCP Nonusers

According to the patients' survey, there were no statistically significant differences in age, sex, and smoking status between SA-DCP users and nonusers (Table 2). According to the remote monitoring data of CPAP devices, SA-DCP nonusers were older than SA-DCP users (mean 59.1, SD 13.8 vs mean 55.3, SD 10.8; $P<.049$; Table 3). Compared with nonusers, SA-DCP users perceived their own abilities to use ICT to be better (mean 4.2, SD 0.8 vs mean 3.2, SD 1.2; $P<.001$); they used computers, tablets, or smartphones more often (58/58, 100% vs 27/33 81%; overall $P=.002$); and they were more accustomed to using electronic services (mean 4.8, SD 0.5 vs mean 4.1, SD 1.2; $P=.006$; Table 2). There was no statistically significant difference in how regularly SA-DCP users and nonusers used the electronic services (Table 2). SA-DCP users thought that communication about SA-DCP and how to log in had been clear, although SA-DCP nonusers thought that it had not (yes 52/58, 91% vs yes 7/33, 24%; overall $P<.001$; Table 2). Compared with SA-DCP users, SA-DCP nonusers preferred phone calls or physical appointments with HCPs to manage their health-related issues (Table 2). Neither SA-DCP users nor SA-DCP nonusers had any major concerns about the data security and protection of digital health care services (Table 2).

Table 2. Patient responses to the survey.

Characteristics	Use of SA-DCP ^a		P value

Patients' Rationales for Using or Not Using SA-DCP

Patients were asked about their rationale for using or not using the SA-DCP (Table 4). SA-DCP users mostly adopted the

SA-DCP because they thought that signing up for the SA-DCP was part of their treatment process (42/58, 72%). SA-DCP nonusers did not adopt the SA-DCP mainly because they were unaware of it (15/33, 46%).

Table 4. Patients' rationales for using or not using the sleep apnea digital care pathway (SA-DCP).

Patients' rationales for using or not using the sleep apnea digital care pathway (SA-DCP)	Values, n (%)
Patients' rationales for using the SA-DCP (n=58)	
I thought signing up for SA-DCP was part of my treatment process	42 (72)
It was recommended to me	39 (67)
It allows me to take care of my affairs regardless of time and place	31 (53)
I am very accustomed to using electronic services	25 (42)
I can more easily get information about sleep apnea and its treatment	18 (31)
I prefer to use electronic services for my treatment	15 (26)
I can more easily get information about CPAP ^a therapy	15 (26)
I can take care of things related to my care more safely during the current COVID-19 period	12 (21)
By using SA-DCP, I am more committed to my treatment	8 (14)
Other reasons	2 (3)
Patients' rationales for not using the SA-DCP (n=33)	
I am not aware of SA-DCP	15 (46)
I prefer physical appointments	13 (39)
I prefer phone calls	10 (30)
I am aware of SA-DCP, but I forgot to log in	9 (27)
I do not know how to use electronic services	7 (21)

I do not feel the need to log into SA-DCP as part of my CPAP therapy	1 (3)

^aCPAP: continuous positive airway pressure.

Patients' Prefamiliarization With CPAP Therapy Before the Initial Guiding Session

A larger proportion of SA-DCP users had familiarized themselves with prior information about CPAP therapy before the initial guiding session of CPAP therapy than SA-DCP nonusers (43/58, 74% vs 16/33, 49%; $P=.02$; [Table 2](#)). Among the 48 SA-DCP users who familiarized themselves with information about CPAP therapy beforehand, 29 (67%) performed it through the SA-DCP ([Table 2](#)). Most SA-DCP nonusers (6/16, 38%) said they had received the preliminary information from a spouse or a relative who had already used a CPAP device. The other sources of information for both groups were the internet (6/59, 10%), private health care providers (3/59, 5%), primary health care units (2/59, 3%), and the Duodecim medical information database (2/59, 3%). SA-DCP users also received information from occupational health care units (2/43, 5%) and the Facebook sleep apnea support group (2/43, 5%). Correspondingly, SA-DCP nonusers received

information from specialized care units (2/16, 13%), research articles (1/16, 6%), and AEC (1/16, 6%).

The initial guidance sessions of CPAP therapy were carried out with small groups of patients (4-8 patients at a time). According to HCPs, the initial guiding sessions were smoother for patients who had already familiarized themselves with prior information about CPAP therapy through the SA-DCP ([Textbox 1](#)). The problem was that many patients still did not have prior information about CPAP therapy; therefore, most of the initial guiding sessions had to be implemented according to their needs. According to the HCPs, patients found the instructional videos available in the SA-DCP to be useful and clear ([Textbox 1](#)). Patients were also instructed to familiarize themselves with them and other information material found on the SA-DCP even after the sessions if they had further questions.

Patients' Information Needs About Sleep Apnea and CPAP Therapy

SA-DCP includes electronic messaging functionality between patients and HCPs and information about sleep apnea, its treatment, and CPAP therapy. According to the survey responses

of SA-DCP users, most patients looked for information about the SA-DCP, sleep apnea, self-treatment of sleep apnea, and cleaning and maintenance of the CPAP device (Table 5). The messaging functionality of the SA-DCP and its "frequently asked questions" function were not widely used; only 38% (22/58) of SA-DCP users used them (Table 5).

Table 5. Functionalities of the sleep apnea digital care pathway (SA-DCP) used by patients according to the SA-DCP users survey (N=58).

	Values, n (%)
The number of patients who familiarized themselves with the following information materials	
Welcome to SA-DCP	55 (95)
Sleep apnea	45 (78)
Cleaning and maintenance of the CPAP ^a device	43 (74)
Self-treatment of sleep apnea	42 (72)
CPAP therapy	39 (67)
Preparing for the CPAP therapy initial guiding session	38 (67)
Sleep apnea and driving ability	32 (55)
CPAP therapy in unusual everyday situations	28 (48)
Controls, rehabilitation, and social security	25 (43)
Frequently asked questions	22 (38)
The patient has communicated with the HCP ^b in matters related to his or her treatment through the messaging functionality of SA-DCP	22 (38)

^aCPAP: continuous positive airway pressure.

^bHCP: health care professional.

During the treatment period, both SA-DCP users and SA-DCP nonusers sought additional information regarding their treatment without contacting HCPs (23/58, 39% vs 9/33, 27%; $P=.48$; Table 2). Among 23 SA-DCP users who sought more information, 8 (35%) performed it through the SA-DCP. The other reported information sources for SA-DCP users were the internet (9/23, 39%), Facebook sleep apnea support group (1/23, 4%), patient organizations (1/23, 4%), rehabilitation (1/23, 4%), and professional education (1/23, 4%). SA-DCP nonusers received additional information from the following sources: the internet (5/9, 56%), Facebook sleep apnea support group (1/9, 11%), scientific articles (1/9, 11%), and information material provided by private health care services providers (1/9, 11%). Most SA-DCP nonusers and SA-DCP users who sought more information about CPAP therapy and sleep apnea received the information they needed (8/9, 89% vs 21/23, 91%; $P>.99$; Table 2).

Patients' Communication Practices With HCPs

During the treatment period, 52% (17/33) of SA-DCP nonusers and 57% (33/58) of SA-DCP users contacted HCPs (Table 2). Among 33 SA-DCP users who contacted HCPs, 17 (52%) used the SA-DCP, and the rest used other contact methods (Table 2). SA-DCP users who preferred contact methods other than SA-DCP messages were older (mean 63.3, SD 9.4 vs mean 55.7, SD 10.8; $P<.04$). Phone calls were the most important form of contact for SA-DCP users (10/33, 30%). SA-DCP nonusers (9/17, 53%) mostly contacted HCP via phone calls. The next most common contact method for both groups was a physical visit to an AEC or a primary health care unit. The

contact mostly concerned CPAP therapy; this was the case for 88% (15/17) of SA-DCP nonusers and 70% (23/33) of SA-DCP users (Table 2). Most SA-DCP nonusers and SA-DCP users who contacted HCPs received the help they needed (16/17, 94% vs 31/33, 94%; $P=.41$; Table 2).

According to the phone call register data, the annual number of phone calls to an AEC was still high even after the introduction of SA-DCP (Table 1). An exact comparison of phone calls to AECs per patient between different years could not be made because the number of new CPAP therapies in the OUH varied between different years, and the number of annual phone calls also showed contacts with HCPs from patients whose CPAP therapies had started in previous years (Table 1). The results of 2019 mainly represent a situation in which the SA-DCP was not yet in use at OUH because it was introduced at the very end of 2019. The results of 2021 represent a situation in which the SA-DCP had been in use at OUH for approximately 2 years. HCPs also indicated the same; there was no significant decrease in the number of phone calls, and there were still many phone calls related to CPAP therapy (Textbox 1). HCPs emphasized that they try to guide patients during phone calls to use the SA-DCP more in matters related to their care. Although the patients' affairs were handled mostly with phone calls, the HCPs thought the instructional videos and informational materials included in the SA-DCP were valuable. It was possible to better explain things to patients with them (Textbox 1). For example, HCPs may instruct the patient during a phone call to watch SA-DCP's educational video to get a better understanding of the matter. The HCPs also emphasized that the SA-DCP is a

good way to deliver the necessary contact information to patients, allowing them to reserve time for the necessary procedures themselves (Textbox 1).

