Abstract

Background: Health care providers can make health guidance more effective by using mobile health technologies such as health apps. Although health care providers need to know who uses health apps, existing studies have yielded inconsistent results.

Objective: The aim of the study was (1) to clarify the prevalence and patterns of health app use to improve health behaviors for preventing lifestyle-related diseases among Japanese workers and (2) to identify the associations among demographic characteristics, health behavior, and internet use and health app use by gender.

Methods: Data were collected from a cross-sectional internet survey in 2023. In total, 2200 participants were included, with an even distribution of men and women in each age group aged 20 to 60 years. The participants were workers with smartphones and reported their gender, age, residence area, marital status, education, employment status, occupation, work pattern, diseases under treatment, health checkups, health guidance, health behaviors, internet use duration, and number of devices used. We asked about current and previous health app use for 1 month. A multivariate logistic regression analysis was conducted by gender.

Results: Of the participants, 472 (21.5%) and 189 (8.6%) were current and previous health app users, respectively. Most current and previous health app users used features that record and track their physical activity and other health behaviors. Health app users—both men and women—were more likely to have health checkups (odds ratio [OR] 1.53, 95% CI 1.12-2.11 and OR 1.51, 95% CI 1.10-2.07, respectively), receive health guidance (OR 2.01, 95% CI 1.47-2.74 and OR 1.86, 95% CI 1.32-2.62, respectively), engage in regular physical activity (OR 2.57, 95% CI 1.91-3.47 and OR 1.94, 95% CI 1.41-2.67, respectively), use the internet for 120-179 minutes per day (OR 1.76, 95% CI 1.13-2.75 and OR 1.70, 95% CI 1.12-2.57, respectively), and were less likely to be older (50-59 years: OR 0.54, 95% CI 0.33-0.88 and OR 0.40, 95% CI 0.25-0.6, respectively, and 60-69 years: OR 0.37, 95% CI 0.22-0.62 and OR 0.47, 95% CI 0.28-0.77, respectively). According to gender, male health app users were more likely to be married (OR 1.69, 95% CI 1.23-2.33) and less likely to work in the security, agriculture, forestry, fishing, manufacturing, or transportation industries (OR 0.62, 95% CI 0.41-0.95). Female health app users were more likely to have a university education or higher (OR 1.55, 95% CI 1.061-2.26), maintain an appropriate body weight (OR 1.52, 95% CI 1.10-2.11), and use 3 or more devices (OR 2.13, 95% CI 1.41-3.23).

Conclusions: Physical activity and health guidance are strong predictors of app use. Health care providers should assess the target populations' preferences for app use based on their characteristics, support their app use, and enhance the effectiveness of health guidance.

Introduction

Internet and communication technologies are developing rapidly worldwide. The proportion of people aged 20-59 years who use the internet in Japan is 95.2-98.4% [1]. The proportion of households with smartphones has risen from 49.5% to 88.6% in the past decade, and individuals are more likely to use a smartphone than a PC when connecting to the internet. Against this background, mobile health (mHealth) technologies have been developed and improved to support behavioral change and disease management. Thousands of health management apps (health apps) are available for smartphones, and their technical features include tracking behavior manually or semiautomatically, app communities, and app reminders [2]. In addition, these apps use behavior change techniques such as goal setting, self-monitoring, and feedback to help users improve their health habits [2]. Interventions involving health apps are increasing and are being evaluated [3-5]. A review of health app interventions reported improved physical functioning, adherence to prescribed medications, ease of symptom evaluation, and reports to care providers for people with chronic conditions [3]. In another review, most studies demonstrated significant improvements in health outcomes [4].

In Japan, one-third of men and one-fifth of women have obesity or overweight [6], leading to chronic diseases that increase medical costs. To prevent chronic diseases, promote health, and extend life expectancy, improving individuals' lifestyles from a young age is important. Consequently, health checkups and guidance are provided to almost all segments of the population in Japan [7]. Under the Industrial Safety and Health Law, employers are required to conduct annual health checkups for full-time employees to prevent the worsening of employee health due to work. Furthermore, employers must endeavor to provide health guidance to employees who need to improve and maintain their health. Additionally, as a strategy to prevent lifestyle-related diseases, medical insurers are obligated to provide a specified health checkup to all insured persons aged between 40 and 74 years under the Act on Ensuring Medical Care for Elderly People. Based on the checkup results, specific health guidance is provided to individuals identified as having a high risk of developing lifestyle-related diseases. Thus, Japan has a unique health care system that aims to promote individuals' efforts to improve their lifestyles based on checkup results. Health care providers, such as physicians, nurse practitioners, and dietitians, are required to provide efficient and effective health guidance. However, workers in Japan often face challenges in receiving health guidance due to time constraints. Health apps have the potential to address this issue by monitoring workers' health-related data and facilitating message exchanges between health care providers and workers. This allows workers to receive health guidance even if they do not frequently meet with health care providers. Given the high rate of smartphone and internet use among the Japanese working population, mHealth can be used to make health guidance more efficient and effective.

Recent studies have examined the effectiveness of using an app for specific health guidance [8,9]. However, health care providers need to know which individuals use health apps to

manage their health and lifestyle to effectively provide health guidance in this manner.

Several studies have examined factors associated with the use of health apps. Regarding sociodemographic factors, some studies [10-12] report that women are more likely to use or have health apps than men, while other studies [13-16] report no difference between men and women in terms of having or using health apps. Several studies [10,12,13,15,17] found that younger generations were more likely to have or use health apps, whereas other studies [11,15,16] found no differences between generations. Although Carroll et al [10] reported that individuals with greater education were more likely to have health apps, other studies [11,13-16] found no difference among educational levels. Regarding chronic conditions, Ernsting et al [13] reported that individuals with 1, 2, and 3 or more chronic conditions were more likely to use health apps than those without chronic conditions.

Conversely, Langford et al [17] reported that individuals without a self-reported history of hypertension were more likely to have health apps on their tablets or smartphones than those with a self-reported history of hypertension. Makowsky et al [14] and Robbins et al [18] found no association between health app downloads and chronic conditions. Three studies [10,13,18] that examined health apps and physical activity reported that individuals who maintained physical activity were more likely to use or have health apps than those who did not. On the contrary, Fewings et al [16] found no difference between diet-related app use and physical activity or other health behaviors such as vegetable, fruit, and fast food consumption and smoking status. However, these studies are not easily comparable because of differences in their methods and duration. Consequently, the factors associated with health app use are inconsistent across them. Moreover, few studies have examined health app use and identified its associated factors, which are expected to differ between countries because of variations in the prevalence of smartphones, health care systems, and internet literacy. mHealth technologies are developing rapidly, and attitudes toward and confidence in using health apps may change.

Against this background, we aimed (1) to clarify the prevalence and patterns of health app use to improve health behaviors and thus prevent lifestyle-related diseases among Japanese workers and (2) to identify the associations between demographic characteristics, health behavior, and internet use and health app use by gender. We focused on health apps that have functions for tracking lifestyle, body weight, and medications; searching for health information; and interacting with other users to improve health behaviors and prevent lifestyle-related diseases. Since gender differences exist in the prevalence of lifestyle-related diseases and health behaviors among Japanese citizens [6], gender may influence app use patterns. Therefore, we hypothesized that the factors related to health app use would differ between men and women. We examined which sociodemographic, health behavior, and internet use factors were associated with health app use by gender. Moreover, health care providers should consider clients' preferences for tools that support behavior change during health guidance. For instance, understanding who prefers to use health apps for behavior

change during health guidance is useful. Similarly, health care providers can more efficiently introduce health apps to clients by considering factors related to app use. In this study, we specifically focused on the current and previous use of health apps for over a period of more than a month. This is because most smartphones come with preinstalled health apps, and some apps offer a free 30-day trial. Consequently, health app users may use these apps intermittently. For example, they might temporarily stop using them once they can manage their target health behaviors or before the 30-day free trial ends.

Methods

Sample and Procedure

Data for this study were collected from a cross-sectional internet survey conducted by the research company Cross Marketing on February 13-14, 2023. The total number of participants was 2200. We collected data from an equal number of men and women in each age group from 20 to 60 years. Eligible participants were aged 20-69 years, were workers (including part-time work), and had a smartphone. Potential participants were sent an email asking them to complete a preliminary survey to verify their eligibility. Eligible participants were then asked to complete the main survey. The survey was terminated once the target number of participants was reached. Of the 2873 potential participants who completed the preliminary survey, 76.9% (n=2200) completed the primary survey.

All survey procedures were performed by Cross Marketing. Cross Marketing has over 5 million panelists registered across the country. They regularly collect basic information from registered panelists, which was confirmed before conducting the survey. They screened for panelists whose response times were extremely shorter than expected and excluded them. In addition, responses related to demographic characteristics were examined, and panelists with contradictory or inconsistent answers were excluded.

Measures

Demographic Characteristics

We asked the participants about their gender, age, area of residence, marital status, education, employment status, occupation, and work patterns.

Health and Medical Services and Health Behaviors

We asked participants four questions: (1) "Do you have any diseases under treatment?" (yes or no responses), (2) "Do you have annual health checkups or physical examinations?" (yes or no responses), (3) "Have you received health guidance from a doctor, nurse, or dietician?" (3 response options ranging from 0 to ≥ 2), and (4) "Do you implement the following health behaviors (select all those that you implement): do not smoke, engage in regular physical activity, drink moderately or do not drink, get enough sleep each day, maintain an appropriate weight, and eat breakfast every day?" We reclassified response options into a single dichotomous outcome variable of receiving health guidance (never or more than once).

Internet Use

We asked participants, "Apart from using the internet for work purposes, how much time do you spend on the internet per day? (4 response options ranging from <60 to ≥ 180 minutes)." Participants were asked to choose all of the devices they used to access the internet on a daily basis (eg, smartphones, computers, tablets, mobile phones (excluding smartphones), internet-enabled television receivers, home game consoles, and wearable devices). We categorized the participants according to the number of devices they used: 1, 2, or 3 or more.

Current and Previous Use of Health Apps

The participants were asked, "Have you ever used health apps to improve health behaviors for chronic disease prevention or weight loss? (Specifically, health apps that have functions for tracking lifestyle, body weight, and medications; searching for health information; and interacting with other users to improve health behavior for weight loss or prevent lifestyle-related diseases)." The response options were "currently using health apps for over 1 month," "have used health apps in the past for over 1 month," and "never used health apps (including having downloaded health apps and only used them for less than 1 month)." Participants who are currently using health apps for over 1 month and those who have used health apps in the past for over 1 month were asked the following questions: "What features of the apps do you (or did you) use?" (13 response options, multiple answers), "Do you (or did you) pay to use the health apps?" (yes or no responses), "Do you (or did you) use the apps in conjunction with wearable devices (including those who do not have wearable devices)?" (yes or no responses), and "How motivated are (or were) you to use the apps?" (5 response options, multiple answers). Participants who had never used health apps (including those who downloaded health apps but only used them for less than 1 month) and those who had used health apps in the past for over 1 month but stopped using them were asked why they did not use or stopped using health apps (8 response options with multiple answers).

Statistical Methods

Descriptive statistics were used to describe the participants' demographic characteristics, health and medical services, health behaviors, internet use, and health app use status. We reclassified the response options into a single dichotomous outcome variable of the use of health apps. We categorized participants who are currently using health apps for over 1 month and those who have used health apps in the past for over 1 month as "users (current and previous)," and those who have never used health apps (including those who had downloaded health apps but only used them for less than 1 month) as "nonusers." We also used the 2-tailed *t* test and chi-square test to check for differences in these factors according to gender.

We used the chi-square test to clarify the relationship between current or previous use of health apps and age, educational background, occupation, health checkups, health guidance, health behaviors, internet use duration, and number of devices used to access the internet for men and women separately. In addition, binary logistic regression analyses of data from men and women were conducted. The dependent variables were the

use of health apps, and the independent variables were age, education, occupation, health checkups, health guidance, health behaviors (smoking, physical activity, drinking, sleep, appropriate weight, breakfast, and snacking), internet use duration, and number of devices used to access the internet. Odds ratios (ORs) and 95% CIs were calculated. Multivariable logistic regression analyses were conducted with all the independent variables included, and adjusted ORs and 95% CIs were calculated. Multicollinearity in multivariable logistic regression models was assessed using the variance inflation factor. Pseudo- R^2 values were also calculated to determine the proportion of variance in the dependent variable that can be explained by the independent variables. Data were analyzed using SPSS Statistics (version 22; IBM Corp).

Ethical Considerations

All the participants were asked to read the information privacy statement and informed consent form, and if they agreed to participate in the survey, they clicked an icon to begin answering the questionnaire. Completion of the internet survey was considered consent to participate in the study. Participants were not asked for any personally identifiable information. There are privacy agreements between Cross Marketing and its panelists. Participants who completed the survey were given points by Cross Marketing as a reward. Ethics approval was granted by the Research Ethics Committee of Nagoya City University, Graduate School of Nursing (ID22042-2).

Results

Participants' Characteristics

The average age of the 2200 participants was 44.7 (SD 13.5; men: mean 44.9, SD 13.6 and women: mean 44.6, SD 13.3)

years (Table 1). Most of the participants lived in the Southern Kanto (n=779, 35.4%), Kinki (n=355, 16.1%), and Tokai (n=299, 13.6%) regions, which included metropolitan areas. Nearly half of the participants were unmarried (n=1126, 51.2%) and had an education at the university level or higher (n=1114, 50.6%). Many participants worked full-time (n=1284, 58.4%) and had fixed hours (n=1433, 65.1%). Almost all the participants had no disease under treatment (n=1818, 82.6%). Many participants had undergone health checkups (n=1370, 62.3%) and did not receive health guidance (n=1615, 73.4%). Regarding health behaviors, many participants did not smoke (n=1329, 60.4%), while a few participants did not snack (n=238, 10.8%). One-third of the participants reported using the internet for 60-119 minutes per day, and almost all used smartphones or PCs to do so (n=1972, 89.6% and n=1429, 65%, respectively).

There were statistically significant differences in the participants' demographic characteristics according to gender. More men than women were married, had a university education or higher, worked full-time, and engaged in flexible or discretionary work. The occupation among men was more likely to be security or agriculture, forestry, fishery, production, transportation, and construction, while among women, it was more likely to be office work. In terms of health behaviors, men were more likely to engage in regular physical activity and not snack, while women were more likely not to smoke or maintain an appropriate weight. Men were more likely to spend more time using the internet and to use more devices than women.

Table 1. Demographic characteristics, health-related factors, and internet use according to gender.

Health App Use Status

Of the participants, 472 (21.5%) were current users of health apps for at least 1 month, 189 (8.6%) had used them for at least 1 month in the past, while 1539 (70%) had never used them (this last figure includes those who downloaded health apps but only used them for less than 1 month), with no significant differences according to gender (Table 2). Almost all current and previous health app users used features to track physical activity (n=487, 73.7%) and physical data, such as weight (n=256, 38.7%), sleep status (n=138, 20.9%), and food or diet

(n=137, 20.7%). Among current and previous users, 84.4% (n=558) did not pay to use the health app, and 28.6% (n=103) used the health app in conjunction with wearable devices, with significant gender differences. Most users were motivated by their own desire for health management (n=504, 76.2%). Men were more likely to be motivated by referrals during health guidance and offers from their companies or health insurers than women. The reasons for not using or stopping to use health apps were that participants were unfamiliar with or uninterested in health apps and that the apps were cumbersome.

Table 2. Status of health app use according to gender.

	All	Men	Women	<i>P</i> value ^a
Use of health apps (n=2200), n (%)				.55
Currently using health apps for at least 1 month	472 (21.5)	239 (21.7)	233 (21.2)	
Used health apps previously for at least 1 month	189 (8.6)	101 (9.2)	88 (8)	
Never used health apps	1539 (70)	760 (69.1)	779 (70.8)	
Participants who reported current and previous use of health apps (n=661)

^aChi-square test.

Relationships Between Current and Previous Health App Use and Demographic Characteristics, Health-Related Factors, and Internet Use

The results of the chi-square test indicated significant differences in terms of marital status ($P=.001$), education ($P<.001$), occupation ($P=.001$), health checkups ($P<.001$), health guidance ($P<.001$), physical activity ($P<.001$), maintaining an appropriate weight ($P=.01$), internet use duration ($P=.03$), and number of devices ($P<.001$) in health app use among men (Multimedia Appendix 1). There were significant differences in terms of age ($P=.003$), education ($P<.001$), health checkups ($P<.001$), health guidance ($P<.001$), physical activity ($P<.001$), drinking in moderation or not drinking ($P=.04$), getting enough sleep ($P=.01$), maintaining an appropriate weight ($P<.001$), eating breakfast ($P=0.02$), internet use duration ($P=.01$), and number of devices ($P<.001$) in health app use among women (Multimedia Appendix 2).

Adjusted ORs for current and previous health app use among men and women were shown in Figures 1 and 2, respectively. The ORs for current and previous health app use were significantly higher for participants who had health checkups (men: OR 1.53, 95% CI 1.12-2.11 and women: OR 1.51, 95% CI 1.10-2.07), received health guidance (men: OR 2.01, 95% CI 1.47-2.74 and women: OR 1.86, 95% CI 1.32-2.62), engaged

in physical activity (men: OR 2.57, 95% CI 1.91-3.47 and women: OR 1.94, 95% CI 1.41-2.67), and used the internet for 120-179 minutes per day (men: OR 1.76, 95% CI 1.13-2.75 and women: OR 1.70, 95% CI 1.12-2.57) and significantly lower for those aged 50-59 years (men: OR 0.54, 95% CI 0.33-0.88 and women: OR 0.40, 95% CI 0.25-0.66) and 60-69 years (men: OR 0.37, 95% CI 0.22-0.62 and women: OR 0.47, 95% CI 0.28-0.77) for both men and women. Additionally, the ORs for current and previous health app use were significantly higher for men who were married (OR 1.69, 95% CI 1.23-2.33) while being significantly lower for men who had a job in the security, agriculture, forestry, fishing, production, or transportation industries (OR 0.62, 95% CI 0.41-0.95). For women, the OR for current and previous health app use was significantly higher for those with a university education or higher (OR 1.55, 95% CI 1.061-2.26), those who maintained an appropriate weight (OR 1.52, 95% CI 1.10-2.11), and those who used 3 or more devices (OR 2.13, 95% CI 1.41-3.23). Multimedia Appendix 3 shows the results of the chi-square test and logistic regression model for the data of combined men and women. The variance inflation factor of all the independent variables in the logistic regression models ranged from 1.07 to 1.38. Therefore, multicollinearity was not present in any of the models. The R^2 values were 0.186 for the model of men and 0.172 for the model of women.

Figure 1. Forest plot showing adjusted odds ratios for health app use among men (n=1100).

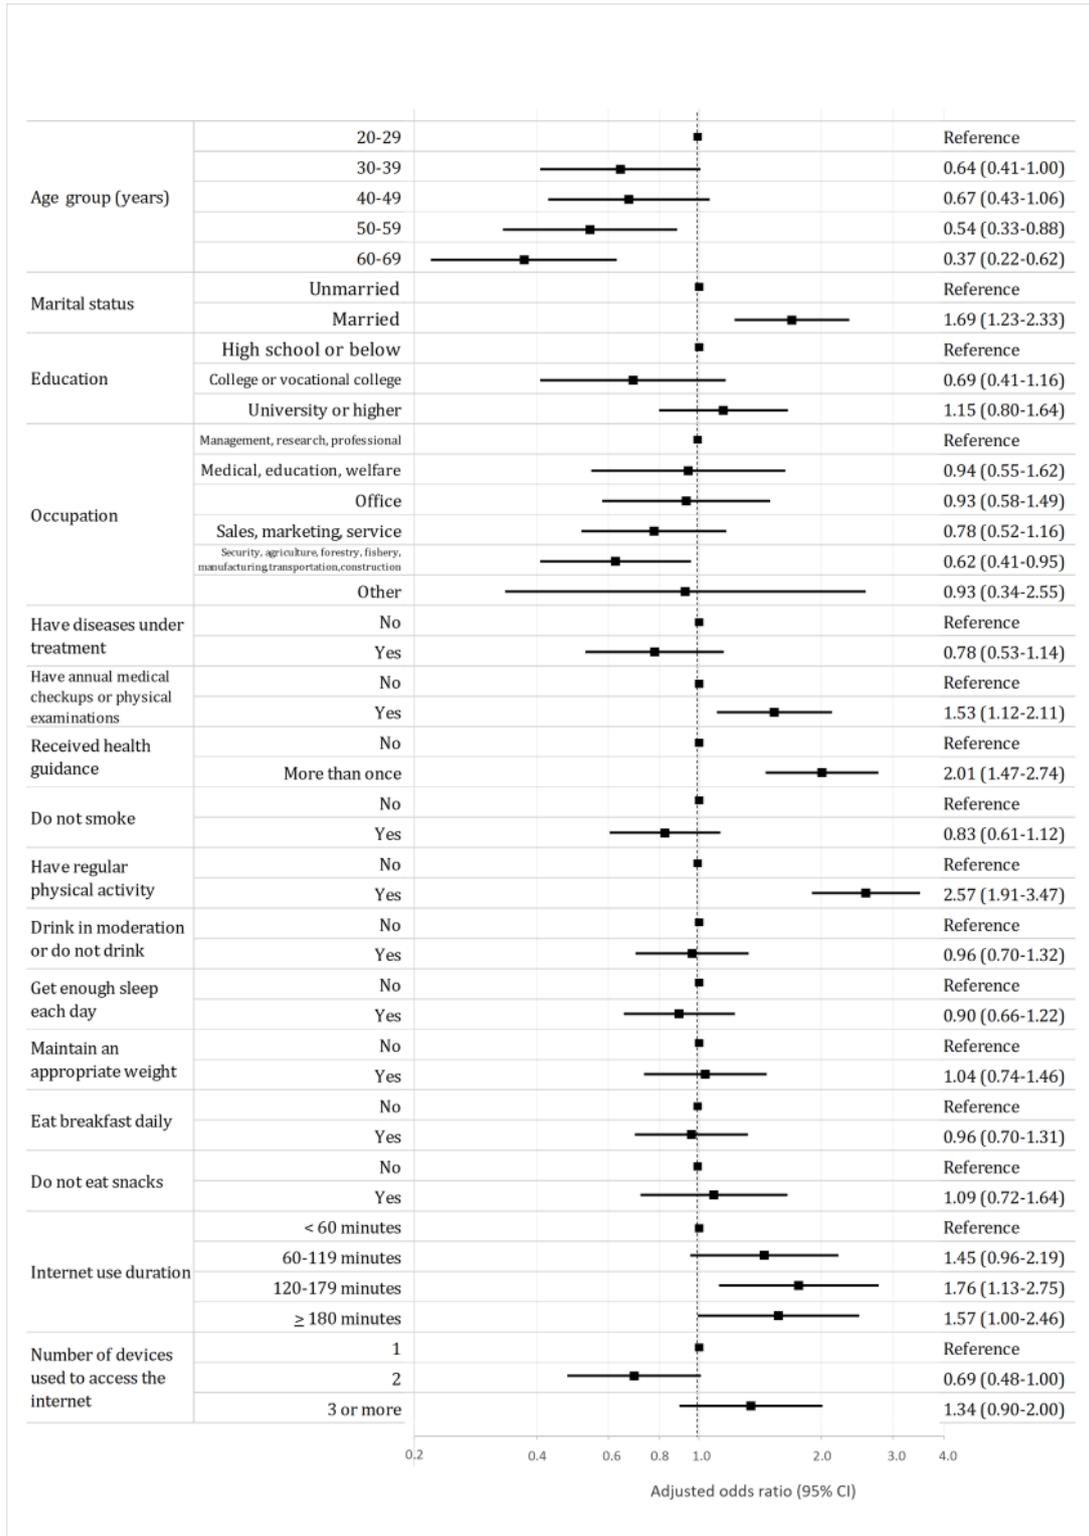

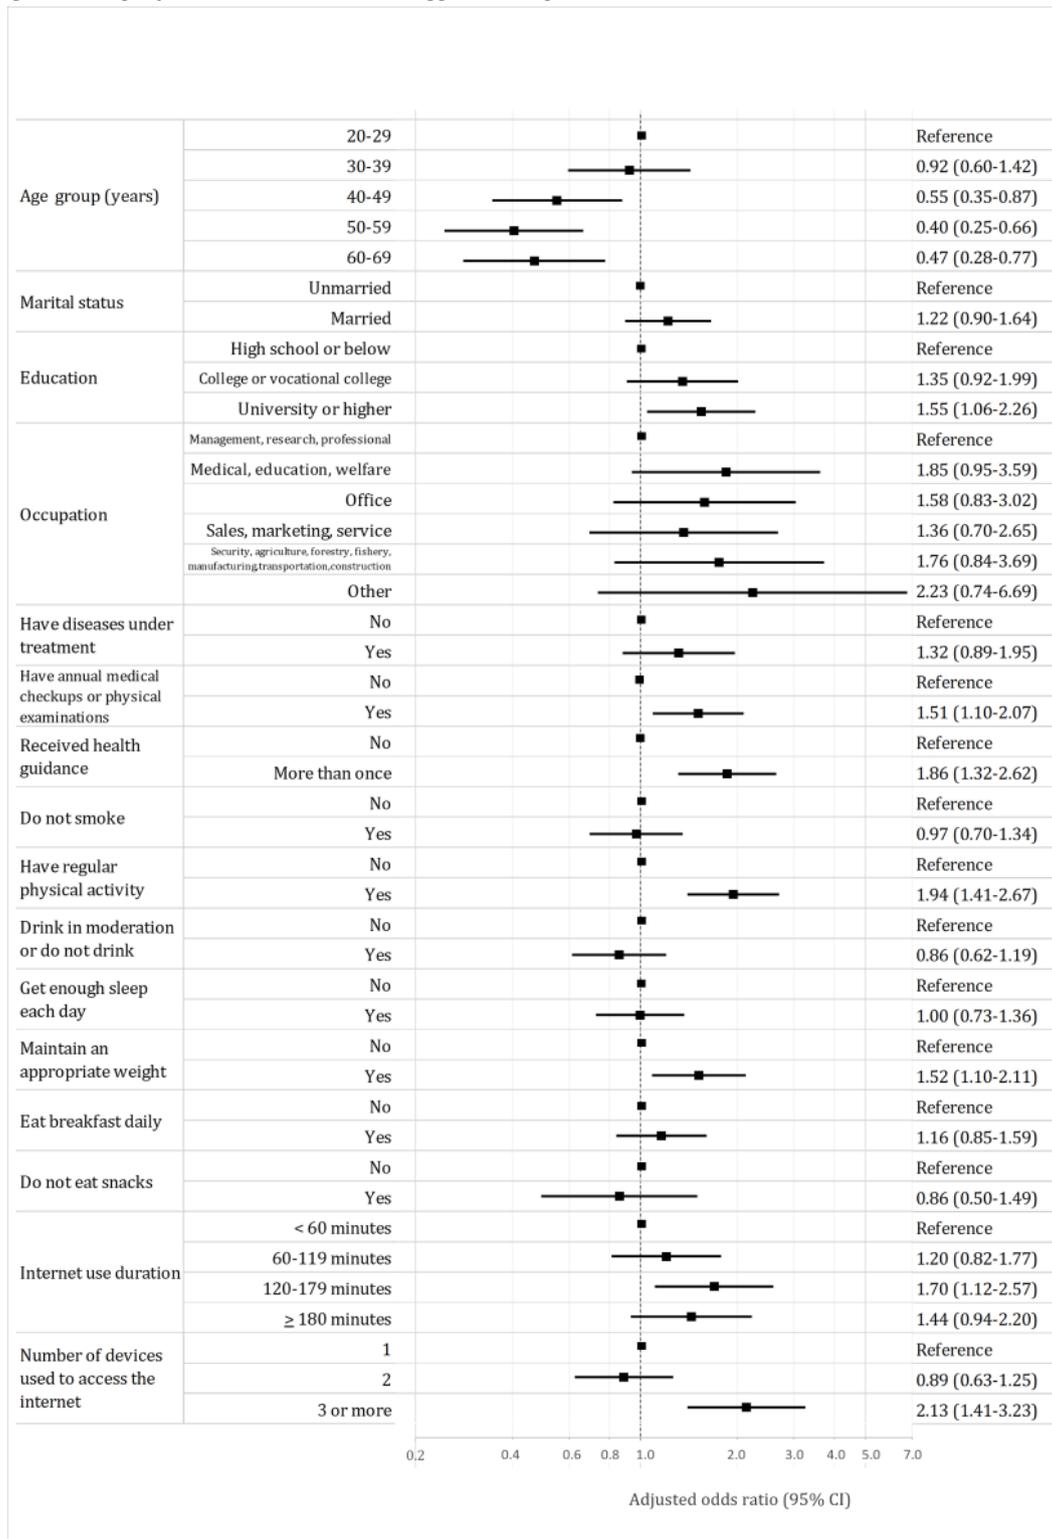

Figure 2. Forest plot showing adjusted odds ratios for health app use among women (n=1100).

Discussion

Principal Findings

In this study, we aimed to map and create an overview of health app use among Japanese workers and factors correlated with health app use by gender. Most current and previous health app users used features that record and track their physical activity and other health behaviors. Health app users were more likely

to be younger, receive health guidance, engage in regular physical activity, and spend more time on the internet for both men and women. In terms of gender differences, male health app users were less likely to be married and less likely to work in the security, agriculture, forestry, fishing, production, or transportation industries, whereas female health app users were more likely to have a university education or higher, maintain an appropriate weight, and use 3 or more devices.

The proportions of current and previous health app users were 21.5% (n=472) and 8.6% (n=189), respectively. Ernsting et al [13] reported that the rate of health app use was 20.5% in a survey conducted in Germany in 2015, whereas Xie et al [11] reported that 38.4% of the respondents used health apps in a survey conducted in China between 2016 and 2017. In a survey conducted in Australia in 2020, Fewings et al [16] showed that 25.7% and 37.8% of the respondents were current and previous users of diet-related apps, respectively. These surveys were conducted between 2015 and 2022. Despite the increasing proportion of smartphone use among Japanese citizens [1], the prevalence of health app use among Japanese workers was low compared to the rates reported in these previous studies. However, our findings may have been influenced by the fact that we asked whether participants used health apps continuously for over a month.

The reasons for not using health apps and discontinuing their use were unfamiliarity with the apps and a lack of interest in them. Recording and tracking lifestyle and physical data, which app users in this study reported doing frequently, are useful for self-monitoring and are effective behavior change techniques [19]. Health apps have the potential to be effective tools for improving lifestyles, and their use can be increased by demonstrating their benefits and removing barriers to their use through easy-to-use interfaces.

App users in this study were likelier to have annual health checkups and receive health guidance than those who did not use the apps. A review of health checkups showed that general health checkups are associated with increased chronic disease recognition and treatment, risk factor control, preventive service uptake, and improved patient-reported outcomes [20]. Individuals who undergo a health checkup may reflect on their health status, intend to change their behavior, and consequently use health apps for behavior change. In our study, 13.5% (n=89) of the participants who used a health app reported being introduced to it during health guidance. Similarly, Hogan et al [15] showed that encouragement from health care team members to use an app was strongly associated with app use in a survey study. Individuals who trust the information provided by an app or website are more likely to use the app [16]. Encouragement from a health care provider to use a health app may increase trust in the app and promote its use. However, the features and contents of many apps lack a theoretical basis and safety [21]. Therefore, ensuring quality in the theoretical basis of the app and the safety of the information is crucial [2].

In this study, app users were more likely to engage in physical activity, which aligns with the results of previous studies [10,13,18]. In a qualitative study that explored the perspectives of young adults on apps related to behavior change, Dennison et al [22] showed that the appeal and usefulness of apps depend on whether a user is already motivated to change their lifestyle. Features such as self-monitoring tools and app reminders encourage motivated individuals to change their behavior; app use then helps cement behavior change. However, determining a causal relationship between app use and physical activity engagement based on the results of our cross-sectional survey is challenging, as app users may include individuals with greater

motivation and interest in physical activity who are already engaging in physical activity [10,18].

We found no correlation between app use and diseases under treatment, similar to previous studies [14,18]. Individuals who use digital self-tracking tools are motivated to maintain their well-being rather than monitor or mediate medical problems or illnesses, and many monitor their progress in fitness or athletic training [23]. App users may include individuals willing to use the app to improve their health status and maintain their well-being by engaging in physical activity, regardless of whether they are undergoing treatment for any diseases. In this study, women using the app were also likely to maintain an appropriate weight. Weight is an important and easy-to-understand health parameter and is related to aesthetic satisfaction. Female users may intend to use the app to monitor their weight and maintain their well-being.

The app users in this study were likely to spend more time on the internet. Barriers to using health apps are that they are time-consuming and burdensome [22]. Those who spend a lot of time on the internet each day may spend some of that time using a health app and may not face these issues. Conversely, those who spend less than an hour on the internet may find it challenging to use a health app because they do not have enough time to spend on the internet or because they find it burdensome. Meanwhile, those who used the internet for more than 180 minutes did not use health apps significantly. Using the internet for a long time is an unhealthy habit, and these individuals may not be interested in using apps for disease prevention.

Female app users were more likely to use more than 3 devices to access the internet. Oshima et al [24] showed that smartphone ownership was associated with access to health care services, such as looking for health information and receiving necessary medical care. People must search for information about health apps to use suitable apps. In this study, women who used multiple devices may have had higher internet literacy, could easily access information about health apps, and found their favorite apps compared to those who used smartphones only. There was no association between app use and the number of devices among men. App users are uncomfortable with apps operating without user awareness or permission and want awareness of all features and control of all app settings [22]. Therefore, people must be skilled in using devices and technologies for apps. Men were more likely to use multiple devices than women, indicating that the former may be more skilled in using devices and technologies. Thus, the use of multiple devices does not appear to have affected the use of apps by men.

Strengths and Limitations

One strength of this study is that it included participants from diverse backgrounds nationwide. As people may use apps intermittently, we examined both current app use for more than 1 month and previous app use lasting longer than 1 month. We clarified the status of app use and the characteristics of those currently using or who have previously used health apps to improve health behaviors. We found common factors associated with app use in men and women as well as differences. Health care providers can use this information to assess whether the

target population is suited to use health apps and how to motivate them to use health apps. For instance, during health checkups and health guidance, both men and women are easily motivated to use health apps for their health management, and health care providers can support them in using health apps. As for women, health care providers need to support them by asking how long they spent on the internet and how many devices they use, and then consider whether they can use health apps. Health care providers can enhance the effectiveness of health guidance by assessing whether a target population prefers to use an app based on their characteristics and by supporting them in using the app to improve their behavior.

Nonetheless, this study has several limitations. First, due to the cross-sectional design, we could not clarify a causal relationship between app use and the mentioned factors. For example, as mentioned earlier, we could not clarify whether participants who engaged in physical activity used the app to manage it or whether app users could manage their physical activity because of using the app. Second, this study involved a web-based survey conducted through a research company. Therefore, the possibility of sample bias cannot be excluded. The proportion of smartphone users among Japanese people aged between 20 and 49 years is more than 90% [1], and the participants in this study were not a specific population compared to the general population. However, people who participate in web-based surveys may be generally interested in internet technology, such as health apps. Therefore, the proportion of current and previous app users may be higher than the actual proportions in the general population.

Meanwhile, the rate of annual health checkups in this study was lower than that of the Japanese population (62.3% vs lowest in 20s: 68.4%; and highest in 50s: 77.4%) [25]. Participants may have been less interested in health behaviors or had difficulty accessing health care services, indicating that the proportion of current and previous app users may be higher in reality. Third, as we inquired regarding previous app use, recall bias is possible. Fourth, we could not clarify various situations of app use. We defined the duration of continuous app use as using an app for more than 1 month and could only clarify current or

past app use. However, there are numerous health apps, and their health behavior targets vary. We expect that health app use patterns vary, with participants changing the apps they use in a short time and using multiple apps simultaneously. Future studies are needed to develop a more detailed understanding of app use for health guidance. Finally, although we focused on health-related factors (diseases under treatment, checkups, health guidance, and health behaviors) and internet use (use duration and number of devices), other related factors may influence app use. Future research should clarify the characteristics of individuals who will use a health app when it is offered to a target population and what outcomes will be achieved by using it. In addition, interviews are needed to better understand the kinds of mHealth apps that should be designed for Japanese workers.

Conclusions

This study clarified the status of current and previous use of health apps and related factors to prevent lifestyle-related diseases among Japanese workers. Compared to previous studies, the rate of app use among Japanese workers was low. The reasons for not using apps and discontinuing their use were unfamiliarity and a lack of interest in apps. Therefore, the number of app users can be increased by promoting effective apps for lifestyle improvement and providing easy-to-use and evidence-based apps. Health app users were more likely to be younger, receive health guidance, engage in regular physical activity, and spend more time on the internet for both men and women. Physical activity was strongly associated with app use. Although we could not clarify a causal relationship between app use and engagement in physical activity, app users may be interested and actively engage in physical activity. Health guidance was also strongly associated with app use. The introduction of an app by a health care provider may increase trust in it and promote its use. Health care providers can improve the effectiveness of health guidance by assessing whether a target population prefers to use an app based on their characteristics and by supporting them in using the app to improve their behavior.

Abstract

Background: Poor sleep is a common problem in adolescents aged 14 to 18 years. Difficulties with sleep have been found to have a bidirectional link to mental health problems.

Objective: This new research sought to involve young people in the co-creation of a new app, particularly those from underserved communities. The Sleep Solved app uses science-based advice to improve sleep-related behaviors and well-being. The app was developed using the person-based approach, underpinned by the social cognitive theory and the social-ecological model of sleep health.

Methods: Young people (aged 14-18 y) were recruited from across the United Kingdom to contribute to patient and public involvement (PPI) activities. In partnership with our peer researcher (MHJ), we used a multitude of methods to engage with PPI contributors, including web-based workshops, surveys, think-aloud interviews, focus groups, and app beta testing.

Results: A total of 85 young people provided PPI feedback: 54 (64%) young women, 27 (32%) young men, 2 (2%) genderfluid people, 1 (1%) nonbinary person, and 1 (1%) who reported “prefer not to say.” Their levels of deprivation ranged from among the 40% most deprived to the 20% least deprived areas. Most had self-identified sleep problems, ranging from 2 to 3 times per week to >4 times per week. Attitudes toward the app were positive, with praise for its usability and use of science-based yet accessible information. Think-aloud interviews and a focus group identified a range of elements that may influence the use of the app, including the need to pay attention to language choices and readability. User experiences in the form of narrated audio clips were used to normalize sleep problems and provide examples of how the app had helped these users.

Conclusions: Young people were interested in using an app to better support their sleep and mental health. The app was co-created with strong links to theory- and evidence-based sleep hygiene behaviors. Future work to establish the effectiveness of the intervention, perhaps in a randomized controlled trial, would provide support for potential UK-wide rollout.

Introduction

Background

Poor sleep is a common issue among adolescents, with significant effects on school performance [1], mood, and behavior [2,3]. Since the 1990s, the amount of sleep per night that adolescents self-report has decreased significantly [4,5]. Poor sleep can impact adolescents' mental health [6]; reduced sleep duration has been associated with loneliness, low mood [7], and depression [8] and can affect adolescents' physical health over time [9].

Adolescence is a period of significant biological and psychosocial changes. These changes include a shift in the sleep-wake cycle, a change in the circadian rhythm [10], and a gradual behavioral shift toward later bedtimes [11-13]. The shift toward later bedtimes is more noticeable on school nights compared to weekends, with later sleep times making it more difficult for adolescents to wake up when they need to [12,13]. Rather than later bedtimes, adolescents have been shown to sleep better when sticking to a regular bedtime routine with consistent sleep and wake times [14].

Sleep hygiene, which can be defined as behavioral practices that promote good sleep, plays a key role in adolescents' sleep quality. Differences in sleep hygiene behavior may partly mediate the relationship between sociodemographic factors and sleep health [15]. Across the wealth of sleep hygiene literature, 3 sleep hygiene behaviors are reported as having a key impact on sleep: avoiding behavioral and cognitive arousal before bedtime, spending less time in bed, and setting a regular wake time [16].

Diet may also play a role in adolescents' sleep [17,18]. The UK National Diet and Nutrition Survey from 2016 to 2019 found that those aged 11 to 18 years had the highest consumption of sugar-sweetened soft drinks and mean saturated fat intake [19]. Diets high in fat and sugar have been associated with shorter sleep duration [20] and significantly higher prevalence of sleep disturbance in adolescents [21] compared to a healthier diet. A high caffeine intake has been associated with sleep problems, including later bedtimes, shorter sleep duration [22,23], difficulty sleeping, and morning tiredness [24]. Dietary influences on sleep may disproportionately affect adolescents from lower-income households. A descriptive analysis of UK survey data from 2005, 2009, and 2014 found that adolescents aged 11 to 15 years from families with lower levels of affluence reported fewer healthy eating behaviors, higher sugary drink consumption, and lower intake of fruits and vegetables [25].

Previous research has indicated that adolescents from more socioeconomically deprived neighborhoods typically experience poorer sleep quality, a shorter sleep duration, and increased daytime sleepiness [26]. They also have lower sleep efficiency, spending more time awake at night [27]. Possible causes may include more chaotic, noisy [28,29], or crowded living environments with lower neighborhood safety, higher levels of

crime, or concerns about violence [27,30] when compared to adolescents from higher-income homes [9,31]. Therefore, adolescents from areas of higher socioeconomic deprivation are more likely to experience poorer-quality sleep.

There is a bidirectional relationship between insomnia and mental health difficulties [32-35]. Anxiety may perpetuate and worsen insomnia, with those who experience emotional dysregulation in childhood being more likely to experience anxiety disorders in adolescence [36-38]. As poor sleep during adolescence may be a precursor to mental health problems, targeting poor sleep behaviors early may prevent the development of mental health difficulties, such as anxiety or depression, at a later stage [32].

However, engaging with adolescents at an early stage can be a challenge. There is evidence suggesting that adolescents are less likely to engage with mental health support services due to perceived stigma, embarrassment [39], or a preference for less formal advice and support [40-44]. Instead, smartphones can be a key route to engaging with adolescents; a range of apps to support adolescents with their sleep and well-being have been designed. Delivering Online Zzz's With Empirical Support (DOZE), a 4-week intervention, was developed in co-creation with Canadian adolescents [45]. This intervention includes the ability to track sleep time, average time to fall asleep, and nighttime awakening. A "tips" section provides education to users on how best to make changes to their sleep, such as winding down before bed [45]. Similarly, Sleep Ninja was developed in partnership with Australian adolescents through a series of focus groups focusing on the app design [46,47]. The app features 6 educational sessions, a sleep-tracking function, sleep tips, and reminders to wind down in the evening [46]. Finally, the Sleepio app uses cognitive behavioral therapy for insomnia (CBTi) in 6 web-based, 20-minute sessions [48]. Sleepio has shown promising results in a small population of adolescents (N=39) with mental health problems [48]. However, no apps to date have been co-created with adolescents from the United Kingdom, and none have been co-created with those from disadvantaged backgrounds.

The apps described previously are all intended to provide in-depth support through extended use (4-6 sessions). However, there is some evidence that, for many adults and adolescents, a single session of sleep hygiene advice may be sufficient to improve sleep [49]. Our study aim was to design a highly accessible app suitable for adolescents with lower literacy levels that did not require extensive engagement for users to benefit from sleep hygiene advice and support. The purpose of this app was to serve as an accessible first step of a stepped program of support [50], which would guide adolescents with more persistent and serious sleep problems toward the in-depth support provided by existing apps (specifically, Sleep Healthy Using the Internet [SHUTi] [51,52]).

The Goal of This Study

This paper details the co-creation and optimization of a novel, brief, stepped-care intervention to support adolescents with

sleep problems (Table 1) from its initial design phases to co-creation with adolescents from a range of collaborative youth organizations, charities, and educational partners. After outlining the development process, the feasibility of the app and feedback

in light of real-world testing are explored. The process was iterative, and contributor-suggested amendments were used to make changes to the intervention as the co-creation process progressed.

Table 1. The 2 stages of Sleep Well.

Intervention stage and app	Details	Time when it was offered
Stage 1		
Sleep Solved	A web-based application co-created with adolescents to provide brief (six 5- to 10-min sections) and accessible advice and behavior change support to help improve their sleep. The short Sleep Solved intervention may be sufficient as an intervention for less serious sleep problems.	At sign-up (for iOS and Android users)
Phone Downtime	An Android app created by a University of Bristol PhD student before this study. Phone Downtime allows users to set their desired wake and sleep times to support their sleep schedule while using the Sleep Solved app.	At sign-up (for Android users only)
Stage 2		
SHUTi ^a	A six 20-min-session program to treat insomnia based on internet-delivered cognitive behavioral therapy was adapted from a version of SHUTi shown to be effective for adults in the United States [51,52]. The content was coadapted in this study to better suit adolescents in the United Kingdom.	Bite Back [53] and SHUTi [51] are offered if adolescents score highly on measures of anxiety and depression (RCADS ^b) or insomnia (Insomnia Severity Index) after 6 weeks of access to Sleep Solved.
Bite Back	Developed by researchers in Australia, Bite Back [53] is a web-based 6-session positive psychology program designed to improve well-being and resilience in adolescents.	Bite Back [53] and SHUTi [51] are offered if adolescents score highly on measures of anxiety and depression (RCADS) or insomnia (Insomnia Severity Index) after 6 weeks of access to Sleep Solved.

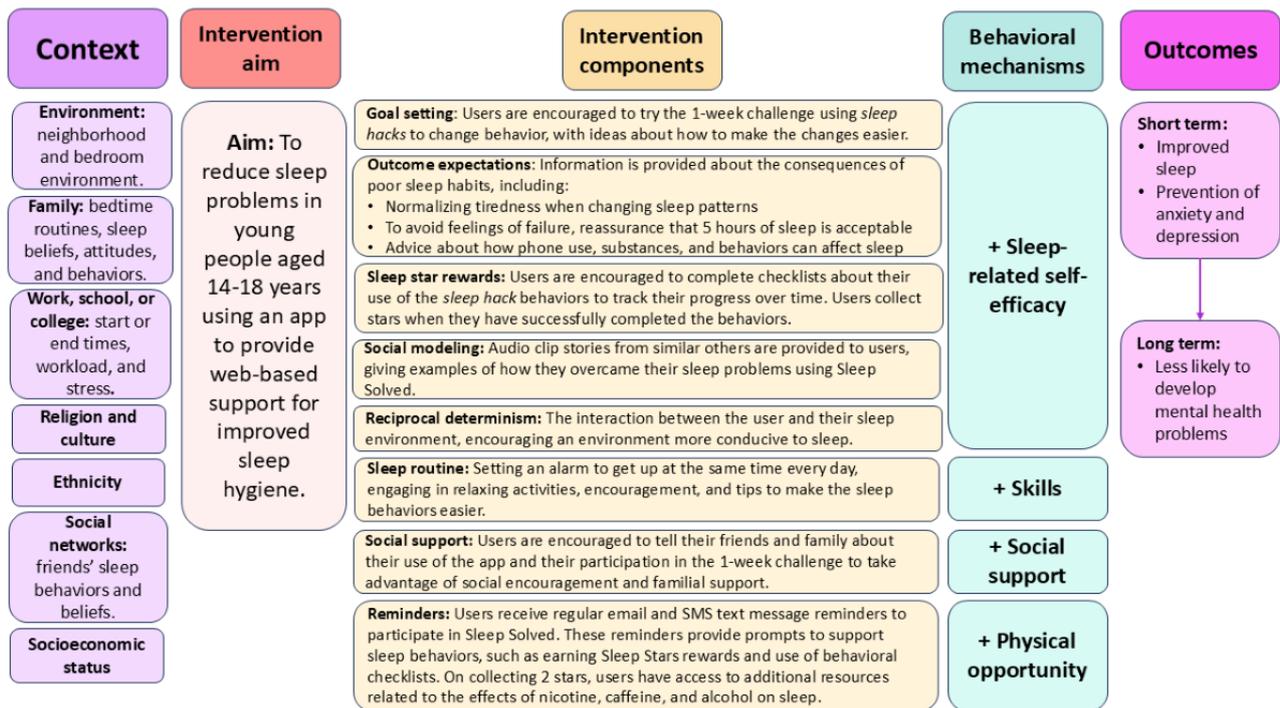

^aSHUTi: Sleep Healthy Using the Internet.

^bRCADS: Revised Child Anxiety and Depression Scale.

The person-based approach was used in the development of the Sleep Solved intervention to provide adolescents with a theoretically informed app that was engaging, clear, and appropriate for their needs [54,55]. This involved initially drawing on clinical theory and evidence to specify the core required intervention elements to support behaviors that would help adolescents sleep better, summarized in a logic model (Figure 1). The social cognitive theory by Bandura [56] was used to underpin the behavioral elements of Sleep Solved, whereas the social-ecological model of sleep health [57] was

chosen to represent the multifactorial nature of various moderators on sleep and sleep-related interventions at the individual, social, and societal levels, such as the influence of social networks or family [57]. The logic model features 8 intervention components that make up the key content of the app. How these components relate to social cognitive theory, moderators from the social-ecological model of sleep, and the underpinning behavioral mechanisms is outlined in the following paragraphs.

Figure 1. The Sleep Solved logic model.

We drew on theory and evidence to create guiding principles (Table 2) that were intended to encourage engagement with Sleep Solved. The coproduction work described in this section was then used to co-design the app content and format. Details

regarding the virtual co-design of the design aspects of the intervention have been published separately (A Duffy, unpublished data, May 2022).

Table 2. Guiding principles for Sleep Solved.

User characteristics	Design objective	Features to address the objective
<ul style="list-style-type: none"> Very low tolerance for engaging with advice that is obvious, dull, not credible, or irrelevant to their sleep context Low patience for engaging with apps that are dull, uninteresting, unfriendly, patronizing, or misleading or have a confusing user experience and intrusive advertising 	<ul style="list-style-type: none"> To ensure that all advice is immediately engaging and viewed as interesting, trustworthy, and relevant To ensure that the app itself is designed to be engaging, friendly, entertaining, and motivating and hold the user's interest and attention, with no advertising 	<ul style="list-style-type: none"> Present novel content in the most concise and engaging format possible Simple, short sentences Good functionality; consistent navigation, theme, gestural design, and user flow Optimized for mobile use Provide evidence of credibility and trustworthiness (eg, team expertise and scientific validity of the advice) Focus on core principles of sleep relevant to a wide range of situations Personalized using relatable stories from other adolescents with sleep problems Gamification—users can collect stars to encourage engagement with the app
<ul style="list-style-type: none"> Great diversity in needs and preferences for how advice is presented, in accordance with users' social identity and levels of (health) literacy 	<ul style="list-style-type: none"> To ensure that the advice is appropriate for people with different identities, social contexts, and learning preferences; variety of text, images, and audio clips to reflect different learning styles Simple language, short sentences, and use of images or icons may be more engaging Consistent navigation structure; similar graphics, gestural designs, and theme throughout the app for consistency and ease of use Sleep tips throughout 	<ul style="list-style-type: none"> Ensure that role models and stories are relevant to diverse contexts and identities Present advice in a variety of accessible formats Provide links to a wider range of additional resources or formats (eg, relaxing music, mindfulness, and in-depth resources) Include a summary of useful hints and tips to improve sleep
<ul style="list-style-type: none"> The importance of choice or free will as opposed to paternalistic advice 	<ul style="list-style-type: none"> Choice architecture—framing advice as an option; emphasizing the benefits of the desired behavior vs the consequences of the undesired behavior 	<ul style="list-style-type: none"> Avoid telling adolescents what they should do (eg, avoid giving a prescribed amount of sleep that adolescents should be getting) to reduce feelings of anxiety and inadequacy in the target population (aged 14–18 years) Present facts, actions, and consequences Frequently asked question pop-ups allowing for more information if required
<ul style="list-style-type: none"> A preference for web-, app-, or technology-based interactions over face-to-face 	<ul style="list-style-type: none"> App use involves interactions with mobile technology rather than face-to-face interactions 	<ul style="list-style-type: none"> Adolescents using apps may prefer app- and technology-based interactions

Advising adolescents to improve their sleep using a smartphone device known to disrupt sleep may seem counterintuitive, particularly as the nighttime use of smartphones and social media has been linked to disturbed sleep and poor academic achievement [58-61]. However, apps are a key method for engaging adolescents; 81% of adolescents use the internet to seek health-related information [62], whereas digital health interventions to support people with their sleep are flourishing [63]. To avoid too much phone exposure too close to bedtime, users were encouraged to use the app to decide on their preferred sleep behaviors and environment ahead of time, earlier in the evening. Later sections of Sleep Solved remind users that looking at a bright phone screen too close to bedtime could affect their ability to get to sleep [64].

Methods

Phase 1: Initial Intervention Development

Sleep Solved Ideas and Concept Generation

To explore adolescents' views and experiences of sleep and well-being, a web-based focus group was conducted with the Bristol Young People's Advisory Group (YPAG). Patient and public involvement (PPI) contributors were presented with initial ideas for key intervention concepts (eg, a focus on how "science-based" research could help them sleep better and why spending less time in bed could help). Contributors were asked what they thought of these concepts and were invited to share additional ideas for supporting their sleep and well-being.

Sleep Solved Ideas: Name and Design

To involve PPI contributors who preferred to provide written feedback, a Qualtrics survey (Qualtrics) was used to elicit feedback regarding the look and feel of Sleep Solved. PPI contributors were asked for feedback via closed- and open-ended

questions and to share ideas about the app's name, logo, color palette, and theme as well as the study's recruitment materials:

- Potential app names: preferred name from 7 options—*Sleep Solved*, *Snooze It*, *Science2Sleep*, *Slumber Master*, *Rest Pro*, *Sleep Tracker*, and *Awake to Sleep*
- Color palettes: three options—(1) crimson red, roundel blue, international orange, and black; (2) black, opaline green, deep cream, and pale roundel blue; and (3) Oxford blue, light orange, deep cream, and ruby
- Logos: from a range of 11 possible logo designs
- Design themes: a total of 6 options from other youth-oriented media

New Theme Designs for Sleep Solved

On the basis of the feedback from the first Qualtrics survey, our design partners at PIP Creative designed 2 tailored themes to give the Sleep Solved app a consistent look and feel. PPI contributors were invited via a second Qualtrics survey to rank how much they liked the themes (0-100) and share their thoughts and suggestions regarding the visual design.

New Logo Designs for Sleep Solved

On the basis of the feedback from the first Qualtrics survey, 4 viable app logos were developed by PIP Creative. These logos were presented to PPI contributors via a third Qualtrics survey, and contributors were requested to rank their preferred logos. Comments about the logos were encouraged using open-ended questions.

Sleep Well Design Feedback

To determine the preferred timing of offering the 3 components of Sleep Well (Phone Downtime, Sleep Solved, and SHUTi [51]), 3 different pathway options were presented to adolescents in a fourth Qualtrics survey. For each pathway, PPI contributors were invited to share how likely they were to take part in the Sleep Well study for 6 weeks, giving a rating from 0 (“not at all”) to 100 (“a lot”) and their reasons why.

PPI Contributors

Adolescents aged 14 to 18 years were recruited to co-design the intervention through partnerships with national educational groups and charities: the Association of Colleges, the E-ACT multiacademy trust, the McPin Foundation, the Bristol YPAG, and Off The Record Bristol. We invited contributors aged between 14 and 18 years who attend secondary school or college and had an Android smartphone.

PPI contributors were recruited from across the United Kingdom. A poster advertising the research was shared within schools and colleges. For recruitment from charities, emails were sent to adolescents within the target age range inviting them to contribute to PPI activities to improve a new sleep app.

PPI contributors could express their interest by scanning a QR code from the poster or following a link within each email. Prospective PPI contributors answered demographic Qualtrics survey questions (age, gender, and ethnicity), how often they had sleep problems, and their preferred method of engagement (one-to-one meeting in person or web-based discussion, web-based group discussions, or written comments). The levels of deprivation were estimated using contributors' postcodes against the 2019 English indices of deprivation data. To ensure that adolescents from ethnically diverse and disadvantaged backgrounds were well represented, we prioritized input from volunteers from ethnic minority groups and more disadvantaged areas [65]. Over the course of a year, PPI contributors engaged in a variety of coproduction activities (Table 2), including identifying behaviors for the app to address; choosing the preferred name, appearance, and other key design elements; providing feedback on how prototype versions of the app could be improved; and trying out the app in real-life use and providing further feedback. PPI contributors shared their views according to their preferred method of contribution (Table 3). PPI contributions and activities are listed in Multimedia Appendix 1.

Table 3. Potential patient and public involvement contributors—preferred method of contribution (N=356).

Expressions of interest (January 2022-March 2022)—“Please select any of the ways you would be happy to talk to us”	Contributors, n (%)
Only written comments	219 (61.5)
Written comments	292 (82)
Web-based group discussion with other adolescents	65 (18.3)
One-to-one web-based meeting (eg, via Zoom)	63 (17.7)

Phase 2: Intervention Optimization

Web-Based Think-Aloud Interviews

We invited contributors to provide detailed feedback on every aspect of the prototype app as it was developed using think-aloud interviews as an opportunity to identify barriers to engagement and feasibility and suggest improvements. PPI contributors met with a researcher via Microsoft Teams (Microsoft Corp) or Zoom (Zoom Video Communications) and provided verbal consent to take part in a one-to-one think-aloud interview. Contributors were given a web address and

instructions on how to view Sleep Solved as it would appear on a mobile device. PPI contributors were encouraged to verbalize their immediate thoughts and feelings when interacting with Sleep Solved to provide as much information as possible about their impressions of the app and overall user experience [54]. Contributors were prompted for further information if required—such as “What are you thinking now?” or “What made you choose that option?”—and were encouraged to suggest ways of improving it (see Multimedia Appendix 2 for the topic guide). Interviews were audio recorded and transcribed verbatim. PPI contributors received a £22 (US \$28.56) digital voucher for each hour of participation to thank them for their

input after taking part in a think-aloud interview. All contributors who provided feedback via a Qualtrics survey were entered into a prize draw to receive a £50 (US \$64.92) digital voucher. A versatile multiretailer voucher was carefully chosen by the research team in light of the cost-of-living crisis so that it could be used by contributors to purchase essential items such as food and toiletries. From PPI activity workshops 1 and 2, a total of 4 participants (n=2, 50% male; n=1, 25% female; and n=1, 25% genderfluid) also took part in the think-aloud sessions.

All feedback and suggestions from PPI contributors' think-aloud interviews were collated in a table of changes ([Multimedia Appendix 3](#)). This was used directly as a basis for informing intervention changes rather than being subjected to analysis methods. Simple changes (such as clarifying text or rewriting a section that a participant found difficult to understand) would be made directly. Substantial changes were only made if they met the following criteria: (1) the proposed change was suggested by several PPI contributors, (2) the proposed change was likely to have an impact on users' behavior, and (3) the proposed change aligned with the guiding principles for the intervention [54].

Once changes had been made, we obtained additional feedback from participants regarding the updated version of Sleep Solved in further think-aloud interviews [66,67]. The table of changes process continued until no new important suggested changes were raised in feedback from think-aloud interviews [66].

Sleep Solved Real-Life Testing: Think-Aloud Interviews

A selection of our PPI contributors was invited to trial the app for a period of 1 week after taking part in an initial think-aloud interview. After their trial, they were invited for a second think-aloud interview. PPI contributors were encouraged to follow the advice provided and keep a sleep diary for their personal reference during the follow-up interview ([Multimedia Appendix 4](#)).

Sleep Solved Real-Life Testing: Web-Based Workshops

The next stage of optimizing Sleep Solved started as soon as the "Must Have" changes were completed. Workshop attendees

were contributors from the McPin Foundation's Young People's Network. All contributors were invited to use Sleep Solved for 1 week. Contributors with Android smartphones were also invited to use Phone Downtime alongside Sleep Solved. All were given a sleep diary checklist to complete and provide feedback about their experiences ([Multimedia Appendix 5](#)). A group workshop covered contributors' experiences of engaging with every aspect of the app. Contributors were asked about elements of Sleep Solved that they liked or found useful and those that they did not like or found unhelpful or that did not work as expected. Questions explored contributors' own sleep experiences and factors that helped them sleep well. The workshops were documented by group facilitators, with any suggested changes noted in the table of changes. A number of users created and recorded personal accounts of how they had benefited for other app users to listen to.

Ethical Considerations

Ethics approval for the think-aloud interviews was granted by the University of Bristol School of Psychological Science Student Research Ethics Committee (ethics approval code 13084). PPI contributors provided verbal informed consent to take part in a one-to-one think-aloud interview. All data were anonymized, and all identifying information was removed. In compensation for their time, PPI contributors were offered a multiretailer digital voucher of £22 (US \$28.56) for each hour of participation after taking part in a think-aloud interview. All contributors who provided feedback via a Qualtrics survey were entered into a prize draw to receive a £50 (US \$64.92) digital voucher." (I've included the ethics approval statement that was there previously.)

Results

Overview

An overview of the Sleep Solved content is provided in [Textbox 1](#).

Textbox 1. An overview of the Sleep Solved intervention content.

How can Sleep Solved help me sleep better?

- Introduction to Sleep Solved: types of sleep problems, how sleeping better will help the user, and who made the app
- Explanation of the Phone Downtime app and link to download in Google Play

How can less time in bed help me sleep better?

- 3 kinds of sleep (deep, dreaming, and light)
- 5 to 6 hours and deep and dreaming sleep is what the brain needs. A lot of time in bed leads to additional light sleep—which the brain does not need as much.
- If the user does not sleep well one night, they will sleep better another night.
- Pop-up explaining the “point” of light sleep
- Explanation of why spending time in bed during the day can make it harder to fall asleep at night

Why could sleeping in make me feel bad?

- Explanation of the purpose of cortisol and its role in the sleep-wake cycle
- Graphs to evidence how irregular wake-up times impact cortisol release and how this, in turn, can impact mood
- Pop-up with tips to avoid napping impacting sleep (≤ 20 min, before 3 PM, and with the curtains open) and an explanation of why

How can I stop worrying in bed?

- Examples of common bedtime worries and explanation that this trains the brain to worry in bed
- Getting up after 20 min if unable to sleep and going back to bed when they feel sleepy
- Tips for calming activities to engage in instead
- Reiteration that, if they do not sleep well one night, they will sleep better another night
- Pop-up—tips on calming the mind before bed
- List of tips for calming the mind in bed

What to do to sleep better?

- The 1-week challenge; users are encouraged to try the 3 “sleep hacks” (sleep hygiene behaviors) for 1 week—getting up at the same time every day, helping their brain calm down before bed, and getting up after 20 min if unable to sleep.
- Pop-ups take the users to previous pages to remind them of the science behind the advice.
- Tips on how to make the “sleep hacks” easier—choosing what they want to do before they go to bed, telling friends and family about the challenge for help and support, and putting their phone out of reach so they will be unable to check it
- Normalization of tiredness and reiteration of napping rules
- Voice recordings (including transcripts) of adolescents explaining how they made the hacks work for them
- Link to personal reminders and diary
- Link to Sleep Healthy Using the Internet

Track my progress and earn stars (added as a result of patient and public involvement feedback)

- Optional reward system—switch to turn weekly challenge on or off
- Each day, the user selects whether they used the sleep hacks, partially used the sleep hacks, or did not use the sleep hacks the night before.
- If they used or partially used the sleep hacks, they earn a blue star.
- If the user collects 5 blue stars in a week, they earn a gold star.

What other things could stop me sleeping well?

- Problem and solution pairs explaining the science behind how various lifestyle factors (eg, caffeine, vaping, and social media) can impact sleep and offering harm reduction solutions

Links to help the brain calm down

- Links to calming sounds, mindfulness and meditation resources

User journey

- The user is presented with a splash screen with an animated Sleep Solved logo.
- Each key element is unlocked in a linear sequence once all pages (besides the optional pop-ups) of the previous element have been viewed.
- Element G—“What other things could stop me sleeping well?”—is unlocked 3 weeks after the user downloads Sleep Solved. Early access to this section is unlocked if the user earns 2 gold stars (see element F).
- The user can navigate back to the main menu at any stage using the hamburger menu.

Phase 1: Intervention Development

Sleep Solved Ideas and Concept Generation

PPI contributors from the Bristol YPAG felt that the 3 ideas presented to them were novel. Many were keen for the app to be “soothing” and “simple,” with “noises that help you get to sleep” when feeling worried. These suggestions were implemented through a calming choice of colors; simple gestural app navigation; and the inclusion of “Links to help your brain calm down,” such as music and meditation sessions. The “How can I stop worrying in bed?” section gave ideas on calming activities.

Contributors expressed an interest in how phone use, food, and drink can affect sleep. These questions were addressed in the “What other things could stop me sleeping well?” section, which presents problems (how food, drink, and nicotine can affect sleep) with solutions (what users can do instead). How phone use can affect sleep at night was covered in the “How long should I try to get to sleep?” section, where users are advised to “avoid bright lights such as phone screens. Bright light can make your brain think it’s time to wake up!”

Sleep Solved Ideas: Name and Design

Results from the first Qualtrics survey helped create the overall look and feel of Sleep Solved. PPI contributors gave feedback on five different elements:

1. Potential app names: of the 7 options, “Sleep Solved” was chosen as the preferred name.
2. Color palettes: a black, opaline green, deep cream, and pale roundel blue color scheme was selected, with an average “like” score of 71% (SD 20.72%). Contributors shared that these colors were “simple,” evoking thoughts of “the sea” and “spring awakening.”

3. Logos: a bold sans-serif logo in all capital letters was chosen, with an average “like” score of 69% (SD 10.63%). Contributors liked the “bright colours” and readability.
4. Design themes: dark navy was chosen, with cartoonlike graphics in lime green, blue, purple, and orange. Praise was given for the “colourful,” “clear” design, which was “easy to find.”
5. Sleep Well recruitment materials: changes were made to the poster to make the fonts easier to read and the features of the app clearer.

New Theme Designs for Sleep Solved

On the basis of the feedback from the first Qualtrics survey, 2 potential app themes were designed by PIP Creative. Theme 1 was chosen in the second Qualtrics survey with an average “like” score of 68%. Contributors liked the “sleepy colour theme” and dark colors, which “connotate sleep”; “contrasting colours are cool, it’s very appealing.” They preferred brightly colored icons as these “draw in my attention.” Less praise was given to theme 2, a softer theme with rounded dark purple and navy iconography: “it’s not as vibrant and interesting” and “too dull, doesn’t draw my attention.”

New Logo Designs for Sleep Solved

In total, 4 logos were presented to PPI contributors in the third Qualtrics survey. PPI contributors found a colorful, bold logo made of interconnecting shapes “difficult to read...because of the colour scheme.” A bold sans-serif logo was chosen in white and yellow. The bright colors featured in a geometric fan shape next to the logo, making it “better [for] being colourful” but still easy to read.

Sleep Well Design Feedback

The results of the fourth Qualtrics survey are shown in [Tables 4 and 5](#).

Table 4. An overview of the Sleep Solved intervention content.

Route	How likely are you to take part for 6 weeks? (0-100), mean (SD)
1—Phone Downtime for 6 weeks, then access to Sleep Solved for 6 weeks, then access to SHUTi ^a	64.3 (26.1)
2—Phone Downtime and Sleep Solved for 6 weeks, then access to SHUTi	63.3 (25.4)

^aSHUTi: Sleep Healthy Using the Internet.

Table 5. An overview of patient and public involvement contributors' preferred Sleep Solved intervention content (n=23).

	First place		Second place		Third place	
	Values, n (%)	Values, mean (SD)	Values, n (%)	Values, mean (SD)	Values, n (%)	Values, mean (SD)
Route 1	7 (30)	2.09 (0.83)	7 (30)	2.09 (0.83)	9 (39)	2.09 (0.83)
Route 2	7 (30)	1.70 (0.55)	14 (60)	1.70 (0.55)	1 (4)	1.70 (0.55)
Route 3	9 (39)	2.22 (0.93)	2 (8)	2.22 (0.93)	13 (56)	2.22 (0.93)

When asked to rank their preferred options for phasing the steps of the intervention, there was no clear leader. Route 3 was ranked as contributors' first choice 9 times but was ranked in last place by 13 PPI contributors. As route 2 was ranked second by most people (14/23, 60%), this was chosen as a compromise as very few (2/23, 8%) ranked this as their last-placed option compared to route 3 (13/23, 56%). PPI contributors shared that they felt that route 2 was the most time-efficient, logical option:

I think [Route 2 is] the best way for people to be able to see how the app is helping their sleep schedule which encourages them to keep using it...then they can determine whether they need the SHUTi app or not. [PPI contributor; female; aged 17 years; White British ethnicity]

Phone Downtime and Sleep Solved don't require much effort so they can be both done at the same time. [PPI contributor; male; aged 14 years; White British ethnicity]

[Route 2] is less time consuming. [PPI contributor; nonbinary person; aged 18 years; White British ethnicity]

Phase 2: Intervention Optimization

Web-Based Think-Aloud Interviews

Results from the think-aloud interviews were largely positive, with praise for the clear, easily understood content and ease of functionality:

I like the way it's broken up into sections. [JK02]

I think one of my favourite parts about it is the explanations behind a lot of it. I like knowing kind of why I'm doing something rather than just saying like this person says it works. [JK06]

"Science based"—makes it more trustworthy, I'm hopeful. [JK05]

It's nice to know, there's various ways that you can improve your sleep, there's not just one way, and that it's okay if one doesn't work for you because there's always another and that you can start off easy and then like, build up. [JK03]

Nevertheless, the interviews identified numerous small but important ways in which the intervention could be improved. A summary of the think-aloud feedback and the changes implemented can be found in [Table 6](#). Examples from the table of changes can be found in [Multimedia Appendix 2](#). Less positive responses focused on areas in which users found information difficult to understand as it was originally presented or fonts were hard to read.

Table 6. Summary of changes to Sleep Solved as a result of think-aloud interview feedback.

Section of Sleep Solved and problem identified	Changes made
Overall design	
<ul style="list-style-type: none"> “The contrast of the light blue text to the white background on highlighted words makes it difficult to read—I have dyslexia. Prefer the white text on a dark background.” [JK04] “The terms ‘anxiety’ and ‘depression’ could be seen as quite negative or serious terms.” [GT01] 	<ul style="list-style-type: none"> Light blue font was changed to darker blue font throughout to be easier to read. We retained the use of bold and italic for emphasis. References to anxiety or depression were changed to “worried” or “low mood” throughout to reduce any negative connotations.
How can Sleep Solved help me sleep better?	
<ul style="list-style-type: none"> “Who made this app?”: “Might be good to include more information on why these people are interested in contributing to the app.” [JK02] “This section is unnecessary; I don’t care who made the app—I trust if you say it’s backed by science.” [MJ02] “Get good marks—isn’t clear that you’re talking about school. ‘Do better in school’ would be better.” [MJ01] “Improve your grades would be better.” [MJ02] 	<ul style="list-style-type: none"> The “Who made this app” page was changed to an optional popout: “Who made this app? Tap here.” Photos introducing each team member were amended to a brief paragraph of text recognizing the valuable contributions of hundreds of adolescents and providing links to partner charities. References to improving grades were removed as it was felt that this may not be an achievable goal or may not be a priority for all the adolescents using the app.
Why could sleeping in make me feel bad?	
<ul style="list-style-type: none"> “The order of the information is hard to understand.” [MJ01] “Is it OK to nap when I’m tired?”: “Why do you have to nap before 3pm?” [GS01 and JK06] “Why 20 minutes?” [JK06] 	<ul style="list-style-type: none"> The text on the final card, “Getting up at the same time every day trains your brain to release cortisol at the right time,” was moved to the first slider. The “if you sleep late your cortisol levels peak late” text was combined with “this may make you feel tired and sleepy when you have to get up earlier” to improve understanding. Explanatory text was added to clarify that a 20-min nap would prevent users from sleeping too long or too deeply. Furthermore, we provided evidence of the science behind this recommendation—that, if users sleep late in the day, their brain will release cortisol on waking, making them feel more awake and making it more difficult to sleep later that night.
How can I stop worrying in bed?	
<ul style="list-style-type: none"> “My brain never really stops thinking, maybe tell us how to stop thinking.” [JK07] 	<ul style="list-style-type: none"> Text changed from “thinking” to “worrying”: “Lying awake at night, you might start to worry about: how tired you will feel in the morning, all the other worrying things in your life. This trains your brain to worry in bed instead of sleeping!”
What to do to sleep better?	
<ul style="list-style-type: none"> “The title, ‘What to do to sleep better’ does not make it clear that this is the one-week challenge.” [MJ01] 	<ul style="list-style-type: none"> A front page was added stating the following: “This is your one-week challenge! Try these sleep hacks for 1 week!”
Track my progress and earn stars	
<ul style="list-style-type: none"> Caffeine—problem: <ul style="list-style-type: none"> “An exhaustive list of everything that contains caffeine would be helpful. This could be presented as a mind-map to make it more visually appealing.” [MJ06] Caffeine—graph: <ul style="list-style-type: none"> “Would be good to indicate the 10hr period somewhere on the graph.” [MJ06] “The sun/moon/cloud symbols don’t really add anything—they’re confusing.” [MJ06] Food—solution: <ul style="list-style-type: none"> “It would be good to have a more extensive list of the things that you can eat.” [MJ06] 	<ul style="list-style-type: none"> A list of all drinks and foods containing caffeine was added as a pop-up section. Changes were made to a graph depicting caffeine levels in the body over time. Consumption of 2 caffeinated drinks was shown over the course of a day, and more accurate timings were added to represent how caffeine levels in the body change over time. More foods were added to the list.

Sleep Solved Real-Life Testing: Think-Aloud Interviews

hack use during their 1-week trial of the Sleep Solved app before their second think-aloud interview and the perceived strengths and limitations of each hack.

^aGetting up at the same time every day.

^bNo limitations suggested.

^cCalming your brain.

^dLess time in bed.

^eAN: avoiding napping.

Set an Alarm to Get Up at the Same Time Every Day (Hack 1)

PPI contributors reported great variability in their sleep and wake times before trying hack 1, largely due to varying class schedules. Many of those involved reported a notable change in their sleep schedules after trying this hack: falling asleep and rising earlier. However, hack 1 was not feasible for PPI contributors who had to work late-night shifts and, therefore, had a variable sleep schedule. Within the socioecological model, this would correspond to the work, school, and college moderator, which recognizes the impact of variable school, college, and work start times on sleep, particularly in children and adolescents [57,68]. Several PPI contributors described needing motivation to continue the sleep hack on the weekends

or during the holidays. This was particularly relevant when taking examinations as they were more likely to try to “catch-up” on sleep on the weekends and were more reluctant to get up at the same time as on weekdays.

Help Your Brain Calm Down Before You Go to Bed: Do Not Do Anything Exciting or Stressful (Hack 2)

Relaxation strategies were perceived as positive by most PPI contributors, finding that this advice helped them reduce their anxious thoughts and fall asleep faster. Calming activities described by contributors included reading, watching television, listening to relaxing music, and ensuring that they stopped homework or revision activities with enough time to “wind down” before bed. Others explained how stopping the use of social media apps before bed had really helped improve their

sleep, feeling more “refreshed” on waking. However, a minority found it difficult not to use their phones in the hour before bed, and they continued to message their friends, use social media, and watch videos. In the socioecological model and our logic model, this is represented by the social networks moderator—the friends, acquaintances, and networks that contribute to roles, expectations, beliefs, and behaviors regarding sleep [57].

If You Do Not Get to Sleep After 20 Minutes, Get Up and Do Something Calm Until You Are Sleepy (Hack 3)

Despite initial worries that following this hack would be “impossible,” contributors reported finding it easier to fall asleep on returning to bed instead of their usual practice of using their phone or lying awake unable to sleep. Although perceived as initially challenging, after a few days of practice, many could follow the hack, and their sleep latency improved over time. For a minority, this was their favorite sleep hack, and one user described counting to their 20-minute target as so restful that they fell asleep. PPI contributors reported that spending less time in bed helped reduce the overthinking and associated anxiety that they experienced. However, one contributor had concerns that getting up and moving around may disturb other people in their household.

Overall Acceptability

Sleep Solved was deemed acceptable by the PPI contributors. They were appreciative of the range of text formats, simple language, and the use of bullet points to break up information, as well as the use of bright imagery. They described the interactive “slider” navigation elements as “engaging,” “fun,” and “encouraging.” Users praised the science-based content, which provided them with simple yet clear explanations of the reasoning behind the (seemingly contradictory) behaviors to sleep better, such as spending less time in bed. The use of choice architecture (the framing of the advice given as an option, consistent with the guiding principles) was well received. Contributors were given the benefits of the desired behavior compared to the consequences of undesired behaviors. By not telling users which behavior they “should” be doing, many were keen to follow the behavior when the benefits and reasoning for the advice were well explained:

I think it explaining that little bit more makes you feel more kind of like it's a good thing, because I'm more aware of what's going on rather than just this is what I'm being told it's going on in my brain, but it makes you feel more kind of knowledgeable in it. It feels very personalized because I can kind of relate to that, that is exactly...how I feel. [PPI contributor C4; female; aged 18 years; sleep problems 2-3 times per week]

Being given clear reasons for following the suggested behaviors in a particular way was similarly well received by users:

[The science-based approach] it's informative in a non-patronising way. If you're patronised, then you're not going to listen...Like if your parents tell you to do something, they're describing [it to] you, but if you know why you should do it, you're more likely to be doing it. [PPI contributor C1; female; aged 17 years; sleep problems 2-3 times per week]

It's a bit humorous as well, which is quite interesting. Rather than...just telling you what to do and what not to do. [PPI contributor C2; female; aged 16 years; sleep problems 2-3 times per week]

Web-Based Workshop 1: Sleep Solved Real-Life Testing

Feedback from these users was positive. PPI contributors considered the bullet points, visual aids, and graphs to be “helpful for understanding.”

Set an Alarm to Get Up at the Same Time Every Day (Hack 1)

This hack was cited as being harder to stick with, particularly on the weekends or during holidays. PPI contributors felt that not having to get up for school or college made their sleep “less disciplined” (M1) as on these days they were able to procrastinate, putting off getting up and out of bed for longer (M2 and M3). However, one contributor liked the fact that, by charging their phone at the other side of the room, they could not be tempted to check on it; they felt that this advice was very helpful (M2).

Help Your Brain Calm Down Before You Go to Bed: Do Not Do Anything Exciting or Stressful (Hack 2)

All PPI contributors liked the concept of taking part in calming activities before bed, sharing that they felt “more refreshed when I wake up” (M3). Stopping exciting or stressful activities such as homework, revising for examinations (M3), or watching Netflix or TikTok before bed (M7) was “really helpful” (M7) and helped them sleep (M2). One PPI contributor shared that this was their examination season, so they were keen to get as much sleep as possible (M1).

If You Do Not Get to Sleep After 20 Minutes, Get Up and Do Something Calm Until You Are Sleepy (Hack 3)

Although this sleep hack was the favorite of some PPI contributors (M7), others worried that they may disturb other people in their family when getting out of bed or moving around (M2), which, when considering the socioecological model, recognizes the impact of moderators such as family, socioeconomic status, and environment on sleep [57]. For some, counting the 20 minutes until it was time to sleep was like “counting sheep,” and they found that they fell asleep anyway (M3).

Web-Based Workshop 2: Phone Downtime Testing

Overview

PPI contributors also tested the Phone Downtime app for 1 week, which was an app that was included for Android users of Sleep Solved. Users were encouraged to set the time when they usually went to sleep and woke up. The Phone Downtime app enabled users to tell when they were using their phone during the time they planned to be asleep (during a time window preset by the user).