Patient Adherence to CPAP Therapy

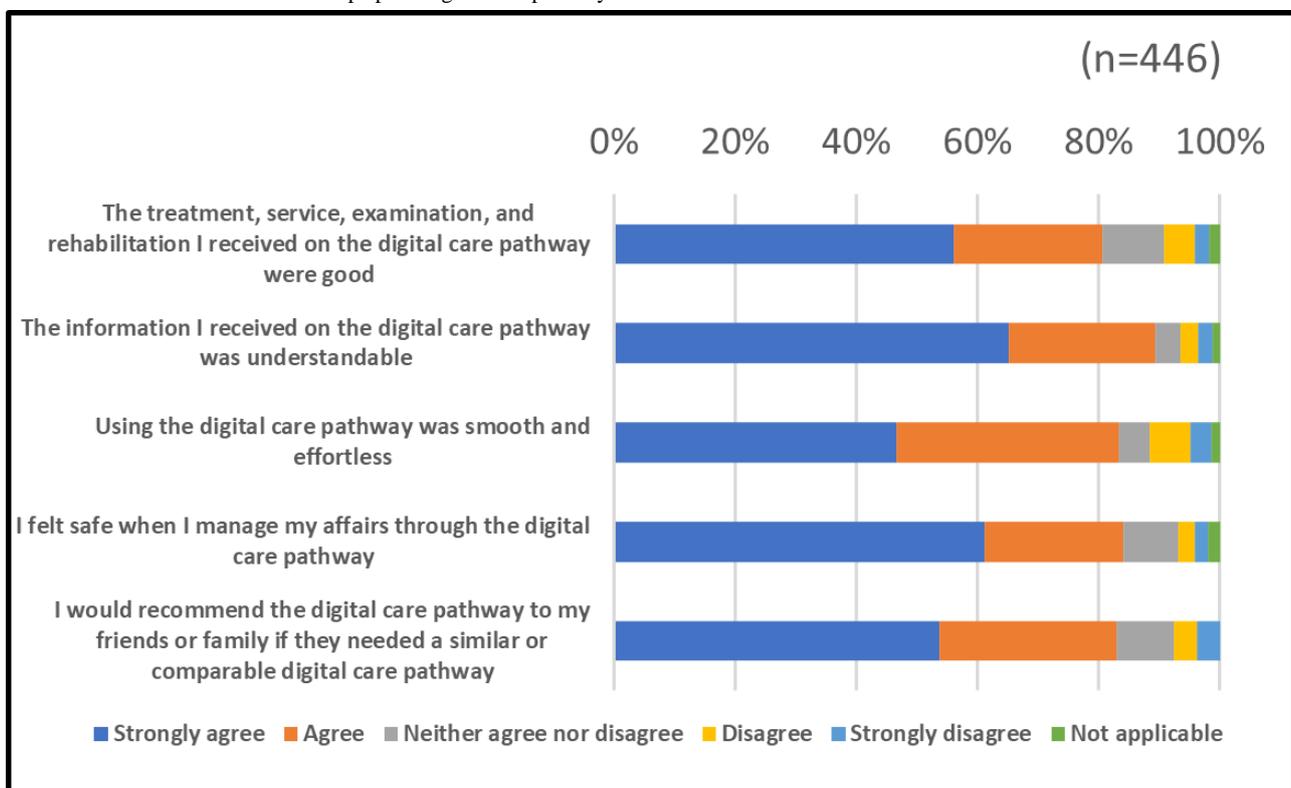

According to the patients' responses to the survey and remote monitoring data of CPAP devices, adherence to CPAP therapy was high in both groups (Tables 2 and 3). Both groups used the CPAP device on average for >6 hours per night and on >90% of nights (Tables 2 and 3). On the basis of the patients' own assessments, adherence to CPAP therapy was high in both SA-DCP nonusers (mean 4.8, SD 0.5) and SA-DCP users (mean 4.7, SD 0.8; Table 2). In addition, according to the patients' survey, 72% (42/58) of SA-DCP users reported that SA-DCP had made them more motivated to perform their own CPAP therapy (Table 2). Most patients in both groups believed that

CPAP therapy helped them treat sleep apnea (Table 2). The remote monitoring data of CPAP devices showed that CPAP therapy had significantly reduced the number of AHIs for both groups (Table 3).

Patient Feedback About SA-DCP

A total of 446 patients responded to the customer feedback survey; their feedback is shown in Figure 1. Patient feedback on the SA-DCP was generally positive; most of them agreed or strongly agreed with the survey claims (Figure 1). When examining the results, it should be noted that the questions of the patient feedback survey are common to every DCP in the OUH. As the functionalities offered by DCPs vary according to the care chains of different diseases, not all the questions are necessarily valid for every DCP. For example, examinations are not offered through the SA-DCP.

Figure 1. Patient feedback about the sleep apnea digital care pathway.

Of 446 patients, 102 (22.9%) who responded to the survey provided free-form feedback on the SA-DCP. Moreover, 22 patients gave generally positive feedback about the SA-DCP. For the most part, they did not elaborate on their feedback. According to 2 respondents, the possibility to use the services remotely was a good thing, and according to 2 respondents, the SA-DCP was a good and modern service. However, 19 patients thought that they did not need to use the SA-DCP, or that it did not add value to their treatment. Moreover, 11 respondents mentioned that communication and information about the SA-DCP should be improved. According to 9 respondents, the SA-DCP contained good and comprehensive information about sleep apnea and its treatment, as well as CPAP therapy. However, 3 respondents mentioned that although the SA-DCP contained good information, the same information can be found on the internet. With regard to SA-DCP's messaging feature, 5

respondents thought it was a functional solution. Conversely, 9 respondents said that they encountered problems or delays related to messaging and 9 respondents desired new features for the SA-DCP, such as better search functionality. As the information content of SA-DCP was only available in Finnish during the research, some respondents presented English language support as a need for future development. According to 5 responses, SA-DCP's user interface was clear, and its usability was good. In contrast, 4 respondents stated that the user interface could still be improved. Three respondents had technical problems and challenges when using the SA-DCP. Two users reported that the SA-DCP worked well technically. Three respondents said that they would not like to manage their affairs through digital services. Four respondents reported that they had experienced challenges using the SA-DCP, especially in relation to finding their own care path.

Discussion

Principal Findings

This study investigated whether the 3 main goals for introducing the SA-DCP at OUH were achieved. The first aim of introducing the SA-DCP was to shorten the initial guiding sessions of CPAP therapy on the assumption that the patients would have familiarized themselves with prior information about CPAP therapy in advance through the SA-DCP. The second main aim was to reduce the number of patients' phone calls and contacts to HCPs, especially when the information can be found in the SA-DCP. The primary goal of implementing SA-DCP at OUH was to improve patients' adherence to CPAP therapy. However, according to the results of this study, not all the objectives of introducing the SA-DCP were achieved.

On the basis of the HCP's responses to this study, shortening the initial guiding sessions of CPAP therapy had not been fully achieved, although a significantly larger number of SA-DCP users had familiarized themselves with prior information about CPAP therapy compared with SA-DCP nonusers. In this regard, it can be said that SA-DCP has contributed to the better preparation of patients for sessions. The initial guiding sessions were smoother for patients who had already familiarized themselves with prior information regarding CPAP therapy through the SA-DCP. However, many patients still did not have prior information about CPAP therapy; therefore, most sessions had to be implemented according to their needs. Because digital services may require care process changes to get the most out of them, 2 HCPs mentioned that the initial guidance sessions could also be carried out remotely in the future; however, this would require that the patients for whom this procedure would be suitable should be identified in advance [11,12].

Despite previous studies showing that DCPs would make it possible to reduce the number of patient phone calls to HCPs, this did not happen in the case of SA-DCP [37,38]. The annual number of phone calls to an AEC was still high even after the introduction of SA-DCP, according to the phone call register data. As the number of patients' phone calls related to CPAP therapy was still high, HCPs mentioned that it was difficult to assess the actual change in the number of phone calls. However, they perceived that the number of patient calls did not decrease significantly. Previous studies have shown that patients' ability to use electronic services also promotes the use of digital health care services [39,40]. However, Jansen et al [41] found that despite the regular use of new digital technologies and services such as electronic banking, few of their study participants supported using these tools for communicating with their HCPs. The same behavior pattern can also be observed in the case of SA-DCP. Although SA-DCP users in this study perceived their ability to use ICT to be good and used computers, tablets, or smartphones regularly and were accustomed to using electronic services, only approximately half of them contacted the HCP with SA-DCP messages when needed. Among SA-DCP users, phone calls were the most important other contact method. The notable finding was that SA-DCP users who preferred another contact method were older.

Patient concerns about data security and protection have weakened their willingness to use electronic communication methods in health care [15,42]. On the basis of this study, this would not be an explanatory factor for the low use of SA-DCP messages, as both SA-DCP users and SA-DCP nonusers were not significantly concerned about the data security and protection of digital health care services. Zanaboni and Fagerlund [43] discovered that communicating via electronic tools was less time-consuming from the patient's perspective than communicating via phone calls. However, some participants indicated that the time elapsed to receive a response from the HCP was more important than the time spent using the service itself. Long response times have been seen as one of the most important reasons for patients' dissatisfaction with electronic communication in health care [39,44]. In a Norwegian study, older patients hoped that their electronic messages would be answered the next day at the latest; otherwise, they experienced dissatisfaction with the service [39]. From the patients' point of view, they may perceive that a phone call is a quick and convenient way to handle their health-related matters [45-47]. The fundamental difference is that a phone call involves real-time interactive communication, whereas SA-DCP messages can be defined as asynchronous communication [48]. The patient may ask follow-up questions during the phone call and the HCP can answer them immediately. When using electronic communication tools, there may be delays in answers to questions and possible follow-up questions because of asynchronous communication, as the patient and the HCP may not be dealing with the issue simultaneously [48].

One of the main goals of introducing the SA-DCP was to improve patients' adherence to CPAP therapy. This study showed no statistical difference between SA-DCP users' and nonusers' adherence to CPAP therapy. Adherence to CPAP therapy was high in both groups according to the patients' own estimates and remote monitoring data of CPAP devices. Both groups performed CPAP therapy regularly and reported that it helped them to treat their sleep apnea. In addition, 72% (42/58) of SA-DCP users reported that SA-DCP motivated them to perform their own CPAP therapy. Unfortunately, this study did not ask why the participants felt this. The role of the SA-DCP was to complement CPAP therapy by providing information and an electronic communication channel. It did not include clear mechanisms for influencing patients' behavior related to their own health as digital health interventions typically do, for example, in relation to weight management [49-51]. The CPAP therapy clearly helped the participants in this study to reduce the number of AHIs. Presumably, the biggest motivation for performing CPAP therapy came from alleviating sleep apnea symptoms and not so much from using the SA-DCP; therefore, the SA-DCP was not a significant factor in explaining adherence to CPAP therapy.

This study investigated HCPs' perspectives on the SA-DCP and its usefulness for their work. Although previous studies determined that DCPs could potentially free health care services capacity for other purposes and reduce the workload of HCPs, the results of this study do not support these results in the case of SA-DCP [27,28]. The HCPs who participated in the study were unable to define significant changes in their workload and

work practices after the introduction of SA-DCP. The primary aim of HCPs was for patients to use the SA-DCP more so that its benefits could be better used. Previous studies have highlighted that DCPs can promote work flexibility, for example, by enabling HCPs to respond to patients' DCP messages at nonurgent, not only prerreserved times [27,31]. The responses of HCPs in this study pointed out the same. With the help of the DCP, patients can access the information it contains before and after contact with HCPs, thus reducing patient follow-up questions [12]. From this perspective, HCPs felt that educational videos and information materials on SA-DCP were beneficial because, through them, the patients could better understand things. From a technical point of view, the SA-DCP's weak integration with existing ICT systems was seen as one of its key shortcomings and an area for future development. The lack of interoperability with existing ICT systems has been found to weaken the willingness of HCPs to use digital health care services and increase their workload [10,52]. According to the interviewed HCPs, lack of integration reduced the fluency of their work, increased the workload of one responder, and can cause risks from the perspective of information protection and patient safety when patient information is copied manually between different programs.

Digital health care services are intended to help patients become more active actors, more adherent to their own care, and change their behavior in a more favorable direction for their health [49-51,53,54]. Promising results have already been achieved, for example, in treating obesity with the help of digital services [30,51]. In the case of SA-DCP, it was hoped that patients would be active and familiarize themselves with the information contained in it about sleep apnea and CPAP therapy. According to the patient survey, most SA-DCP users have done so. Although most SA-DCP users familiarized themselves with the information in SA-DCP, there was no statistically significant difference in the proportion of SA-DCP users and nonusers who sought additional information about their illness or CPAP therapy. From this perspective, it cannot be said that SA-DCP users are more active actors. It has been established that digital health care services can lower the threshold for patients to contact HCPs [37,54,55]. According to this study, there was no statistically significant difference between the percentage of SA-DCP users and SA-DCP nonusers who contacted HCPs during their treatment period. However, this study did not ask how often the patients contacted the HCPs. On the basis of the results of this study, it seems that patients sought additional information about their illness or contacted HCPs when they had a real need, regardless of the information source or communication method.

Most SA-DCP users thought that the treatment they received through the SA-DCP was good; it was fine technically, a safe service, and the information it contained was clear and understandable. However, some patients still did not use SA-DCP, although the relative number of active SA-DCP users increased during the study period. Lack of digital literacy is one of the barriers to promoting the use of digital health care services. Older adults, in particular, tend to have lower digital literacy than the general population [39,56]. Mannheim et al [40] emphasized in their study that older adults are not a

homogeneous group in terms of digital literacy and should also be better included when designing digital health care services [40]. On the basis of the patient survey, there was no statistically significant difference in the age of SA-DCP users and SA-DCP nonusers, but based on remote monitoring data from CPAP devices, SA-DCP nonusers were older. According to this study, SA-DCP nonusers perceived their abilities to use ICT to be worse; they used computers, tablets, or smartphones more rarely and were less accustomed to using electronic services than SA-DCP users. SA-DCP nonusers preferred phone calls or physical appointments to manage their health-related issues with HCPs. The results showed a statistically significant difference in how clearly the patients perceived the communication about SA-DCP. Only 24% (7/38) of SA-DCP nonusers considered communication to be clear, and ignorance of the SA-DCP was the most common reason for them not to use the SA-DCP. After the diagnosis of sleep apnea, the patients received an information letter containing information about the disease and its treatment. This letter also included information on the SA-DCP and how to use it. Did SA-DCP nonusers think the SA-DCP was not adequately explained because they did not want to use digital health care services in the first place and preferred to conduct their health-related issues through phone calls or physical visits? They may not have paid attention to the SA-DCP information letter if they do not typically use or are not willing to use digital health care services or if they perceive they have weak skills in using them.

One of the key findings of this study is that the nonuse of SA-DCP and its functionalities among patients with sleep apnea means that its full potential is not being used. This can be seen, for example, in the initial guiding sessions of CPAP therapy, when some patients still come without prior knowledge. Although the number of SA-DCP users increased during the years covered by this study, not all SA-DCP functionalities were significantly used. In particular, this was reflected in the fact that SA-DCP messages were not widely used; therefore, the number of calls to AECs was not reduced. This study found that lower digital literacy and older age were significant factors in explaining the nonuse of the SA-DCP. Older SA-DCP users more often favored other contact methods, such as phone calls, when contacting HCPs during their treatment period. In the future, special attention should be paid to how digital health care services are designed according to the needs of older adults with weak digital literacy. Care processes should be better adapted to the requirements of digital health care services. Clearly, only the traditional information letter about SA-DCP is not sufficient to encourage all patients to adopt it. If there are challenges in deployment, patients could be more actively encouraged to adopt the SA-DCP and offered support. Previous studies have highlighted that the desire of older adults to use digital health care services can be supported by offering guidance and peer support [39,56]. Studies have also emphasized that both professionals and patients should be closely involved in DCP development to obtain the best benefit and that development should be a continuous process [10,29]. With age, various functional limitations, such as diminished eyesight related to diabetes or deteriorated motor skills owing to rheumatism, can increase and thus make it more difficult to use digital services [57,58]. Therefore, special attention should be

paid to the usability and accessibility of digital services. The real end users should be involved in the design process, as the interviewed HCPs highlighted [22,25,58].

Limitations

Our study had some limitations. Patients with sleep apnea give up CPAP therapy for different reasons, which can bias this study's data regarding patients' adherence to CPAP therapy. Most patients who responded to the survey had continued CPAP therapy for ≥ 1 year, and remote monitoring data on CPAP devices were collected in connection with 1-year control. Unfortunately, when the study was carried out, no information was available on the proportion of SA-DCP users and SA-DCP nonusers who had discontinued CPAP therapy. This would have provided additional information about patients' adherence to CPAP therapy. Previous results have highlighted that high attrition rates hinder achieving the full benefits of digital health care services. During the implementation of the study, the SA-DCP did not enable the automatic collection of log data on the activity of patients using the SA-DCP, but through the automatic log data, it was only possible to determine that the patient had used the SA-DCP. Therefore, this study did not examine patients' adherence to SA-DCP use, but only whether they had used the service.

On the basis of the study's results, approximately half of SA-DCP users still contacted HCPs in a way other than through SA-DCP messages, although they reported having good digital literacy. Most SA-DCP nonusers also preferred phone calls to contact HCPs. However, in this study, SA-DCP users and SA-DCP nonusers were not asked why some preferred phone calls to contact HCPs instead of electronic messaging. Future research is needed to better understand this behavior pattern. This study did not ask patients how many times they contacted HCPs; it only investigated whether the patients contacted HCPs during their treatment period. Information on the number of

contacts would have provided valuable information on whether using the SA-DCP can lower the threshold for contacting HCPs.

One of the goals of the SA-DCP was to increase patients' adherence to CPAP therapy, and most SA-DCP users felt this was the case. Although the results of the survey and the remote monitoring data of the CPAP devices showed that there was no statistically significant difference in adherence to CPAP therapy between the groups, it would have been beneficial to ask SA-DCP users why most of them felt that the SA-DCP had increased their adherence to CPAP therapy. However, this was not investigated in this study. The sample size of the interviewed HCPs was small in this study. However, the answers to the HCPs were mostly consistent. Most of them thought there were no significant changes to their workload and work practices; there were still many phone calls from patients. At the time of writing, the SA-DCP did not enable the automatic collection of log data about the number of electronic messages. If this information had been available, it would have enabled a better comparison between the volumes of phone calls and SA-DCP messages.

Conclusions

According to this study, not all the goals set for introducing the SA-DCP have been achieved. The HCPs who participated in the study could not define significant changes in their workload and work practices after the introduction of SA-DCP. The SA-DCP has brought more flexibility to HCPs' work practices regarding patient communication. Despite using SA-DPC, some patients still wanted to communicate with HCPs by phone. Adherence to CPAP therapy was high in both SA-DCP users and nonusers. Patients' lower digital literacy and older age were the most significant factors explaining the nonuse of the SA-DCP. In the future, more attention should be paid to how these user groups should be considered in the design and introduction of the DCPs.

Acknowledgments

This research was funded by the Strategic Research Council (336278 and 358417). The authors are grateful to the study participants who generously gave their time to share their views on the sleep apnea digital care pathway. The authors would also like to thank the health care professionals from Oulu University Hospital who helped in the practical implementation of the study.

Authors' Contributions

All authors participated sufficiently in the work to take public responsibility for the appropriate portions of the content. JH, TH, and JR were responsible for study conception and design. JH, HM, PL, and TH performed data acquisition. JH analyzed and interpreted the data. JH, TH, MT, PL, and JR drafted the manuscript.

Conflicts of Interest

PL and HM have been involved in the national and regional development of the digital care pathways of Health Village. All other authors declare no other conflicts of interest.

Abstract

Background: Robotic spine surgery has continued to evolve since its US Food and Drug Administration approval in 2004, with products now including real-time video guidance and navigation during surgery. As the market for robotic surgical devices evolves, it is important to consider usability factors.

Objective: The primary objective of this study was to determine the user experience of a surgical-assistive robotic device. The secondary objective was to evaluate workload, usability, the After-Scenario Questionnaire (ASQ), and the System Usability Scale (SUS). In addition, this study compares the workload, usability, and satisfaction survey of the device among different occupational groups using the device.

Methods: Doctors (n=15) and nurses (n=15), the intended users of the surgical assistant robot, participated in the usability evaluation. Participants performed essential scenarios for the surgical assistant robot and provided scenario-specific satisfaction (ASQ), workload (NASA Task Load Index), and usability (SUS) scores.

Results: Both doctors and nurses had task success rates of 85% or higher for each scenario. ASQ results showed that both doctors and nurses were least satisfied with ease of completing the task of registration (group 1: mean 4.73, SD 1.57 and group 2: mean 4.47, SD 1.8), amount of time it took (group 1: mean 4.47, SD 1.63 and group 2: mean 4.40, SD 2.09), and support information satisfaction (group 1: mean 5.13, SD 1.50 and group 2: mean 5.13, SD 1.89). All participants had low workloads, and the overall Task Load Index score had a *P* value of .77, which is greater than .05. The SUS results showed that the overall usability mean for doctors was 64.17 (SD 16.52) and the mean for nurses was 61.67 (SD 19.18), with a *P* value of .84, which is greater than .05, indicating no difference between the 2 groups.

Conclusions: In this study, doctors and nurses evaluated the interaction of the device in a simulated environment, the operating room. By evaluating the use experience and usability of the device with real intended users, we can develop a more effective and convenient user interface.

KEYWORDS

robot spine surgery; usability; satisfaction; System Usability Scale; surgical navigation systems; robotics; surgery; neurosurgery

Introduction

Background

Spine surgery is used to treat degenerative diseases and deformities of the spine, with 45 million surgeries performed

annually in the United States [1]. The use of robotic-assisted navigation is increasing as the number of patients undergoing lumbar spinal fixation increases [2]. Spine surgery typically involves 7 people in the operating room, with an operator surgeon, a surgical first assistant (who may be a doctor or

physician assistant nurse, depending on operating room staffing), and scrub nurse in the sterile area and a circulating nurse and radiologist in the nonsterile area. Nonoperative personnel include an anesthesiologist and an anesthesiologist assistant. The use of robotics in spine surgery is usually reserved for difficult anatomical areas where it is difficult to fix screws blindly. Spinal fusion surgery is the insertion and fixation of pedicle screws into the vertebrae to eliminate pain by preventing movement between vertebrae [3]. It is also used for quick insertion in severe scoliosis, collapsed vertebrae, or long-level fusion in patients with difficult anatomy, usually at the iliac screw, C1, C2, C7, T1, and T2, or for other reasons. This is usually used for kyphosis and scoliosis correction.

Robot Spine Surgery

Surgical navigation systems are used to plan the procedure and guide the surgeon in inserting the screws [1]. Robot spine surgery is popularly used to increase the accuracy of inserting

screws in the spine, and the first robot used in spine surgery was the Spine Assist (Mazor Surgical Technologies), which received Food and Drug Administration clearance in 2004 [4]. The third-generation Mazor X system was cleared by the Food and Drug Administration in 2016 and, compared to previous generations, has a robotic arm that is attached to the patient's body and can be viewed through a camera to ensure that the screws are inserted and the robotic arm is moving well [5]. The Mazor X Stealth Edition technology, which adds real-time image guidance and navigation during surgery, was cleared in 2019 and combines the best of both worlds: traditional spinal robotic surgery guidance and real-time software confirmation [5,6]. Figure 1 shows the evaluation device, which consists of a robotic arm, main console, and optional staff console, and is manufactured in South Korea. Like the Mazor X Stealth Edition technology, this product is capable of real-time image guidance and navigation during surgery.