PPI contributors liked being able to choose their own goals and sleep times and the fact that working days were flexible to accommodate part-time jobs on different days. A new awareness of for just how long they were using their phones at night was welcome as it helped them better schedule their bedtime.

The Need for Interaction

A large proportion of PPI contributors were keen on the addition of a progress chart, journal, or sleep diary. Many expressed a wish to track and measure their sleep behavior changes over time. In its initial prototype stage, adolescents did not feel that there was much to attract them to Sleep Solved once they had completed all the sections. They suggested adding an interactive reward system (eg, where they could collect points and monitor their progress over time).

As a result of contributor feedback, an optional reward system was added to Sleep Solved. Under a new section, “Track my progress and earn stars,” users can activate their rewards using a toggle switch to turn their weekly challenge on or off. Each day, a pop-up asks the user whether they (1) used the sleep hacks, (2) partially used the sleep hacks, or (3) did not use the sleep hacks the night before. If they used or partially used the sleep hacks, they earn a blue star. If the user collects 5 blue stars in a week, they earn a gold star. Collecting 2 gold stars enables early access to supplementary content within the app, which provides additional information about the influence of behaviors such as vaping, drinking caffeine, and diet on sleep.

While the need for adolescents to continue to return to the app was not a requirement for effective engagement [69], similar sleep behavior apps have also used elements of gamification and reward systems. These include users tracking their sleep for 3 nights out of 7 to progress to their next “belt” in Sleep Ninja [45], gift cards for users of Sleepio, a digital app to improve sleep behavior using internet-based cognitive behavioral therapy [70], and monetary rewards for children who met their predefined sleep goals [71]. In an exploration of young adults’ perspectives on gamification in health apps, rewards such as badges and progress indicators were viewed more positively than self-rewards [72]. Young adults with depression and anxiety have expressed a preference for self-tracking behaviors over time; gamified elements that rewarded progress toward their behavior “goals” increased their motivation to engage with the app and regularly track their behavior [73].

PPI contributors were keen to share their own sleep-related experiences for other adolescents who may use the app in the future. A total of 7 adolescents who participated in the workshops recorded relatable stories related to poor sleep and how Sleep Solved had helped them. A variety of ages, ethnicities, and regional accents were represented following the guiding principle to “ensure that role models and stories were relevant to diverse contexts and identities.” These were presented to app users as playable audio clips.

Discussion

Principal Findings

This study used the person-based approach to design and optimize the first step of a 3-stage, app-based intervention aimed at improving sleep-related behaviors in adolescents aged 14 to 18 years. Sleep Solved was considered acceptable, feasible, and easy to use by PPI contributors, including those from underrepresented and diverse backgrounds.

This study highlights that offering varied means of contributing to intervention coproduction is helpful in terms of maximizing the speed of the co-creation process and the diversity of the sample of PPI contributors. It also confirms that, for advice to be engaging for adolescents, it is essential that it is perceived as trustworthy and novel and framed as a choice. A key finding from this study was the importance of offering our PPI contributors varied methods of contribution. This allowed contributors to express feedback in the way in which they felt most comfortable, resulting in diverse and complementary insights.

Web-based surveys were the most popular contribution method and allowed us to purposively recruit adolescents from low-income communities. Web-based surveys facilitated quick feedback on multiple-choice decisions, such as the app name, theme colors, and pathway options for the study. The second most popular contribution method was to take part in a web-based, one-to-one, think-aloud interview. These interviews provided in-depth feedback, allowing us to iteratively optimize the app over a 7-month period.

In comparison to previous research, this study used a 3-stage, app-based intervention, incorporating a co-created first stage followed by CBTi (SHUTi) and mental health support (Bite Back). Levenson et al [74] also designed adolescent sleep interventions with stakeholder input and involvement in a series of 3 focus groups with young adults, adolescents, and health care professionals with experience working with adolescents. These focus groups informed the development of a clinic-based sleep intervention for adolescents aged 13 to 15 years. Similarly, the “Momentum” intervention for young people with insomnia and mental health difficulties was co-created with young people aged 7 to 17 years, with participants encouraged to give feedback on the “look and feel.” As advised in the recommendations from the Momentum study, Sleep Well has features that encourage interaction, such as games, videos, interactive elements, quizzes, and rewards.

As with our SHUTi insomnia intervention [51], Palermo et al [75] also used CBTi to develop a 4-session CBTi intervention for adolescents with insomnia and co-occurring mental health conditions. Participants were encouraged to complete sleep diaries during treatment. The results indicated a high level of acceptability and feasibility, with high compliance; 85% (n=34) completed all 6 intervention sessions. Later pilot-testing indicated that the CBTi intervention was associated with improvements in insomnia symptoms, sleep quality, and sleep onset latency.

Focus group and workshop contributors, who were recruited from existing networks such as the Bristol YPAG and the McPin Foundation, were generally highly confident and motivated to engage with the study. They engaged thoroughly with the app over the course of a week, providing important suggestions, and were sufficiently confident to record their personal experiences for inclusion in the app.

Strengths

In line with our guiding principle to ensure that Sleep Solved was perceived as interesting, trustworthy, and novel, our results

highlighted that PPI contributors particularly valued the accessible presentation of the science-based advice in Sleep Solved. The perception of the advice as novel was important as adolescents have been shown to have a very low tolerance for behavior change interventions that they perceive as dull or boring [63,64]. The perception of the advice as trustworthy may be a key distinguishing feature of Sleep Solved; in a review of the 76 sleep-related health apps available on Google Play, less than 1 in 3 contained evidence to support their claims [60]. In line with our guiding principle to ensure that advice is framed as a choice, PPI contributors particularly appreciated not feeling “patronized” by the advice in Sleep Solved.

The key strength of this study is that our intervention was coproduced from start to finish, with quality in-depth, varied, and iterative feedback from PPI contributors. The role of the peer researcher (MHJ) in building ongoing, trusting relationships with contributors was a key feature of this success.

Limitations

One major limitation is the representativeness of our PPI contributors. Of those invited to share their feedback, only a small proportion volunteered to contribute to co-design. Therefore, it is likely that our contributors were a more highly motivated subsection of our target demographic, and it is

possible that their recommendations may not always represent the views of less motivated adolescents.

In addition, a significantly smaller number of adolescents aged 14 to 15 years volunteered to share their views in think-aloud interviews and group workshops. It is possible that recommendations from those who did not wish to engage with us in more depth may have differed from the suggestions of the adolescents aged 16 to 18 years who helped us develop the app.

Future Work

To foster a more representative PPI sample, forming early relationships with individuals from the relevant community with whom recruitment procedures can be coproduced [69] will likely be beneficial. The formation of these relationships may be made easier by having a more diverse research team [70].

Conclusions

In conclusion, offering multiple methods of providing feedback allows for the collection of holistic feedback from a diverse range of contributors. This feedback resulted in an app viewed as acceptable and engaging by the adolescents who have tried it to date. Further evaluation is needed to determine the feasibility and acceptability of the intervention in a larger group of adolescents, and future research should explore ways of engaging hard-to-reach young people in intervention development research.

Acknowledgments

The authors would like to gratefully acknowledge the support of their partners in the recruitment of patient and public involvement contributors, namely, the Association of Colleges, the E-ACT multiacademy trust, the McPin Foundation, the Bristol Young People’s Advisory Group, and Off The Record Bristol. The authors would also like to thankfully acknowledge the work of PIP Creative in the graphic design development of the Sleep Solved intervention. Finally, the authors are very grateful to the funders of this research, The Prudence Trust. LY is a National Institute for Health and Care Research (NIHR) Senior Investigator, and her research program is partly supported by the NIHR Applied Research Collaboration West and NIHR Health Protection Research Unit in Behavioural Science and Evaluation.

Conflicts of Interest

LR reports having equity ownership in BeHealth Solutions, LLC, who originally licensed the Sleep Healthy Using the Internet (SHUTi) program from the University of Virginia. Somryst, a commercial prescription digital therapeutic for insomnia, was developed based on the SHUTi program by Pear Therapeutics, who subsequently sold their license to Nox Health. Nox Health has a royalty agreement with BeHealth Solutions, LLC and the UVA Licensing and Venture Group. LR is a consultant of Nox Health. The terms of this arrangement have been reviewed and approved by the University of Virginia in accordance with its conflict of interest policy.

Abstract

Background: Artificial intelligence (AI)–based chatbots have emerged as potential tools to assist individuals in reducing anxiety and supporting well-being.

Objective: This study aimed to identify the factors that impact individuals' intention to engage and their engagement behavior with AI-based well-being chatbots by using a novel research model to enhance service levels, thereby improving user experience and mental health intervention effectiveness.

Methods: We conducted a web-based questionnaire survey of adult users of well-being chatbots in China via social media. Our survey collected demographic data, as well as a range of measures to assess relevant theoretical factors. Finally, 256 valid responses were obtained. The newly applied model was validated through the partial least squares structural equation modeling approach.

Results: The model explained 62.8% (R^2) of the variance in intention to engage and 74% (R^2) of the variance in engagement behavior. Affect ($\beta=.201$; $P=.002$), social factors ($\beta=.184$; $P=.007$), and compatibility ($\beta=.149$; $P=.03$) were statistically significant for the intention to engage. Habit ($\beta=.154$; $P=.01$), trust ($\beta=.253$; $P<.001$), and intention to engage ($\beta=.464$; $P<.001$) were statistically significant for engagement behavior.

Conclusions: The new extended model provides a theoretical basis for studying users' AI-based chatbot engagement behavior. This study highlights practical points for developers of AI-based well-being chatbots. It also highlights the importance of AI-based well-being chatbots to create an emotional connection with the users.

Introduction

Overview

According to the World Health Organization (2019), >80% of people worldwide face challenges in accessing mental health services [1]. This lack of access can be attributed to various factors, such as inadequate attention to health care, limited availability of medical resources, and the inability to afford the high costs of treatment [1,2]. Accessibility and scalability of mental health services need to be addressed [3].

An artificial intelligence (AI)–based well-being chatbot can engage in conversations with humans in a relatively natural manner, offering companionship, emotional support, and guidance for emotional well-being [4]. Therapeutic well-being chatbots work by simulating how a mental health professional would treat a user [5], and companionship well-being chatbots facilitate or develop a social relationship with the user through chatting to alleviate and channel negative emotions, such as loneliness and irritability [6,7]. These new digital interventions provide considerable relief to individuals who need

psychotherapeutic help but are plagued by a lack of time, space, or resources to access it [8-10]. Individuals who have interacted with these chatbots have expressed satisfaction with their experiences and have shown a positive attitude toward the future development of this technology [11]. These chatbots allow users to discuss private topics anonymously, effectively avoiding any feelings of shyness that may arise [12]. Well-being chatbots have also been used by professionals as an effective complementary tool to traditional face-to-face therapy [13,14]. In addition, they contribute positively to the dissemination of mental health knowledge and the promotion of healthy behaviors [11,15].

A growing number of research findings support the idea that digital mental health interventions, for instance, well-being chatbots, reduce the risk of chronic diseases by improving patients' psychosocial well-being and promoting other health behaviors [16-18]. They can help users overcome barriers to mental health support, and users can anonymously accept help from chatbots [19-21]. Scholars have taken notice of this phenomenon, and chatbot effectiveness, software design and development, use, and user satisfaction are being emphasized [22,23]. However, the problem of low engagement and high dropout rates between users and chatbots have not been prioritized, particularly in studying engagement behaviors through theoretical models. This will severely influence the user experience and effectiveness [3,8]. Exploring the factors influencing users' engagement behavior with well-being chatbots is critical to comprehend and refine this association, to serve users better [8,24].

This study aimed to investigate user intention to engage with well-being chatbots and engagement behavior by developing a new theoretical model that combines the theory of interpersonal behavior (TIB), diffusion of innovation (DOI), and trust. The goal is to understand the relationships among various factors and analyze their impact on the intention to engage and engagement behavior. We gathered data through a web-based survey to examine this model and identify the relationships between different factors. This research contributes to expanding the existing knowledge on theoretical models, particularly in the context of a human-centered digital mental health intervention. In addition, it will assist in designing, developing, and improving user-centered well-being chatbots; alleviating the problem of mental health medical resources; and helping to improve the overall well-being of the population. We have two research questions related to the objective of this study: (1) What factors influence users engaged with AI-based well-being chatbots? (2) How could AI-based well-being chatbot service be improved using the results of this study to improve users' engagement and experience?

Theoretical Background Rationale

Published studies about adoption of AI-based well-being chatbots tend to focus on either emotional or technical components of this technology but not on a more integrated approach to study this new technology [25-30]. Particularly in digital health adoption, the most used theories, the technology acceptance model and unified theory of acceptance and use of technology, mostly focus on general technology adoption drivers

[31,32]. Explaining the interaction of AI-based well-being chatbots with users goes beyond a simple technical interaction, it has been documented that they can create a psychological connection, like a friendship [33,34]. Therefore, we use the TIB, specifically its affect construct, to understand the relationship between a user and an AI-based well-being chatbot [29,30]. AI-based well-being chatbots are innovative technologies in the field of mental health care and personal well-being, and the application of DOI theory is beneficial for studying the factors that contribute to the adoption of AI-based well-being chatbots [35]. Trust is a key factor, particularly when dealing with personal and sensitive data [36,37], like the sharing process between the user and AI-based chatbots when it concerns mental health and personal well-being [38]. Without trust in the treatment intervention, the expected health outcomes between both parties may not be achieved [39]. The study brings these theories together through a new approach that combines relevant psychological factors for the adoption of AI-based well-being chatbots, which can be measured with the TIB and trust theory and the technical and innovation component of this new technology, which can be measured with the DOI theory.

Engagement Behavior in Digital Mental Health Intervention

Mental well-being is an increasingly important health topic of public concern. AI-based chatbots empower mental health and well-being through AI technology to provide emotional support to human beings [40]. AI-based chatbots enable user interaction based on text or voice support and complete corresponding tasks, recognizing users' emotions and providing solutions [41]. The services of AI-based chatbots for mental well-being as a new digital mental health intervention to users are evolving, and it is crucial to study users' engagement behavior.

Engagement is a multidimensional concept that includes not only the formation of interest or adherence to a predefined plan, but also the development of trust, integration, and ongoing participation [42]. In this study, engagement behaviors are defined as the behaviors of users interacting with a well-being chatbot. The well-being chatbot serves as a new type of digital health intervention that provides users with mental health self-management and psychotherapy services [42]. Users' engagement is an important factor, influencing the effectiveness of mental health interventions [43]. Research has shown that high engagement is associated with high intervention effectiveness [29,30,44,45]. In mental health treatment, participation in ongoing treatment is necessary for recovery [46,47]. A study of a digital mental health intervention found that >70% of users failed to complete all treatment modules and >50% withdrew before completing all treatment modules in general [29,48]. An analysis of mental health applications use showed that the average 15-day retention rate was only 3.9% [49]. Another study showed that mobile apps that emphasized user participation in design increased the effectiveness of interventions for depression and anxiety [50]. In a meta-analysis study of the impact of digital mental health engagement on mental health outcomes, users with higher levels of access showed substantial or moderate improvements in postintervention mental health outcomes [29]. This study explores the relationship between factors around engagement

behaviors. This will help to uncover the insight of users' willingness to engage and their engagement behaviors and improve the design capabilities and services of well-being chatbot.

TIB Theory

TIB was developed by Triandis [51] in 1977. It is similar to the ABC (attitude-behavior-context) model by Stern [52], combining internal and external factors, including affect, social factors, perceived consequences, habit, and facilitating conditions, to understand intended behavior [53]. In the context of engagement with well-being chatbot research, TIB is a well-suited theoretical model because well-being chatbots operate in a way similar to social software, where communication with users is accomplished through text dialogue and voice dialogue [54]. Users communicate trial experiences and results, and even recommend an AI-based chatbot to others [55]. The affect factor can seriously impact an individual's willingness to communicate [56]. People will recommend their favorite products to each other, and this recommendation behavior will influence the individual's intention [57]. Individuals past communication habit of using mobile apps will influence their willingness to use them [58]. If individuals frequently use instant messaging apps, they will be accustomed to this online communication method. TIB contains the above 3 critical aspects known as affect, habit, and social factors. Therefore, TIB is chosen as a theoretical basis for our model.

DOI Theory

DOI describes the process by which people embrace new ideas, use new products, and engage in new practices [59]. In general, only a few people have an attitude of developmental acceptance of new ideas and are willing to try them out and embrace them in the initial stages. As these people propagate them, gradually, more people begin to embrace them; the innovative idea or product thus diffuses through the population and eventually reaches saturation [60].

DOI was proposed by Rogers [59] in 1995, it helps us to understand the characteristics of an innovation and what attracts users to it. According to Rogers' research, 5 key features influence the adoption of an innovation: relative advantages, complexity, compatibility, observability, and trialability. Well-being chatbots are an innovative technology that has

emerged in recent years, but they are not widespread in daily life. As their contribution to the mental health field, studying their dissemination among people leads to its understanding and acceptance by more people can contribute to human health and well-being. Therefore, extending the TIB model by adopting the properties of DOI is crucial. Among the 5 characteristics, observability can be considered equivalent to the combined effect of demonstrability and visibility [61]. Visibility was not used in this study because AI-based chatbot engagement was treated as a personal experience. Still, results demonstrability was used in our research model. Trialability was also not adopted because there was no evidence of whether the user had trialed a chatbot.

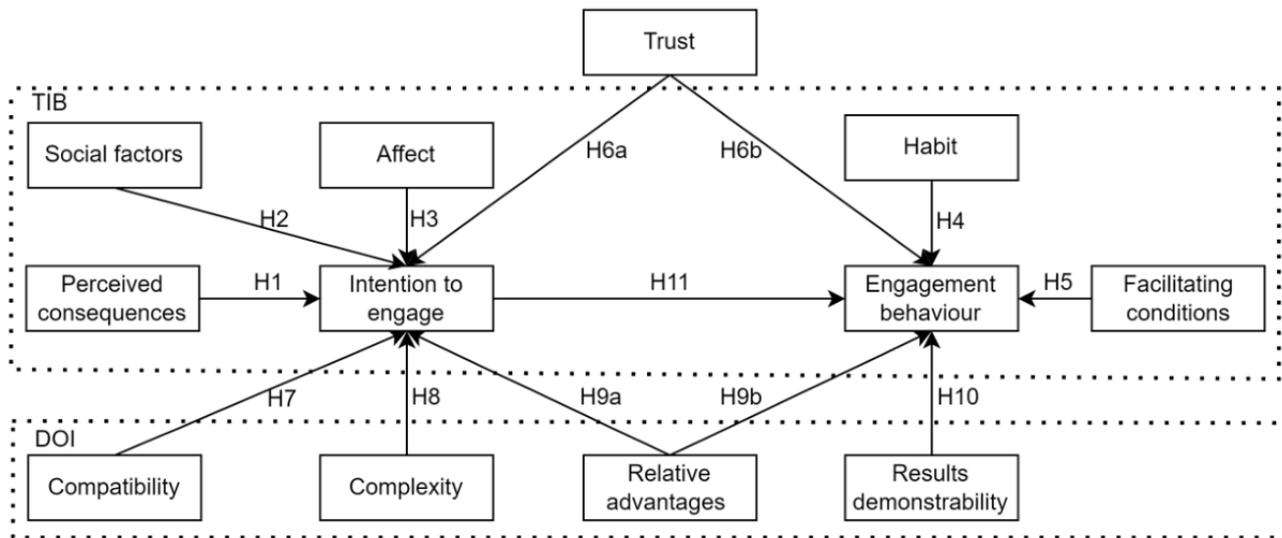

Trust

Trust is defined as the willingness of one party to accept the actions of another party, irrespective of the latter's ability to control them [62]. The trust placed in machines is determined as the willingness of users to accept the information generated by machines and to adhere to their recommendations [63]. This indicates that one party intends to form a relatively secure attachment to the other, despite the potential for negative outcomes [64]. This represents a psychological mechanism that can reduce uncertainty and increase the likelihood of successful interaction with other entities within the environment [65]. Trust is a prerequisite for any social interaction and is instrumental in fostering collaboration and cooperation between individuals [66]. It serves as a key factor in successful transactions and establishing long-term relationships [67]. In the field of mental health, trust is of paramount importance in the relationship between patients and health care professionals [68,69]. The interactive behavior of users with chatbots for health purposes is analogous to that of patients with their doctors; the establishment of collaborative and cooperative relationships based on trust is conducive to the achievement of health objectives [70,71]. Therefore, trust represents a crucial element in the investigation of engagement with chatbots.

Research Model and Hypotheses

Following the theoretical rationale, TIB, DOI, and trust were combined to support the understanding of users' intention to engage with AI-based well-being chatbots and engagement behavior in our research, as shown in [Figure 1](#).

Figure 1. Research model. DOI: diffusion of innovation; H: hypothesis; TIB: theory of interpersonal behavior.

Development of Hypotheses

Perceived consequences are the positive or negative results of an action after it has occurred and the possibility of the outcome occurring [72]. When the perceived consequences are positive, the individual will be prompted to engage with the behavior to achieve advantages; when the perceived consequences are negative, the individual's willingness to engage with the behavior will be reduced [53]. It had been validated to have a relevant effect on behavioral intention [53,73]. Well-being chatbots offer mental companionship and emotional support, contributing positively to users' emotional and mental well-being [9]. Therefore, we assume that perceived consequences will be positively related to the intention to engage with well-being chatbots (hypothesis 1).

Social factors are related to the extent to which people are influenced by others who are significant to them [51,73]. Individuals in a group or those observed by a group will comply with some of the unwritten rules within the group, and the likelihood that an individual will act in accordance with the group's demands increases under the pressure of the group [51,74,75]. Social factors have been shown in several studies to positively influence individual behavioral intention [73,76-78]. In health care, the influence of social factors was examined and affirmed from multiple perspectives in a study of clinicians' adoption of mHealth (mobile health) tools [79]. In chatbots that provide services in a social context, users' decisions are influenced by perceptions of how those around them use these services [78]. Regarding the context of a well-being chatbot engagement, we hypothesize that social factors will be positively related to the intention to engage with well-being chatbots (hypothesis 2).

Affect is used to describe the mental representation of internal bodily sensations associated with emotions, behaviors, or personality tendencies [80]. It is the purely emotional part of an individual's attitude and contains positive or negative emotions, for instance excitement, joy, depression, and displeasure [81,82]. Affect has been shown to have an influence on behavioral intention in studies on information technology

applications [76,83,84]. In the context of AI-based well-being chatbot engagement research, we assume that affect will positively influence individuals' intention to engage with AI-based well-being chatbots. Thus, we propose that affect will be positively related to the intention to engage with well-being chatbots (hypothesis 3).

Habit is a learned behavior, an automatic response to a steady stream of contextual cues [85], and it is regarded as a major influence on behavior [86]. A study has shown that an individual's habits can predict future behavior to some extent [87]. Because the popularity of the internet as well as smartphones and the effectiveness of using digital interventions for health behaviors have been proven [51,53,54], this has caused health care apps to gradually become a way to optimize people's daily health care behavioral habits [88]. As the well-being chatbot serves as a health care information system, we assume that habit will be positively related to engagement behavior (hypothesis 4).

"Facilitating conditions" is a term that refers to objective elements in the environment that enable the easy execution of behavior [51]. In the IT context, it is defined as the resources necessary to support the use of a system, such as access to the internet or a smartphone [31]. Facilitating conditions have been identified as a key factor which influenced individuals' behavior related to engagement [83]. Thus, we hypothesize that facilitating conditions will be positively related to engagement behavior (hypothesis 5).

Trust has been recognized as one of the critical factors in human-robot interaction research [89,90]. Users' trust in AI-based chatbots is based on the AI-based chatbot's performance and services being dependable, trustworthy, and being able to assist in achieving the user's intended purpose [37]. Developing and nurturing trust in the psychotherapy process to establish a good therapeutic relationship through engagement and ultimately effective treatment is crucial [91,92]. Meanwhile, trust was identified to have a major influence on the intention to act on eHealth websites [93]. Accordingly, trust influences users' willingness to intent and engage with AI-based well-being chatbots [91-93]. So, we assume that trust positively

influences an individual's intention to engage AI-based well-being chatbots (hypothesis 6a) and trust positively influences users' engagement behavior (hypothesis 6b).

Compatibility refers to the extent to which the innovation matches the existing values and beliefs, previous experiences, and demands of potential users [59,94]. It provides a good indicator of how extensively an innovation complies with potential users' lifestyles, needs, and preferences [60]. In previous research, compatibility was identified as one that influenced the intention to behavior [95]. Well-being chatbots meet the real-time needs of users [96-98], and chatbot mobile apps match the habits of smartphone users [99]. In this research, we assume that compatibility will be positively related to the intention to engage with AI-based well-being chatbots (hypothesis 7).

Complexity is a measure of how difficult it is to understand and use an innovation [59]. It is a systematic form that is associated with almost all aspects of health care [100]. Complexity has been proven to have an impact on digital technology in health and well-being apps [101]. In another study on health care chatbots, complexity had a strong impact on the ability of chatbots to successfully provide health information and adoption behavior [100,102,103]. In this research, we assume that low complexity will be positively related to the intention to engage with well-being chatbots (hypothesis 8).

Relative advantages is a term that refers to the degree to which an innovation is better than the object it replaces [94]. Innovation with greater relative advantage is beneficial for its diffusion [104]. It has been shown that an innovation will not be used if potential users believe that there is no comparative advantage in the adoption of the innovation over its earlier counterparts [105]. AI-based well-being chatbots are more empathetic than their earlier counterparts and even have memory functions, these advantages motivate users to interact and engage with them more [96,106-110]. Thus, we assume that relative advantages will be positively related to the intention to engage with AI-based well-being chatbots (hypothesis 9a) and relative advantages will be positively related to engagement behavior (hypothesis 9b).

Results demonstrability is the degree to which innovative results are presented and disseminated [61]. Innovations will be more adopted if they generate demonstrably positive results; if the converse is the case, the chances of the innovation being adopted become lower [94]. Studies have shown that results demonstrability is a potential predictor of behavioral adoption [111]. AI-based well-being chatbots can serve users as an mHealth app. Thus, we assume that results demonstrability will be positively related to the intention to engage with AI-based well-being chatbot engagement (hypothesis 10).

Intention to engage in a behavior is the most direct determinant of an individual's behavior [112]. Exploring the relationship between intention to engage and engagement behavior helps to improve user experience and interaction effectiveness [9,113]. This also has a positive effect on the design of well-being chatbots in terms of enhancing user engagement [114,115]. Therefore, the intention to engage influences engagement and is an important factor in the study of user engagement with

well-being chatbots. We assume that intention to engage with AI-based well-being chatbots will be positively related to engagement behavior (hypothesis 11).

Age, gender, education and chronic disease status were implemented in the research model as control variables [116].

Methods

Ethical Considerations

Approval was obtained from the NOVA Information Management School Ethics Committee, NOVA University of Lisbon (INFSYS2023-5-257970). The procedures used in this study adhere to the tenets of the Declaration of Helsinki. All participants were aged at least 18 years, and informed consent was obtained from them. All data were collected anonymously, and participants were not compensated.

Data Collection and Sample

The questionnaire was developed in English on the Qualtrics platform. The survey was designed per the guidelines and the Checklist for Reporting Results of Internet E-Surveys (CHERRIES), which is presented in [Multimedia Appendix 1](#) [117]. We explained to participants that participation was voluntary, and their data would be collected anonymously. We took measures to ensure that participants clearly understood what a well-being chatbot entails by introducing its concept and benefits at the start of the survey. Meanwhile, we described the functionality and use of an AI-based well-being chatbot. We engaged 2 experts and 2 colleagues to review and evaluate the questions to ensure that the topics were clear, relevant to the subject matter, and easy to understand. Once the questionnaire was finalized, a translator translated the questions into Chinese. Then, another translator was responsible for doing a back-translation and comparing it with the original English version to ensure accuracy [118]. Then, 40 participants were selected for pretesting to validate the questions' understandability and the survey scale. No issues were reported that could indicate that the survey items were unreliable. Action was taken to prevent potential issues with single source and common source bias. The questionnaire was placed in 3 different web platforms to ensure the maximum coverage and avoid a single-source bias [117,119,120].

We distributed the survey on 3 popular social media mobile apps: WeChat, Weibo, and Douban. WeChat is China's most popular social media network, with 1.3 billion active users in 2022 [121]. Weibo is China's second-largest social platform after WeChat, with 582 million active users at the end of the first quarter of 2022 [122]. Douban is an interest-oriented social network community with 75 million users as of 2020 [123,124]. Publishing the questionnaire across the 3 social media platforms will ensure fair data collection.

The framework's independent and dependent variable items were collected in a single questionnaire. We assessed if there was a clear understanding of what was being measured by the constructs, to avoid the risk of common source bias [119,120]. The aim was for the respondents to avoid using the same mental process or heuristics when replying to questions about different constructs [119,120,125]. The assessment of our pilot survey

was that there was no reason for concern. For added precaution, additional features were incorporated in the final survey to enable psychological separation. While designing a survey, psychological separation should ensure that the measures of the different constructs are unrelated [120]. Different instructions for different sections of the survey were provided, and the sections of the survey that measure different constructs were physically separated [120].

Finally, 256 valid replies from well-being chatbot users were collected from May to October 2023. The web-based survey did not impose any restrictions on participants other than being an adult aged ≥ 18 years.

Measurement

The scales of all the variables in this study were produced concerning the relevant literature. Minor modifications were carried out according to the characteristics of AI-based chatbots. We used a 7-point scale to assess the variables from 1="strongly disagree" to 7="strongly agree." The questionnaire with the measurement items and references for each variable are provided in [Multimedia Appendix 2](#).

Data Analysis

The data were analyzed using the partial least squares structural equation modeling (PLS-SEM) approach using Smart-PLS (version 4.0) [126], which is suitable for analyzing and predicting complex models and nonnormally distributed data. PLS-SEM can also handle models that include both reflective and formative variables [127].

Reflective and formative construct measurements were included in the research. In reflective measurement models, causality flows from the underlying construct to the indicator. In contrast,

in formative measurement models, causality flows in the opposite direction, from indicators to constructs [128]. Reflective constructs measure entities with a series of positively correlated items [129,130]. In contrast, the formative construct is a singular construct which is constituted by the aggregation of multiple indicators without any a priori assumptions regarding the interrelationships between these elements [129,130]. Reflective and formative measurement models should be evaluated separately [128].

Results

Sample Characteristics

Of the 256 valid samples, all had experience in using AI-based chatbot for mental health care. The participants' average age was 30.9 years, and 55.9% of participants were younger than 30 years. The average age in other studies in China with the same scope as this study has ranged between 21 and 34.8 years [25-28]. The high proportion of young women was also present in demographic data from other studies, particularly studies on health technology adoption behaviors [109,131,132]. A recent Chinese study from 2023 showed that 77% of users of digital mental health technologies in China were female [28], which aligns with our study participants' demographics. Approximately 91% of the participants held higher education degrees, which is more prevalent in innovation technology adoption studies [133,134]. However, the number of participants with chronic diseases was close to that of those without any disease, which is also reflected in the results of previous studies, which have found that chronic diseases have an impact on health applications [116]. The sample characteristics are shown in [Table 1](#).

Table 1. Demographic data (n=256).

Characteristics	Participants, n (%)
Age (years)	
18-29	143 (56)
30-44	84 (33)
45-59	13 (5)
≥ 60	16 (6)
Gender	
Women	187 (73)
Men	69 (27)
University education	
Degree	234 (91)
No degree	22 (9)
Chronic disease status	
Yes	111 (43)
No	145 (57)

Measurement Model

Formative and reflective constructs were included in our model. They were measured separately. First, for reflective constructs, the construct items' reliability was assessed by computing the value of each item. The loading values of all reflective construct items were above the threshold of 0.7, and they were accepted [135] and are listed in Multimedia Appendix 3. Then, we applied the Cronbach α reliability coefficient and composite reliability (CR) to measure their internal consistency. All Cronbach α and CR scores were above 0.7, and the model was proven to have good reliability [135]. Meanwhile, we examined convergence

validity by assessing the average variance extracted (AVE); the value of AVE for each construct was >0.5 [135]. All detailed indicators for mean, SD, Cronbach α , CR, and AVE are shown in Table 2. We used the heterotrait-monotrait (HTMT) ratio as the main criterion to assess discriminant validity, following the latest guidelines recommendation [135-137]. The HTMT values were below the threshold value of 0.90 [135], thus confirming discriminant validity. The results are shown in Table 2. In addition, cross-loadings and the Fornell-Larcker criterion were also evaluated for discriminant validity, and the results also confirm discriminant validity (Multimedia Appendices 3 and 4).

Social factors (SF) were measured as a formative construct in our research model [53]. We assessed the collinearity among indicators of the formative construct by calculating the variance inflation factor (VIF). The VIF values (Table 3) were below the cutoff value of 5 [135], which meant that there was no

collinearity. Finally, we implemented a bootstrapping approach with 5000 resamples for identifying the statistical significance of each path. Social factor (SF) 1 and SF2 present statistically significant outer weights; SF3, SF4 and SF5 did not present statistically significant outer weights. Thus, we verified the SF3,

SF4 and SF5 outer loading values, which were all >0.5 [135]. This aspect means that all SF items were relevant.

Table 3. Indicators of formative construct.

SF ^a	VIF ^b	Outer weights	P values (outer weights)	Outer loadings	P values (outer loadings)
SF1	2.386	.224	.04	.826	<.001
SF2	2.411	.421	<.001	.881	<.001
SF3	2.441	.253	.07	.834	<.001

SF5	2.520	.198	.13	.738	<.001

^aSF: social factor.

^bVIF: variance inflation factor.

In addition, we used Harman 1-factor test method to probe for common method variance (CMV).

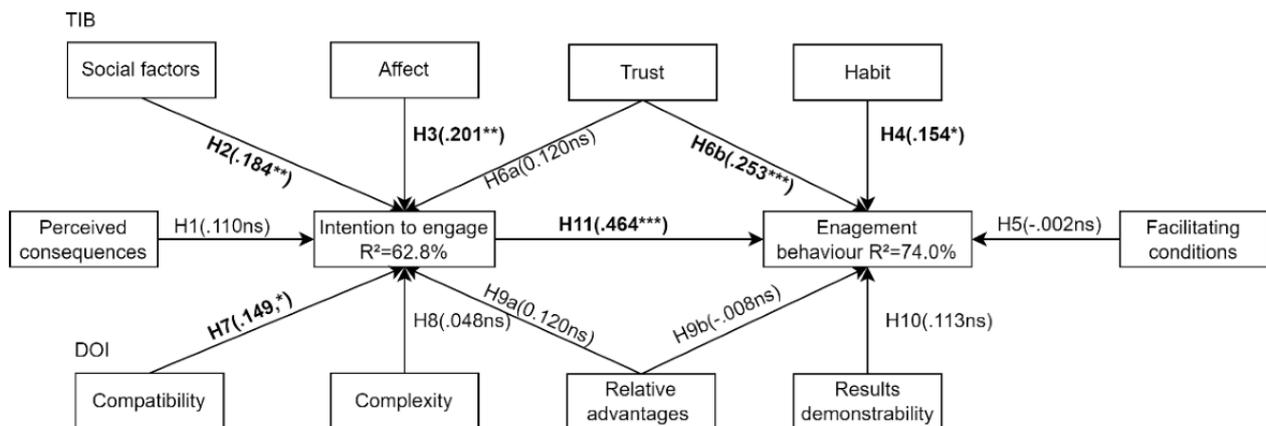

The total variance extracted by 1 factor was less than the recommended threshold of 50%. Hence, this data should not present any problem with CMV [120]. Afterward, the marker variable technique was adopted to assess the CMV, and an unrelated construct was defined as a marker variable to determine the relationship between it and each construct in the research model [125]. We obtained 0.055 (5.5%) as the maximum shared variance with other variables. Therefore, the value can be considered low [138]. After verification by 2

methods, it was concluded that the influence of CMV can be excluded from this study [120,125].

Structural Model

The structural model explained 62.8% variance in intention to engage, and 74% of variance in engagement behavior. Both R² are regarded as high by the literature [135]. High R² values indicate that our key target variables can be well predicted via the PLS path model [135]. Figure 2 shows the structural model results and identifies which latent variables are statistically significant.

Figure 2. Structural model results. DOI: diffusion of innovation; H: hypothesis; ns: nonsignificant; TIB: theory of interpersonal behavior. *P<.05; **P<.01; ***P<.001.

Regarding the intention to engage, affect ($\beta=.201$; $P=.002$), SF ($\beta=.184$; $P=.007$), and compatibility ($\beta=.149$; $P=.03$) were statistically significant. Hypotheses 2, 3, and 7 were supported. Perceived consequences ($\beta=.110$; $P=.12$), trust ($\beta=.120$; $P=.11$), complexity ($\beta=.048$; $P=.47$), and relative advantages ($\beta=.120$; $P=.16$) were not statistically significant; hence hypotheses 1, 6a, 8, and 9a were not supported.

About engagement behavior, intention to engage ($\beta=.464$, $P<.001$), habit ($\beta=.154$; $P=.01$) and trust ($\beta=.253$, $P<.001$) were statistically significant, and facilitating conditions ($\beta=-.002$; $P=.98$), relative advantages ($\beta=-.008$; $P=.91$), and results demonstrability ($\beta=.113$; $P=.10$) were not statistically significant. Hypotheses 11, 6b, and 4 were supported, and hypotheses 5, 9b, and 10 were rejected, as shown in Table 4.

Table 4. Hypothesized path analysis.

Hypothesis	Path	β	<i>P</i> values	Supported
H1	Perceived consequences → intention to engage	.110	.12	No
H2	Social factors → intention to engage	.184	.007	Yes
H3	Affect → intention to engage	.201	.002	Yes

H6a	Trust → intention to engage	.120	.11	No
H6b	Trust → engagement behavior	.253	<.001	Yes
H7	Compatibility → intention to engage	.149	.03	Yes
H8	Complexity → intention to engage	.048	.47	No
H9a	Relative advantages → intention to engage	.120	.16	No
H9b	Relative advantages → engagement behavior	-.008	.91	No
H10	Results demonstrability → engagement behavior	.113	.10	No
H11	Intention to engage → engagement behavior	.464	<.001	Yes

The PLSpredict algorithm was used to assess the framework predictive power. The method uses training and hold out samples to generate and evaluate predictions from PLS path model estimations [139,140]. The guideline recommendation was followed, and the number of folds was set to 10 [140]. This approach was done because it is possible to achieve a statistical power of 80% to detect minimum R^2 values of 0.1 in the endogenous constructs in the structural model for a significance level of 1% [137,140]. The first parameter to be evaluated was the Q^2_{predict} of the indicators concerning our endogenous variables that was above 0, showing that the model demonstrates predictive power [140]. To evaluate the predictive magnitude, we compared the PLS-SEM study model with the naive linear regression model (LM) to see if it can outperform the LM benchmark [140]. Because the prediction errors distribution

was considerably asymmetrical, with high kurtosis values (>1) [135], the mean absolute error was the more appropriate prediction statistic [140].

The PLS-SEM analysis yielded lower prediction errors for most of the dependent variables' indicators, as seen in Table 5; this indicates a medium predictive power for the study model [140]. When complex models are used, involving several theories, such as those explaining human behavior, R^2 values higher than 0.5 can be regarded as substantial [135,137]. The model in this research study is complex, and achieving medium predictive power is challenging in such models [137,140]. Given that this research model shows a substantial R^2 for a complex model and medium predictive power, it provides confidence in its use for real-world applications [135,137,140].

Table 5. Prediction summary.

Indicators	Q^2_{predict}	PLS_SEM_RMSE ^a	PLS_SEM_MAE ^b	LM_RMSE ^c	LM_MAE ^d	Kurtosis	Skewness

^gITE: intention to engage.

Discussion

Principal Findings

The TIB was considered in this study, and it was extended with the DOI theory and trust to explore in depth the factors influencing users' engagement behavior with AI-based chatbots for well-being. The new extended model was well explained, with R^2 values of 62.8% for the variance in intention to engage and 74% for the variance in engagement behavior. RQ1 was answered in this study. AI-based well-being chatbots are gradually beginning to play an active role in the field of mental health. In this context, this study obtained important results, including affect, habit, SF, trust, compatibility and intention to engage as determinants influencing users' engagement behavior. By extending the TIB to include important research variables in the model, a foundation was laid for future, related theoretical research and practice. The study's results affirmed the significance of affect on users' intention to engage. Our measurement of user affect contains both positive and negative emotions [141]. From the user's perspective, there is a willingness to engage with the chatbot. It indicates that users have a positive impression of the well-being chatbot's service and that users are inclined to deal with their emotions by engaging with a well-being chatbot. Users are beginning to be comfortable with the service as a mental health intervention that is available anytime, anywhere, without an appointment [142]. From the perspective of well-being chatbot characteristics, empathetic chatbots can understand users' emotions and provide professional psychological counseling or companionship [96]; for instance, suggesting meditation, outdoor activities, or socializing with friends [7,143,144]. This proactive intervention on users' emotions promotes users' willingness to participate with sustained engagement behaviors.

Habit has been extensively studied in previous research on health app use and engagement behavior [145]. In the current information age, smartphone use has become ingrained in people's daily lives. Engaging with mobile apps for specific purposes has become a habit for many individuals [146]. This study confirmed that habits were an essential factor influencing users' engagement behavior, aligning with other studies' findings [147]. In addition, the significant influence of SF indicated that the opinions of friends, family, and medical professionals substantially impacted individuals' intention to engage with well-being chatbots. This finding is consistent with previous studies [78].

Furthermore, as AI-based well-being chatbots represent an innovative technology in a digital mental health intervention, proactively exploring methods for promoting their adoption is worthwhile. This research model incorporates features from the DOI framework to extend the TIB model. Among these features, compatibility was found to impact the intention to engage significantly, while the other 3 aspects did not demonstrate statistical significance. Because chatbots work like any other social software, the experience is consistent with past experiences [148,149]. They can be used easily and without extra effort, making users more willing to use them, which is also consistent with previous research [150].

Trust, habit, and intention to engage were statistically significant for chatbot engagement. They are both internal (subjective) elements of individuals [151,152], whereas other factors had no statistically significant influence, such as facilitating conditions, relative advantages, and results demonstrability. It indicated that the user's subjective sense of experience played a decisive role in engagement compared with other factors [153,154]. This suggests that a lack of user-centeredness in product design or a lack of information about mental health services in terms of content that meets users' needs could directly reduce user engagement [155]. Consistent with the findings of this study, it further underlines the importance of user-centeredness.

Potential explanations for the constructs that were nonsignificant are also addressed. The facilitating conditions hypothesis was not supported, aligning with previous research [32,156]. When engaging with an AI-based well-being chatbot, users' ability to access smartphones, computers, or the internet, as well as their knowledge of how to use them, did not become barriers—most likely because our respondents were young and highly educated [157]. It could have been expected that complexity would be statistically significant; nonetheless, other studies of new technologies in health care, when complexity was evaluated as part of DOI, also obtained nonsignificant results [13,91,94,157-160]. A possible explanation, also supported by the literature, is that early adopters of new technologies, as in the case of our study, have a higher cognitive ability and are more accustomed to managing complexity, so they do not perceive complexity as an obstacle to using new technologies, including AI-based well-being chatbots [13,91,94,157,160]. Some research indicates that relevant advantages could influence users' willingness to adopt new technologies in the initial implementation phase [161,162]. However, not all studies support this. The nonconfirmation of the relative advantages hypothesis in our research suggests that individuals focused more on the experiences and value derived from chatbots' services rather than the direct benefits of outcomes [163]. The emotional component—affect—is much more relevant than technical factors, minimizing their impact on the model. Among younger people with higher level of education, perceived consequences show different influences on behavioral intention [164]. In our study, perceived consequences had a nonsignificant impact on the intention to engage with a well-being chatbot, suggesting that individuals become more focused on their engaging experience rather than on the positive or negative consequences.

Age, gender, education, and chronic disease status as control variables were not statistically significant for the 2 dependent variables (intention to engage and engagement behavior) in the model. Our study respondents were young, were mostly highly educated, included a high proportion of women, and had a ratio of respondents with chronic diseases aligned with the literature [25-28,116]. In addition, early adopters exhibit behavior toward a technology that differs from those who adopt it later [94,157,160]. AI-based well-being chatbots are a new technology, currently being used by early adopters with no significant heterogeneity, which, at this early stage of

implementation, does not contribute to significant results for the control variables.

Theoretical Implications

First, we provided an integrated perspective of TIB, DOI and trust to uncover the critical factors influencing chatbot intention to engage and engagement and how these factors influence individual decision-making. In previous studies, the technology acceptance model and unified theory of acceptance and use of technology were considered the most used and integrated information systems theories, and there were few relevant adoptions of TIB [165]. However, we believed that affect and habit in TIB were most appropriate for explaining AI-based well-being chatbot use behavior based on its characteristics. The new integrated model provides important theoretical support for future research on AI-based chatbots and other products.

Trust is among the most important factors determining human intention to adopt smart technology products [166]. Adding trust to the research model explained users' intention to engage and engagement behavior in a multidimensional way. The results of this study provided empirical evidence for the completeness of future AI information system application models. Nowadays, AI technology is being increasingly applied in diverse information systems and the autonomy of information systems has been enhanced. Theoretically validating the impact of trust on AI products is imperative.

Practical Implications

The results of our study model can provide guidance on better implementing AI-based well-being chatbots to increase their adoption. The triangulation between users, companies that develop AI-based well-being chatbots, and mental health practitioners is highly relevant and should be considered during the system's development and real-world use. In our model, affect had a statistically significant impact on the intention to engage with AI-based well-being chatbots. It is crucial for designers and developers to recognize the influence of users' affect on their willingness to engage with AI-based well-being chatbots. Affect describes a wide range of feelings, both positive and negative [72]. Developers should address the needs of users in different emotional states during the design and development process while simultaneously enhancing the system's ability to recognize emotions and build emotional connections between chatbots and users [167,168]. Because affect is a complex dimension that transcends the purely IT aspects of the chatbot, developers should seek the support of mental health practitioners from the early stages of these systems' development. Habit is also a statistically significant construct, so providing good support services should be a key area of focus for AI-based well-being chatbot companies, as they contribute to user experience and help maintain users' habits of continuous engagement with the chatbot. According to our model results, SF also contribute to the intention to engage AI-based well-being

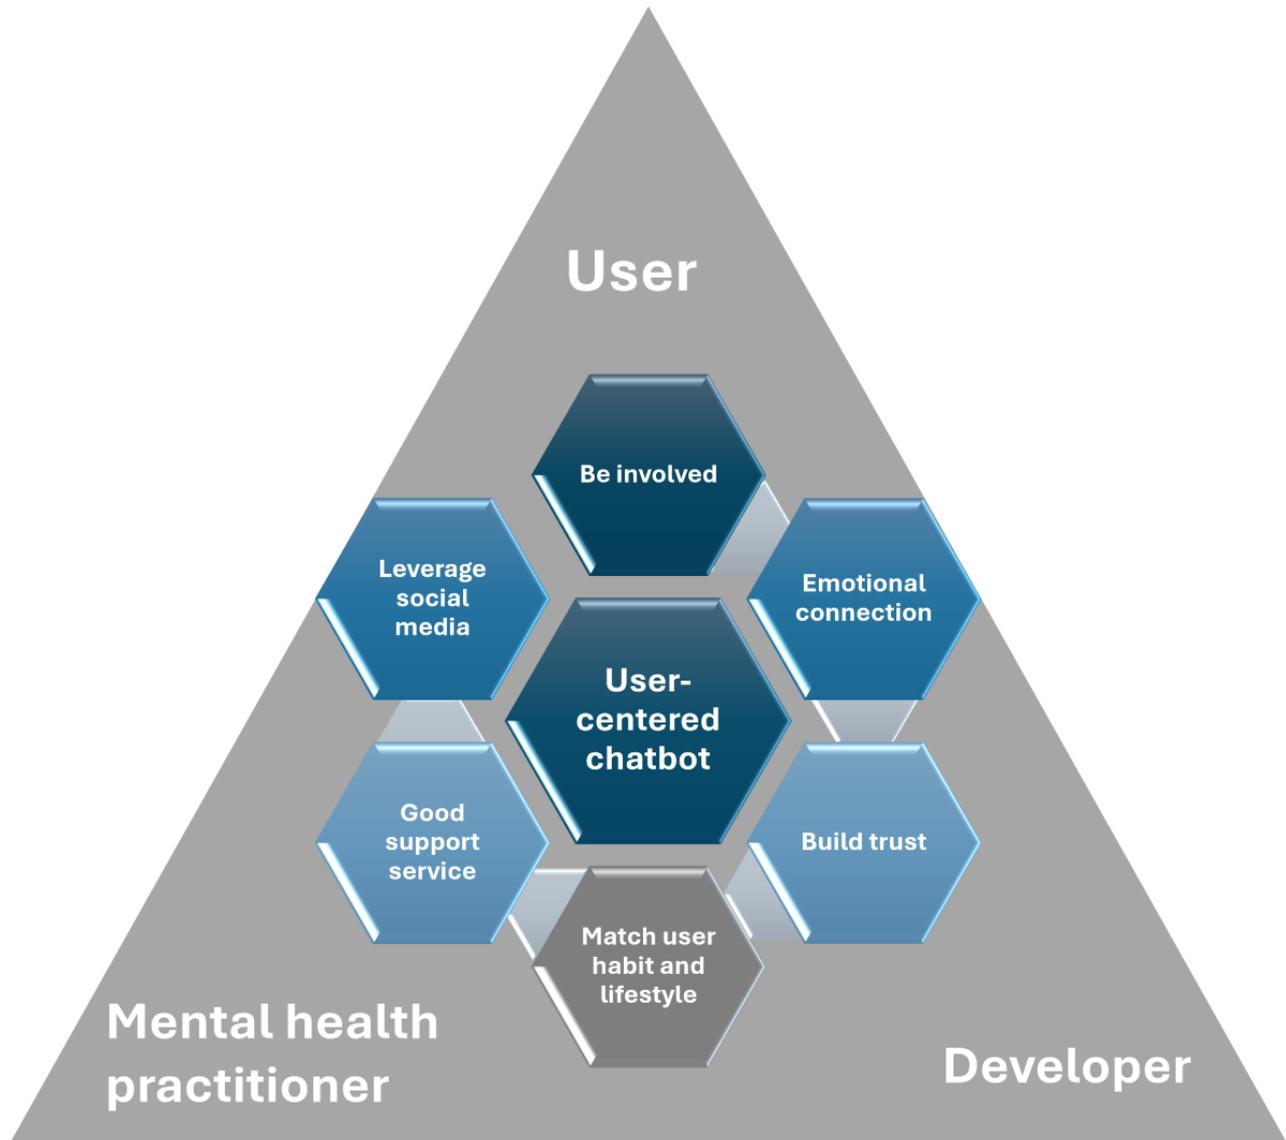

chatbots. It suggests that individuals relevant to users can influence the adoption of AI-based well-being chatbots [51]. This indicates that mental health practitioners may influence users' intention to engage with AI-based well-being chatbots. For companies developing AI-based well-being chatbots, it is important to engage with mental health practitioners. Developers could also leverage social media to promote their AI-based well-being chatbots, considering the relevance of SF.

Trust was another statistically significant construct in the model. Establishing user trust is pivotal for driving participation behavior, and devising strategies to cultivate user trust requires careful consideration. They should consider introducing mental health practitioners into the system development process [169]. The incorporation of mental health practitioners enhances the efficacy and competitive advantage of chatbots, while reinforcing user trust and fostering their intention to engage. In some current practices, mental health experts have already been involved in the chatbot development process, with positive outcomes [170].

Another relevant construct in the model is compatibility. It is recommended that users be included in the entire life cycle of the AI-based well-being chatbot, as this allows a comprehensive understanding of users' habits and lifestyles, thereby facilitating product compatibility [8,171]. By communicating with users in greater depth, it is possible to gain insights into their interactions with the chatbot and to establish trust. The emotional connection between AI-based well-being chatbots and their users represents the core value of this technology, requiring designers and developers to prioritize a user-centered approach in their work [172].

Although this research did not cover older people or those with special needs, future developments specifically targeting these groups should account for the fact that they may not have access to certain resources or may have lower digital literacy [173]. In these cases, the constructs of complexity and facilitating conditions, which were nonsignificant in this research, should play a critical role. Less complex systems and providing the right resources should increase the adoption of AI-based well-being chatbots within these groups.

The involvement of mental health practitioners and users, integrating and applying their feedback throughout the AI-based well-being chatbot's development, is essential for successfully implementing the chatbot's entire life cycle. It is crucial to use AI-based well-being chatbots for therapeutic purposes under the guidance of qualified professionals to prevent misuse, which could potentially result in risky behaviors [174,175]. Figure 3 provides a graphical representation of the suggested practical implications. RQ2 about improving user experience and engagement from a practical point of view, leading to enhanced service levels was answered.

Figure 3. Suggested practical implications.

Limitations and Future Research

Our study used a convenience sample for which an online, multiplatform collection approach with a large coverage of the Chinese population was used to prevent single-source bias [120]. Still, the approach was not entirely random because we only posted the questionnaire, making it available, and we did not send messages to all platform users. In addition, the data source was from only one country. Future studies could use probabilistic sampling approaches. Access to large databases of AI-based well-being chatbot users could support studies with random sampling. Future research should expand the data sources to include participants from different countries and ethnicities, as well as special target populations (eg, people diagnosed with depression, older people). A multicountry approach as the next step may be used to evaluate if the findings are generalizable. Future studies could also collect the independent and dependent variables in different moments in time to reduce the probability of common-source bias [120]. Collection of real use data from the AI-based well-being chatbots could also be an advantage in future studies. Specific

criteria for measuring engagement, such as the number of minutes of participation in using the chatbot, the number of logins, and the number of completed modules were not counted [176]. A future study may also explore engagement with AI-based well-being chatbots from mental health practitioners' perspective, as well as conduct qualitative research or quantitative research.

Conclusions

AI-based well-being chatbots provide users with emotional support to help alleviate conditions such as loneliness and anxiety. They are an effective solution to the lack of resources for mental health care. Exploring the factors affecting their use carries great significance. This paper extended past models by using DOI and trust theory, based on TIB. It proposed an integrated model that effectively explained the factors affecting individuals' acceptance and engagement with AI-based well-being chatbots. Among them, affect, habit, and trust play vital roles. The important theoretical role of the TIB model in the context of chatbots was validated. In addition, recommendations for the design of well-being chatbots were

presented. For example, human-centered design concepts, characterization have important practical implications. attention to ethical issues, and building trust through

Abstract

Background: Symptom checkers are designed for laypeople and promise to provide a preliminary diagnosis, a sense of urgency, and a suggested course of action.

Objective: We used the international symptom checker app (SCA) Ada App as an example to answer the following question: How do general practitioners (GPs) experience the SCA in relation to the macro, meso, and micro level of their daily work, and how does this interact with work-related psychosocial resources and demands?

Methods: We conducted 8 semistructured interviews with GPs in Germany between December 2020 and February 2022. We analyzed the data using the integrative basic method, an interpretative-reconstructive method, to identify core themes and modes of thematization.

Results: Although most GPs in this study were open to digitization in health care and their practice, only one was familiar with the SCA. GPs considered the SCA as part of the “unorganized stage” of patients’ searching about their conditions. Some preferred it to popular search engines. They considered it relevant to their work as soon as the SCA would influence patients’ decisions to see a doctor. Some wanted to see the results of the SCA in advance in order to decide on the patient’s next steps. GPs described the diagnostic process as guided by shared decision-making, with the GP taking the lead and the patient deciding. They saw diagnosis as an act of making sense of data, which the SCA would not be able to do, despite the huge amounts of data.

Conclusions: GPs took a techno-pragmatic view of SCA. They operate in a health care system of increasing scarcity. They saw the SCA as a potential work-related resource if it helped them to reduce administrative tasks and unnecessary patient contacts. The SCA was seen as a potential work-related demand if it increased workload, for example, if it increased patients’ anxiety, was too risk-averse, or made patients more insistent on their own opinions.

KEYWORDS

symptom checker app; qualitative interviews; general practice; perceived work-related psychosocial stress; job satisfaction; professional identity; medical diagnosis

Introduction

The right to diagnose is reserved for physicians and is a core element of professional authority [1]. Finding the proper diagnosis as part of GPs' expertise has been reported to contribute to physicians' perceived job satisfaction [2]. Patients also play an important role in the process. They first assess their symptoms, schedule an appointment, present their symptoms, and react to the diagnosis [3,4].

But what happens when technologies enter this process? Here we explore this with the example of the perspectives of general practitioners (GPs) on the Ada App, an internationally available symptom checker app (SCA).

Since the 1950s, physicians and computer scientists have been exploring how computers can be used to assist and improve the diagnostic process [5,6]. Part of the technologies are primarily designed to assist trained physicians or other health care professionals. Other technologies, such as symptom checkers, are designed for laypersons. A plethora of different apps exist [7]. The wording about what browser- and app-based symptom checkers actually deliver is rather heterogeneous, as the debate is ongoing [8]. For the purpose of this study, we use an operational definition: symptom checkers provide lay users with preliminary diagnoses, give a first sense of urgency, and suggest a course of action [9]. As such, we understand symptom checkers as "sociocultural artifacts" that are "(nonhuman) participants in networks of meaning and power relations" [10].

Symptom checkers are discussed ambivalently in the literature. Some expect that symptom checkers could outperform physicians' diagnostic capabilities [11], increase anxieties in patients [12], disrupt the doctor-patient relationship [10,13-15], or cause overuse of the health care system [16,17]. Further perspectives suggest that physicians' expertise and authority remain unchallenged by symptom checkers [10,18,19], patients could be empowered [12,18], and symptom checkers might have the potential to reduce physicians' workload and relieve an overburdened health care system [15,20,21]. Therefore, despite physicians not being the primary target group, symptom checkers might have far-reaching impacts on their work in terms of work content and work organization. These two dimensions are central to established models of perceived work-related stress [22-25].

As GPs are the primary access point to the health care system for patients [26], they might be particularly affected by laypersons' respectively patients' use of symptom checkers and the aforementioned impacts such as the use of the health care system or changes in the doctor-patient relationship. To date, little is known about the lived experiences and perspectives of GPs in regard to SCAs. A survey among GPs in the United States showed that only 30% had first-hand experiences with chatbots in health care [27]. One survey from Finland analyzed the experiences of health care professionals with a symptom checker at occupational health clinics and found that symptom checkers were of limited relevance in their daily work [15]. In both studies, the attitudes of the respondents mirrored the aforementioned discourse. While the studies give a first overview of relevant topics in the field, there is no in-depth

analysis of how GPs experience SCAs as nonhuman participants in their daily work and how they see SCAs in relation to their own "apostolic function" [4], that is, their expectations on patients, their illness concepts, and personal and professional values and attitudes. Depending on how GPs disintegrate or integrate SCAs in their "apostolic function," this, too, might have further impacts in regard to job satisfaction and perceived work-related stress.

This study is embedded in the multidisciplinary joint project CHECK.APP, in which the ethical, legal, and social implications of SCAs in general practice in Germany are analyzed using the example of the Ada App [28]. The Ada App [29] had originally been conceptualized as a clinical decision support system but was later redesigned for laypersons. Laypersons enter their symptoms guided by the questions in the app and will be presented with a ranking of several potential diseases in combination with a sense of urgency and potential courses of action. It appeared to be a promising case for a wider phenomenon. Its advertising campaign #tellada won the German brand award in 2019 and included slogans such as "How are you? Be honest" [30,31]. At the same time, the actual number of users remained unclear. A health insurance had planned to implement the app, but it canceled its plans due to data privacy concerns [32-34]. As such, the app represents the aforementioned ambivalence around SCAs. In this study, we take a technology-in-practice approach [35] and will focus on GPs' lived experiences with the SCA and their perspectives on it. From an occupational health perspective, we are particularly interested in the following research questions: (1) How do GPs experience the SCA in relation to the macro, meso, and micro levels of their daily work? (2) How does this relate to their professional identity, job satisfaction, and psychosocial resources and demands?

Methods

Study Design

In a scoping review on the impacts of laypersons' use of SCAs on physicians in primary care, we showed that while some publications include the perspectives and voices of physicians, they primarily portray expectations rather than lived experiences [36]. In this empirical study, we aimed to fill this gap by exploring the experiences of GPs in Germany through the in-depth reconstructive analysis of semistructured qualitative interviews. The interview study was embedded in the joint project CHECK.APP which integrates the perspectives of users, experts, and GPs and works with a mixed methods research design, including a scoping review on ethical, legal, and social aspects [8], a survey among the wider German population, a diary and interview study with app users, qualitative interviews with GPs, and qualitative interviews with experts with regards to SCAs in general and the German health care system in particular [28].

Sample

We used several common recruitment strategies: as we know from previous studies, it is almost impossible to contact GPs directly by telephone, as practice assistants act as gatekeepers [37,38]. We contacted GPs by letter, email, or fax, depending

on the information available through internet searches, and sent follow-up messages after 2-4 weeks. In addition, one of the GPs in the collaborative project (RK), who was not directly involved in this part of the study, contacted GPs through his institute's

practice network. Our final sample included 8 GPs from different regions of Germany, representing different theoretically derived dimensions of our intended sample (Table 1).

Data Collection

We developed the interview guide in several rounds, translating our research interests into final interview questions [39] (Multimedia Appendix 1). Two researchers (NR and CP) and one research assistant (EÖ) each conducted at least one of the interviews. Each interviewer obtained verbal and written consent for their interview. All 3 interviewers were trained sociologists with 3 (EÖ), 6 (NR), and 10 (CP) years of professional experience in health services research and occupational medicine. The interviews were conducted between December 2020 and February 2022 using the video conferencing tool VidyoConnect (version 21.6.3.17468; Vidyo Inc), which is provided by the University Hospital of Tübingen. The interviews lasted between 30 and 63 minutes and were recorded using an external audio recorder. The videos were not recorded. The files were transcribed by a certified office and pseudonymized by NR.

Data Analysis

The interviews were analyzed by NR, EÖ, and CP using the integrative basic method [40]. This reconstructive-interpretive method allowed the reconstruction of manifest and latent meanings by analyzing semantics, syntax, and metaphors. We chose agency and positioning as analytical approaches [40] because these proved particularly promising for understanding how GPs see and navigate themselves and their agency in a network of potentially conflicting participants and interests. We used the “Risk assessment of work-related psychological stress” of the Joint German Occupational Safety and Health Strategy (Gemeinsame Deutsche Arbeitsschutzstrategie) which operationalizes established models of work-related perceived stress [41] as a core sensitizing concept [42] for our analysis. It defines work content, social relations, work organization, work environment, and new forms of work as dimensions of work-related stress.

All interviews were interpreted line by line in order to identify the main motives and modes of thematization. Analytical case protocols were written for each interview. Interviews were continuously compared with each other. For the purpose of quality assurance, the analyses were discussed with MAR and researchers of the joint project [40]. Furthermore, we conducted a member check [43] with study participants and experts on SCAs in Germany in April 2022. The reporting of this study follows the Standards for Reporting Qualitative Research guidelines [44].

Ethical Considerations

The ethics committee of the Medical Faculty and University Hospital of Tübingen has approved the study (464/2020BO). All study participants were informed and gave consent verbally and in written form.

Results

Overview

The results reflect the perspectives of GPs and are presented along the main stages of the diagnosis process: the unorganized

stage, the patient’s decision to see a GP, and the shared process of exploring the patient’s condition.

Doctor, Have You Heard of Ada?

The GPs in this study were mostly receptive to digitalization in their area of practice and used digital tools to varying degrees to manage patient volumes and streamline workflows. These included tools that helped to free up the telephone line, tools that helped with documentation, and tools that enabled easy and direct digital communication between patients and the practice. Several GPs made it clear that the digital tools were not suitable for all patient groups but helped to relieve capacity for those patients who did not use digital tools (eg, ensuring telephone availability). Although the GPs in this study were rather receptive to digital tools, only one GP was aware of symptom checkers in general and the introduced SCA in particular. This GP used it as an additional interlocutor:

GP 3: (2) So I personally use it for patients with ... rare symptoms or unusual laboratory constellations ... too. So then ... I ask Ada, ... simply to get differential diagnoses again and then think about it: Could any of these differential diagnoses be correct?

Interviewer: During the consultation?

GP 3: No, in the evening on the couch (laughs).

Interviewer: (laughs) So you don’t finish work, but still google about Ada in the evening ... another symptom?

GP 3: Exactly. So that’s ... I usually already have an idea, and if it’s a more complicated case, I also take a blood sample. And the blood values ... I go through them in the evening anyway. And if I then somehow come to a standstill or think maybe I’ve forgotten something in the differential diagnosis, then I often use Ada and ... see if it gives me new ideas, new impulses, yes. [female, <45 years old, rural area]

This means that our results reflect expectations rather than experiences of the specific SCA and SCAs in general. However, the differences between GPs who were familiar with the SCA and those who were not were mainly in aspects of the app’s practicality, not in perspectives on the app or their work.

The SCA in the Black Box of the “Unorganized Stage”

GPs normalized patients’ desire to explore their condition and considered it helpful if patients had already thought about their symptoms, as this might help some patients to accept the outcome of the consultation.

So there is the example of the well-informed, intelligent patient who has already obtained preliminary information, which may not always be correct, but which sometimes makes it more difficult to find a diagnosis because it is unfiltered information. But I would say that, looking at all patients, it is easier if the patients have been informed in advance. You often have to revise patients’ misjudgements, but they have already considered the issue in more detail. That is on average ... It certainly always depends on the type of patient you have in the

practice, but ultimately it helps rather than harms if the patients are preinformed. [GP 8, male, 55+ years old, big city]

At best, the SCA could help patients reflect on their condition in preparation for a consultation with their GP, or reduce unnecessary patient anxiety. However, patients may include irrelevant information or omit relevant information, leading to misleading results. GPs portrayed patients as laypeople who often focus on and present subordinate aspects, use the wrong search terms when searching the internet, or are unable to assess the quality of information and follow the most appropriate course of action. According to GPs, internet searches in particular can increase patients' uncertainty and anxiety, as they may experience a flood of (negative) information and focus on the most serious potential outcomes. Some GPs preferred the SCA to internet searches because the information might be more evidence-based and focused. As such, GPs did not consider the SCA to be suitable for all patients, but only for those with eHealth literacy, general health literacy, and anxious patients, for whom the SCA might be the lesser of two evils compared to internet searches.

(...) then the app might come up with an initial result that is not quite as bad as a search engine. I don't know whether this will reassure patients, because someone who is worried about their health from home doesn't know whether they'll trust the app's result, and in the end the app has to present the result, so if in doubt, they'll go to their doctor. If one or two people with a cold don't rush straight to the GP's surgery, then perhaps there could be a marginal relief effect for GP surgeries... [GP 7, male, 45-55 years old, suburban area]

However, GPs mostly portrayed patients' path to information as a black box for GPs, as patients did not necessarily disclose their sources of information. It became clear that GPs also rarely actively asked patients where they got their information from, as they considered the source of information to be secondary once patients were in the consultation room. GPs therefore focused on what they could control: direct contact and discussion with patients. In addition, GPs emphasized that asking about the source of information would in most cases take up scarce time without adding value to their work. They felt it was more important to probe the patient's understanding of their condition ("disease model" [German: Krankheitsmodell]).

(Better) Too Early, (Than) Too Late—The SCA and Patients' Timing

GPs expressed that they were dependent on patients' decisions about when to see a doctor. They expected patients to go to the GP at the right time, but in their narratives, patients often went either too early or too late. This reasoning was embedded in the GPs' understanding of health care as a system with limited resources, with the scarcest resource being health professionals' time. In all interviews, GPs referred to the context of their working conditions, which may also shape their expectations of SCA. All GPs reported an intense workload with a high number of patient contacts. The workload has been increased by the COVID-19 pandemic. When in doubt, GPs preferred

patients to seek help too early to avoid avoidable suffering. For them, the most important question about the SCA was: would it encourage patients to seek help at the right time? If it was too risk-averse, it would send patients too early and lead to oversupply, sabotaging the GP's mandate.

So, the back pain doesn't have to be something bad, you're doing this and this and this and we'll talk again in a fortnight and you'll tell me how it's gone then. So a watchful waiting approach. Whereas so-called red flags in general medicine, that is, obviously highly conspicuous and potentially dangerous symptom indications, lead to immediate consequences. This is how we handle evidence-based general medicine, at least in my practice. If the Ada app now turns everything into red flags ... it not only destroys our health care system but also unsettles patients and does the opposite of what is also very important in general practice, namely the prevention of overdiagnosis. For a variety of reasons, of course also for reasons of cost, the economic costs, but also (pauses) to ... yes, to keep the feeling of illness away from patients. [GP 5, male, 45-55 years old, rural area]

Conversely, if the SCA was not risk-averse enough, it would lead to underuse for patients. GPs attributed the potential for both to the SCA. The SCA could give wrong results and exacerbate the challenge of resource scarcity, or it could give patients the right sense of urgency and self-care instructions for simple cases. However, GPs felt that this risk or potential of the SCA would ultimately depend on the competence or personality of the user, not the technology itself.

Some GPs were considering how to integrate the SCA into their workflow, particularly with regard to practicalities that might have the potential to reduce unnecessary patient contact and thus workload. Some imagined that the results could be made available to GPs in advance.

So ultimately it's just a decision: He has to come or he doesn't have to come, or I have to visit him or not visit him. Those are the two things that are ultimately at the end of the decision-making tree. Yes. And I have to make the decision in the end when I have looked at it and realize: OK, it doesn't look very good somehow. Then you just have to say: You have to come. Or you just have to say: I'm going there. So, that ... (2) But you don't have to ask about all this previous history because it's already done. And, well, you have to be able to rely on it, that's the crucial thing (laughs). [GP 4, male, 55+ years old, suburban area]

In this way, the SCA would document the initial history and become a tool for communication between the patient and the GP, while the GP would ultimately decide how to proceed.

Finding Diagnosis—Humble Paternalism and the Art of Sense-Making

GPs described finding a diagnosis as a process that could involve several steps, patient contacts, and time (watchful waiting, see

also the response of GP 5 above). From the GPs' perspective, both GPs and patients had a common goal: to find out what the patient had and to take the necessary measures. GPs and patients also shared the challenge of limited knowledge (see also the response of GP 3). However, from the GPs' perspective, GPs as medical experts and patients as medical laypeople had different knowledge limitations and different roles in the process. In the interviews, GPs positioned themselves as experts who, as such, were better able to search for information and assess information quality (including internet searches in medical databases and popular search engines), given their existing broad medical knowledge and years of professional experience. GPs positioned themselves as the medical authority who knew better, but who also had an ethical and legal responsibility to do their best to reach the right conclusion and treatment. GPs expected trust from their patients and offered skepticism in return. In the diagnostic process, they expected patients to share (information relevant to the GP) but not to overshare (information irrelevant to the GP) and thus to contribute smoothly to the GP's work.

So my favorite patient is the one who describes their complaints and not immediately their interpretation: "I read on Google, and that fits together." (laughs) "No, stop, (laughs) that's what I do (laughs). I would need your complaints (2) and not your interpretation of your complaints, please leave that to me." Hm, well, I would say about 20% of patients already prepare information from the internet. But to be honest, that bothers me more than it helps. [GP 6, female, 55+ years old, big city]

The GPs in this study reacted negatively to terms such as "self-diagnosis," which we used in the interview guide in reference to common wording in the literature on SCA. Our interviewees rarely used the term "diagnosis" themselves. Rather, they spoke of "ideas," "assessments," "interpretations," "perceptions," "categorizations," etc in relation to SCA, but also in relation to their work. GPs considered it potentially helpful for patients to gain an initial understanding of their case, as long as they remained open to the GPs' guidance. They therefore describe the process of exploration as one of guided shared decision-making, with the GP guiding the patient and knowing best, but ultimately knowing that the patient will decide their own direction.

When it came to the SCA in this process, the GPs drew clear boundaries.

But yes, I actually see myself more as a symptom checker myself, so (laughs) people come to me and tell me their symptoms and I'm the one who helps them categorize them. (...) I think I can do that better than any app (laughs). [GP 1, female, <45 years old, rural area]

The GPs ascribed to the SCA the potential to act as a nonhuman actor. The SCA could help guide the process of exploration—but it could also be an uncontrollable element that "spits out diagnoses," as one GP stated. GPs problematized the SCA if it disrupted their workflow and the doctor-patient relationship. GPs were concerned that the SCA could create avoidable extra

work over which GPs had no control if GPs had to deal with the impact of the app on patients before they could focus on their work. The SCA was seen as an intruder if it cemented patients' insistence on their ideas and lay diagnoses, thus causing extra work:

So I think that if the app ... for example, really just says: "Go to your GP at short notice, he should clarify this," I have no problem with that at all, I think that's a great thing. Then I don't have to do a lot of educational work, I can look at the patient and then make a decision and discuss it with them. However, if the app now throws specific diagnoses into the room, and that's what it does here, i.e. infection with the bacterium Clostridium difficile, then it could be that the app leads to more work for me because then I first have to work through the app's diagnoses and reassure the patient, and above all I have to justify why I think this is not the right thing to do, even though the app suggests it. (...) I would find that unfortunate. [GP 2, male, <45 years old, suburban area]

The GPs positioned themselves as the real intelligence against the artificial intelligence (AI) behind the SCA. From their point of view, the SCA could not offer anything that a human could not: the SCA had no empathy and could not offer physical examinations. GPs could send patients to a specialist when they reached the limits of their expertise, while the app would not send users to another, more appropriate app. They made it clear that the diagnostic process is more complex than a compilation of symptoms. From the GPs' perspective, diagnosing and finding the line between ill and not ill was a process of making sense of information. The SCA could collect potentially relevant information, and at best, organize it, but would not be able to make sense of it. GPs presented their view as limited but more objective, neutral, and less biased than that of the SCA, whose results were seen as one-dimensional. Ultimately, GPs concluded:

That depends on what the take-home message is for the patient at the end of the AI utilization, as I just said. If the take-home message is: You have complaints that (3) ... should result in a doctor's consultation within the next week - then I think that's fine. (00:30:55) If it's different, (...), then I would say to the patient: OK, now ... we're starting from scratch, please don't tell me anything about Ada, but tell me everything you told Ada again because I'm not going to let an AI take my decision-making away from me. If I go through a PHQ-9 questionnaire ... with my patient who has depression, then the questionnaire doesn't make the diagnosis, I do. But it can contribute to the validation of the diagnosis, in addition to my medical skills. And that's why AI can be part of the doctor-patient relationship, but in my view, it can't replace it - at least in the GP sector, where it's all about relationships. [GP 5, male, 45-55 years old, rural area]

Discussion

SCAs as a “Proximate Future”

This study is one of the first empirical studies of GPs' perceptions of SCA in their daily work. One of our main findings is that SCAs seem to be much less relevant in the current daily work of GPs in Germany than we had initially expected from the scientific literature and public discourse on symptom checkers. There may be several reasons for this. As we found out in the joint project, the use of symptom checkers is not widespread in the German population, that is, only a small proportion of patients actually use symptom checkers [45]. Furthermore, patients have been shown to be reluctant to share their source of information with physicians for fear of criticism from their physicians and disruption of the physician-patient relationship [46], so even if patients are using the particular SCA or other symptom checkers, they are unlikely to tell their GPs. In addition, GPs in this study reported that they did not ask patients about potential sources of information and did not differentiate between digital sources, but used the umbrella term “internet searches” for all types of digital tools. GPs might consequently have experiences with patients who use symptom checkers but might not be aware of this experience. To date, symptom checkers are rather a “proximate future” in German health care, a yet unachieved future envisioned by tech companies or other stakeholders as to be “just around the corner” and to be about to solve pressing issues of the present [47]. Centering “proximate futures” and the associated techno-utopian or techno-dystopian visions tend to distract from the unresolved issues of the present [47]. For us, then, the question is what we learn about the present work of GPs through the lens of GPs' perceptions of symptom checkers.

GPs' Perception of the SCA in Their Daily Work

GPs used language that presented the SCA and symptom checkers as “(nonhuman) participants in networks of meaning and power relations” [10]. Our results address SCA in GPs' perspectives in relation to the macro, meso, and micro levels of their work.

At the macro level of the German health care system, we are to date not only facing a demographic change in the German population and among GPs (in 2022, about 36.6% of the GPs in Germany were 60 years or older [48]) but also a shortage of GPs due to lack of young practitioners, physicians' wish for more part-time work, and an uneven distribution between urban and rural, as well as high- and low-income areas [49,50]. This is prognosed to intensify within the next decade. Some authors envision symptom checkers or other AI- or algorithm-based technologies as promising tools in a health care system of increased scarcity [17,51]. At present, symptom checkers are hardly used among the population in Germany [45,52] and—as shown by our data—are hardly known among GPs. GPs were critical about the future potentials of symptom checkers as useful participants in the German health care system if symptom checkers were too risk-adverse or not risk-adverse enough and led patients to the medically wrong time within the health care system. Patients' individual decisions to follow the suggestions of the SCA might thus have impacts on the macro level and

lead to over- or undersupply. Nevertheless, patients' current decision-making process is more complex than following the results of a symptom checker [52,53].

At the meso level, GPs considered the SCA as a nonhuman participant on the organizational level of the practice and the interpersonal level of the physician-patient relationship. Digitization in the German health care system is a fragmented and slow process [54,55]. On an organizational level, GPs work in an environment that is characterized by a patchwork of technologies that lack interoperability. They perceived symptom checkers to feed into this pattern instead of improving it. Some GPs currently use digital tools to streamline patient contacts and administrative tasks. GPs welcomed the SCA as a potential future technology if it facilitated documentation and administration or helped to reduce unnecessary patient visits. In regards to the physician-patient relationship, GPs located the SCA in the black box of the patient's search as part of the patient's “unorganized stage” [4] and “prediagnosis work” of patients [3], where it might complicate but not fundamentally damage the GPs' and patients' shared process of exploration. The SCA was attributed to the larger phenomenon of internet searches and “Dr Google” [56] which does not create a new phenomenon, but at worst reinforces an already existing one, namely patients who distrust their own health literacy, anxious patients, or patients who insist on their own assessment instead of trusting that of the GP. However, as the SCA is hardly present in the GPs' daily work, it is not perceived as having a real impact on the meso level.

On the micro level, GPs positioned the SCA in relation to themselves. GPs in this study reacted negatively to terms such as “self-diagnosis,” often used in the popular and scientific literature on symptom checkers [16,46,57], and rejected the idea that the SCA could provide a proper diagnosis. They saw the SCA as lacking the holistic view, empathy, accumulated experience, and flexibility of human physicians ([58]). Similar to other studies, GPs saw diagnosis as a process of making sense of data and information and understood the SCA as monodimensional and static, full of correct information but unable to make full sense of the data (cf. [58]). They saw themselves as real, complex, and flexible, adaptive intelligence, acknowledging their own biases and knowledge limitations, compared to an artificial, schematic thinking intelligence ([10,20,58]). They therefore framed medicine as science and art, and technology as data minus art in the present and the future. As such, the SCA would not touch the GP's professional expertise. This perspective also resonates with the current quality of symptom checkers. Databases in medicine might grow, but are biased and reinforce inequalities, and health data is of economic and political interest [59-62]. When it comes to SCAs, currently, the diagnostic accuracy of symptom checkers does not match the vision [63-65] even after decades of research [6,7,66], but they have the potential to provide an initial sense of urgency [17,63,64].

The SCA in Relation to Perceived Work-Related Resources and Demands

From an occupational health perspective, we were particularly interested in what our findings mean in the context of

professional identity, subjective job satisfaction, work content, work organization, social relationships, and work-related psychosocial resources and demands [67]. The focus on the SCA in the following should not obscure the fact that the causes of the main work-related stressors for GPs can be found and should be addressed at the macro level [68,69].