Figure 1. The CUVIS spine robot system: robotic arm (left), main console with navigation optical infrared tracking camera (middle), and the control workstation (right). OTS: optical tracking system.

Usability

According to IEC (International Electrotechnical Commission) 62366-1 [7], usability has the following meaning: a “characteristic of the user interface that facilitates use and thereby establishes effectiveness, efficiency and user satisfaction in the intended use environment.” ISO (International Organization for Standardization) 9241-210 [8] defines usability as the “extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use.” These

documents demonstrate that good usability in medical device design is essential to preventing error-related risks.

Evaluating usability focuses on determining whether the test device is easy for users to use. To evaluate the user experience of the device, we used usability tests and surveys for effectiveness, efficiency, satisfaction, and workload. The usability test was mainly used to identify use errors and efficiency, while the After-Scenario Questionnaire (ASQ) was conducted to evaluate the satisfaction of each task. NASA Task Load Index (NASA TLX) was used to measure the workload of the device, and System Usability Scale (SUS) was used to

check the overall system usability of the device. Both ASQ and SUS identified the satisfaction and efficiency of the device, but in this study, ASQ identified the efficiency and satisfaction of each scenario, while SUS evaluated the satisfaction and efficiency of the device in the overall workflow.

Methods

Recruitment

We recruited 30 medical staff from Severance Hospital in South Korea. There were 15 doctors and 15 nurses. The intended users of the device are doctors and operating room nurses. Due to the different tasks that doctors and nurses have to perform when using the device overall, both groups were selected to participate in the usability test. We recruited through recommendations from colleagues and notice on the bulletin board at the Future Medicine Research Center at Gangnam Severance Hospital. Doctors and nurses who have experience using a robotic surgical device or navigation system were selected. For doctors, we selected those with the necessary knowledge of spine surgery, and for nurses, we selected those with experience in the operating room. However, those who had worked in the operating room for less than 1 year were excluded. After confirming these inclusion and exclusion criteria, the screening was conducted.

Testing Procedure

One participant per session participated in the usability test, with the participant completing the assessment in a sequence guided by a facilitator, and an observer in the observation room videotaping the assessment and completing an observation sheet.

A total of 2 moderators and 2 observers participated in the evaluation, with one of the moderators acting as a nurse if a doctor participated in the evaluation, and one of the moderators acting as a doctor if a nurse participated in the evaluation. In addition, observers were used to reduce bias by having 2 observers observe the usability test to ensure that one person's opinion was not biased.

The facilitator introduced the participants to the usability test, obtained their informed consent, and trained them on the device for 20 minutes. Participants were allowed to interact with the device as much time as they needed. Afterward, 15 minutes were allowed between the training and evaluation to ensure that the training did not directly influence the evaluation [9]. Doctors and nurses were given different tasks because of the different job duties they do when operating with assessment devices. The tasks given to nurses focus on doctors' instructions from preoperative preparation to surgery, while doctors focus on the surgery itself rather than preparing devices.

Participants then completed the evaluation for 40 minutes, with 8 scenarios (24 tasks) for doctors and 12 scenarios (41 tasks) for nurses. Doctors were asked to complete the following scenarios: preparation for use, preplanning of surgery, fixation of patient marker, scan, registration, verification, revisions of surgical planning, and navigation; nurses were asked to complete the following scenarios: preparation for use, system operation, initializing manipulator, drape, preparation of surgery, scan, registration, verification, planning of surgery, navigation, use of the emergency stop switch, and cleaning up after surgery. Tasks for each scenario are shown in [Tables 1](#) and [2](#).

Table 1. Use scenarios of doctors.

Use scenario/task number	Task description
Preparation for use	
Task 1	Check the contents related to the emergency button, foot switch, and foot jamming in the user manual.
Task 2	Check the hand jamming label on the robotic arm manipulator.
Preplanning of surgery	
Task 3	Select the spine level as follows: <ul style="list-style-type: none"> • L4-L, L4-R • L5-L, L5-R
Task 4	After loading the first CT ^a data, check the CT data.
Task 5	Create an implant screw insertion path for target L4-L and L4-R and change the insertion path by moving the screw in the MPR ^b view.
Task 6	Create an implant screw insertion path for target L5-L and L5-R and change the insertion path using the arrow.
Task 7	Check for collision between each screw.
Fixation of patient marker	
Task 8	Attach the patient marker to the patient.
Scan	
Task 9	Attach the registration tool adapter to the end effector.
Task 10	After activating the hand guide function by pressing the AP ^c button, change the position of the end effector according to the guidance on the pop-up window.
Task 11	For C-Arm scan, attach the source calibrator to the end effector in the direction of AP and move the end effector to enable tracking by OTS ^d .
Task 12	Check if the ROI ^e includes the calibration marker, and the position and direction of the letters “R,” “G,” and “J” match the image, and then check pass or fail of registration.
Registration	
Task 13	Perform segmentation to distinguish the surgical target in the image. <ul style="list-style-type: none"> • L4-L, L4-R • L5-L, L5-R
Task 14	Perform labeling to assign target level information of ROI of 3D image and 2D image segmented for each spine level.
Task 15	Adjust the ROI box so that the ROI of target L4 covers all the L4 vertebra area.
Task 16	Perform 2D and 3D image registration for each spine level.
Verification	
Task 17	After adjusting the CT image to overlay appropriately for target L4, check the registration result using the preview button and select whether to approve it.
Task 18	After selecting whether to approve for target L5, perform image registration again so that the ROI includes all the vertebra area.
Revision of surgical planning	
Task 19	Check the plan on 2D and 3D images, respectively.
Task 20	As a result of planning for the entire target, check whether the robot can move in an area.
Navigation	
Task 21	Insert the screw of target L4-L.
Task 22	Through the [PRE-OP] screen, indicate the values for the insertion depth of the L4-L taper, the amount of force applied to the end effector, and the patient’s movement.
Task 23	Through the [INTRA-OP] screen, indicate the values for the insertion depth of the L4-L screw, the amount of force applied to the end effector, and the patient’s movement.
Task 24	Move the end effector to the ready position for screw insertion to the target L4-R.

^aCT: computed tomography.

^bMPR: multiplanar reconstruction.

^cAP: anterior-posterior.

^dOTS: optical tracking system

^eROI: region of interest.

Table 2. Use scenarios of nurses.

Use scenario/task number	Task description
Preparation for use	
Task 1	Check the contents related to the emergency button, foot switch, and foot jamming in the user manual.
Task 2	Check the hand jamming label on the robotic arm manipulator.
Task 3	Check if there are any abnormalities in the exterior of the robot marker frame and robotic arm.
Task 4	Place the main console and staff console in a convenient location during surgery.
Task 5	After checking the device and accessories in the operating room, assemble the marker ball.
Task 6	Assemble the surgical tools such as the tapper's driver and marker.
Task 7	Assemble the surgical tools such as screwdriver and marker.
Task 8	Assemble the clamp to be used to fix the patient marker.
System operation	
Task 9	Connect the power and cables of the robotic arm, main console, and staff console.
Task 10	After connecting the foot switch of the robotic arm, turn on the power of the robotic arm.
Initializing manipulator	
Task 11	After logging in, select the surgical method and imaging device.
Task 12	Check the connection status of the foot switch.
Task 13	After selecting the robot position as "right," initialize the manipulator (required to check movement notification sound and operation LED ^a).
Task 14	Verify that the line laser on the robot marker intersects the area within range (required to check movement notification sound and operation LED).
Drape	
Task 15	Follow the on-screen instructions to drape the patient to prevent infection (proceed in order of manipulator drape, base drape, and robot marker drape).
Task 16	After installing the end effector of the robotic arm, assemble the marker ball where the robot marker drape is installed.
Task 17	Move the manipulator to the ready position.
Preparation for surgery	
Task 18	Move the robotic arm for patient surgery.
Task 19	Check the surgical tools through OTS ^b , and if all surgical tools are not checked by the OTS camera, check if they are within the operating area.
Task 20	The robot marker is not being recognized by the OTS camera due to damage to the marker ball. Replace with a new marker ball.
Task 21	Please load the surgical data.
Scan	
Task 22	Check if the ROI ^c includes the calibration marker, and the position and direction of the letters "R," "G," and "J" match the image, and then check pass or fail.
Registration	
Task 23	Perform segmentation to distinguish the surgical target in the image. <ul style="list-style-type: none"> • L4-L, L4-R • L5-L, L5-R
Task 24	Perform labeling to assign target level information of ROI of the 3D image and 2D image segmented for each spine level.
Task 25	Adjust the box so that the ROI of target L4 covers all of the vertebra area.
Task 26	Perform 2D and 3D image registration for each spine level.
Verification	

Use scenario/task number	Task description
Task 27	Use the slide control at the bottom of the image to check whether the 2D and 3D images match to check the registration result.
Task 28	For target L4, move the CT ^d (DRR ^e) image by using the triangular button to adjust the 2 body images to be similar.
Task 29	For target L4 whose registration result has been adjusted, use the preview button to check the registration result and select whether or not to approve it.
Task 30	After selecting whether or not to approve for target L5, perform image registration again so that the ROI includes all of the vertebra area (target L5: registration failed).
Task 31	After displaying the planned data on the screen through the preview button for each target for which the registration result has been adjusted, check if the registration is completed normally.
Task 32	Depending on the registration result of target L5, select whether or not to approve (target L5: registration completed normally).
Planning of surgery	
Task 33	Check whether the robot can move to the planned position.
Navigation	
Task 34	On the screen, move the end effector of the robotic arm to the planned guide position relative to target L4-L.
Task 35	Move the end effector to the original position for the guide.
Task 36	On the screen, move the end effector of the robotic arm to the planned guide position relative to target L4-R.
Use of the emergency stop switch	
Task 37	(At the moment, the manipulator is positioned too close to the patient.) Press the emergency button.
Task 38	Release the emergency button.
Cleaning up after surgery	
Task 39	Shut down the main console.
Task 40	Shut down the robotic arm.
Task 41	Disconnect the cable.

^aLED: light emitting diode.

^bOTS: optical tracking system.

^cROI: region of interest.

^dCT: computed tomography.

^eDRR: digitally reconstructed radiograph.

The test environment as shown in [Figure 2](#) is organized to resemble the operating room. Participants used the device following prompts presented on a stand monitor. The test environment was organized similar to an operating room, considering the use environment of the robot spine surgery. An operating room bed, an upper torso dummy, and a patient monitoring device were prepared similar to the actual operating room environment. The temperature and humidity of the evaluation room were measured and recorded right before the evaluation. Similar to a real operating room, the temperature

was kept between 20 °C and 24 °C, and the humidity was between 30% and 60%.

The evaluation facilitator guided the participant if they requested assistance with a use scenario, and an observer recorded all participant interactions from outside the test room with a 1-way mirror. The test observation environment setting is shown in [Figure 3](#). The observer used a program from Media Express to record the progress of the usability evaluation. At the end of the evaluation, 3 types of questionnaires were administered.

Figure 2. Test environment: the simulated environment is organized to resemble the operating room in which the evaluator is used.

Figure 3. Test observation environment: we set up monitoring equipment to observe and record the entire evaluation process in real time.

Statistical Analysis

ASQ Measure

After each scenario, the participants completed the ASQ created by Lewis [10] and developed from the ISO 9241-11 standard questionnaire [11]. This is one of the most popular surveys for assessing usability because it is the simplest and its 3 items are easy for participants to understand [11]. As shown in [Textbox](#)

1, the ASQ consists of 3 questions, each corresponding to the user's satisfaction with the ease, efficiency according to the time taken to complete the scenario, and validity of the information provided. Participants responded to each question on a 7-point Likert scale [10,12]. Participants rated their satisfaction about the device's usability based on each task scenario [13]. A score of "1" means strongly disagree, and a score of "7" means strongly agree [14]. We found the mean and SD for the 3 questions participants asked ASQ.

Textbox 1. After-Scenario Questionnaire (ASQ).

ASQ1: Overall, I am satisfied with the ease of completing the tasks in this scenario.

ASQ2: Overall, I am satisfied with the amount of time it took to complete the tasks in this scenario.

ASQ3: Overall, I am satisfied with the support information (digital help, messages, and documentation) when completing the tasks.

NASA TLX Measure

NASA TLX measures cognitive workload, and like usability, workload is a complex construct that determines the amount of physical and mental effort required to use an interface [15,16]. The workload is assessed by the US NASA TLX [15,17]. The most effective way to assess a worker's perceived job difficulty is to ask questions directly to workers who have experienced the job. As shown in Figure 4, the Task Load Index (TLX) uses 6 dimensions to measure workload. The 6 metrics are mental demand, temporal demand, physical demand, performance, effort, and frustration [16,18]. The NASA TLX scores are

evaluated by dividing the score into 21 steps, subtracting 1 from the score, and multiplying it by 5 to express it on a scale of 0 to 100 [19,20]. On a scale of 100, when the score is lower, the workload is lower. Less work means a less complex and easier-to-use user interface. On a 100-point scale, the workload can be described as low (0-9), medium (10-29), rather high (30-49), high (50-79), and very high (80-100) [21]. In the NASA TLX, performance assesses satisfaction with task completion, with the lowest number representing perfect and the highest number representing failure [22]. The point system for mental, physical, temporal, effort, and frustration part ranges from very low to very high [15,16,19,22,23].

Figure 4. NASA Task Load Index.

NASA Task Load Index (TLX)

Hart and Staveland’s NASA Task Load Index (TLX) method assess work load on five 7-point scales. Increments of high, medium and low estimates for each point result in 21 gradations on the scales

Name :	Task :	Date :
--------	--------	--------

Mental Demand How mentally demanding was the task?

Very LowVery High

Physical Demand How physically demanding was the task?

Very LowVery High

Temporal Demand How hurried or rushed was the pace of task?

Very LowVery High

Performance How successful were you in accomplishing what you were asked to do?

PerfectFailure

Effort How hard did you have to work to accomplish your level of performance?

Very LowVery High

Frustration How insecure, discouraged, irritated, stressed, and annoyed were you?

Very LowVery High

SUS Measure

As shown in [Textbox 2](#), the SUS consists of 10 items that assess the participant’s level of agreement with the overall usability of the system, with odd-numbered items being positive and even-numbered items being negative [24]. SUS is the most commonly used usability assessment questionnaire [24]. Participants responded to each item on a 5-point Likert scale [13]. The scale ranges from 1=strongly disagree to 5=strongly agree [25,26]. To calculate the SUS score from the points

acquired from the 5-point Likert scale, the following subtractions were used. For odd-numbered items, subtract 1 from the user response, and for even-numbered items, subtract the user responses from 5. With this calculation, the value range changes from 0 to 4. The most positive response is 4. The scores from each converted response were multiplied by 2.5 to a total possible point of 100. The SUS is percentage-based and divided into 5 levels: A (>80.3), B (68-80.3), C (68), D (51-68), and F (<51) [24]. A score of 85 is considered very good usability, and a score of 68-84 is considered good usability [25,26].

Textbox 2. System Usability Scale (SUS) items.

SUS1: I think that I would like to use this system frequently.

SUS2: I found the system unnecessarily complex.

SUS3: I thought the system was easy to use.

SUS4: I think that I would need the support of a technical person to be able to use this system.

SUS5: I found the various functions in this system were well integrated.

SUS6: I thought there was too much inconsistency in this system.

SUS7: I would imagine that most people would learn to use this system very quickly.

SUS8: I found the system very cumbersome to use.

SUS9: I felt very confident using the system.

SUS10: I needed to learn a lot of things before I could get going with this system.

Data Analysis

ASQ, NASA TLX, and SUS results were computed using SPSS (version 22; IBM Corp) [27]. Descriptive statistics were performed on for doctor and nurse characteristics. Doctors and nurses were compared on age, gender, work experience, and use experience with similar devices. For the questionnaire items, values were compared between groups using 2-tailed *t* tests for normality and Mann-Whitney *U* tests for nonparametric tests. Figures are presented as the mean and SD, and $P < .05$ was considered significant.

Ethical Considerations

This study was approved by the institutional review board of Yonsei University Health System, Gangnam Severance Hospital (3-2022-0493). All the participants who passed the screening signed an informed consent form. Furthermore, all information collected about the participants was anonymized. This study complied with the Code of Ethics. Participants received monetary compensation for participating in the evaluation.

Results**User Statistics**

In total, 15 doctors and 15 nurses, each representing the intended users of the surgical assistant, participated in the evaluation. Participants were recruited from doctors and nurses at Severance Hospital. Table 3 shows the sociodemographic characteristics of participants. Both doctors and nurses were between the ages of 30 and 39 years. For both doctors and nurses, those with different experience levels were recruited, and opinions were collected from all the participants. In particular, those with more experience with surgical devices were able to gather relevant opinions because they were more familiar with the device or the existing surgical methods, while those with less experience focused on whether the device was easy to use without much experience. Doctors' professional experience ranged from 2 to 20 years, with an average of 7.53 (SD 5.45) years of professional experience. The nurses' professional experience ranged from 5 to 26 years, with an average of 12.93 (SD 6.43) years. The surgical assistants had used Medtronic (Medtronic), Stryker (Stryker Corp), and Curexo (Curexo, Inc), with an average of 3 (SD 2.36) years of experience.

Table 3. Sociodemographic characteristics and experience of the test participants (N=30).

More than 5 years, less than 10 years	0 (0)	0 (0)
More than 10 years	1 (7)	0 (0)

Task Completion

The 15 doctors performed 24 tasks within 8 large scenarios, while the nurses performed a total of 41 tasks within 12 scenarios. As shown in [Table 4](#), for the doctors, all 8 scenarios

had a success rate of 90% or higher, with the lowest success rate for the revising a surgical plan scenario. As shown in [Table 5](#), for nurses, all 11 scenarios except the surgical plan had a success rate of 90% or higher, with the planning of surgery scenario having an 87% success rate.

Table 4. Task completion rate in doctors.

	Task pass rate (%)	Task failure rate (%)
Preparations for use	96.67	3.33
Preplanning of surgery	98.67	1.33
Fixation of patient marker	100	0
Scan	96.67	3.33
Registration	100	0
Verification	96.67	3.33
Revision of surgical planning	93.33	6.67
Navigation	98.33	1.67

Table 5. Task completion rate in nurses.

	Task pass rate (%)	Task failure rate (%)
Preparations for use	97.50	2.5
System operations	96.67	3.33
Initialization manipulator	100	0
Drape	93.33	6.67
Preparation for surgery	91.67	8.33
Scan	100	0
Registration	98.33	1.67
Verification	91.11	8.89
Revision of surgical planning	86.67	13.33
Navigation	100	0
Use of the emergency stop switch	100	0
Cleaning up after surgery	95.56	4.44

Among the scenarios in which the doctors did not successfully complete a task during the assessment, the critical tasks were as follows: in task 11, the participant failed to follow the process of attaching the source calibrator in the opposite direction to track the optical tracking system and did not recognize the correct attachment method. In addition, pressing the anterior-posterior scan button and moving the end effector closer to the dummy proceeded correctly, but before attaching the source calibrator, the optical tracking system process could not be performed because it did not proceed in the existing pop-up window and proceeded to the data acquisition step. In task 18, participants selected the target but were unable to click the “Re-matching” button. To proceed with rematching, a target needs to be selected and pressed, but the Re-matching button could not be clicked because the target was not selected. In task 21, the participant did not recognize whether the robot movement was completed by continuously pressing the foot switch without releasing it. In this case, the participant said that he was unable to perform the task because there was no indication on the screen that the robot’s movement was complete, and there was no visual or audible user interface.

The nurse was unable to complete task 28 due to difficulty using the image adjustment feature. Participants were asked to move the computed tomography image and adjust the body image to be similar but could not comprehend how to use the “Adjustment” function or the “Re-matching” function (the user did not recognize the intended function itself). Even when the “Adjustment” function was used, it was observed that the user could not use the “Adjustment” function in the way intended by trying to adjust the overlaid screen itself rather than adjusting the screen by pressing the button. If an accurate match is not made, the manipulator may move to a different location than the user’s target location, causing potential harm. In addition, nurses had difficulty using the reassembly feature of task 30. The “Re-matching” function could not be used because the target was released while pressing the “Disapproved” button in the rematching task, or the “Adjustment” function was used rather than using the “Re-matching” function. Participants failed to perform the task because they did not recognize that the

“Re-matching” function could only be used by resetting the target that was released when pressing the “Disapproved” button, or that “Re-matching” meant rematching. This caused potential harm by moving the manipulator to a location different from the user’s target location. Nurses were unsuccessful in tasks such as registration, verification, and navigation because these tasks are usually performed through doctors’ orders. During the scenarios, there were no given orders, forcing the nurses to make their own decisions, which they are not accustomed to.

Overall, 4 doctors said that when creating a screw position in the planning stage, the position is created in a completely different part from the actual location; thus, it would be better if the position could be created closer to the target, and when moving the position, that it would be better to be able to check other position paths at the same time. In total, 7 doctors said it would be better if there was notification or guidance for the arrival of the robot arm at the target so that moving to the guided position can be recognized. In addition, 5 doctors and 8 nurses found that in the overall process of selecting and adjusting the region of interest (ROI) box to the target area, it was inconvenient to select and release the box, and that it was difficult to adjust because of its excessive rotation.