Studies have repeatedly shown that GPs in Germany have a high workload, long working hours, and a higher prevalence of burnout [70,71]. The GPs in this study are no exception to this and faced an even increased workload due to the COVID-19 pandemic. Lack of enough time is a key stressor for GPs. As a consequence, their perspective on both patients and the SCA alike is structured by the question: Who or what will cost time for what? GPs see some aspects of the SCA as a potential resource in their work. Similar to other publications, the SCA is seen as a better source of health information for patients using internet searches than, for example, popular search engines or digital encyclopedias ([12,46]). The SCA is seen as potentially increasing work demands if it increases patients' anxiety, is too risk-averse and sends patients to the doctor unnecessarily or makes patients more insistent on their view, that is, if the effects of the SCA add to the already high workload or interfere with the doctor-patient relationship as an important part of GPs' work. GPs also see the SCA as a potential resource if it "streamlines access to physicians" [58], for example, if they can see and work with the results and inform patients whether or not they should come to the practice ([17]). The latter aspect has implications for the organization of work of GPs and possibly the practice team, for example, the question of when and how to integrate the results of the SCA into the workflow [72]. A study of a symptom checker embedded in an occupational health clinic shows that physicians do not integrate the results into their workflow [15]. As implementation theories and patient-reported outcome studies have shown, the additional information will only be used by health care professionals if it is meaningfully embedded into workflows [73-75]. In another recent study, the use of an AI-based chatbot did not reduce the workload of GPs or the duration of patient visits [76]. Furthermore, if the integration of SCAs leads to an even higher density of patient-related decisions to be made by the GP or the practice team, or if they are dealt with during breaks, the potential resource could become a demand.

For the GPs in this study, similar to other studies, patient work and especially the doctor-patient relationship is an important resource in terms of their subjective job satisfaction [68], as well as finding the proper diagnosis [2]. It has been shown that administrative tasks are the least favored tasks and inhibit job satisfaction [2,77]. Anything that threatens job satisfaction is viewed critically by GPs and—from an occupational health point of view—has to be seen as critical in terms of work-related psychosocial stress, even more so if it increases an already high workload. The SCAs were seen as a potential resource if they allowed GPs to focus on patient contact, thus reducing unfavored work tasks and allowing more time for favored work content. Some authors envision the physician-patient relationship to transform fundamentally through patients' use of SCAs [78]. GPs in this study appear to be protective of the physician-patient relationship. This study shows that GPs currently see the SCA

as another means of diversifying patients' access to knowledge, rather than as a challenge to the doctor-patient relationship or their professional identity as medical experts. Treating the source of information as secondary and focusing on direct interaction with the patient can also be read as a resource for maintaining control in a network of increasing numbers of nonhuman participants. In this way, GPs also protect important pillars of their job satisfaction: the physician-patient relationship, their medical and interpersonal expertise, and the lead in the diagnostic process.

Strengths and Limitations

This study focuses on the perspective of GPs, although practice assistants also play an important role in general practice [79]. Initially, we had aimed to conduct 10 interviews with GPs that represent heterogeneous lived experiences in general practice [28]. Finding interview partners proved to be a challenge. GPs are known to have very high workloads and long working hours, so it is generally difficult to involve them in research studies [37,38,80]. The situation was exacerbated by the fact that we were looking for interview partners at the peak of the COVID-19 pandemic due to the funding period. We used various common strategies to reach out to GPs and eventually succeeded in finding 8 interview partners. The interviews were conducted between December 2020 and February 2022. We do not see striking differences between earlier and later interviews, probably also due to the fact that no COVID-19-related symptom checkers were used in Germany which might have introduced symptom checkers to a wider population. The sample only includes White GPs despite attempts to reach GPs of color and Black GPs. In addition to the aforementioned challenges, we assume unfitting sampling strategies and too homogeneous professional networks of the researchers as further reasons. It remains unclear, which impact race would have had on the perceptions of and experiences with the SCA. Within the given sample, the interview partners represent a variety of contexts and experiences and the data are rich enough to include shared patterns and conflicting perspectives [81]. Our results create resonance [40] with existing literature but also expand it. On the one hand, in terms of the issues raised by GPs in this study, we see strong parallels with the discourse on SCAs that we developed in our corresponding scoping review [36]. On the other hand, our data suggest that neither techno-utopian nor techno-dystopian visions of the literature are a dominant perceived reality in general practice in Germany. Instead, practitioners operating in a health care system of increasing scarcity display an attitude of techno-pragmatism in their daily work.

Conclusions

Some of the current scientific literature on symptom checkers presents rather techno-utopian visions of symptom checkers as a means to make health care more humane by supporting health care professionals and patients [58,82], democratizing access to knowledge and expertise [12,18], and relieving a burdened health care system [15,20,21]. Others emphasize techno-dystopian visions of a technology that outperforms or replaces humans [11,83] and becomes an uncontrollable participant in health care systems [16]. Our results show that

symptom checkers are a “proximate future” [47] rather than a lived experience among GPs in Germany. The German Federal Association of Statutory Health Insurance Physicians established the so-called Patient-Navi [84], which shows similarities to symptom checkers, and some health insurance agents are working on their own symptom checkers. Our results help to understand the context in which these technologies might enter

and to identify possible long-term effects in the future. Given the fact that the main challenges for GPs and patients can be found on the macro level of the health care system, this study also highlights that singular technological solutions do not solve complex societal issues, but can at best be one means in a plethora of means taken.

Acknowledgments

We thank all interview partners for their time and perspectives. The project was fully funded by the German Federal Ministry of Education and Research (grant 01GP1907A). The work of the Institute of Occupational and Social Medicine and Health Services Research Tübingen was supported by an unrestricted grant from the employers' association of the metal and electric industry Baden-Württemberg (Südwestmetall). The funding bodies had no role in the design of the study phases, during its execution, in the analyses of the data, or in the decision to submit any results. We acknowledge the support from the Open Access Publishing Fund of the University of Tübingen.

Conflicts of Interest

None declared.

Abstract

Background: Youth in out-of-home care encounter substantial mental health challenges because of the absence of stable family and social support systems. Their vulnerability is heightened by trauma, neglect, and abuse. They struggle, especially when transitioning to independent living, coping with loneliness, anxiety, and pressure.

Objective: This study aimed to develop a mobile app with high accessibility and long-term continuous effects to support independent living and improve mental health among youth in out-of-home care. The approach used was the systematic and step-by-step intervention mapping (IM) framework.

Methods: The program was created using the IM framework and had 6 steps. Drawing from data from individual and focus group interviews and literature reviews, we developed a logical model of the problem. We established program outcomes and objectives, defining performance objectives and variable determinants. We identified theoretical and evidence-based methods that influence determinants. The app design integrated these methods into practical applications, allowing for the creation of self-management and emotional support tools. The development process included ongoing discussions between app designers and the research team to ensure that user needs and preferences were addressed.

Results: Individual interviews and focus group discussions revealed challenges in managing daily routines and regulating emotions. The program design was based on the transtheoretical model, social cognitive theory, and elaboration likelihood model. Key features included goal setting, structured routines, emotion recognition flashcards, character models demonstrating emotion regulation strategies, verbal persuasion, and self-monitoring tools to support habit formation and emotion regulation. An implementation plan was developed to facilitate the app's adoption, execution, and maintenance, while an evaluation plan was established, including app usage analytics, user logs, and feedback surveys. A randomized controlled trial will be conducted to assess the app's impact on mental health outcomes, focusing on reducing anxiety and depressive symptoms, improving emotion regulation, and enhancing daily living skills.

Conclusions: The IM framework was beneficial in developing a mobile app to enhance the mental health of youth in out-of-home care. The study produced a program grounded in theory and evidence that caters to the needs of these individuals. Further research should aim to verify the app's effectiveness in real-world settings and refine it continuously based on user input.

Introduction

In South Korea, “out-of-home youth” refers to individuals aged 9-24 years who have been separated from their guardians due to family conflicts, abuse, violence, neglect, family dissolution, or elopement and thus require social protection and support [1].

Youth in out-of-home care settings, such as child welfare facilities, orphanages, group homes, and youth shelters, are vulnerable to mental health issues due to the absence of stable family and social support systems [2,3]. This vulnerability is worsened by trauma, neglect, and abuse, which are prevalent among these youth [4-6]. As a result, they face long-term mental health challenges, and recent evidence reports that individuals who have lived in out-of-home care experience higher mortality rates in adulthood, largely due to increased rates of self-harm, accidents, and other mental health and behavioral factors [7].

These youth are especially vulnerable when transitioning from out-of-home care to living independently [4,5]. They often fail to make realistic and specific plans for independence, resulting in anxiety and pressure [8]. When individuals leave shelters, they face a sudden lack of support, leading to economic challenges such as housing instability, inadequate job opportunities, and financial hardship [9,10]. During the transition from youth to adulthood, individuals often face various crises, and the lack of a social support system can intensify feelings of isolation, loneliness, and despair, ultimately impacting their mental health [4,5,8]. Similarly, unaccompanied youth who are homeless experience high rates of obesity and poor diet quality, with many having deficiencies in essential nutrients. This exacerbates their physical and mental vulnerabilities, contributing to long-term health issues [11].

Various interventions have been proposed to address the mental health challenges of out-of-home care youth [12]. Some studies have attempted interventions for mental health, such as art therapy [13], cognitive behavior therapy [14,15], and family therapy [16]. These interventions predominantly rely on face-to-face counseling. Furthermore, a systematic review of interventions for care-experienced children and young people found that over half of the reviewed studies were conducted in the United States, raising concerns about regional bias and the generalizability of these interventions to other contexts [17].

In addition, according to a meta-analysis by Trubey et al [12], interventions aimed at improving the mental health of children and young people in out-of-home care showed significant positive effects on depression, anxiety, and social functioning difficulties in the short term (0-6 months); however, there was no evidence of effectiveness for long-term outcomes (>6 months) [12]. Furthermore, youth in out-of-home care often lose contact with the facilities when they become independent, leading to inconsistent management and heightened vulnerability [4,5]. Hence, youth living independently should receive ongoing and structured assistance.

The intervention mapping (IM) framework is effective in designing systematic, evidence-based health interventions [18]. For example, Svendsen et al [19] developed a self-management app for low back pain, improving adherence and outcomes through tailored advice. Hadjiconstantinou et al [20] addressed psychological and behavioral factors in their type 2 diabetes management program, and Wong et al [21] enhanced recovery and autonomy with a stroke self-management intervention. These studies demonstrate the use of IM in designing various health interventions.

In this study, we created a mobile app to enhance independent living, accessibility, and long-term mental health benefits for youth in out-of-home care based on the IM approach.

Methods

Overview

A mobile app was developed from October 2023 to June 2024 to enhance the mental health of youth in out-of-home care. The app was created using the IM approach, which is a systematic method that integrates theoretical and empirical evidence to create impactful health promotion programs tailored to the needs of youth in out-of-home care [18]. It involves engaging stakeholders throughout the program development process to ensure that their perspectives and needs are considered [22]. It consists of six steps: (1) a logical model of the problem, (2) program outcomes and objectives (logical model of change), (3) program design, (4) program production, (5) program implementation plan, and (6) evaluation [18].

Step 1: Logical Model of the Problem

Establish and Work With a Planning Group

Initially, we established a multidisciplinary planning group to incorporate expertise from various domains, with a particular focus on mental health improvement, youth care, and social welfare. The group consisted of a psychiatric and mental health nurse with a PhD, a PhD graduate in child and family studies, 2 social workers serving as directors at youth shelters, and a social worker employed at a youth shelter. The planning group worked closely with an app development team, which included an app developer, a designer, and a lead app developer who also served as the server and web developer, to ensure that the digital platform was appropriately tailored to meet the needs of youth in out-of-home care. To gather feedback directly from the target population for this intervention without exposing them to the pressures or responsibilities of participating in a formal planning group, we decided not to include youth in the planning group. Instead, we conducted individual interviews to assess their needs.

Needs Assessment

We conducted a needs assessment to analyze respondents' mental health and quality of life issues, as well as their

underlying causes. The methods used for this assessment included conducting a literature review, holding individual interviews with youth living in youth shelters, and organizing focus group interviews with shelter workers.

The target population for this intervention was youth aged 18-25 years who receive out-of-home care at youth shelters and are preparing for independent living after leaving such care. This focus was motivated by two main reasons. First, previous research indicated that youth in out-of-home care are vulnerable to mental and physical health issues due to the absence of stable family and social support systems [2,3,7]. Second, youth in out-of-home care in South Korea must transition to independent living between the ages of 18 and 25 years. Thus, our target population consisted of individuals aged 18 to 25 years who are in the process of transitioning to independence.

Individual Interviews With Youth

We conducted individual interviews with 5 youths residing in 2 youth shelters. The participants were chosen purposefully to include those who could share their experiences living away from family and preparing for independence. The interview questions were designed to gather insights into the participants' experiences with mental health difficulties and their specific needs, which were crucial in structuring the intervention. The participants were asked questions such as "Have you ever experienced psychological or emotional difficulties?" and "Have you sought help during tough times?" In addition to these, they were asked about concerns related to independent living, including "What is your biggest worry as you prepare to live independently?" and "What challenges do you expect to face in your daily life after leaving the youth shelter?" as well as "What emotional or psychological challenges do you anticipate after becoming independent?" To explore their perspectives on digital interventions, participants were asked, "If there was a mental health program available through a mobile app, what kind of support would you want?" Finally, they were asked, "What advice would you like to give to the program developers?" and "Is there anything else you would like to add?" The interviews, conducted in the counseling rooms of the shelters, lasted around 1 hour.

Focus Group Interviews With Shelter Workers

We also conducted 2 focus group interviews with 10 shelter workers from 2 youth shelters. These workers were selected based on their experience of working at youth shelters for 1 year or more and their deep understanding of the experiences of out-of-home youth. The interviews focused on discussing the mental health challenges faced by these youth, instances where assistance was sought, and the need for intervention programs. To begin the interviews, the participants were asked to introduce themselves by sharing how long they have worked in their roles and a brief overview of their responsibilities. We then explored perspectives on the mental health status of youth residing in youth shelters, asking, "What do you think about the mental health condition of these youths?" As the conversation progressed, we delved into specific experiences while working in youth shelters: "Have you observed any cases of mental health difficulties among these youths?" Thereafter, we discussed experiences in assisting youth in need: "Have you

encountered any instances where a youth sought help with mental health issues?" To further understand their insights, we asked, "In your opinion, what do you think is beneficial for the mental health of youths?" We also discussed the potential of mobile applications in this context, asking, "If a mental health promotion program were to be delivered through a mobile app, in what ways do you think it could be helpful?" To conclude the interviews, we asked, "What advice would you like to give to the program developers?" and "Is there anything else you would like to add?" Each interview lasted about 1 hour and was conducted in the meeting rooms of the two youth shelters.

All interviews were audio-recorded and subsequently transcribed. The interviews were exploratory, focusing on gathering real-world needs and collaborating with stakeholders. Insights obtained from the open-ended, semistructured interviews were integrated iteratively, and any emergent trends were reviewed with the planning group.

Finally, we outlined the intervention's context, which includes the population, community, and setting. In the final step of Phase 1, we defined the program's goals.

Step 2: Program Outcomes and Objectives: Logical Model of Change

In the second step, we identified the expected outcomes from the results of Step 1. We defined the performance objectives for these outcomes and chose their determinants. A matrix was created to outline the change objectives that would impact the determinants and help achieve the performance objectives.

Step 3: Program Design

In Step 3, we conceptualized and designed the program, selecting theory- and evidence-based change methods to achieve the change objectives determined in Step 2. Theoretically, grounded change methods were translated into practical applications, with behavior change techniques (BCTs) [23] systematically applied. This phase focused on ensuring that each component of the program was based on evidence-based methods and tailored to meet the specific needs of youth in out-of-home care. Key tasks included identifying and selecting appropriate change methods based on established theories like the transtheoretical model (TTM), social cognitive theory (SCT), and elaboration likelihood model (ELM).

The TTM was chosen for its effectiveness in promoting behavior change through consciousness-raising and reinforcement management. Liu et al [24] demonstrated that TTM-based interventions help individuals understand the benefits of behavior change and maintain positive habits. By applying TTM, we aimed to support users in recognizing the value of structuring their daily routines and encouraging long-term adherence to healthy behaviors.

The SCT was incorporated for its focus on self-efficacy and observational learning. The theory postulates that internal processes, such as goal setting and self-efficacy, lead to behavioral outcomes [25], which informed our decision to apply SCT. This model supports users in setting goals, building self-efficacy, and learning emotion regulation strategies by observing others.

The ELM was selected to enhance emotional recognition through repeated exposure to emotional stimuli. Petty and Cacioppo [26] emphasized that repeated messaging can significantly influence attitudes and behavior, making ELM a suitable model for improving users' emotional awareness and regulation. This theory helps explain how consistent exposure to emotional content can lead to deeper emotional understanding and behavior change.

These theoretical methods were then translated into practical applications by designing specific features within the mobile app to deliver the selected change methods effectively. We prioritized a user-centered design approach, as recommended by Johnson et al [27] and Bakker et al [28], for enhancing the app's usage and effectiveness. The practical applications were developed to be user-friendly and engaging, allowing users to easily interact with the app and incorporate desired behaviors into their daily routines. The aim was to create a structured theoretical framework to help youth in out-of-home care manage their daily lives independently and improve their emotion regulation abilities.

Step 4: Program Production

Each component of the intervention app was developed systematically by integrating theoretical foundations, designing the user interface, and implementing functionalities. This step aimed to ensure the app's practical applicability and functionality. Educational content, messages, and images depicting characters and emotions were also developed in a structured manner. An iterative development process was employed, working with the app development team to check and revise the prototype. Regular meetings were held with the lead app developer to communicate requirements, review screen designs, and discuss necessary modifications. These discussions were essential to consider and finalize the design modifications and ensure that the app met all the requirements.

Step 5: Program Implementation Plan

The fifth step involved creating a comprehensive program implementation plan. This plan included strategies to ensure that the mobile app, which was designed to improve the mental health of youth in out-of-home care, was effectively adopted, used, and maintained over time.

Step 6: Evaluation Plan

The sixth step was to develop a plan to evaluate if the app had achieved its goals and objectives. This plan focused on conducting a thorough assessment of the app's effectiveness, covering both process and outcome evaluations.

Ethical Considerations

This study was approved by the Eulji University Institutional Review Board (approval EU23-43). Participants in the needs assessment interviews received detailed information about the study, and written consent was obtained before their participation. They were assured of their right to withdraw consent verbally at any stage of the interview, even after it had started, without facing any negative consequences. All collected data were anonymized and securely stored in encrypted files, accessible only to the research team. As an expression of

gratitude, participants were offered a gift card worth 50,000 Korean won (approximately \$35 USD).

Results

Step 1: Logical Model of the Problem

Our literature review revealed that young people living in youth shelters often experience a high prevalence of mental health issues, like anxiety, depression, suicidal thoughts, and a poor quality of life [4]. After leaving youth shelters, they often experience isolation, loneliness, despair, and suicidal thoughts as they navigate the challenges of independent living [7].

Individual interviews were conducted with 5 adolescents aged 18-23 years who had been living in shelters for 5 months to 5 years. Many of the participants appeared to be either overweight or obese. Participants have experienced feelings of loneliness, depression, and, in some cases, suicidal thoughts. When facing difficult times, they sought support primarily from their romantic partners, peers, and shelter staff. When asked about their biggest concerns regarding independent living, financial stability was the primary worry, especially related to securing housing and managing living expenses after leaving the shelter. Day-to-day challenges, such as waking up on time and preparing meals, were significant concerns for many due to their limited experience in these areas. They described their current unstructured daily lifestyle—waking up late, spending most of their time lethargically in the shelter, and frequently looking at their smartphones. This reflects a lack of knowledge about healthy daily routines and the absence of motivation to maintain them (lack of knowledge about the advantages of daily routines, lack of motivation to structure daily routines). Psychologically, they expressed fears of dealing with loneliness after becoming independent. They mentioned that they would appreciate having a mobile app they could use daily, especially one that included visual elements like characters to make the experience more engaging.

Focus group interviews were conducted with shelter staff between the ages of 29 and 59 years, who had 1 to 9 years and 11 months of work experience. They specialized in counseling psychology, social welfare, youth education, counseling, and youth studies. The staff explained that the mental health of adolescents entering shelters recently was worse compared to those in the past, with many experiencing higher levels of depression and anxiety. Most adolescents spend the majority of their day on their phones, engaging in social media, calls, YouTube videos, and games. During their days off, they often wake up around 1-2 PM, have meals at the shelter, socialize with friends, and return just before bedtime. This indicates a lack of motivation to adopt healthy behaviors, such as exercise or balanced meals, and the absence of habits that support a healthy lifestyle (lack of knowledge about the importance of healthy behaviors, lack of habit in maintaining healthy behaviors).

The staff observed that some adolescents at the shelter have difficulties with emotional regulation, including depression and anxiety, and actively seek counseling. At times, some adolescents stay up past bedtime due to self-harm urges and

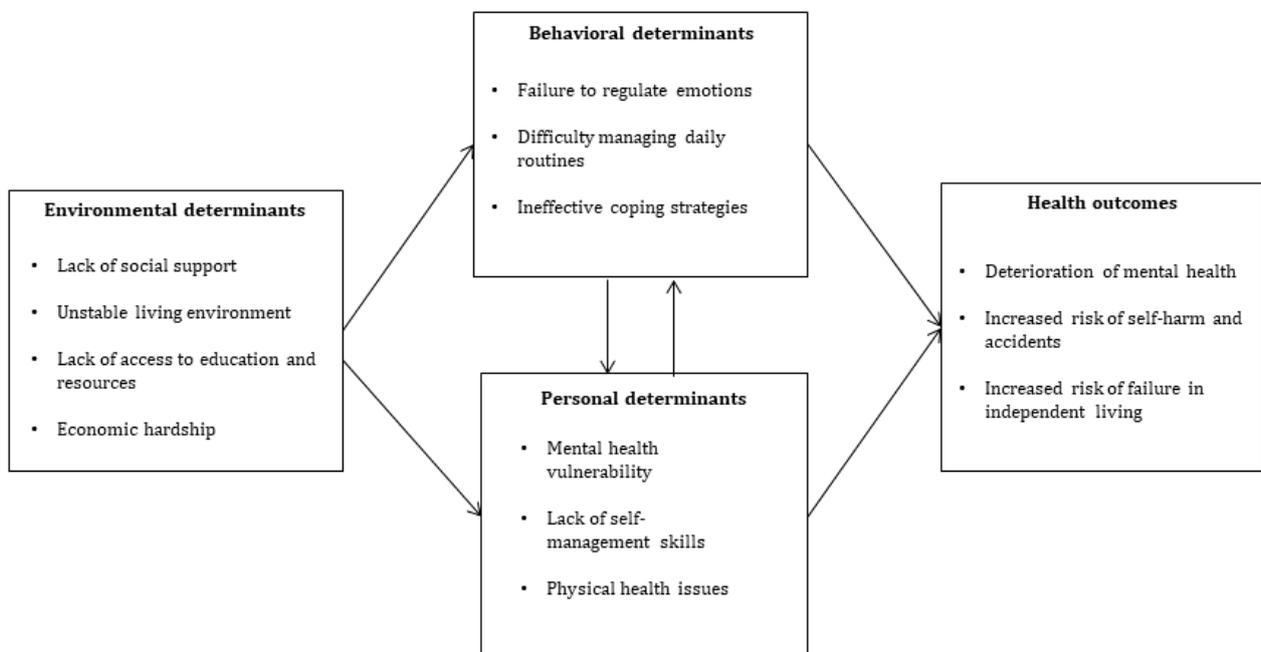

turn to teachers for assistance. They also discussed how adolescents struggle to regulate their emotions even in the presence of peers and teachers. Furthermore, when these adolescents transition to living independently, they experience loneliness and depression, prompting them to seek support. This is connected to the lack of strategies for emotional regulation and the absence of motivation to implement those strategies consistently (lack of knowledge about emotional regulation strategies, lack of motivation to regulate emotions).

The staff mentioned that some adolescents struggle to manage their daily lives and emotions even after becoming independent. In some cases, they choose to return to the shelter. In addition, some adolescents do not maintain contact after leaving. Therefore, the staff suggested that a mobile app could assist youth in managing their daily lives and emotions postindependence. The program will help youth develop the

knowledge and habits necessary for managing their emotions, as well as motivate them to consistently track and regulate their emotional states (lack of habit in tracking emotions, lack of acceptance of one's emotions).

Out-of-home youth living in shelters encounter challenges due to a lack of support from family and caregivers, resulting in feelings of anxiety, depression, and a tendency to engage in self-injury. In their transition to independent living, many youth face loneliness, leading to feelings of powerlessness, difficulties in daily life management (lack of structured routines, poor habit formation), and struggles with emotional regulation (lack of emotional regulation strategies, lack of motivation). The proposed program aims to empower youth in out-of-home care to address these challenges by effectively managing their daily lives, regulating their emotions, and improving their stability and emotional well-being (Figure 1).

Figure 1. Logical model of the problem.

Step 2: Program Outcomes and Objectives: Logical Model of Change

Based on the findings of the initial phase, the expected program outcomes were: (1) young people managing their daily lives independently and (2) young people enhancing their emotion regulation. Specific performance objectives for independently managing daily lives included structuring and maintaining daily routines, as well as developing healthy habits. In addition, performance objectives for enhancing emotion regulation in young people involved in expressing their emotions and implementing strategies for emotion regulation.

There is evidence that knowledge influences attitude, leading to behavioral changes. Habit formation is crucial for lasting behavioral change, especially when dealing with changing attitudes and temptations [29]. In this study, knowledge, attitude, and habits were chosen as determinants. For out-of-home youth with little family and adult support, forming habits is a key factor in being able to manage daily life and emotions independently. The change objectives are outlined for each of the four performance objectives in the three determinant areas (Table 1).

Table 1. Matrix of change objectives.

Outcome and PO ^a	Determinant		
	Knowledge or cognition	Attitude or motivation	Habit
Young people manage their daily lives independently			
PO 1. Young people structure and maintain their daily routines (e.g., time management, scheduling)	K.1. Identify the advantages of structuring daily routines	A.1. ^aPO: performance objective.

Step 3: Program Design

The theory-based program design and practical applications to achieve change objectives are detailed in [Table 2](#). Core components of the program include structuring and maintaining

routines, and regulating emotions delivered by a smartphone app. The design was based on behavioral change theories to provide users with tools to manage their daily lives and emotions. BCTs [23] were applied to operationalize the theoretical methods and provide structured guidance to users.

Table 2. Explanations of changeable determinants, theory- and evidence-based change methods, and practical applications.

Determinant, change objective, and theory	Method	BCTs ^a	Practical application	Text description	
Knowledge or cognition					
<ul style="list-style-type: none"> K.1. Identify the advantages of structuring daily routines K.2. Identify the importance of healthy behaviors 	Transtheoretical model	Consciousness raising	4.1 Instruction on how to perform a behavior	Intro session with educational messages on the app	The intro session provides users with educational messages explaining the importance of structuring daily routines and maintaining healthy behaviors.
<ul style="list-style-type: none"> K.3. Identify and name a range of emotions 	Elaboration likelihood model	Message repetition	4.1 Instruction on how to perform a behavior	Emotion flashcards	Flashcards repeatedly show various emotions to help users recognize and label their emotions more accurately.
<ul style="list-style-type: none"> K.4. Identify strategies to regulate one's own emotions 	Social cognitive theory	Observational learning	2.1 Others monitoring with awareness	Observing a character model regulating their emotions	Users learn emotion regulation strategies by observing how character models handle their emotions.
Attitude or motivation					
<ul style="list-style-type: none"> A.1. Recognize the advantages of structured daily routines A.2. Recognize the importance of healthy behaviors 	Social cognitive theory	Goal setting	1.1 Goal setting (behavior)	Setting daily routines, including healthy behaviors	Users set personal goals for structured routines and healthy behaviors, such as regular exercise and a balanced diet, to develop positive habits
<ul style="list-style-type: none"> A.3. Express an accepting attitude towards one's own emotions 	Elaboration likelihood model	Message repetition	5.4 Self-assessment of affective consequences	Selecting an emotion flashcard and choosing the corresponding word for the emotion	The flashcards and repeated exposure help users build a positive attitude toward acknowledging their emotions.
<ul style="list-style-type: none"> A.4. Express an attitude of openness to regulate emotions 	Social cognitive theory	Observational learning	3.3 Social support (emotional)	Character showing empathy toward their emotions	Character models in the app show empathy towards users' emotions, helping to build a supportive and motivating environment for emotion regulation.
<ul style="list-style-type: none"> A.4. Express an attitude of openness to regulate emotions 	Social cognitive theory	Verbal persuasion	15.1 Verbal persuasion to boost self-efficacy	Offering positive reinforcement through verbal encouragement	Verbal encouragement, such as "you can do it," boosts users' confidence in their ability to regulate emotions and motivates them to make initial efforts.
Habit					
<ul style="list-style-type: none"> H.1.a. Monitor the progress of achievement of daily routines H.1.b. Stick to routines to turn them into habits H.2.a. Monitor the progress of achievement of healthy behaviors H.2.b. Stick to healthy behaviors to turn them into habits 	Social cognitive theory	Self-monitoring	2.3 Self-monitoring of behavior	Tracking daily achievements using a calendar function	Users track daily routines using a calendar that displays progress from the start of the month to the present day. Progress is visualized with a cake filling piece by piece on the daily screen.

Determinant, change objective, and theory	Method	BCTs ^a	Practical application	Text description
Social cognitive theory	Feedback	2.2 Feedback on behavior	Informing and displaying routine accomplishments	The program provides feedback by completing the cake visual when all daily routines are achieved, motivating users to maintain routines.
Transtheoretical model	Reinforcement management	10.2 Material reward	Rewards for maintaining routines; points for achievements	Users earn points for maintaining routines and healthy behaviors, reinforcing positive habit formation.
				<ul style="list-style-type: none"> • H.3.a. Incorporate emotional expression into daily routines • H.3.b. Track one's own emotions
Social cognitive theory	Feedback	2.2 Feedback on behavior	Notifications to encourage the expression of emotions	If users do not log their emotions, the app sends a pop-up notification reminding them to record their emotions as part of their daily routine.
Social cognitive theory	Self-monitoring	2.4 Self-monitoring of the outcome of behavior	Visualizing weekly emotions in a graph	Users can monitor their emotions through visual graphs that summarize their emotional states over time, encouraging self-reflection and awareness.
				<ul style="list-style-type: none"> • H.4. Incorporate regulating emotions into daily routines
Transtheoretical model	Reflection	15.4 Self-talk	Keeping an emotion diary	Users keep an emotion diary to reflect on their emotional states, helping to improve emotional regulation.
Transtheoretical model	Reinforcement management	10.2 Material reward	Points for completing each routine task and diary entry	Users earn points for completing routine tasks and maintaining an emotion diary, encouraging consistency in emotional regulation.

^aBCT: behavior change technique.

Consciousness-raising techniques from the TTM helped users understand the benefits of organizing routines and fostering healthy behaviors [30]. Emotion recognition was enhanced using the ELM through repeated exposure to emotion flashcards [26]. Observational learning from the SCT was applied by character models demonstrating emotion regulation [25].

To further enhance motivation, the SCT's goal setting allowed users to establish routines and healthy behaviors independently, while verbal persuasion and supportive character models built confidence in emotion regulation. Self-monitoring and reinforcement strategies from the SCT and TTM supported habit formation and emotional regulation [31,32].

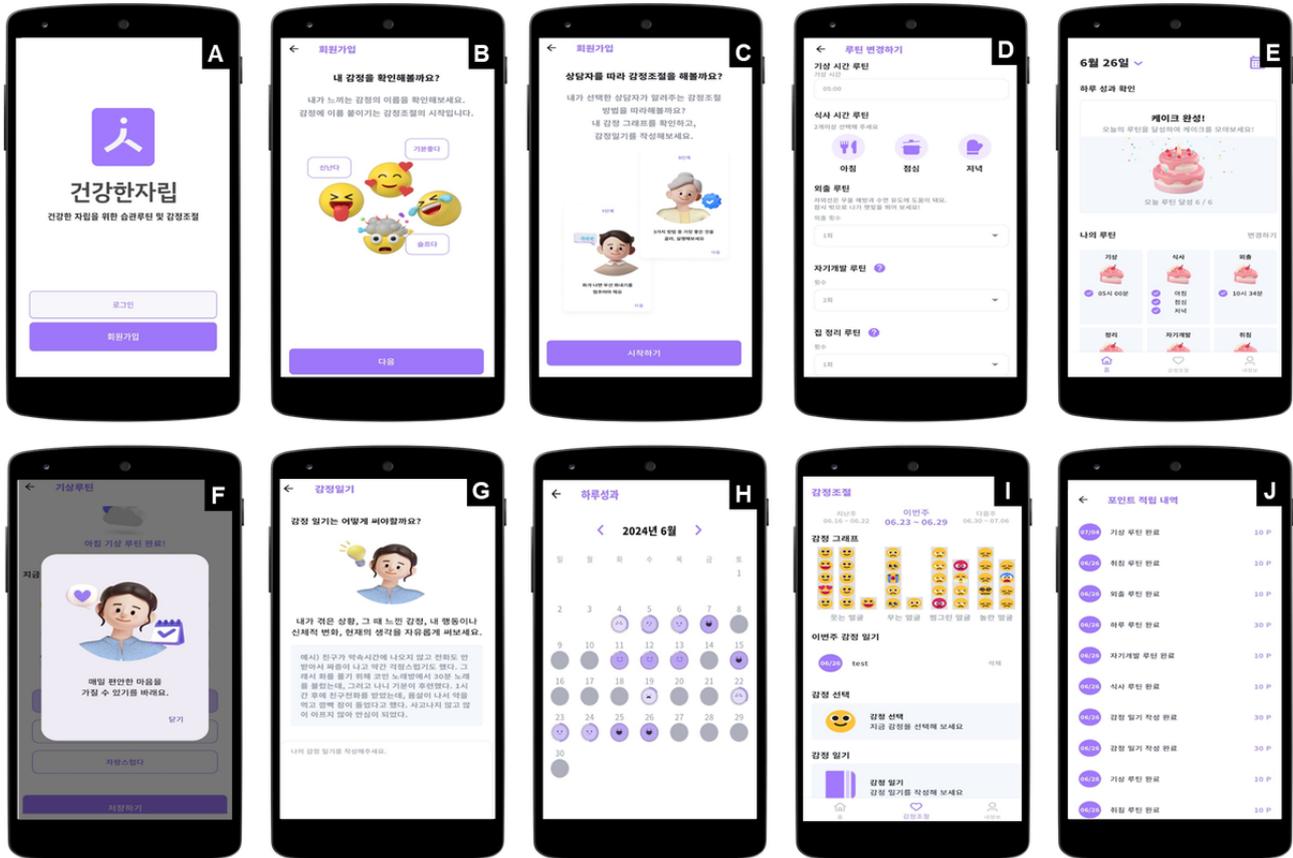

These theoretical methods were operationalized into practical strategies through the application of BCTs [23], including goal

setting, self-monitoring, and reinforcement, which facilitated users in adopting and sustaining behavior changes in their daily routines.

Step 4: Program Production

The fourth step involved developing the specific components of the program to give it a viable form. To create an app for youth in out-of-home care, the program was designed by incorporating information gathered in Steps 1 to 3. Prototypes were utilized in designing the app's structure and main features, focusing on making the interface intuitive and visually appealing for easy use by the youth. Figure 2 offers an overview of the mobile app's user interface, showcasing the main components and navigation elements. It presents the home screen comprehensively, including the dashboard, navigation menu, and key interactive features like touchable buttons and icons.

Figure 2. Overview of the app interface. A: Login screen. B, C: Introduction to the app’s purpose and features for managing routines and regulating emotions. D: Screen for setting and modifying daily routines, such as wake-up time, bedtime, meal frequency, and personal development activities. E: Visual representation of daily achievements using a cake image that fills as routines are completed. F: Feedback section where users select their feelings after completing routines and receive messages from a counselor. G: Emotion diary for recording and managing feelings. H: Calendar that shows monthly progress. I: Graph that visualizes emotional changes over time. J: Points section where users can view and track points earned for completing routines.

Once users sign in and provide their information, they can use the app after obtaining approval from the administrator. Approved users receive guidance on using the app, including details regarding the importance of daily routines and healthy behaviors. Users then select a character to represent themselves and another character to act as their counselor. Subsequently, they set their daily routines, which include wake-up time, bedtime, number of outings per day, number of meals per day (at least 2), personal development activities (eg, reading, exercising, and studying), and household chores (eg, cleaning and washing dishes). The default home screen displays the current date and provides visual feedback, showing a cake image that is filled in based on routine completion. In addition, the calendar function allows users to visually track their daily achievements and serves as a self-monitoring tool to easily observe their progress.

During the day, users can input whether they completed their routines and the time spent doing so. They can then select their emotions from a list of 12 emoticons, along with appropriate verbal expressions. The counselor’s character provides messages based on the selected emotions to create an emotionally supportive environment. For instance, if a user chooses “anxious,” they receive advice such as, “Something is making you anxious. Consider the causes and prioritize tasks to write down. Talking or writing about your problems can help calm

your negative emotions.” This can aid users in recognizing and managing their emotions.

The Emotion Regulation tab shows facial images gathered over a week in a graph, allowing users to visually monitor their emotional changes. In addition, users can write emotion diaries to document and analyze their feelings, aiding in improved understanding and management of emotions.

In the My Info tab, users can view basic information such as their characters, accumulated points, and set routines. They can also check and modify their routines at any time. The Settings tab offers options to change passwords, set notifications, and log out or reset accounts.

The development of the mobile intervention app followed a structured process that included defining requirements, screen planning, development, testing, and deployment. The development environment consisted of both a web-based system for data and user management and a mobile application. The mobile application was developed as a hybrid app designed for both Android and iOS platforms to maximize accessibility for users. The app was registered and made available through the Google Play Store and Apple App Store. User data was securely stored in the MySQL database, and the server was hosted on Amazon Web Services to ensure robust data protection. Security measures were carefully implemented to protect user information. User authentication was managed using JSON

Web Token, providing a secure method for validating user sessions. All data transmissions were encrypted using SSL/TLS through the HTTPS protocol, ensuring that sensitive information remained protected during communication between the app and the server. In addition, server access control was strictly managed to further enhance security.

Step 5: Program Implementation Plan

The fifth step is a detailed plan on how we envision the adoption, implementation, and long-term maintenance of the app within shelter settings. The program uses outcomes (adoption and implementation) that were developed with specific performance objectives for both the shelter staff and youth. Using

normalization process theory [33], we identified changeable determinants that could influence the successful integration of the app into daily routines. These determinants were crossed with performance objectives to establish clear change objectives. The theoretical foundation for our strategies is based on BCTs [23], which informed the methods for fostering app adoption and ensuring its sustained use. Practical strategies include training sessions for staff, peer ambassador programs, and motivational tools for the youth, which were all designed to encourage continuous engagement with the app. Table 3 outlines the detailed performance objectives, change objectives, and corresponding strategies for both adoption and implementation.

Table 3. Plan for program adoption and implementation.

Program use outcomes, performance objectives, and determinants (NPT ^a)	Change objectives	BCTs ^b	Practical strategies
Adoption outcome			
Shelter staff adopt the app			
Coherence: Staff understand the benefits of the app	Staff will develop an understanding of how the app supports mental health management	4.1 Instruction on how to perform a behavior	Provide informational sessions and materials on the app’s benefits for mental health.
Staff encourage youth to use the app regularly			
Cognitive participation: Staff engage in the program	Staff will actively promote app use to youth in their daily routines	1.8 Behavioral contract	Staff will commit to a plan to introduce the app to youth and track usage
Collective action: Staff train youth on app use	Staff will train youth to use the app and integrate it into daily life	4.1 Instruction on how to perform a behavior	Staff will provide step-by-step training on app functionality and its benefits.
Implementation outcome			
Youth use the app daily			
Coherence: Youth understand how the app helps manage emotions	Youth will understand the purpose of the app and its features	4.1 Instruction on how to perform a behavior	Educational sessions and motivational posters will explain the app’s purpose.
Cognitive participation: Youth engage in regular use	Youth will commit to using the app daily to track emotions and routines	8.1 Behavioral practice or rehearsal	Youth will be encouraged to practice app use through daily emotional logging and tracking routines.
Reflexive monitoring: Youth track progress and give feedback	Youth will evaluate how the app helps them manage their daily routines	2.3 Self-monitoring of behavior	Youth will log daily routines and emotions; feedback will be collected for improvement.
Sustainability			
Maintain app usage long-term			
Collective action: Peer ambassadors promote the app	Ambassadors will share success stories to encourage long-term app use	6.3 Information about others’ approval	Peer ambassadors will share their experiences and offer support through group sessions.
Reflexive monitoring: Continuous improvement	Youth will provide feedback for app improvements	1.5 Review of behavior goals	Regular feedback sessions will be held to improve app functionality and user experience.

^aNPT: normalization process theory.

^bBCT: behavior change technique.

Step 6: Evaluation Plan

The sixth step involved creating a detailed and comprehensive plan to evaluate the designed mobile app. This evaluation plan

aims to systematically analyze the implementation process and effectiveness and identify areas for improvement, if necessary.

Process Evaluation

Process evaluation confirms whether the app is being implemented as planned and assesses the fidelity of its implementation. Key indicators include the number of youths using the app, frequency of app usage, levels of user engagement, and the frequency with which users use the key features of the app. These data will be collected through various methods, including app usage analytics software, user logs, and feedback surveys from youth residing in shelters. Real-time data collection will be implemented to analyze usage patterns and engagement levels. User logs will track individual user activities to help identify the most and least used features. Regular feedback surveys will assess subjective user experiences and satisfaction, covering aspects such as ease of use, usefulness of features, and overall satisfaction. In addition, in-depth interviews will be conducted to gain a more detailed understanding of user experiences, focusing on the strengths, weaknesses, and areas for improvement of the app. This comprehensive data collection will help determine if the app is being implemented as planned, identify any unforeseen issues, and understand the most beneficial features to users.

Effectiveness Evaluation

The program's effectiveness will be assessed through a randomized controlled trial. Participants will be assigned randomly to either the experimental or control group using computer-generated random allocation. The experimental group will receive the app intervention, while the control group will receive standard care provided by the shelters during the trial. In consideration of ethical concerns, the control group will be given access to the app after the intervention period has ended, ensuring that all participants can benefit from the app. The evaluation will focus on the app's effects on youth's mental health, daily living skills, and emotion regulation. Key measures will include decreases in anxiety and depressive symptoms, better emotion regulation, and improved daily living skills. Data collection methods will include pre- and post-surveys, standardized mental health assessment tools (such as the Beck Depression Inventory and Generalized Anxiety Disorder Scale), and user interviews.

Quantitative data analysis will be conducted using IBM SPSS (version 26). The 1-way, repeated-measures, multivariate ANOVA will be used to assess the intervention effects. Qualitative data from interviews and open-ended survey responses will undergo thematic analysis to gain deep insights into user experience and app effectiveness. This thorough evaluation plan aims to systematically evaluate the app's implementation process and outcomes, aiming to enhance youth's mental health. Our goal is to optimize the app's effectiveness and promptly make any necessary improvements.

Discussion

Principal Results and Comparisons With Previous Work

A mobile app was developed in this study to enhance the mental health of youth in out-of-home care using the IM approach. The

app was created through a systematic and step-by-step development process.

Earlier studies have used the IM approach to create successful health promotion programs for different health concerns [19-21]. Nonetheless, IM-based mental health promotion initiatives aimed at youth residing in shelters are scarce. Furthermore, programs developed in previous studies frequently depend on brief interventions centered on in-person counseling, posing challenges in maintaining lasting impacts [12,17]. In South Korea, mental health apps such as MindLink [34] and Mind Café provide early intervention and emotional support to youth, but they are not specifically designed for youth residing in shelters. MindLink, for example, focuses on psychosis intervention, while Mind Café provides short-term emotional support through counseling, but it may be limited due to cost-related barriers to sustained access. These apps are valuable for their specific purposes but lack tailored features to address the unique needs of youth in out-of-home care. The mobile app developed in this study was created to overcome these limitations by providing accessible emotional support and daily management functions to youth. Emotion flashcards and self-monitoring tools assist users in recognizing and regulating their emotions independently, helping them cultivate their ability to self-manage even after leaving the shelter.

Our program was designed after conducting a comprehensive needs assessment of youth living in shelters. A previous study has emphasized the importance of a thorough needs assessment to improve program effectiveness [35]. This study investigated the behavioral and environmental factors influencing mental health issues by reviewing literature and interviewing youth in out-of-home care and shelter staff with the aim of providing tailored interventions.

We designed a program using theories like the TTM, SCT, and ELM to improve the scientific validity of the program's mental health promotion program. By integrating these theories, our program identified knowledge, attitudes, and habit formation as key determinants, applying each theory's methods to enhance the app's effectiveness. Previous studies that incorporated these theories have shown positive outcomes.

We prioritized a user-centered design approach to enhance the app's usage and effectiveness. To increase youth's engagement and persistence, we implemented various strategies. For instance, users have the option to personalize their experience by selecting both their own character and their counselor's character. The app's user-friendly design, combined with a visual reward system for completing daily tasks, sparks interest and boosts engagement, encouraging continuous use. Users can establish their daily routines and receive visual cues indicating progress, such as a cake image that fills up as they complete tasks, providing a sense of achievement. When users choose an emotion from a list, the counselor responds with appropriate messages to foster emotional support. For example, if a user selects "anxious," the counselor's character might suggest, "Identify what's causing your anxiety and focus on tackling simple tasks first. Acknowledging and addressing your problems can help alleviate negative feelings." This feature enhances emotional support and equips users with tools to manage their

emotions effectively. The Emotion Regulation section displays facial expressions accumulated over a week, allowing users to monitor changes in their emotions. By keeping emotion diaries, users can record and reflect on their feelings, which enhances their emotional awareness and regulation skills.

Limitations

The interviews conducted during the needs assessment of this study's development process focused on gathering real-world needs and collaborating with stakeholders. Therefore, insights obtained from these interviews were integrated iteratively, and any emergent trends were reviewed with the planning group. However, using formal analysis frameworks in future projects could enhance rigor and reliability. This study focused on developing a mobile app but did not confirm its effectiveness through application and evaluation. This limitation hinders the assessment of the app's effectiveness and user satisfaction. Future research should validate the app's long-term effectiveness in real-world scenarios. The study specifically targeted youth living in shelters in a specific region, limiting the generalizability of the findings to youth in other regions and cultural contexts. Further research is necessary to evaluate the

app's use among youth from various regions and cultural backgrounds.

Conclusions

This study outlines the development process of a mobile app aimed at enhancing the mental health of youth in out-of-home care using the IM approach. The app was created to assist youth in managing their daily lives and regulating their emotions independently, offering high accessibility and continuous support. The systematic development process and theoretical foundations for designing the app's structure and features are described, along with plans for evaluating its process and effectiveness.

Although real-world use of the app was not evaluated in this study, the systematic approach and substantial stakeholder involvement in the development phase indicate its potential effectiveness. Future research should focus on assessing the app's real-world usage and incorporating user feedback for continuous improvement. Additional studies are anticipated to establish a strong foundation for developing and implementing digital health interventions that can significantly improve the mental health and well-being of youth in out-of-home care.

Abstract

Background: Current methods of monitoring cognition in older adults are insufficient to address the growing burden of Alzheimer disease and related dementias (AD/ADRD). New approaches that are sensitive, scalable, objective, and reflective of meaningful functional outcomes are direly needed. Mobility trajectories and geospatial life space patterns reflect many aspects of cognitive and functional integrity and may be useful proxies of age-related cognitive decline.

Objective: We investigated the feasibility, acceptability, and preliminary validity of a 1-month smartphone digital phenotyping protocol to infer everyday cognition, function, and mood in older adults from passively obtained GPS data. We also sought to clarify intrinsic and extrinsic factors associated with mobility phenotypes for consideration in future studies.

Methods: Overall, 37 adults aged between 63 and 85 years with healthy cognition (n=31, 84%), mild cognitive impairment (n=5, 13%), and mild dementia (n=1, 3%) used an open-source smartphone app (mindLAMP) to unobtrusively capture GPS trajectories for 4 weeks. GPS data were processed into interpretable features across categories of activity, inactivity, routine, and location diversity. Monthly average and day-to-day intraindividual variability (IIV) metrics were calculated for each feature to test a priori hypotheses from a neuropsychological framework. Validation measures collected at baseline were compared against monthly GPS features to examine construct validity. Feasibility and acceptability outcomes included retention, comprehension of study procedures, technical difficulties, and satisfaction ratings at debriefing.

Results: All (37/37, 100%) participants completed the 4-week monitoring period without major technical adverse events, 100% (37/37) reported satisfaction with the explanation of study procedures, and 97% (36/37) reported no feelings of discomfort. Participants' scores on the comprehension of consent quiz were 97% on average and associated with education and race. Technical issues requiring troubleshooting were infrequent, though 41% (15/37) reported battery drain. Moderate to strong correlations ($r \geq 0.3$) were identified between GPS features and validators. Specifically, individuals with greater activity and more location diversity demonstrated better cognition, less functional impairment, less depression, more community participation, and more geospatial life space on objective and subjective validation measures. Contrary to predictions, greater IIV and less routine in mobility habits were also associated with positive outcomes. Many demographic and technology-related factors were not associated with GPS features; however, income, being a native English speaker, season of study participation, and occupational status were related to GPS features.

Conclusions: Theoretically informed digital phenotypes of mobility are feasibly captured from older adults' personal smartphones and relate to clinically meaningful measures including cognitive test performance, reported functional decline, mood, and

community activity. Future studies should consider the impact of intrinsic and extrinsic factors when interpreting mobility phenotypes. Overall, smartphone digital phenotyping is a promising method to unobtrusively capture relevant risk and resilience factors in the context of aging and AD/ADRD and should continue to be investigated in large, diverse samples.

Introduction

Background

Alzheimer disease and related dementias (AD/ADRD) place immense pressure on our health care system. They represent a global issue that is worsening and will be exacerbated by insufficient disease screening methods and a lack of ecologically valid outcome measures for clinical trials [1]. New and innovative approaches for early detection and monitoring are direly needed to address this global crisis. In this paper, we present results from a proof-of-concept study demonstrating the promise of smartphone digital phenotyping to capture clinically relevant risk factors and outcomes in the context of aging and AD/ADRD.

Decades of clinical trial research indicate that early intervention will be critical for effective AD/ADRD treatment [2-5]. Biomarker testing (eg, positron emission tomography neuroimaging and cerebrospinal fluid), traditional neuropsychological evaluation, and clinician- or informant-rated assessments have historically been the gold-standard methods for detection and diagnosis. However, these methods present drawbacks, including limited accessibility (eg, proximity and cost), scalability (ie, logistical constraints for wide-scale clinical implementation), prognostic value (ie, inconsistent correspondence with clinical progression), and ecological validity (ie, poor representation of real-world functioning) [6-10]. Traditional neuropsychological measures are also affected by sociocultural factors, such as educational quality, socioeconomic status, native language status, and acculturation, rendering them inappropriate for the increasingly diverse global population [11-20]. Subtle difficulties in complex everyday tasks signal early decline and are critical to assess; however, standard functional assessments are limited by recall bias, availability of an informant reporter, bias due to attributes of the informant, outdated items, and poor sensitivity [21-27]. Patterns and trajectories of cognitive and functional decline are also extremely heterogeneous and person-specific [28-30] and are thus difficult to assess using a one-time standardized assessment measure. Taken together, health care systems are ill-equipped to screen for early signs of cognitive impairment at scale, as evidenced by recent estimates that 92% of cases of mild cognitive impairment (MCI) remain undiagnosed [31-34]. In addition to poor screening methods, traditional clinical trial outcome measures are not sufficiently meaningful and precise to demonstrate therapeutic benefit at early stages [4,25,35-40]. Thus, a growing priority in the field of AD/ADRD is to develop and implement sensitive and functionally meaningful screening

and outcome measures as new therapies are evaluated earlier in the disease course [41].

New digital assessment methods have great potential for efficient, accessible, sensitive, and objective assessment of early cognitive and functional changes reflecting risk for AD/ADRD [6,7,42-46]. Digital tools can capture microlevel behavioral data with increased sensitivity and reduced sample size requirements compared with traditional paper-and-pencil neuropsychological measures and functional scales [47]. Gathering this information at home can address accessibility limitations for those in rural environments or who face hardships traveling to and from a clinical site, and may provide a more reliable and ecologically valid representation of real-world functioning compared to traditional evaluation at a single time point in a highly controlled setting [48-50]. As global technology use and affordability of personal devices continue to rise [51,52], new technologies can potentially address crucial gaps in the scalability and accessibility of current methods and counteract higher rates of missed diagnosis among populations experiencing low socioeconomic status [34,53-57].

Digital phenotyping is one innovative approach that uses the “moment-by-moment quantification of the individual-level human phenotype in situ” based on interactions with technology, including smartphones and smart home devices, to capture social and behavioral data passively, continuously, and with minimal interference [58-60]. It collects high-frequency, fine-grained data reflecting everyday behaviors “in the wild” without relying on user engagement, subjective reports, or burdensome procedures. Preliminary support has been demonstrated in psychiatry studies leveraging a host of sensors (eg, GPS, accelerometer, Wi-Fi or Bluetooth signals, ambient sound and light, app use, call and text message metadata, and keystroke dynamics) and imputed behavioral features (eg, time spent at home, sleep cycles, level of socialization, and routine or anomalies) to predict clinical outcomes, including depression and bipolar disorder symptoms, suicide risk, psychosis relapse, and depression treatment response [61-70]. In the context of neurodegenerative disorders, several sensors—particularly keystroke dynamics and phone or battery use metrics—have shown associations with neuropsychological test performance, diagnostic severity, and even gray matter volume in clinical cohorts, including those with MCI, Alzheimer disease (AD), frontotemporal dementia, and multiple sclerosis [71-77].

Basic questions of feasibility, acceptability, and ethical considerations related to data privacy are important to weigh when considering the highly sensitive nature of digital phenotyping data in vulnerable populations [78-80]. Few studies have proactively addressed these questions in the context of

older adults with cognitive decline [65]. Furthermore, many existing studies have used exploratory approaches without a priori hypotheses [81]. As described by Hackett and Giovannetti [7] and Leaning et al [66], some of the many interpretive and logistical challenges of digital phenotyping can be mitigated with conceptual models and clinically informed features to provide context to results and improve reproducibility.

In this paper, we present findings from a proof-of-concept study evaluating a smartphone digital phenotyping protocol to assess cognition, everyday function, and mood in a cohort of older adults with and without cognitive decline. Here, we focus on smartphone-derived GPS data as the digital phenotyping sensor of interest. Our study design and analytic approach were informed by a conceptual framework proposed by Hackett and Giovannetti [7] based on established trends in cognitive neuroscience, neuropsychology, neurology, and computer science literature [7]. The conceptual framework (ie, the Variability in Everyday Behavior [VIBE] model) posits that pathological cognitive decline is accompanied by a reduction in everyday activities, worsening mood, and lower scores on standardized neuropsychological measures. These declining

mean-level trends occur alongside increases in intraindividual variability (IIV) on measures of cognition and everyday function as individuals become more inefficient and work to compensate for underlying disease progression [7]. Trends of decreasing *levels* of everyday activity and increasing *variability* in everyday activities may be indexed by passively obtained smartphone data such as GPS trajectories, hence the focus of this study.

Objectives

The primary aims of this study were twofold: (1) to examine the feasibility and acceptability of a digital phenotyping protocol among older adult smartphone users, and (2) to examine associations between passively obtained GPS movement trajectories collected over a 1-month study period and traditional validated measures of cognition, everyday functioning, mood, and mobility habits collected at baseline. Data were collected using the Learn, Assess, Manage, and Prevent (LAMP) platform, an open-source platform for research and clinical use, via the mindLAMP app [82-84]. Data for the second aim were analyzed and interpreted according to the following a priori hypotheses based on our conceptual framework (ie, the VIBE model), shown in [Textbox 1](#).

Textbox 1. Hypotheses informed by the Variability in Everyday Behavior model for individuals along the continuum from healthy cognition to MCI.

Cognition and function

Average GPS metrics of activity will show a positive linear relation with measures of cognition and function, whereas GPS intraindividual variability (IIV) for all categories will show a negative relation with cognition and function.

Mood

Average GPS metrics of activity will show a negative linear relation with depression (ie, greater overall mobility will be associated with less depression), whereas GPS IIV for all categories will show a positive relation with depression (ie, greater mobility variability will be associated with more depression).

Mobility

Average GPS metrics of activity will be positively associated with objective and subjective measures of gait speed, life space, and community participation.

The study also included two exploratory aims: (1) to examine relations between GPS features and participant intrinsic and extrinsic factors (eg, sociodemographic and contextual) to inform the selection of covariates or moderating variables in future studies and (2) to explore whether patterns of mobility—rather than absolute amounts of mobility—also relate to validators. Overall, our results provide preliminary support for the feasibility, acceptability, and validity of digital phenotyping in older adults, along with key insights that can be used to inform future studies.

Methods

Recruitment

Participants aged >60 years with healthy cognition, diagnoses of MCI, or mild AD were recruited from specialty dementia clinics and the community within the Philadelphia region, beginning in January 2022. Recruitment also involved contacting previous participants of other research studies within our laboratory, consistently attending community outreach events to establish trust and familiarity with our research team, and providing educational presentations on topics related to cognitive health and aging at local community centers. Individuals who expressed interest in participating in our study were contacted

by a member of the study team to schedule a study appointment. During the scheduling call, the team member reviewed basic eligibility criteria (eg, age, use of a smartphone, and availability of a study partner), and participants who met criteria were scheduled for an initial session. Inclusion and exclusion criteria were reviewed again in detail at the start of the baseline session to ensure eligibility. General inclusion criteria for all participants were (1) aged ≥ 60 years, (2) fluent in English, (3) existing smartphone user (iOS or Android; meeting minimum software version compatibility) for at least 1 year before joining the study, (4) Wi-Fi connectivity at home, (5) phone use on a daily basis; (6) no plans to purchase or switch to a new smartphone over the next 4 weeks, and (7) availability of an informant reporter who has knowledge of the participant's daily functioning. Exclusion criteria were (1) a history of severe psychiatric or nervous system disorders (other than dementia), (2) current metabolic or systemic disorders, (3) severe sensory or motor deficits precluding smartphone use, (4) intellectual disability, and (5) scheduled surgery or major travel over the 4-week study period. Participants with self- or clinician-reported diagnoses of healthy cognition, MCI, or mild AD completed comprehensive neuropsychological testing during a baseline visit (as described in the subsequent sections), and Jak/Bondi neuropsychological actuarial criteria were used to confirm

diagnostic group membership [85]. Follow-up consensus diagnosis was used to account for atypical clinical factors that may impact the accuracy of actuarial diagnosis (eg, English as a second language and co-occurring mood or psychiatric concerns).

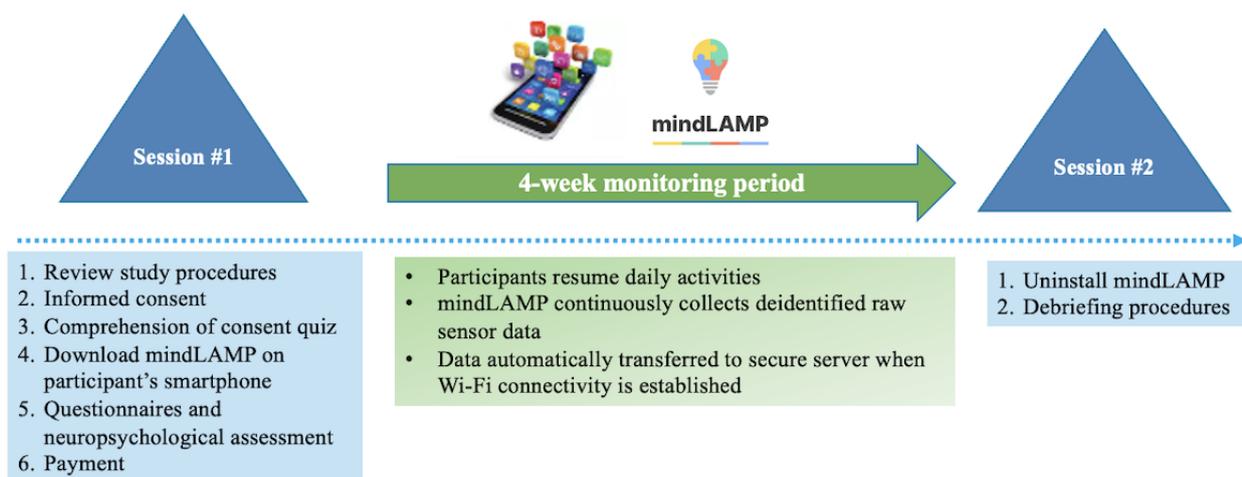

Study informants were also recruited for each participant to corroborate responses on the self-reported functional decline validation measure, to confirm other data pertinent to clinical history, and to provide assistance with potential technical difficulties—particularly for participants with MCI or dementia. General inclusion and exclusion criteria for all informants included (1) aged ≥ 18 years; (2) fluent in English; (3) cognitively healthy with no diagnosis of dementia, MCI, or other neurological and psychiatric disorder; (4) available and willing to complete study questionnaires in person, by phone, or by web; (5) having at least weekly contact with the participant; and (6) reports that they are knowledgeable of the participant's daily functioning and smartphone use.

Study Procedures

Study Timeline

Participants meeting eligibility criteria were scheduled for an in-person visit (session 1) and were enrolled in the study for

Figure 1. Study timeline.

Privacy and Security Safeguards

The LAMP platform was used for the collection of digital phenotyping (GPS) data via the mindLAMP smartphone app, which is available for free on the Apple App Store and Google Play Store. LAMP is an open-source platform for research and clinical use developed by the Division of Digital Psychiatry at Beth Israel Deaconess Medical Center [83]. It uses industry-standard encryption protocols to render information collected from smartphones unidentifiable and transmits data to a secure cloud database via Health Insurance Portability and Accountability Act (HIPAA)-compliant methods whenever Wi-Fi connectivity is established. Participants logged in to mindLAMP via a randomly generated 10-digit user ID (UID) generated within the LAMP platform by the study coordinator,

approximately 4 weeks. As outlined in Figure 1, participants and informants completed 2 study visits, separated by 4 weeks. Session 1 lasted 2 to 4 hours and included a detailed review of study procedures, informed consent, comprehension of consent quiz, cognitive testing, questionnaires, and configuration of the study app (mindLAMP) on participants' personal smartphones (ie, downloading mindLAMP, logging in using participant-specific secure credentials, and enabling continuous location services). At the completion of session 1, participants were instructed to resume their daily routines for 4 weeks and were compensated US \$50 upfront for their participation. They were asked not to enter low battery or airplane mode and not to log out of the mindLAMP app, which would impact GPS data quality. During the 4-week study period, mindLAMP passively and securely collected GPS data without user engagement. At the end of the study period, participants completed session 2 (in-person or remotely), which consisted of debriefing questionnaires. The mindLAMP app was deleted from participants' smartphones at session 2, halting data collection.

which was only used for the collection of digital phenotyping data. Therefore, no personally identifiable information is associated with the data collected by mindLAMP. Participants' 6-digit study ID, used for all other clinical data collected within the laboratory at Temple University, is linked to their mindLAMP UID on a university-approved secure research database only (REDCap [Research Electronic Data Capture; Vanderbilt University]).

The aforementioned security and privacy information was thoroughly reviewed with participants during informed consent at session 1. This process included a review of written and visual handouts depicting privacy safeguards, examples of the scope of data collected, and results of other published studies that used mindLAMP [86]. Participants could choose to end study participation and have their study data deleted at any time. After

reviewing the consent form, a 10-item comprehension of consent quiz with yes or no response options was administered to ensure participants completely understood the information outlined in the consent form. This quiz covered details including the purpose of mindLAMP (eg, “This study requires downloading the mindLAMP app which collects information from my smartphone sensors”), possible risks or benefits to study participation, such as potential battery drain (eg, “It is possible that I will notice a reduction in my phone’s battery life while mindLAMP is running on my phone”), and data security and encryption methods (eg, “The mindLAMP app uses a secure encryption system called ‘hashing’ to make all information that it collects unidentifiable and untraceable”). [Multimedia Appendix 1](#) presents the complete comprehension of consent quiz. Incorrect items were further reviewed until comprehension was established. These procedures were informed by the Digital Health Checklist and other materials from the Research Center for Optimal Digital Ethics health team, which encourages digital health researchers to proactively identify gaps in the communication of study risks, benefits, and privacy and security details [78,79].

Backend Technical Implementation

Data collection and storage were supported by a self-deployed version of the open-source LAMP Platform. A Temple University-approved secure cloud server (1-TB capacity) was purchased and configured with the LAMP application programming interface to enable research participants to connect to the LAMP platform and access the mindLAMP app. Study data were stored in our instance of the mindLAMP database (ie, our copy of the LAMP platform located on a study-specific cloud server) via CouchDB, ensuring a standardized data format consistent with other studies using the LAMP platform [84]. The functionality of the mindLAMP app itself is continually maintained by the team at mindLAMP at the Beth Israel Deaconess Division of Digital Psychiatry. Ongoing security monitoring and backup of study data were maintained by Temple University IT. To monitor unexpected periods of missing data due to potential technical issues (ie, phone powered off, mindLAMP logged out, or permissions reset), we created a code to automate an email alert to the study team (Cronjob) when there were >3 days of missing sensor data. In these instances, the email message included the UID and the corresponding missing sensor, and a member of the study team promptly reached out to the participant to troubleshoot.

Measures

Feasibility and Acceptability

To assess feasibility, we tracked the number of participants who completed the 4-week study period after providing consent and completing session 1 and those who requested to withdraw for any reason. Feasibility was also operationalized by performance on the comprehension of consent quiz, which demonstrates participants’ ability to comprehend complex technical information specific to digital phenotyping studies. To gauge acceptability of the informed consent and overall study procedures, we administered a debriefing survey at session 2 after participants had completed the full study period. Participants were asked to rate their level of satisfaction with

the explanation of the study procedures at session 1 on a scale of 4 (very satisfied—all components of the study were clearly explained) to 1 (very unsatisfied—all components of the study were poorly explained).

Participants were also asked if they experienced any major difficulties with their phones, if they experienced any feelings of discomfort or paranoia due to the study app running on their smartphones, or if there were any major changes in how they used their smartphones during the study period (yes or no). If they answered “yes” to changes in smartphone use, participants selected all applicable options, including “I used my phone less/more overall,” “I charged my phone less/more,” “I carried my phone with me less/more,” and “other.” Finally, troubleshooting contacts between study staff and participants were tracked and reported as part of feasibility findings.

Validators

Overview

Validation measures administered at session 1 included neuropsychological tests used widely in the clinical diagnosis of MCI and dementia; self- and informant-report measures of cognitive decline and everyday functioning; questionnaires pertaining to mood; and measures of gait speed, geospatial life space, and community participation. These measures have demonstrated strong psychometric properties and were therefore used together as validation comparisons against digital phenotyping data. More details are provided in the subsequent sections.

Neuropsychological Tests

The neuropsychological test battery included the Hopkins Reading Test [87] as an estimate of premorbid intellectual ability (IQ), the Mini-Mental State Examination [88] as a global cognitive screener, and tests of attention (Trail Making Test-Part A [89] and Wechsler Memory Scale—Revised Digit Span Forward [90]), processing speed (Salthouse Letter and Pattern Comparison [91]), executive function (Trail Making Test-Part B [89] and Wechsler Memory Scale—Revised Digit Span Backward [90]), episodic memory (Hopkins Verbal Learning Test—Revised Delayed Recall [92] and Brief Visuospatial Memory Test-Revised Delayed Recall [93]), and language (Animal Fluency [94] and Boston Naming Test 30-item version [95]). Raw scores of each test were transformed into demographically corrected *t* scores using the Calibrated Neuropsychological Normative System [94], adjusting for age, sex, education, and estimated premorbid IQ (ie, Hopkins Reading Test score), which enabled more accurate estimation of cognitive ability within our diverse sample. An average *t* score was computed for the 2 tests within each cognitive domain to generate composite scores for attention, processing speed, executive function, delayed memory recall, and language abilities to streamline presentation of results.

Reported Cognitive Decline and Everyday Functioning

Self-reported cognitive decline was collected using the Everyday Cognition Scale-Short Form [96]. Self- or informant-reported everyday functioning was captured with the Functional Activities Questionnaire (FAQ [97]). Self-reported FAQ was used for participants with healthy cognition, and

informant-reported FAQ was used for participants with MCI or dementia. Higher scores on these measures indicate more cognitive decline and more functional impairment, respectively.

Mood

Mood symptoms were indexed using the 15-item Geriatric Depression Scale (GDS [98]), a widely used self-report measure of depressive symptoms among older adults that requires participants to indicate whether they experience a list of common depression symptoms in a “yes/no” format. Raw scores were transformed into demographically corrected *t* scores using the Calibrated Neuropsychological Normative System as mentioned earlier. Higher *t* scores indicate higher levels of depression.

Gait Speed, Life Space, and Community Participation

The Timed Up and Go Test (TUG) was administered at session 1 as an objective measure of gait speed. This task measures the time it takes to rise from a chair, walk 10 feet, turn, walk back to the chair, and sit down. It is widely used to examine balance, functional mobility, gait speed, and fall risk in older adults [99,100]. Participants also completed the University of Alabama at Birmingham Life-Space Assessment (LSA), a self-report measure of mobility for community-dwelling older adults [101]. It captures the level of independence and spatial extent of a person’s life over the preceding month and has shown strong associations with mobility within the home and community and with performance of activities of daily living [102]. Constricted life space has also been associated with risk for MCI and dementia [103,104]. The Australian Community Participation Questionnaire (ACPQ) 15-item version was administered as an additional measure of concurrent validity and assesses the extent to which someone engages in a range of community activities. Subscales include contact with immediate household, extended family, friends, and neighbors; participating in organized community activities; taking an active interest in current affairs; and religious observance [105]. An index of breadth of participation across the 7 domains was derived using a mean-split procedure for each domain, followed by summing these scores to generate an overall index ranging from 1 to 7 (as described by Brett et al [106]).

Other Participant Features

Demographic

Demographic data included participants’ self-reported biological sex assigned at birth, age, race, ethnicity, current living status (alone or with others), current occupational status, educational attainment, and other information related to socioeconomic status (eg, highest household annual income).

Technology Use

Participants completed a 6-item Habitual Smartphone Behavior subscale [107] to assess smartphone use patterns, providing responses ranging from “strongly agree” to “strongly disagree”

to questions such as “Smartphone usage is part of my daily routines.” We also asked participants, “Do you usually have your phone with you when you leave home?” (smartphone portability), to which they could reply, “Yes- I almost never leave my house without my phone,” “In between—I leave my house without my phone about half the time,” or “No, I often leave my house without my phone.” The Mobile Device Proficiency Questionnaire was administered as a measure of digital literacy [108]. Participants also indicated their smartphone operating system (Android vs iOS).

Seasonal and COVID-19 Factors

Dates of study participation were collected and coded as winter, fall, spring, and summer to explore potential seasonal effects on mobility habits. Because study participation took place during the COVID-19 pandemic for some participants, we asked about the impact of the COVID-19 pandemic on social participation, routines, and mobility behaviors at the time of study participation. Participants were asked, “On a scale of 1-5, how isolated or cut off from family and friends are you feeling due to limited/canceled social gatherings resulting from COVID-19?” “On a scale of 1-5, how disruptive has the COVID-19 pandemic been to your daily routines and activities?” and “On a scale of very much limited to very much expanded, how much has the COVID-19 pandemic changed your mobility/your movements outside of the home?”

Self-Reported Health Changes During the Study Period

At the end of the study period during session 2, participants reported whether there were any changes in their overall health during the study period by responding to a single question on the debriefing survey. Response options included (1) yes, significant change; (2) yes, a little change; or (3) no change. If they endorsed any change in health, they were given the option to elaborate.

Digital Phenotyping (*mindLAMP*)

Though the *mindLAMP* app enables the collection of a wide array of deidentified passive and active data, this study focused on passively obtained GPS data. *mindLAMP* was configured to continuously record the device’s GPS coordinates at a maximum frequency of 1 Hz. Raw data outputs include latitude, longitude, altitude, and the coordinates’ estimated accuracy. At study completion, these raw data were extracted from the study server and processed into daily summary features (Table 1) using a publicly available R script developed by Barnett and Onnela [109,110]. GPS data from smartphone devices are prone to large amounts of missing data [111]; therefore, advanced multiple imputation methods based on weighted resampling of the observed data were used to account for missingness before feature calculation. These imputation methods are automatically incorporated within the aforementioned processing script and are described in detail in the study by Barnett and Onnela [109].

Table 1. Daily GPS features generated from mindLAMP raw data.

Category and feature	Feature description
Activity	
Distance traveled	The sum of all flight lengths that day (m)
Radius of gyration	Average distance (m) a person is from their center of mass (average position) on a given day
Maximum diameter	Maximum diameter (m); longest pairwise distance between any 2 pause locations that occur that day
Maximum distance home	Maximum distance from home (m); distance between home and farthest pause location from home that day
Average flight length	The average length of all flights that day (m)
Average flight duration	The average duration of all flights that day (s)
Inactivity	
Home time	Time spent at home (min); amount of time spent that day within 200 m of home (the significant location with the largest total amount of time between 9 PM and 6 AM throughout the study period).
Probability paused	Fraction of time a person is stationary (paused) during a day, relative to time spent mobile or in flight.
Routine	
Circadian routine	Physical circadian routine; the fraction of time a person is in the same place (within a 200 m radius) at the same time of each day throughout the study period. Ranges from 0=completely different routine to 1=identical routine.
Weekend circadian routine	Physical circadian routine weekend or weekday stratified; similar to circadian routine except comparisons are stratified by grouping together weekends and grouping together weekdays. Higher scores reflect greater overall routine.
Location diversity	
Significant location entropy	Location entropy across a person's significant locations for the day; large values indicate spreading time out across many different locations fairly evenly for that day; small values indicate a concentration at a few significant locations.
Significant locations visited	The number of significant locations a person is within 200 m of that day. Determined using K-means on the set of all pause locations with a minimum duration of 10 minutes (longer pauses given additional weight and no 2 cluster centers within 400 m of one another).
Other	
Minutes missing	The number of minutes of missing data preimputation in a person's GPS mobility trace that day (min)

Supplementary materials from Barnett and Onnela [109] give a full description of GPS features and the methods used to calculate each. A flight is defined as a segment of linear movement; pauses are periods when a person does not move; and curved movement is approximated by multiple sequential flights.

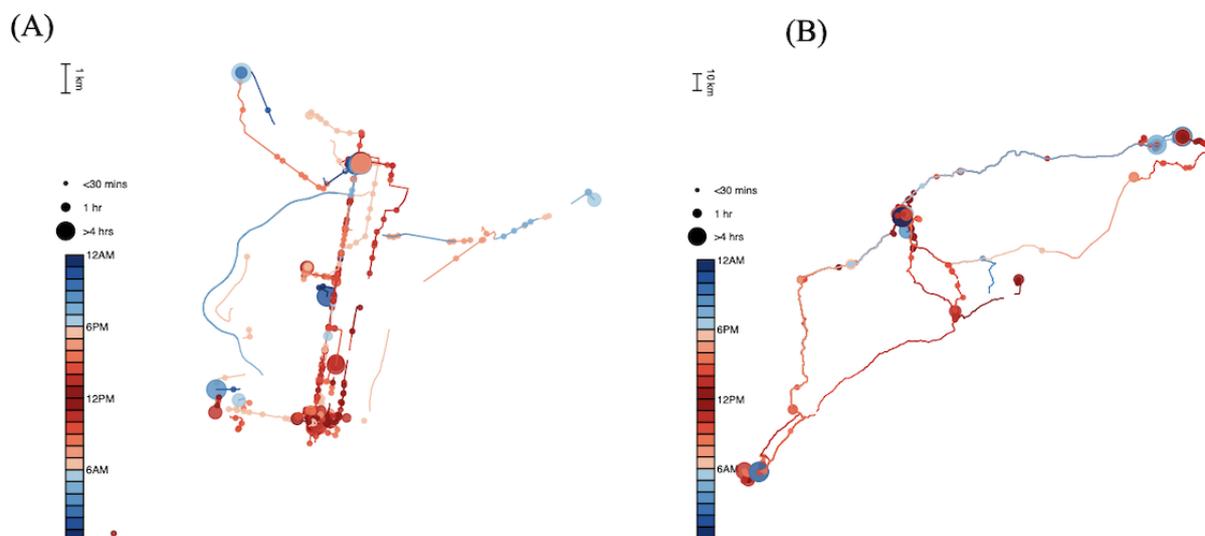

Statistical Analyses

Preliminary Processing

The individual mobility traces derived from GPS data were visually inspected by examining each participant's deidentified mobility plots averaged across the study period (Figure 2). These plots are generated automatically through our processing script and enable visualization of overall mobility habits, amount of time spent at various locations, and time of day. Following visual inspection, daily mobility features (Table 1) were collapsed into monthly overall average and monthly (day-to-day)

individual SD (iSD) for each participant to generate estimates of mean mobility and mobility IIV across the study period. For example, 30 days of daily distance traveled estimates for 1 participant were reduced to an average distance traveled per day, and an iSD of daily distance traveled across the 30-day study period. This approach enabled the examination of a priori hypotheses as an important first step in the validation of GPS data. All variables (GPS and validation measures) with highly skewed distributions were transformed using $\log(x+c)$ transformation to reduce the influence of outliers and make parametric analyses more robust. Pearson correlation analyses were used to explore relations among individual GPS features.

Figure 2. Example mobility plots depicting overall trajectories over 4 weeks for 2 participants. Solid lines depict flights from one location to another; circles indicate periods spent stationary, with larger sizes reflecting more time spent stationary at that location, color-coded by the time of day. (A) A 67-year-old woman living in northern Philadelphia. (B) A 70-year-old woman living in a suburb of Philadelphia.

Other preprocessing steps were completed in individual cases. Specifically, some participants had unanticipated travel during their scheduled study period (which was an exclusion criterion for validation purposes). In these cases, we extended their study duration and excluded days spent traveling from the raw data before feature extraction. In total, 3 (8%) of the 37 participants reported major unanticipated health changes during the study period (1 (3%) reported eye surgery, 1 (3%) reported a major fall with loss of consciousness, and 1 (3%) reported a fall with head trauma and COVID-19 infection) and were excluded from preliminary validity analyses in this study, because major health events during passive data collection would confound relations with baseline validators.

Primary Analyses

Descriptive statistics were first used to examine feasibility and acceptability outcomes across the entire sample ($N=37$; aim 1). Next, Pearson or Spearman correlation analyses were used to examine the relations between the mean (monthly average) and IIV (monthly iSD) of each mobility feature against validators collected at session 1 (ie, cognition, everyday function, mood, and mobility; aim 2). All validity analyses were conducted across the entire sample after excluding 3 participants with major health events (final n for aim 2 validation analyses=34). Given the small sample size, we interpreted correlation coefficients with $r>0.3$ as meaningful, regardless of statistical significance. Correlations surviving Bonferroni correction of $P<.0038$ (α corresponding to .05/13 GPS features) are noted to account for multiple comparisons. As mentioned earlier, we tested several a priori hypotheses based on our proposed conceptual framework (ie, the VIBE model, see [Textbox 1](#)). Specifically, we predicted that GPS mean-level activity metrics would show a positive linear relation with global cognition, function, and mood, whereas GPS IIV metrics would show a negative relation with cognition, function, and mood. Hypotheses from the original VIBE model were adjusted to

consider trends along the continuum from healthy cognition to MCI only (excluding trends from MCI to dementia), given this study sample only included 1 participant with dementia. We also predicted a positive linear relation between GPS mean-level activity metrics and objective and subjective measures of gait speed, life space, and community participation that would reflect concurrent validity.