Usability (ASQ)

After the usability evaluation, doctors and nurses were surveyed using the ASQ for each scenario. For both doctors and nurses, the ASQ for registration was divided into 2 parts: first, segmentation and labeling, and second, ROI setting and image matching. As shown in Tables 6 and 7, among the registration items, both doctors and nurses had the lowest scores for the ROI setting and image matching, followed by ease of completing the task (group 1: mean 4.73, SD 1.57 and group 2: mean 4.47, SD 1.89), amount of time it took (group 1: mean 4.47, SD 1.63 and group 2: mean 4.40, SD 2.09), and support information satisfaction (group 1: mean 5.13, SD 1.50 and group 2: mean 5.13, SD 1.89). The doctors’ opinions were mainly that it was inconvenient to have to click on the line precisely; thus, the ease of adjustment should be improved. Nurses reported that they were less sensitive to the 360-degree rotation button at the

top of the ROI box and had difficulty clarifying the image while adjusting the ROI box.

Table 6. After-Scenario Questionnaire result in group 1 (doctors).

	Ease of completing the task, mean (SD)	Amount of time it took, mean (SD)	Support information satisfaction, mean (SD)
User manual	5.56 (1.12)	5.54 (1.28)	5.63 (1.19)

Cleaning up after surgery	6.47 (0.88)	6.40 (1.02)	6.40 (1.02)

^aROI: region of interest.

Tables S1 and S2 in [Multimedia Appendix 1](#) show categorization by use experience with similar devices. The ASQ results did not show significant differences in satisfaction based on use experience and years of experience with robotic surgical systems. For doctors, those with more than 3 years of experience using robotic surgical systems found it easier and faster to perform tasks. For nurses, participants with more experience using similar devices scored higher than those with less than 3 years of experience on the need to prepare before surgery.

Workload (NASA TLX)

Table 8 shows the results of the workload of the assistive robotic surgery devices by occupational group for mental demand, physical demand, temporal demand, performance, effort, frustration, and overall TLX. The Mann-Whitney *U* test comparing the TLX scores of the doctors and nurses, including mental demand ($P=.81$), physical demand ($P=.90$), temporal demand ($P=.87$), performance ($P=.81$), and frustration ($P=.81$) and the independent 2-sample *t* test comparing the TLX scores of effort ($P=.64$) and overall TLX ($P=.77$) showed no significant differences in the scores. Doctors' workload levels were

generally in the medium (10-29), and nurses were also in the medium (10-29) except for effort.

Table 8. Result of NASA Task Load Index.

	Group 1 ^a (n=15), mean (SD)	Group 2 ^b (n=15), mean (SD)	<i>t</i> test ^c (<i>df</i>)	<i>U</i> test ^d	<i>P</i> value ^e
Mental demand	30.67 (25.97)	29.33 (29.39)	N/A ^f	106.5	.81
Physical demand	13.00 (15.09)	11.33 (12.17)	N/A	109.5	.90
Temporal demand	15.00 (17.63)	22.33 (30.58)	N/A	108.5	.87
Performance	25.00 (28.09)	28.33 (26.16)	N/A	106	.81
Effort	29.67 (24.60)	34.33 (28.78)	-0.477 (28)	N/A	.64
Frustration	19.00 (22.22)	18.33 (26.70)	N/A	106	.81
Overall Task Load Index	22.06 (18.58)	24.00 (16.96)	-0.299 (28)	N/A	.77

^aGroup 1: doctors.

^bGroup 2: nurses.

^cBecause the data were normally distributed, a independent 2-sample *t* test was used.

^dBecause the data were not normally distributed, the Mann-Whitney *U* test was performed.

^e*P* values were determined with the independent 2-sample *t* test and Mann-Whitney *U* test for continuous variables.

^fN/A: not applicable.

Figure 5 shows a boxplot of the NASA TLX results for doctors and nurses. In addition, Figure 6 shows the NASA TLX results for all evaluation participants (doctors and nurses). The box plots show the maximum (45-100), median (5-25) minimum (0), first quartile (0-17.5), and third quartile (12.5-52.5), with

the center box showing the median of 50% of the cases. When comparing the workload of the doctors and nurses, there was no significant difference as shown in Table 8, and we can see that 3 categories, physical demand, temporal demand, and frustration, have lower workloads than the others.

Figure 5. Workload results by group: distribution of the NASA TLX scores for doctors and nurses. TLX: Task Load Index.

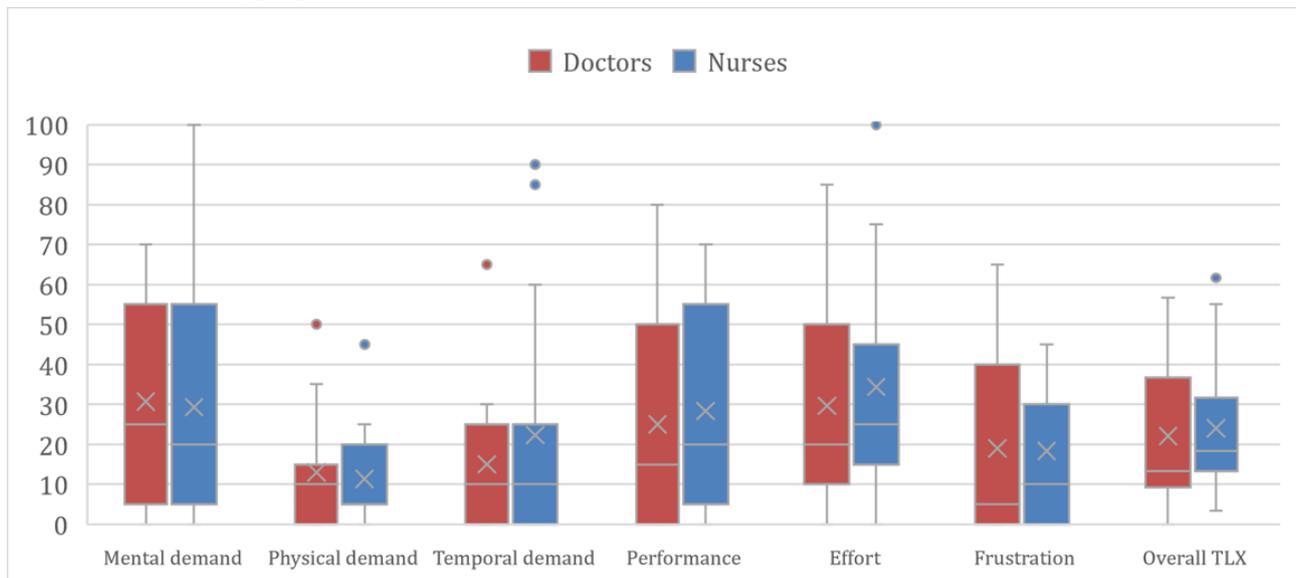

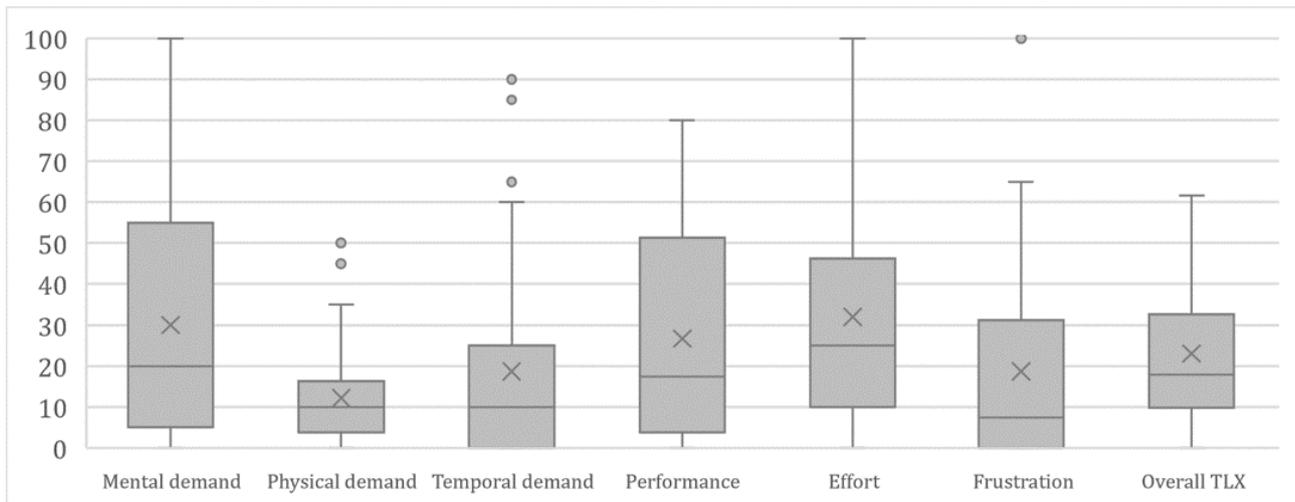

Figure 6. Workload results: distribution of the overall NASA TLX scores. TLX: Task Load Index.

In Tables 9 and 10, NASA TLX scores were compared based on use experience with similar devices. Participants who had been using robotic surgical systems for more than 3 years, both doctors and nurses, reported that the evaluation device required a lot of effort to use. Participants had difficulty using the evaluation device because it was more complex than similar

robotic surgical devices. However, when it comes to temporal demand, those who have been using robotic surgical systems for more than 3 years reported that it is not time-consuming. The workflow of the evaluation device is not much different from existing robotic surgical devices, and the graphical user interface is easy to use and can be performed quickly.

Table 9. Comparison of the NASA Task Load Index by use experience of doctors.

	All, mean (SD)	Less than 3 years, mean (SD)	More than 3 years, mean (SD)
Mental demand	30.67 (25.97)	27.00 (28.21)	38.00 (21.68)
Physical demand	13.00 (15.09)	14.00 (16.12)	11.00 (14.32)
Temporal demand	15.00 (17.63)	18.50 (19.87)	8.00 (10.37)
Performance	25.00 (28.09)	22.50 (28.80)	30.00 (29.15)
Effort	29.67 (24.60)	21.50 (19.59)	46.00 (27.48)
Frustration	19.00 (22.22)	15.50 (20.20)	26.00 (26.79)

Table 10. Comparison of the NASA Task Load Index by use experience of nurses.

	All, mean (SD)	Less than 3 years, mean (SD)	More than 3 years, mean (SD)
Mental demand	29.33 (29.39)	25.91 (22.56)	38.75 (46.61)
Physical demand	11.33 (12.17)	12.27 (12.72)	8.75 (11.81)
Temporal demand	22.33 (30.58)	28.64 (33.70)	5.00 (5.77)
Performance	28.33 (26.16)	22.27 (24.73)	45.00 (25.50)
Effort	34.33 (28.78)	30.45 (25.73)	45.00 (38.08)
Frustration	18.33 (26.70)	15.45 (15.40)	26.25 (49.22)

Usability (SUS)

Both doctors and nurses who participated in the usability test completed the SUS questionnaire. Table 11 shows that the mean score of SUS was 64.17 (SD 16.52) for doctors and 61.67 (SD 19.18) for nurses. The nonparametric Mann-Whitney *U* test was used to analyze *U* values and *P* values presented in Table 11.

When comparing the SUS scores of the doctors and nurses ($P=.84$, greater than .05), we can see that there was no significant difference between the 2 values. Figure 5 is a boxplot comparing the SUS scores of the doctors and nurses, showing a baseline of 68, which is the average SUS score. For the nurses and doctors, this corresponds to a grade of D on the SUS scale.

Table 11. Result of the System Usability Scale (SUS).

	Group 1 ^a , mean (SD)	Group 2 ^b , mean (SD)	<i>U</i> test ^c	<i>P</i> value ^d
SUS1: I think that I would like to use this system frequently.	2.33 (1.14)	2.60 (1.14)	96.5	.51
SUS2: I found the system unnecessarily complex.	2.4 (1.02)	2.67 (1.25)	92.5	.41
SUS3: I thought the system was easy to use.	2.93 (0.77)	2.93 (1.00)	104	.74
SUS4: I think that I would need the support of a technical person to be able to use this system.	2.00 (1.32)	1.00 (0.97)	65	.05
SUS5: I found the various functions in this system were well integrated.	3.00 (0.82)	2.93 (1.06)	109.5	.90
SUS6: I thought there was too much inconsistency in this system.	2.67 (0.94)	2.47 (1.31)	111	.97
SUS7: I would imagine that most people would learn to use this system very quickly.	2.87 (0.88)	3.20 (1.11)	82	.22
SUS8: I found the system very cumbersome to use.	2.53 (1.09)	2.73 (1.06)	100.5	.62
SUS9: I felt very confident using the system.	2.87 (0.81)	2.73 (0.88)	65	.05
SUS10: I needed to learn a lot of things before I could get going with this system.	2.07 (1.18)	2.00 (1.10)	106.5	.81
Overall, SUS score on 0 to 100 normalized scale	64.17 (16.52)	61.67 (19.18)	107.5	.84

^aGroup 1: doctors.

^bGroup 2: nurses.

^cBecause data were not normally distributed, the Mann-Whitney *U* test was performed.

^d*P* values were determined with an independent 2-sample *t* test and the Mann-Whitney *U* test for continuous variables.

When we compared participants' use experience with the device between those who had used it for more than 3 years and those who had used it for less than 3 years, we found that for doctors, those who had used it for more than 3 years had lower SUS scores than those who had used it for less than 3 years. For doctors, the average SUS score for participants with 3 or more

years of experience is 55.5 (SD 19.13), while the average SUS score for those with less than 3 years is 68.5 (SD 13.05). For nurses, similar to doctors, we found that participants who had used a similar device for more than 3 years had lower scores than those who had used it for less than 3 years, at 53.75 versus 64.55 (Table 12).

Table 12. System Usability Scale (SUS) comparison by use experience of a similar device.

	Group 1 ^a			Group 2 ^b		
	All, mean (SD)	Less than 3 years, mean (SD)	More than 3 years, mean (SD)	All, mean (SD)	Less than 3 years, mean (SD)	More than 3 years, mean (SD)

Discussion

Principal Findings

This study is a summative evaluation to examine the usability of the frameless stereotaxic navigation system (model CS200) that is used as an auxiliary tool for guiding the surgical tool to the target position and posture planned by the user in the incision or percutaneous spinal surgery. Regarding the use scenario, (1) task success, (2) use error, (3) satisfaction (ASQ), (4) workload (NASA TLX), and (5) SUS related to the usability of the test device were evaluated and analyzed. The usability test was conducted by professional medical staff who have completed specialized medical education and obtained professional medical qualifications. The participants in the usability test were doctors

and nurses who have experience in using spinal surgery robots or navigation systems in operating rooms.

For doctors, all 8 scenarios had a success rate of at least 93% or higher, and for nurses, all 12 scenarios had a success rate of at least 87% or higher. Doctors had the lowest success rate of 93% on the "revision of surgical planning" scenario. In the ASQ results, the average score for "ease of completing the task" was 5.66 (SD 0.36), the average score for "amount of time it took" was 5.54 (SD 0.52), and the average score for "support information satisfaction" was 5.70 (SD 0.30). When performing the usability evaluation, the "revision of surgical planning" scenario had the lowest success rate; however, the 3 ASQ scores were higher than the average: 5.80 (SD 0.83), 5.93 (SD 0.68), and 5.93 (SD 1.29).

The “image matching” scenario had the lowest score for each item in the satisfaction score, even though it had a 100% success rate. We found that a high success rate on the evaluation task does not necessarily indicate high usability satisfaction. Despite the high task success rate in the usability test, the low satisfaction rate in the questionnaire that evaluated the usability aspects of the device indicates a lack of satisfaction with the device.

Although there were no difficulties in performance, the task of adjusting the ROI within the “registration” scenario was criticized for its difficulty in accurately adjusting the ROI and its lack of usability. Nurses, like doctors, had the lowest success rate of 87% in the “revision of surgical planning” scenario. However, the ASQ survey results for the “registration” scenario, which had the highest success rate of 98%, showed the lowest scores for “ease of completing the task” with a mean of 4.47 (SD 1.89), “amount of time it took” with a mean of 4.40 (SD 2.09), and “support information satisfaction” with a mean of 5.13 (SD 1.89). Similar to the doctors, when adjusting the ROI box, many of the nurses commented that the 360-degree rotation button at the top was not sensitive, and the video was difficult to see clearly. In addition, both doctors and nurses reported that when moving the robot arm using the footswitch during the “navigation” scenario, there was no visual or audible indication of how far the robot arm had moved and whether it had completed its movement, resulting in collisions between the robot arm and the patient stack. If used with real patients, this could lead to a significant risk of patient injury. We believe that the usability of these screens needs to be improved.

When comparing the workloads of the 2 groups who primarily use the assessment tool, we found that there was no difference, and that the workloads of mental demand and performance are high for both groups. Doctors and nurses commonly commented that the process was too complicated and laborious and that they had doubts about the accuracy of the ROI adjustment. In addition, since the robot assists in surgery, we thought it would be a quick process, but we found that the robot needed more time to move than expected, which affected the workload.

The SUS also showed no significant difference between doctors and nurses, with slightly lower-than-average satisfaction scores. The doctor gave the system a low score on the usability scale because it was too time-consuming to use in the actual operating room. Nurses gave low scores because of the time-consuming setup prior to actual surgery. Both doctors and nurses gave low scores, especially on the items that they felt they would need technician support to use the system and that they would need to learn about the system before its use, because many of them had never used an assessment device before and were not familiar with it. In addition, the lack of usability, with no explanation of what to do next on the device and no prompts to prevent errors, contributed to the low scores. At the hospital where participants work, engineers who have no difficulty using similar devices are present to aid doctors and nurses in using the device. Because of their reliance on engineers, many of the participants had difficulty in using the device alone and commented that they needed the engineers’ support. This suggests that the device needs to be highly usable with an easily understandable user interface and a screen design that is familiar

to medical staff so that they can use the device without engineers’ assistance. Overall, when evaluating usability, there was no significant difference between participants who had used similar devices for more than 3 years and those who had used them for less than 3 years, except for ASQ and SUS, which evaluate satisfaction, and NASA TLX, which evaluates the difficulty of the operator’s job. It was found that there were differences in job duties when using the equipment that they were familiar with as well as differences in the time taken to perform the tasks. In other items, there seems to be no problem in using the device once they are familiar with it.

Table S3 in [Multimedia Appendix 1](#) shows the improvements made to the device since the usability evaluation. The user interface was improved by quantifying and intuitively displaying data that used to be shown only as graphs. Confusing highlighted buttons that hindered the use of the device were rearranged to decrease the errors made by users.

To further increase the usability of the device, the footswitch needs to be improved to recognize how much movement is required to move the device by displaying the information on the interface. In particular, during the navigation phase, it would increase the usability if a notification or on-screen guidance appeared when the target was reached while moving to the location guided by the robotic arm. In addition, the drape is divided into 3 stages, while other similar devices only have 1 drape, increasing the risk of contamination.

Although the participants have experience using third-party equipment, they had difficulty using this evaluation device for the first time because they were not familiar with it; however, we do not think there will be any major problems once they are accustomed to the evaluation device. In addition, as a robot that guides the position of the screw in the patient’s body, it should have a more accurate and simpler workflow, making it more competitive with other products.

Limitations

This study is limited by the fact that our evaluation took place at a single institution, Severance Hospital in South Korea. In South Korea, robotic surgery is not yet widely used, and many people have not used robotic surgical instruments before; thus, they are still unfamiliar with robotic surgical instruments. However, the strength of this study is that we conducted usability tests with doctors and nurses in the operating room, who are the closest users of the new system, the surgical assistant robot.

Conclusions

In group 1, a success rate of 93% or higher was observed in all 24 tasks. In group 2, a success rate of 87% or higher was observed in 38 of 41 tasks. A success rate of 80% was observed in the task related to marker ball view confirmation (task 18), 80% in the task related to the use of the “Adjustment” function (task 28), and 75% in the task related to using “Re-matching” (task 30).

In addition, subjective data such as follow-up questions and surveys were more effective in identifying shortcomings and judging the usability, satisfaction, and effectiveness of the device

than quantitative data such as the number of use errors (task completion rate) and satisfaction evaluation scores. In terms of error, participants provided a lot of feedback, including suggestions for mitigating potential risks. Although the task success rate was high, the workload and SUS scores were lower

than the baseline, suggesting that improving the device user interface would increase the usability of the system. We recommend that the results of this test can be used in other usability engineering processes to improve the overall usability, satisfaction, completeness, and efficiency.

Authors' Contributions

HC wrote the paper and conducted all user experience evaluation, data collection, statistical analysis, and data interpretation. SK conducted user experience evaluation and data collection, such as comparison of the NASA Task Load Index, After-Scenario Questionnaire, and System Usability Scale by use experience. All authors conducted study design and reviewed the final paper.

Abstract

Background: In North Carolina, HIV continues to disproportionately affect young African American women. Although mobile health (mHealth) technology appears to be a tool capable of making public health information more accessible for key populations, previous technology use and social determinants may impact users' mHealth experiences.

Objective: The objective of this study was to evaluate mHealth usability, assessing differences based on previous technology use and social determinants among a sample of African American women in emerging adulthood.

Methods: As part of a National Institute on Drug Abuse-funded randomized controlled trial with African American women (aged 18-25 years), counties were assigned to receive an evidence-based HIV risk reduction intervention through mHealth and participants were asked to complete usability surveys at 6- and 12-month follow-ups. Participants' first survey responses were analyzed through 2-tailed *t* tests and linear regression models to examine associations with previous technology use and social determinants ($P < .05$).