Exploratory Analyses

A series of exploratory analyses examined relations between GPS metrics and other participant factors such as demographics, technology habits, and smartphone type, as well as environmental factors (eg, COVID-19 and seasonal impact). Our goal was to better understand what intrinsic and extrinsic factors are associated with GPS trajectories in older adults so that future studies can consider these variables as potential covariates or moderators. This is important given the high heterogeneity in individual features and incidental factors that may impact the generalizability of between-group differences in GPS trajectories. Spearman correlation analyses were used for continuous, dichotomous, and ordinal variables, and 1-way ANOVA was used for categorical variables with a Welch test for unequal group variances.

To explore the utility of a GPS composite score, a Gaussian mixture modeling (GMM) approach was used to generate a nuanced yet singular representation of mobility trajectories. For each participant's set of daily GPS features ([Table 1](#)), we fit a GMM with $k=3$ mixture distributions to allow for flexible modeling with consideration of differences in the distribution for each person due to various factors (eg, weekend and weekday differences). The choice of $k=3$ was determined to maximize clustering complexity subject to our sample size limitations to avoid overfitting. This method also allowed us to reduce the full set of GPS features to a single dimension. Next, we created a distance matrix between each pair of participants in the sample

by calculating the integral of the squared distance between each GMM density (the larger the distance, the more different the pair's overall mobility patterns). After calculating the distance matrix, we used multidimensional scaling (MDS) to extract a 1D representation of this distance matrix (hereafter termed "MDS1"), akin to a principal component [112]. This MDS1 metric is a relative measure that represents the similarity of overall mobility patterns across participants. For example, if 2 individuals have similar MDS1 values, their overall mobility patterns are similar, whereas 2 individuals with very different MDS1 values demonstrate different mobility patterns. The MDS1 variable was used in exploratory correlation analyses to identify whether patterns of mobility relate to validators, in contrast to total amounts of variability in individual mobility features.

Ethical Considerations

All aspects of the study protocol received ethics approval from the institutional review board at Temple University (protocol number 27013). As described earlier, all participants provided informed consent, were given the option to opt-out of study participation at any time, and were compensated for their time and effort. Study data were deidentified according to privacy procedures outlined earlier. Participants were compensated US \$50 upfront for their participation.

Results

Participant Characteristics

A total of 37 individuals participated in our study between April 2022 and January 2024. The full sample was included in the analysis of feasibility and acceptability outcomes, whereas a

subset ($n=34$, 92%) was included in preliminary validity analyses after excluding those who experienced major unexpected health changes. The 3 (8%) participants excluded due to major health events were aged on average 70.9 (SD 6.9) years, 67% (2/3) were female, 100% (3/3) identified as non-Hispanic White, and they completed on average 16.9 (SD 1.8) years of education. In addition, 2 (67%) of the 3 participants were Android users, and all had healthy cognition.

Of the validation subset ($n=34$), participation was distributed fairly evenly across all 4 seasons: 6 (18%) in the winter, 10 (29%) in the fall, 9 (26%) in the spring, and 9 (26%) in the summer. Participants' age ranged from 63 to 85 (mean 71.6, SD 5.5) years and they were on average highly educated (mean 16.4, SD 2.7 years; range 10-20 years). A majority of participants identified as female (23/34, 68%) and non-Hispanic or Latinx (33/34, 97%). A total of 56% (19/34) participants identified as White, 35% (12/34) as Black or African American, and 6% (2/34) as Asian. Most participants lived with others (23/34, 68%) and were retired (27/34, 79%). The majority (26/34, 76%) of participants were iPhone users, whereas 8 (24%) were Android users. Most participants met diagnostic criteria for healthy cognition ($n=28$, 82%) with a minority meeting criteria for MCI ($n=5$, 15%) or mild dementia ($n=1$, 3%). Scores on the Mini-Mental State Examination ranged from 24 to 30 (mean 28.3, SD 1.3), and according to the FAQ, participants on average experienced minimal difficulties with everyday functioning (mean 1.5, SD 2). Average responses on the GDS revealed low levels of self-reported depression (mean 1.5, SD 1.5) [113]. Participant demographic characteristics are detailed in [Table 2](#), and scores on validation measures of cognition, everyday functioning, mood, and mobility are outlined in [Table 3](#).

Table 2. Participant demographics. Includes data from subset (n=34) included in validation analyses.

Feasibility and Acceptability (Primary Aim 1)

All 37 (100%) participants who began the study completed the 4-week monitoring period and session 2 without requesting to withdraw. Participants scored on average 97% (SD 5.7%) on the comprehension of consent quiz. In total, 2 (5%) participants had an initial score of 80% (8/10 questions correct), 7 (19%) scored 90%, and 28 (76%) scored 100% on their first attempt. The most frequently incorrect item was “Using the mindLAMP app will help improve my cognitive functioning,” to which 5 (13%) participants answered “yes.” Better performance on the comprehension of consent quiz was associated with higher education ($r_s=0.65$; $P<.001$) and differed across racial groups ($F_{2,33}=8.4$; $\eta^2=0.34$; $P=.001$), with better performance among White participants versus Black participants according to post hoc comparisons ($P=.02$). When including education as a covariate, group differences for race remained statistically significant, though a lower effect size was noted ($F_{2,32}=3.3$; $\eta^2=0.17$; $P=.049$). Performance on the quiz was not associated with age, English as a second language, or cognitive status (all P values $>.05$).

Satisfaction ratings on the debriefing questionnaire at session 2 (ie, responses to the question “How satisfied are you with the study team’s explanation of this study? Did the study team accurately convey what it would be like to participate in this study during the consent process at your first study visit?”) revealed high levels of satisfaction. Specifically, 84% (31/37)

of participants reported they were “very satisfied,” and 16% (6/37) reported they were “satisfied.”

Regarding new issues with or changes to phone use, 92% (34/37) of participants reported they did not experience any new problems using their smartphone during the study period. However, 1 (3%) participant experienced technical issues that were determined to be unrelated to the study application, 1 (3%) reported that some of their text messages were disrupted (unrelated to the study app as we did not collect information from text messages), and 1 (3%) reported that their phone was “a little slow and lack of charge.” In total, 97% (36/37) of participants reported they did not experience any feelings of being uncomfortable, suspicious, or paranoid due to the study app running on their smartphone. Although participants were instructed to go about their daily lives and smartphone use as they normally would, 46% (17/37) of participants reported there were major changes in how they used their smartphone during the study period. Specifically, 3% (n=1) used their phone less overall, 41% (n=15) charged their phone more, 5% (n=2) carried their phone less, and 14% (n=5) carried their phone more.

Troubleshooting contacts related to missing GPS data were infrequent. During the entire study period across 37 participants, only 6 incidents were logged affecting 5 (14%) unique participants, with causes including (1) Android phone went into “safe mode,” (2) location permissions reset from “always” to “only while using app,” (3) outdated version of mindLAMP installed on phone, (4) low battery mode enabled, and (5)

mindLAMP app was accidentally deleted. All incidents were promptly resolved by the study coordinator remotely by speaking with the participant over the phone to guide them to either reconfigure their phone settings or re-download and login to mindLAMP.

Validity Analyses (Primary Aim 2)

Preliminary Analyses

Examining the untransformed GPS data revealed that on average each day, participants spent 1074 (SD 192) minutes at home (ie, about 18 hours), traveled 42,676 (SD 34,694) m, spent time at 1.56 (SD 0.54) unique locations, and had 423 (SD 352) minutes of missing GPS data (approximately 29% of the day, which reflects relatively high data quality and frequency relative to other smartphone digital phenotyping studies using interval sampling approaches [111]). Correlations among GPS features revealed strong associations among features reflecting activity (distance traveled, radius of gyration, maximum diameter, and maximum distance from home), which were negatively associated with features reflecting inactivity (time spent at home and stationary time) and the 2 indices of physical circadian routine. Significant locations visited and significant location entropy were intercorrelated, suggesting a distinct construct related to location diversity. These associations together support the conceptual GPS feature categories outlined in Table 1 and are used throughout to streamline the presentation of results. Tables S1 and S2 in Multimedia Appendix 2 present descriptive statistics of GPS data and intercorrelations among all GPS features.

Relations Between Average Mobility Features and Measures of Cognition, Mood, and Everyday Function

We predicted significant relations between monthly average GPS activity features and baseline neuropsychological measures, mood, and everyday function, such that greater overall mobility

would be associated with better performance on neuropsychological tests, less depression, and less reported cognitive and functional decline. Most correlations were in the predicted direction (Table 4; results for individual neuropsychological tests and function questionnaires are reported in Table S3 in Multimedia Appendix 2).

Correlations with neuropsychological composites and individual tests showed that greater GPS activity was associated with better scores on the language composite (Table 4) and Digit Span Forward test (Table S3 in Multimedia Appendix 2). GPS measures of inactivity and physical circadian routine were associated with lower language composite and individual test scores. Of note, correlations between greater physical circadian routine and lower language scores were the only relations to survive correction for multiple comparisons ($P < .0038$; Table 4; Table S3 in Multimedia Appendix 2). Associations between GPS activity features and the memory composite were not significant and weak but were in the opposite direction of most other neuropsychological composites. Analyses of individual neuropsychological tests showed greater average flight length was associated with worse delayed verbal recall ($r = -0.38$, $P = .03$; Table S3 in Multimedia Appendix 2), but the correlation coefficient was not statistically significant after correction for multiple comparisons.

Regarding mood, more inactivity (eg, more home time), greater routine, and less location diversity were associated with greater depression symptoms (Table 4). Less location diversity was also associated with greater reported functional impairment (FAQ; $r = -0.36$, $P = .04$; Table S3 in Multimedia Appendix 2). However, the associations between mobility features and self-reported mood and function did not survive correction for multiple comparisons. Correlations between GPS features and self-reported cognitive decline on the Everyday Cognition Scale-Short Form were weak and not statistically significant (Table S3 in Multimedia Appendix 2).

^f*P* < .01 (2-tailed).

^gItalics indicate correlation coefficients surviving Bonferroni correction (*P* < .0038).

Relations Between Average GPS Features and Measures of Gait Speed, Life Space, and Community Participation

Contrary to our hypotheses, performance on the TUG measure of gait speed was not associated with any of the average GPS features (Table 5). By contrast, self-reported measures of geospatial life space (LSA), and community participation (ACPQ) were associated with many GPS features. Overall, greater GPS activity was associated with more self-reported life space and more community participation, whereas greater

inactivity and physical circadian routine were associated with less geospatial life space and less community participation. Correlations between greater radius of gyration, less physical circadian routine, and greater geospatial life space survived correction for multiple comparisons (*P* < .0038; Table 5). Relations with the ACPQ were driven by the domains of extended family and friends (eg, participants who reported they tend to visit friends more often demonstrated significantly higher levels of GPS activity and lower physical circadian routine indices; *P* < .0038; Table S5 in Multimedia Appendix 2).

Relations Between GPS Variability and Measures of Cognition, Mood, and Everyday Function

We predicted a negative relation between day-to-day variability in GPS features and baseline measures of cognition, mood, and everyday function, such that greater IIV would be associated with lower neuropsychological test scores, more depression, and more reported cognitive and functional decline. Contrary to our hypotheses, we saw that higher variability in most GPS features (ie, greater day-to-day iSD in mobility habits) was associated with *better* scores on neuropsychological measures of attention and language, as seen in [Table 6](#) and in [Tables S6 and S7 in Multimedia Appendix 2](#). Correlations between greater IIV in home time and physical circadian routine and higher language composite scores survived correction for multiple comparisons ($P < .0038$; [Table 6](#)). Again, relations with memory were in the opposite direction, such that higher GPS IIV in

location entropy was associated with a worse memory composite. Analyses with individual tests showed significant associations between higher GPS IIV in average flight length and worse verbal memory and higher GPS IIV in location entropy and worse visual memory ($P < .0038$; [Table S7 in Multimedia Appendix 2](#)). Regarding relations with mood, greater IIV in location diversity was associated with less depression, though results did not survive correction for multiple comparisons. This was contrary to expectations but consistent with the aforementioned results suggesting greater variability in mobility habits is overall beneficial. GPS IIV was not significantly associated with self-reported cognitive decline or functional impairment, though results are directionally consistent, such that greater IIV was weakly related to less reported functional decline ([Table S7 in Multimedia Appendix 2](#)).

Exploratory Analyses

Relations Between GPS Metrics and Participant Intrinsic and Extrinsic Factors

To inform future studies in the selection of covariates or moderating variables, we conducted exploratory correlations between GPS average and IIV features and various participant, environmental, and contextual factors (Tables S8 and S9 in [Multimedia Appendix 2](#)). Average GPS features were unrelated to several sociodemographic factors, including age, sex, and cohabitation status (all *P* values >.05). Higher education was associated with less location diversity only ($r=-0.35$; $P=.04$) but was not significant after correction for multiple comparison. By contrast, lifetime annual income and native language status appeared to be more relevant. Overall, higher lifetime income and native English language status were associated with greater

levels of GPS activity, less routine, and greater location diversity ($0.36 \leq |r| \leq 0.55$). The association between higher lifetime income and greater GPS activity measures (radius of gyration and maximum distance from home) remained significant after correction for multiple comparisons ($P<.0038$; Table S8 in [Multimedia Appendix 2](#)).

Technology factors were largely unrelated to average GPS features. Phone type (iPhone vs Android) was unrelated to all features except for the overall number of minutes missing; iPhone users had significantly less missing GPS data than Android users, and the relation remained significant after correction for multiple comparisons ($r=-0.64$; $P<.0038$). More habitual smartphone use was associated with less location diversity only ($r=-0.40$; $P=.02$), though this relation did not survive correction for multiple comparisons. Whether or not participants typically carry their phone when leaving home (smartphone portability) was unrelated to all average GPS

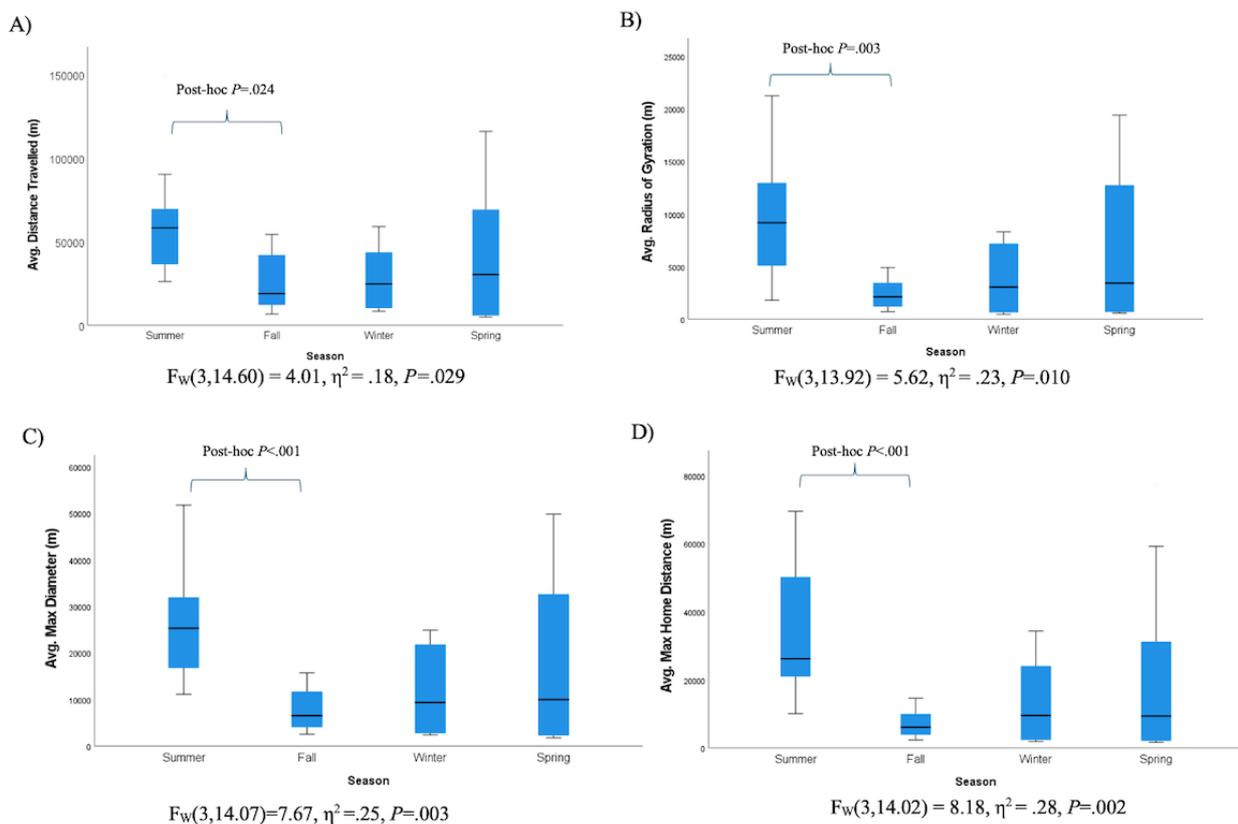

features, as was digital literacy as measured by the Mobile Device Proficiency Questionnaire (all P values $>.05$). Regarding the impact of COVID-19, individuals who reported more COVID-19-related isolation (ie, due to limited or canceled social gatherings) demonstrated significantly less location diversity ($r=-0.51$; $P<.0038$), whereas those who reported a greater expansion in mobility habits due to COVID-19 demonstrated more location diversity ($r=0.34$; $P=.047$), though this latter relation was not significant after correction for multiple comparisons.

One-way ANOVA of average GPS features was used to explore group differences across categorical demographic variables (race, occupational status, and season), with the Welch test for unequal group variances. Group differences for race (Black, Asian, and White) were observed only on the minutes missing feature ($F_{2,30}=6.32$; $\eta^2=0.30$; $P=.005$), with Black participants having greater amounts of missing GPS data than White and

Asian participants according to post hoc comparisons ($P=.003$ and $P=.02$, respectively). A follow-up chi-square test was performed to examine the relationship between race and phone type given prior findings that Android users have greater missing data than iPhones [114]. The relation was significant, such that a greater proportion of Black participants owned Androids, $\chi^2_2=6.9$, $P=.03$ ($N=33$), suggesting that group differences in missing data could be related to phone type.

No group differences in average GPS features were observed according to current occupational status (eg, retired and working full vs part-time). By contrast, several activity features were significantly different across the winter, fall, spring, and summer seasons ($4.01 \leq F_{3,30} \leq 8.8$; $0.18 \leq \eta^2 \leq 0.28$; all P values $<.05$). According to post hoc comparisons, these differences were driven by significantly greater GPS activity in the summer versus fall months (Figure 3).

Figure 3. One-way ANOVA of GPS activity features by season.

Spearman correlations between GPS IIV features and the participant factors assessed earlier are detailed in Table S9 in Multimedia Appendix 2. Similar to the results with average GPS metrics, relevant sociodemographic factors appeared to be income and native language status. Higher lifetime income and native English language status were associated with more variability in activity, routine, and location diversity features ($0.35 \leq |r| \leq 0.56$), with associations between higher income and greater IIV in activity (radius of gyration, maximum diameter, and maximum distance from home) surviving correction for multiple comparisons ($P<.0038$).

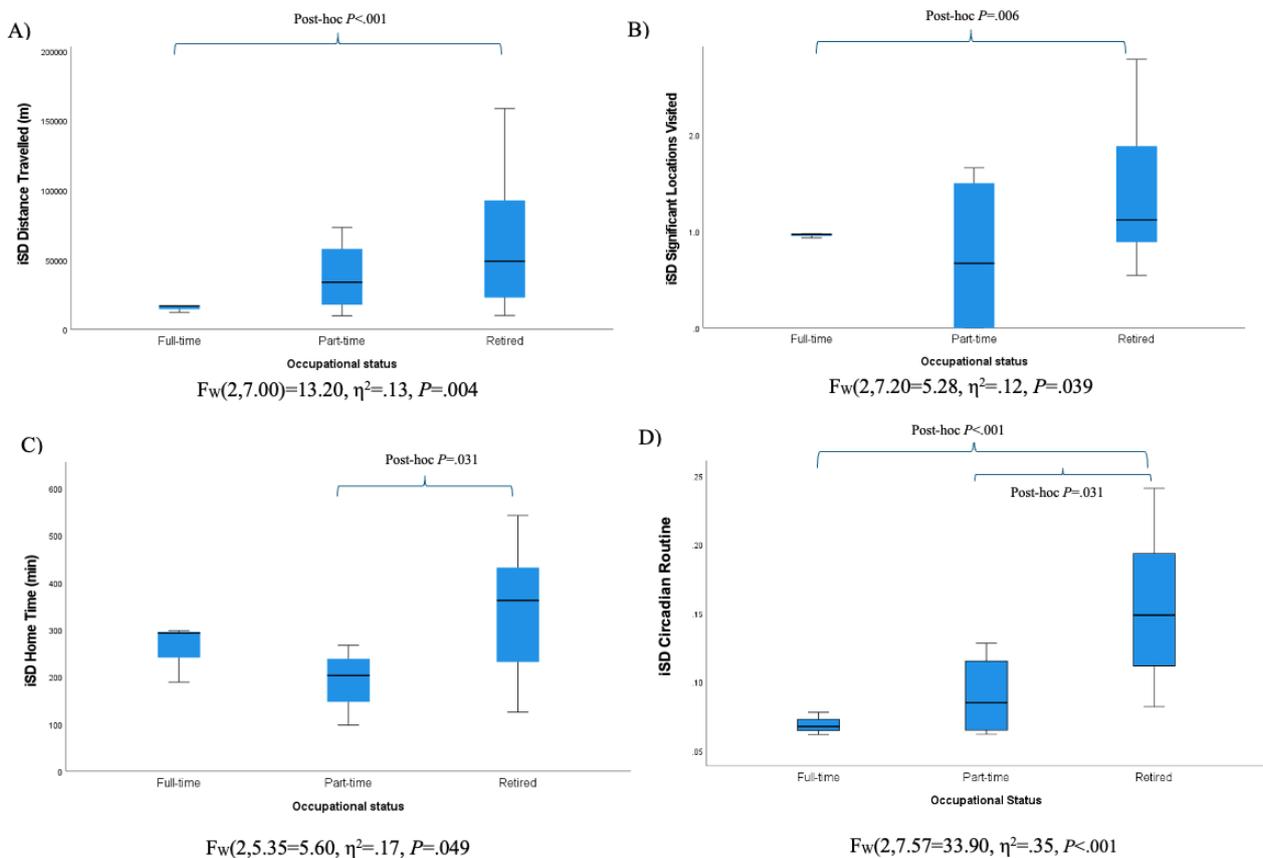

Phone type was more prominently related to GPS IIV measures than GPS average measures; iPhone users showed greater GPS IIV than Android users on several GPS features ($0.34 \leq r \leq 0.52$), though only greater GPS IIV in minutes missing survived correction for multiple comparisons ($P<.0038$). Of note, iPhone ownership was also positively correlated with income ($r=0.49$; $P=.005$), making it difficult to determine whether higher levels of IIV among iPhone users relate to differences in phone type or to behavioral differences in lifestyle afforded by higher income. Regarding other technology factors, habitual smartphone use and smartphone portability were unrelated to GPS IIV metrics, whereas digital literacy was related to more

variability in routine only ($r=0.34$; $P=.047$)—though this relation did not survive correction for multiple comparisons. Individuals who reported more COVID-19–related social isolation had significantly lower IIV in location diversity (ie, more day-to-day consistency in the number of locations visited; $r=-0.55$; $P<.0038$), whereas those who reported a greater expansion in mobility habits due to COVID-19 had greater IIV in location diversity ($r=0.37$; $P=.03$), though this latter relation was not significant after correction for multiple comparisons.

One-way ANOVA of GPS IIV features across categorical demographic variables revealed a significant difference across racial groups on only 1 measure—IIV for flight length ($F_{W2,18.63}=11.96$; $\eta^2=0.12$; $P<.001$). This group difference was

driven by lower IIV in Asian participants compared with both Black participants and White participants according to post hoc tests. Effects of current occupational status were observed on several IIV metrics ($5.28 \leq F_{2,31} \leq 33.90$; $0.12 \leq \eta^2 \leq 0.35$; all P values $<.05$), such that retired participants demonstrated significantly greater IIV in mobility habits compared to those working full- or part-time (Figure 4). Consistent with the results of GPS average metrics, several GPS IIV metrics differed according to the season of study participation, with significantly more IIV in activity features observed during summer months versus the fall and spring months ($2.41 \leq F_{3,30} \leq 3.78$; $0.19 \leq \eta^2 \leq 0.27$; all P values $<.05$).

Figure 4. One-way ANOVA of GPS intraindividual variability features by occupational status.

Relative Mobility Patterns

A GMM, MDS approach was used to derive a relative mobility feature (MDS1), including all GPS features simultaneously. This allowed us to explore how similarity in mobility patterns, as reflected through a 1D value, related to validators of cognition, function, and mood. Relative mobility patterns were moderately associated with a cognitive measure of language ($|r|=0.36$; $P=.04$) and a global cognitive screener ($|r|=0.31$; $P=.08$; Table S10 in Multimedia Appendix 2). Relative mobility patterns were also associated with depression ($|r|=0.39$; $P=.02$) and community participation ($|r|=0.51$; $P=.002$). Of note, only the relation between MDS1 and community participation (ACPQ) survived correction for multiple comparisons ($P<.0029$). While the MDS1 feature represents a linear contrast

combining multiple individual GPS features that excel at differentiating mobility patterns across the sample, this comes at the cost of interpretability of the associations related to MDS1 (eg, positive vs negative correlation coefficients are not meaningful); however, these results provide additional converging evidence that individuals with similar mobility profiles may have similar levels of underlying cognitive ability, depression, and community participation.

Discussion

Principal Findings

This study investigated a 4-week smartphone digital phenotyping protocol as a novel method to assess everyday cognition, function, and mood in a cohort of 37 older adults. Our

preliminary, proof-of-concept results suggest that theoretically informed digital phenotypes of mobility are feasibly captured from older adults' personal smartphones and are associated with clinically relevant data pertinent to cognitive aging and AD/ADRD. Findings and implications provide key insights to inform the design and interpretation of future studies using this method in larger, more diverse cohorts.

One of our primary aims was to examine the feasibility and acceptability of smartphone digital phenotyping among older adults. All participants completed the 4-week monitoring period without dropping out, and 97% (36/37) reported no feelings of discomfort during debriefing procedures. By contrast, almost half (17/37, 46%) reported changes in how they used their smartphone, with 41% (15/37) endorsing charging their phone more frequently. Battery drain was a communicated risk and is common in high-frequency continuous data collection, including GPS [111]. Increased phone charging behavior may limit the naturalistic aspect of this approach and will be important to address in future designs—particularly if battery power is considered as a digital biomarker in and of itself. Future studies should explore whether lower sampling frequencies are sufficient, as this can be adjusted via the LAMP platform and would lead to less battery drain. It is also likely that advances in smartphone battery life span will ultimately circumvent this issue; in the interim, participants may be provided with portable batteries for daily outings.

We were also interested in how participants would respond to and comprehend complex technical details of this study. Participants demonstrated good comprehension of study procedures, as demonstrated by an average score of 97% on the comprehension of consent quiz, and all reported satisfaction with the study team's initial review of study procedures. These findings are encouraging given the dearth of studies investigating older adults' attitudes and concerns about passive sensing technologies [78,115] and suggest that our upfront efforts to enhance privacy, security, transparency, and comprehension were effective [79]. However, despite high overall comprehension, we observed that higher education and identifying as White versus Black were associated with better performance on the comprehension of consent quiz—suggesting the language used in our materials may not be culture-free and should be revised using co-design or focus group approaches with increasingly diverse perspectives. Importantly, the most frequently incorrect item on the quiz pertained to potential benefits of study participation (“Using the mindLAMP app will help improve my cognitive functioning,” yes or no). Clear communication of potential benefits in research is a core ethical requirement, and future study materials should clarify expectations for potential benefits to facilitate trust, particularly among historically marginalized groups [116-119].

Regarding our second primary aim of establishing preliminary validity, we observed converging support that unobtrusively obtained movement trajectories from smartphones are related to established clinically relevant variables, including cognition, function, and mood. This is not surprising but is highly encouraging. Movement trajectories reflect many facets of everyday cognition, including the ability and motivation to travel outside the home, the degree of someone's spatial routine,

number of unique locations someone can visit, and the total amount and duration of movement—behaviors that require abundant cognitive and psychological resources. Here, individuals with better cognition, less functional impairment, and less depression did, in fact, demonstrate greater overall mobility according to several GPS features. Specifically, they traveled farther, spent less time at home, and had greater diversity in the locations they visited. Although these associations did not remain statistically significant after correction for multiple comparisons, these moderate-level effects in a relatively small sample are encouraging as they are consistent with our hypotheses and with prior studies showing greater physical activity, less time at home, greater life space (the extent of movement through the environment during daily functioning), and engagement in a variety of activities (environmental complexity) are associated with better cognition, less depression, and reduced risk for MCI and dementia or AD/ADRD [66,103,104,120-128].

Inconsistent with our hypotheses, individuals with better cognition demonstrated significantly *greater* day-to-day variability in GPS features and *less* physical circadian routine, and these associations did survive correction for multiple comparisons. We also saw that greater mobility variability and less routine were associated with less depression, although associations did not survive correction for multiple comparisons. Regarding depression, it is conceptually reasonable that more varied mobility habits could be protective against depression, and this has been demonstrated in at least 1 study of younger adults where lower location diversity was associated with more depression symptoms [129]. With respect to the significant negative associations between cognition and routine, it is possible that the older adults in our cohort with more cognitive difficulties intentionally engaged in more predictable and less demanding daily activities to compensate for underlying mild difficulties, leading to more consistent physical circadian routines and lower day-to-day variability in mobility habits. This is a pattern identified in the literature and is often recommended as an intervention in clinical practice [130-134].

The VIBE model predictions regarding variability were informed by observations that individuals with cognitive impairment demonstrate increased IIV compared with healthy controls while performing single, standardized tasks in the clinic or laboratory where task demands are the same for everyone. Greater IIV on constrained tasks reflects an inability to maintain consistent levels of performance [7,135,136]. This study instead involved unconstrained mobility habits, which individuals may modify to compensate for cognitive difficulties. Therefore, the observation of GPS IIV as indicative of positive rather than negative outcomes may be specific to unconstrained geospatial routines or to our relatively functionally healthy sample. We may still observe that greater IIV associates with worse outcomes when considering more fine-grained digital biomarkers (eg, diurnal phone use patterns and accelerometer-based sleep estimates) that are relatively more constrained, as has been identified in other studies examining IIV in gait speed, medication-taking routine, and computer use [137-139]. We may also see that greater IIV in broad everyday behaviors is a marker of resilience early on but becomes

maladaptive in later stages of neurocognitive decline. Larger samples with greater heterogeneity in cognitive ability are needed to answer this question, in addition to longitudinal designs that would enable monitoring of within-person IIV trends over time. In the meantime, our relatively cognitively healthy sample provides insights into how variability behaves in early stages and unconstrained settings. Consistent with past reports of significant task and timescale effects on IIV [140], IIV in continuous mobility trajectories may be mechanistically distinct from IIV in constrained settings.

Concurrent validity was supported by strong and significant associations between mean-level GPS features and baseline scores on the LSA and the ACPQ—self-report measures of geospatial life space and community activity participation, respectively. These 2 constructs are highly relevant in the context of aging and AD/ADRD and represent key measures of risk. The LSA measures the extent, frequency, and independence of movement within and outside the home. Constricted life space has been associated with increased risk of AD, MCI, and cognitive decline in racially diverse groups and may represent an early functional marker of prodromal decline as individuals compensate for early subtle difficulties and limit their range of movement or activity complexity [103,104,130]. Social engagement—particularly leaving the home to visit friends—protects against social isolation, promotes cognitive reserve, and represents a complex activity requiring cognitive flexibility [141-145]. Thus, the ability to unobtrusively and longitudinally measure these key risk and resilience factors without the burden or bias of self- or informant-report represents a noteworthy application for smartphone-derived mobility trajectories. Minimal associations were identified between GPS features and the TUG measure of gait speed. It is possible that low heterogeneity in TUG scores or small variations in the administration of the TUG played a role. It is also likely that gait speed and coordination are lower-level features of mobility that are independent of broader mobility habits, at least within this sample of functionally independent older adults.

We examined many individual and contextual influences on mobility features to inform future studies in selecting covariates or moderating factors. This is a critical open question in the field of digital phenotyping [66], and our preliminary results provide important insights into which sociodemographic, contextual, and technological factors should be considered when interpreting these data. Age, education, sex, race, and cohabitation status appeared to be minimally associated with most mean-level and variability metrics, providing partial support for the objectivity of digital phenotyping features. Nonetheless, other sociodemographic factors, including higher lifetime income and native English language status, were moderately associated with several mobility metrics that appear to be advantageous (ie, greater activity and greater IIV). This could reflect an association between social determinants of health and access to transportation, opportunities for socialization outside of the home, or an ability to engage in spontaneous activities—and may suggest mechanisms for income and acculturation as resilience factors.

Other extrinsic factors with relatively clear and interpretable effects included season, COVID-19–related effects, and

occupational status. Participants demonstrated greater activity, less home time, and more mobility variability in the summer months, which is reasonable given the increased leisure activities that typically occur in the summer. Therefore, seasonal differences are relevant if interpreting data in pre-post designs, suggesting investigators should aim to control for season or re-evaluate during the same season if possible. Participants reporting more COVID-19–related isolation visited fewer locations, whereas those reporting more COVID-19–related mobility expansion visited more. Individuals who were retired demonstrated more variable mobility habits than those working full or part time, which aligns with differential degrees of consistency depending on occupational status. In addition to shedding light on which factors are relevant when interpreting digital phenotyping data, these associations provide additional validation for the mobility features in this study.

Phone type was unrelated to all mean-level GPS metrics except for the number of minutes of missing data, which was significantly lower for iPhones. This finding is consistent with a previous study by Kiang et al [114] that identified lower rates of missing GPS data among iOS users and overall bodes well for the generalizability of mean-level metrics across different phone types and operating systems. Missing data were also higher among Black participants, which could be due to a higher proportion of Android ownership among Black participants in our study. Thus, controlling for phone type may be important when interpreting the minutes of missing data feature. iPhone users also demonstrated more variability in most GPS features, although only the missing data feature remained statistically significant after correction for multiple comparisons. Given iPhone ownership was positively associated with income, it is difficult to interpret whether increased variability among iPhone users was related to operating system factors, to aspects of resilience associated with income, or whether this reflects a spurious finding. Future studies with larger sample sizes should work to clarify these questions.

In considering the neuropsychological correlates of our GPS features, relations with cognition were strongest and most consistent for measures of language. In fact, relations between GPS features and the language composite were the only ones to survive correction for multiple comparisons (ie, less overall physical circadian routine, greater IIV in circadian routine, and greater IIV in home time were all strongly [$|r|>0.5$] associated with the language composite at $P<.0038$). This was somewhat unexpected given language abilities are typically not as critical to the completion of everyday activities compared to domains such as executive functioning [146,147]. Nonetheless, intact language functioning (specifically semantic access and retrieval) relies on left temporal and prefrontal integrity and connectivity, which are highly relevant neuroanatomical regions in the pathogenesis of AD. Interestingly, relations between GPS features and measures of memory were in the opposite direction compared to other cognitive domains; for example, more day-to-day variability in average flight length was associated with worse delayed memory performance. This finding may reflect inefficient planning and daily errors resulting in occasional backtracking when visiting common locations due to forgotten items. In general, differential relations between

GPS features and measures of memory and language—2 cognitive domains implicated in AD pathology—suggest relations between GPS features and cognitive abilities may not be as straightforward as our model predicted. Future studies should continue to investigate whether mobility phenotypes are uniquely related to specific neuropsychological and neuroanatomical correlates, rather than focus on a global cognitive composite. This may involve developing even more fine-grained GPS features to capture distinct functional difficulties in everyday life (eg, backtracking and repetitive motions).

Limitations and Strengths

Our study has several limitations that are worth noting. Our relatively small sample size of 37 individuals coupled with a relatively large number of analyses limits generalizability; thus, findings should be considered preliminary and proof-of-concept. Digital phenotyping is a new research area with relatively few established standards, yet preliminary validation of digital phenotypes has been reported in samples of under 50 participants [61,73,148,149] for ≤ 30 days of data collection [73,150-152]. Another major limitation is the restricted diversity of our cohort in terms of cognition and diagnostic severity (which precluded investigation of diagnostic group differences), demographics (ethnicity, education, and socioeconomic status), and severity of depressive symptoms. Furthermore, all participants lived within driving distance of Temple University and therefore reflected an urban and suburban cohort. In addition, individual data-processing exclusions were required to account for unanticipated travel and health events. Given our aim of establishing preliminary validity, there was a need to ensure participants met strict inclusion criteria, which included relative stability in their health and physical location. This level of control and oversight may be unrealistic in larger, longitudinal studies and may need to be replaced by advanced statistical methods in the future [153]. Finally, it is worth mentioning that mobility traces from smartphone GPS sensors are a proxy for actual movement trajectories and depend upon the participant having their smartphone on their body, requiring multiple imputation and inference for missing GPS data before feature calculation during preprocessing [109]. It is also critical that participants are the unique users of their smartphones, as others have mentioned issues with shared devices [154,155]. Sensors worn on the body may provide more accurate and reliable measures of mobility patterns but present other drawbacks (eg, may be perceived as more intrusive by participants, may disrupt existing habits, and are typically costly).

This study has several strengths. Our cohort was well characterized compared to many prior digital phenotyping studies, including a comprehensive neuropsychological battery with 10 individual neurocognitive tests, objective and subjective validation measures, and application of combined actuarial and consensus diagnosis criteria to accurately classify participants. Our study design and hypotheses were theoretically informed by a conceptual model, which improves the interpretability and replicability of our findings. Toward this aim, we examined a range of interpretable mobility features (ie, 13 monthly average features and 13 monthly iSD features) with correction for multiple comparisons before reducing features into a principal

component (MDS1). Results from the singular MDS1 component provided additional evidence that individuals with similar cognitive, functional, and mood profiles may demonstrate similar mobility profiles. Although many GPS features were intercorrelated, the presence of differential and unique correlations suggests individual features may be useful in clarifying specific behaviors and should be preserved as we continue to learn more about what these features signal. In addition, relative mobility profiles similar to the singular MDS1 component may be useful in identifying and classifying individuals with similar levels of underlying community participation and functional resilience. With regard to our technical protocol, the use of an open-source platform and a publicly available data processing script facilitates replicability, which is key to ongoing validation efforts [156]. Attempts at minimizing missing data using an automated checking script represent another strength and should be incorporated in future studies given the impact of missing data on subsequent findings [66]. Finally, our device-agnostic approach leveraging personally owned smartphones versus a study-issued device represents a notable strength as it promotes the naturalistic, unobtrusive nature of this method and affords increased scalability.

Future Directions

Future studies with larger and more diverse cohorts will be critical to replicate the present findings and address open questions. Given the lack of accessible and unbiased diagnostics available to individuals from low-income and marginalized groups [53-55,157], increased diversity in terms of race, ethnicity, educational attainment, and socioeconomic status is a priority for subsequent studies. Validating this method in more clinically heterogeneous samples will be critical to evaluate its ability to distinguish between age-related cognitive decline, neurodegenerative decline, and other medical or psychiatric conditions, and between various clinical and biological subtypes of dementia and ADRD. Both activity-level and IIV metrics should be evaluated, as variability appears to be fundamentally distinct from mean-level metrics and relates to AD risk [158]. Next steps will also investigate relations between validation measures and other sensors (accelerometer, device state, and steps) to extend the present findings and test our theoretical framework in behavioral features other than mobility trajectories. Machine learning or cluster approaches integrating multiple sensor streams may be helpful in determining clinically useful digital phenotypes, thereby reducing the analytic burden and narrowing the focus on clinically relevant, nonredundant features. Additional open questions include the test-retest reliability of digital phenotypes; the incremental utility of ecological momentary assessment, which can provide context to passive data [7,49,159]; determining the minimum necessary sensor sampling rate and duration to reduce battery drain; and evaluating within-day variability, diurnal patterns, and time of day effects on GPS features [26,49,75,138,160].

Because there is no ground truth for the application and interpretation of digital phenotyping data in aging and ADRD populations, additional studies are needed so that results can be compared across samples and insights can be consolidated to inform gold-standard approaches and normative data. As the

field continues to evolve, it is likely that longitudinal monitoring of within-person fluctuations will be the ideal approach to capture individually relevant changes rather than population- or group-based approaches [7,63,156,161]. This is particularly relevant in the context of first-line primary care screening and ADRD clinical trials, where scalable risk detection, trial screening, and treatment response measures are direly needed. However, with longitudinal designs and increased sample sizes, it will be important to consider whether the data storage, processing, and interpretation burdens justify breaking from the status quo. Workflows that enhance the efficiency and scalability of this method will be critical, not just for research participants and patients but also for those collecting and interpreting the data [7,80,111].

Conclusions

As the population of older adults continues to rise, efforts to identify new tools to detect risk for future cognitive decline and measure treatment response are critical, particularly as new pharmacological interventions gain approval. Current gold

standard methods are costly, burdensome, not widely accessible, and not part of routine clinical care. Measures that are sensitive to cognitive decline that can be passively and affordably integrated into everyday life without burden, disruption, or self-report bias are needed to serve as a first-line approach. Our study demonstrates that unobtrusively obtained GPS movement trajectories from personal smartphones may in the future be one such first-line approach, enabling clinicians and researchers to efficiently assess cognitive status, mood, and dementia risk on a broader scale. Individuals with at-risk data profiles may ultimately be referred for more comprehensive evaluation and directed toward appropriate intervention or research settings, leading to cost savings, reduced burden, and faster access to care. Much work remains to be done before we determine how smartphone digital phenotyping can be integrated into our current health care system; however, preliminary results suggest that it is a worthwhile endeavor and serve to inform follow-up studies that are necessary to answer important, outstanding questions.

Acknowledgments

Abstract

Background: When older adults (OAs) can no longer live independently at home, they have the option to choose from various types of geriatric care institutions, such as residential facilities or nursing homes. For several years now, thanks to the development of interactive television (iTV), social link functions have been accessible directly on televisions, tools that are already integrated into residents' rooms. The acceptance of technologies specifically targeting older users, as well as iTV, has been widely documented in the literature, incorporating factors from the innovation resistance model.

Objective: This research aims to enrich the acceptance of existing models of innovation by OAs living in different settings.

Methods: User tests were carried out to evaluate OAs' experiences with iTV and identify the factors involved in its acceptance. A total of 32 OAs living at home, in nursing homes, or in residential facilities in France were interviewed between November 2022 and June 2023. iTV acceptance was examined using an interview grid based on the technology acceptance model and included the following factors: intention to use, perceived usefulness, perceived ease of use, user resistance, anxiety, facilitating conditions, and user characteristics.

Results: The deductive qualitative analysis based on the technology acceptance model helped to identify 33 concepts.

Conclusions: This study has contributed to the literature on the acceptance of iTV by OAs living at home and in geriatric institutions, particularly by enriching existing models and proposing new avenues for reflection.

Introduction

Background

Older adults (OAs) experience perceptual, physiological, and cognitive changes with aging [1,2], which may affect their daily independence. When it is no longer possible for them to remain

at home (due to, eg, the presence of cognitive problems, functional problems, or a combination of both cognitive and functional problems) [3], OAs may choose between different types of accommodation, including residential facilities (RFs) or nursing homes (NHs). In France, RFs represent a step between home and institutional care [4]. For several years now, and especially since the COVID-19 pandemic, NHs and RFs

have been equipped with information and communication technologies (ICTs; eg, tablets, computers, and smartphones) to promote a feeling of connection between residents and their relatives [5,6]. However, access is not the same as accessibility. In fact, OAs appear to experience stress when using technology, also known as technological anxiety, which is described as (free translation) “a negative psychological state associated with the use or fear of having to use ICT. This experience produces feelings of anxiety, mental fatigue, skepticism and inefficiency” [7]. OAs who are anxious and lack confidence in their own abilities also show greater resistance to gerontechnologies [8-10] and an increased need for support.

With the development of interactive television (iTV), social networking functions (eg, social networks, video calls, and text messages) are now accessible directly on the television screen [11,12]. The appeal of this new technology, in contrast to other ICTs, is rooted in its familiarity. Given that television systems are already a fundamental component of OAs' daily routines (ie, their main source of information and entertainment) [12], iTV may offer a less anxiety-inducing alternative to traditional ICTs [12-16]. Although iTV seems to be able to facilitate access to social link functionalities within geriatric institutions, its long-term use depends on several other factors, including organizational (eg, staff turnover and additional workload), human (eg, health, self-efficacy, and technological and social habits), ethical (eg, privacy and agism), and technological factors (eg, technical and ergonomic problems with iTV and nonexistent or inadequate training) [17-19]. The literature on the acceptance of technologies by OAs is often stereotypical [20], considering the older user to be resistant to any form of innovation and lacking motivation to use a technology [21]. However, some authors [21] challenged these studies, explaining that while OAs value their independence, privacy, and social interaction, products designed specifically for this population focus mainly on safety and assistance aspects. In the technology paradoxes framework [22], consumers face paradoxes while using technology, creating negative emotions, such as anxiety and stress. To combat these emotions, consumers tend to adopt various pre- or postacquisition coping strategies to avoid or confront the technology. Applying this framework to older consumers, Wilson-Nash and Tinson [23] found that most of the strategies adopted by OAs are confrontational, showing that despite previous assumptions of lack of dynamism or willingness [24,25], OAs are keen to master the technology. There is a wealth of literature on the factors influencing the adoption of technological innovations, and several explanatory models have been developed. The 2 main ones are the technology acceptance model (TAM) proposed by Davis [26] and the unified theory of acceptability and use of technology (UTAUT) proposed by Venkatesh et al [27].

Models of Technology Acceptance

According to the TAM, the acceptance of technology, that is, the extent to which a product will be used or not, depends on 2 main factors: perceived usefulness (PU) and perceived ease of use (PEOU) [26]. Subsequently, other extended versions of the TAM emerged, culminating in the proposal of an integrative model named UTAUT [27]. Venkatesh et al [27] differentiate between the determining factors, that is, factors influencing the

intention to use (IU) or the use of technologies, and the moderating factors, that is, factors influencing the determining factors. These include expected performance; expected effort; social influence; and the presence of facilitating conditions (FCs), such as documentation. Although these models have been used in a variety of contexts, their original field of application is the workplace. Venkatesh et al [28] then proposed a second version of the UTAUT (UTAUT 2), which is better adapted to the context of consumer use. Three other factors have been added to the existing determining factors: hedonic motivation, monetary value, and habit. Finally, these same authors proposed ways of developing the model, such as integrating contextual factors (eg, organization and physical environment) and individual factors (eg, user and technology characteristics) [29]. At the same time, Chen and Chan [8] have been looking at the acceptance of technologies by OAs and have developed the Senior TAM. This model incorporates factors from both TAM and UTAUT, such as PU, PEOU, attitude to use, FCs, self-efficacy, and anxiety about gerontechnologies. The authors also added age-related factors such as perceived health, cognitive ability, attitude to aging, satisfaction with life, social relationships, and level of physical functioning. Age, gender, level of education, and economic status were also considered as control variables.

Innovation Resistance

The adoption of a technological innovation may also depend on the user's degree of resistance to change, that is, to the maintenance of the status against the pressure of change [30]. Any disruption to users' routines can alter their psychological equilibrium, which then needs to be adapted to reduce resistance [31,32]. An innovation can only be adopted once the initial resistance has been overcome by users [33]. Several authors have attempted to identify the factors influencing this resistance, such as the practice habit, and the perceived risk of the innovation [34] or the innovation, propagation mechanism, and user characteristics (UCs) [33]. According to Joseph [35], 3 types of factors seem to influence resistance: functional, psychological, and informational factors. Finally, user resistance (UR) seems to depend on several multidimensional factors.

The Acceptance Model Used in This Study

In their study on the acceptance of iTV, Im et al [36] proposed an integrative model combining the models of acceptance (TAM [26]) and resistance to innovation [33]. They aimed to go beyond previous theoretical frameworks to better explain the dynamic nature of adoption [37]. According to these authors, the factors influencing iTV adoption are PEOU, PU, UCs (eg, previous experience with innovations and self-efficacy), resistance to innovation, and IU. However, this model does not consider the characteristics of OAs (eg, cognitive and physical disorders, lack of digital literacy, technological anxiety, and low sense of self-efficacy) [2,38,39], nor does it consider the specific characteristics of geriatric residents [40].

This paper presents a qualitative study investigating the factors that might influence the acceptance of the iTV system by OAs living at home, in RFs, and in NHs. The first step was then to create an acceptance interview grid addressing both the specific features of the technology and those of the population studied.

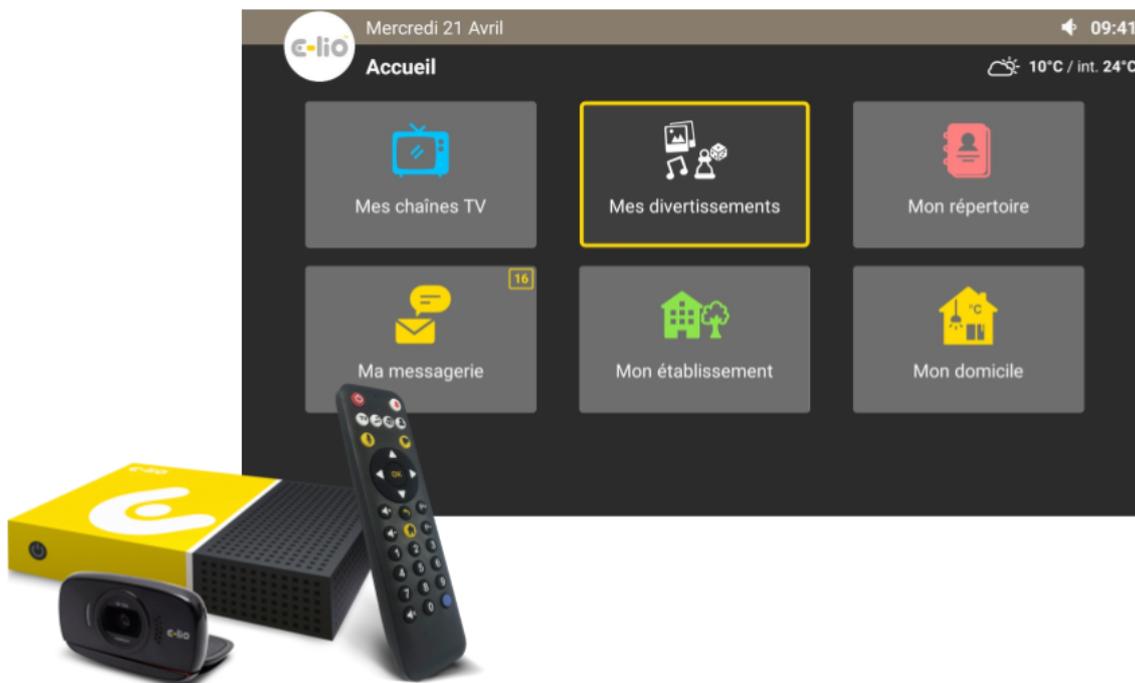

Therefore, this study aimed to enrich existing models of acceptance by suggesting new lines of thought on the determinants of acceptance proposed in these models.

Methods

Overview

The method used was borrowed from the user-centered design and the qualitative and quantitative methods of user testing [41]. The aim was to place participants in real-life conditions based on pre-established iTV use scenarios. By combining observation and interviews with the participants, the researcher was able to identify the difficulties encountered when using the technology. As part of this study, the participants could receive cues if they were stuck, asked for help, or made a mistake.

Figure 1. The e-lioTV system and the main menu interface: the box, camera, and remote control.

Questionnaires and Interview Grid

To identify the different profiles of participants, we administered a sociodemographic and a technological habit (eg, frequency of use of technologies) questionnaire. A semistructured interview to examine iTV acceptance was conducted at the end of the user tests. An interview guide (Table 1) was constructed based on the literature on the acceptance of technologies [26,43,44], and in particular iTVs [36], among OAs [8]. The final extended TAM (e-TAM) consists of the following seven

Materials

The iTV

The iTV selected for the user tests (e-lioTV) is a system developed by Technosens [42] and installed in geriatric institutions since 2011. A total of 53 NHs and RFs in France are equipped with this iTV, which is installed directly in residents' bedrooms. This iTV consists of a box connected to a television screen and offers communication (eg, text messages, photos, and video calls); entertainment (eg, television channels and radio); and information services (eg, news from the institution; Figure 1). All these functions can be accessed via a single remote control.

dimensions: (1) IU; (2) PU; (3) PEOU; (4) UR; (5) anxiety; (6) FCs (eg, peer support and self-efficacy); and (7) UCs (eg, previous experience and interest in technology, social influence, and perceived health). Participants were asked to give their opinion on statements using a 5-point Likert scale ("1" indicating "strongly disagree," "2" indicating "disagree," "3" indicating "neutral," "4" indicating "agree," and "5" indicating "strongly agree"). We then asked them to explain their responses.

Table 1. The interview guide based on the extended technology acceptance model.

Dimensions and affirmations	References
Perceived utility <ul style="list-style-type: none"> “E-líoTV is practical for me.” “E-líoTV provides me with various useful functions and services.” 	[36]
Perceived ease of use <ul style="list-style-type: none"> “It takes much time and effort to understand and use e-líoTV.” “I found e-líoTV easy to use.” 	[26,36]
User resistance <ul style="list-style-type: none"> “Using e-líoTV is burdensome.” “E-líoTV is not for me.” 	[36]
Anxiety <ul style="list-style-type: none"> “I’m afraid of using e-líoTV.” “I’m afraid that if I press the wrong button on the remote, I might break something on e-líoTV.” 	[43]
Intention to use <ul style="list-style-type: none"> “I want to have e-líoTV in my home.” “I would recommend others using e-líoTV.” 	[36]
Facilitating conditions <ul style="list-style-type: none"> “In general, if I have a problem with a device, I ask my family or care staff for help.” “It is easy for me to understand and use new devices.” 	[36,44]
User characteristics <ul style="list-style-type: none"> “The people I care about push me to use messages and video calls.” “In general, I’m curious to learn how to use a new device.” 	[44,45]

Participants and Recruitment

Participants of the study lived in geriatric institutions (eg, NH and RF) or at home and were not e-líoTV users. Participants living at home were recruited in Paris, while others were recruited in the Saint-Etienne and Grenoble regions. The inclusion criteria were that the participants should be (1) aged >60 years, (2) literate, and (3) able to use a television remote control by themselves. Exclusion criteria were (1) having a Mini-Mental State Examination score of <16 [46] and (2) having visual, hearing, or motor problems that prevented them from using a television remote control, unless they could be compensated for by a technical aid. To this end, for NH and RF residents, professionals were asked to draw up a preliminary list of willing residents who met the above criteria.

In total, 38 participants were approached (RF: n=10, 26%; NH: n=12, 32%; and home: n=16, 42%) between November 2022 and June 2023. Before each scenario, the researcher asked whether the participant wished to continue. Of 38 participants, 5 (13%) chose to stop before the end of the test due to increasing fatigue and 1 (3%) person was excluded because he was illiterate. A total of 32 participants were included, including 23 (72%) women and 9 men (28%). The demographic characteristics of the 3 groups are presented in Table 2. These data seemed in line with the literature, with participants living in NH belonging almost entirely to the category of those aged >80 years [4]. In this study, it is interesting to note that almost all the participants living at home had a higher education degree (postgraduate degree) compared with the institutionalized participants.

Table 2. Sociodemographic characteristics of participants (N=32).

	Gender, n (%)		Age (y), n (%)			Education, n (%)	
	Women (n=23)	Men (n=9)	60 to 69 (n=5)	70 to 79 (n=11)	>80 (n=16)	Undergraduate (n=17)	Postgraduate (n=15)
NH ^a (n=7)	4 (17)	3 (33)	0 (0)	1 (9)	6 (38)	7 (41)	0 (0)
RF ^b (n=9)	7 (30)	2 (22)	3 (60)	1 (9)	5 (31)	8 (47)	1 (7)
Home (n=16)	12 (52)	4 (44)	2 (40)	9 (82)	5 (31)	2 (12)	14 (93)

^aNH: nursing home.

^bRF: residential facility.

To explore participants’ technological expertise, we assessed the frequency of mobile phone use by functionality (eg, calling, answering a call, sending a text message, and checking a text message) and the overall frequency of computer and tablet use. We then categorized their expertise with the technology as follows: a person is considered an “expert” if they use the feature or technology “several times a day” or “every day or almost every day,” and a person is considered a “nonexpert” if they do

not use the feature or technology or if they use it “every week” or “every month.” According to Table 3, most participants (RF: 9/9, 100%; NH: 6/7, 86%) in the RF group and NH group were not experts in the use of computers, unlike participants in the home group. In addition, some of the participants in the RF group (make a call: 5/9, 55%; send a text message: 4/9, 44%) used their mobile phones more frequently than those in the NH group (make a call: 1/7, 14%; send a text message: 0/7, 0%). It

is interesting to note that among the smartphone users (NH: n=0, 0%; RF: n=6, 67%; and home: n=15, 94%), those living

in RF tended to restrict the use of their mobile phones to calling and messaging.

Table 3. Technological expertise of participants (N=32).

Level of expertise	Mobile phone, n (%)				Computer, n (%)	Tablet, n (%)
	Make a call	Answer a call	Send a text message	Receive a text message		
NH^a (n=7), n (%)						
Expert	1 (14)	2 (29)	0 (0)	0 (0)	1 (14)	0 (0)
Nonexpert	6 (86)	5 (71)	7 (100)	7 (100)	6 (86)	7 (100)
RF^b (n=9), n (%)						
Expert	5 (56)	8 (89)	4 (44)	5 (56)	0 (0)	1 (11)
Nonexpert	4 (44)	1 (11)	5 (56)	4 (44)	9 (100)	8 (89)
Home (n=16), n (%)						
Expert	14 (88)	15 (94)	15 (94)	15 (94)	16 (100)	5 (31)
Nonexpert	2 (12)	1 (6)	1 (6)	1 (6)	0 (0)	11 (69)
Total (N=32), n (%)						
Expert	20 (62)	25 (78)	19 (59)	20 (62)	17 (53)	6 (19)
Nonexpert	12 (38)	7 (22)	13 (41)	12 (38)	15 (47)	26 (81)

^aNH: nursing home.

^bRF: residential facility.

Procedure

The tests were carried out individually and systematically by 2 people (BN and a colleague). While the first author conducted each part of the procedure, the other researcher was invited to observe and take notes. Informed consent was obtained on the day of the appointment after the participant had been reminded of the objectives of the research. Before starting the scenarios on the iTV, the overall cognitive level of each participant was assessed, either by the institution's psychologist or by the researcher (first author), using the Mini-Mental State Examination. Then, participants were asked to complete a sociodemographic questionnaire and to share their technology use habits. After a brief presentation of the principle and overall functioning of the iTV (eg, the different components of the tool, such as the box, camera, and remote control, and the main features), participants' first impressions were gathered. The iTV was used through 3 scenarios of increasing difficulty, each with more steps than the last (eg, answering a video call, checking a text message, and making a video call). The researcher then collected participants' opinions or recommendations on the iTV throughout the scenarios. Once the 3 scenarios had been completed, the semistructured interview, based on the e-TAM, was conducted. If necessary, the researcher asked participants to develop some answers. Finally, and at the participant's request, the researcher could also provide an additional explanation of the iTV's marketing status and target audience, as well as the rest of its functionalities not used in this test (eg, radio, news from the institution, and games). Participants were then invited to react on their behalf, as well as on behalf of someone close to them.

Ethical Considerations

Ethics approval for this study was obtained from the Université Paris Cité Research and Ethics Committee in November 2021 (approval number 00012021-91). Validation of the data management procedures and related compliance with the General Data Protection Regulation was obtained from the data protection office and registered in the general register of Greater Paris University Hospitals (Assistance Publique-Hôpitaux de Paris) in February 2022 (20220228123925). The collected data were anonymized in such a way that identification of individuals or sources of information is not possible. Participation in the study was voluntary and subject to the signing of an informed consent form. Participants were informed of their right to withdraw from the research project (resulting in the deletion of their data) and their right to access and rectify information concerning them.

Qualitative Analysis

Two authors participated in the qualitative analysis (BN and ASR). Deductive thematic analysis was carried out based on the transcribed user tests. The aim was to identify the factors that could influence performance on the iTV and, therefore, its acceptance, based on the e-TAM factors. To this end, we took inspiration from the Qualitative Analysis Guide of Leuven [47] following three preliminary steps before coding the interviews: (1) highlighting important elements and writing a mini report on the participant's characteristics, (2) designing conceptual schemes, and (3) validity testing. Once the conceptual schemes had been tested and validated, we were able to draw up a list of concepts used to code the transcripts. These concepts were classified according to the e-TAM factors, allowing us to develop some of them further or even to create new ones. An

overall conceptual framework for our transcripts, in the form of a mind map, was thus created. Finally, each concept was described, including a short summary of the points raised in the interviews and a few key verbatims.

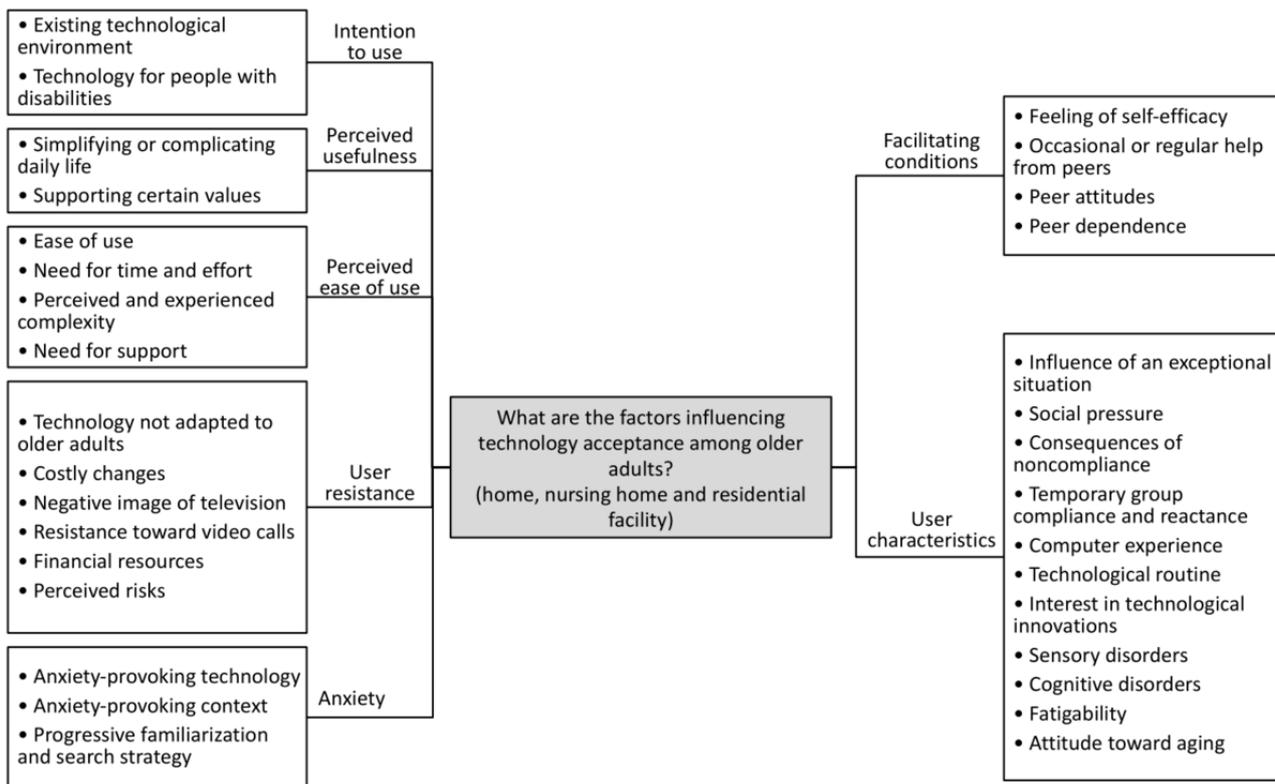

UCs. A summary of the 33 concepts found during the deductive qualitative analysis is presented in Figure 2. Figures 3-9 show the number of participants who rated 1, 2, 3, 4, or 5 on the Likert scale. Different colors and symbols are used to represent the 3 living environments.

Results

Overview

According to the e-TAM, iTV acceptance depended on 7 factors: IU, PU, PEOU, UR to iTV, anxiety when using iTV, FCs, and

Figure 2. Mind map of themes and subthemes from the deductive qualitative analysis based on the extended technology acceptance model.

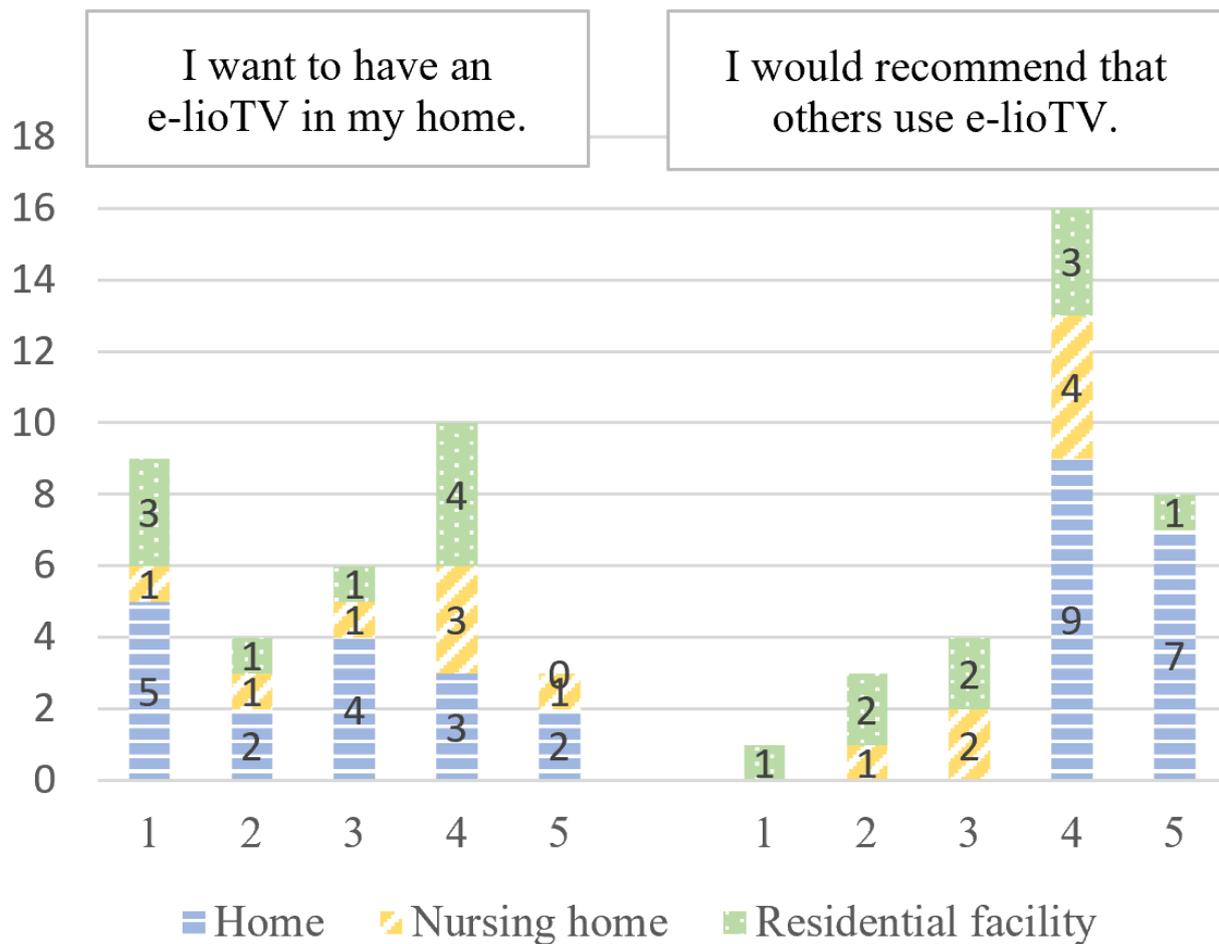

IU Dimension

Overview

Although they seemed to perceive an interest in iTV in general, participants were equally divided between those who would

like to have an iTV at home (13/32, 41%) and those who would not (13/32, 41%). However, all participants living at home would still recommend iTV to their friends and family (Figure 3).

Figure 3. Intended use of interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Existing Technological Environment

Many participants (30/32, 94%) already owned several technologies, some for several years, and had well-established communication and information habits. Some of them (6/32, 19%) saw no point in using an iTV as a complement. The technology was perceived as a gadget with no added value compared to existing technology (fewer functions or accessibility options, such as voice):

Me personally? No, no, I won't use it...Because I have other things, things that react to my voice, things that are much more responsive. [Participant 2, home group]

There was a multiplicity of everyday technologies:

I have enough machines to do it. [Participant 13, home group]

It is interesting to note that this barrier only concerned OAs living at home, that is, in this study, the participants who owned the most technology.

Technology for People With Disabilities

E-litv could be seen as a technology for people who are losing their independence with temporary or permanent cognitive or mobility impairments. In fact, one of the advantages of the iTV identified was the centralization of functions on a technology that is already used on a daily basis and located in a single room, often the most frequented in the home. In the event of a call, this could reduce the risk of falling (getting up in a hurry if the phone rings):

It's certain that if one day I'm a lot less mobile, and if I'm less able to flit from one thing to another, I'll use this device. [Participant 2, home group]

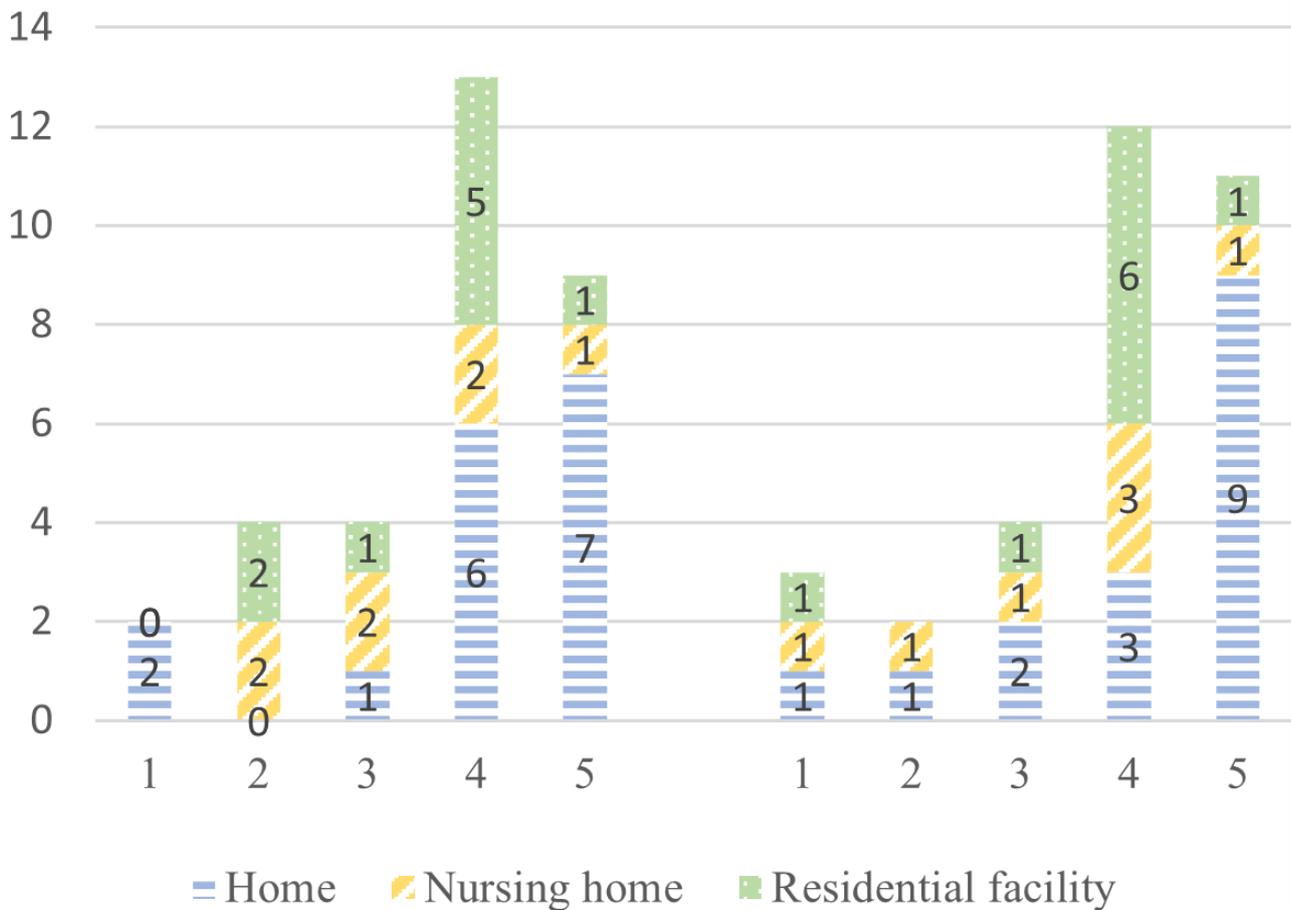

However, this comment was only made by OAs living at home (7/32, 22%), and if we observe the left side of Figure 3, no link can be made between living settings and the IU.

PU Dimension

Overview

The iTV seemed practical for most participants living at home (13/16, 81%) and in RF (6/9, 67%), with the services offered perceived as useful (Figure 4). However, the opinions of the participants living in NHs seemed to be more nuanced.

Figure 4. Perceived usefulness of interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Simplifying or Complicating Daily Life

Most participants (22/32, 69%) had a very positive attitude toward iTV and were satisfied with the principle of having a television screen that brings together several functions (23/32, 72%). According to 1 participant, this principle is “very clever” (Participant 3, home group) and avoids the multiplication of technologies in the home (10/32, 31%). Using a television system also means that functionalities such as games can be accessed on a larger screen. Furthermore, it is easier to position oneself in front of a camera on a television screen than on a smartphone. However, some participants (4/32, 12%) seemed to consider technological innovations as an unnecessary complication of everyday life. For example, even before the operation of the iTV was explained to them, some participants showed no interest in discovering this technology:

I don’t need it because I just want to keep watching the news and that’s all...I’m starting to say: “Whoa, let’s just stay as we are, let’s not complicate our lives.” [Participant 6, NH group]

The value of technology can also be linked to a person’s lifestyle and job. One former farmer, who had always lived in a rural environment, had never understood the usefulness of a computer:

And then, in the countryside, it’s not really that useful. The main thing is to have the essentials. [Participant 14, NH group]

Supporting Certain Values

According to some participants (12/32, 37%), the iTV’s features were relevant because they supported values that were important to them, including connection with the outside world; the iTV could facilitate interaction with loved ones and provide people with the opportunity to take part in moments of life through photos and video calls:

Oh yes, indeed, you can travel that way. [Participant 7, NH group]

Autonomy and health was also important; other participants appreciated the reflection involved when using the iTV, as well as the games:

That way, he can do cognitive remediation on his own. [Participant 3, home group]

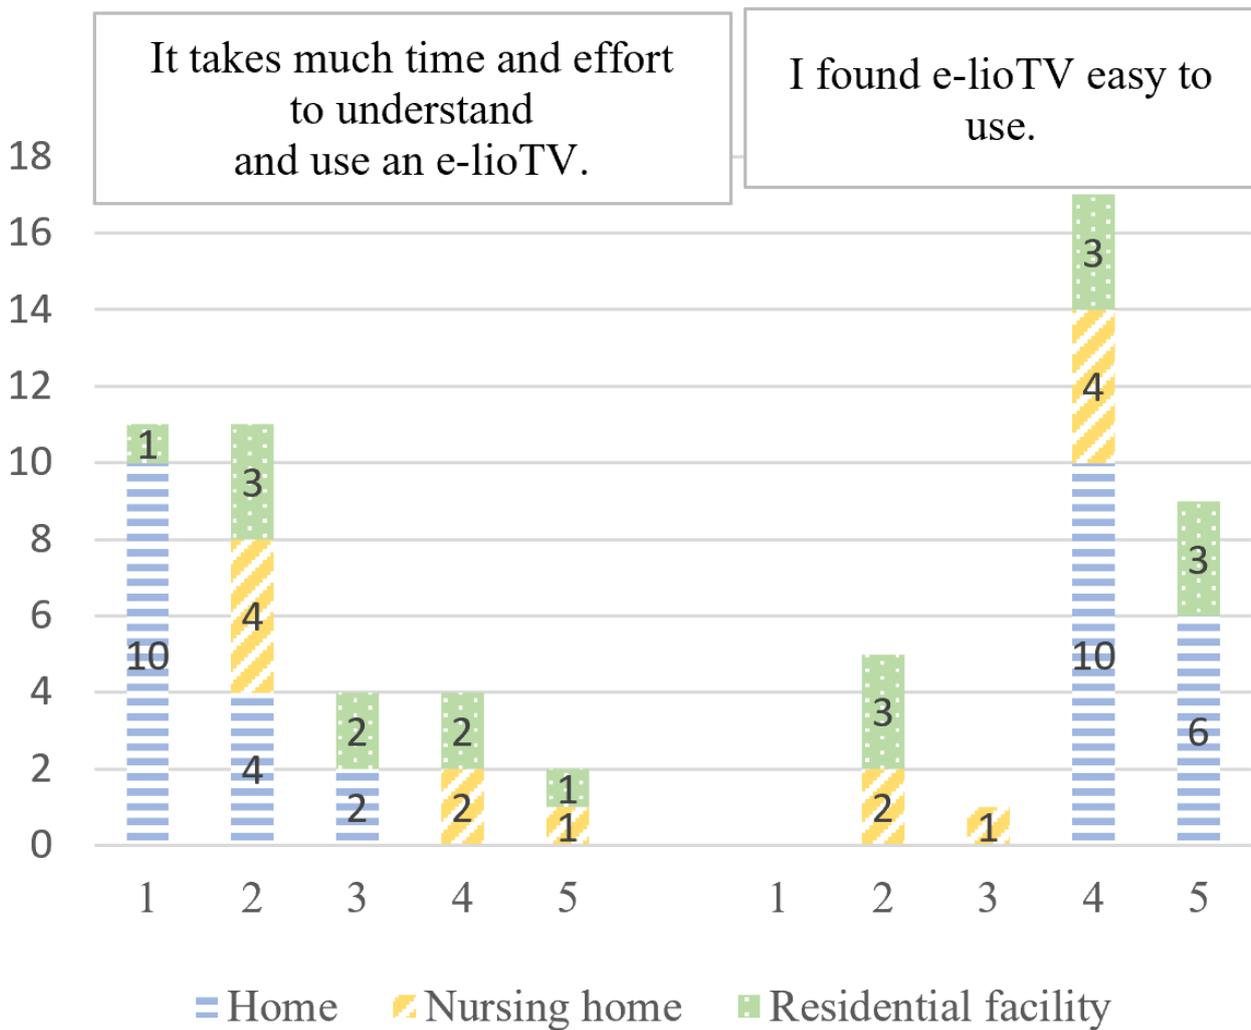

Video calls could also help to reassure family and friends.

PEOU Dimension

Overview

Most participants found the iTV easy to use (NH: 4/7, 57%; RF: 6/9, 67%; and home: 16/16, 100%). However, a few participants living in RFs (3/9, 33%) and NHs (3/7, 43%) reported that they needed a little more time to learn how to use it (Figure 5).

Figure 5. Perceived ease of use of interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Ease of Use

The iTV seemed easy to use for most participants (26/32, 81%), even for those with no computer skills or with mild cognitive impairment. Several participants (14/32, 44%) found that the remote control had few new buttons, making it easy to identify the most important ones. The icons also seemed logical and easy to understand. The information inserted on the television screen served as a memory aid; instead of spending time looking for the solution, they felt that the system was doing the work for them by pointing out the right buttons, something that is all the more relevant for OAs:

Well yes, everything has been spoon-fed, you know.
[Participant 1, home group]

It's visual, but maybe you need that more when you're older too. [Participant 14, home group]

This guidance greatly reduced the amount of information to be memorized, facilitating familiarization with the system and success during the first moments of interaction, an important phase in forming a good first impression. Finally, the participants had the feeling that they were being supported:

It's pretty simple, isn't it, because you're really being taken by the hand from the beginning to the end.
[Participant 1, home group]

Finally, 1 participant was used to a certain complexity on a daily basis (2 remote controls) and seemed pleasantly surprised to be able to do so many things with just 1 remote control.

Need for Time and Effort

Although the iTV was considered rather easy to use, some participants (17/32, 53%) said that they needed time to get used to it. This time was needed to develop automatisms and reflexes and to become familiar with the buttons and the iTV's operating principle, that is, looking at the screen to find the right button:

It requires some adaptation, and adaptation takes a little longer now. [Participant 11, home group]

However, although learning and problem-solving take longer with age, participants were not bothered, also because they had more time to spend on this than young adults:

It took me a little while to find it, but does it need to be immediate? I'm not sure. [Participant 8, home group]

Regarding the need for effort, several participants (6/32, 19%) emphasized the cognitive resources required to handle the iTV. Using this tool seemed to have a cost in terms of attention and mental flexibility to make the link between the guidance on the screen and the buttons on the remote control, select the relevant information on the screen, and remember the actions of certain buttons:

I was doing gymnastics between looking at the screen, looking at the remote control. [Participant 6, NH group]

Perceived and Experienced Complexity

Some participants (9/32, 28%) experienced difficulties in learning how to use the iTV, such as recognizing the icons on the remote control, pressing the buttons gently, or identifying the actions to be performed on the television screen. One participant stressed the need to simplify the technology as much as possible to avoid discouraging users:

It can be very discouraging for someone who doesn't understand it very well, and maybe not curious enough to insist either. [Participant 14, home group]

Indeed, when faced with several failures, 1 participant was tempted to give up:

Pfff. What am I going to do? I can't do anything. I'm stuck. [Participant 15, RF group]

Beyond the experienced complexity, the perceived complexity could influence the way the iTV was approached. Indeed, even before using the device for the first time, participants had already formed an initial impression based on their personal experience with their television. Some participants (4/32, 12%) perceived the remote control as complex (those who were using a remote control with fewer buttons on a daily basis), while others imagined that the iTV would be simple to use, similar to an

ordinary television. But this first impression could be misleading, particularly because of the difficulty of applying knowledge of other technologies to this device:

It looks very simple, but in the end, you have to find out what it means on the remote control. [Participant 14, home group]

I don't know why...I end up thinking about how to use a remote control. [Participant 14, home group]

Need for Support

Most participants (14/32, 44%) said that they needed extra support or even guidance to be able to use the iTV. The fact that there were no instructions and that they had to manage on their own from the start seemed to disconcert some of them:

We're letting people get started without giving them a user manual? [Participant 2, home group]

One participant highlighted the necessity for OAs to record all details in writing. A summary note of the remote control with the actions associated with each button might be enough, particularly in the early stages of the interaction. However, 1 participant was reluctant to have a user manual, considering it too complicated in general. Another participant preferred to have support from someone, particularly to reassure her during the first moments of interaction:

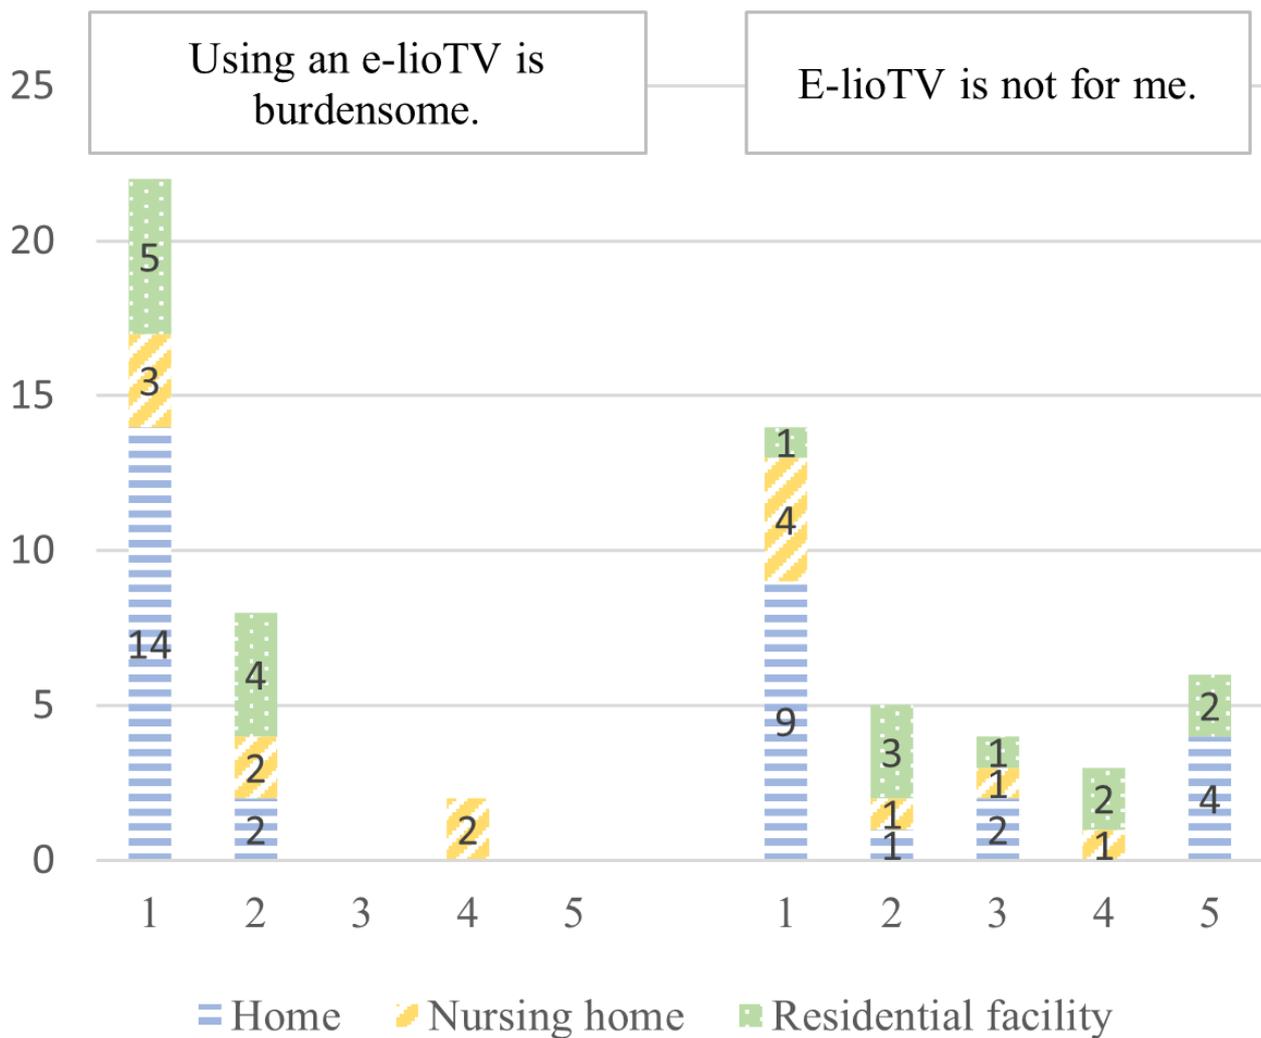

Well, at least.... I don't know, one or two days to fully understand the buttons. [Participant 15, RF group]

UR Toward the iTV

Overview

Although participants did not seem to find the iTV use burdensome (30/32, 94%), almost half of them (13/32, 41%) felt that iTV was not adapted to their needs and uses or did not give an opinion (Figure 6).

Figure 6. User resistance toward interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Technology Not Adapted to OAs

Some participants (7/32, 22%) immediately thought that the iTV was not suited to them or their NH neighbors for various reasons, including health conditions, with a participant stating, “We’re all a bit lost, I don’t think it’s really suited to our home” (participant 6, NH group). Other reasons included poor knowledge of technology use and age. This last point can be seen as self-agism. One participant seemed outraged by this stereotype:

[This television is not for me] Why? Because I’m stupid? And I’m old? [Laughs]. [Participant 7, NH group]

Finally, although participants found the functionalities rather useful, they almost systematically considered that the iTV was made for someone else, seeing no point in changing their habits.

Costly Changes

Some participants (4/32, 12%) had a negative attitude toward application updates or the switch to smart televisions, showing annoyance or even stress when using them. OAs found it difficult to adapt to change, with each new feature requiring an

effort to understand and learn, which became even more demanding with age (eg, slowness and need for repetition):

That’s what’s annoying, it’s the constant updates that turn everything upside down. So, you make an effort to keep up with it, you start to assimilate it more or less and that’s it, off you go again. [Participant 12, home group]

So, although the television remote control is used on a daily basis, most participants (5/32, 16%) were not used to using other buttons apart from the television channels to keep control of the situation. Therefore, using an iTV necessarily requires a learning curve. Another explanation for this annoyance could be the imbalance between the cost and benefit of the change, as it was not necessarily perceived as an improvement, especially if it made other functions less accessible. One participant showed particular resistance, mainly because using iTV made it harder for her to access television channels.

Negative Image of Television

A few participants (5/32, 16%) said that they disliked television in general, preferring to use another technology (eg, computer) or do another activity. The television system is generally

perceived as a technology that isolates people and encourages immobility. In addition, 2 participants (6%) found the programs they watched uninteresting. In this case, the television system was confused with the functionality of the television channels, affecting the overall iTV experience:

But I'll tell you, honestly... logically I don't like TV.
[Participant 15, RF group]

Resistance Toward Video Calls

A few participants (8/32, 25%) did not like making video calls because they were either uncomfortable with seeing themselves on a screen (7/32, 22%) or perceived video calls as an intrusion into people's privacy (1/32, 3%).

Financial Resources

Several participants (6/32, 19%) quickly raised the issue of the iTV's price. Aside from the usefulness of the system, this aspect was quickly considered by the participants when they were planning to use the system:

What bothers me is the money, to change television.
[Participant 14, NH group]

Moreover, as soon as the question of a subscription was raised, the participants seemed reluctant.

Perceived Risks

The participants (10/32, 31%) showed a certain reluctance toward technology in general or toward the iTV in particular because risks, such as addiction and social barriers (6/32, 19%). Several participants felt that the use of technology represented a social barrier, intruding between people and making communication difficult:

But it's frightening how many people have their smartphones and don't look at the person next to them. It's crazy. [Participant 1, home group]

Also, 2 participants (6%) showed contempt or annoyance toward people who spend a lot of time on their phones. One participant feared becoming an addict and refused to learn how to use a digital tool:

There are dangers there, I have to be careful.
[Participant 8, NH group]

Finally, 1 participant feared that iTV would be used as an excuse to reduce the number of carers or reduce the number of family visits.

Another barrier was excessive solicitation (4/32, 12%); some participants showed a certain resistance to ICTs (eg, social networks and iTV) because of oversolicitation. According to 1 participant, receiving text messages every day was inconceivable. Indeed, this form of remote communication is relatively recent:

No, no, no, once in a while! If people send me messages every day, it's going to explode. [Participant 1, RF group]

Oversolicitation could then lead to annoyance or even refusal to use the technology:

I don't want that but that's the flaw, it's the instantaneity of today's world. [Participant 12, home group]

However, 1 participant mentioned the possibility of an evolution in this resistance with the evolution in the importance of certain values with age, that is, favoring social contact over entertainment:

Human contact is even more important at that age than seeing a documentary on which she falls asleep, eh. [Participant 12, home group]

Another barrier was a lack of control over data (4/32, 12%); 2 (6%) participants mentioned the dangers of the internet and the importance of data protection. One of them was very reluctant to go online because someone she knew had been scammed. Generally speaking, the lack of control over technology seemed to bother the participants:

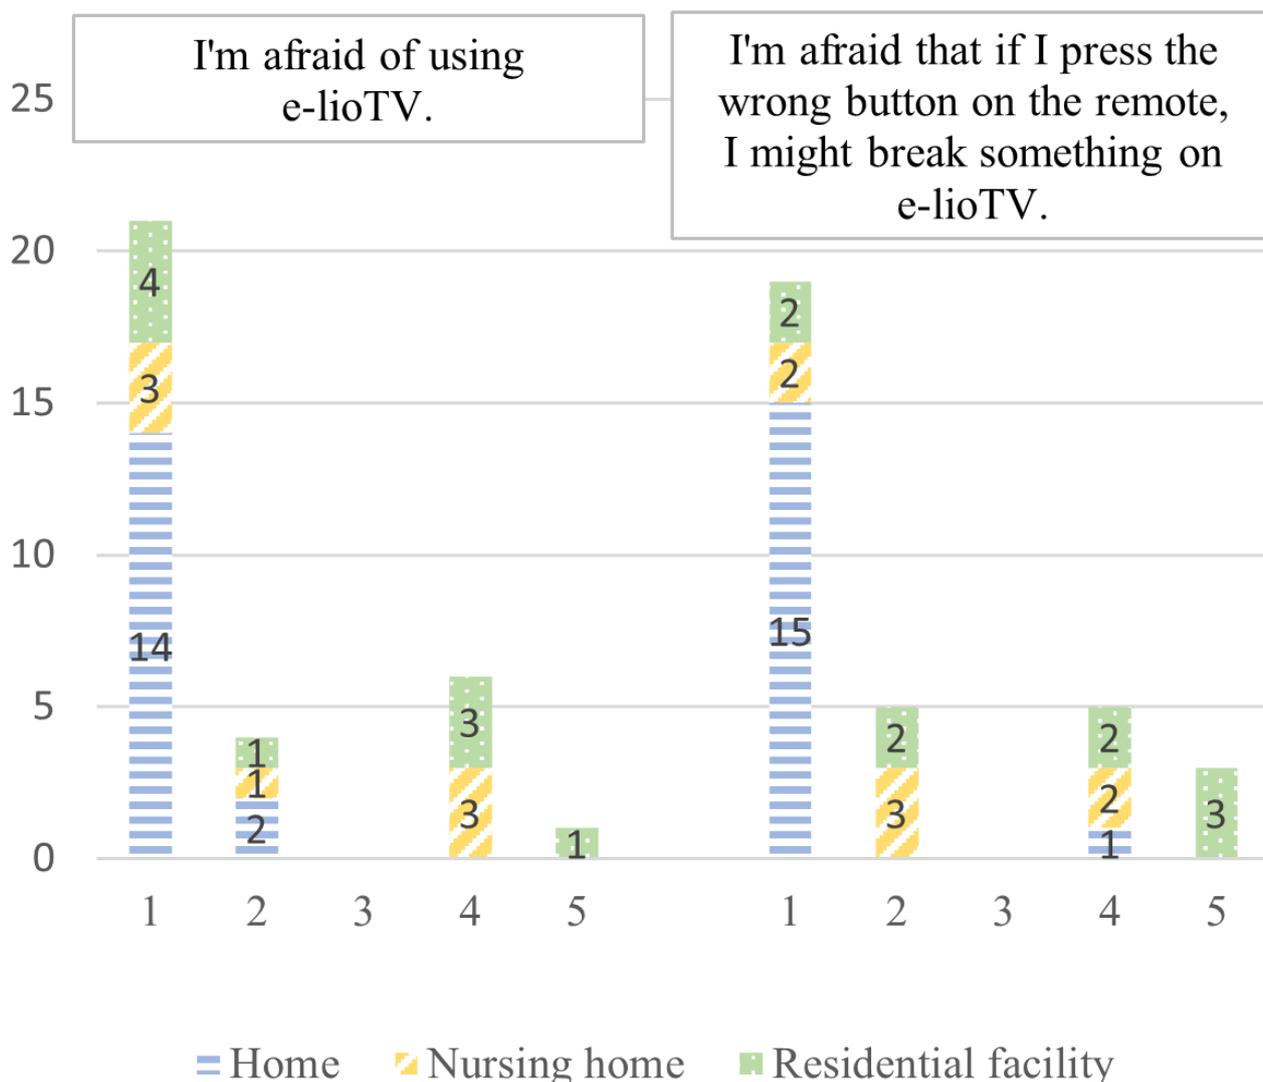

And can we deactivate this action? That's the problem. [Participant 12, home group]

Anxiety Toward iTV Use

Overview

The majority reported no apprehension about using (25/32, 78%) or even making mistakes on the iTV (24/32, 75%; [Figure 7](#)). The few participants (7/32, 22%) who reported some anxieties were those who lived in RFs or NHs.

Figure 7. Anxiety while using interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Anxiety-Provoking Technology

Several participants (14/32, 44%) reported feeling anxious when using their device: fear of making irreparable mistakes and getting stuck, having lost their bearings:

I'm not going to look too hard when it's set, because I'm always afraid of going wrong anyway. [Participant 14, home group]

Some participants (4/32, 12%) felt this apprehension every time they used their technology, while others (10/32, 31%) were especially stressed during the learning phase:

Computers really put me off because I can't get the hand of it... Oh yes, I screw up... I lose things... Pfff. [Participant 11, home group]

This apprehension was not the same depending on the technology: some participants (3/32, 9%) felt more comfortable with their computer than with their smartphone, with which they were less used to interacting, while others (2/32, 6%) apprehended using the television system:

I hope there's no remote control. [Participant 3, home group]

The remote controls seemed to generate stress because of their diversity (ie, each brand of television has a different remote control, as a participant stated: "Look, I don't really like remote controls, but because they change all the time" [Participant 5, home group]); a large number of buttons; or the presence of generic buttons (eg, colored buttons with no symbols on it and arrows). During the test, 1 participant did not feel confident because of the workload required by the iTV functioning (ie, linking the information on the screen with that on the remote control). These anxious OAs did not necessarily show resistance, but they saw the iTV as inevitably more complicated to use, making it difficult to apply their digital literacy:

I do it all the time. I was looking for something more complicated. [Participant 11, RF group]

To cope with this technological anxiety, some participants (4/32, 12%) adopted coping strategies such as neglect (eg, a participant preferred having someone operate her TV for her) or avoidance

(eg, ignoring certain buttons or functions on their television and remote control), stated as follows:

Oh no, no, I just do the channel and that's it. No, I haven't explored it, and I don't even know what these are [arrow buttons]. [Participant 7, NH group]

Anxiety-Provoking Context

One participant mentioned the influence of the context in which the technology was used on the stress felt at the time of use:

For train tickets for example, I don't know... there's something about it, there's the urgency and the stakes.
[Participant 5, home group]

According to her, what was most stressful was the stakes behind the successful use of the technology, as well as the potential consequences if it failed (eg, automated teller machine and train tickets). In the case of iTV, the ringtone used to notify the user of a call could also be stressful, with the user rushing to find the button to pick up the call (2/32, 6%).

Progressive Familiarization and Search Strategy

Some participants (11/32, 34%) were not afraid of pressing the wrong button and dared to explore. This confidence may have come from their own experience of computers or from their confidence in their ability to solve problems: they were aware that it was always possible to go back or ask for help:

Well, sometimes the experience consists of going back.
[Participant 2, home group]

You can go wrong at first, but you can go back, you can fix it. [Participant 10, RF group]

The participants' level of apprehension could then influence their strategies for finding solutions. If they found themselves stuck, some (5/32, 16%) opted for testing unknown or unused buttons, while others preferred to test randomly, seeing the mistake as an opportunity to learn something else. It is interesting to note that this confidence was acquired gradually, as OAs learned how the technologies worked and overcame their initial reluctance:

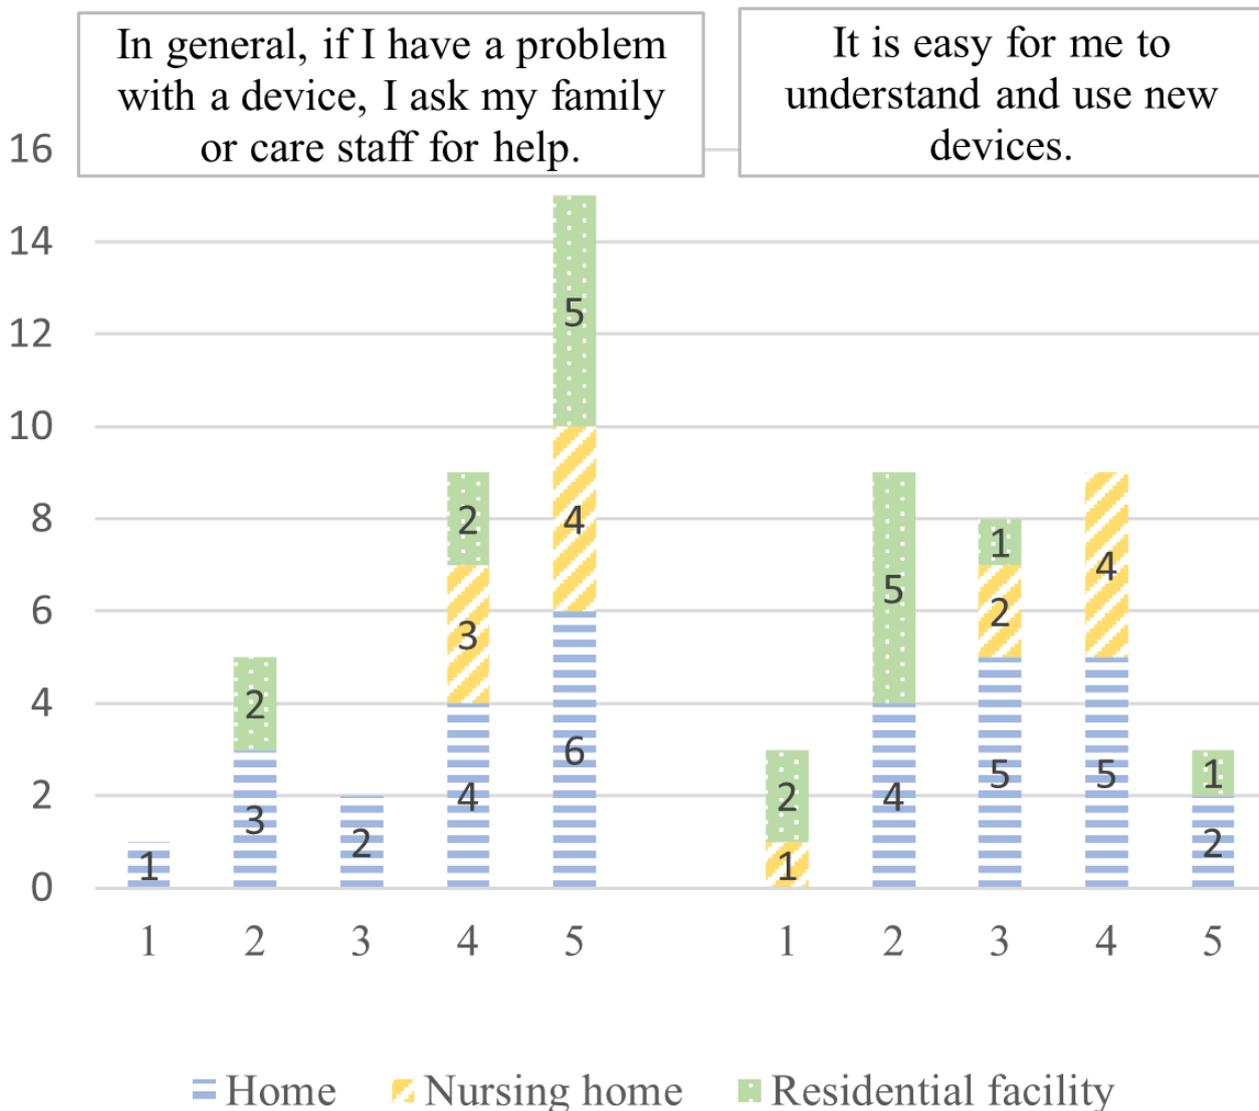

Now it's easy, because I've learned, but before, no, it was a real barrier. [Participant 5, home group]

FC Dimension

Overview

Most participants (24/32, 75%) considered having support from their families or care staff (those living in NH or RF; [Figure 8](#)). The few respondents who did not call on family and friends in case of problems were those who lived at home (4/16, 25%) and in RFs (2/9, 22%). However, when it came to their ability to learn how to use a new device, the participants were more divided: of 32 participants, 8 (25%) were undecided, 12 (38%) were fairly confident, and 12 (38%) were not. Interestingly, the participants who were least confident about using a new device were those living in RFs.

Figure 8. Facilitating conditions for the use of interactive television by older adults living at home, in residential facilities, and in nursing homes (1: strongly disagree; 5: strongly agree).

Feeling of Self-Efficacy

As shown on the right of Figure 8, participants’ feelings of self-efficacy varied considerably. Some participants (12/32, 37%) were confident in their ability to use and solve problems on the iTV, as 3 (9%) of them pointed out the role of expert that they assumed among their friends and family. Therefore, autonomy in finding solutions (eg, consulting YouTube [Google LLC] tutorials and online forums) could be an indicator of a feeling of personal efficacy. It is interesting to note that the feeling of anxiety depended on the technology and remained variable with time. For example, a participant felt confident using the iTV but doubted their ability to use a tablet. Even before they started the test, other participants (12/32, 37%) were skeptical about their ability to use the iTV independently, as a participant stated, “I’ll need help with this” (Participant 2, RF group), and seemed to consider its use as very difficult or impossible:

I was looking for something more complicated.
[Participant 11, RF group]

One participant even questioned their place in this test, stating “I’m wasting your time, aren’t I?” [Participant 7, NH group]. This lack of confidence in their abilities could have influenced their first experience with the iTV in several ways. As participants used the iTV, mistakes could be more prominent than successes, as a participant stated, “Well, that’s a good start!” [Participant 9, RF group], and they tended to blame themselves (eg, slowness, lack of thinking, and impatience and haste) for the slightest problem they encountered, never questioning the design or functioning of the technology:

Well, maybe it’s because I’m not paying enough attention. [Participant 6, home group]

The tests revealed the difference between participants who were actively looking for a solution and those who gave up at the first sign of difficulty and preferred to rely on the researcher’s help. Finally, a bias identified among some participants (4/32,

12%) was the supposed comparison with other people, younger or of the same age, making the situation even more frustrating:

I'm sure someone younger would have understood straight away. [Participant 14, home group]

Occasional or Regular Help From Peers

In most cases (20/32, 62%), peers provided occasional assistance, in particular, to help participants in the event of a problem, to support them as they familiarize themselves with a new technology or feature, or to explore other functionalities:

My son told me "there's a yellow line there." He says you have to press really hard. [Participant 14, NH group]

Training people in a new technology or function sometimes meant reassuring them during the first moments of interaction. On a few occasions, participants' relatives were able to act as advisers, pointing out the following additional features that could meet their needs:

- Audio message to address difficulty in writing SMS text messages
- Subtitle option to address difficulty in understanding a television program
- Pause function on television to help with urinary problems

Finally, other participants could also benefit from regular help with administrative formalities. In this case, the relatives provided more than just help as they were doing things directly for the participants. Help often came from younger family members and occasionally from friends or digital advisers via local councils. For participants living in institutions, the care staff were able to absorb some of the family's support role, especially when the family was not nearby. This feeling of trust between the resident and the professionals could facilitate the adoption of a new tool.

Peer Attitudes

Some participants (4/32, 12%) complained about the annoyance and impatience of their relatives:

My nephew often reproaches me: "You're not watching! It's indicated!" [Participant 16, RF group]

Moreover, peers may have lost interest when faced with the participant's resistance or may not be available to help if problems arise:

My family... they'll tell me "I don't have the time!" [Participant 15, home group]

However, as 1 participant pointed out, the trainer's attitude can be passed on to the learner and, therefore, influence their attitude toward the technology.

Peer Dependence

Several participants (10/32, 31%) depended entirely on their relatives for certain tasks (eg, video calls and tax declarations), which could accentuate the gap between their current skills and modern technological requirements:

For example, I have taxes, but my son does them, so I don't even know how to do them myself. [Participant 11, home group]

Depending on several people can constitute a barrier and complicate the day-to-day use of technology. For example, 1 participant was very frustrated and angry at having "lost" her computer when she moved into an institution, and another reported his dependence on his wife for the tablet they share. This dependence could be induced by peers or desired by the participants themselves. In the first case, peers might think that they were helping by sparing them the difficulties associated with the technology. This could be frustrating for 1 participant, who felt she was capable of managing her own accounts:

Because he's afraid I don't know how to manage my account, so he checks!...No, because I don't need him, I do it myself. [Participant 16, RF group]

In the second case, some participants tended to wait to be contacted or for someone to do it for them: although they had taken part in the test and shown their ability to use remote control, some participants living in NH (2/7, 29%) preferred to delegate its use to care staff, mainly because of the anxiety-provoking technology:

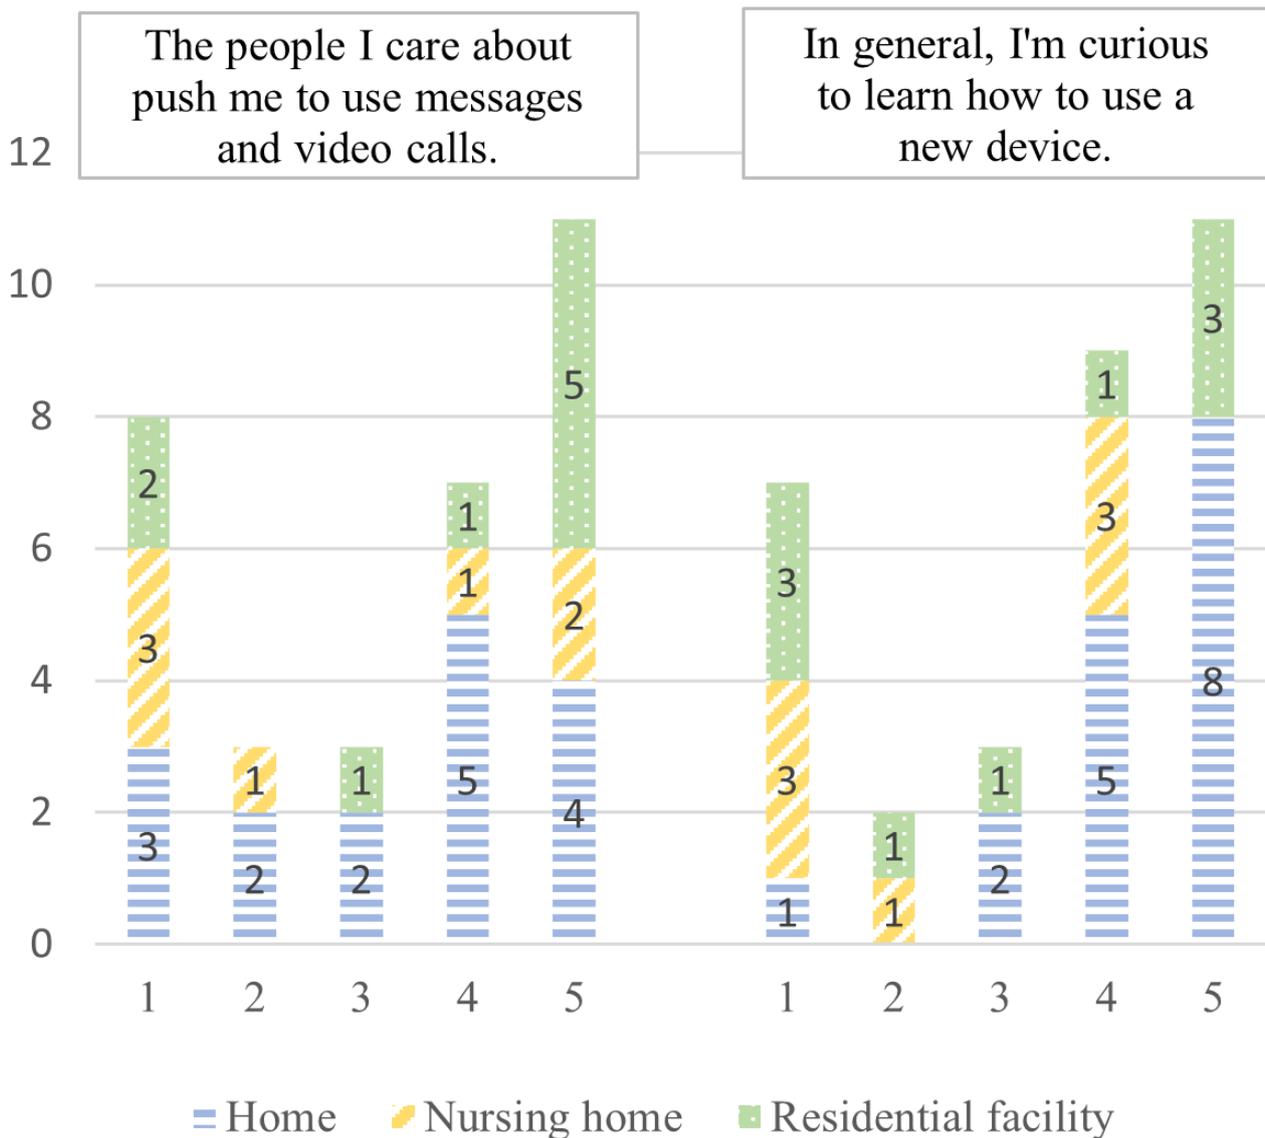

When they come, if the TV is on or off, they put it on for me or turn it off. I mean, I know how to turn it off, but still... I don't feel safe using it. [Participant 14, NH group]

UC Dimension

Overview

The participants from the 3 settings appeared to be divided into 2 groups in terms of the perceived social pressure and their curiosity about technology (Figure 9). In contrast to participants living in RFs who perceived a strong influence from their relatives (6/9, 78%), participants living at home and in NHs seemed more divided.

Figure 9. Participants' characteristics (1: strongly disagree; 5: strongly agree).

Finally, participants living at home seemed to be more curious about the idea of discovering a new technology (13/16, 81%) compared to participants living in RFs and NHs, who seemed more nuanced.

Influence of an Exceptional Situation

In response to exceptional situations (eg, a relative moving abroad and the COVID-19 pandemic), peers may have adopted different behaviors in an attempt to maintain cohesion within the group of friends or family. For example, during the COVID-19 pandemic, several participants (11/32, 34%) mentioned using video calls to stay in touch with their loved ones and to take part in activities (eg, a multimedia café organized by a laboratory). As a result of these exceptional situations, certain functionalities such as video calls or text messages may have become the norm in terms of communication within the family, within a group of friends, or even in the professional environment (eg, association). The iTV could then

have more added value since the COVID-19 pandemic and confinements, with the more widespread use of video calls:

If she'd had that [iTV with video calls], it would have made our lives a lot easier because we could have seen her. And it would have been nice for her, you know. [Participant 5, home group]

Social Pressure

Both private and professional peers could have a direct influence on the use of a feature or technology by encouraging the use of particular apps (eg, Google Maps [Google LLC] to find the way home and Skype [Microsoft Corp] for remote meetings; 3/32, 9%). Relatives could also offer participants a technology (eg, a tablet, smartphone, or a connected watch), first perceiving it as a gadget and then, after a period of familiarization, discovering its usefulness in everyday life:

No, no, it [connected watch] was offered to me because... I said it was a gadget, but when I saw the applications... [Participant 2, home group]

Furthermore, some participants (4/32, 12%) felt forced to use several apps depending on the habits of the person they were talking to (eg, Messenger [Meta Platforms], WhatsApp [Meta Platforms], and Signal [Signal Technology Foundation]):

I receive messages from people who each have the good idea of having a different application. [Participant 2, home group]

They also felt oversolicited by their peers: depending on the generation, it is not usual to receive text messages every day or several times a day. However, this influence did not necessarily enable participants to become more skilled at using the features. In the case of video calls, 1 participant (3%) simply received the calls without really understanding how they worked:

He calls my sister, the kids, and we all see each other on the mobile. But I'm not the one doing it, I don't know how. [Participant 11, home group]

Finally, 2 (6%) participants pointed out their own influence on their mode of communication:

It would be the other way round...It's easier for me to read than to listen. So, I prefer to have messages... [Participant 3, home group]

They pointed out the frequency of exchanges with their loved ones:

And then I solicit them too, to get news. [Participant 7, NH group]

Consequences of Noncompliance

Whether or not participants are resistant to ICTs (eg, video calls messages), they sometimes represent the only way for them to keep in touch with their loved ones living abroad (5/32, 16%):

I have children who live in Japan, so I only see them that way. [Participant 8, home group]

For them, resisting these innovations would mean isolation and rejection by their peers. One participant felt excluded from his family following his refusal to use several technologies, and another felt ashamed of being out of step with her RF neighbors:

I told them I'm hopeless, I'm old-fashioned! So, they laughed because it can seem completely absurd nowadays. [Participant 9, RF group]

Finally, 1 participant saw no alternative but to submit to the group norms:

Well, it's not that they [the peers] push me, it's mandatory. [Participant 5, home group]

Temporary Group Compliance and Reactance

The adoption of certain modes of communication (eg, video calls) may have been only temporary, which is the time needed to overcome the exceptional situation that had prompted relatives to adopt them in the first place (eg, the COVID-19 pandemic and relatives moving abroad). Thus, the social pressure present at a given moment is not necessarily effective

with time, especially if the participants were initially resistant to change or video calls (7/32, 22%):

Well, I'm the one who doesn't want to...We used to do it during the COVID with the young persons who couldn't come and see us. Otherwise, I don't like it, I don't like being seen, I don't think it's... for me anymore. [Participant 11, RF group]

Although 1 participant communicated a lot via text messages, she seemed annoyed by the regular solicitations from her peers, thus provoking psychological reactance:

[People who are important to me push me to use messages and video calls] Yes, that's true, but I don't reply [laughs]. [Participant 7, NH group]

Computer Experience

Most participants (18/32, 56%) saw their previous experience with technology (eg, smartphone, computer, or tablet) as facilitating, if not essential, for using iTV. This technology seemed to partially use knowledge already acquired through other technologies (eg, icons and navigation), making it easier for people who already had certain reflexes and rudimentary knowledge to learn:

Yes, there are lots of gestures now that are new, that have been learned and that correspond. [Participant 9, home group]

Certain symbols that were once incomprehensible (eg, menu and contact) have come to mean something, thanks to the use of technology in everyday life, and therefore, familiarity with technical vocabulary and overall operation:

But finally, I think it's an icon [contact] that has become universal now, for everyone who uses a smartphone. [Participant 9, home group]

However, some participants (3/32, 9%) stressed that it was not necessary to have highly developed digital literacy to use iTV:

It's quite accessible to people who don't have any skills, well, who don't have a... how should I say... a culture. [Participant 16, home group]

Sometimes, certain prior knowledge could even hinder the use of iTV, as in the case of 1 participant who had learned to press hard on the remote control buttons, thus causing several actions on the iTV instead of 1 action.

Some participants (2/32, 6%) pointed out the late access their generation had to the internet. Indeed, several participants (3/32, 9%) had acquired more or less advanced computer skills or even automatic skills with the arrival of computers in the workplace. However, the training received and the use of digital technology (whether at work or not) often date back several decades. So, with the rapid development of technology, 1 participant said she felt out of date:

Let's just say it's changed so much since then, it's evolved so much that I'm sure I'm... [out of date]. [Participant 16, RF group]

However, 2 (6%) participants thought that the digital literacy of OAs would evolve rapidly in the future:

But I think that use will increase because, in NH, you are dealing with an age group that is of my generation and I belong to a generation that has had very little access to the internet. [Participant 8, home group]

Technological Routine

In many cases (11/32, 34%), using the computer, tablet, or television was part of a well-established routine:

I've had this habit for a very, very, very long time. [Participant 4, home group]

This routinized use could then lead to various events, such as the creation of habits that are difficult to disrupt. In addition, this routine was all the more difficult to change, and it was hard to establish with peers. Other problems included the development of automatisms, making it harder to transfer knowledge to other technologies:

I'm so used to [typing] 3, that's it. But that's to find the right button [on the remote control]. [Participant 6, NH group]

Another problem was the neglect of buttons not used on a daily basis:

As I only ever use the same buttons, there may be things I have that I don't even look at. [H-14]

Interest in Technological Innovations

Participants (14/32, 44%) seemed curious to discover the iTV functionalities and found it fun to try to figure out how the iTV worked, perceiving mistakes as challenges to be overcome.

Some participants (3/32, 9%) were rather curious about new technologies in general (eg, robots and computers), being interested in them since the early days of computing. The time and effort invested at the time would have made it easier for them to learn how to use a new technology:

So I bought some books, I didn't understand anything... And I read and reread the same thing over and over again, and then that was it, I was able to design programs. That may also explain why, perhaps more quickly than others, I quickly understand how to use the software. [Participant 2, home group]

Two (6%) participants emphasized the importance of initial motivation in the learning process, noting that imagining the potential benefits of technology can stimulate its exploration:

It can be exciting, in the sense that it's great, I'm going to have something better and everything. [Participant 4, home group]

Although curiosity seems crucial when learning to use the iTV, it may not be enough due to the apprehension of making irreparable mistakes or the lack of PU:

But I don't see what it's for, what it can lead to. Yes, I see it as a game. [Participant 10, RF group]

Sensory Disorders

With advancing age, sensory problems (9/32, 28%; eg, visual, auditory, and touch) could appear and develop with time, limiting the use of certain technologies, such as smartphones

(eg, difficulty typing on a small keyboard) and television (eg, visual fatigue). Participants who wore glasses to improve near vision generally did not wear them to watch television (11/32, 34%). In the case of iTV, these participants then had difficulty recognizing certain symbols on the screen and the remote control:

Oh maybe with glasses I'd see better. [Participant 10, home group]

In terms of hearing, 1 participant with hearing aids felt the sound of the iTV was not loud enough: on a daily basis, he used headphones plugged directly into his television. With regard to touch problems, some participants (5/32, 16%) found it difficult to press certain buttons correctly (eg, arrows and back buttons) because of their design (ie, size and shape of the button) or their location (ie, in the middle of 2 buttons). One participant was convinced that she pressed the right button when, in fact, she pressed the wrong one:

*That's what I've pressed now, isn't it? [Researcher]
You pressed just below it. [Participant 14, NH group]*

Cognitive Disorders

With age, certain cognitive disorders can affect memory, information processing speed, and mental flexibility. During the test, some participants (15/32, 47%) could not remember and frequently asked for the function of buttons they had already used (eg, camera button). Performing the action once seemed insufficient for the information to be retained, which underlines the importance of reminding people on the screen of the buttons to use. Two participants (6%) complained that they were slow in thinking, learning, or even adapting to a new way of functioning:

You have to adapt, and it takes a bit longer to adapt now... You're not as fast and your brain doesn't work as quickly as it did a few years ago. [Participant 11, home group]

Another manifestation of cognitive impairments was the false recognition of certain actions and buttons. Some participants (5/32, 16%) tried to remember a button they had supposedly already used instead of scanning the remote control again to identify the right button. Because of the difficulties mentioned above, 1 participant living at home could not imagine the iTV being used by people with cognitive impairments. Two (6%) others living in NHs felt that they had been in decline for some time, partly due to various events (eg, retirement, the COVID-19 pandemic, and heatwaves) also affecting the residents around them. Thus, 1 participant no longer considered herself "adapted" [Participant 6, NH group] to new technologies such as iTV, while another complained that her life had "shrunk" [Participant 7, NH group], giving her the feeling she "no longer had time to do anything" [Participant 7, NH group]. Finally, participants conscious of their cognitive decline and the impact on their performance questioned and blamed themselves more often for the difficulties encountered during the test:

Yes, but maybe if our brains were a bit more developed, we wouldn't do anything stupid either. [Participant 16, RF group]

Fatigability

As people age, they may become more fatigued, impacting the time spent on certain activities. Because of the effort required to discover the iTV (eg, gymnastics between the screen and the remote control, searching for information, and the number of steps in the scenario), some participants (8/32, 25%) apparently reached cognitive saturation, with increasing difficulty in maintaining their attention, refocusing after a distraction, or even blocking on a task:

The trick is to pay attention, you can't do random things. You have to try and think, which isn't always easy at our age. [Participant 10, RF group]

The fatigue accumulated throughout the test may have hampered the use of the iTV and led to frustration if the participant got stuck on a task already completed:

My brain doesn't want to work anymore. [Participant 4, RF group]

For example, 1 participant gradually lost sight of the test objective, constantly wanting to return to the TV channels instead of following the instructions. By making repeated mistakes, 2 (6%) participants admitted confusing good and bad learning.

Attitude Toward Aging

Among the participants living at home, some seemed to perceive the onset of cognitive problems as imminent and inevitable. Beyond the participants' current state of health, the image they had of aging and their perception of the time they had left in good health, or even to live, could influence their commitment to iTV, as well as its acceptability. One participant seemed impatient, declaring that he had no more time to lose with technologies that were complex to learn or that didn't meet his needs:

This thing is a tool, so it has to provide me with the services I need quickly and immediately. I've got no time to lose in my life, I've got 89 anyway [laughs]. [Participant 9, home group]

Others did not see the point of learning to use the iTV, believing that they didn't have much time left to enjoy it:

I'm in my 91s this year. So maybe I won't get much out of it. [Participant 14, NH group]

Discussion

Principal Findings

The main aim of this research was to contribute to the enrichment of existing models of acceptance of innovations by OAs. This study focused on the acceptability of an iTV system by 32 people living in different settings (eg, home, NH, and RF). A deductive qualitative analysis based on e-TAM identified 33 concepts, each related to the following themes: IU, PU, PEOU, UR, anxiety about the iTV, FCs, and UCs.

Advantages of the Methodology Used

This qualitative research complements a previous study, currently being submitted, aimed at assessing the perceived

usability and ability of OAs to use the iTV. The data extracted from these tests were self-reported and subject to certain biases. For example, some authors have shown the influence of stereotypes on the perceived ability to innovate [48], while others have discovered that OAs who reported using smartphones were in fact only using the basic functions of the phone (ie, making calls and sending SMS text messages) [49]. Therefore, using a purely quantitative study does not allow for a comprehensive understanding of the mechanisms behind the acceptance of technological innovations.

The deductive qualitative analysis used in this study is based on the Qualitative Analysis Guide by Leuven [47]. One of the advantages of this analysis method is the combination of approaches used. The transcripts were first analyzed separately, using a case-oriented narrative approach. This approach ensured that the interaction between the ideas from each transcript and the specific characteristics of the participants was not overlooked, particularly with the help of conceptual diagrams. Then, by cross-referencing all these ideas, more global concepts were developed. It was only at this point in the analysis that all the data were interpreted, allowing themes to be developed by drawing on the richness of the data and doing justice to the complexity of the experiences of the participants [50].

Technology Paradoxes

This qualitative analysis has highlighted the different behaviors of OAs when they are confronted with the use of technological innovation. Participants (20/32, 62%) were both very curious about the functioning of iTV and anxious about having to use a television remote control. Some (15/32, 47%) said that they were already beyond the stage of being apprehensive about using technology, with 1 participant mocking these anxious people:

You'd think we were going to bring out the atomic bomb! "No, no, no, I don't want to touch it! It's going to be dangerous!" [Participant 4, home group]

It is interesting to note that these behaviors seemed to be influenced by different factors, such as the level of digital literacy or place of residence. In our study, the participants who lived in institutions (16/32, 50%) were also the ones who were the least familiar with the use of smartphones or computers. These results are in line with the literature on the use of technology by OAs [51-53] and highlight the nuances of older users' experience when confronted with technological innovations.

In addition to current models of technology acceptance (eg, TAM and UTAUT), the authors have proposed a framework of technology paradoxes [22,23]. This model states that users, when using a technology, are subject to a certain number of paradoxes that create strong emotions, such as anxiety and stress. Wilson-Nash and Tinson [23] identified 3 types of paradox: functional, social, and psychological.

Among the functional paradoxes, the paradox of chaos versus control was the origin of several situations reported by participants and classified in the category of resistance. In the case of the participant complaining about the addition of functions on her television, she experienced the transition from

a situation of control (ie, watching television channels) to a chaotic situation (ie, YouTube starting at the same time as the television), resulting in frustration and the stress of losing one's bearings.

In order to deal with the emotions generated by paradoxes, users may adopt various coping strategies before or after acquiring technology to avoid them or confront them. Wilson-Nash and Tinson [23] have identified 5 coping strategies used by OAs: neglect, partnership, control, adjustment, and acceptance. The partnership strategy seems to have been used by some participants in this study (3/32, 9%) via a mechanism of humanization of the technology. The participants tended to consider the indications displayed on the left of the television screen as instructions to follow or even tips given by the iTV. The participants spoke of the "interrelationship" and mutual assistance that existed between them as users interacting with the remote control and the television screen:

View the photos, I press OK? Because they tell me to. [Participant 11, home group]

Therefore, the personification of iTV observed by the researcher could prove to be a strategy for confronting the technology, enabling participants to overcome their anxiety when using the iTV. It would be interesting to investigate the humanization of technology further and to test whether reinforcing this feeling (eg, the presence of a virtual agent on the iTV) could influence the perceived usability and acceptability of the iTV.

Technologies are often perceived as isolating people from others, as evidenced by the risks perceived by the participants in this study. However, almost all participants (24/32, 75%) also admitted to calling on certain members of their family or friends to resolve problems encountered with their technology. Thus, mastering the technology, which is another adaptation strategy, also includes a social dimension.

The acceptance strategy put forward by Wilson-Nash and Tinson [23] states that OAs, because of their life experience and time perspective, have a greater tolerance of technology faults. In this study, the difficulties encountered and the time required to understand how the iTV worked did not seem to have a major influence on its perceived usability. Therefore, error tolerance may be a differentiating factor between generations, as may apprehension when learning how to use an iTV.

Sense of Self-Efficacy and Performance

The feeling of self-efficacy refers to the evaluation of one's personal abilities, not one's personal worth [39]. Belief in one's abilities can influence the level of effort put into using and learning the technology, as well as thoughts and emotional reactions when using the technology [54]. Thus, the fact of not believing in one's abilities, or even failing several times, does not normally influence one's self-esteem but, on the contrary, can greatly harm motivation and performance. In this study, by blaming themselves for the difficulties they encountered, the participants tended to feel ashamed of not succeeding and even devalued themselves:

So turning it off, I don't know where it is. That's what I told you, eh, I'm ashamed but... [laughs].
[Participant 9, RF group]

In this case, the perceived inability to use an iTV seemed to influence self-esteem. Furthermore, Arning and Ziefle [55] stated that when a device presents technical difficulties, OAs experience a loss of technical confidence and begin to question their own value. These elements refer to the paradox of competence versus incompetence proposed by Wilson-Nash and Tinson [23], where users can feel both a sense of accomplishment when using technology successfully and a sense of self-doubt when encountering difficulties.

Authors have also found that OAs who consider themselves targeted by a stereotype tend to reduce their capacity for innovation (ie, their ability to mobilize their resources) to avoid appearing incompetent [48]. Therefore, against stereotypes may indirectly influence older users' feelings of efficacy.

Another factor that can influence OAs' sense of self-efficacy is institutionalization, which is often associated with an increase in the degree of dependency of OAs. An institutionalization syndrome is characterized by apathy, indifference, reduced cognitive ability, difficulty in expressing feelings, and loss of autonomy [56]. The lives of residents in geriatric institutions are routinized to facilitate the organization of care, implying that residents may lose control over their activities. However, residents who are given control over their daily lives are more socially active, more involved in activities, happier, healthier, and live longer than those who are kept staff-dependent [57,58]. Nevertheless, beyond the possibility of exercising control, the desire for personal control tends to diminish with age, as does self-esteem and the belief in efficacy [39]. One participant in this study, living in an NH, relied heavily on the care staff to use her television. Although she took part in the test and showed that she was capable of using television, she preferred to delegate its use on a daily basis, in particular, because it made her anxious. Other levers exist, such as the presence of a role model (ie, a person with whom we can identify [age and sex] and who is able to manage) or resorting to social persuasion (ie, support and encouragement from carers and care staff) [39].

The Influence of Motivation on the Acceptability of ICTs

Several participants (3/32, 9%) stressed the influence of motivation in the acceptance of a technology or feature. According to the literature, there is an essential distinction between voluntary behavior and behavior resulting from external pressure or control [59]. Intrinsically motivated behaviors are performed because of interest and to satisfy innate psychological needs for competence and autonomy, whereas extrinsically motivated behaviors are often carried out for external and instrumental reasons.

In the literature, enjoyment has often been used to represent this notion of intrinsic motivation [60]. Therefore, the enjoyment experienced when using a technology could reduce the perception of the effort made during its use [61] and thus be a predictor of the IU [60]. In this study, some participants (3/32, 9%) expressed curiosity about the iTV and emphasized the

playful nature of its handling, taking a certain enjoyment in discovering its functioning. What was categorized as an interest in technological innovations could, therefore, represent a source of intrinsic motivation for the participants. This study appears to align with existing literature, although there are certain limitations to the concept of enjoyment. Indeed, while the use of the iTV could be enjoyable, some participants (13/32, 41%) saw no point in using it on a daily basis. Therefore, PU remains an essential factor in the long-term acceptance of technology.

Another aspect raised in this study is the extrinsic motivation to use a new technology. Some participants (4/32, 12%) mentioned a certain pressure to learn how to use a computer, for example, with the digitization of administrative services (eg, train e-tickets and tax). Indeed, 1 participant said that under normal circumstances, she would never have explored a new technology on her own. However, although this digitalization is pushing OAs to acquire digital knowledge, this learning process remains costly. The obligation, combined with the difficulty of increasing skills and knowledge, seemed to irritate these participants. Indeed, to avoid constantly disturbing her family and friends, 1 participant put a certain amount of pressure on herself to solve her problems on her own:

They seem to say that we all have to learn and manage. But it's not... it's not easy, is it? [Participant 11, home group]

Limitations

This study had several limitations, such as the small number of user tests conducted. The small sample in the study prevented us from generalizing the results to OAs living at home, in NH, and in RF.

Another limitation was the recruitment method for OAs living at home. Owing to technical and logistical constraints, user tests with these participants were conducted solely in the Paris region, while tests with OAs in NHs and RFs primarily took place in rural areas of the Grenoble region.

The final limitation of the study was the influence of experimenter bias, which could either negatively impact or inadvertently enhance participants' acceptance of the iTV. Throughout the scenarios, the researcher was able to provide clues on how to use the iTV, if the participants asked for them, if they were blocked, or if they made a mistake. The presence of the researcher in this supportive role could then help the participants to overcome the problems encountered more easily, thereby reducing the perceived difficulty of use and anxiety:

[I felt confident when I used e-litv] Yes, but because you were there, sweetheart!... Otherwise, it would have gone out of the window. [Participant 4, RF group]

However, the presence of the researcher could also increase anxiety, placing the participants in a situation of evaluation:

*It's the setting in a way. It's an exercise, I have to pass, so there's stress. [Participant 9, home group]
And I don't know... You're destabilizing me [laughs]. [Participant 7, NH group]*

Future Work

This research was inspired by the user-testing method, which is rooted in user-centered design. This method enabled us to observe the behavior of OAs, as they familiarized themselves with the iTV, and to identify the factors influencing its use. However, this evaluation was a time evaluation and did not allow us to monitor and understand changes in acceptance with time. A future study could focus on the long-term use of the iTV, specifically examining how the influence of the factors identified in this research evolves with time. It would be valuable to investigate whether these factors continue to affect acceptance of the iTV after several months of use. Moreover, the e-TAM developed in this study was based on different models from the literature (eg, TAM and Senior TAM). Another perspective could be to incorporate concepts from user experience research to propose a unified model.

Recommendations

Overview

Conducting user tests with OAs living in different living environments requires techniques to be personalized and adapted, in particular, to compensate for their frailty and low levels of self-efficacy and digital literacy [62]. The following recommendations seek to share best practices for implementing user-centered design methods with OAs. They are intended for researchers and companies aiming to develop user-friendly technologies tailored to OAs.

Prioritize the Use of Codiscovery Learning

The think-aloud method requires users to express their thoughts, feelings, and actions while interacting with a tool. During the user tests, we observed that OAs struggled to verbalize their experiences while using the iTV, often forgetting to do so altogether. This is consistent with findings in the literature indicating that concurrent think-aloud practice induces greater cognitive load and stress in older participants, thus negatively affecting their performance [63-65]. Therefore, researchers should prioritize codiscovery learning, where users collaborate in teams. This approach encourages them to verbalize their thought processes while interacting with one another to complete tasks [64].

Account for Desirability Bias in Researcher-Participant Interactions

During user tests, participants often feel that they are being evaluated, leading them to adopt behaviors that present them in a positive light. This social desirability bias can result in excessively positive feedback about the device, even in the face of clear usability limitations. Among the various tactics adopted by participants, some may portray themselves as weak or dependent to elicit assistance, for example: "So, uh, I don't know how to do this... As I said, I'm not good at this!" (Participant 9, RF group). In such cases, researchers can respond to each question with another question and reassure the participant that they are on the right track [62]. This technique, integrated into the protocol of this study, enabled some participants with lower self-efficacy to successfully complete each scenario.

Conclusions

This study aimed to describe in detail the factors influencing iTV acceptance among OAs living in different settings (home, NH, and RF), using the example of e-livTV. A total of 32 OAs used the communication functionalities of the iTV system (ie, messaging and video calling) and shared their opinions about the learning process, daily use, and iTV adoption. On the basis of the e-TAM built on the technological acceptance literature, 33 concepts were identified among the 7 determinants of iTV use (IU, PEOU, PU, UR, anxiety toward iTV use, FCs, and UCs). No new determinant was found during the qualitative analysis, even though some factors (eg, FCs and UCs) were completed and extended to consider all the nuances of OAs' experience when interacting with an iTV system.

To conclude, the iTV acceptance seemed to be context, technology, and characteristic dependent. The participants

seemed to agree with recommending the iTV to others; they also found using the iTV relatively easy and pleasant, and thus, they felt confident when using it. Almost all participants considered having support from their family and friends to learn or use a new technology. However, the participants had a divided opinion on iTV IU, the feeling of self-efficacy, and social pressure.

It is also interesting to point out the dimensions that generated the most disagreement between the institutionalized participants and those living at home. While participants living at home seemed to be quite consistent on some dimensions, the institutionalized participants shared more nuanced opinions about the usefulness of the iTV, the effort required to learn how to use it, the resistance to iTV, and the apprehension about pressing the wrong button. Finally, persons living at home were more curious about and interested in technological innovations than other participants.

Acknowledgments

This research was funded by Technosens (Grenoble), Association Nationale de la Recherche et de la Technologie (grant 2021/0344), and the article processing charge was funded by Assistance Publique-Hôpitaux de Paris. This paper was part of the doctor of philosophy thesis (Convention Industrielle de Formation par la Recherche) of BN, which aimed to study the development and use of an iTV system in older person care institutions. The authors would like to sincerely thank the Technosens team, especially Cindy Chassang for her scientific supervision and Frédéric Lorent, Mélissa Neyrand, Yoann Roche, and Cyril Thevenet for their support during the evaluation stage. Finally, the authors would like to thank the older person care institutions for agreeing to welcome the user tests and all participants for their contribution to this study.

Authors' Contributions

The study was conceptualized and formally analyzed by BN and ASR. BN was involved in the investigation and project administration of the study. BN, ASR, and MP were involved in the study methodology, writing the original draft, and reviewing and editing it. All authors have read and agreed to the published version of the manuscript. The funders had no role in the design of the study; the data collection, analyses, or interpretation; the writing of the manuscript; or the decision to publish the results.

Abstract

Background: COVID-19 created an opportunity for using teleconsultation as an alternative way of accessing expert medical advice. Bangladesh has seen a 20-fold increase in the use of teleconsultation during the pandemic.

Objective: The aim of our study was to assess the influence of service quality and user satisfaction on the intention to use teleconsultation in the future among users of national teleconsultation services during the pandemic.

Methods: A cross-sectional survey was conducted in 2020 among users of the national teleconsultation service—Shastho Batayon for acute respiratory infection. A validated mobile health service quality model based on structural equation modeling and confirmatory factor analysis was used to analyze the data with SmartPLS (version 3.0).

Results: Among the 2097 study participants, 1646 (78.5%) were male, 1416 (67.5%) were aged 18 - 39 years, 1588 (75.7%) were urban residents, 1348 (64.2%) had more than 10 years of schooling, and 1657 (79%) were from middle-income households. From a consumer perspective, the quality of the service platform ($\beta=.946$), service interaction ($\beta=.974$), and outcome ($\beta=.955$) contributed to service quality. Service quality was positively associated with user satisfaction ($\beta=.327$; $P<.001$) and intention to use teleconsultation services ($\beta=.102$; $P<.001$). User satisfaction was positively associated with the intention to use teleconsultation services ($\beta=.311$; $P<.001$).

Conclusions: The increase in the use of teleconsultation during the pandemic indicated that such services were potentially used for emergencies. However, the future use of teleconsultation will be dependent on the quality of service and user satisfaction. Our findings are relevant for low-income contexts where teleconsultation services are used to address gaps in service delivery.

KEYWORDS

telemedicine; COVID-19; LMIC; low- and middle-income countries; Bangladesh; service quality; user satisfaction; structural equation modeling; digital health

Introduction

Background

Globally, 58% of countries have adopted telemedicine to address the disruption of health care services during the COVID-19 pandemic [1]. Telemedicine facilitates the delivery of remote

health care services at low cost [2] and has shown to enable quick and equitable access to health care for patients in hard-to-reach areas [3]. Telemedicine has been effectively used to provide health services during previous SARS-CoV-2 and Middle East respiratory syndrome outbreaks [4], and during the COVID-19 pandemic, the use of telemedicine has increased globally to minimize the risks of viral transmission [5,6].

Researchers around the world reported widespread use of telemedicine in many low- and middle-income countries (LMICs) where the provision of protective gear, vaccines, and hospital facilities was inadequate during the pandemic [7-13].

In Bangladesh, there was severe disruption of primary health care provision during the early stage of the pandemic, as health systems responded to lockdown measures, deaths among health care providers, and the need to mitigate and limit the spread of COVID-19 [14]. One of the response measures by the government of Bangladesh was to make the existing national teleconsultation platform “Shastho Batayon 16263” toll-free [15]. As travel restriction was in place and access to face-to-face consultation was limited, calls to the national teleconsultation platform increased 20-fold during the pandemic [16]. However, there were concerns about the negative impact of the sudden increase in demand for teleconsultation services on the existing infrastructure and human resources of Shastho Batayon (SB) [17] and whether any compromise in terms of service quality of the platform would negatively impact patient satisfaction and intention to avail teleconsultation services in the future [18].

Although the promises are offered by telemedicine in low-resource settings, ensuring the quality of telemedicine services is a major challenge [19]. Despite the challenges of quality, however, there are benefits of using telemedicine during a pandemic such as COVID-19 [20], and it is likely that many patients and providers will continue to use this service in the postpandemic period [21]. Hence, it is important to understand how the service quality of telemedicine affects patient satisfaction and intention to use the service in the future [22].

The World Health Organization’s guiding principles for implementing telemedicine services during COVID-19 listed “user satisfaction” as one of the key components for evaluation [23]. In health care, service quality is a major indicator of patient satisfaction [24-27]. Satisfaction is associated with increased user retention and intention to use the service in the future [24,25,28].

There are a number of theories and models that address quality dimensions of information and communication technology-based services. A systematic review of the service quality models identified 30 models, which described that the most common dimensions were tangibles, reliability,

responsiveness, empathy, and assurance [29]. In a developing country context, the mobile health (mHealth) service quality model tested by Akter et al [30] measures the association between service quality and satisfaction on the intention to use the service in the future. This conceptual model describes platform quality, interaction quality, and outcome quality as primary dimensions of service quality for mHealth and proposes a direct association between service quality and patient satisfaction and an indirect association between service quality and intention to continue to use the service through patient satisfaction [30]. The conceptual model has been previously validated for Bangladesh. Using the model for mHealth service quality, we aimed to assess the influence of service quality and satisfaction on the intention to use SB services in the future among the users who availed the service during the pandemic. The insights from this study will significantly contribute to the sustainability of national teleconsultation services during future health emergency situations and beyond.

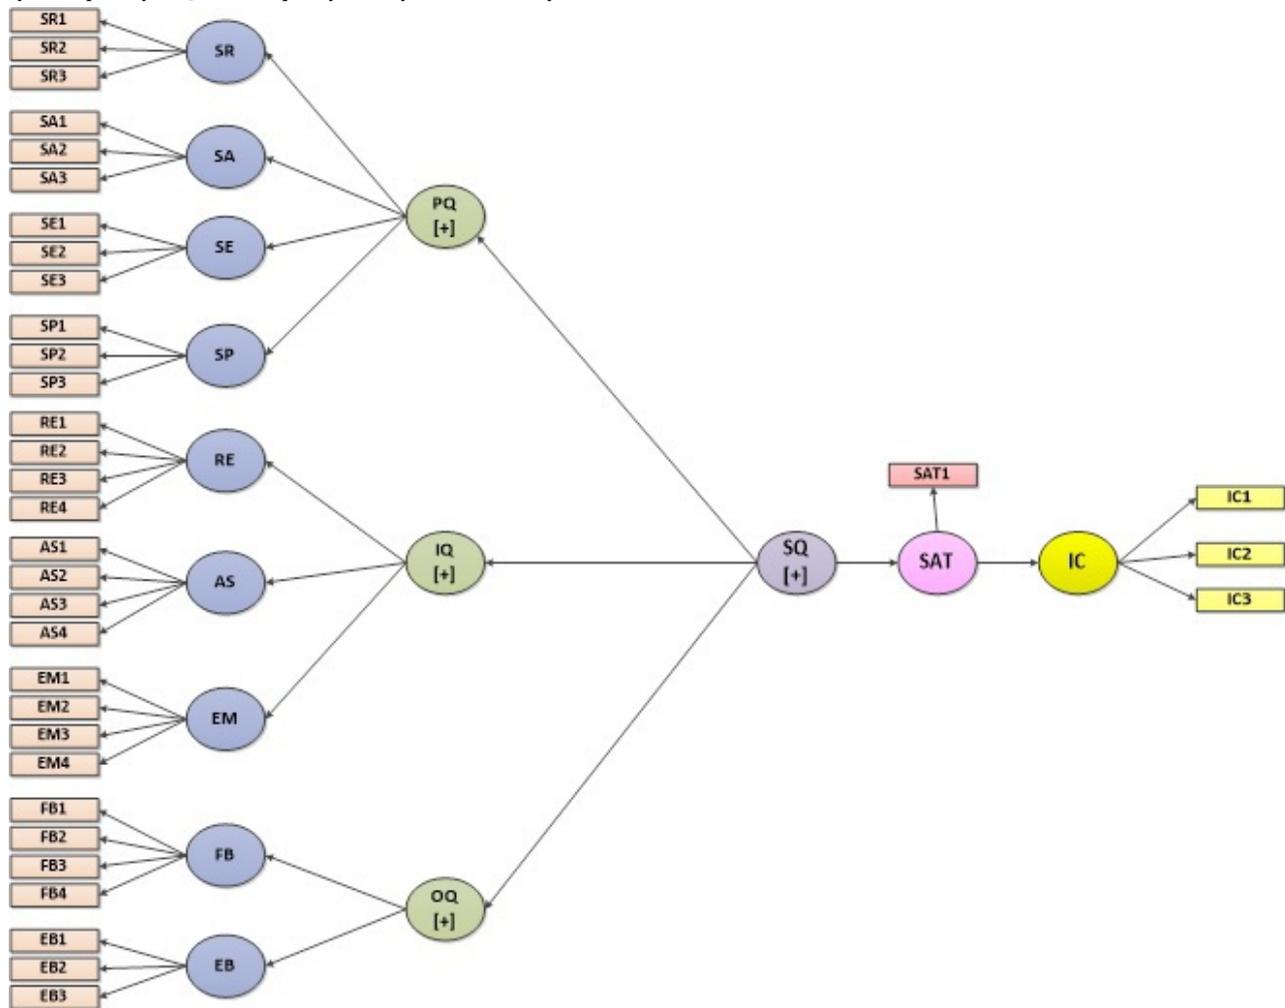

Theoretical Framework

For this study, we used the mHealth service quality model [30] to design the study. A number of empirical studies have used the mHealth service quality model to describe the association between service quality and users’ intention to continue using eHealth services [24,30-32], but the model by Akter et al [30] is chosen, as it was used to teleconsultation in the context of LMICs. The conceptual framework and the hypotheses are detailed in the following subsections.

Conceptual Model: A Hierarchical, Multidimensional Service Quality Model

The conceptual model (Figure 1) of service quality used in this study postulates a direct relationship between service quality and satisfaction and that service quality indirectly works on intention to use, mediated by satisfaction [33-36]. In the service quality model, service quality comprises 3 primary dimensions (platform quality, interaction quality, and outcome quality) and 9 subdimensions. The dimension platform quality has systems reliability, systems availability, systems efficiency, and systems privacy as subdimensions; the interaction quality dimension has responsiveness, assurance, and empathy as subdimensions; and the outcome quality dimension has functional benefit and emotional benefit as subdimensions.

Figure 1. Conceptual framework of service quality conceptual model for national teleconsultation services users during the COVID-19 pandemic in Bangladesh, October-December 2020 (N=2097). AS: assurance; EB: emotional benefit; EM: empathy; FB: functional benefit; IC: intension; IQ: interaction quality; OQ: outcome quality; PQ: platform quality; RE: responsiveness; SA: systems availability; SAT: satisfaction; SE: systems efficiency; SP: systems privacy; SQ: service quality; SR: systems reliability.

Definition of the Constructs

The definitions of constructs such as platform quality, interaction quality, outcome quality, user satisfaction, and intention to continue are detailed in [Multimedia Appendix 1](#).

Hypotheses

In this study, we tested 3 hypotheses:

- Hypothesis 1: SB service quality has a positive impact on user satisfaction.
- Hypothesis 2: User satisfaction with SB is positively associated with the intention to use the services in the future.
- Hypothesis 3: SB service quality is positively associated with the intention to use the service in the future.

Methods

Study Settings and Participants: SB

The Ministry of Family and Welfare of Bangladesh, in an effort to facilitate access to health services, runs a national health helpline with SB through its Management Information System division. The service is available 24/7, and callers can consult

doctors and get limited prescriptions and referrals. During the COVID-19 pandemic, the SB number was made toll-free.

We conducted this study among the users of SB from October 19, 2020, to December 31, 2020. Our study participants were those who called SB with their flu-like syndromes and were provided a provisional diagnosis of suspected or confirmed COVID-19. We approached the participants from the random list collected from the Management Information System database who sought teleconsultation services from any geographical area of Bangladesh and were interested to join the study, and those participants were enrolled as study participants. We were provided with a total list of 7400 people, with batches of 100 participants sent out each day from SB, and finally, 2097 participants were enrolled in the study. All the interviews were conducted over the phone.

Sample Size

To use structural equation modeling (SEM), the number of constructs (latent variables), number of observed variables, and effect size of the loading coefficient with a 95% confidence level and 80% power were considered with a view to calculating the required sample size through Enrico multivariate software

[37]. To identify the effect size of the loading coefficient of 0.15, 35 observed variables, and 15 latent variables with 95% confidence level and 80% power, the minimum required sample size was 378. Thus, the study fulfills the requirement of the necessary sample size to apply SEM by collecting information from 2097 participants.

Data Collection

Within 2 weeks of seeking care from SB by the selected caller, we administered this satisfaction survey about their call to SB. We collected a list of 100 callers (randomly selected) every day based on our selection criteria (suspected or confirmed COVID-19 cases) from October 19, 2020, to December 31, 2020.

The list was then divided and distributed among the data collectors for conducting a telephone survey. Data were collected using a questionnaire previously validated in Bangladesh [32]. All the data were collected through a web-based Android-based data collection app or tool by trained data collectors. In total, 5% of the interviews were randomly rechecked by the supervisor to ensure the data quality and validity of the interviews.

Ethical Considerations

The study was approved by the institutional review board of the International Centre for Diarrheal Disease Research, Bangladesh (protocol: PR#19091). Informed verbal consent was taken from all the study participants over the phone. In total, 31 study participants' age was below 18 years so we took informed assent from their guardians over the phone to participate in the study. The privacy, anonymity, and confidentiality of the research data and information were strictly maintained.

Variables

The questionnaire included questions on user demographics (age, sex, socioeconomic status, and place of residence). To understand users' perception of service quality, the questionnaire included questions related to systems reliability, availability, efficiency, privacy, responsiveness, assurance, empathy, functional, emotional benefit, and satisfaction along with the intention to continue using the service in the future. A 5-point Likert scale with a range from 1=strongly disagree to 5=strongly agree was used to measure the responses. The statements used in the questionnaire were previously validated in Bangladesh [32]. The questionnaire is available in [Multimedia Appendix 2](#).

Normality Check

The assessment of data normality was conducted through the estimation of skewness and kurtosis for each measurement item. The skewness values ranged from -0.319 to 0.069 , while kurtosis values ranged from -0.543 to 0.671 , where values within the range of ± 2 for skewness and ± 5 for kurtosis are deemed acceptable indicators of normal distribution [38], our dataset exhibited no substantive issues with skewness or kurtosis.

Data Analysis

From the list of 7400 individual users of SB, we were able to reach only 2163 due to incorrect numbers, switched off phones, unavailable networks, use of neighbors' or relatives' phone numbers for SB services, and because callers did not receive our calls. The initial response rate was 29.2%. Of those we were able to reach, 3.9% ($n=66$) of respondents refused to participate in the study so our final sample was 2097.

SmartPLS (version 3.0) was used to analyze the data. Component-based SEM or partial least squares (PLS) path modeling was used to understand the direct effect between service quality and satisfaction and satisfaction and intention and the indirect effect between service quality and intention. Confirmatory factor analysis (CFA) was used to test the hypotheses. First-order CFA was used to test the validity and reliability of measurement items of the constructs. Second- and third-order CFA were used in the measurement model because there are latent variables that were constructed as dimensions of another variable. To assess the second-order reflective model of service quality, this study used PLS Graph (version 3.0; SmartPLS GmbH) [39] and PLS path modeling with a path weighing scheme for the inside approximation [40-42].

Results

Sociodemographic Characteristics of Study Participants

Among the 2097 study participants, the majority were from urban areas ($n=1588$, 75.7%), had more than 10 years of schooling ($n=1348$, 64.3%), and were from middle-income households ($n=1657$, 79%; [Table 1](#)). Most of the service recipients were male ($n=1646$, 78.5%), 67.5% ($n=1416$) were between 18 and 39 years of age, 63.2% ($n=1325$) were married, and 37.3% ($n=782$) had more than 4 members in their household ([Table 1](#)).

Assessment of the Measurement Model

The study assesses the psychometric properties of the first-order measurement model by examining reliability, convergent

validity (Table 2), and discriminant validity (Table 3). Cronbach α , composite reliabilities, and average variance extracted from the data exceeded the cutoff values of 0.5, 0.7, and 0.5,

respectively (Table 2), which indicate adequate scale reliability and validity [40,43]. The model was considered satisfactory in terms of reliability, convergent validity, and discriminant validity. The result showed that the composite reliabilities and

average variance extracted from the second- and third-order scales were greater than 0.8 and 0.5, respectively, which indicated that the higher-order measures were reliable (Table 2).

Structural Equation Modeling

Our results showed that the third-order construct, service quality, was associated with the second-order constructs—platform

quality ($\beta=.946$), interaction quality ($\beta=.974$), and outcome quality ($\beta=.955$), which explained 90%, 95%, and 91% of the overall quality variance, respectively (Figure 2). The second-order construct, outcome quality, was significantly

associated with their first-order constructs—functional benefit ($\beta=.987$) and emotional benefit ($\beta=.979$; Figure 2). All the path coefficients from service quality to second-order and third-order components were significant at $P<.001$ (Figure 3). Therefore,

we found that the 31 items, grouped into 9 factors, can be used to measure the overall service quality of SB teleconsultation services.

Figure 2. Path coefficients of the research model for national teleconsultation services users during the COVID-19 pandemic in Bangladesh, October–December 2020 (N=2097). AS: assurance; EB: emotional benefit; EM: empathy; FB: functional benefit; IC: intension; IQ: interaction quality; OQ: outcome quality; PQ: platform quality; RE: responsiveness; SA: systems availability; SAT: satisfaction; SE: systems efficiency; SP: systems privacy; SQ: service quality; SR: systems reliability.