Results: The mean System Usability Scale (SUS) score was 69.2 (SD 17.9; $n=159$), which was higher than the threshold of acceptability (68.0). Participants who had previously used a tablet indicated higher usability compared to participants without previous use (mean 72.9, SD 18.1 vs mean 57.6, SD 11.4; $P < .001$), and participants with previous smartphone use also reported higher usability compared to participants without previous use (mean 71.9, SD 18.3 vs mean 58.0, SD 10.7; $P < .001$). Differences in SUS scores were observed among those reporting homelessness (mean 58.3, SD 19.0 vs mean 70.8, SD 17.2; $P = .01$), unemployment (mean 65.9, SD 17.2 vs mean 71.6, SD 18.1; $P = .04$), or current school enrollment (mean 73.2, SD 18.5 vs mean 65.4, SD 16.5; $P = .006$). Statistically significant associations were not observed for food insecurity (mean 67.3, SD 18.6 vs mean 69.9, SD 17.7; $P = .45$).

Conclusions: Although above-average usability was observed overall, these findings demonstrate differences in mHealth usability based on past and current life experiences. As mHealth interventions become more prevalent, these findings may have important implications for ensuring that mHealth apps improve the reach of evidence-based interventions.

KEYWORDS

HIV; Black women; mobile apps; social determinants of health; prevention; substance use; usability

Introduction

In 1981, the first report was published identifying the disease that was later known as AIDS, marking the official beginning of the HIV epidemic [1]. In that same year, IBM's first PC was sold to the public [2]. As the HIV epidemic persists, there may be an opportunity to embrace the digital age we are living in and leverage technological solutions as we work toward the shared goal of ending the HIV epidemic.

HIV incidence rates remain disproportionate based on race in the United States, as rates for Black or African American women are 10.9 times higher than rates for White women [3]. Further, the highest rates of HIV diagnoses occur in the US South [3]. Many interventions have been developed for Black or African American women [4-8], but barriers such as lack of transportation, limited childcare access, concerns over privacy, and community-level stigma impede access to HIV testing and prevention services [9,10].

Most Americans have smart mobile devices [11]. These devices show promise in diminishing barriers and connecting key populations with public health information through increasingly convenient and private pathways. Research has demonstrated that being a woman, young, and African American are characteristics associated with being more likely to prefer mobile health (mHealth) when given a choice or to use mobile devices to seek health information [12,13], supporting mHealth interventions as potentially effective tools for this key population.

However, individuals may experience and engage with mHealth interventions differently. As the prevalence of mHealth apps continues to increase [14], there is a need to understand mHealth usability. In a scoping review of electronic health applications from 2014-2017, the rate of new health applications available outpaced the rate of published usability studies [15]. The authors explained that while most digital health apps are developed commercially, the results of commercial usability studies are not typically published [15]. Because of the limited reported data for mHealth usability, this study examined the usability of an mHealth HIV prevention intervention among young African American women in the US South.

A previous study adapted a best-evidence, women-focused HIV behavioral intervention for young African American women (the Young Women's CoOp), which demonstrated efficacy in reducing sexual risk [16]. In preparation for a trial to test intervention delivery, an mHealth version of the Young Women's Coop was developed [17]. This analysis of usability scores for the Young Women's CoOp mHealth app examines whether previous technology experience and social determinants are associated with mHealth experiences.

Methods

Overview

Analyses in this paper encompass an assessment of the usability of the Young Women's CoOp intervention that was adapted to an mHealth platform. The parent study reached 652 young African American women (aged 18-25 years) in North Carolina

who reported recent condomless sex with a male partner and substance use. A complete description of the parent study's eligibility criteria and procedures can be found in the study protocol paper [18].

In a 3-arm randomized trial implementing a cross-over design, 3 counties were assigned to receive the in-person delivery of the Young Women's CoOp intervention, the mHealth delivery of the Young Women's CoOp intervention, or standard HIV counseling and testing. Among the enrolled sample, 197 women were in the counties assigned to receive the mHealth delivery, which consisted of a 1-on-1 mHealth orientation and an Android tablet preloaded with the app that contained the 2-session intervention. Following the orientation, a tablet was provided to each participant to take with them. The study team requested that tablets be returned at the 6-month follow-up appointment.

The usability of the mHealth intervention was evaluated using a modified version of the 10-item System Usability Scale (SUS) [19]. SUS scores range from 0 to 100, with scores above 68 considered above average [20]. To account for participants missing follow-up appointments, mHealth participants completed the usability survey as part of an audio-computer-assisted self-interview (ACASI) at both 6-month and 12-month follow-ups. For participants who completed the usability survey at both follow-ups, only their first (6-month) survey response was considered. ACASI was administered in person in an attempt to engage and collect responses from mHealth users who may have had difficulty using the tablet or lost the tablet and who may have had challenges completing a tablet-hosted survey.

Social determinants (homelessness, unemployment, food insecurity, and school enrollment) were measured at study enrollment. Social determinant variables were either assessed as dichotomous questions (homelessness and school enrollment) or recoded into dichotomous variables (unemployment and food insecurity). Homelessness, unemployment, and school enrollment assessed an individual's current state and food insecurity asked about one's household. Descriptive statistics and 2-tailed *t* tests were used to assess bivariate associations between social determinants and usability scores. Linear regression was conducted to examine these associations while controlling for previous tablet use and previous smartphone use. Analyses were conducted in Stata 17 (StataCorp) using the threshold of $P < .05$ for statistical significance.

Ethical Considerations

The full study received approval from the Office of Research Protection's Institutional Review Board at RTI International (IRB ID number: 13836). Further, committees from Wake County Human Services and Durham County Department of Public Health, along with administration from the Guilford County Department of Public Health, granted study approval. All participants provided written informed consent. Several procedures were instituted to protect the privacy and confidentiality of study participants, including all staff members involved in data collection and analysis signing and abiding by Staff Agreements of Confidentiality. Additionally, each participant was assigned a unique alphanumeric participant identifier to limit study data being connected to identifying

information, such as name and contact information. Study participants were compensated for completing the baseline appointment with US \$50 in gift cards, the 6-month follow-up appointment with US \$70 in gift cards, and the 12-month follow-up appointment with US \$100 in gift cards.

Results

The overall mean SUS score was 69.2 (SD 17.9; n=159). Less than 12% (n=19) of participants did not have experience with a tablet or smartphone before the study. Variability of SUS scores by previous technology use and social determinants is shown in Table 1.

Participants who had previous tablet use reported higher SUS scores on average than participants who had not previously used a tablet (72.9, SD 18.1 vs 57.6, SD 11.4; $P<.001$). Similarly, participants who had previously used a smartphone had a higher

mean SUS score than participants who had not (71.9, SD 18.3 vs 58.0, SD 10.7; $P<.001$).

Additionally, the mean SUS scores were under the acceptable threshold for participants reporting food insecurity, homelessness, unemployment, or no current school enrollment. Statistically significant differences in mean SUS scores were observed among those reporting homelessness (58.3, SD 19.0 vs 70.8, SD 17.2; $P=.01$), unemployment (65.9, SD 17.2 vs 71.6, SD 18.1; $P=.04$), or current school enrollment (73.2, SD 18.5 vs 65.4, SD 16.5; $P=.006$). Statistically significant associations were not observed in the SUS score based on food insecurity (67.3, SD 18.6 vs 69.9, SD 17.7; $P=.45$). When accounting for previous mobile technology experience in each model, homelessness and current school enrollment were statistically significant, but unemployment and food insecurity were not statistically significant (Table 2).

Table 1. Bivariate associations between System Usability Scale (SUS) score and previous technology use and social determinants of health.

	Frequency, n (%)	SUS score, mean (SD)	P value
Previous tablet use			<.001
Yes	121 (76.1)	72.9 (18.1)	
No	38 (23.9)	57.6 (11.4)	
Previous smartphone use			<.001
Yes	128 (80.5)	71.9 (18.3)	
No	31 (19.5)	58.0 (10.7)	
Homelessness			.01
Yes	20 (12.6)	58.3 (19.0)	
No	139 (87.4)	70.8 (17.2)	
Unemployment			.04
Yes	67 (42.1)	65.9 (17.2)	
No	92 (57.9)	71.6 (18.1)	
Food insecurity			.45
Yes	41 (25.8)	67.3 (18.6)	
No	118 (74.2)	69.9 (17.7)	
In school			.006
Yes	77 (48.4)	73.2 (18.5)	
No	82 (51.6)	65.4 (16.5)	

Table 2. Associations between System Usability Scale (SUS) score and social determinants of health, adjusting for previous tablet use and smartphone use.

Independent variables	Coefficient (95% CI)	P value
Homelessness	-9.0 (-16.8 to -1.1)	.03
Unemployment	-4.9 (-10.1 to 0.3)	.07
Food insecurity	-1.5 (-7.5 to 4.4)	.61
In school	6.2 (1.1 to 11.3)	.02

Discussion

As mHealth continues to become more prevalent, these findings show an overall above-average usability for the mHealth adaptation of the Young Women's CoOp intervention. Notably, there were differences in SUS scores based on a participant's past experiences with technology. Although less than 12% of the study sample had not previously used a smartphone or tablet, this proportion was higher than what may be expected for this age group based on national survey data for young adults [11]. This finding suggests the importance of considering ways the digital divide and other factors may impact familiarity with mobile technology when designing mHealth interventions for this key population. In this study, before participants were given tablets with the mHealth intervention, they received a brief orientation to the app. Given the lower reported usability among those who lacked experience with mobile technology, these findings suggest examining further whether providing more guidance during app orientation could improve app usability for those with limited previous experience. Additionally, ongoing and other technology support (eg, a chat feature where trained staff can provide technology support to users within the app) may be strategies to explore with guidance from the intended end users to see if they improve mHealth experiences for individuals with less mobile technology experience.

Given privacy and stigma-related barriers that may hinder access to in-person HIV prevention programs and services for young African American women [9,10], mHealth could be an attractive solution. However, our findings exemplify that not only previous experience with technology but also diversity in participants' life circumstances, such as homelessness and school enrollment, can be associated with usability. Though the format may appear

well-positioned for young adults, it is imperative to consider how a surge in the use of mHealth may miss the opportunity to maximally address existing health disparities if some users encounter barriers when operating the mHealth app that undermine their experiences. Additional guidance and support will be essential for those with factors associated with lower usability.

This study should be considered in relation to a few limitations. All participants completed the intervention using a study-issued Android tablet. Noting how a device's model or operating system may affect usage, some user experiences may have been shaped by the device specifications. In future usability studies, it may be valuable to have participants use their own devices to minimize the chance that device unfamiliarity affects assessments of app usability. Further, participants were asked to assess usability at 6- and 12-month follow-ups. Though participants still had access to the app before returning the device at their follow-up appointment, there was potential for recall bias as usability may have been assessed months after a participant's last app interaction. Additionally, it should be noted that all experiences with the app and data collection occurred before the COVID-19 pandemic. With a greater shift to digital formats for health, education, social, and other services throughout the pandemic, access to mobile devices and familiarity with receiving information through mobile technology may have increased since this study.

Despite these limitations, the study prompts important considerations as the health sector embraces digital technology. The overall above-average usability score signals the potential value of using mHealth as a delivery method in the public health toolkit to further expand the reach of evidence-based interventions to those who may need it the most.