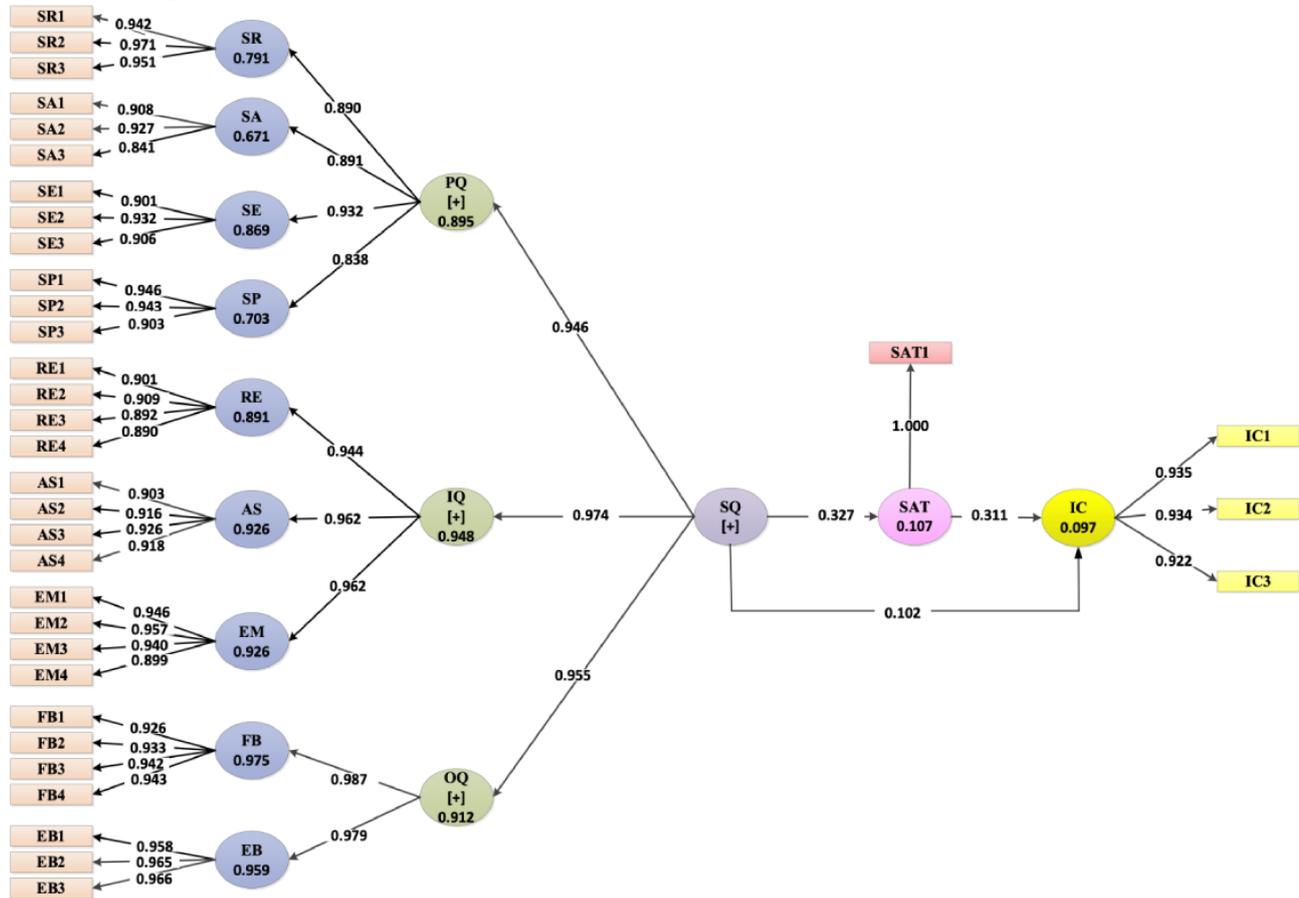

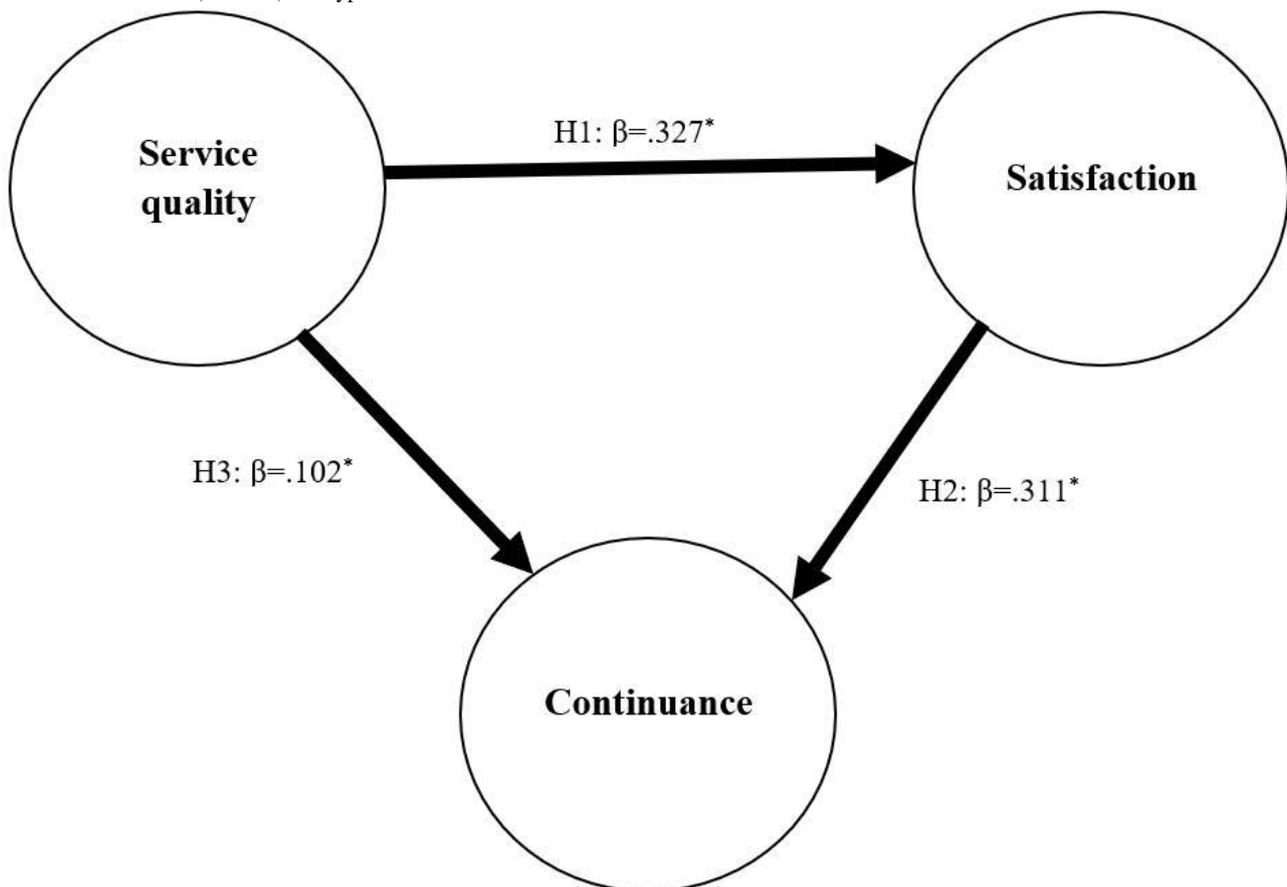

Figure 3. Testing hypotheses regarding the association between Shastho Batayon service quality, user satisfaction, and continuance intention, October-December 2020 (N=2097). H: hypothesis. * $P < .001$.

Hypotheses Testing

- Hypothesis 1: The β from service quality to satisfaction was .327, indicating that SB service quality was positively associated with user satisfaction.
- Hypothesis 2: The β from satisfaction to intention to continue use was .311, indicating that user satisfaction with SB was positively associated with the intention to use the services in the future.
- Hypothesis 3: The β from service quality to continuance intention was .102, indicating that SB service quality was associated with the intention to use the service in the future.

Discussion

Principal Findings

Our study describes the use of toll-free national teleconsultation services (SB) during the COVID-19 pandemic using a service quality model validated in Bangladesh [16]. In our analysis, we assessed the impact of service quality on user satisfaction and intention to use SB services in the future. During the pandemic, with the rapid increase in the number of calls to SB, the service provision had to be scaled up rapidly to cater to the needs of the population. However, our study indicates that teleconsultation services such as SB have to pay attention to service quality if they want the service recipients to continue to avail the services beyond the pandemic. In the context of Bangladesh, researchers have described [44,45] factors such as usefulness, perceived reliability, price value, technology anxiety,

expectations, performance, disconfirmation, and enjoyment influencing the adoption, satisfaction, and continuance of mHealth and telemedicine services in Bangladesh [44,46-49], although in most cases, the studies did not use validated scales for service quality. In most cases, the mHealth interventions studied were small-scale or were being piloted among both rural and urban populations. Only 1 study was conducted to conceptualize and validate service quality scales [31]. To our knowledge, this is the first study to assess the association between service quality and both user satisfaction and intention to use the service in the future for national teleconsultation service.

The service quality of SB was positively associated with user satisfaction. This finding emphasizes the importance of looking at the SB service from the viewpoint of “systems as service” as described by earlier researchers [30]. In terms of the 3 subdomains of service quality, such as platform quality, interaction quality, and outcome quality, SB services were perceived to provide the needed health care during the COVID-19 pandemic. Although in other studies, the price of the service was an important determinant of user satisfaction along with service quality [50], calls to SB were made toll-free during the pandemic period, which could have contributed to both increase in the number of calls [51] and user satisfaction. It is important that the insights related to the rapid scaling up of the SB services while maintaining service quality during emergencies are systematically recorded and included in the standard operating procedures in the future.

We found that service quality and user satisfaction were important determinants of the intention to use SB services in the future. Similar findings about the association between telemedicine service quality and user satisfaction on intention to use the services have been reported from both developed and developing countries [52,53]. Whether users will continue to use SB services for their future health care needs after the COVID-19 pandemic will depend on both service quality and user satisfaction. A sound technological platform is a necessity for providing reliable teleconsultation services. However, service quality also depends on the quality of interaction between the service providers and the users. Interaction quality could be improved by adequately training the service providers to respond to users' needs with empathy and assurance [31]. Another issue to consider is the specific nature of the COVID-19 pandemic, where normal health care delivery was disrupted [54], and it was not easy to reach trained medical professionals [55]. During the pandemic, a protocolized management of COVID-19 was approved nationally [56] and was implemented through SB. However, in normal circumstances, people might prefer reaching out to trusted health facilities and doctors, as trust between provider and patient has been shown to be a crucial component of adherence to treatment [57,58]. In Bangladesh, previous studies have shown that preference for trusted health care professionals and lack of trust on telemedicine doctors created a significant barrier in the use of teleconsultation.

Though telemedicine services have improved and technological development has risen in recent years, SB services are only limited to teleconsultation and e-prescription [51]. In addition, prescriptions provided by telemedicine are limited to adhere with health regulations [59]. Despite its limitations, SB has proven to be an important source of health information during emergency situations where normal health care delivery is disrupted [60]. The low-cost access to professional medical advice provided has the potential to bolster health care provision in the future. It is important, therefore, that the SB services are monitored to ensure the quality of service provision and address the gaps. It is also important to think through how best to optimally use SB services to enhance health care access and use during nonpandemic times. In this regard, it is important to address the existing digital divide that is apparent in the use of SB. Most of the callers of SB were better educated, young, male, and urban residents. It will be important to address the barriers faced by population groups that do not use SB services.

Overall, the findings of our study suggest that decision makers should consider "service quality" as an important strategic objective to ensure positive satisfaction and continuance intentions. Good-quality teleconsultation services can help health providers enhance health care coverage during pandemics.

Policy makers can develop a tailored regulatory framework to ensure the quality of SB services. In this regard, investments in robust telecommunication infrastructure, especially in rural and hard-to-reach areas, are important to enhance technology accessibility and connectivity. Although teleconsultation services such as SB cannot be an alternative to regular health care, there are important lessons to be learnt from SB. The SB physicians were trained thoroughly in dealing with patients with professionalism and empathy, which led to increased patient satisfaction. As patient satisfaction was an important determinant of intention to use the service in the future, there should be constant efforts made to train health care providers to prioritize patient-centered care, incorporate patient feedback, and ensure user-friendly and accessible telemedicine platforms. Finally, a commitment to research and development, including resource allocation for studies on telemedicine's impact on user satisfaction, needs to be made to foster innovation and improvement of teleconsultation services.

The strength of the study is the use of a validated service quality model to understand the impact of service quality on patient satisfaction and intention to continue using the service [30]. Another strength of this study is its focus on pandemic health care needs. The study had a few limitations: first, the context of the study is a single provider, and the study applies to the pandemic context. The findings regarding SB's acceptability may not be generalizable to a nonpandemic context. In the study, we were only able to measure the intention to continue to use the SB services rather than the actual continuance. In the future, longitudinal studies could be conducted to follow up and measure service quality and satisfaction in relationship to the actual continued use of the application.

Conclusions

This study used a validated framework to evaluate national teleconsultation services in Bangladesh during the COVID-19 pandemic. The findings of this study imply that service quality in health care is an important factor to improve user satisfaction. This study is significant in the context of Bangladesh and other LMICs, where there are human resource constraints in health care, which can be addressed through teleconsultation services [61]. The key to improving service quality and users' satisfaction is a combination of an enabling environment and infrastructure that includes a robust platform, trained workforce, data privacy and confidentiality, and proper policies and legislations [30,32]. Additionally, our study findings imply that any teleconsultation service must have a guideline for service providers to ensure that good quality service is provided through teleconsultation. While the advances in telemedicine hold immense promise for improving health services, optimal benefits can be availed if service quality is adequately evaluated and monitored.

Acknowledgments

The authors are thankful to all the participants who took part in the study. The authors thank the Synesis IT team and the Management Information System team of the Directorate General of Health Services. The authors would like to thank Dr Sifat Parveen Sheikh for all her support in the project. The Swedish International Development Cooperation Agency and Global Affairs Canada gratified the authors by providing funds for the project. The authors also thank the governments of Bangladesh, Canada, Sweden, and the United Kingdom for providing core or unrestricted support.

Data Availability

The dataset is not publicly available due to the data privacy policy of the organization. Our institutional review board has required that the personal information of the participants is not disclosed. Data related to this manuscript are available upon request to those who meet the criteria of the organization's policy from Ms Shiblee Sayeed (shiblee_s@icddr.org) at the research administration of the International Centre for Diarrheal Disease Research, Bangladesh.

Abstract

Background: As the SARS-CoV-2 virus created a global pandemic and rapidly became an imminent threat to the health and lives of people worldwide, the need for a vaccine and its quick distribution among the population was evident. Due to the urgency, and on the back of international collaboration, vaccines were developed rapidly. However, vaccination rollouts showed different success rates in different countries and some also led to increased vaccine hesitancy.

Objective: The aim of this study was to identify the role of information sharing and context sensitivity in various vaccination programs throughout the initial COVID-19 vaccination rollout in different countries. Moreover, we aimed to identify factors in national vaccination programs related to COVID-19 vaccine hesitancy, safety, and effectiveness. Toward this end, multidisciplinary and multinational opinions from members of the Navigating Knowledge Landscape (NKL) network were analyzed.

Methods: From May to July 2021, 25 completed questionnaires from 27 NKL network members were collected. These contributors were from 17 different countries. The responses reflected the contributors' subjective viewpoints on the status and details of the COVID-19 vaccination rollout in their countries. Contributors were asked to identify strengths, weaknesses, opportunities, and threats (ie, SWOT) of the respective vaccination programs. The responses were analyzed using reflexive thematic analysis, followed by frequency analysis of identified themes according to the represented countries.

Results: The perspectives of NKL network members showed a link between organizational elements of the vaccination rollout and the accompanying societal response, both of which were related to strengths and weaknesses of the process. External sociocultural variables, improved public communication around vaccination-related issues, ethical controversies, and the spread of disinformation were the dominant themes related to opportunities and challenges. In the SWOT 2×2 matrix, *Availability* and *Barriers* emerged as internal categories, whereas *Transparent communication and promotion* and *Societal divide* emerged as key external categories.

Conclusions: Inventory of themes and categories inspired by elements of the SWOT framework provides an informative multidisciplinary perspective for effective implementation of public health strategies in the battle against COVID-19 or any future pandemics of a similar nature.

Introduction

On March 11, 2020, the World Health Organization declared the COVID-19 pandemic [1]. COVID-19 first appeared in December 2019 in Wuhan, China. This disease, caused by the SARS-CoV-2 virus, led to an unprecedented challenge for health institutions that required most countries to integrate their efforts to globally mitigate the spread of the disease [2-4].

Various policies to control the spread of the virus have been adopted in different countries. Some of them were drastic, such as national lockdowns, as well as initiating the widespread use of individual protection devices and means [5]. The individual protective measures included recommending frequent hand washing and application of sanitizers, maintaining social distance, and mandatory wearing of face masks or respirators. However, even a simple measure of covering the face proved to have psychological, cultural, religious, and behavioral implications at both the individual and communal levels [6]. Moreover, the policies aimed to stop the spread of the virus impacted the psychological well-being of the population [7]. These implications should be considered in public campaign strategies aimed at achieving effective public consent toward the adoption of protective measures.

The publication of the genetic sequence of SARS-CoV-2 on January 11, 2020, resulted in the explosion of comprehensive studies on the virus and stirred global research and development activity to develop vaccines against the virus [8]. To accelerate this work, next-generation vaccine technology platforms have been deployed and the first COVID-19 vaccine candidate entered human clinical testing as early as March 16, 2020. In December 2020—in record time and following collaborative efforts of the global scientific community, pharmaceutical companies, and governments—several types and brands of vaccines based on different technologies and mechanisms of action became available for mass deployment [9].

The importance of mass vaccination has been established in the context of previous epidemics such as in the case of smallpox eradication and the incidence reduction of measles and polio [10]. The goal of mass vaccination programs is to interrupt person-to-person disease transmission by surrounding infected people with a high proportion of vaccinated individuals who

have developed protective antibodies against the infection (ie, reaching “herd immunity”) [11]. Public health experts have prioritized increased vaccination delivery with the hope to resume socioeconomic activities [12]. According to one study, to reduce the number of confirmed COVID-19 cases and deaths, it was estimated that, on average, the administration of 80 vaccine doses per 100 people was necessary [13]. However, the efficacy of vaccination is challenged by an increasing number of mutated strains, clinically proven possibilities of reinfection, and globally uneven rates of vaccination [14,15].

The vaccination process depends on various societal factors such as vaccine hesitancy, vaccine refusal, practical aspects of its application, and uneven/unequal vaccine rollout [16]. Even prior to the COVID-19 pandemic, the World Health Organization identified vaccine hesitancy as one of the top 10 global threats to public health [17]. After the appearance of COVID-19, this issue has gained a completely different dimension, and several people showed different degrees of vaccination acceptance from total refusal to hesitation, including health workers [18]. Levels of COVID-19 vaccine acceptance and obstacles to its rollout are country- and context-dependent [19]. Research has shown that most people are neither absolutely for nor against COVID-19 vaccines [20,21]. Hence, to begin to understand vaccine acceptance, it is important to gain insight into the reasons behind individual and collective decision-making [22].

SARS-CoV-2 is a novel virus, and various questions about dealing with this threat by mass vaccination emerged during the pandemic, including the efficacy of vaccines, the duration of the vaccine’s effect, and the impact of new virus variants [23]. The rapid vaccine development raised questions regarding safety, availability, and efficacy [24]. This is not surprising given the fact that vaccine development usually takes 10-15 years, whereas COVID-19 vaccines were developed in less than 1 year [25]. In addition, there are various factors that can increase disease spread and mortality rates that seem incoherent with the proposal for a uniform global vaccination rollout. The mortality rates were lower in countries investing more in the health system and vice versa [15,26]. Research from the United States showed that prosperous states with a higher population of older people and a higher number of physicians had a lower rate of vaccine hesitancy compared to that of other states [12].

The availability of vaccines, both in terms of the number of doses and equal distribution, has been an important issue within various countries, involving technical as well as socioeconomic aspects [27]. Timing is also very important since seasonal and environmental factors play important roles in the reduction of COVID-19 symptomatology [15,28]. Due to the numerous factors involved, interdisciplinary collaboration appears to be an appropriate solution to tackle vaccine hesitancy [29].

To facilitate a discussion on a successful vaccination rollout process, in this study, an analysis inspired by the strengths, weaknesses, opportunities, and threats (SWOT) framework was performed to explore perceptions and establish an informative perspective of the vaccination campaigns in 17 countries during the first phase of the mass vaccination programs in the first half of 2021. To facilitate this research, the scholars from the interdisciplinary Navigating Knowledge Landscape (NKL) research network were surveyed between May and July 2021. They were asked to provide information and their own opinions about the vaccination rollout programs in their respective countries. The participating scholars belonged to different disciplines, creating a specific combination of sociological and cultural analytical competences merged with medical and public health expertise. The aim of this interdisciplinary and transnational analysis was to better understand how information-sharing practices and social context were intertwined to coproduce public opinion on vaccination as a response to the COVID-19 pandemic.

SWOT, as a strategic planning framework, is usually used in evaluation of an organization, plan, project, or business activity. It is therefore a significant tool for situation analysis that helps managers identify organizational and environmental factors affecting performance and operations [30]. The framework can be used to identify favorable and unfavorable factors and conditions, solve current problems in a targeted manner, recognize the challenges and obstacles faced, and formulate strategic plans to guide scientific decisions [30-33]. The SWOT framework strives to offer a comprehensive, systematic, and accurate description of the scenario in which a topic is located [34]. SWOT analysis has two dimensions: internal and external. The internal dimension includes organizational factors focusing on strengths and weaknesses, whereas the external dimension includes environmental factors, namely opportunities and threats [30]. Since SWOT analysis is primarily used in organizational studies, our goal was to use its elements as a conceptual and narrative analysis tool where focus was placed on the intertwining viewpoints of social, political, and public health

practices. A similar approach has already been applied as a research method in which aspects of the SWOT framework were used to yield more precise and organized data [35]. However, to date, a SWOT-based analysis of the COVID-19 vaccination campaign has only been reported for India and Zimbabwe [36-38]. Therefore, with this study, we aimed to offer a new transdisciplinary and multinational viewpoint of the vaccination process.

Methods

Study Design

The data set included 25 contributions from 27 members of the NKL research network, collected from May to July 2021. These members contributed their viewpoints through a questionnaire aimed at mapping, in a representative manner, the rollout of the vaccination campaigns against SARS-CoV-2 during the early stages when vaccines were available to the general public.

All contributions were collected in a public data set, which is available with open access in Mendeley Data [39].

Study Sample

The 27 contributors were from 17 different countries: Australia, Austria, Croatia, Czech Republic, Germany, Hungary, Italy, Norway, Portugal, Romania, Serbia, Slovenia, South Korea, Sweden, Turkey, Ukraine, and the United Kingdom (including England and Scotland). Three contributions from the same country were received from Slovenia, Sweden, and Portugal; two from Croatia and the United Kingdom; and one contribution from each of the rest of the countries. Two contributions were coauthored (from Australia and Sweden). The contributors come from different academic backgrounds, but most of them are experts in the fields of life sciences, sociology, philosophy, and medicine. However, it is important to note that the contributors were expressing their own opinions and perceptions.

Measures

The questionnaire contained three parts asking about the status and details of COVID-19 vaccination in the respondent's country. Contributors were asked to return a short-text (ie, narrative) answer of 200-300 words per part. In this study, we focused only on the SWOT-related aspect of the responses (ie, Part 1) and the responses to the other parts of the questionnaire (Parts 2 and 3) were considered only to identify the eventual contribution to the SWOT-inspired analysis. SWOT elements were selected among the entire response text during the analysis process. The specific questions are presented in [Textbox 1](#).

Textbox 1. Questionnaire items.

- Part 1: The national vaccination program
- Describe the COVID-19 vaccination program in your country: what were its strengths, main weaknesses, opportunities to improve it, and threats to its success?
- Part 2: Public discourse and ethics
- How would you describe public responses to your country’s vaccination program? What is your impression on the various collective attitudes toward the vaccination program in your country? Were there any ethical issues or concerns around the vaccine program in your country?
- Part 3: Personal experience
- What is your personal experience, opinion, or attitude regarding COVID-19 vaccination?

Ethical Approval

Ethical approval for this study was obtained from The University of Edinburgh, Scotland, United Kingdom.

Data Analysis Procedure

To fulfill the study’s aims and obtain results, reflexive thematic analysis [40] and descriptive statistics (frequency analysis) of the themes were performed. This method is considered appropriate for exploratory research such as our study. Moreover, flexibility of the thematic analysis and opportunity for theme development seemed a great fit and application for our data set [40,41]. The open-ended questions allowed for formulating responses that enabled the respondents to frame the description of the vaccination process in their countries according to their own personal views.

For the purposes of reflexive thematic analysis, we divided the responses into four categories according to the elements of the SWOT framework. The subcategories of each category were identified and a list of the themes for each SWOT element was established. In a subsequent step, we analyzed the data for patterns and recurring topics. We looked for country-specific differences and similarities in regulations and practices. In

addition, close attention was paid to how the experts made sense of their experiences with the vaccination process and how the issues addressed were expressed. In presentation of the research results, focus was placed on themes identified throughout the reflexive thematic analysis. The results were then contextualized based on the existing literature.

Following that, frequency analysis of the identified themes was performed in relation to the corresponding countries. In the case of multiple contributions from the same country referring to the same theme or subtheme, only one data point was counted. The obtained results are presented in the form of tables and graphs.

Results

Thematic Analysis

Overview of Themes

Reflexive thematic analysis of collected contributions was performed independently by two researchers (VK, KN). Through the process of the reflexive thematic analysis [40], the numbers of themes respectively belonging to the elements of strengths, weaknesses, opportunities, and threats were established (Figure 1).

Figure 1. Graphical presentation of the established themes within each of the strengths, weaknesses, opportunities, and threats (SWOT) elements.

Thematic analysis of the vaccination process yielded a nearly even distribution of the four SWOT elements across all included countries and contributors, with 7 themes identified for strengths, 5 themes identified for weaknesses, 6 themes identified for opportunities, and 7 themes identified for threats. In total, analysis of the SWOT elements covered 25 different themes.

The contributors shared their subjective perceptions of the effectiveness of the vaccination campaigns in their countries, which ranged from claims of success to voices of criticism. The United Kingdom was the first country in the world to start the COVID-19 vaccination program in December 2020. Shortly afterward, the vaccine rollout was launched in the United States and the countries of the European Union, albeit with some delay (3 months) in Ukraine. In many countries represented in this study, the vaccination rollout started with some constraints, poor planning/management, and delays with vaccines delivery, but improved over time. In Portugal, an efficient organization of the vaccination process was achieved with the change of the Head of the Vaccination Task Force. In the countries of the European Union, the vaccination process was coordinated with that of other member countries (Croatia), although this collaboration was not always perceived as efficient, as pointed out by a contributor from Sweden.

A successful vaccination program was achieved in the United Kingdom, being respectively described as “overall...a large success” and “an overwhelming success” [39]. The contributions from Portugal and Serbia highly rated the results of the vaccination programs in their respective countries in relation to the high vaccination rate and being ahead of plans/schedule. A relatively successful vaccination process was also reported in Croatia, Hungary, Italy, and Norway. Efficient implementation was noted in Turkey, and an active vaccination process was described in South Korea with major public facilities offering vaccinators discounts or exemptions from paying admission or usage fees. For some other countries, the collected contributions reported low vaccination coverage in the survey period (May to July 2021), including Australia, Romania, and Ukraine. The respondent in Romania specifically reported low coverage for high-risk groups and people over 65 years old. Moreover, very low coverage of rural areas occurred due to lack of local community involvement, especially mayors, policy makers, and family doctors, with some of the latter refusing to dispense vaccines.

Slow rollout of the vaccines was noted in Australia, Austria, and Germany. In Australia, the delayed vaccine rollout has been described as a “vaccine stroll out,” as by July 2021, only 6% of the Australian population had been vaccinated [39]. Moreover, some individuals in priority groups such as older people or those with disabilities living in long-term care homes were still waiting for their second or even their first dose of the vaccine. In addition, in some countries, the vaccination points were hard to access in remote, rural areas (Australia).

If we are to judge vaccination rollout success by looking at the percentage of people who had received at least one dose of the vaccine during the time period corresponding to our data collection, the most successful country in our sample was the

United Kingdom, with approximately 70% of the population receiving at least one dose (Multimedia Appendix 1) [42]. The lowest percentage was reported in Ukraine, where only approximately 8% of people had received a single vaccine dose [42].

Strengths

The primary themes related to strengths included (1) societal discussion/consensus on priorities to get the vaccine, (2) defined vaccination strategy/plan, (3) vaccine availability, (4) positive attitudes toward vaccines and the vaccination process, (5) practical aspects of the vaccination solved (eg, medical personnel satisfied, sites easy to access, fast process, no long queues), (6) well-designed public communication campaign on the vaccination process, and (7) flexibility to provide vaccines.

High availability of vaccines was reported in Hungary, Italy, Sweden, and the United Kingdom. Following the controversies around the possible side effects of AstraZeneca vaccines, stocks of the European Union–approved vaccines were excessive in Slovenia. The wide availability of vaccines to whoever wanted them was considered a strength of the vaccination campaigns. In Romania, free vaccination has been offered to everybody who wanted one, including those with Romanian or European citizenship. In Portugal, vaccination was available independent of legal status, including to undocumented migrants. Free vaccination was also offered in Serbia to people from abroad, primarily citizens of neighboring countries, with no restrictions.

Medical workers played a key role in achieving successful vaccination campaigns. Family doctors contributed to the success of the vaccine rollout in Croatia and a helpful approach was reported by the medical staff of the Czech Republic. For Portugal, strong commitment of health care professionals and communication initiatives of the medical doctors to clarify doubts related to the vaccine’s side effects were noted.

Transparent planning and strategies, as well as prioritization of people with higher infection risk or greater vulnerability, were commonly reported strengths of the vaccination programs. In most countries, the prioritization was perceived as fair, although in some countries controversial cases of people from nonpriority groups being vaccinated early also occurred (Portugal, Slovenia). The priority groups in most countries included older adults, those with underlying health conditions, and workers exposed to a high infection risk. By contrast, vaccination of health care professionals has not been prioritized in Sweden. In all countries, the vaccine was provided free of charge, dispensed on a voluntary basis; however, mandatory vaccination was reported for medical workers in Italy and South Korea and for people in high-risk jobs in Australia. Moreover, an easy registration process, owing to easy-to-access platforms such as apps, web pages, or via the phone, was described for Turkey and Ukraine. Automatic enrollment based on medical records via general practitioners (eg, family doctors) was available in the United Kingdom. An efficient registration process in the Czech Republic was also claimed as a strength.

Weaknesses

The primary themes related to weaknesses were as follows: (1) social divide due to the vaccine distribution and side effects,

(2) unclear vaccination strategy/plan, (3) lack of vaccines, (4) negative attitudes or hesitancy toward vaccines and the vaccination process, and (5) barriers to access vaccines.

Lack and shortage of vaccines were emphasized in Ukraine and Turkey, as well as at the beginning of the vaccination rollout in some other countries, where delayed deliveries were also reported. Delayed rollout to the remote Aboriginal communities was noted in Australia. The registration process was essential in achieving an effective rollout of the vaccines. Poor functioning of the distribution organization was highlighted by many participants from different countries, especially in the early stages of vaccination programs. Getting a vaccination appointment was rated as difficult in Sweden.

Trust was pointed out as an important issue in several contributions. A low level of trust in the medical science (Croatia), in the effectiveness and safety of the vaccines (Ukraine, Romania, Slovenia), and in the official authorities (Slovenia) were reported. An overall high level of skepticism in society at large was observed (Germany). Lack of enthusiasm and willingness to be vaccinated or vaccine hesitancy were widely reported (Austria, Norway, Romania, Slovenia, Ukraine). Despite the very successful vaccination process in Serbia, only a small percentage of younger people and health workers were vaccinated in the country. High hesitation among young people was also reported in Slovenia. In contrast, in Ukraine, young people were rather eager to be vaccinated, despite the high level of general hesitancy noted in the country. In Australia, vaccine hesitancy was exacerbated by the risks of side effects reported for the AstraZeneca vaccine.

Lack of clear and coherent communication on how to receive the vaccination was considered an important barrier to access in Slovenia. The need for suitable and unequivocal guidelines about vaccination was stressed in Italy, as constant changes have confused the population and discouraged vaccination, while different rules in different parts of the country and frequent regulation changes were noted to have discouraged vaccination in Germany. Unavailability of scientific information to foreigners/migrants, especially for those not fluent in the local language (eg, the home workers caring for the older population) was stressed for Italy. The digitally based vaccination approach was considered an important barrier to those not having adequate digital abilities. In Sweden, despite having one of the highest internet coverage rates in the world, people living in socially disadvantaged areas, including asylum seekers and migrants, and older adults or people with cognitive impairment who did not master the digital skills required were at risk to be excluded from accessing important information. A low level of digitalization was also mentioned as an obstacle to vaccination success in Romania.

Opportunities

The primary themes related to opportunities were as follows: (1) adding more flexibility; (2) increasing vaccine availability and multiple options for registration; (3) active outreach to marginalized groups, vulnerable citizens, refugees, and ethnic minorities; (4) improving the role of the media (better communication) and national awareness campaigns; (5)

information sharing about the usefulness of the vaccination process; and (6) provisions for vaccinated individuals.

The freedom to choose to make an appointment for vaccination, no matter where people were registered (Sweden), and adding more flexibility to accessing vaccination (Croatia) were considered among the opportunities to improve the vaccination rollout.

To motivate people to be vaccinated, financial support (approximately US \$30) was offered in Serbia. Vaccination coupons or exemptions from admission or usage fees of public facilities (approximately US \$900) were introduced by a National Vaccine Injury Compensation Program in South Korea. In addition, this country also allowed a one-day “vaccination leave” from work to be taken the day after receiving the vaccine, along with an additional one-day leave in the case of experiencing some subsequent side effects [39]. In Ukraine, in the unlikely case that vaccination would cause disability or death, a compensation allowance (approximately US \$21,000-27,000) was promised by the government.

Among the opportunities to improve the vaccination process, the freedom to choose among the available vaccine brands/types was recognized as a good strategy to counteract the arising doubts about a certain brand of vaccine (Slovenia, Ukraine). The choice of vaccine brand was also available in Turkey and in Serbia, contributing to successful vaccination campaigns. Finally, a more responsible role of media was mentioned as an opportunity to improve people’s attitude toward vaccination, as pointed out for Croatia and Ukraine. Moreover, in various countries, the respondents suggested that improvement of communication strategies and specific information programs might be crucial to reach vaccine-hesitant citizens and facilitate the vaccine rollout.

In addition to traditional media, social media were noted to play a role. Social media influencers were identified to positively contribute to motivating people to be vaccinated, producing a “crowd effect,” as reported for Croatia and Ukraine, where public figures, such as the President and the health minister gave declarations through the media. Vivid promotions in favor of vaccination by persuasive political and medical discourses, accompanied by enthusiastic argumentations in favor of science and against conspiracy theories and vaccination skepticism, were described for Slovenia.

Threats

The primary themes related to threats were as follows: (1) appearance of new virus strains/lower efficacy of the vaccines, (2) unforeseen side effects of the vaccines, (3) spreading disinformation, (4) ethical controversies, (5) legal controversies, (6) religious controversies, and (7) a change in the behavior of vaccinated individuals that facilitates the spread of infection.

Low trust in the efficacy and safety of the vaccines (Romania, Slovenia, Ukraine); a negative influencing role played by some media communications, especially when stressing the side effects (Serbia, Sweden), and alleged corruption related to the vaccine prioritization (Slovenia) were regarded as relevant threats to be considered for achieving successful mass vaccination campaigns. Insufficient information, disinformation,

or misinformation in the media and on the internet were reported for the Czech Republic, Sweden, and Romania, while development of conspiracy theories about vaccines was pointed out for Slovenia and Ukraine. Disputable communication from the government regarding vaccines and other public health measures such as lockdowns was described for Germany. Lack of adequate public communication strategies was also noted in Slovenia. Failures in communication with people from different cultural groups were reported in Australia.

Ethical concerns associated with the use of leftover doses were pointed out by respondents from Sweden and Portugal, referring to a lack of planning for how to handle leftover vaccines that could not be administered the next day or to the overall mismanagement of vaccine administration. In contrast, the opportunity to get a leftover dose was marked as a strength at the beginning of the vaccination campaign in Ukraine, where this was the only option to be vaccinated for those in nonpriority groups. Confusing messages from religious leaders and local

community priests were reported in Romania. Concerns of disobeying the Islamic conduct codes raised by vaccination opponents was described for Turkey, as during the month of Ramadan fears were prompted that vaccination during the fasting period was not acceptable.

Frequency Analysis

Overview

To explore the distribution of the responses by countries, frequency analysis was performed (Figures 2-5). Responses reporting a certain theme are marked in the figures in green color and assigned a value of 1, whereas those that did not mention the theme are marked with light yellow and assigned a value of 0. The total score corresponds to the sum of values of all related responses. Additionally, the average percentage of responses distributed for each element and theme was calculated (Multimedia Appendices 2-5).

Figure 2. Overview of the opinions covering strengths-related themes by country. Green indicates presence of a theme (assigned a value of 1) and yellow indicates absence of the theme (assigned a value of 0). The total score corresponds to the sum of values of all related responses.

	Australia	Austria	Croatia	Czech Republic	Germany	Hungary	Italy	Norway	Portugal	Romania	Serbia	Slovenia	South Korea	Sweden	Turkey	UK-England	UK-Scotland	Ukraine	Total

Strengths

Three themes dominated the analysis of strengths, each being covered in 7 reports: societal discussion/consensus on priorities to get the vaccine, defined vaccination strategy/plan, vaccines’ availability, and flexibility to provide vaccines.

The strengths theme “societal discussion/consensus on priorities to get the vaccine” was mentioned in Croatia, Romania, Sweden, Turkey, UK Scotland, UK England, and Ukraine. “Defined vaccination strategy/plan” was reported in Croatia, Italy, Slovenia, Sweden, Turkey, UK (England), and Ukraine. “Wide vaccines availability” was indicated in Croatia, Hungary, Serbia, Slovenia, Sweden, and the United Kingdom. “Positive attitudes of the society toward vaccines and vaccination process” were reported for Croatia, Italy, Portugal, and Sweden. Logistic aspects of the vaccination being solved (including satisfaction of the medical personnel, sites easy to access for registration, fast process, no waiting in line) were noted for Romania, while well-designed public communication on the vaccination process was described for the Czech Republic, Hungary, and Serbia. Flexibility to provide vaccines was highlighted as a potential strength in the contributions from Croatia, Czech Republic, Portugal, Serbia, Slovenia, Turkey, and Ukraine. Relatively even distribution was identified across strengths categories with the exception of practical aspects of the vaccination solved that was reported by only one contributor.

Weaknesses

Most frequently reported weaknesses were barriers to access the vaccination (13 reports) and negative attitudes or hesitancy toward vaccines and the vaccination process (9 reports).

Social divide due to the vaccine distribution and side effects were considered weaknesses in Australia, Austria, Croatia, Germany, Hungary, Italy, Portugal, and Sweden. Unclear vaccination strategy/plan was described in Germany, Hungary, and Portugal. Lack of vaccines was noted in Australia, Croatia, Germany, Italy, Portugal, Slovenia, Turkey, and Ukraine (note that the questionnaire addressed these issues only related to the first 6 months of the vaccination campaigns). Negative attitudes or hesitancy toward vaccines and the vaccination process were described in Australia, Austria, Hungary, Portugal, Slovenia, Sweden, Turkey, UK England, and Ukraine, while barriers to access vaccination, including problems with prioritization, registration, and unfair/nontransparent distribution of the vaccines were noted in Australia, Croatia, Germany, Hungary, Italy, Czech Republic, Portugal, Romania, Slovenia, Sweden, Turkey, UK Scotland, and Ukraine. In addition, 72.2% of the contributions reported barriers to access vaccines as a weakness. Conversely, only 16.6% of our sample reported an unclear vaccination strategy/plan as weakness.

Opportunities

The frequencies of the selected opportunities to improve the vaccination process were rather low including a maximum of 5 countries. Adding more flexibility to the vaccination process was mentioned in Croatia and Ukraine; increasing availability of the vaccines and multiple options for registration were mentioned in Croatia, Germany, Romania, and Ukraine; active reach of marginalized groups, vulnerable citizens, refugees, and ethnic minorities was mentioned in Australia and Sweden; improving the role of the media (better communication) and national awareness campaigns were indicated in Portugal, Romania, and Slovenia; information spreading about the usefulness of the vaccination process was highlighted in Croatia, Portugal, Slovenia, Sweden, and Ukraine; and monetary provisions for vaccinated individuals were mentioned in Serbia and Ukraine. Contributors did not report opportunities in large numbers. The highest percentage (27.7%) of responses related to the opportunities-related themes was attributed to spreading information about the usefulness of the vaccination process.

Threats

Concerning the possible threats to a vaccination campaign's success, the contributors from Australia, Serbia, and Ukraine remarked the possible appearance of new virus strains and lower efficacy of the vaccine; unforeseen side effects were noted as possible threats in the contributions from Serbia and Sweden; spreading disinformation were noted or could be concluded from the abstracts from Australia, Croatia, Czech Republic, Romania, Slovenia, South Korea, Sweden, and Ukraine. Other possible threats to vaccination success mentioned were ethical (Czech Republic, Germany, Italy, Portugal, Romania, Slovenia, South Korea, UK Scotland, and Ukraine), along with legal (Italy) and religious controversies (Romania). Ethical controversies (50%) and spreading information (44.4%) were the most highly represented threats-related themes.

In this study, the mainly acknowledged threat feature for achieving successful vaccination campaigns reported by the respondents was related to the likely occurrence of viral mutations, resulting in new virus strains with the ability to escape the immunizing effects of the present available vaccines. This fact has been pointed out as a relevant source of uncertainties and doubts about the vaccines' effectiveness as well as about their overall reliability and utility.

Discussion

Principal Findings

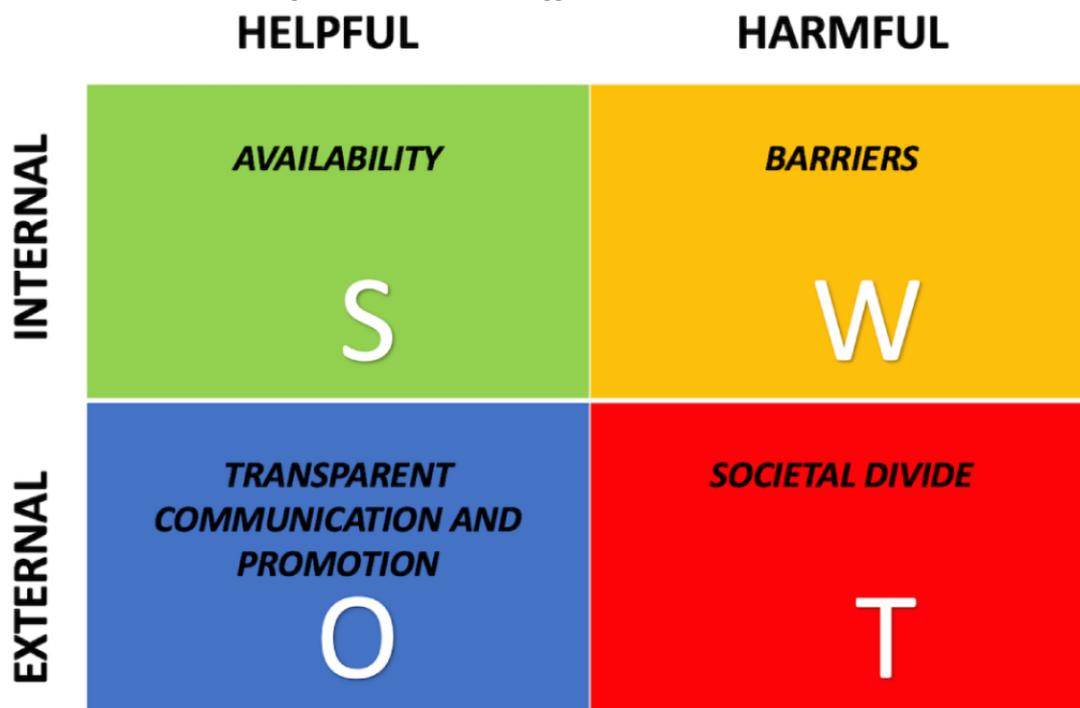

Since its introduction in the 18th century to the present day, vaccination has been one of the most effective tools in the battle

against infectious diseases [10,43]. Owing to the high efficacy of vaccines, the public health burden of infectious diseases has been significantly reduced throughout the years [10]. However, despite their proven track record, the phenomenon known as "vaccine hesitancy" has been around almost as long as vaccination itself. This reluctance to accept an injection of an "unknown substance" into the body is exasperated by a need to vaccinate a large number of healthy individuals, including in the case of COVID-19 [44].

This study, based on an analysis of interdisciplinary experts' viewpoints in 17 different countries inspired by the SWOT framework, allowed us to identify 25 themes distributed across the four SWOT elements. To our knowledge, this is the first study to analyze and compare the vaccine rollout process in various different countries. The frequency of the appearance of these themes and their distribution across the countries allowed us to select those that stand out. As the contributions were inspired by the SWOT framework, the presented analysis could be easily synthesized into the four main overarching SWOT categories (Figure 6). With respect to the strengths of the vaccination process, the identified seven themes correspond to a single category referred as *Availability*, being the major strength of the successful vaccination program. When weaknesses were described, the five themes identified could be best described by a single category termed *Barriers*, which were either not recognized or not addressed by the vaccination programs. The external aspects of opportunities described via the six themes identified fit under category *Transparent communication and promotion*, which allows other societal forces to contribute to the vaccination process. Finally, the seven themes describing threats correspond to the *Societal divide* category, where a polarized society has the potential to spoil even well-thought-out initiatives.

We believe that these categories offer the best representation of the most frequently reported themes in each of the SWOT elements. However, due to the intertwining factors present in the vaccination rollout process, it is important to not look at this distribution as a binary (presence/absence) phenomenon. This is particularly relevant when splitting the identified themes into "internal" and "external" categories. In the current SWOT 2x2 matrix (Figure 6), *Availability* and *Barriers* are labeled as internal categories, whereas *Transparent communication and promotion* and *Societal divide* are suggested as external categories [45]. However, within the *Societal divide* category labeled as a threat, there are ethical, religious, and legal controversies reported as important themes. Therefore, one cannot classify a controversy per se as a threat, as controversies can serve just as much as a source of debate with the potential to improve the vaccination process.

Figure 6. Synthesized themes under the strengths (S), weaknesses (W), opportunities (O), and threats (T) framework.

The specific time window when the study was performed corresponds to a relatively early phase of the vaccination process (on average half of the population had been vaccinated in the analyzed countries). This leads to a very specific bias in the submitted data: urgency to tackle an important and pressing issue. We reiterate that our study analyzed the subjective viewpoints of the respondents; hence, some of the themes across these categories were dependent on the various individual, psychological, emotional, and societal aspects specific to the given time window. The sudden appearance of COVID-19 and its rapid spread called for appropriately rapid responses. Considering psychological factors of egocentrism, information availability, social/group confirmation, individual motivation, and emotional affect as foundations of that rapid decision-making process, it is easily possible to misjudge and/or misperceive the key elements of the reasoning arising from the complexity of the situation [46]. However, although there were 27 individual respondents from 17 different countries, our results did not show country-specific differences. Hence, our findings can contribute to the development of strategies that will maximize the promotion of strengths and opportunities while minimizing weaknesses and threats globally.

The identified themes are consistent with the research on this topic [36,38]. The most prominent theme in the existing literature, which was also present in our study, explores the effective medical and public health system measures mapping on the key strengths identified herein. This shows how preparation and prevention strategies work, and how they can be used as a base of the powerful pushback against the spread of COVID-19. Moreover, a positive attitude toward vaccination has been defined as a strength in similar studies in India and Zimbabwe [36,38].

The application of the SWOT framework to complex societal processes can also be seen as a source of confusion. For

example, a “strength” is considered as an internal aspect of the process, which can be understood to relate to the vaccination campaign itself. From this perspective, the attitude toward vaccination does not seem to be an internal component but rather an external aspect of SWOT and thus should be more appropriately classified as an opportunity rather than a strength. However, application of the SWOT framework in such complex scenarios requires consideration of the vaccination campaign as part of a sociotechnical system, thus incorporating vital elements of the social environment within the situated practice of vaccination. Combining our findings obtained from individuals from 17 different countries with previous research, it can be concluded that good organization that addresses the availability of vaccines coupled with an engaging societal discussion would represent a key strength/opportunity of the vaccination process.

A lack/shortage of vaccines combined with various logistical challenges have been reported as major issues for the success of vaccination campaigns within previous research [47,48]. The demand-supply gap combined with lack of knowledge and supporting infrastructures have been reported as particular weaknesses [36,38]. Compounding unequal vaccine distribution with unknown disease progression and an uncertain response to the vaccine seems to be the biggest barrier in the vaccine rollout [13]. Similarly, the respondents of this study recognized the practical issues of availability and fairness of distribution, and coupled these issues with the related attitudes and social division. This points to the fact that social distrust needs to be addressed within a vaccination plan as a major barrier. For both strengths and weaknesses, no clear geographical divide was present.

Increasing the public awareness about the vaccine effects through transparent communication and promotion stood out as a key opportunity-related theme. Communication reports on

the widespread acceptance of COVID-19 vaccines have shown to be effective tools to further increase vaccine acceptance [49]. Moreover, in an attempt to promote vaccination, some public figures have been vaccinated on television [49]. It is interesting to see that people who used mainstream media outlets as their major source of information on health were more likely to get vaccinated [50]. Our data support the notion that transparent information-sharing about biological mechanisms, efficacy, as well as side effects of the vaccines motivates people to join vaccination programs. Previous research has identified the potentially influential role of media in increasing people's trust in vaccines when they hear politicians, celebrities, or other famous people talking positively about them [36]. Trust in vaccines, medical science, and medical professionals—together with other involved stakeholders, including government and policy makers—was highlighted in the analyzed contributions as an important factor. These findings align with previous research that found lack of communication from trusted providers and community leaders as one of the main reasons for low COVID-19 vaccination rates [44]. Communication of vaccine information and promotion of its uptake in the digital era includes the use of social networks [51]. However, the use of social networks is also associated with risks due to the wildfire-like dynamics of rumors in the digital environment and issues with unknown algorithms used by for-profit entities filtering information [52,53]. Social networks are expected to drive healthy public debates; however, they instead frequently reinforce like-minded “bubbles” and increase polarization [53,54].

Discussions on matters of autonomy (an individual's right to choose) and state power have always been at the center of public health ethical dilemmas [29]. In the specific case of COVID-19 vaccines, besides the tensions between public health and individual interest/autonomy, other ethical challenges relate to the rapid design and testing of vaccines and who gets the vaccines (first) [55]. Public health authorities need to implement efficient, flexible, responsive, and resilient strategies to successfully fight the pandemic and raise awareness of all of the dangers arising with this disease [56]. Surprisingly, in our findings, the question of one's autonomy did not crystalize as a theme. Instead, other ethical controversies and spreading of disinformation were found to be the most frequently reported themes within the threats element. In the present digital era, information accessibility is at its peak; however, it is important to be aware of the source of the information given that rumors and fake news are rampant [17,57].

When discussing the threats element in the SWOT framework, it was interesting that unforeseen side effects of the vaccine have not been considered as the most prominent threat theme, whereas other research shows that the most common reason for vaccine hesitancy or refusal is due to the concerns related to the side effects/safety [50,58,59]. The emergence of new virus strains was mentioned as a threat, since they decrease the efficacy of the vaccine and hence can contribute to the further spread of COVID-19. As people were already worried about

the lack of information about safety, testing, and efficacy of COVID-19 vaccines, the new variants were seen as a contributor to the negative perception of the vaccines in society [15,60]. The synthesizing category for the threat element of *Societal divide* implies that social polarizations have the potential to paralyze a society when facing a complex public health crisis. Here, it should be stated that silencing the controversies is certainly not the path to avoid such an outcome. A society where controversies are not openly discussed is not without these controversies, but rather this situation would give rise to potentially dangerous and isolation subcultures. Although *Societal divide* was recognized as a threat in our sample, there were no clear examples where this has significantly directly influenced the vaccination process. Consequently, although the awareness of controversies as a potential threat was voiced, if the social environment is developed within the context of *Transparent communication and promotion* (opportunity), the *Social divide* may never reach the level of polarization to create adverse effects on public health campaigns.

Study Limitations

The collected responses represent the subjective viewpoints of experts who volunteered to take part in the study. Therefore, extrapolation to the national level must be drawn out with caution. In addition, due to the lack of research using this same methodology and implementing it on a multinational level, there were no relevant studies to make direct comparisons with and contrast conclusions. Moreover, SWOT analysis was not performed in its original form addressing organizational dynamics. Instead, this thematic analysis of expert viewpoints was only inspired by the SWOT framework. Therefore, the results of this study should be further examined and more research is needed on this topic in general. Further studies could consider interdisciplinary and multinational frameworks to find the best practice in public health policies that could yield improved vaccination rollout results globally.

Conclusion

This study was based on a collection of short responses to a specifically designed questionnaire, written by researchers from different countries and fields of expertise, thus bringing together multidisciplinary and cross-national opinions on vaccination rollout. This represents the first analysis of the vaccination process in 17 different countries inspired by the SWOT framework. The obtained results highlight the connection between organizational aspects of the vaccination rollout and corresponding societal response, both being related to the strengths and weaknesses of the process. The opportunities and threats corresponded to external societal factors, better public communication of vaccination-related issues, ethical controversies, and the spread of disinformation. The inventory of 25 SWOT-related themes and the resulting 2×2 SWOT matrix represents an approximate best-practice viewpoint for the successful implementation of public health policies—as represented by this multidisciplinary team—in the fight against COVID-19.

Acknowledgments

This study represents an activity of the interdisciplinary network Navigating Knowledge Landscapes. The study was supported by the European Union through the European Regional Development Fund, as the Scientific Centre of Excellence for Basic, Clinical and Translational Neuroscience, under grant agreement KK.01.1.1.07.0071, project “Synergy of molecular markers and multimodal in vivo imaging during preclinical assessment of the consequences of the ischemic stroke (SineMozak)” (to SG).

Data Availability

The data sets supporting the results presented in this study can be found in the online repository [39].

Authors' Contributions

VK, KN, MV, and SG designed the study. VK, KN, and LM performed data acquisition, organization and analysis, and wrote the first version of the manuscript. VK, KN, LM, LL, ZT, MV, HM, ALS, and SG contributed to the interpretation of the data collected, framed the results, and critically revised the manuscript. All authors approved the submission to the journal.

Abstract

Background: The extant literature suggests that women are more vulnerable to COVID-19 infection and at higher risk for developing long COVID. Due to pandemic mitigation recommendations, social media was relied upon for various aspects of daily life, likely with differences of usage between genders.

Objective: This study aimed to explore the role and functions of social media in the lives of long-hauler women.

Methods: Participants were purposively snowball-sampled from an online health promotion intervention for long-hauler women with COVID-19 from March to June 2021. During this time, one-on-one, semistructured interviews were conducted online until data saturation was agreed to have been achieved (ie, 15 interviews). Interview transcripts and field notes were analyzed using an emergent, inductive approach.

Results: In total, 15 women were enrolled. The main roles of social media included facilitating support group participation, experience sharing, interpersonal connections, and media consumption. Emergent themes demonstrated that participants rely on social media to fulfill needs of emotional support, social engagement, spirituality, health planning, information gathering, professional support, and recreationally for relaxation. As long-hauler women turn to social media to discuss symptom and health management as well as the intention to vaccinate, this study demonstrates both the associated benefits (ie, decreased isolation) and challenges (ie, misinformation, rumination, resentment, jealousy).

Conclusions: The public health implications of these findings support the development of gender-tailored health promotion interventions that leverage the benefits of social media, while mitigating the negative impacts, for women with long COVID.

KEYWORDS

COVID-19; long COVID; long-haulers; women; gender; social media; digital media; qualitative study

Introduction

The COVID-19 Context

The COVID-19 pandemic, caused by SARS-CoV-2, was declared on March 11, 2020, and was accompanied by recommendations to implement prevention measures, such as masking, vaccination, testing, social distancing, isolation, and quarantine [1-5]. In the United States, as of June 16, 2023, there had been more than 103.4 million cases of COVID-19, of which more than 6.1 million required hospitalization and more than

1.1 million resulted in death [6,7]. Of those who become infected, about 30% develop postacute sequela SARS-CoV-2 (PASC), also known as chronic COVID-19 or long COVID, characterized by symptoms of varying severity that persist for 4 weeks or more after infection (eg, chronic fatigue, pain, cognitive dysfunction, muscle deconditioning, impaired concentration, and persistent ageusia and anosmia); these patients are commonly referred to as long-haulers [8-13]. Overall, women have been found to be more likely than men to develop long COVID (ie, 9.4% vs 5.5%) [14-16]. This

disproportionate trend requires further investigation into the differential experiences of long COVID among women.

Long COVID Among Women

The literature shows that there may be an association between biological sex and COVID-19 infection and recovery; however, this fails to consider the role of gender, the social environment, and gendered social norms [17]. For instance, women primarily constitute social assistance and health care workforces and face increased expectations of caregiving in the family setting, increasing the risk of COVID-19 infection [18]. As long COVID results from COVID-19 infection, differential exposure and incidence among women predisposes them to the risk for developing persisting symptoms [19]. Persistent symptoms experienced more so by long-hauler women include fatigue, difficulty breathing, muscle pain, and cognitive dysfunction, as well as the negative psychosocial outcomes of anxiety, depression, and posttraumatic stress disorder (PTSD), particularly among those who have been hospitalized [20,21].

Social Media and COVID-19

Due to stay-at-home orders and the prioritization of social distancing as the primary means to prevent the spread of COVID-19, in the online environment, social media emerged as a key tool to adjust to the new normal, necessitating research on its roles and functions. Overall, in the United States, 97% of Americans indicate owning a cell phone of any kind, 85% indicate owning a smartphone, and 85% of US households have a broadband internet connection [22,23]. Using these technologies, 85% of US adults indicate going online at least once a day and 31% indicate that they are online “almost constantly” [22]. Among mixed findings in the COVID-19 literature, women report higher usage of social media compared to men, with assumedly differential motivations for engagement and use of platform functions [24]. Due to the prevalence of individuals being online for work and personal use, it is necessary to evaluate the role of technology and social media within the context of the pandemic and, specifically, the experiences of long-hauler women [25].

Among long-haulers specifically, social media played a vital role in developing the long-hauler identity and encouraging clinical acknowledgement. The term “long COVID” originates from social media users’ posts online [26]. Posts sharing long COVID experiences typically include a diagnosis or test result, the symptoms experienced, the length of time symptoms have persisted, an emotional response, and information and resources [27]. The growing conversations among long-haulers on social media shifted the experience of long COVID from anecdotal, exposing an invisible disability, to clinical [26,27]. With the creation of a shared identity, long-haulers were able to identify one another and further subdivided themselves into categories accounting for their intersecting identities (eg, long-hauler, woman, and mother).

Social media has been used to mitigate the impacts of lost social connections, social distancing, and isolation [21,22]. In the literature, social media has been demonstrated as a key tool used to maintain social connections, while adhering to social distancing recommendations, limiting feelings of isolation [28].

Additionally, as loneliness has been associated with decreased use of healthful coping behaviors, social media has been found to mediate the association during periods of isolation, such as during the COVID-19 pandemic [29]. There are linkages between daily use of social media and lowered measures of social isolation, as well as inversely with infrequent use of social media and higher measures of isolation [30]. Despite the positive outcomes associated with using social media during the pandemic, downfalls remain. For example, in a study focusing on older adults, internet use reflected coping efforts but did not necessarily enhance or sufficiently improve well-being [31]. Due to the mixed effects and roles of social media, throughout the pandemic, there is a unique opportunity for researchers to investigate the role of social media in social connections, isolation, and support, as well as in perpetuating access to information or misinformation among long-hauler women [32].

Overall, the literature suggests that social media sites impact users’ ability to maintain social connections, seek social support, and access information, as well as affect isolation, social comparison, and the spread of misinformation [33,34]. According to the information systems literature, gender is associated with differential motivations to use social media sites (eg, relational uses for women vs information gathering for men) and differential perceptions of information shared online [35,36]. To the best of our knowledge, despite the gendered associations relevant to social media use in other fields, few studies have assessed the differential role of social media during the pandemic, by gender, from the public health perspective. Due to an overwhelming focus on women’s experiences as essential workers and with reproductive care during the COVID-19 pandemic, there is scant literature more broadly centering on women. The experiences of women were chosen as a focus in this work due to their disproportionate burden of long COVID and their higher rates of activity and gender-specific engagement patterns on social media sites [37]. This work therefore aimed to fill a gap in the extant literature by investigating the role of social media in the experiences of long-hauler women alone.

Methods

Study Design

The data used in this study were derived from an online health promotion intervention for long-hauler women with COVID-19. Participants were recruited using snowball and purposive sampling through 2 social media sites, Facebook and Slack; the participants were recruited from 16 Facebook groups and 1 Slack group, as well as 2 websites of organizations for long-hauler women. Those eligible to participate in the study met the inclusion criteria of living in the United States, being aged 18 years or older, who spoke English, and who self-identified as long-haulers due to persistent COVID-19 symptoms for 4 weeks or more after infection.

Ethical Considerations

The University of South Carolina Institutional Review Board (Pro00109358) reviewed and approved the study protocol.

Recruitment began after group and organization administrators approved posts including the study description, a flyer, and researcher contact information. The study was then advertised in each group.

Recruitment

The recruitment period spanned 2.5 months from March to June 2021. After screening for eligibility and receiving informed consent, a total of 15 semistructured, one-on-one interviews were conducted from April to June 2021 using the online videoconferencing software Zoom [38]. Each interview lasted between 30 and 50 minutes. Participant demographics were collected through the interview process. All interviews were audio-recorded and, upon completion, field notes were written. Each participant was compensated with a US \$30 e-gift card for their time and effort spent participating in the study. Data saturation was agreed to have been reached, by the 2 researchers involved in interview coding, after 15 interviews.

Data Collection

Data were collected on the participants' self-reported long-hauler status, the impact of persistent COVID-19 symptoms on their lives, coping strategies, and overall experiences. In these conversations, discussions of the roles of technology and social media arose organically following the semistructured interview guide. All interviews were recorded and transcribed using the service Otter.ai [39]. All artificial intelligence-derived transcripts were reviewed and verified by members of the research team. Interviewer field notes were used as additional data.

Data Analysis

The data were analyzed following a predominately inductive approach for the thematic analysis of the interviews, as the

themes identified were derived directly from the data [40-42]. The analysis process was comprised of 6 stages beginning with data familiarization and preliminary code construction, followed by the obtaining, revising, labeling, and reporting of key themes [43]. MAXQDA software was used to analyze interview transcripts [44]. In the initial phase of the thematic analysis, 2 members of the research team independently coded the transcripts, following an open coding scheme, to identify emergent themes [45-47]. The initial development of the codebook was performed after half of the interviews (ie, 7) were coded. We discussed at length the creation of the codebook to ensure accuracy of the initial codes, themes, domains, definitions, exemplar quotes, and organization. Once the codebook was finalized, the same 2 members of the research team continued to independently code the remaining transcripts. We then engaged in a collaborative review process to confirm alignment with the final codebook and to ensure consistency in the application of codes. In comparing themes, we identified similarities, differences, and interactions between themes. We used an axial coding approach to categorize the main themes and subthemes, which then guided the selection of direct quotes to demonstrate the key findings. Peer debriefing and intercoder agreement techniques were used to ensure reliability throughout the data analysis [48,49].

Results

Participant Details

The study participants, in alignment with the inclusion criteria, all identified as women. The participants were primarily aged between 36 and 65 years ($n=12$, 80%), served as essential workers ($n=9$, 60%), and lived with others ($n=13$, 87%) in the eastern region of South Carolina ($n=10$, 67%). Table 1 lists the participant details.

Table 1. Demographic characteristics of long-hauler women (N=15).

Characteristics	Participants, n (%) ^a
Age (years)	
20-35	2 (13)
36-50	6 (40)
51-65	6 (40)
>65	1 (7)
Occupation	
Health care provider	5 (33)
Educator	4 (27)
Business owner	4 (27)
Student	1 (7)
Retiree	1 (7)
Living situation	
Living with others	13 (87)
Living alone	2 (13)
Regional location	
East	10 (67)
Central	3 (20)
West	2 (13)

^aThe percentages might add up to more than 100 because of rounding.

Benefits and Challenges

Long-hauler women indicated that their most used social media features included participating in support groups, posting, commenting, connecting with others, and consuming media. They used these features of social media sites to fulfill needs such as emotional support, social engagement, spirituality, health

planning, information gathering, professional support, and recreation. The different functions of social media also resulted in a variety of benefits and challenges throughout the participants' coping with long COVID. [Tables 2](#) and [3](#) present the benefits and challenges related to the themes and subthemes identified and exemplar quotes.

Table 2. Emergent themes and subthemes of the beneficial roles of social media identified by long-hauler women.

Themes and subthemes	Exemplar quotes
Social connection	
Group membership	“So I said, ‘Well, maybe if I am part of something...it is gonna be like a, like a, like a motivation for me to go through something for me. Um, because again, we are always thinking about others, you know, like, what, why am I complaining.”
Social support	“I may not exactly know what you’re going through, but I am here to help and here to listen because a lot of times you just want a hearing—somebody to hear you.”
Network building	“I also was posting and doing that, which, like, kept me motivated [to continue] sharing and connecting with other people...”
Belonging	“I probably gravitated more towards that group...and I would talk about that Facebook group a lot. Like, it felt like that was like a support group, and it felt like, you know, I am not crazy, like some other people are having it, too. And I would be active in, like, commenting on, like, you know, answering people’s questions or, like, sharing, like, a connection that I have with another person that wrote on there.”
Religiosity and spirituality	
Prayer	“I join[ed] an online group for praying.”
Fellowship	The loss of a group member highlighted a sense of duty and belongingness toward one another in the online prayer group.
Online worship	“I will go to one of my favorite pastors on YouTube and listen.”
Meditation	“I am in a meditation group that I go to online, and we do meditation together. And then, there is, like, headspace and calm, those apps. So, there is a wide variety of different things. Like chakras, and then there is, you know, just all different kinds of relaxation and tension. Like, you squeeze your arms and look at your feet.”
Information gathering	
Long hauler–shared information	“It is kind of, like, you form your own little support groups of people that had COVID. And, you know, their symptoms vary, and you are like, ‘Oh, what did you do for this?’ Or like the hair loss. That is another thing—hair loss. My hair is still not well, or whatever. And then, you know, people debating, like, ‘Are you taking the vaccine? Are you not getting the vaccine?’ So having those little groups to talk—it is good.”
Symptom management	“I downloaded an app on my phone, and I am monitoring, like, I am documenting all of my activities for the day every day so that I can document, like, different symptoms that I am having and, like, what is, like, a trigger.”
Physician-shared information	In reference to streaming YouTube videos: “...the different doctors and, like, what their findings are, what their recommendations are.”
Recreation	
Entertainment	“I will allow myself; it does not happen every day, but, like, just to play some mind games, you know, a game of solitaire or a game...on my phone just to give myself a break.”
Relaxation	“To help go to sleep at night. They try to, kind of, get me to relax, or whatever. And so, I think the biggest thing for me is disconnecting from all the things that I have going on, and I just...I struggle with that.”

Table 3. Emergent themes and subthemes of the challenging roles of social media identified by long-hauler women.

Theme and subthemes	Exemplar quotes
Social connection	
Anxiety	“They can really increase anxiety.”
Resentment	“...it was hard. There would be resentment, and there is resentment now with the group, too, as terrible as it sounds, even jealousy, because I will see people that will write on Facebook, like, ‘Oh, like, I had COVID in December 2020’ or ‘I had COVID in January 2021,’ and a part of me just, like, would hate it because it is...like you knew, like people were advising you not to travel. And that would be what it was, especially around the holiday season, hearing people talk about, you know, having so-and-so over from, like, California, and then they got sick afterwards. And, like, it just makes you go crazy because there is so much more now. But I am trying not to, like, think like that because I mean, I do not know everyone’s experiences, and maybe, they really did avoid it or did their best to not get it, and they got it because we are in a pandemic.”
Information gathering	
Misinformation and health literacy	“Sometimes, I can understand a lot of the stuff, but there is some things that I am not as familiar with...”
Oversaturation and pandemic fatigue	“...after a while, like, even that [social media use] got to be so overwhelming because, again, like, everyone is, like, posting the same thing.”

Social Connection

A majority of the women interviewed highlighted the role of social media in reducing social isolation by providing social connection. Social connections were found to be fostered through multiple functions of social media, such as personal networks, following networks, and group membership, as well as more broadly through engagement with other users, known or unknown. Long-hauler women emphasized the importance of social media as a tool to maintain connection with their social networks when unable to be present in person. Emergent subthemes related to the main theme of social connection included the benefits of belonging fostered through social support, group membership, and network building, as well as the challenges of anxiety and resentment.

Group Membership and Network Building

One participant noted the function of social media in mediating “the loss of family time and not being able to be together and doing the things we have always done as a family.” Another participant described the stress associated with physical, in-person gatherings in the time of COVID-19:

I tried to host a barbecue out in our little place at the lake, and it caused me so much anxiety. I could not even eat my birthday barbecue, could not really interact with people.

At a time when minimizing physical contact with others was recommended, the online environment was found to aid in maintaining social health. Networking, a distinct feature of social media platforms, connecting individuals with others they may or may not be geographically close to, emerged as instrumental to long-hauler women’s social connection and, further, social support. Participants shared motivations for seeking membership and experiences as members of online support groups for COVID-19 long-haulers. One participant noted:

I was looking for, you know, for common ground, for folks that were experiencing some of those same things that I was, and I was also looking to support

them with what I knew about my mind, body, [and] skills...

Facebook emerged as a popular social media platform among long-hauler women due to its functionality to host support groups. Many long-hauler women reported using Facebook groups to build their social networks, while also providing social and emotional support to other long-haulers. Upon reflecting on her participation in online social support groups, a participant shared:

I probably gravitated more toward that group...and I would talk about that Facebook group a lot. Like, it felt like that was like a support group, and it felt like, you know, I am not crazy, like some other people are having it, too. And I would be active in, like, commenting on, like, you know, answering people’s questions or, like, sharing, like, a connection that I have with another person that wrote on there.

Long-hauler women demonstrated the role of online groups in expanding their social networks to include other long-haulers outside their direct networks. As a result of their group membership, the majority of the participants indicated providing and receiving emotional and instrumental social support through connections fostered by membership in online support groups.

Social Support

Further, participants explained the role of online groups in facilitating social support from connections because “[they] are experiencing similar things that I am experiencing, so I know that it is not just me.” One participant described her role in providing emotional social support through online social connections:

I may not exactly know what you are going through, but I am here to help and here to listen because a lot of times you just want a hearing—somebody to hear you.

Participants demonstrated the crucial role of validation and affirmation as emotional social support when received from other group members regarding their emotions, symptoms, and

overall experiences. Participants indicated receiving validation and affirmation when posting, commenting, and being active within their support groups. One participant discussed the benefits of continued engagement in these groups:

I also was posting and doing that, which, like, kept me motivated [to continue] sharing and connecting with other people...

As a result of providing and receiving social support within their online networks of long-hauler women, the majority of the participants report a positive effect on their sense of belonging.

Belonging

We found that because social media is able to connect users, participation on the platforms and in groups aids in maintaining social health through online belongingness, while also adhering to public health recommendations (eg, social distancing, isolation, quarantine). In bolstering social connections and aiding in emotional regulation, another long-hauler explained that social media motivates her to remain strong and encourages resilience. She explained:

So I said, well, maybe if I am part of something...it is gonna be like a, like a, like a motivation for me to go through something for me. Um, because again, we are always thinking about others, you know, like, what, why am I complaining.

Another participant noted the benefit of belonging to a support group:

I joined the COVID long-haulers' Facebook group because another new thing with my shortness of breath is I noticed if I eat a lot at one time, I am way shorter of breath, and I do not know why. So, I was, like, "Oh, I am gonna see if anybody else has had these symptoms. So, I actually, like, made a post about it. And I liked that group because it makes you realize, like, you are not alone. There is all these other people that also do not have answers and also have similar symptoms as you.

Participants described how their group membership and sense of belonging decreased their feelings of loneliness and isolation, particularly when sharing experiences and symptoms with other long-haulers.

Anxiety and Resentment

Despite the potential benefits of participating in online groups, there remain potential consequences of participation as well. Although the findings indicated social media aids in mitigating feelings of loneliness and creating a sense of belonging, they also indicated increasing anxiety and resentment among long-hauler women. One participant noted that "they can really increase anxiety." As related to seeing the posts of others within their social networks and in groups, a participant said:

...it was hard. There would be resentment, and there is resentment now with the group, too, as terrible as it sounds, even jealousy, because I will see people that will write on Facebook like "Oh, like, I had COVID in December 2020" or "I had COVID in

January 2021," and a part of me just, like, would hate it because it is...like you knew, like people were advising you not to travel. And that would be what it was, especially around the holiday season, hearing people talk about, you know, having so-and-so over from, Like, California, and then they got sick afterwards. And, like, it just makes you go crazy because there is so much more now. But I am trying not to, like, think like that because I mean, I do not know everyone's experiences, and maybe, they really did avoid it or did their best to not get it, and they got it because we are in a pandemic. But it is stuff like that. Like, I feel like I am more, like, insecure with my experience. I get jealous of other people's experiences. There's just, like, a lot of negative-ness with it...

In sharing this anecdote, the participant voiced her frustration toward and resentment of those who, after participating in high-risk activities, shared their COVID-19 experiences online. Engagement with such individuals and their posts then led to this participant's insecurity in their own experiences.

Religiosity and Spirituality

In addition to the impacts of social media on social health, participants highlighted its role in also maintaining their spiritual health. In addition to joining online groups topically centered around COVID-19, a participant indicated, "I join[ed] an online group for praying." She detailed the group, demonstrating its resemblance to that of other support groups, albeit not solely related to COVID-19, with the added element of religion. Overall, the participant's sentiments indicated that the group positively impacted her overall well-being. When describing the loss of a member of the group, she highlighted the role of fellowship and connection in the group as they lifted one another up in prayer and, in doing so, created belongingness, community, and strength.

Another participant demonstrated the role of social media as related to religiosity and spirituality by noting her use of video-streaming platforms to seek spiritual support. She described her engagement as, "I'll go to one of my favorite pastors on YouTube and listen." During a time when physically gathering with others, as in the case of congregating for religious observances, was considered high risk, social media provided an avenue through which long-haulers could maintain their spiritual practices. Relatedly, participants indicated using social media to engage in guided meditations. One shared her daughter's role in encouraging her participation:

She gave me some resources online, in an app, and then my daughter uses a different...she uses Spotify. So, she gave me that information, and so I kind of just went off of those suggestions, and now, I have my favorite guided meditations that I use on Spotify, and they are effective.

Other participants said that they similarly engage in guided meditations but also participate in groups specific for meditation and relaxation. One participant described the meditation group and smartphone apps used:

I am in a meditation group that I go to online, and we do meditation together. And then, there is, like, headspace and calm—those apps. So, there is a wide variety of different things. Like chakras, and then there is, you know, just all different kinds of relaxation and tension. Like you squeeze your arms and look at your feet.

Information Gathering

Apart from social networking, one of the most prominent functions of social media is the sharing of news and information. Within the context of the COVID-19 pandemic, social media served as a conduit for sharing COVID-19 news, government policies and announcements, updated prevention guidelines, and general information. The findings demonstrated that long-hauler women used social media to seek information related to COVID-19 vaccines, symptoms, and symptom management strategies, as well as to follow news related to emerging treatments.

Long Hauler–Shared Information

Regarding COVID-19 information, topics of interest were primarily related to symptoms and health management. Long-hauler women indicated turning to online support groups to gather information from those with similar experiences. One participant illustrated the symptom and health discussions within these groups:

It is kind of like you form your own little support groups of people that had COVID. And, you know, their symptoms vary, and you are like, “Oh, what did you do for this?” Or like the hair loss. That is another thing—hair loss. My hair is still not well, or whatever. And then, you know, people debating, like, “Are you taking the vaccine? Are you not getting the vaccine?” So having those little groups to talk—it is good.

Alongside using support groups for discussion, long-haulers indicated also using smartphone apps to track symptoms and create health care plans. One long-hauler discussed her experience:

I downloaded an app on my phone, and I am monitoring, like, I am documenting all of my activities for the day every day so that I can document, like, different symptoms that I am having and, like, what is, like, a trigger.

Due to the persistent nature of COVID-19 symptoms experienced by long-haulers, monitoring symptoms is in the interest of patients to aid in symptom management and for use with health care providers in creating treatment plans.

Physician-Shared Information

In addition to sharing information across networks of long-haulers on social media, participants also noted gathering information through online interactions with physicians and mental health professionals. One participant indicated obtaining pandemic-related information from physicians on YouTube as she watched “...the different doctors and, like, what their findings are, what their recommendations are.” Due to the increasing burden of mental health challenges coupled with

physical symptoms, as expressed by the participants, social media offers a platform for mental health resource sharing, at a time when many cannot access needed services. One participant detailed these difficulties:

I had been looking for, like, counseling, and a lot of the counseling in our plan has, like, basically stopped taking people. Like, I think it is, like, kind of like, overwhelmed right now, and, like, I would call, like, a whole list, and I would go through the whole list, and, like, they are not taking new patients. So, I just have to be persistent about it.

In coping with barriers (ie, wait lists, cost) to accessing mental health services, participants indicated using social media as a tool to gain information from professionals. For instance, a participant said that she “join[ed] a group...they had a list of faculty members that were starting groups...you did not have to pay for it.” This participant was able to engage in mental health services through a free and accessible online group operated by mental health professionals. This function of social media is valuable in responding to increasing mental health needs by addressing barriers to accessing professional psychological support.

Misinformation and Health Literacy

The potential consequences of users obtaining information from social media, particularly that which must be scientifically based, include a lack of or difficulty in understanding, as well as the distribution of and access to unvalidated content or misinformation. Illustrating the difficulty in understanding sought-out information, a participant shared:

Sometimes I can understand a lot of the stuff, but there is some things that I am not as familiar with...

Due to the evolving nature of scientific discovery over the course of the pandemic, there were difficulties in grasping timelines and emergent findings that inhibited understanding and perpetuated misunderstanding. In the case of long-haulers, their increased need for health care exposes them to complex medical jargon that may require a higher level of health literacy to mitigate misunderstanding. Overall, due to the need for regularly updated COVID-19 information, social media functions as both a benefit and a hindrance to its dissemination. Social media provides users with increased access to information, while also providing a platform through which misinformation may be widely shared.

Oversaturation and Pandemic Fatigue

Further, despite the benefits of engaging in support groups and accessing pandemic-related information online, participants indicated differing perspectives on the amount of information shared. Referencing a long-hauler Facebook support group, a participant noted:

And, like, the nice thing about it is they share loads of information.

Alternatively, another participant shared that due to the sameness and sheer volume of pandemic-related content on social media:

...after a while, like, even that [social media use] got to be so overwhelming because, again, like everyone is, like, posting the same thing.

Due to oversaturation and misinformation, a participant noted that she is “disappointed with social media.” This disappointment has kept the participant from participating in COVID-19 and long-hauler groups.

Recreation

In addition to the networking and information-gathering functionalities of social media, participants also indicated leveraging social media for entertainment, recreation, and relaxation. In coping with their diagnosis, symptoms, anxiety, and the state of the world, long-hauler women indicated using social media and smartphone apps to play games, watch videos, and listen to music. One participant described consuming content on social media as a method to cope with the anxiety of attending post-COVID-19 appointments. Another participant shared:

I will allow myself; it does not happen every day, but, like, just to play some mind games, you know, a game of solitaire or a game...on my phone just to give myself a break.

Another participant indicated using the social media site YouTube as a way “to help go to sleep at night.”

They try to, kind of, get me to relax or whatever. And so, I think the biggest thing for me is disconnecting from all the things that I have going on, and I just...I struggle with that.

These findings suggest that social media is a method by which participants seek entertainment, recreate, and relax. These functions serve as social media-based coping mechanisms to alleviate mental health burdens.

Discussion

Principal Findings

Long-hauler women identify engagement in online support groups to be a primary use of social media during the COVID-19 pandemic. These groups are typically disease specific and can be described as communities where individuals can congregate and engage in broader group discussions as a form of social connection [50]. Support groups function to allow members to affirm their long-hauler identity, maintain connections, combat isolation, seek support, compare experiences, share remedies, and coruminate [51-53]. Long-hauler women seek reassurance through channels of connection with others who share their disease-specific identity and to cope with a social environment characterized by mortality, unemployment, resource loss, and psychological burdens of prevention measure adherence and disease [54].

Online support groups have been previously assessed in various disease contexts in the literature. A systematic review of the role of online support groups for patients with prostate cancer found that the groups not only aided in participant decision-making through their dissemination and exchange of information but also provided participants with social support

[55]. A review of support groups for patients with breast cancer demonstrated that the benefits or consequences of participation in social support groups are inconclusive [56]. A systematic review of studies assessing the impacts of social support groups on patients with chronic conditions found that they demonstrate a wide array of support group implementation and outcome measurements that complicate their use in the context of the COVID-19 pandemic [57]. Within the context of COVID-19, online support groups act as a tool to comply with social distancing guidance, while maintaining connections and combating isolation, depression, and anxiety [51,52]. Additionally, a systematic review of COVID-19-specific social support groups demonstrated that although they are effective in addressing participants’ psychological and psychosocial needs, due to their responsiveness to the emerging needs and challenges faced by participants, there remains a need for further research [58].

This study presented both benefits and challenges associated with the participation of long-hauler women in COVID-19-specific social support groups. The benefits include the validation of shared experiences, decreased isolation, and motivation to pursue symptom management and recovery. The challenges for long-hauler women’s participation include experiences of increased anxiety due to rumination within the groups, resentment and jealousy due to others’ posts of unsafe pandemic activities or recovery, and an insecurity of experiences as a result of comparison. Additionally, there is the complication of pandemic fatigue, as instigated by the overwhelming amount of posts within social support groups. Within the extant literature, overexposure to pandemic news may act as a disaster stressor that acts as a risk factor for negative psychosocial outcomes [59]. As demonstrated through these findings, related to social support and network building, social media presents an opportunity for individuals to receive support and engagement with others, while also facing potential, associated challenges.

Additional engagement on social media revolved around spirituality, entertainment, recreation, and relaxation. Beyond disease-specific support groups, long-hauler women reported relying on groups that specifically serve to maintain spiritual health. Digital media, more broadly, allows long-hauler women to engage in spiritual practices alone or with others, as desired. These novel functions are significant as spiritual health has been identified as a key coping mechanism to facilitate resilience [60]. Further, digital media has demonstrated its usefulness in the coping of long-hauler women, as they noted its use for entertainment, recreation, and relaxation through audio and visual content. The emerging pandemic literature has sought to assess the complex benefits and consequences of media usage, motivations, stress, and psychosocial outcomes that have been found to differ by demographics [61]. Despite the complex mechanisms of coping within the literature, long-hauler women in this study identified digital and social media used for entertainment to be a positive coping strategy.

In addition to the features of social media facilitating coping, long-hauler women also relied on networking sites to access pandemic-related information. One unique feature of social media is the unprecedented speed with which information can

be shared, particularly evolving pandemic information, but it also presents the risk of misinformation and associated difficulties in mitigating its negative impacts [62,63]. A key consequence, due to the nature of social media, is the tendency for information that sparks outrage, typically containing misinformation, to move the most quickly through social channels, likely stifling needed, correct information [63]. Therefore, as outrage impacts the visibility of trending topics, depending on the content, it can alter individuals' risk perceptions [63]. This study corroborated these trends due to participants' disappointment with the distribution of information and with social media overall. Additionally, when evaluating what constitutes misinformation, it is necessary to consider nuances in the perspectives of various key players (eg, patients, providers, scientists), as well as their potential contributions to the knowledge base (eg, symptomology, diagnostic criteria).

As social media content allows misinformation to trend due to its outrage-evoking characteristics, the COVID-19 pandemic is seen as syndemic with an infodemic. Within the infodemic, long-hauler women expressed experiencing difficulty in understanding health information presented online as related to vaccines, symptom management, and news. In addition to the threats posed by misinformation to public health prevention efforts, social media presents users with a plethora of information that operates to mitigate the associated negative effects [33]. Social and cultural factors influencing the perceptions of and responses to health information and risk communication are related to personal control, uncertainty, trust in institutions, and trust in media, as well as an overall sense of immediacy [63].

Associated with COVID-19 information, long-hauler women turn to social media and online social support groups to discuss symptom and health management, as well as the intention to vaccinate. Digital media, beyond social media, has benefited women with chronic COVID-19, allowing them to document and track their symptoms. As chronic COVID-19 is characterized by persistent symptoms, symptom management support and remedy information sharing were found to be salient uses of social media among women with long COVID. This finding aligns with evidence within the extant literature where social media has been used throughout the pandemic, by broader populations, to share medication strategies, anonymously seek information, crowdsource information, and engage in advocacy [64-67]. Overall, social media is used by long-hauler women to cope, exchange social support, maintain spirituality, and seek

entertainment, while also disseminating information relevant to the long-hauler experience.

Strengths and Limitations

Our findings are in alignment with “uses and gratifications theory,” which posits motivations for social media use as revolving around meeting certain needs, including social connection, knowledge, and relaxation, among others [68,69]. This study contributes to the sparse, evolving literature, with findings focusing on the social media usage of long-hauler women specifically.

Our study is also subject to several limitations. First, there were constraints on the analysis due to a small sample size with limited demographic variability. Second, the structure of the questions asked restricted our ability to identify patterns of usage by platform, relying, rather, on broader trends. Additionally, as support groups were used for recruitment, the findings may not be representative of the experiences of women not engaged on social media or in online support groups.

Public Health Implications

Although this study is additive to the evolving literature, strengthening the present evidence base beyond quantitative, descriptive analyses that do not account for gendered experiences, it demonstrates a need for further research. Future deductive work should consider, concurrently, comparing the uses of social media across the spectrum of gender and age based on known differences in usage. Due to the reliance on social media platforms to gather knowledge, further work is necessitated to evaluate the content and quality of information shared within online discussions and support groups. Future research should use an intersectional framework to assess the role of social media across a variety of additional identities women hold (eg, race/ ethnicity, preexisting conditions, socioeconomic status).

Conclusion

The findings of this study support the development of gender-tailored health promotion interventions that leverage the benefits of social media, while mitigating the consequences, for women with chronic COVID. As social media serves as a pandemic mitigation tool, there is a need to better understand patterns and experiences of usage [70-72]. Informed by our findings, long-hauler women should be met where they are, through the platforms and functions that they currently use, in order for public health interventions to aid them in managing long COVID and its associated effects.

Abstract

Background: Human mobility data have been used as a potential novel data source to guide policies and response planning during the COVID-19 global pandemic. The COVID-19 Mobility Data Network (CMDN) facilitated the use of human mobility data around the world. Both researchers and policy makers assumed that mobility data would provide insights to help policy makers and response planners. However, evidence that human mobility data were operationally useful and provided added value for public health response planners remains largely unknown.

Objective: This exploratory study focuses on advancing the understanding of the use of human mobility data during the early phase of the COVID-19 pandemic. The study explored how researchers and practitioners around the world used these data in response planning and policy making, focusing on processing data and human factors enabling or hindering use of the data.

Methods: Our project was based on phenomenology and used an inductive approach to thematic analysis. Transcripts were open-coded to create the codebook that was then applied by 2 team members who blind-coded all transcripts. Consensus coding was used for coding discrepancies.

Results: Interviews were conducted with 45 individuals during the early period of the COVID-19 pandemic. Although some teams used mobility data for response planning, few were able to describe their uses in policy making, and there were no standardized ways that teams used mobility data. Mobility data played a larger role in providing situational awareness for government partners, helping to understand where people were moving in relation to the spread of COVID-19 variants and reactions to stay-at-home orders. Interviewees who felt they were more successful using mobility data often cited an individual who was able to answer general questions about mobility data; provide interactive feedback on results; and enable a 2-way communication exchange about data, meaning, value, and potential use.

Conclusions: Human mobility data were used as a novel data source in the COVID-19 pandemic by a network of academic researchers and practitioners using privacy-preserving and anonymized mobility data. This study reflects the processes in analyzing and communicating human mobility data, as well as how these data were used in response planning and how the data were intended for use in policy making. The study reveals several valuable use cases. Ultimately, the role of a data translator was crucial in understanding the complexities of this novel data source. With this role, teams were able to adapt workflows, visualizations, and reports to align with end users and decision makers while communicating this information meaningfully to address the goals of responders and policy makers.

Introduction

Background

The COVID-19 pandemic has had a significant impact on the world, with more than 6.82 million deaths and more than 670 million cases globally as of February 2023 [1]. Public health measures, specifically physical distancing policies, were implemented throughout the world in 2020, playing a major role in the early phases of the COVID-19 global pandemic [2-4]. In general, these policies were based on the assumption that individual and population movement dynamics of those infected with COVID-19 were likely to impact the degree of spread. Studies have drawn a strong association between public health measures (eg, stay-at-home orders, physical distancing requirements) and reductions in population movement. Implementing distancing policies during the prevaccine era had the potential to mitigate the spread of disease and ultimately decrease demand on health care systems [5,6].

Nations took varying approaches to enacting COVID-19 public health measures. The People's Republic of China implemented travel restrictions and widespread population-based quarantine measures until the end of 2022. Italy, affected by COVID-19 in February 2020, instituted a nationwide quarantine until mid-2021 [7]. The United States took a patchwork approach to social distancing policies, which varied across the country by jurisdiction. Some cities had strict social distancing policies while others did not institute a stay-at-home order. During the latter part of 2020 and into 2021, the lack of a coordinated nationwide approach left cities and states to independently determine when to relax or reinstitute policies during subsequent epidemiologic waves due to new COVID-19 variants.

Using data in disasters involves a wide array of processes and skills in order to result in effective use and impact on decision-making. The process of using data includes data collection, processing, analyses, product creation (eg, visualization), and sharing [8,9]. An emerging body of evidence now recognizes the importance of collaboration, communication, and data literacy, all human factors, as important to effective use of data [10]. For government agencies around the world, understanding near real-time movement of individuals and groups was extremely difficult [11]. Key decision makers had to establish timely policies with limited, evolving information [12]. Physical distancing policies faced the same, if not more nuanced, challenges in using timely evidence, as the data and information that represented population-based movements were emerging from novel data sources not previously used for a pandemic of unprecedented proportions. Human mobility data, which are passively generated by digital devices that track information over both time and geography, provide a unique data source that reflects human movement in disaster settings [13]. In 2010, mobility data predicted population movement after the Haiti earthquake, and early studies in 2020 showed

that stay-at-home orders were associated with decreased population movement [14].

In response to the opportunities that mobility data presented for decision-making in the early phase of the COVID-19 pandemic, these data were analyzed by researchers from a wide range of disciplines with the intention of understanding disease dynamics as well as the impact of physical distancing policies on human movement at the national, regional, and local levels [15]. Klein et al [16] characterized physical distancing behaviors in the United States during the autumn of 2020, highlighting urban-rural differences and concluding that physical distancing policies were associated with changes in movement patterns. Much of the current research has focused on analyzing such data and anticipating the influence on policy making, including how the applications with these quantitative data were able to predict disease spread or identify future outbreak locations [17,18]. Although movement data had been used by governments in the past, use during the COVID-19 pandemic posed new challenges [19].

A network of global researchers, response planners, and policy makers collaborated in early 2020 with the aim of translating mobility data in order to positively impact response planning and policy making. With access to anonymized and privacy-preserving mobility data from Facebook (Meta), the COVID-19 Mobility Data Network (CMDN) facilitated the responsible and meaningful use of widely available human mobility data by policy makers around the world [20,21]. Mobility data sets were shared with trusted partners (eg, researchers) to collaborate with the public sector to inform response and recovery. Facebook also created a differential privacy framework to protect the privacy of individuals in aggregated data sets, informing public sector response to the COVID-19 pandemic. Over 150 researchers from around the world joined the network, contributing their scientific and analytic skills to develop methods necessary to transform these new data sources to meet the needs of their government counterparts. Both researchers and policy makers assumed that collecting, analyzing, and sharing mobility data would provide insights to help both policy makers and response planners guide their activities to mitigate the human, economic, and social impacts of COVID-19.

Despite the ability to collect, analyze, and share mobility data results around the world, there lacked evidence for how mobility data were used in response planning and policy making. There also lacked evidence and knowledge of which processes or steps in this applied research were more or less effective. Recent evaluations of mobility studies in COVID-19 have shown that applied research, or translational research, is often neglected, limiting the ability of decision makers and the public to take action and benefit from these efforts. In the outbreak modeling community, Nixon et al [19] reviewed 136 papers but found that only 1 in 4 papers evaluated the performance of the models and few disclosed the uncertainty of the data and transparency

of the methodology. In addition, more than 50% of the studies focused on predictions at the national level when policy makers and planners more frequently focus on local-level decision-making, and these approaches were least useful for decision-making [19]. Although quantitative methods can, to some degree, provide evidence on the accuracy of mobility data, complementary qualitative methods can provide evidence of their use in the social dynamic environments of disasters.

Study Objectives

This study focused on advancing the understanding of how researchers, policy makers, and response planners used human mobility data during the COVID-19 pandemic for the purpose of supporting decision-making related to stay-at-home orders and social distancing policies. Using qualitative methods to investigate the near real-time and lived experiences and perceptions of those using mobility data, the study used a constructivist point of view to describe experiences of researchers and practitioners who used these data in response planning and policy making. The study aimed to identify themes related to what would make the data more usable and valuable for public health practitioners, response planners, and researchers in disaster and emergency settings.

This study was framed within the information management and disaster response fields. The role of data and information management in disaster contexts is tightly linked to situational awareness. As described by Vieweg [22] and others [23,24], situational awareness refers to understanding the disaster environment, including hazards and emerging threats; they also described that improved situational awareness enables informed decisions related to response and recovery activities. In addition, data, whether traditional or novel, are perceived as valuable and useful when results can improve an individual's or group's situational awareness of the disaster environment. Situational awareness is assumed to be dynamic and often constantly changing, and uncertainty of the disaster environment is common.

Specific aims of the study were to explore the following:

- How groups use human mobility data and the results in response planning and policy making
- What processes and ways of working were used to analyze human mobility data and visualize or communicate the results
- Human factors related to processes described in the previous bullets, including various purposes for using mobility data, communication dynamics, and translational activities that enable the use of the data

Methods

Ethical Considerations

This project used preexisting interview information acquired for Crisis Ready's User Feedback Project and collected for the purposes of project assessment and evaluation. As such, the initial data collection was not reviewed by an institutional review board and did not collect informed consent from interview participants. This exploratory study used these data to understand how mobility data in the CMDN were being used

during a large-scale global public health disaster. It was reviewed by the Northwestern University institutional review board and deemed not human research, as it was secondary data analysis with no identifiers (STU00214214).

Approach

Our study was grounded in a phenomenology approach to understand how individuals were making sense of novel mobility data and incorporating the data into preexisting workflows. The unprecedented and highly uncertain and dynamic environment experienced by the interviewees both due to the COVID-19 pandemic and novel data source was best aligned with this methodological approach. Our analytical approach used thematic analysis to identify patterns of behavior and opinion as well as understand how individuals navigated the many new inputs during this time. The analysis team consisted of 3 individuals (JLC, ST, SBW). JLC is an emergency medicine physician, humanitarian practitioner, data specialist, and researcher with qualitative experience. ST is an emergency management professional with over a decade of experience at the intersection of public health, health care, and emergency management. SBW is a public health evaluator and research project manager with experience in qualitative methods.

Data Collection

Study data included interviews completed with individuals participating in the CMDN and selected using a combination of convenience and purposive sampling to have global representation and to enroll participants from different sectors (ie, public health practitioners, response planners, or researchers) to include a variety of experiences and perspectives. Interviews were deidentified and professionally transcribed before being shared with the study team, who uploaded the data to Dedoose Version 9.0.17. Study data were defined as narrative data from interviews and demographic information.

Analysis

We used thematic analysis with an inductive approach to understand our data. ST and SBW independently open-coded 2 transcripts each, assigning codes to all concepts identified in the interview data. The entire team (JLC, ST, SBW) met to review the initial codebook and refine it by combining similar concepts from approaches derived from the literature [25-27]. ST and SBW then exchanged transcripts and blind double-coded them using the initial codebook. The entire team refined the codebook further and blind triple-coded a fifth transcript. The codebook was refined and finalized ([Multimedia Appendix 1](#)).

ST and SBW blind double-coded all interview transcripts in a systematic manner guided by coding practices outlined by MacQueen et al [26]. Coding discrepancies were documented and discussed, and the code was changed to reflect the agreed-upon code and placement. If ST and SBW could not come to an agreement, JLC was engaged in the conversation, and discussion continued until consensus between the entire coding team was reached using previously published codebook methods for team approaches to coding [28,29]. All coded excerpts were reviewed by code. Team members reviewed each quote excerpt and summarized and organized them into themes

and concepts to look for common experiences, examples, and opinions.

To increase the validity, initial project findings were presented to stakeholders of participants in CMDN and peer researchers before the conclusion of analysis. This activity included peer review activities and a hybrid member-check and data party [30-32]. The analysis team conducted 2 meetings over the course of 2 days where project overview, transcript excerpts, and findings were presented to the group. Participants were asked if the information resonated with them, made sense, and reflected their understanding based on their experience; they were also asked to share their thoughts for next steps for using these data for application in future emergencies. Feedback from this meeting was used to check the themes developed in the final analysis. There were no additional themes identified based on the feedback.

Results

Participants

The anonymized and deidentified data set consisted of 33 interviews conducted with 45 researchers and practitioners involved in CMDN from June 2020 to September 2020. The majority of interviewees were from North America (28/45, 62%), with a predominance from the United States (26/45, 58%), followed by Asia (11/45, 24%; Table 1). Of the interviewees, 62% (28/45) were men, and 38% (17/45) were women. In addition, 47% (21/45) of the interviewees had practitioner roles, while 42% (19/45) had primary research roles. Specific interviewees' roles included state-level Chief Information Officer, consultant supporting a state-level response, data scientist in city government, emergency manager, and assistant professor of epidemiology. A few interviewees described their roles as hybrid, encompassing both researcher and practitioner activities.

Table 1. Participant demographics (n=45).

Characteristics	Results, n (%)
Gender	
Male	28 (62)
Female	17 (38)
Continent	
Africa	1 (2)
Asia	11 (24)
Europe	2 (4)
North America	28 (62)
South America	3 (7)
Professional field	
Practitioner	21 (47)
Researcher	19 (42)
Other	5 (11)

Principal Findings

Themes

Our principal findings are organized into the following 3 sections: (1) ways in which mobility data were used in response

planning and policy making, (2) how data were processed, and (3) human factors that contributed to successful use (Table 2). The findings presented are resultant of triangulation from interviews from different groups (ie, researchers, practitioners) and reflexivity in the determination of themes.

Table 2. Taxonomy of themes by research question.

Research question	Themes
How groups use human mobility data and its results in response planning and policy making.	<ul style="list-style-type: none"> • There was a perception that mobility data analyses could or did improve situational awareness. • There was uncertainty on how results were ultimately used.
How mobility data were processed and ways of working	<ul style="list-style-type: none"> • Misaligned data purpose with priorities was common. • The team had difficulty interpreting meaning from results. • Some teams determined the results were of limited value.
Human factors enabling or hindering the use of data	<ul style="list-style-type: none"> • Human factors play a significant role in how mobility data were used. • Researcher-practitioner teams that were more successful had open communication styles, enabling near real-time learning. • Adapting processes, which was dependent upon communication, was often required to use the data successfully.

Use in Response Planning and Policy Making

Researchers and policy makers in the CMDN used mobility data to improve understanding of population movement; influence resource provision; and influence policies, specifically stay-at-home orders. Themes emerged among these narratives related to (1) the perception that mobility data analyses could or did improve situational awareness, (2) uncertainty on how to interpret mobility data results, and (3) the perceived lack of value despite understanding the results.

Response planning and policy making are often related but distinctly different activities. Response planning involves tactical, action-oriented activities such as daily planning and logistics, while policy making focuses on planning and articulation of actions to guide involved stakeholders who are often required to abide by or execute these policies. This qualitative study revealed that, for both response planning and policy making, there were no common uses of these data across user groups. In general, those interviewed in the study sought to better understand where people were moving as well as understand situational changes in their specific locality (eg, national, county, and city levels).

Mobility data helped many teams better understand specific group movements and helped others allocate resources such as personal protective equipment (PPE) and plan food distribution sites. One team used the data to further understand the movement of essential workers with the intention of better understanding disease spread in a large city. The mobility data helped them rank neighborhoods that had larger percent changes of movement during the citywide stay-at-home order compared with movement patterns before the pandemic (ie, baseline).

The mobility data has been used, and especially to identify the neighborhood that has [a] high proportion of essential service workers who had to report to work during [a] surge of COVID-19 cases. [We] calculated percent change of the commuting patterns during Week 13—the morning commute time, which is almost the end of March and all of April, the exact time the [city] experienced [a] huge surge of COVID-19 cases. [Practitioner, United States]

Other government offices described using mobility data for PPE distribution along with other data sources to help with situational awareness and planning.

The [County] Office of Emergency Management is building an early warning system of areas that could become hotspots with the potential to overwhelm the medical and public health systems. Density and mobility are key indicators in this customized early warning system. We infuse the mobility data from these reports into a larger system that helps anticipate areas of potential viral spread, thus allowing for a more proactive response in regards to PPE supply distribution, and targeted community testing. [Researcher, United States]

Interviewees mostly described how they intended to use mobility data, rather than reporting policy-related actions taken as a result of the data analyses. They also described how they used the data to plan for reopening or relaxation of existing stay-at-home orders. Many other interviewees expressed uncertainty about how the data were actually used in policy making.

I share[d] it with our health director every week and with the rest of our data group. And I think the thing that they're just mostly looking [at] when we move to phase one of the reopening, like how much did people start moving around more or were people still staying at home. And I think from this, we concluded that people were starting to move more. [Practitioner, United States]

So, one of the things we can do with it is show that if you allow unrestricted travel during the Eid holidays, this outbreak, it's gonna spread really fast and it's gonna spread everywhere." And so, they got the CDR (call detail records) data. We did some modeling. We showed what would happen and I'm not gonna say that that's what influenced them, but they did extend the lockdown so that people couldn't travel during the Eid holidays. [Researcher (located in the United States), India]

Improving Situational Awareness

Although the Use in Response Planning and Policy making section describes specific use cases, interviewees often described

how the data were used for general situational awareness. Many believed that the data could help them understand movement of people during stay-at-home orders or during relaxation of these orders. Some groups felt the data improved their situational awareness of localized outbreaks of COVID-19 and future COVID-19 transmission monitoring.

Facebook has actually given us the ability to not just look at overall levels of movement, but to be able to look at where people are moving from and to over the space of time. Because we've had these fairly localized point outbreaks. [Researcher, Australia]

We've been able to use that data to put together essentially risk maps saying, okay, given that we saw transmission there last week, let's go back and look up what the transmission patterns in and out of that area, wherever the preceding couple of weeks. [Researcher, Australia]

These are 2 examples where mobility data enabled understanding of the movement of people over space and time, as well as transform their situational awareness into risk maps, a form of visualization. Although many described the data influencing their situational awareness, there were no findings that revealed accounts of explicit changes in decision-making.

Uncertainty

This section presents the multifaceted nature of not only understanding how mobility data were used in this disaster but also the uncertainty that individuals faced that became barriers to data use. There was significant uncertainty around how to transition from the idea that mobility data could be useful to actually transforming the data to assist in response planning and policy making. For example, even though practitioners and policy makers believed that mobility data could improve situational awareness of when and where people were moving, there was uncertainty around how to formulate a specific way in which mobility results could influence response planning.

I mean, [public health scientist] has told us repeatedly, this is very helpful for them to know...Exactly how to then use it for their response, I think that is a much harder question. [Researcher, India]

And, so, they came up with their recommendations...and unfortunately, I was not involved with the direct communication with the data requesters...so my answer to your question is, I don't know how the result of the analysis has shaped any policy decisions and any change of the course of actions. [Practitioner, United States]

So, I don't know exactly how he's been using it. I know he's been monitoring it just to see whether there are any places that raise any flags." [Practitioner, United States]

These excerpts reflect how both researchers and practitioners felt they did not know or lacked confidence on the exact use of the data for response planning or policy making. It remains unclear whether this uncertainty is due to limited skills in

problem formulation with novel data, unfamiliarity with analytical methods, or challenges with communicating results.

Processes and Ways of Working

Themes

This section describes how mobility data were processed. We present 4 ways of processing the data that respondents described: (1) identifying data purpose, (2) tools and products, (3) data preparation, and (4) results and data sharing. The themes that emerged were (1) the initial purpose for using mobility data was often misaligned with groups' priorities, (2) results sharing was often limited when the results lacked meaning, and (3) the results were deemed of little or no value.

Identifying Data Purpose

In order to use mobility data, understanding the purpose of use is one of the first crucial steps. The study revealed that each team's intention to use mobility data was linked to their perceived purpose of using the data. Although seemingly intuitive, it remains an important distinction. Many researchers and practitioners aimed to use the data to better understand where people were moving to and from and if groups were abiding by policies such as movement restrictions or stay-at-home orders. Others sought to correlate mobility data with other data sources to better understand the dynamics of COVID-19 disease transmission.

Most researchers relied upon practitioners to identify the specific purpose of using mobility data in their regions or localities and awaited direction from them. Some teams were able to identify specific questions for the data but often adapted their questions over time. In many circumstances, this was due to changing environments and, more importantly, an evolving understanding of what the mobility data could and could not answer for their specific questions.

Initially we were interested in...are people staying home, but then as we started to phase open, we also started tracking it even more closely to see, okay, now that we're opening, are we seeing [that] more people are moving about and things like that. [Practitioner, United States]

I think the ask has changed a little bit around what we're layering the data with. The initial hope was to work with the county health department to better understand cases and different rates that we could correlate the mobility with. So, we could say, people were extremely mobile here, and we're seeing a spike in cases later on in these specific hospitals. Unfortunately, we weren't able to get that second piece of data, and with the aggregated data that we get from the county about the city as a whole we aren't seeing any correlations with that. [Practitioner, United States]

Other teams did not ultimately share the results of the data because they were either unable to confidently interpret the results or felt that the results were not relevant to their needs and priorities.

We're not really sure how to move forward with the public health department I think, because we're still unclear how exactly we should use this data to prioritize any sort of EpiModel. [Researcher, United States]

...But the reaction, I remember when I first saw this [visualization] was, "Cool visualization. But, what am I gonna do with this? And what is it actually going to tell me? [Practitioner, United States]

These excerpts show the diversity of data purposes among groups. Some groups' data purpose evolved over time due to environmental changes or their ability to use the data with other sources.

Tools and Products

There was no standardized way researchers and practitioners teams used data tools, analysis software, or visualization platforms for their collaborative efforts. Ultimately, tools and products were described as vehicles with which to share information with other data teams, policy makers, and response planners. Some groups used geographic information systems (eg, ArcGIS software) and online mapping tools (eg, OpenStreet map), while others used data visualization tools such as Tableau and ShinyApp. Some products were spreadsheets (eg, csv files) that were shared by researchers to data teams within government offices. In some instances, both researcher and practitioner interviewees felt that providing analyses in these data formats helped practitioners create final reports.

So, I do know one outcome of that is that we requested that we get the all-city data from each timeframe and [he] was able to also upload that as CSV for us too, and that lines up with the PDF. So, at one point, we were trying to replicate what the PDFs had and couldn't, and that actually helped us lead to asking for the data. [Practitioner, United States]

Data Preparation

The components of data preparation include data cleaning, validation, and transformation, often bringing together different data types from various sources [33]. Mobility data were a novel data type for most researchers and practitioners and required them to take additional time to familiarize themselves during the data preparation process. Some interviewees described the preparation stage of "cleaning" mobility data, such as changing formats and structures to more easily align with other data sources to make the analysis relevant for their purposes.

In fact, we also asked them to change a little bit in terms of the columns and the rows that we wanted them to change because they were not compatible as Interviewee 067 was mentioning. So, we have to do a lot of work by ground. [Researcher, India]

Many groups prioritized preparing the mobility data to better meet their local environment. They often reworked the data to meet their planning geography, whether it was formal administrative units or planning geographies such as jurisdictions.

There's one for [city location]. There's one for [neighborhood]. All of these different areas are more canonical for people. So, the data we receive are mapped to these, and it makes a lot of sense to people used to working with this geography. So, so long as all the other sources can be mapped to the same thing, that would probably make sense to the city and decision makers. [Volunteer, United States]

For many groups, tailoring and preparation meant just learning more about what the data represented and becoming more familiar with mobility data. The process of preparing the data was in and of itself a way to learn and gain knowledge about the data and what it could ultimately mean for policy making and response planning.

Yeah, so we spent about five, six days working on the data and trying to understand what it represented. So, it's probably a lot of back and forth with various people and from Facebook. [Researcher, Thailand]

These excerpts reflect the need for teams from different contexts to further adapt the data to meet their specific needs, which took time to prepare.

Results and Data Sharing

Results were shared with national ministers, district mayors, emergency response teams, public health teams, and the European Commission, to name a few. Researchers frequently shared analytical results with practitioners in multiple formats (eg, graphs, maps) and sometimes even spreadsheets. Simplification, context alignment, and narrative text were often necessary to help readers understand what the results meant. For example, a data fellow in a city office simplified graphs to help her colleagues better interpret the results, anticipating areas of confusion and working to mitigate them. Other teams created their own charts from the data analysis to better visualize and share the results.

And if you can imagine a figure with a lot of noise, individuals that maybe don't have the experience that I do or people in the network have, may find that confusing. So, I did very simple things. I apply some smoothing algorithm so as to show trends rather than actual aggregated data. And that way I could mitigate the confusion regarding noise from the data... [Researcher, United States]

First we look at the report that you [guys] send us. We take a look at that, understanding a little bit better. And then whatever insights that we gather from that report, I translate those into our actual report that we hand out to the city manager and use the CSV to create those charts. [Practitioner, United States]

These excerpts reflect individuals and teams tailoring results or translating analytical findings to address "noise" or "confusion" with the aim to improve understanding and sharing with others.

Narrative statements accompanying analytical results were also common as practitioners sent reports to response planners and policy makers. Many felt that adding summaries or explanations

helped transform the data results into meaningful information. Others used bullet formatting to help prioritize findings but included more lengthy results to be reviewed at the discretion of the end user.

And if we were sharing this report more broadly with our policy folks, that's what they're looking for, is that summary. But I think I shared our 20-some odd page weekly, right? So, we do that same thing. Here's the top five or six bullets you need to know about and validate the rest if you want. [Practitioner, United States]

Teams needed not only to communicate and share results with one another but also the skills and time to interpret the results and understand their meaning. Some challenges laid in understanding the mobility metrics, such as how movement was measured in relationship to trips taken during a time period.

So, these [are] some insights...that were not provided by the original graphs. And then, another thing that I thought was very insightful is this...when you stratify by districts, you see that it's driven mainly by these three districts up here. Some districts that are behaving, if we can say that, are adhering to the social distance policy. [Researcher, United States]

Some lacked confidence in sharing the results with response planners and policy makers. Others described uncertainty in their interpretation of results and felt that the risks of sharing this information were too great to take on. Ultimately, this prevented many interviewees from sharing results with decision makers.

I guess the thing about this data is that it is really difficult to know how to interpret any one city, or any one weekend change. And I would be cautious about advising changes on that until we have more data on what that change actually represents. [Researcher, United States]

Other environmental factors such as information and data overload prevented many from not only understanding the results but also identifying their value for decision-making. For many, understanding the data and translating the findings for others required significant time, often time that many did not feel they had.

This is a pretty detailed report, and I think some people looking at it would be kind of intimidated by it or wouldn't have the time to really be able to go in and dig in deep, so I think we have thought a lot about how to give high-level updates that are meaningful and impactful. [Practitioner, United States]

These excerpts highlight that additional processing was needed to distill results in order to feel comfortable sharing them. Different groups created different products to best meet the needs of their specific users and decision makers.

Human Factors

Themes

Interviewees spoke about human factors, including data translation, communication, and adaptation, that contributed to

successful use of mobility data. The following 3 themes emerged: (1) human factors played a significant role in how mobility data were used, (2) researcher-practitioner teams that were more successful had open communication styles, enabling near real-time learning, and (3) adapting processes was often required to use the data successfully, which was dependent upon communication.

Data Translation

Data translation skills include behaviors such as communication skills and the ability to communicate both technical aspects of data (eg, analysis, metrics) and relevant information meaning and value of the data itself in various formats. Data translation in the context of using mobility data during the COVID-19 pandemic was tightly linked to human information processing abilities and creating products that could provide situational awareness for response planners and decision makers.

And so, I think for us, that was the key thing: that the [researcher] was willing to do, and work with us on, and understand that...it was a process that we all had to work through, and he, [was] just available and willing to work with us and willing to help us navigate this new type of data. [Practitioner, United States]

Data translation helped both researchers and practitioners understand the specific purpose for which to use the data. This enabled teams to refine geographic approaches to meet city, county, and regional contexts during stay-at-home orders and the many evolving COVID-19 epidemiologic environments, including relaxation of restrictions. Although team communications were primarily remote, these social interactions were viewed as important in enabling teams to understand what data opportunities lay ahead and adapt to changing environments, evolving collective knowledge about the data's value, and optimal methods to present results to decision makers.

Communication

Teams communicated using different modalities and frequencies. Some groups had daily calls early in the collaboration, others connected on weekly Zoom meetings, and some primarily communicated via email. Most researchers did not communicate directly with response planners and policy makers but rather with data teams in government offices. The few that shared results directly did so via situation reports, updates in daily emergency operational cell meetings, or via WhatsApp and email. In South America, communications were via WhatsApp and direct voice communications from the researcher to the scientist in the country and then to national ministers.

I am part of [a] directory of people that are indirectly [in] discussion with the minister of science...I sent him an email directly to the minister and he ignored me. The same Professor said, well, it's easier if you [to] send me the reports and I am [in] a channel of communication with him. [Researcher, South America]

Trusted relationships played a role in successful communications and often required some adaptations as teams determined more effective ways of sharing the results.

Although the route of communication was important, interviewees described the nature of communication including listening and back-and-forth communication as essential parts of a successful collaboration.

I don't know, it's so boring and simple, but I think it's just about listening, and just keep asking questions to really understand where they're at. And I think I was really helped along too by the communications director, because she was really open about asking questions when she didn't understand things.
[Researcher, United States]

Communication often led to changes in ways of working and adapting approaches, such as redefining the purpose for using mobility data, simplifying results, and helping better translate the analytical results into meaningful findings that could be shared in a more understandable way.

Adaptation

Researchers and practitioners adapted their approaches, workflows, and communications to align with the local context. Over the course of the pandemic, response activities and policies in many jurisdictions changed, requiring many groups to reassess their original purpose for using mobility data. One team adapted their initial purpose from monitoring movement to monitoring movement after various restrictions were being lifted. Some increased the frequency of reporting as one jurisdiction went into lockdown. Others adjusted their approach to analysis once they gained a deeper understanding of what the data could and could not be used for.

I think the teams that I've had the best experiences with in terms of the use of these data and the teams that have also gotten the most out of it have been the ones where there have been these sort of clear lines of communication, and ability to change and upgrade things as we move forward. [Researcher, multiple locations]

I've been asked to provide a second report. So, I shared the presentation I gave this morning, but I also wrote a report similar to this, since they've just gone into lockdown...So, usually, they'll ask for a report on a monthly basis, – but when something happens, I try to be ready to give those as they request and have it ready to give it as quickly as I can.
[Researcher, Botswana]

These excerpts are evidence of adaptation being facilitated by strong and open communication.

Discussion

Principal Findings

This qualitative study, grounded in a phenomenology approach, analyzes the perceptions of researchers and practitioners who used mobility data during the first year of the COVID-19 pandemic. This study contributes to the emerging knowledge on how groups in disaster settings are using novel data sources for decision-making, specifically response planning and policy making. It also highlights the importance of human factors (ie,

communications, data translation, and adaptation) as critical for the success of individuals and groups in defining a purpose for which to use novel data, identifying value in the data results, and ultimately using data in disaster response activities.

Although some groups used mobility data for distributing resources, most were unsure of how these data directly affected policy making. Evidence-based decision-making for policy making during COVID-19 remains an area of investigation, and published studies support our findings of limited use. A qualitative study of the perceptions of scientific experts and advisors in 11 countries described how evidence was thought to play a small role in overall policy making [34].

Humanitarian studies of data use in disaster environments have shown that, often, those who are managing, analyzing, and sharing data are often not the same individuals who are making decisions in emergency operations centers or leadership meetings [35]. The individuals we spoke to indicated this was the case in their partnerships as well. With novel data, it can take time to understand what the data represent and how the results are best communicated, requiring data translation skills or roles to help make the collaborations successful. Over time, the researchers and practitioners who were able to communicate and learn from one another were able to make the results more digestible for decision makers, likely due to improved knowledge and understanding and confidence in communicating this information.

There was a common understanding that groups were seeking new data sources to help improve situational awareness. This is in alignment with published literature on data-seeking behaviors and situational awareness. Endsley [36] described the theory of situational awareness in which individuals are described as not just recipients of data but active seekers who align this behavior with their current goals. However, with novel data, bidirectional communication between researchers and practitioners helped build collective knowledge of what the data could actually be used for in their local context. In addition, the direct collaboration between researchers and practitioners enabled teams to adapt quickly along various lines to try to meet the needs of each government group. Morss et al [37] noted that generating usable information among diverse decision makers requires working directly with these users to understand needs and context.

Human factors such as communications as well as adaptive approaches to data analyses and visual presentation were mentioned by many interviewees as steps along the way that helped them better prepare the data results for their intended users. These “soft skills” (ie, communication, interaction, creativity) described by Polese et al [38] are needed in conjunction with “hard skills” (ie, technical, analytical) to use big data. Soft skills are critical factors for the effectiveness of data interpretation and extraction of knowledge [38].

Our study identified a key role among teams—a data translator. Studies on big data note the importance of interdisciplinary and multistakeholder interaction and collaboration to enable more useful interpretation of big data [38]. Humanitarian and disaster organizations have increasingly become aware of the importance of data translators in leveraging big data opportunities [39,40].

Technology companies engaged in social good and business enterprises also recognize the role of data translators to meet their mission and goals [41-43]. Particularly when engaging with a novel type of data, this crucial role requires significant technical knowledge as well as an understanding of how the data can be best used. Often, this requires a shift in mindset for data translators to communicate simple, actionable information and communicate confidence in results. Other published studies on knowledge transfer between researchers and practitioners highlight the importance of social interactions and the social process that occurs in the environment of data, disasters, and decision-making [29,44].

Limitations

Though qualitative research using near real-time data from an unprecedented global disaster has unique value, it faces challenges and limitations in data collection, bias, and generalizability. This study was limited to the first year of the COVID-19 global pandemic and does not reflect evolutions of the policy making and response planning among those interviewed over the course of the pandemic. Although Facebook (Meta) data reflect digital movement of individuals during disasters, other mobility data were not included in this study. Facebook's history of collaborating during disasters and building the Facebook Data for Good program with anonymized and privacy-preserving data sources provided a valuable data set for our exploratory study.

Response bias may also have played a role with the interviewees, but all attempts were made to interview individuals and groups during the period of analyses to ensure information was gathered as proximate to the experience as possible. All interviews were conducted in English, which may bias the results toward the perceptions of individuals and groups who are proficient in this language. Although much research in data and disaster focuses on the impact on decision-making, this study intentionally did not explore direct decision-making. Rather, it focused on exploring and further understanding the preceding processes and human factors that could potentially facilitate or hinder the use of data. It also explored precursors of decision-making, which revealed a notable degree of uncertainty among this interview cohort on actual decision-making.

Conclusion

This phenomenological study using a constructivist perspective with data from the early COVID-19 pandemic environment contributes to the understanding of how novel data sources are used in disaster settings. This study offered a unique opportunity to investigate the application of a novel data source during an unprecedented emergency. This resulted in the challenges of working with, understanding, and communicating these data while simultaneously figuring out how to apply the data for response planning and policy making. The groups we spoke to shared a broad range of perceptions and experiences related to these data, something that is expected in an emergency or disaster setting as well as with a novel data set.

This exploratory study highlights human factors as important facilitators for understanding data purpose, eliciting meaning from the data, and using the data for response planning and policy making. Although there were a few examples of how mobility data were used among specific researcher-practitioner groups, most groups were only able to describe their journey in exploring and learning about the data and share some of the barriers to use. Ultimately, the role of a data translator was crucial for understanding the complexities of this novel data source; adapting workflows, visualizations, and reports to align with end users and decision makers; and communicating this information meaningfully to address the goals of responders and policy makers.

This study complements the larger body of literature evaluating the use of big data, including mobility data during disasters, and highlights the need for a more qualitative perspective on use and value rather than quantitative metrics. Future studies that assess the use of data during disasters should include a focus on human factors, to further understand the role of communication and learning frameworks across diverse collaborative groups, specifically to understand the working relationship between members of these teams and how they navigate roles, expertise, and power in order to achieve their goals. Finally, further qualitative studies are needed to understand more fully the transition from perceived usefulness to decision-making to action in disaster settings.

Acknowledgments

The authors would like to thank all interviewees who took time from their busy roles responding to the largest global pandemic in recent history to provide their feedback and perceptions. The authors would also like to recognize CrisisReady and specifically Caroline Buckee, PhD; Andrew Schroeder, PhD; and Satchit Balsari for their contribution to creating and coordinating the COVID-19 Mobility Data Network. This study was funded in part by the Institute for Global Health Catalyzer Grant and the Peterson Foundation grant from Northwestern University.

Conflicts of Interest

None declared.

Abstract

Background: Young women in Lesotho face myriad sexual and reproductive health problems. There is little time to provide health education to women in low-resource settings with critical shortages of human resources for health.

Objective: This study aims to determine the acceptability and usability of a conversational agent system, the Nthabi health promotion app, which was culturally adapted for use in Lesotho.

Methods: We conducted a descriptive quantitative study, using a 22-item Likert scale survey to assess the perceptions of the usability and acceptability of 172 young women aged 18-28 years in rural districts of Lesotho, who used the system on either smartphones or tablets for up to 6 weeks. Descriptive statistics were used to calculate the averages and frequencies of the variables. χ^2 tests were used to determine any associations among variables.

Results: A total of 138 participants were enrolled and completed the survey. The mean age was 22 years, most were unmarried, 56 (40.6%) participants had completed high school, 39 (28.3%) participants were unemployed, and 88 (63.8%) participants were students. Respondents believed the app was helpful, with 134 (97.1%) participants strongly agreeing or agreeing that the app was “effective in helping them make decisions” and “could quickly improve health education and counselling.” In addition, 136 (98.5%) participants strongly agreed or agreed that the app was “simple to use,” 130 (94.2%) participants reported that Nthabi could “easily repeat words that were not well understood,” and 128 (92.7%) participants reported that the app “could quickly load the information on the screen.” Respondents were generally satisfied with the app, with 132 (95.6%) participants strongly agreeing or agreeing that the health education content delivered by the app was “well organised and delivered in a timely way,” while 133 (96.4%) participants “enjoyed using the interface.” They were satisfied with the cultural adaptation, with 133 (96.4%) participants strongly agreeing or agreeing that the app was “culturally appropriate and that it could be easily shared with a family or community members.” They also reported that Nthabi was worthwhile, with 127 (92%) participants reporting that they strongly agreed or agreed that they were “satisfied with the application and intended to continue using it,” while 135 (97.8%) participants would “encourage others to use it.” Participants aged 18-24 years (vs those aged 25-28 years) agreed that the “Nthabi app was simple to use” (106/106, 100% vs 30/32, 93.8%; $P=.01$), and agreed that “the educational content was well organised and delivered in a timely way” (104/106, 98.1% vs 28/32, 87.5%; $P=.01$).

Conclusions: These results support further study of conversational agent systems as alternatives to traditional face-to-face provision of health education services in Lesotho, where there are critical shortages of human resources for health.

Introduction

Background

Digital health interventions offer considerable promise to develop new models of health care delivery and to have a large public health impact [1]. Digital channels, such as the internet, mobile phone messaging, social media, apps, voice video messaging, and telemedicine have been shown to improve the delivery of health education and care. These tools have tremendous potential to impact large-scale health promotion efforts as a cost-effective and scalable solution to address public health challenges, such as delivering sexual health education [2].

The rapid diffusion of mobile technology and advances in artificial intelligence have facilitated this trend [3]. The use of mobile devices and services has continued to increase globally, though at different rates in developed and developing countries. By the end of 2018, more than 5 billion people worldwide subscribed to mobile services, accounting for 67% of the global population, and this number is expected to exceed 70% by 2025 [4].

In Lesotho, 94% of people aged 18-29 years use smartphones, and 3G data coverage is available in almost 90% of the country [5]. This is an important group to target, as they represent the highest proportion of global consumers of mobile technology. This high penetration of mobile technologies provides an opportunity to assess the usability and acceptability of using new mobile health technologies as an alternative to the traditional face-to-face provision of health education.

Adolescents and young women continue to report low levels of sexual and reproductive health knowledge, and engage in risky sexual behaviors [6]. They also face a myriad of sexual and reproductive health problems, such as unplanned pregnancy, sexually transmitted infections, and HIV infections. Advancing sexual and reproductive health education for adolescents and young women in Africa is particularly important, as HIV accounts for 42% of new HIV infections globally [7], and 4 in 5 young people with HIV live in sub-Saharan Africa [8]. Therefore, developing new ways to provide sexual and reproductive health education in Africa is particularly important.

Lesotho is a lower middle-income country in southern Africa and has the second highest HIV prevalence in the world—at 22.7%—and one of the highest HIV incidences among adolescent girls and young women (0.33%) [9]. The maternal mortality ratio in Lesotho is the second highest in Southern

African Development Community countries (544/100,000 live births) [10]. The ratio of doctors to the population is 0.9 per 10,000. For nurse-midwives, the ratio is 10.2 per 10,000, [11] which poses a challenge to the delivery of face-to-face health education.

Delivering health education via new mobile health tools has the potential to provide alternatives to traditional face-to-face provision of health education. Conversational agents are computer-based animated characters that are designed to simulate face-to-face human interactions. The human-computer interface relies only minimally on text comprehension and prioritizes conversation, thereby making it more accessible to patients with limited health literacy [12]. In health care, patient-facing conversational agents are increasingly used to deliver education, provide self-management of chronic conditions, perform routine tasks, such as appointment booking, and support health professionals' decision-making for diagnosis and triage in mental health [13,14]. These devices have the potential to automate tasks, improve access to health care services, and reduce health professionals' workload.

Prior Work

In the United States, a conversational agent named Gabby was designed to deliver preconception sexual and reproductive health information to reproductive-age African American women. Using Gabby demonstrated significant improvement in addressing reproductive health risks in randomized controlled trials [15,16].

Our research team culturally adapted Gabby to provide sexual and reproductive health education to young women in Lesotho. The newly adapted system, named the Nthabi Preconception Health Promotion App (hereafter referred to as Nthabi) is a patient-facing conversational agent that screens for sexual and reproductive health risks, and uses behavior change techniques, such as motivational interviewing and shared decision-making, to facilitate behavior change related to these risks.

The perceived appropriateness of Nthabi adaptation was studied in focus groups with young women aged 18-28 years (n=33 participants) who had used the system for 4 weeks [17]. Participants reported that adaptations were culturally appropriate, and provided relevant and culturally sensitive clinical information. They emphasized that the physical characteristics, personal and nonverbal behaviors, use of Sesotho (the local language in Lesotho) words and idioms, and clinical content were sensitively delivered and culturally appropriate. Interviews with the Ministry of Health key informants agreed that the adaptation was successful and that the system holds

great potential to improve the delivery of health education content in Lesotho.

Goal of This Study

The goal of this study is to assess the perceived usability and acceptability of the Nthabi Preconception Health Promotion App among 160 young women enrolled in a clinical trial in Lesotho who had used the system for up to 6 weeks.

Methods

Study Design

In this paper, we report the results of a survey designed to assess the perceived usability and acceptability of Nthabi among the first 160 young women who used the system.

Usability is defined as the extent to which young women can use Nthabi to achieve specific goals with effectiveness, efficiency, and satisfaction [18]. Acceptability includes the satisfaction of the young women, attitudes toward using the app, and intention or willingness to continue using the app.

Study Population and Setting

The population studied was young women aged 18 to 28 years in the Leribe and Bera districts of the rural, mountainous, lower middle-income country of Lesotho in southern Africa.

Sampling

This study was conducted to assess the usability and acceptability of using Nthabi as a health education tool in Lesotho; therefore, a convenience sample of 200 young women was chosen from the population of young women in the districts of Leribe and Bera.

Recruitment

Participants were recruited in several ways. First, the research team posted messages on social media (eg, WhatsApp and Facebook) that described the study and asked potential participants to contact the research team to discuss enrolling in the study. A nongovernmental organization called Help Lesotho, which offers mentorship programs to adolescent girls and young women in the Leribe district, saw the social media posting, reached out to the research team, and offered to disseminate the recruitment announcement to their clients.

Second, the research team directly approached young women while they were waiting for consultation at the Adolescent Health Corners (clinics) and HIV and Mother and Child Health ambulatory clinical departments at the Bera and Leribe government district hospitals. Last, students were approached at the Leribe Vocational High School and the Limkokwing University of Technology to identify individuals who might be interested in participating.

Eligibility Criteria

The inclusion criteria were the following: (1) Basotho women aged 18-28 years who were from the districts of Leribe and Bera and accessed health services in these 2 districts, (2) self-reported ability to read and understand spoken English, (3)

access to an Android smartphone, and (4) ability to access internet and Wi-Fi at least once at the end of the study. Those not meeting these criteria were excluded.

Enrollment

The research team assisted the participants in downloading the app on their mobile phones. Participants who were unable to download the app on their mobile phones were loaned a Lenovo Android 11 OS platform tablet to use for 6 weeks. Participants were then assisted to create a unique username and password and were shown how to log on to either their Android mobile phone or tablet and start interacting with Nthabi. Participants were encouraged to use the app at least once daily at their convenience for 6 weeks.

Baseline Data Collection

Sociodemographic information was collected (age, marital status, education level, employment status, recruitment site, and district). A total of 160 participants were enrolled. Participant contact information (phone and WhatsApp number, email address) was collected so they could be reminded to return to the recruitment site so they could access the internet when they were finished using Nthabi, to facilitate survey completion, and return the loaned tablets.

Description of the Nthabi Intervention

Nthabi was adapted in relation to physical characteristics, language, culture, and clinical content appropriate for Lesotho, as previously described (Figure 1) [17]. A description of Nthabi is found in Multimedia Appendix 1.

Briefly, Nthabi is an English-speaking Mosotho (person from Lesotho) nurse-midwife dressed as a professional nurse. Her hairstyle (braids), complexion (medium, similar to the local population), facial expressions (calm and gentle), and mannerisms (a humble professional with a sense of humor) were relatable to young women in Lesotho.

To establish the clinical topics to be included in the system, Ministry of Health key informants recommended 5 sexual reproductive health topics for young women (family planning, HIV, tuberculosis, healthy eating, and using folic acid). The research team then used the Lesotho National Clinical Guidelines on these topics to create evidence-based dialogue for use in Nthabi interactions.

During subsequent interactions with Nthabi, women selected the topic they wanted to discuss. Using conversational dialogue, Nthabi describes why the topic is important and offers suggestions about how to take action on it. The woman engages with the app by selecting a response from a multiple-choice menu that is updated at each turn of dialogue.

To increase the accessibility and use of the system, a decision was made that the app would be fully downloadable to the user's mobile phone, thereby enabling full content availability beyond the Wi-Fi environment. Use and information about the content discussed would be downloaded when the user was in a Wi-Fi environment. Nthabi was available from the Google Play store for downloading on mobile phones or tablets.

Figure 1. Nthabi health education interface.

Data Collection Tool

The survey instrument was based on the System Usability Scale and the Mobile App Rating Scale [19] using previous studies of Gabby adaptation [20,21] and modified for use in Lesotho. To ensure that the questions were clear and not ambiguous, the survey tool was reviewed by 12 health professionals, including nurses working in adolescent health, physicians, and district sexual reproductive health clinicians. The survey was then piloted with young women who met the eligibility criteria, to assess the respondents' understanding and interpretation of the questions. Only editorial changes, to enhance clarity, were required. The final survey contained 22 questions that elicited responses on a 4-point Likert scale (strongly agree, agree, disagree, and strongly disagree). Topics covered in the survey were usability (ease of use and reliability), satisfaction, willingness to continue, how easy it was to understand, content organization, and cultural relevance. The survey also enquired about the degree to which Nthabi helped women make health decisions and the degree to which they would encourage others to use the app.

Data Storage and Analysis

Survey data were captured on an Excel (Microsoft Corp) spreadsheet and stored on a password-protected computer. Data were analyzed using Stata software (StataCorp). Descriptive statistics were used to calculate the averages and frequencies of the variables. Inferential statistics, such as χ^2 tests, were used

to determine any associations among variables. Statistical significance was set as a threshold of $P < .10$, as this was a feasibility study.

Participant Incentives

All participants received 50 Maloti (approximately US \$5) to cover data costs. Participants using tablets were provided an additional 50 Maloti (approximately US \$5) to cover their travel back to the recruitment sites to return the devices.

Ethical Considerations

Once the eligibility of participants was confirmed, the research team explained the purpose of the study, potential risks and benefits, compensation for travel costs, and the right to withdraw from the study at any time. After questions had been addressed, participants were asked to sign an informed consent form and were enrolled.

The study was conducted according to the Consolidated Standards of Reporting Trials (CONSORT) [22] and the adaptations for mobile health interventions [23]. Ethical clearance was obtained from the Boston University Research institutional review board (H-40268), Sefako Makgatho University of Health Sciences Ethics Review Committee (SMUREC/H/343/2021: PG), and the Lesotho Ministry of Health Research Ethics Committee (ID 145-2021). Permission was obtained from the study recruitment sites.

Results

Recruitment

The research team screened 436 young women for eligibility, as shown in the CONSORT diagram (Figure 2). Young women were recruited through social media (eg, WhatsApp and Facebook) or direct contact at Limkokwing University of Technology (n=150), Leribe Vocational School (n=88), Leribe Health Facilities (n=55), Berea Health Facilities (n=84), and Help Lesotho (n=59).

Of those screened, 174 young women were ineligible due to having smartphones without the Android operating system, while 64 young women had phones that were not smartphones, and 10 young women had Huawei Android smartphones that lacked access to the Google Play store.

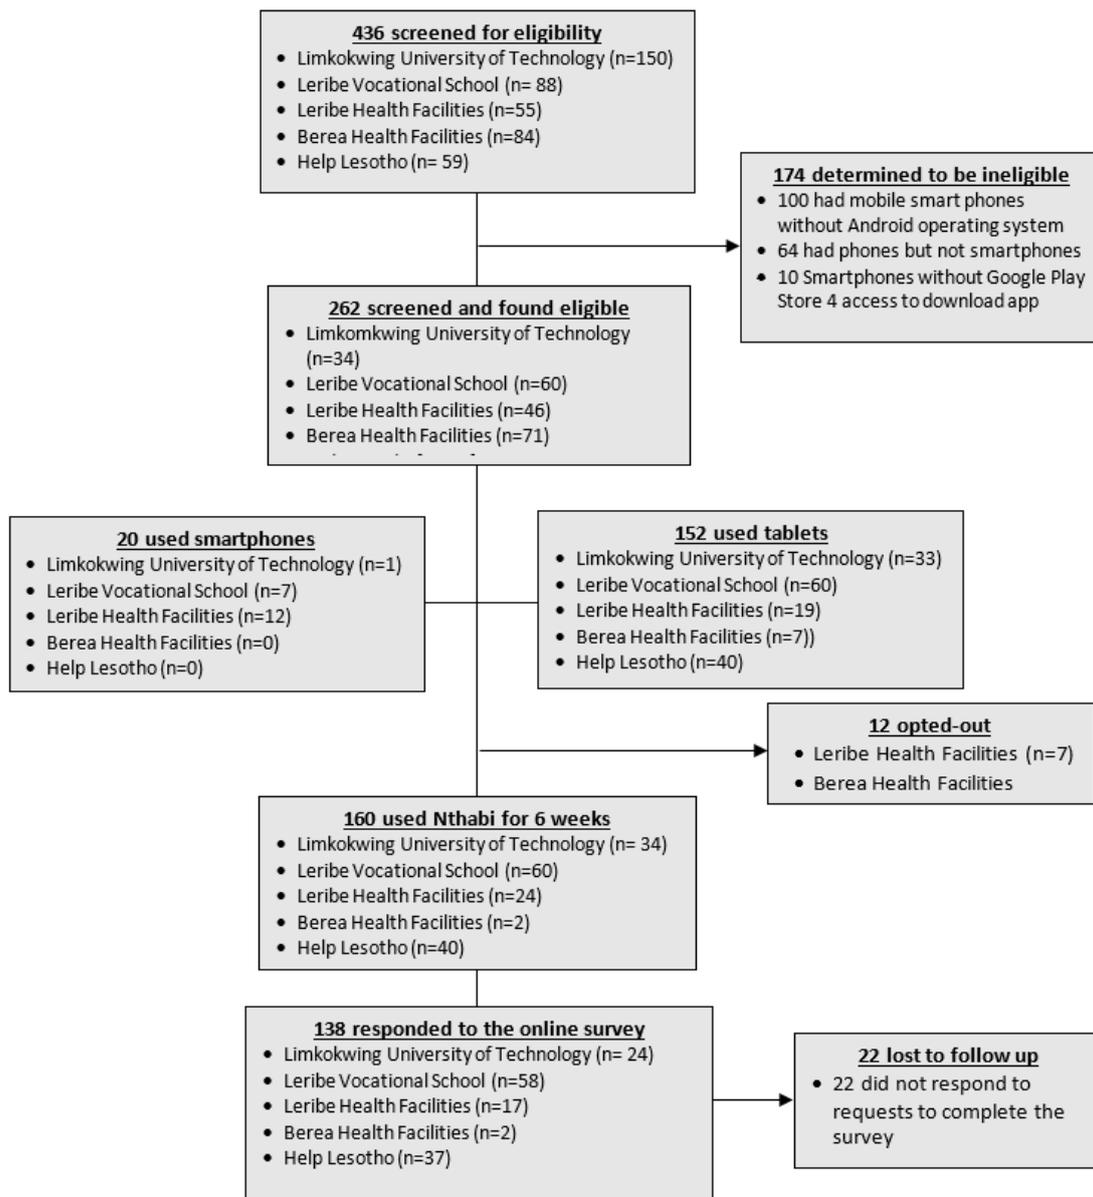

Consequently, 172 participants were eligible, provided consent, and were enrolled. Those enrolled were from Limkokwing University of Technology (34 of 34 screened), Leribe Vocational School (60 of 60 participants screened), Leribe Health Facilities

(31 of 46 participants screened), Berea Health Facilities (7 of 71 participants screened), and Help Lesotho (40 of 51 participants screened).

Of those enrolled, only 20 participants had sufficient memory on their phones to download the Nthabi app, and 152 participants received a tablet device to use. Of those who were able to download the Nthabi app on their mobile phones, 1 of 34 participants was from Limkokwing University of Technology, 7 of 60 participants were from Leribe Vocational School, and 12 of 31 participants were from Leribe Health Facilities.

In the weeks after enrollment, 12 participants opted out of the study because their phones froze and jammed when they tried to load the app. Therefore, 160 young women used Nthabi for up to 6 weeks, with 8 young women using phones and 152 young women using loaned tablets. At the end of 6 weeks, 138 young women responded to the survey (80 young women who had been recruited from the technology and vocational schools, 19 young women from the district health facilities, and 37 young women from the Help Lesotho program), and 22 young women did not respond to requests to complete the survey.

Figure 2. Consolidated Standards of Reporting Trials (CONSORT) diagram.

Sociodemographic Results

Table 1 shows the characteristics of the 138 participants who were enrolled and who completed the survey after 6 weeks. The mean age was 22 years (SD 2.7 years), most were unmarried, 56 (40.6%) participants had completed high school, 39 (28.3%) participants were unemployed, and 88 (63.8%) participants were

students. The recruitment sites of those participants completing surveys were 24 (17.4%) participants from Limkokwing University of Technology, 58 (42%) participants from Leribe Vocational School, 17 (12.3%) participants from Leribe health facilities, 2 (1.4%) participants from Berea Health Facilities, and 37 (26.8%) participants from Help Lesotho.

Table 1. Sociodemographic characteristics of respondents (n=138).

Characteristics	Respondents, n (%)
Age (years)	
18-20	34 (24.6)
21-23	53 (38.4)
24-26	37 (26.8)
27-28	14 (10.1)
Marital status	
Married	11 (8)
Not married	127 (92)
Level of education	
Primary	2 (1.5)
High school	56 (40.6)
College	39 (28.3)

Leribe Vocational School	58 (42)
Leribe Health Facilities	17 (12.3)
Berea Health Facilities	2 (1.4)
Help Lesotho	37 (26.8)

Survey Results

Table 2 shows the survey responses of the 138 young women who completed the survey. Overall, the results show that participants perceived usability and acceptability positively.

Described below are the survey responses corresponding to the components of usability (effectiveness, efficiency, and satisfaction) and acceptability (satisfaction, attitudes toward use, and intention to continue using Nthabi).

Respondents believed the app was helpful, with 134 (97.1%) participants strongly agreeing or agreeing that the app was “effective in helping them make decisions” and “could quickly improve health education and counselling.”

Participants generally liked using the app, with 136 (98.6%) participants strongly agreeing or agreeing that the app was “simple to use,” while 132 (95.7%) participants reported that “symbols and buttons are easy to use,” 130 (94.3%) participants reported that Nthabi could “easily repeat words that were not well understood,” and 128 (92.8%) participants reported that the app “could quickly load the information on the screen.”

Respondents were generally satisfied with the app, with 132 (95.7%) participants strongly agreeing or agreeing that the health

education content delivered by the app was “well organised and delivered in a timely way,” while 133 (96.4%) participants “enjoyed using the interface.”

In addition, 132 (95.7%) participants strongly agreed or agreed that they were able to complete tasks quickly using the app, while 136 (98.6%) participants reported that “I can quickly remember how to use the app after a while,” and 137 (99.3%) participants reported that “it was easy to learn how to use the app.”

The items rated less positively include the following: “it was easy to converse and type responses into the app” according to 95 (68.8%) participants, and “I could easily correct mistakes” according to 106 (76.8%) participants.

They also were satisfied with the cultural adaptation, with 133 (96.4%) participants strongly agreeing or agreeing that the app was “culturally appropriate and that it could be easily shared with a family or community members.”

Finally, they also reported that Nthabi was worthwhile, with 127 (92%) participants reporting that they strongly agreed or agreed that they were “satisfied with the application and intended to continue using it” while 135 (97.8%) participants would “encourage others to use it.”

Table 2. Survey responses on the usability and acceptability of Nthabi app (n=138).

To what extent do you agree with the following statements?	Strongly agree, n (%)	Agree, n (%)	Disagree, n (%)	Strongly disagree, n (%)
It was simple to use this app	90 (65.2)	46 (33.3)	1 (0.7)	1 (0.7)
It was easy to find the information I needed	51 (37)	68 (49.3)	13 (9.4)	6 (4.4)
It was easy to converse and type responses into this app	36 (26.1)	59 (42.8)	33 (23.9)	10 (7.3)
The information on the app screen is well-organized	59 (42.8)	76 (55.1)	1 (0.7)	2 (1.5)
It was easy to learn how to use the app	94 (68.1)	43 (31.2)	1 (0.7)	0 (0)
The symbols and buttons are easy to use	61 (44.2)	71 (51.5)	5 (3.6)	1 (0.7)
I understood how the app works the first time I used it	76 (58.1)	53 (38.4)	6 (4.4)	3 (2.2)
I can quickly remember how to use the app after a while	88 (63.8)	48 (34.8)	1 (0.7)	1 (0.7)
When I made a mistake using the app, I could easily correct the mistake	37 (26.8)	69 (50)	29 (21.1)	3 (2.2)
The app offered error messages that clearly told me how to fix the issues	22 (15.9)	57 (41.3)	52 (37.7)	7 (5.1)
The app could easily repeat words or statements that were not well understood	91 (66)	39 (28.3)	7 (5.1)	1 (0.7)
The app quickly loads the information on the screen	70 (50.7)	58 (42)	8 (5.8)	2 (1.5)
The health education content provided by the app was well-organized and delivered in a timely way	75 (54.3)	57 (41.3)	5 (3.6)	1 (0.7)
I was able to complete tasks quickly using the app	68 (49.3)	64 (46.4)	3 (2.2)	3 (2.2)
The app information was effective in helping me make decisions	74 (53.6)	60 (43.5)	1 (0.7)	3 (2.2)
The app has not stopped working or has ever closed	65 (47.1)	51 (37)	19 (13.8)	3 (2.2)
I believe the app could quickly improve health education and counseling	85 (61.59)	49 (35.51)	1 (0.72)	3 (2.1)
The app interface is nice to use	67 (48.6)	63 (45.7)	4 (2.9)	4 (2.9)
I enjoyed using the app interface	78 (56.5)	55 (39.9)	3 (2.2)	2 (1.5)
I am satisfied with the app and intend to continue using it	78 (56.5)	49 (35.5)	8 (5.8)	3 (2.2)
I want to encourage others to use the app	91 (66)	44 (31.9)	2 (1.5)	1 (0.7)
The app was culturally appropriate and I could easily share it with a family member or community member	79 (57.3)	54 (39.1)	5 (3.6)	0 (0)

Survey Responses by Age, Marital, and Education Status

Table 3 shows selected survey responses of the 138 participants who completed the survey questions by age, education, and marital status.

Participants aged 18-24 years (vs those aged 25-28 years) agreed that the “Nthabi app was simple to use” (106/106, 100% vs 30/32, 93.8%; $P=.01$), and agreed that “the educational content was well organised and delivered in a timely way” (104/106, 98.1% vs 28/32, 87.5%; $P=.01$).

Participants who were married (vs unmarried) agreed that “the educational content was well organised and delivered in a timely

way” (9/11, 81.8% vs 123/127, 96.9%; $P=.02$), and agreed that “the app was nice to use” (9/11, 81.8% vs 121/127, 95.3%; $P=.07$).

Finally, young women who were in high school (vs those in tertiary education) were more likely to agree that “the app offered error messages that clearly told me how to fix the issue” (37/56, 66.1% vs 41/80, 51.3%; $P=.02$), and were “satisfied with the application and intended to continue using it” (55/56, 98.2% vs 70/80, 87.5%; $P=.07$).

Taken together, these results indicate that younger women, those in high school (and usually younger), and those unmarried (and usually younger) perceived Nthabi more positively.

Table 3. Survey responses of young women using Nthabi app by age, marital, and educational status.

	Agree, n (%)	Disagree, n (%)	P value
Opinions of young women and their marital status			
The health education content provided by the app was well-organized and delivered in a timely way			.02
Married (n=11)	9 (81.8)	2 (18.2)	
Not married (n=127)	123 (96.9)	4 (3.2)	
The app interface is nice to use			.07
Married (n=11)	9 (81.8)	2 (18.1)	
Not married (n=127)	121 (95.3)	3 (2.4)	
Opinions of young women and their age range			
It was simple to use this app			.01
18-24 (n=106)	106 (100)	0 (0)	
25-28 (n=32)	30 (93.8)	2 (6.2)	
The health education content provided by the app was well organised and delivered in a timely way			.01
18-24 (n=106)	104 (98.1)	2 (1.9)	
25-28 (n=32)	28 (87.5)	4 (12.5)	
Opinions of young women and their educational status			
The app offered error messages that clearly told me how to fix the issues			.02
Primary school (n=2)	1 (50)	1 (50)	
High school (n=56)	37 (66.1)	19 (33.9)	
Tertiary (n=80)	41 (51.3)	39 (48.8)	
I am satisfied with the app and intend to continue using it			.07
Primary school (n=2)	2 (100)	0 (0)	
High school (n=56)	55 (98.2)	1 (1.8)	
Tertiary (n=80)	70 (87.5)	10 (12.5)	

Discussion

Principal Results

Young women in the lower middle-income country of Lesotho in southern Africa who used the newly adapted Nthabi intervention for up to 6 weeks perceived the usability and acceptability of the system very positively. Most respondents were satisfied with Nthabi and perceived it to be effective, efficient, and culturally appropriate. Participants agreed that Nthabi helped them make decisions and could improve the delivery of health education. They reported it was easy to use and well organized. Most intended to use it beyond the study period and they said they would encourage others to use it.

Improving sexual reproductive health education is a clear priority in Lesotho [9,10]. This study supports the idea that conversational agent technologies can provide sexual and reproductive health education in a rural, mountainous country like Lesotho, which has profound human resources challenges. As additional data are collected, the Ministry of Health and the health development and implementing partners should consider using Nthabi as a health promotion and education tool in Lesotho.

Comparison With Prior Work

These findings are in accordance with our previous research reporting results of focus groups of potential users who used an early version of Nthabi and key informant interviews of Ministry of Health officials. Participants reported that adaptations were culturally appropriate, and provided relevant and culturally sensitive clinical information. These qualitative data and now survey data together highlight the importance of acknowledging the local context when adapting an intervention. Nthabi was adapted to the uses, languages, interests, and realities of young people, as well as the importance of knowing what is preferred by young people as a measure of attractiveness to promote user engagement [24]. Most respondents were satisfied with the educational content and agreed that it delivered culturally appropriate and sensitive sexual and reproductive health information. Adaptations of interventions using appropriate cultural cues have a higher probability of acceptability and usability [25]. Culturally responsive interventions are effective in enhancing knowledge acquisition, attitudes, and satisfaction since they respect cultural diversity and the sociocultural factors that may affect health [26,27].

Participants agreed Nthabi could improve the delivery of health education and help them make health decisions. This finding is similar to findings from other studies conducted in lower

middle-income countries, which provide evidence that a variety of mHealth apps such as voice messages and daily educational text messages can improve young people's sexual reproductive health [28] and have been shown to be feasible and acceptable for improving health education and knowledge among adolescents and young people [29]. Other studies highlighted the broad potential for digital interventions to enhance health promotion and service delivery toward better sexual health [30,31]. However, this is the first study of the acceptability and usability of potentially more engaging and effective conversational agent systems in a low- and middle-income country in southern Africa.

Younger women in this study sample appear to have more positive perceptions of Nthabi than older participants. They found the system simple to use and the content delivered in a way convenient to them. Younger women might be more familiar and comfortable with using new technologies. This is consistent with other studies of women from the global north showing their preference for digital technologies such as readily available information, and their preference for opportunities to learn more about their bodies and health status [32]. Other studies have found that younger people are not only accepting of new technologies in health care settings but are actually looking for more of these technologies to use in health settings [33,34].

Accessibility of Nthabi on Mobile Devices

In Lesotho, 94% of people aged 18-29 years use smartphones, and 3G data coverage is available in almost 90% of the country [5], yet access to public Wi-Fi and data costs remain barriers to using mobile technologies for health education. Nthabi was designed to address our concern that limited internet access would impact participants' use of Nthabi. A decision was made to download the full system to mobile devices so that participants could use the system when not in Wi-Fi environments. While this design allowed the participants to use the system at their convenience, the inclusion of all the content and most importantly, the inclusion of the system voice synthesizer, created significant difficulties for downloading and using Nthabi on most phones due to low phone memory. The finding that only 8 of 172 (4.7%) participants were able to use Nthabi on their phones demonstrates that mobile phone use is possible, though practically, only phones with sufficient

available memory could be used. As it becomes increasingly possible for young women to have regular access to public Wi-Fi, it will become possible for more young women to use Nthabi in the cloud on their phones rather than downloading the full system.

Participants who were unable to download the intervention to their phones were loaned tablet devices. We purchased 20 devices (US \$111 per tablet or US \$14 per participant) and loaned them to participants on a rolling basis. At the end of the study, all tablets were returned. While this is a cost-effective alternative, future studies of large-scale health education programs in low-resource settings using cloud-based interventions will be possible with increased public Wi-Fi availability. We are now planning studies in which fully downloadable and Wi-Fi-enabled systems are available.

Limitations

There are several limitations to this study. First, the results are not nationally representative of women from Lesotho as participants were recruited by convenience from only 2 of the 10 districts of Lesotho. The sample included many participants recruited from the university and vocational schools, and while these participants reported residing in and receiving health services in Berea and Leribe, the results do not necessarily reflect the views of women living in rural areas. Further trials are needed to more definitively identify the perceptions of rural women. A larger study in all 10 districts of Lesotho is planned.

Second, while this study reports on perceptions of successful usability and acceptability, it does not provide evidence that the intervention improved young women's health knowledge, attitudes, and behaviors. Research to further determine the impact of knowledge of the topics discussed by Nthabi is underway.

Conclusions

Nthabi is a potentially useful intervention for providing sexual reproductive health information for young women in the rural, lower middle-income country of Lesotho with limited human resources in health. Further study of the Nthabi system is warranted to determine if the Nthabi health education content and interactive dialogue about sexual and reproductive health can improve women's knowledge, attitudes, and health behaviors.

Acknowledgments

All authors made substantial contributions to draft and critically revise the manuscript. EN-N, MM-M, and BWJ contributed to conceptualizing the study and to data acquisition, analysis, interpretation, and writing the manuscript. TB contributed to conceptualizing the study and as an expert in conversational agents. CJ contributed study design, data collection, and manuscript writing. All authors approved the final draft and agreed to be accountable for all aspects of the work. The authors are grateful to the Lesotho Ministry of Health leadership, young women who participated in this study, and research assistants Paballo Lethunya and Moleboheng Mofolo. The research reported in this publication was supported by the Fogarty International Center of the United States National Institutes of Health (award R21TW011361). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Abstract

Background: A low socioeconomic status is associated with a vulnerable health status (VHS) through the accumulation of health-related risk factors, such as poor lifestyle behaviors (eg, inadequate nutrition, chronic stress, and impaired health literacy). For pregnant women, a VHS translates into a high incidence of adverse pregnancy outcomes and therefore pregnancy-related inequity. We hypothesize that stimulating adequate pregnancy preparation, targeting lifestyle behaviors and preconception care (PCC) uptake, can reduce these inequities and improve the pregnancy outcomes of women with a VHS. A nudge is a behavioral intervention aimed at making healthy choices easier and more attractive and may therefore be a feasible way to stimulate engagement in pregnancy preparation and PCC uptake, especially in women with a VHS. To support adequate pregnancy preparation, we designed a mobile health (mHealth) app, Pregnant Faster, that fits the preferences of women with a VHS and uses nudging to encourage PCC consultation visits and engagement in education on healthy lifestyle behaviors.

Objective: This study aimed to test the feasibility of Pregnant Faster by determining usability and user satisfaction, the number of visited PCC consultations, and the course of practical study conduction.

Methods: Women aged 18-45 years, with low-to-intermediate educational attainment, who were trying to become pregnant within 12 months were included in this open cohort. Recruitment took place through social media, health care professionals, and distribution of flyers and posters from September 2021 until June 2022. Participants used Pregnant Faster daily for 4 weeks, earning coins by reading blogs on pregnancy preparation, filling out a daily questionnaire on healthy lifestyle choices, and registering for a PCC consultation with a midwife. Earned coins could be spent on rewards, such as fruit, mascara, and baby products. Evaluation took place through the mHealth App Usability Questionnaire (MAUQ), an additional interview or questionnaire, and assessment of overall study conduction.

Results: Due to limited inclusions, the inclusion criterion "living in a deprived neighborhood" was dropped. This resulted in the inclusion of 47 women, of whom 39 (83%) completed the intervention. In total, 16 (41%) of 39 participants visited a PCC consultation, with their main motivation being obtaining personalized information. The majority of participants agreed with 16 (88.9%) of 18 statements of the MAUQ, indicating high user satisfaction. The mean rating was 7.7 (SD 1.0) out of 10. Points of improvement included recruitment of the target group, simplification of the log-in system, and automation of manual tasks.

Conclusions: Nudging women through Pregnant Faster to stimulate pregnancy preparation and PCC uptake has proven feasible, but the inclusion criteria must be revised. A substantial number of PCC consultations were conducted, and this study will therefore be continued with an open cohort of 400 women, aiming to establish the (cost-)effectiveness of an updated version, named Pregnant Faster 2.

Introduction

A low socioeconomic status (SES) is associated with a vulnerable health status (VHS), which research suggests is grounded in the accumulation of risk factors, such as inadequate nutrition, smoking, and increased mental stressors [1-4]. For women, a low SES means they are more likely to have a VHS, which translates into a higher incidence of adverse pregnancy outcomes in this group [5-9]. These adverse outcomes originate at least partly in the periconception period [10], during which gametogenesis, embryonic development, and placentation take place, laying the foundation for perinatal outcomes, as well as the child's lifelong health [11,12]. For example, an accumulation of 2 or more maternal risk factors impacts embryonic growth [13], which is associated with midpregnancy fetal weight and birth weight [14]. In addition, infants born small for their gestational age are more susceptible to noncommunicable diseases, such as diabetes mellitus and cardiovascular disease [15]. The effects of adverse pregnancy outcomes therefore hit twice: once in utero and once in later life. This increases the child's chance of a VHS in adulthood, which, once again, may influence pregnancy outcomes. These transgenerational effects are further maintained by impaired health agency, which is associated with a low SES and diminishes the likelihood of seeking necessary care [16]. In accordance with these findings, research shows that women with a VHS are less likely to engage in pregnancy preparation and take up preconception care (PCC) [17].

PCC is usually given by a midwife or an obstetrician and is aimed at identification of possible risk factors for adverse outcomes, ameliorating those that are modifiable prior to pregnancy [18]. This includes adopting healthy lifestyle behaviors and making beneficial choices in general that will increase the chance of having a healthy pregnancy and baby. Although $\geq 80\%$ of women who wish to become pregnant have at least 1 modifiable risk factor for adverse pregnancy outcomes [19,20], the uptake of PCC remains low due to insufficient awareness of risk factors and the benefits of PCC [21]. Women with a low SES may encounter additional barriers when engaging in pregnancy preparation, as they are already burdened by the deprived circumstances in which they live. Supporting this group by making pregnancy preparation easier and attractive might be a suitable way to relieve the inequity regarding their pregnancy outcomes.

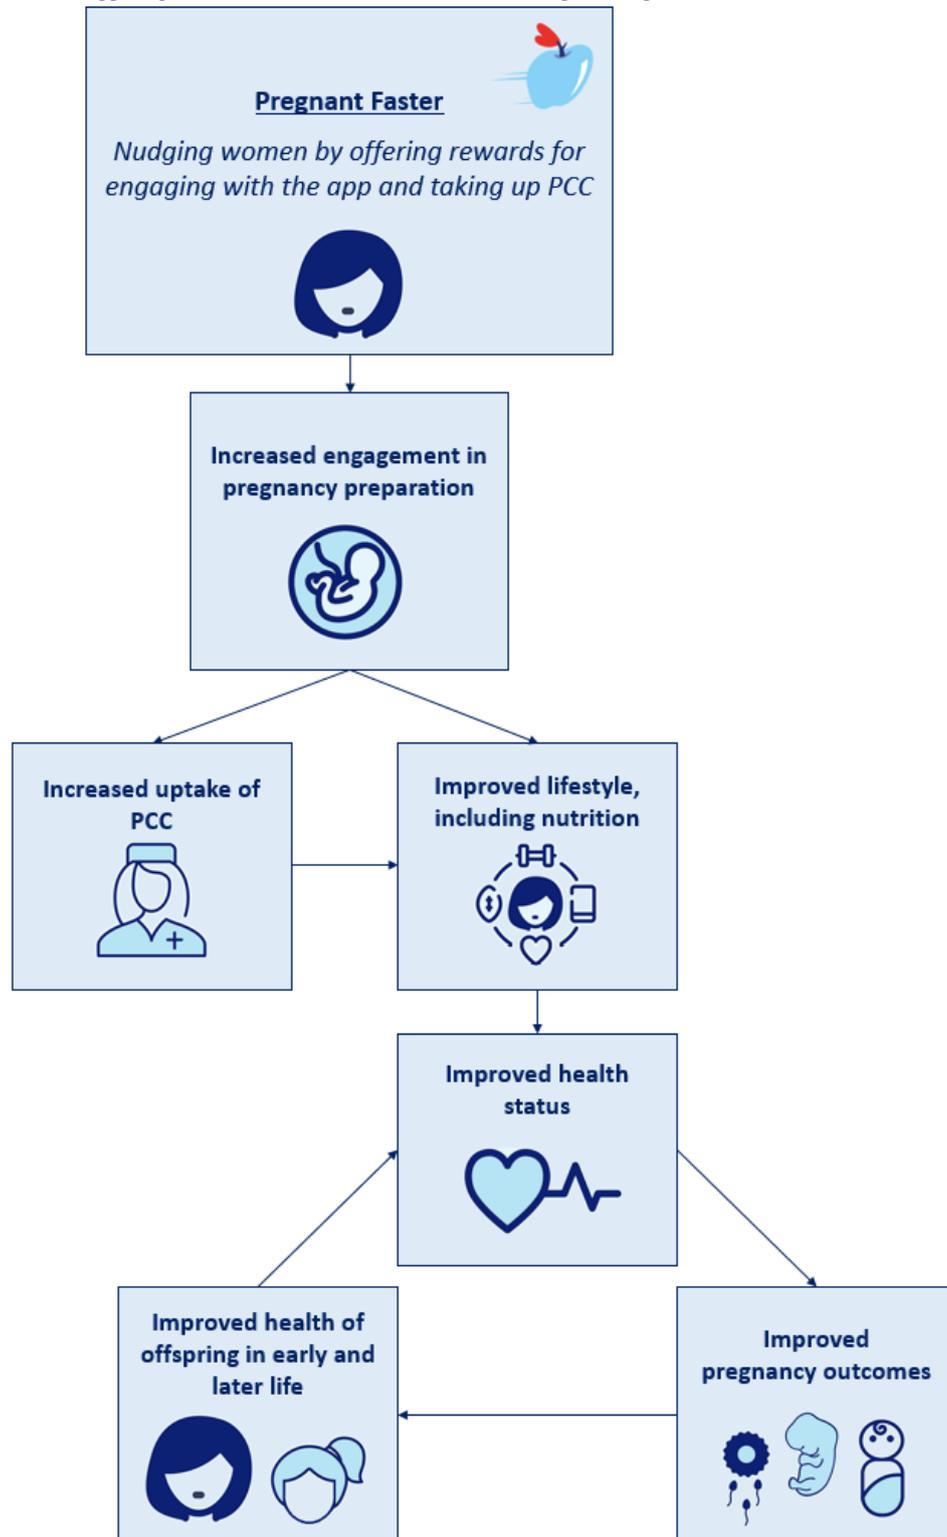

Our research group has previously developed the web-based PCC tool Smarter Pregnancy, an interactive, tailored, mobile

health (mHealth) platform that offers practical coaching and customized feedback on nutrition and other lifestyle behaviors of prospective parents [22]. Smarter Pregnancy has proven to be effective in supporting healthy choices in women with a VHS, in addition to being valued highly by them [23]. To further support PCC engagement in women with a VHS, we have designed an mHealth app that especially fits their needs and preferences [24]: the app-based nudge Pregnant Faster. A nudge is an intervention that stimulates making beneficial choices by increasing the attractiveness and easiness of healthy behavior [25]. An in-depth explanation of nudge theory and its application in health policy can be found in the study by Murayama et al [26].

In the case of Pregnant Faster, participants are nudged through a loyalty program that entails collecting coins by engaging with the app and ordering rewards using those coins. The design of Pregnant Faster can be viewed as a macrolevel nudge, containing multiple microlevel nudges aimed at stimulating pregnancy preparation and encouraging the uptake of PCC. For example, the monetary value of a coin is a microlevel nudge; it varies from €0.06 to €0.26 (US \$0.06-\$0.26), depending on the type of reward. Healthy rewards, such as folic acid supplements, are relatively cheap, steering participants toward picking them over luxury goods, while maintaining their freedom to choose. The most important feature of the app, which also yields the highest number of coins, is the possibility to register for a PCC consultation with a nearby midwife, promoting blended care: an effective way to promote pregnancy preparation [27]. As midwives are the primary health care providers for pregnant women in the Netherlands, PCC consultations are beneficial for the bond between health care provider and client prior to and during pregnancy. The full description of Pregnant Faster's design process, detailing the imbedded nudges, has been published in *JMIR Protocols* [28].

The aim of this pilot study was to determine Pregnant Faster's feasibility pertaining to usability and user satisfaction, the number of PCC consultations booked and visited by participants, and the course of practical conduction regarding the inclusion process, reward allocation, and finalization of the study. In addition, the results of this study will be used to further develop Pregnant Faster and lay the foundation for a larger cohort study to establish its (cost-)effectiveness. Our overall ambition is that Pregnant Faster contributes to the improvement of short-term and long-term health in mothers with a VHS, their children, and future generations (Figure 1).

Figure 1. Aim of the mHealth app Pregnant FASTER. mHealth: mobile health; PCC: preconception care.

Methods

Ethical Considerations

This study was assessed and approved by the Medical Ethical Committee of the Erasmus University Medical Center, Rotterdam, The Netherlands (MEC-2020-0974). Informed consent was obtained from all participants via email.

Considering the low risk of this study, composing a Data Safety Monitoring Board was deemed unnecessary.

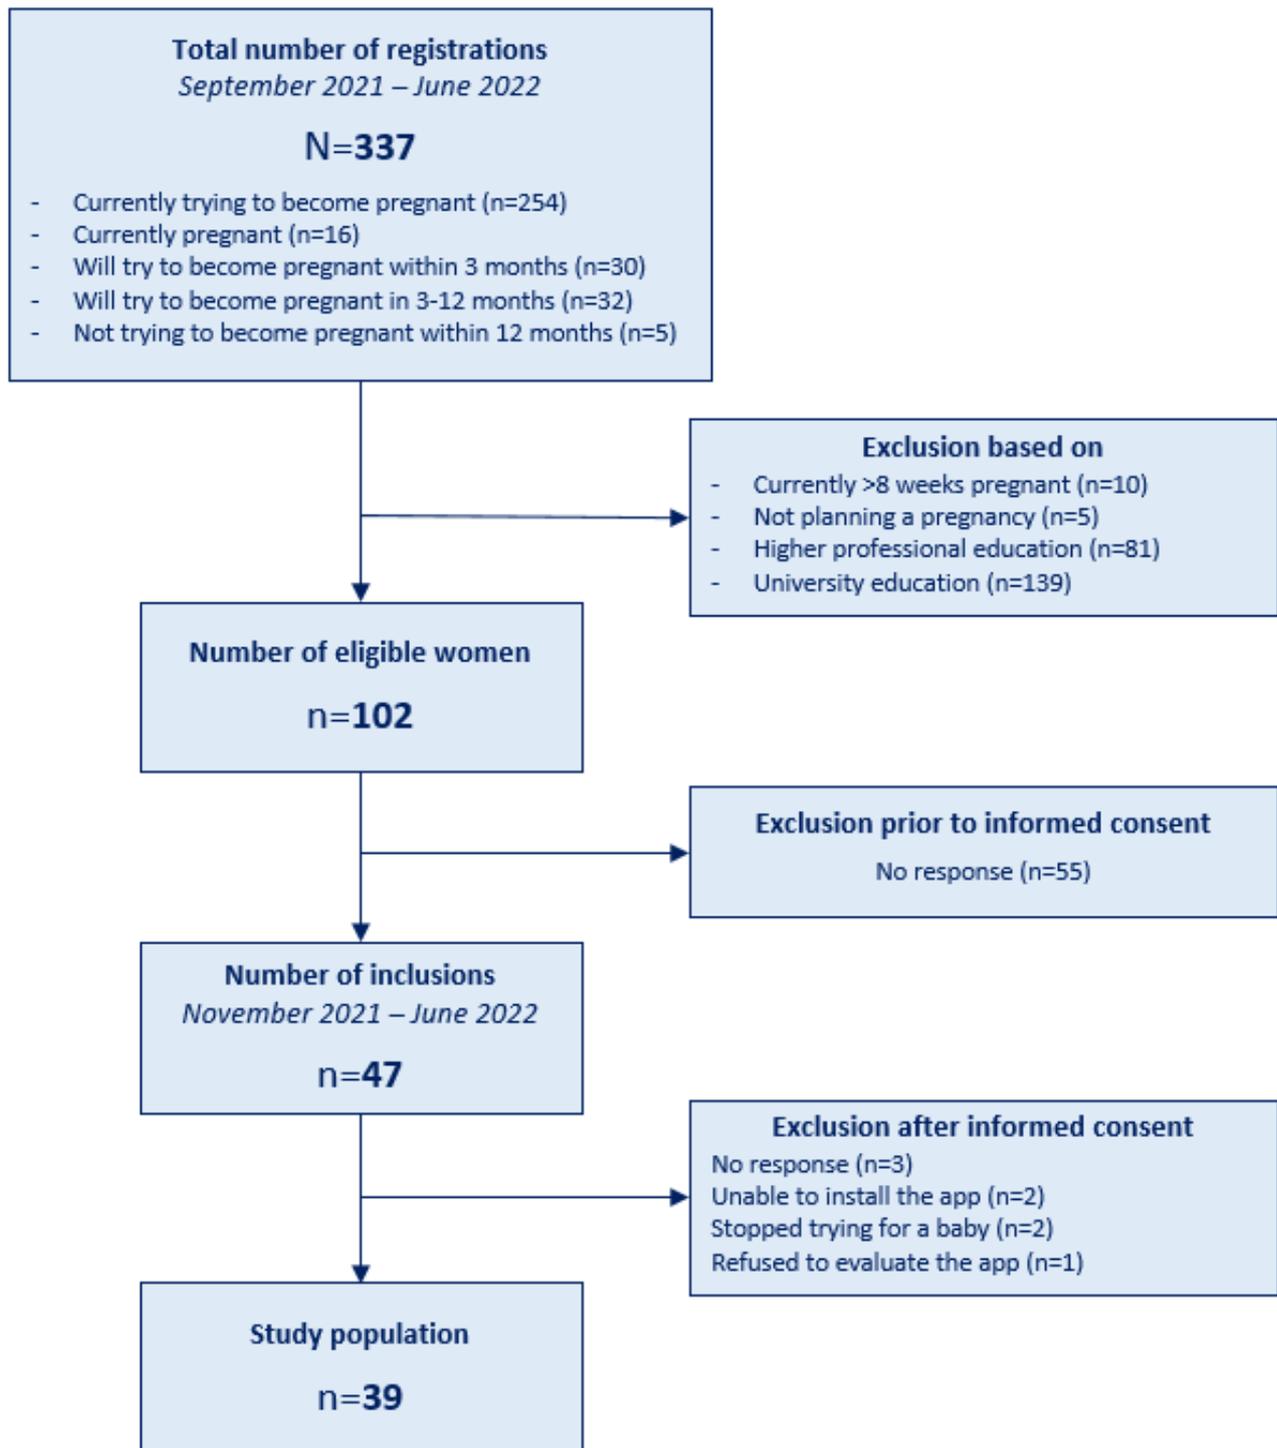

Recruitment and Inclusion

Our aim was to include 40 participants in this study. Between September 2021 and June 2022, 337 women registered for this study, of which 102 (30.3%) were eligible for inclusion. Due to a higher-than-expected confidentiality, integrity, and availability (CIA) Triad classification (a risk score regarding

user information safety [29]), additional security demands were necessary. Fulfilling these demands delayed the launch of Pregnant Faster from September 2021 to November 2021,

leading to a loss of recruited eligible women. From the launch onward, 47 (46.1%) women were included, of which 39 (83%) completed the intervention (Figure 2).

Figure 2. Inclusion flowchart.

Recruitment took place through the Sneller Zwanger website [30], which was distributed through posters and flyers, advertisements on the social media platforms Facebook and Instagram, and midwifery practices that provide primary care to all pregnant women in the Netherlands. Additionally, a collaboration took place with the Dutch influencer Midwife Mother (Dutch *Verlosmoeder*) on Instagram [31-33]. Participants filled in a survey with their first name, age, telephone number,

email address, zip code, educational level, and when they planned on trying to become pregnant (currently pregnant, currently trying, or trying in ≤ 3 , $>3-12$, or >12 months). Pregnant women were asked to fill in their estimated or calculated due date.

Participants were selected based on the following inclusion criteria: assigned female at birth, 18-45 years old, actively trying

to become pregnant within now and 12 months or pregnant with a gestational age of <8 weeks at the start of the intervention, a low-to-intermediate educational level (prevocational or vocational education), and able and willing to download and evaluate the app.

Exclusion criteria were as follows: insufficient proficiency in the Dutch language, not in possession of a smartphone or tablet suitable for the app, and refusal to download or evaluate the app. All excluded women received a free coupon for the Dutch or English version of Smarter Pregnancy [34].

Design

Pregnant Faster was developed by the Erasmus University Medical Center's research group Periconception Epidemiology at the Department of Obstetrics and Gynecology, in collaboration with TJIP The Platform Engineer and the event bureau Improve. A detailed description of the cocreation and design process of Pregnant Faster and the study protocol has been published in *JMIR Protocols* [28].

Intervention

Eligible women were sent the patient information folder, in which the intervention was explained. Inclusion was finalized after a telephone conversation in which further clarification could be provided. An email was sent with instructions on how to download and install Pregnant Faster from Apple App Store (iOS) or via a link (Android). If more than 3 days passed between inclusion and downloading, participants were approached twice by email and telephone and once by a text message to provide further support with installation.

The first log-in marked the start of the 4-week intervention. During this period, participants logged in with their email address and a password, which yielded 1 coin per day per log-in. The first log-in yielded 50 coins as a reward for installation and to immediately stimulate participants to further engage with the app. After log-in, a dashboard appeared, containing 5 buttons:

(1) "Earn coins," (2) "Overview coins," (3) "See a midwife!," (4) "This study," and (5) "Rewards" (Figure 3).

Button 1, "Earn coins," led to a timeline where new blogs and tips appeared daily (Multimedia Appendix 1). Reading this information yielded 4-8 coins. In the same timeline, a daily questionnaire appeared in which participants could tick a box if they ate sufficient fruit and vegetables, exercised, and took folic acid supplements that day. Each ticked box yielded 2 coins per day. Button 2, "Overview coins," displayed when and how coins were earned and how many coins were spent on which products. Button 3, "See a midwife!," contained information regarding what PCC is and who it is for, stimulating participants to register through the app for a PCC consultation. Registering consisted of filling in their phone number, which immediately yielded 25 coins. An additional 75 coins were allocated after the visit was confirmed by the midwife. Button 4, "This study," contained information about the study itself and contact details for support. Button 5, "Rewards," contained an in-app shop where participants could order rewards, including (but not limited to) folic acid supplements, fruit, nail polish, mascara, ovulation or pregnancy tests, and newborn clothing. Rewards were sent to their home address to arrive within 5 business days. If a participant had not logged in for 7 days, they received a manually sent text message and email, encouraging them to read up on the newly offered blogs and tips, earn more coins, and order rewards.

At the end of the intervention, participants were offered a coupon for Smarter Pregnancy via the timeline, which would yield 25 coins upon use and provide them with an additional 26 weeks of coaching. Furthermore, they received an email regarding finalization of the study and available means of support. Earned coins could be spent up to 2 weeks after the intervention ended. The blogs and tips remained accessible for as long as the app remained installed. Figure 4 provides an overview of the study flow.

Figure 3. Pregnant Faster interface.

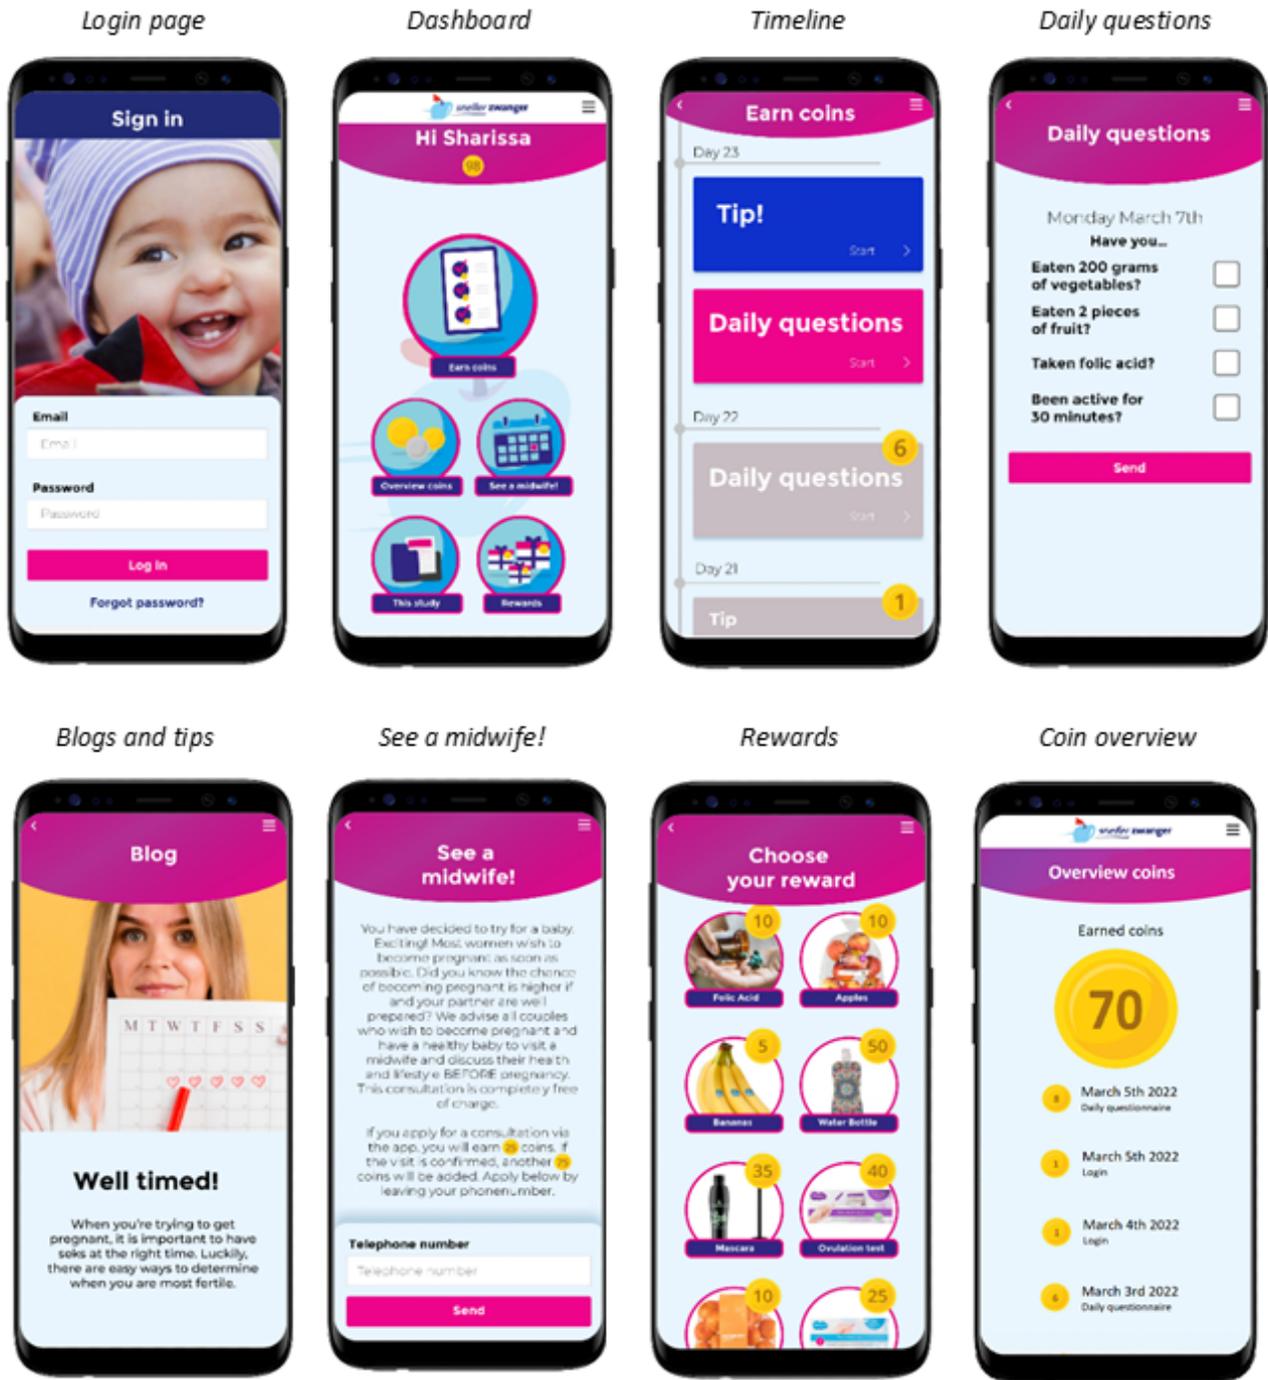

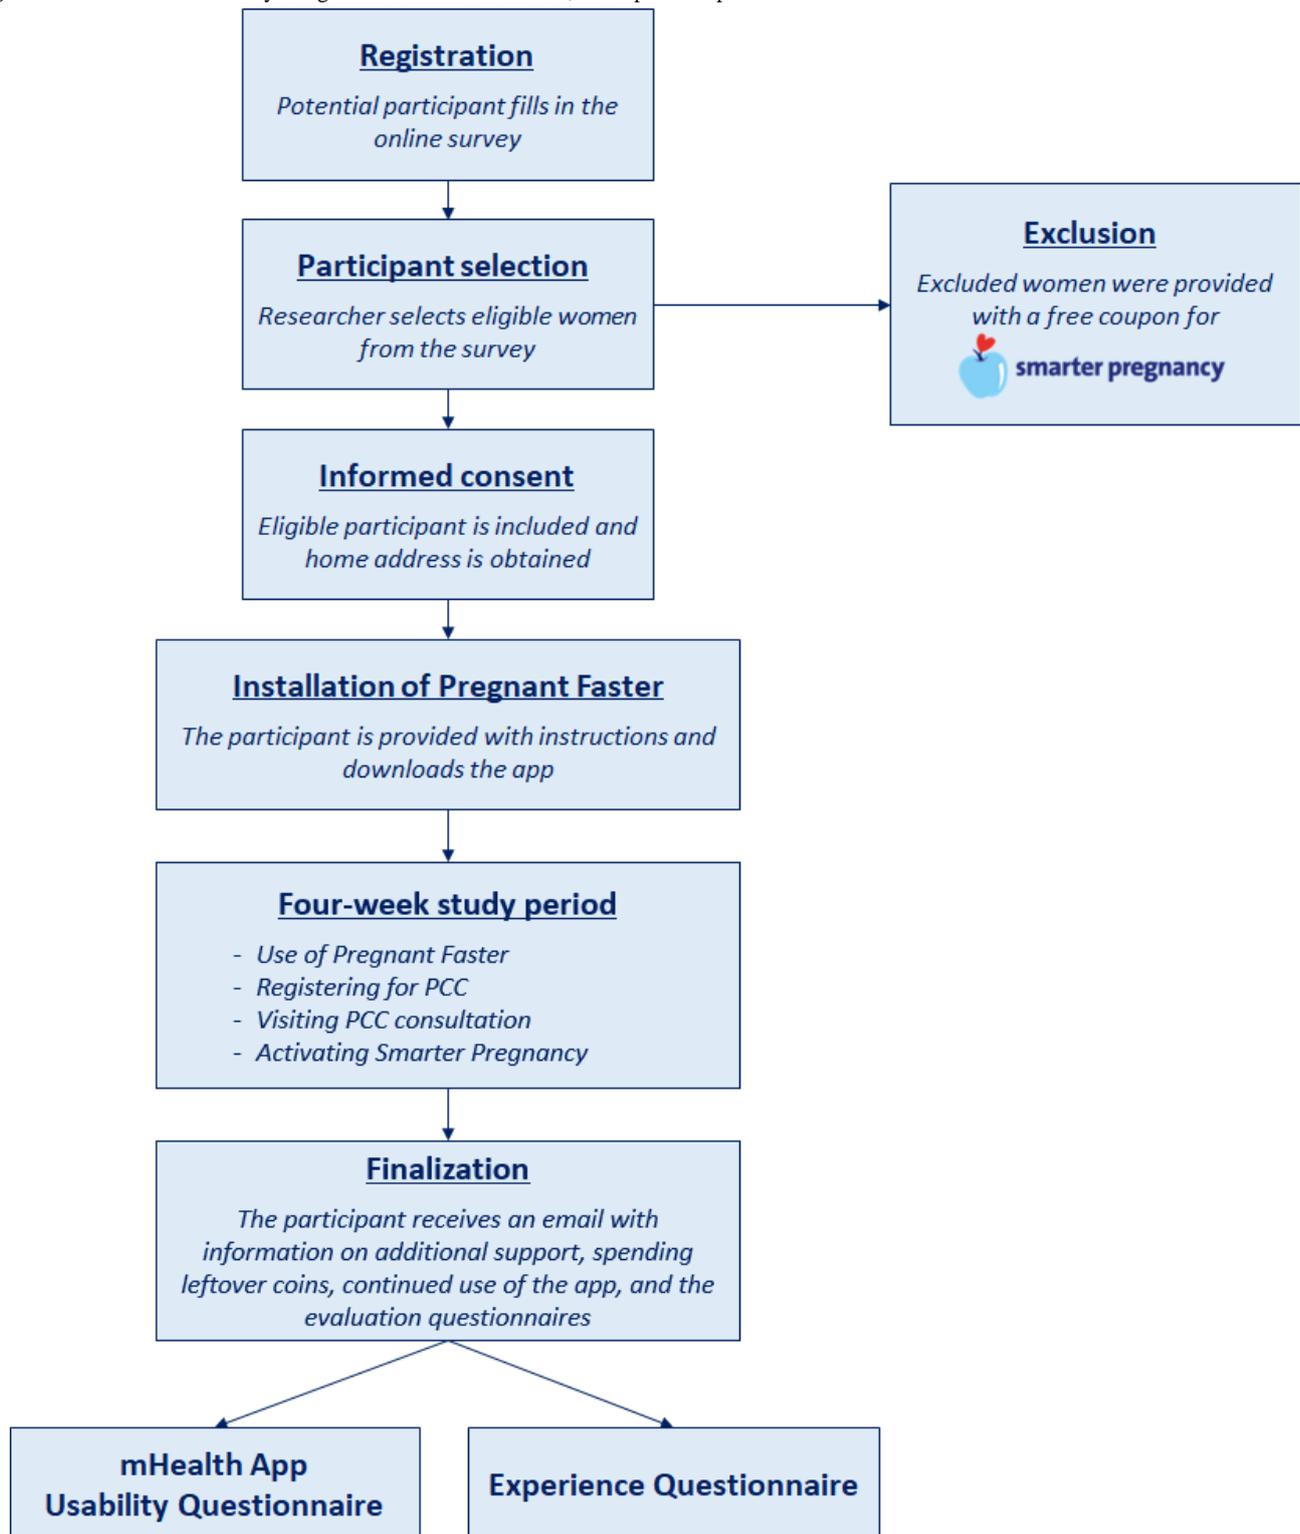

Figure 4. Flowchart of the study design. mHealth: mobile health; PCC: preconception care.

Data Collection and Outcome Measures

During the study, registration and inclusion rates were tracked and a log book was kept to note any encountered barriers and changes to the protocol.

Participants' baseline characteristics were collected prior to inclusion through the selection survey, and home addresses were collected via email after obtaining informed consent. If selected participants did not respond to attempts to include them,

they were contacted twice by email, twice by telephone, and once by a text message.

After using Pregnant Faster for 4 weeks, participants filled in a modified version of the 18-item mHealth App Usability Questionnaire (MAUQ), which uses a 7-point Likert scale (Multimedia Appendix 2) [35]. In addition, the first 10 (25.6%) participants went through a semistructured interview (Multimedia Appendix 3) in which they elaborated on their experiences with the app and, if applicable, the PCC

consultation. The audiotapes of these interviews were used to compose the Experience Questionnaire (ExQ; [Multimedia Appendix 4](#)) that consisted partly of questions using a 5-point Likert scale. The ExQ was offered to the remaining participants, and the first author filled in the ExQ for the first 10 (25.6%) participants, using the audiotaped data provided during the interviews. If a question in the ExQ was not clearly answered in the interview, the participant was approached by telephone to provide an answer. The answers to the open questions in the ExQ were evaluated for notable and recurring comments.

At the end of the study period, data were collected on the number of coins earned, the types of rewards that were chosen, and the number of booked and visited PCC consultations.

Data Analysis

To evaluate the inclusion strategy, the following percentages were calculated: (1) eligibility percentage, (2) inclusion percentages, and (3) intervention completion percentages. The eligibility percentage was determined by dividing the number of women eligible for inclusion by the total number of women who registered for the study. The inclusion percentages were calculated by dividing the number of included participants (who provided informed consent) by the number of total registrations and the number of eligible women who were approached for

inclusion. Completion of the intervention entailed completing the evaluation of the app. The intervention completion percentages were obtained by dividing the number of participants who completed the intervention by the number of eligible women and the number of participants who provided informed consent.

The baseline of the study population is presented in tabular form using the median (IQR) for continuous data and n (%) for categorical data. Data obtained through the MAUQ and the ExQ are presented in bar charts. Notable answers to open questions are presented in narrative form. Data on feasibility from the researchers' point of view are presented as bullet points.

All calculations were carried out using SPSS Statistics 25 (IBM Corporation), charts were created using Excel 2016 (Microsoft), and figures were created in PowerPoint 2016 (Microsoft).

Results

Recruitment, Inclusion, and the Study Population

A total of 337 women registered for the intervention, of whom 102 (30.3%) were eligible for inclusion. Informed consent was signed by 47 (46.1%) women, and 39 (83%) of the 47 women participated and completed the intervention. [Table 1](#) displays participants' baseline characteristics.

Table 1. Participants' baseline characteristics.

Characteristics	Participants (N=39)
Age (years), median (IQR)	30 (27-35)
Mean income neighborhood^a, n (%)	
Below middle	19 (48.7)
Above middle	11 (28.2)
Low to high	4 (10.3)
High	5 (12.8)
Educational level^b, n (%)	
Low	3 (7.7)
Intermediate	36 (92.3)
Trying to become pregnant, n (%)	
Currently trying	32 (82.1)
Within 3 months	5 (12.8)
Within 12 months	2 (5.1)
Mobile operating system, n (%)	
Android	17 (43.6)
iOS	22 (56.4)

^aThe median household income of a neighborhood is determined by the distribution of household income of all households in the country [28]. This table adheres to the original subdivision of the distribution of household income (year 2020): low, <€5,900 (<US \$18,800); below middle, €5,900-21,000 (US \$18,800-\$24,800); middle, €21,000-26,800 (US \$24,800-\$31,700); above middle, €26,800-34,600 (US \$31,700-\$40,900); and high, >€34,600 (>US \$40,900).

^bEducational level [29]. Dutch educational levels are subdivided as follows: low (prevocational education, selective secondary education, or lower), intermediate (vocational education), and high (bachelor's degree, master's degree, or higher).

A 2-month gap arose between the start of recruitment and the intervention, due to the app's CIA Triad classification [29]. A

low classification was expected, but the combination of 40 intended participants and their registering their first name and

email address in the app warranted a slightly higher classification for confidentiality and therefore additional security demands. Despite frequent updates to keep eligible women engaged, 55 (53.9%) of 102 women did not respond when inclusion commenced. Next, we describe these events and the inclusion process in detail.

Between September 2021 and January 2022, 212 (62.9%) women from the total 337 registrations reached in June 2022 registered for the study. Of these 212 women, only 9 (4.2%) were included. To boost the registration and inclusion rates, more flyers and posters were distributed, and the choice was made to include women who were trying to become pregnant within 12 months as opposed to within 3 months, as originally intended. Furthermore, the intervention was expanded from the municipality of Rotterdam to nationwide, delivering rewards through the postal service instead of by car. Midwives throughout the Netherlands were actively approached to ask whether they were interested in participating in the study and were offered support in setting up PCC consultations in their practices. Subsequently, the collaboration with Midwife Mother was renewed, who uploaded another post and multiple stories regarding PCC and Pregnant Faster to her Instagram. All women who were previously excluded based on not living near Rotterdam were contacted and asked to participate.

These efforts showed a limited effect. By May 2022, an additional 54 (16%) registrations and a total of 16 (34%) inclusions were obtained, which led to the decision to drop the inclusion criterion of living in a deprived neighborhood, thereby lowering the chance of including women likely to have a VHS. This choice was made to allow for further development and testing of Pregnant Faster while searching for a more effective way to recruit the intended target group for the planned larger cohort. Another social media campaign was conducted, and all women who were previously excluded based on their neighborhood's median income were invited to participate.

Between May 2022 and July 2022, 71 (21%) more women registered for the study, adding up to the total of 337 registrations. Registration was closed after no new women registered for 2 weeks. From May onward, 31 participants were included, adding up to a total of 47 inclusions, of which 39 (83%) completed the intervention and 8 (17%) dropped out. Of these 8, 3 (37.5%) women who provided informed consent did not respond to instructions on how to install the app or attempts to reach them; 2 (25%) women were unable to install the app: in one case, an iPhone with Belgian settings preventing download from the Dutch Apple Store, and in the other case, the woman who had an Android device was scared by the warning prompted by download of an app outside of Google Play Store. Of the 3 (37.5%) remaining dropouts, 2 (25%) stopped trying to become pregnant and 1 (12.5%) found the questionnaires too burdensome. Table S1 in [Multimedia Appendix 5](#) provides an overview of the eligibility, inclusion, and intervention completion percentages.

PCC Consultations

A total of 17 (43.6%) of 39 participants registered for a PCC consultation, and 16 (41%) consultations were conducted by 9

midwifery practices. One consultation was performed via telehealth by the first author because the midwife chosen by the participant had no experience in providing PCC and did not wish to implement PCC in her practice. The participant who registered for PCC but did not attend a consultation was worried about her health care insurance not covering the costs. Stating to feel overwhelmed, she declined additional support as well as a free telehealth consultation.

The most often reported reason to register for a PCC consultation was to obtain more personalized information (14/17, 82.4%), followed by being curious about what a consultation entails in practice (6/17, 35.3%). The most frequent reason not to register for a consultation was simply not being interested in doing so (6/22, 27.3%). A visual overview of participants' motivation regarding registration for PCC can be found in Figures S7 and S8 in [Multimedia Appendix 6](#).

All participants who visited a PCC consultation agreed that registering through Pregnant Faster is easy (2/16, 12.5%, agree; 14/16, 87.5%, strongly agree) and were glad they had done so (3/16, 18.7%, agree; 13/16, 81.3%, strongly agree).

Coins and Rewards

During the study, participants could earn a maximum amount of 468 coins. Together, they earned a total of 11,791 coins (mean 284, SD 109 per participant; median 276, IQR 221-358; range 79-443). In total, 344 rewards were ordered during the study period (mean 8, SD 6 per participant; median 7, IQR 3-12; range 0-22). One participant did not wish to order rewards because she was happy with "just the app." She stated that she did not feel it was morally objectionable to be rewarded but just that she was not interested in receiving rewards.

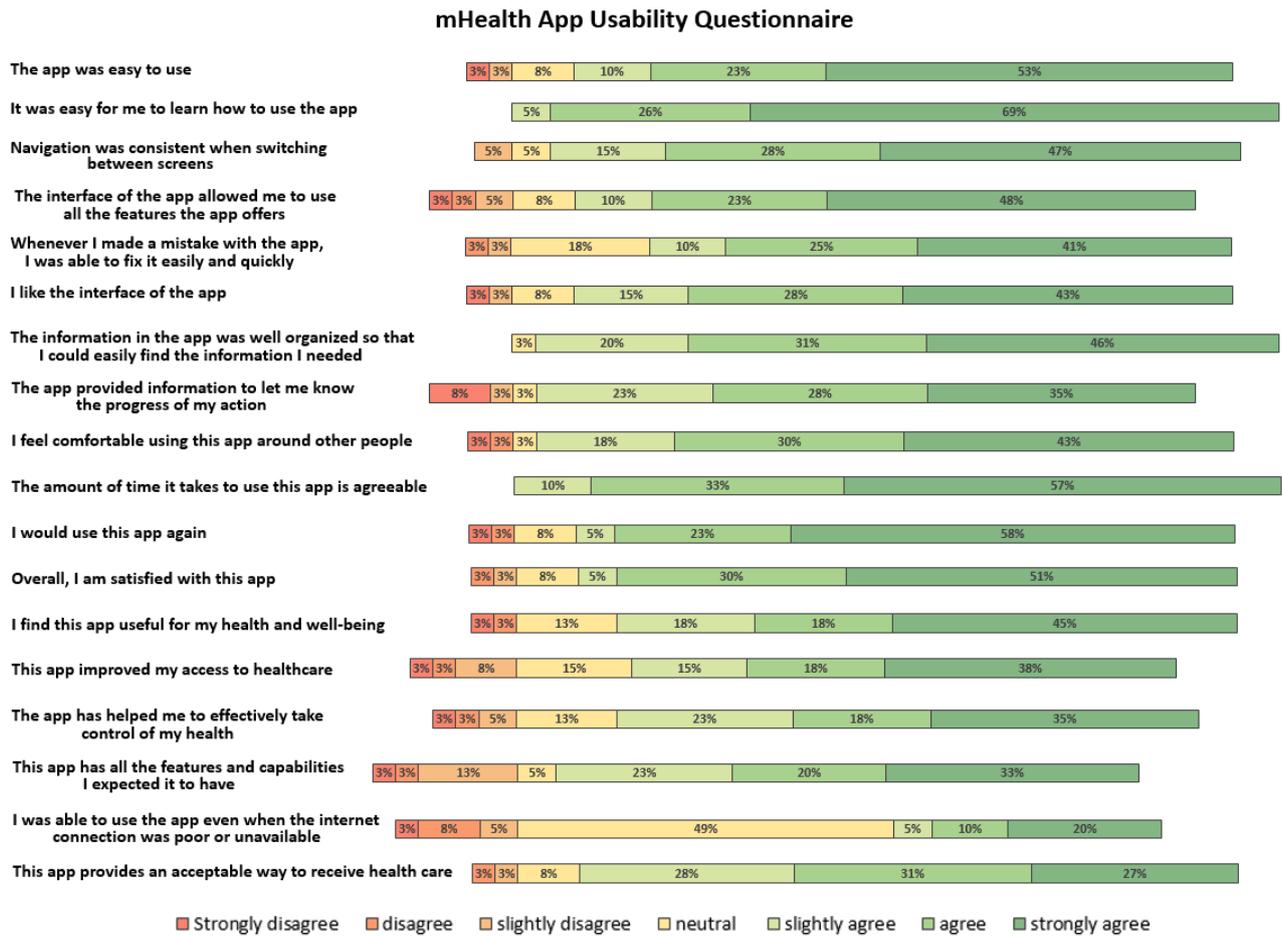

The most popular reward was a €10 (US \$10) book voucher, with 19 (48.7%) of 39 participants ordering the voucher at least once. The second-most popular reward was fruit, with 17 (43.6%) participants ordering fruit at least once and a total of 87 orders (87/344, 25.3%). Bananas were the most popular fruit, amounting to 32 (36.8%) of 87 fruit orders. The third-most popular reward was a set of 2 home pregnancy tests, with 16 (41%) participants ordering this reward at least once. Most participants ordered a reward more than once, displaying their personal preferences and satisfaction regarding their previous order. Table S2 in [Multimedia Appendix 5](#) displays all rewards and their order frequency and percentage.

Feasibility From Users' Point of View

mHealth App Usability Questionnaire

[Figure 5](#) displays the results of the MAUQ. The participants deemed Pregnant Faster's usability satisfying, with the majority of participants agreeing with 16 (88.9%) of 18 statements. With regard to the remaining 2 statements, all participants (N=39, 100%) agreed that the amount of time the app takes is agreeable, and 19 (48.7%) were neutral about being able to use the app with a poor internet connection, indicating they may not have experienced connectivity problems.

Figure 5. Results of the MAUQ. MAUQ: mHealth App Usability Questionnaire; mHealth: mobile health.

Experience Questionnaire

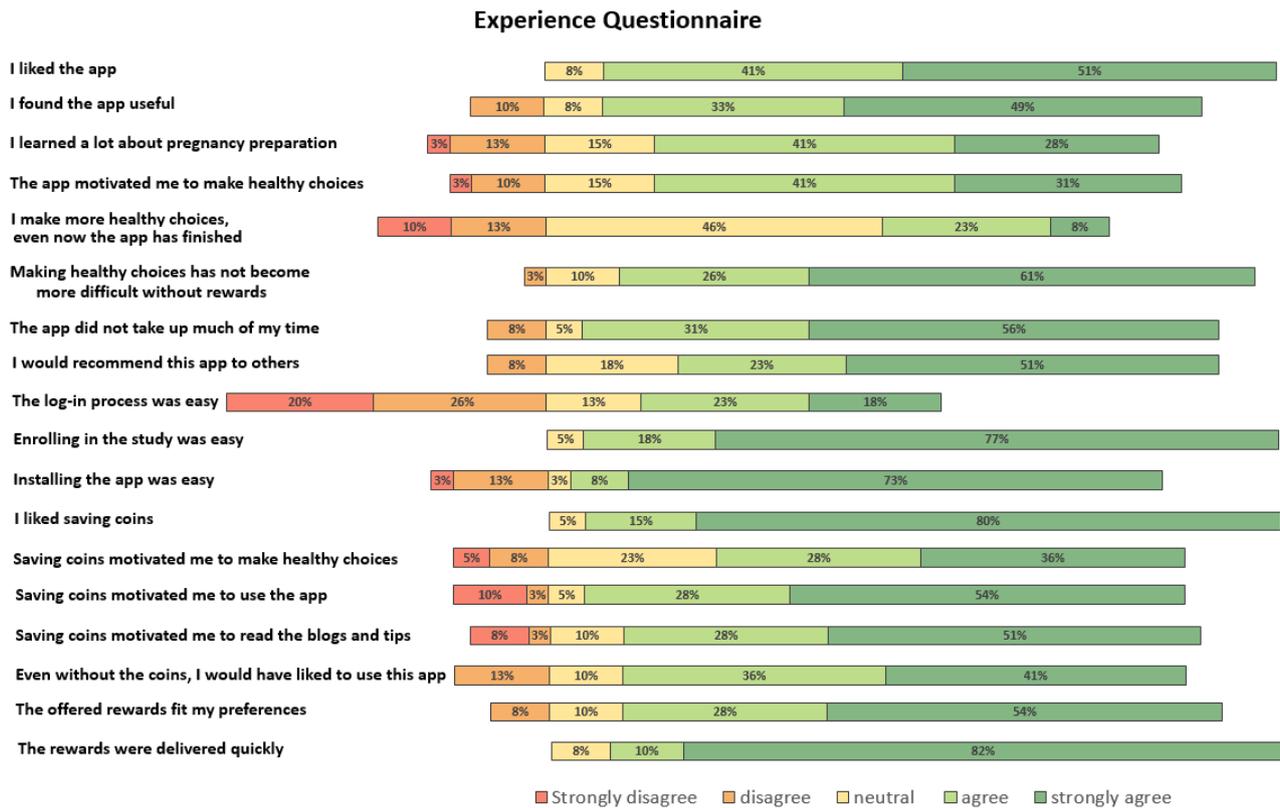

Figure 6 displays the results of the ExQ for which the 5-point Likert scale was used. The majority of participants agreed with 16 (88.9%) of 18 statements, conveying high user satisfaction. Regarding the log-in process, 16 (41%) of 39 participants agreed and 18 (46.2%) disagreed that it is easy, with 5 (12.8%) being neutral. In addition, 12 (30.8%) participants agreed and 9 (23.1%) disagreed with the statement regarding participants making more healthy choices after finishing the intervention. The remaining 18 (46.2%) participants were neutral.

The majority of participants stated that they used the app daily (n=18, 46.2%) or every other day (n=18, 46.2%). Most participants (n=31, 79.5%) reported to have logged in less often than they would have wanted to, the foremost reason being the requirement to log in with an email and password each time

(n=14, 35.9%). Overall, participants rated Pregnant Faster 7.7 out of 10, with 10 being the best rating (mean 7.7, SD 1.0; median 8, IQR 7-8; range 5-9). Multimedia Appendix 6 contains Figures S9-S11, which provide additional results for the ExQ multiple-choice questions.

In the ExQ, participants were given the option to provide additional comments. It was notable that 8 (20.5%) participants commented that they would have liked push notifications to remind them of filling in the daily questionnaire and reading new blogs and tips. One participant recommended personalized notification settings so they would best fit her wishes regarding the subject, timing, and frequency. Furthermore, 3 (7.7%) participants commented that they would like the app to focus on their partners as well, hoping to actively involve them more in preparing for pregnancy.

Figure 6. Results of the ExQ. ExQ: Experience Questionnaire.

Feasibility From Researchers' Point of View

During the study, 11 issues were noted that should be considered before attempting to establish Pregnant Faster's (cost-)effectiveness in a larger cohort study:

- A time gap between the start of recruitment and intervention led to a significant loss of eligible participants and should be prevented.
- Limiting the study population to a local area greatly impedes inclusion rates and causes disappointment in otherwise eligible participants, which may harm the intervention's reputation.
- Using a combination of the neighborhood median income and a low-to-intermediate educational level as a proxy of low SES is not a suitable method to recruit large numbers of women with a VHS.
- Manual selection and inclusion require a significant amount of labor for which multiple researchers have to be available. The same goes for approaching individual midwifery practices for collaboration.
- Use of a classic, relatively complicated information folder and informed consent form can be overwhelming and does not lead to proper understanding of the study nor true consent.
- For participants with Android devices, installation of the app is complicated by not providing the app through the Google Play Store. Additional support is often needed.
- Fruit sent through the postal service often arrive bruised, requiring frequent checks for whether the reward is delivered in good condition, offering refunds when this is not the case. Failed deliveries result in the return of rotten

fruit to the researchers. Since fruit is a popular, healthy reward, a suitable alternative should be considered, such as a voucher.

- Sending rewards daily is laborious. During this pilot, we experimented with a frequency of twice per week, clearly communicating this to participants. Afterward, no dissatisfaction regarding delivery time was noticed.
- Confirmation of PCC consultations requires the researchers to contact midwifery practices, causing a delay in coin allocation, possibly negatively impacting user satisfaction and effectiveness of the reward. Relying on participants self-reporting their visit in the app, combined with automatic coin allocation, should be considered.
- Manually keeping track of booked and confirmed consultations, in addition to manual coin allocation, requires a significant amount of time. For this reason as well, self-reporting should be considered.
- Asking participants to fill in 2 separate questionnaires causes confusion and diminishes the likeliness of completing the evaluation. It is advisable to evaluate user experiences in a succinct manner.

Discussion

Principal Findings

In this pilot study, we aimed to determine the feasibility of the app-based nudge Pregnant Faster, which is designed to fit the needs of women with a low SES and a high likelihood of having a VHS, who have a higher risk of adverse pregnancy outcomes. The aim of Pregnant Faster is to encourage these women by nudging them to adequately prepare for pregnancy through

education by making healthy lifestyle choices and engaging in PCC, which will help improve their pregnancy outcomes.

Pregnant Faster has shown to be feasible from the users' point of view, showing high user satisfaction with a rating of 7.7/10 and PCC uptake by 16 (41%) of 39 participants. Notably, 27 (69.2%) participants stated to have learned a lot about pregnancy preparation and 28 (71.7%) felt motivated by the app to make healthy lifestyle choices. After the intervention ended, 12 (30.8%) participants stated that they more often make healthy choices than prior to using Pregnant Faster.

With regard to the 55 (53.9%) of 102 eligible participants who did not respond when inclusion commenced after the 2-month delay, we suspect that a loss of interest and perhaps of trust in the intervention played a role. The amount of lost eligible women suggests that time is a limiting factor, impacting women's willingness to participate in the intervention. This emphasizes the necessity of quickly responding to their willingness to participate and acceptance of offered care.

Feasibility from the researchers' point of view was satisfactory as well but only with regard to practical conduction, as adjustments to the inclusion criteria were made to up the number of inclusions. Dropping the criterion of living in a deprived neighborhood likely impacted the chance of including women who actually have a VHS. The feasibility of Pregnant Faster from the researchers' point of view can be improved by developing a new method of finding the target group, making the app available via both Apple App Store and Google Play Store, and automating (parts of) the inclusion process and coin allocation, which will limit the number of administrative tasks.

Strengths and Limitations

To the best of our knowledge, Pregnant Faster is the first mHealth intervention that aims to encourage adequate pregnancy preparation and increase the uptake of PCC, promoting blended lifestyle care, by nudging participants with a loyalty program consisting of earning and spending coins. During study conduction and after evaluation, important knowledge was gained concerning the strengths and limitations of this intervention and how best to proceed with a larger cohort study.

Despite our earlier experiences regarding the recruitment of women who likely have a VHS, we did not manage to conduct this study adhering to the original inclusion criteria [28]. It is possible, therefore, that the user feasibility would have been different had the full study population met the intended criteria.

Pregnant Faster has been designed through iterative cocreation, actively involving the target population in its development [28]. Even though adjustments were made, we consider this pilot study to be another step in the iterative cocreation process, as the results will be used for further development of the app and nearly half (19/39, 48.7%) of the study population met the criteria of living in a deprived neighborhood.

Further Development and Future Research

The insights gained through this study have prompted us to re-evaluate which characteristics to use as a proxy for a low SES and the associated VHS. To improve recruitment of the target group, we have hosted meetings with health care

professionals specializing in health-related vulnerability and adverse pregnancy outcomes to gain more insight and develop new inclusion criteria for a larger cohort study. At this moment, we are researching (combinations of) different inclusion criteria based on self-reported vulnerability markers, such as high stress; financial insecurity; addiction to alcohol, drugs, and tobacco; and lack of social support, which are also associated with unfavorable health outcomes [36]. Through developing these new criteria, we aim to be more inclusive and provide support to all women with a certain degree of health-related vulnerability, instead of limiting support to those with a high likelihood of having a VHS based on the educational level and neighborhood deprivation.

We aim to continue promoting Pregnant Faster on social media platforms, such as Instagram and YouTube. These platforms have been known to use algorithms that successfully reach target audiences and prove to be effective tools with regard to providing people with support and education [37,38]. Using these platforms, therefore, will not only support recruitment and benefit the target population but also allow Pregnant Faster to contribute to pregnancy-related health in the general population.

The knowledge gained through this pilot study has inspired us to research different methods of information transfer to ensure the app fits the needs of the target group and improve Pregnant Faster's accessibility for those who experience limited literacy [39]. For the planned cohort study, for example, we have created an audio version and infographic of the patient information folder and informed consent form. Furthermore, we are currently creating additional content for the app, again focusing on multiple methods of information transfer, such as podcasts, videos, and infographics.

On a technical level, the inclusion process and content management system will be adjusted to reduce manual tasks and promote feasibility. Furthermore, we plan to change the log-in procedure to a pin code or fingerprint and enhance the app with daily notifications.

Regarding focusing more on participants' partners, we have chosen to not adhere to this suggestion at the current time, as the tips and blogs already contain information for partners and we are still in the process of establishing (cost-)effectiveness and further developing Pregnant Faster. In research concerning reproductive health, it is known that partners may sometimes take on a more passive role [40], which places the burden of preparing for pregnancy largely on the person who will carry the baby. For future development, therefore, we will consider the possibility of adding personalized settings to allow users to fill in characteristics that will adjust the app's content accordingly, such as relationship status, gender and sexual orientation, and, if applicable, gestational age and the use of donor semen.

In the future, we wish to investigate the possibility of offering Pregnant Faster to all who wish to become pregnant, possibly with rewards if cost-effectiveness is established.

Conclusion

With this pilot study, we have demonstrated that the app-based nudge Pregnant Faster provides a feasible way to stimulate the uptake of PCC and boost participants' motivation to adequately prepare for pregnancy. We will use the knowledge we have

gained through this pilot study to create an updated version of the app, which will be named Pregnant Faster 2. Our next step consists of determining the (cost-)effectiveness of Pregnant Faster 2, for which we will conduct a cohort study of 400 women with a VHS based on newly devised inclusion criteria.

Acknowledgments

This research was funded by ZonMw (ZorgOnderzoek Nederland en het gebied van Medische wetenschappen, health care research in the Netherlands and the field of medical sciences; grant number 543003103). We would like to thank all women who registered for this study and especially those who participated in it. Additionally, we would like to thank all midwifery practices who performed or were willing to perform PCC consultations for this study; Anneroo van der Zande, who helped continue the inclusion process and app development during the first author's maternity leave; and Maaik Stif, owner of EAT.PEASY!, who sponsored this intervention by providing vegan meals as a reward. Lastly, we thank Djanifa da Conceicao, midwife, influencer, and owner of Verlosmoeder, who contributed greatly to our inclusion process. The table-of-content image was provided by Keira Burton via Pexels.

Data Availability

The data sets used in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

RST conceived the study and gained funding. RST, SS, and BB initiated the study design. SS wrote the original draft, and BB, HIM, MS, and RST reviewed and edited the original draft. BB, RST, HIM, and MS supervised the study. All authors have contributed to refinement of the study protocol and approved the final manuscript.

Conflicts of Interest

RST is initiator and developer of the mobile health (mHealth) app Smarter Pregnancy and the ZonMw project "A Loyalty Program to Motivate Vulnerable Women to Engage in Preconception Care: From Voucher to Tablet" (reference number 543003103). Other authors declare that they have no competing interests. The funder had no role in the design of the study, the writing of the manuscript, or the decision to publish the protocol.

Abstract

Background: Cigarette smoking remains one of the leading causes of preventable death worldwide. A worldwide study by the World Health Organization concluded that more than 8 million people die every year from smoking, tobacco consumption, and secondhand smoke. The most effective tobacco cessation programs require personalized human intervention combined with costly pharmaceutical supplementation, making them unaffordable or inaccessible to most tobacco users. Thus, digital interventions offer a promising alternative to these traditional methods. However, the leading smartphone apps available in the market today have either not been studied in a clinical setting or are unable to match the smoking cessation success rates of their expensive offline counterparts. We would like to understand whether QuitSure, a novel smoking cessation app built by Rapidkart Online Private Limited, is able to bridge this efficacy gap and deliver affordable and effective smoking cessation at scale.

Objective: Our objective was to do an initial exploration into the engagement, efficacy, and safety of QuitSure based on the self-reported experiences of its users. Outcomes measured were program completion, the effect of program completion on smoking behavior, including self-reported cessation outcomes, and negative health events from using the app.

Methods: All QuitSure registered users who created their accounts on the QuitSure app between April 1, 2021, and February 28, 2022, were sent an anonymized web-based survey. The survey results were added to their engagement data on the app to evaluate the feasibility and efficacy of the app as a smoking cessation intervention. The data were analyzed using descriptive statistics (frequencies and percentages) and the χ^2 test of independence.

Results: In total, 1299 users who had completed the QuitSure program submitted the survey and satisfied the inclusion criteria of the study. Of these, 1286 participants had completed the program more than 30 days before filling out the survey, and 1040 (80.1%, 95% CI 79.1%-82.6%) of them had maintained prolonged abstinence for at least 30 days after program completion. A majority of participants (770/891, 86.4%) who were still maintaining abstinence at the time of submitting the survey did not experience any severe nicotine withdrawal symptoms, while 41.9% (373/891) experienced no mild withdrawal symptoms either. Smoking quantity prior to completing the program significantly affected quit rates ($P < .001$), with heavy smokers (>20 cigarettes per day) having a lower 30-day prolonged abstinence rate (relative risk=0.91; 95% CI 90.0%-96.2%) compared to lighter smokers. No additional adverse events outside of known nicotine withdrawal symptoms were reported.

Conclusions: The nature of web-based surveys and cohort selection allows for extensive unknown biases. However, the efficacy rates of survey respondents who completed the program were high and provide a case for further investigation in the form of randomized controlled trials on the QuitSure tobacco cessation program.

Introduction

Background

Cigarette smoking remains one of the leading causes of many premature deaths worldwide [1]. According to the World Health Organization (WHO), more than 8 million people around the world die every year, either directly or indirectly (via secondhand smoke), because of tobacco consumption. Hence, the WHO [2] has identified the tobacco epidemic as one of the world's biggest public health threats. Beyond the burden of mortality lies the burden of disease as a result of tobacco consumption. For every 1 individual who dies because of smoking, at least 30 live with a serious illness caused by smoking. Smoking causes many health issues, such as cardiovascular diseases, chronic obstructive pulmonary disease, and 12 types of cancer [3]. More than 67% of smokers face debilitating, and eventually fatal, health issues at some point in their smoking lives [4]. Health risks, as well as death risks for smokers compared to nonsmokers, have worsened, due to the deadly spread of COVID-19 across the world [5]. Meanwhile, the economic costs attributable to smoking and exposure to tobacco smoke globally have been estimated to be US \$1436 per smoker, which is equivalent to around 1.8% of the world's gross domestic product [3,6].

In 2015, 68% (22.7 million) of adult smokers said that they wanted to quit smoking. In 2018, 55.1% (21.5 million) of adult smokers said that they had made a quit attempt in the past year. In 2020, 62.5% of youths (middle and high school students) who currently used tobacco products wished to quit all tobacco products, and 65.4% of youths who currently used tobacco products reported that they had stopped using all tobacco products for 1 day or longer in the past year because they were trying to quit [7]. But on the other side of the coin, a report by the National Institute of Cancer, United States [8], found that in 2020, of the 53.9% of smokers who attempted to quit smoking, only 8.5% of them were successful in doing so. In fact, research has found that it takes about 30 quitting attempts for a smoker to successfully quit [9]. The WHO, in 2022, said that without cessation support, only 4% of smokers will be able to successfully quit.

Smoking Cessation

There are several smoking cessation methods available across the world, including unassisted methods, nicotine replacement therapy (NRT), prescribed medicine (bupropion or varenicline) use, behavioral counseling, quitlines, and the use of mobile apps and websites for smoking cessation [10]. Financial incentives have gained popularity as a cessation method recently [11]. NRT, like nicotine patches, gums, and nasal sprays; medications such as bupropion and varenicline; and nonpharmacological interventions [12] are the most common smoking cessation interventions. However, NRT has shown to have success rates of only 6%-8% [13], while pharmacological interventions, despite their somewhat higher success rates of 14%-20% [14],

come with the risk of side effects such as skin irritation or more serious seizures and are also very expensive [15]. Combined interventions for smokers such as behavioral interventions and long-term assistance or social support are most effective when it comes to smoking cessation [15]. However, they tend to be expensive, highly variable depending on the quality of each individual provider, accessible to only small hyperlocal communities, and cannot be scaled up to achieve population-level impact.

Smartphone Apps for Smoking Cessation

In response to the COVID-19 pandemic, the rate of smoking cessation increased from 23% to 31% [16], which creates the opportunity to encourage and support smokers to quit smoking through different smoking cessation methods. Unconventional methods such as smartphone-based apps can be more useful to increase the odds of quitting success over conventional methods because smartphone use is highly prevalent, is available 24-7, is cost-effective, requires zero-minimal human intervention, and can provide instant and constant support. Seo et al [17] found a total of 603 apps designed for smoking cessation that were available in the US, UK, Australian, and Asian markets [17]. Apps designed for smoking cessation have been downloaded 33 million times globally according to a study done by SensorTower in April 2020 (Nelson, SensorTower.com, personal communication, April 15, 2020). Users who have high engagement with smoking cessation apps have been found to be more likely to be successful in quitting [18,19].

However, literature reviews suggest that only a few apps follow the guidelines for treating tobacco dependence, and most apps use only very simple tools like calculators (41%), calendars (36%), trackers (18%), hypnosis apps (21%), and distractors (10%) [20,21]. According to the WHO, any primary care provider needs to follow the 5As (ask, advise, assess, assist, and arrange) to help a tobacco user [22]. One content analysis study suggested that 96% of the cessation apps addressed "assist" but less frequently addressed the other 4 As [21]. Another review demonstrated that only 11 (6.1%) of the 180 smoking cessation apps available in 2022 have any scientific support [23]. The review also discovered that very few apps offered evidence-based interventions such as mindfulness (18%) or cognitive behavioral therapy (CBT; 2.2%). Other reviews indicated that 88.46% of smoking cessation apps have not been updated by the developers in over a year, and 33.67% of apps have low acceptance by the market with <10,000 downloads [17,21]. Thus, the development of additional smartphone apps that have good user acceptance and are using empirically supported behavior change techniques to deliver smoking cessation interventions appears to be warranted.

The QuitSure Smoking Cessation Program

The QuitSure program (Rapidkart Online Private Limited) has been identified as one such program, which incorporates behavior change techniques like positive psychology, CBT, and mindfulness that have been shown to be effective in smoking

cessation interventions [22,24], and is customized to the smoking habits and psychological needs of the user. It does not include or recommend the use of any pharmaceutical interventions, like oral supplements, medications, or NRTs.

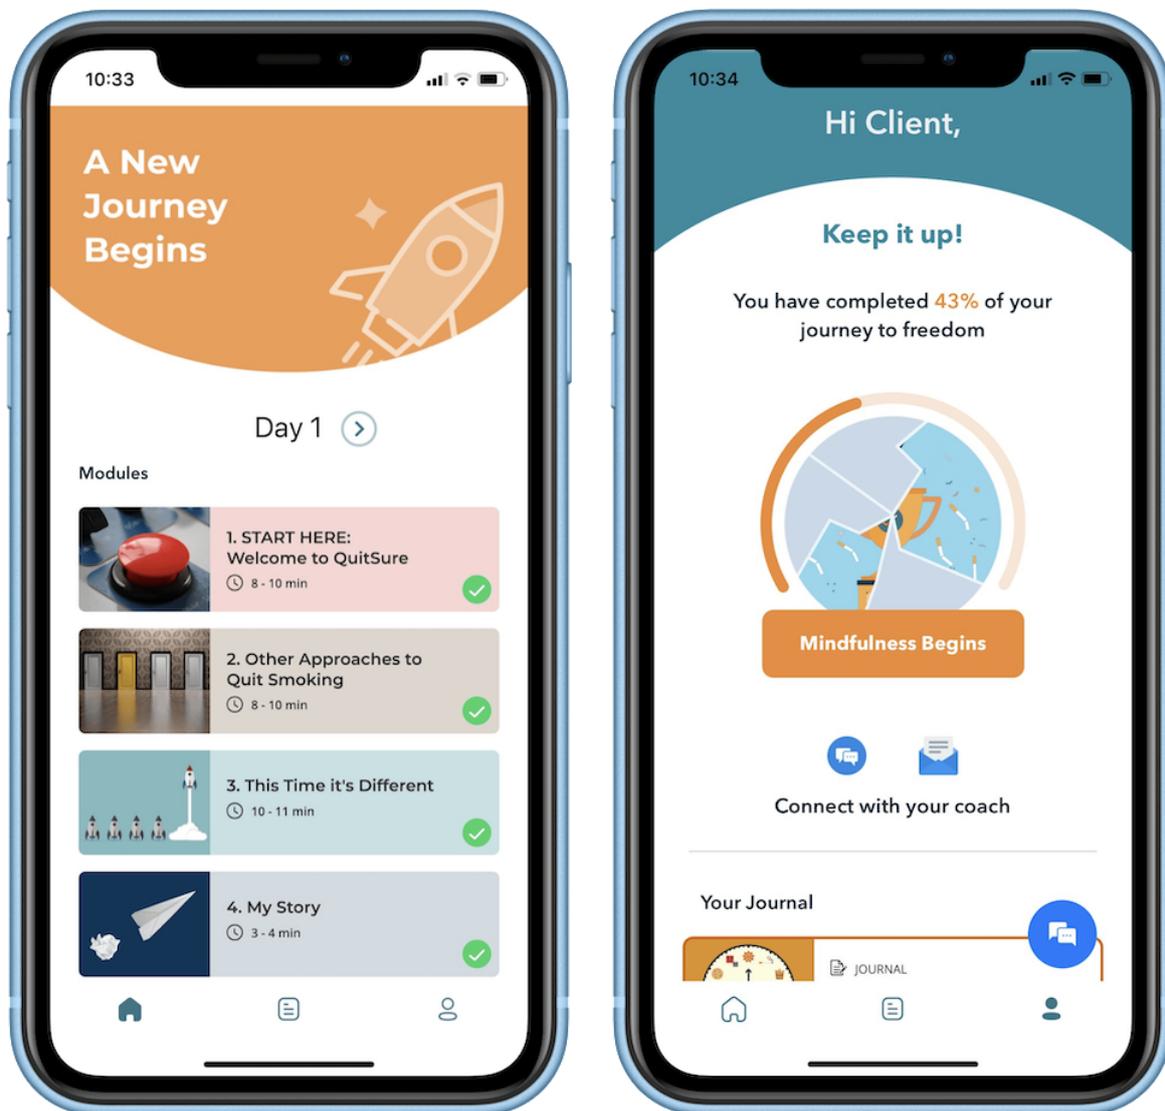

The program follows the 5As recommended by the WHO [22]: it first asks the users about their smoking history such as quantity, patterns, past quitting attempts, and relapse reasons. This also helps the user internalize their smoking behavior. Then, it assesses if they are ready to quit and asks them about their inhibitions to quit. Unless it is a medical condition, it then advises in a clear, strong manner to quit smoking alongside a summary of the program and how it actually works. After understanding the program, willing users are then progressed to the next level, where the app provides the main content on psychology, CBT, and mindfulness [24].

CBT is incorporated by helping users question their beliefs around the positive aspects of smoking and remove them. The app does not demand any lifestyle modification. It simply helps the user accept their smoking triggers and change their response

to these triggers. Under mindfulness, the app provides video exercises to teach users how to smoke mindfully by focusing on every aspect of the smoking experience. This exposes to the user the real effects of cigarettes, both while smoking and after, on their bodies and minds. All the content is delivered using empathy and without administering any guilt or blame to the user to keep the user's mind in a more calm and receptive state.

Users are required to complete the program in a very specific way with a predefined sequence of content and video exercises as shown in the screenshot of the home page in Figure 1 (left). The program requires around 6-10 hours over 6-12 days to complete. During the whole process, the app has a structured, digital journal for users to record their quitting journey and 24x7 chat-based support from trained counselors for users who have additional questions or concerns that are not addressed by the program itself as shown in Figure 1 (right). Once the user has completed the program and quit smoking, the app has postquit tools and chat support available to prevent them from relapsing. Around 12.3% (4124/33,458) of all users reach out to the counselors for support during and after the program.

Figure 1. Screenshots of the home page (left) and profile page (right) of the QuitSure app.

The program is priced at US \$10 and should be affordable to most daily smokers, as the average global retail price of a pack of 20 cigarettes is approximately US \$5 [25,26]. Users only have to pay on day 2 of the 6-day program. This is done, so they can understand how the program is structured and what techniques it uses before committing to it. At the end of the program, users are asked to perform a guided smoking exercise where they smoke their last cigarette and then quit cold turkey. The timestamp when they mark having performed this exercise in the app is considered as their quit date and as their program completion date. The QuitSure app has been updated an average of once every 3 weeks since its launch.

In this paper, we report the results of a retrospective cross-sectional study on users who completed the program between April 1, 2021, and February 28, 2022. Participants who started the QuitSure program but then dropped out before completing it were also surveyed to evaluate the potential areas of improvement for QuitSure. The aim of this study is to evaluate the effectiveness of the QuitSure smoking cessation program to enable smoking cessation among daily smokers. We will also examine the program's usability, feasibility, and acceptance by the market.

Methods

Design

This was a retrospective cross-sectional study to understand, through a web-based survey, smoking cessation outcomes of users who completed the QuitSure program via the QuitSure smartphone app. The survey was conducted in April 2022.

Recruitment

Users who downloaded and registered for the QuitSure quit smoking app between dates April 1, 2021, and February 28, 2022, and satisfied all the following inclusion criteria were sent the web surveys.

The study included (1) users who were daily smokers as defined by the US Centers for Disease Control and Prevention—smoked at least 1 cigarette per day before they did the program and had smoked at least 100 cigarettes before doing the program [6]; (2) adults aged 18 years and older (self-reported); (3) users who were, at minimum, proficient in the English language (since the program content is solely available in English); (4) users who had completed the entire QuitSure program; (5) and users who had a valid email address.

All registered users of the QuitSure app give consent to be contacted for the purpose of research studies at the time of registration.

Web-Based Survey

The surveys were created on the web-based Jotform tool built by Jotform Inc. The forms were set up with Jotform's Health Insurance Portability and Accountability Act (HIPAA) compliant mode, and no personally identifiable data were collected, thus protecting the confidentiality and privacy of the participants. The survey details have been reported in accordance with the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) guidelines [27].

The survey was sent via an automated email from the QuitSure server to all users who fit the inclusion criteria. The email included the relevant details for participation in the study, including the length of the survey, the aim of the study, benefits for the participant, as well as the link to the survey itself. They were encouraged to contact the investigators if they had any questions or concerns. Participation in the survey was voluntary. Participants were granted entry into a lucky draw for a US \$50 Amazon voucher. This amount was chosen as being 5 times the price of the QuitSure program, and the email specified that winning the US \$50 voucher did not depend on whether their experience with the QuitSure program was positive or negative.

To prevent duplication of data, each email included a hidden, unique, non-personally identifiable ID number that appeared in the survey results. For duplicate submissions, the more recent entry was kept. All questions seen by the participant, depending on the conditions, were mandatory. As a result, incomplete surveys were not recorded or used for analysis. No statistical correction methods, such as weighting of items or propensity scores, were applied to adjust for sample nonrepresentativeness.

The first part of the survey confirmed the participants' demographic data and satisfaction of the inclusion criteria. It also explicitly requested informed consent for participation in the study. Participants were shown the remaining sections in the survey only if they consented to participate in the study and met the inclusion criteria defined earlier. The second and third parts of each survey are described in the individual sections below. Prior to launching the survey, we conducted usability and technical functionality testing to ensure that participants could easily navigate and complete the electronic questionnaire. In both surveys, the questions were primarily multiple choice, with the rest requiring integer number entries. All multiple choice questions included the option for free-form "other" entries as well as the option for "none" or "choose not to share" as relevant for that question.

Survey for Program Completers

This survey, referred to as S-Completers, was sent to all users who satisfied the inclusion criteria and had also completed the QuitSure program on the QuitSure app as defined in the introduction. The second section of this survey identified the participants' smoking history, including the outcome of their completion of the QuitSure program. The third section was conditional. Each participant saw a different set of questions depending on their smoking cessation or reduction or relapse outcome after program completion. The number of questions in each section ranged from 4 to 9 depending on the responses of the participant.

Survey for Noncompleters of the Program

This survey, referred to as the S-Incompleters survey, was sent to all users who satisfied the inclusion criteria and who had started the program, but then not completed it, to get a qualitative understanding of the feasibility of the program at scale. The S-Incompleters survey also took the participants' explicit consent for participation in the study and the same demographic data and smoking history questions. The rest of the survey was to understand their reasons for leaving the

program midway. The number of questions in each section ranged from 4 to 9 depending on the responses of the participant. The copy of both survey questionnaires is provided in [Multimedia Appendices 1 and 2](#).

Study Variables

The data collected in the first part of both surveys included demographic information about the participants including gender, age, country of residence, and English proficiency. The second part of both surveys, regarding smoking history and behavior, asked what forms they consumed nicotine in before doing the program, how much and how long they had smoked, and whether they had previously tried to quit smoking using other methods. Those who had completed the QuitSure program were asked for the outcome of their most recent attempt at doing the QuitSure program and if they used any other quit smoking tools, programs, or medications or supplements during or after doing the QuitSure program.

The questions in the third part of the S-Completers survey were dependent on their outcome of doing the QuitSure program. Those who were able to quit 100% since completing the program were asked whether they experienced any mild or severe withdrawal symptoms and weight gain. They were also asked for their current level of cravings to smoke via a Likert scale ranging from 1=none to 5=unbearable. Those who quit for some time, but then relapsed, were asked how long they were able to stay quit and their reasons for relapse. Those who were only able to cut down their smoking level were asked for their new smoking rates and the reasons the program did not help them quit completely. Finally, those for whom the program had no impact, were asked why the program did not work for them. All participants who said they are still smoking were asked their current level of motivation to quit smoking on the Likert scale and whether they would use QuitSure again for their next quitting attempt.

The S-Incompleters survey asked participants why they did not complete the program and whether they were able to quit using a different method since. If they have quit since, then how they quit and what their level of cravings to smoke is. If not, then what their level of motivation to quit is and whether they will use QuitSure as their method of choice.

Ethical Considerations

This study was approved by the institutional review board of the University of California, San Francisco (IRB 21-35619, reference 331340). The email sent to the users described the study's aims and procedures as well as the security and confidentiality of their data. It also clearly stated that participation was voluntary, and they could decline to

participate. The participants were given a consent form with all the details of the study including the purpose of the study. Participants younger than 18 years were not included in the study. The study observed data protection laws in effect at the time it was conducted. Participants were entered in a lucky draw to win a US \$50 gift voucher for Amazon.

Statistical Analysis

Data were collected from 1299 participants from over 25 countries. The survey responses were available in Microsoft Excel (Microsoft Corp) format. The data analysis tools used were descriptive statistics (frequencies and percentages), pivot tables, as well as chi-square tests of independence.

Results

Survey for Program Completers

Of the 13,585 users who were sent the S-Completers survey email, 853 (6.3%) emails bounced. Of the 12,732 delivered emails, 5365 (42.1%) were opened. QuitSure or smoking was not mentioned in the sender or subject lines of the emails, only in the body of the email, to reduce bias based on user perception of the QuitSure program before opening the email. Therefore, we will use this number of email openers as the baseline number of users who were aware of this study. In total, 1906 (35.5%) of those who opened the email clicked on the survey link, and a final 1332 (24.8%) email openers consented to participate in the study and completed the survey. These values are all either equal to or greater than the expected opening (21.5%) and click (8%) rates based on global industry standards [28,29]. Of this set of submitters, 11 were excluded for completing the program in less than 7 days before submitting the survey. An additional 22 were excluded for submitting false data that were significantly different from actual app engagement. A final set of 1299 participants were included in the data analysis for the study. App engagement and preprogram smoking behavior data were not significantly different between those who filled out the survey versus those who did not. A flowchart representing the participant funnel for the S-Completers survey is available in [Multimedia Appendix 3](#).

[Table 1](#) shows the baseline characteristics of the participants, while [Multimedia Appendix 4](#) shows their global distribution. The ratio of male to female participants was found to be 1 to 1.17. The most common age range of participants was found to be 25-34 years (n=431, 33.2%). In total, 97.2% (n=1262) of participants were cigarette smokers, while the remaining 2.6% (n=37) only consumed other forms of nicotine. Five countries, the United States, the United Kingdom, India, Canada, and Australia, had 71.8% (n=933) of the participants.

Table 1. Demographic details of participants.

	Male participants (n=587)	Female participants (n=699)	Others (n=13)	All (N=1299)
Age (years), mean (SD) ^a	35.8 (11.74)	41.83 (12.55)	27.11 (6.82)	39.5 (12.56)
Cigarettes smoked per day, mean (SD)	12.57 (8.02)	14.57 (8.56)	13.30 (5.51)	13.66 (8.83)
Median (IQR; smoking category)	10 (7-20; light)	14 (10-20; average)	13 (10-18; average)	12 (8-20; average)
Years smoked, mean (SD)	15.28 (11.40)	21.13 (12.87)	10.15 (9.69)	18.59 (12.62)
Smoking categories (cigarettes per day), n (%)				
Very light (<5)	75 (12.8)	47 (6.7)	0 (0)	122 (9.4)
Light (5-10)	119 (20.2)	109 (15.6)	3 (25)	231 (17.8)
Average (11-20)	233 (39.6)	301 (43.1)	8 (61.5)	542 (41.7)
Heavy (>20)	160 (27.2)	242 (34.6)	2 (15.4)	404 (31.1)

^aTo calculate the mean, the midpoints of each age group were considered (calculated as upper limit+lower limit/2, ie, 25+35/2 and so on).

Smoking behavior of participants prior to doing the program was grouped into 4 categories as very light (<5 cigarettes per day), light (5-10 cigarettes per day), average (11-20 cigarettes per day), and heavy (>20 cigarettes per day) [30]. The participants smoked an average of 13.66 (SD 8.83) cigarettes per day.

Effectiveness of the Smartphone App for Smoking Cessation

Participants were divided into 4 overlapping subsets based on the duration between completing the program and submitting the survey. The 4 durations chosen were 7 days, 30 days, 3

months, and 6 months, which are the commonly used smoking cessation milestones [31]. Table 2 shows the self-reported outcome of completing the program for each of these groups. Overall, 88% (1144/1299), 80.9% (1040/1286), 82.4% (991/1203), and 72.4% (725/1002) of participants had maintained prolonged abstinence for 7 days, 30 days, 3 months, and 6 months, respectively. In total, 35 of the 1203 (2.9%) participants were able to cut down on their smoking level in 30 days after the completion of the program, and 19 of the 1002 (1.9%) were able to sustain it for over 6 months after program completion.

Table 2. Prolonged abstinence after program completion.

	Participants with 7-day prolonged abstinence (1144/1299, 88%)	Participants with 30-day prolonged abstinence (1040/1286, 80.9%)	Participants with 3-month prolonged abstinence (991/1203, 82.4%)	Participants with 6-month prolonged abstinence (725/1002, 72.4%)
OR ^a (95% CI)	1.32 (86.8-89.7)	1.20 (79.4-82.3)	1.39 (80-84.6)	1.43 (69.8-75.8)
Participants by smoking behavior, n/N (%)				
Very light (<5)	107/122 (87.7)	95/121 (78.5)	84/101 (83.2)	57/87 (65.5)
Light (5-10)	209/231 (90.5)	196/228 (86)	183/207 (88.4)	132/173 (76.3)
Average (11-20)	491/542 (90.6)	446/535 (83.4)	405/466 (86.9)	319/425 (75.1)
Heavy (>20)	333/404 (82.4)	301/401 (75.1)	271/340 (79.7)	215/316 (68)
Participants by country, n/N (%)				
United States	351/393 (89.3)	324/388 (83.5)	278/357 (77.9)	242/315 (76.8)
United Kingdom	88/104 (84.6)	73/103 (70.9)	67/97 (69)	56/86 (65)
India	226/266 (84.6)	195/261 (74.7)	158/231 (68.4)	129/200 (64.5)
Canada	78/87 (90)	72/86 (83)	58/75 (77)	51/67 (76)
Australia	68/75 (91)	65/75 (87)	54/67 (81)	50/59 (85)

^aOR: odds ratio.

The participants who were able to quit smoking as a result of the program and had maintained prolonged cessation at the time of filling out the survey (n=891) experienced varying degrees of withdrawal symptoms, as shown in Tables 3 and 4. Overall, 41.9% (n=373) experienced no mild withdrawal symptoms, and

86.4% (n=770) experienced no severe withdrawal symptoms. In total, 41.9% (n=373) experienced no weight gain after quitting with the QuitSure app; 39.6% (n=353) gained less than 5 kg, while 18.5% (n=165) gained more than 5 kg after quitting.

Table 3. Mild withdrawal symptoms reported by participants (n=891).

Symptom	Participants, n (%)
No mild withdrawal symptoms	373 (41.9)
Some mood issues	349 (39.2)
Mild sleep disturbances	196 (22)
Coughing or mild nausea	167 (18.7)
Mild digestive changes	145 (16.3)
Low energy or weakness	143 (16)
Mild headaches	131 (14.7)
Tingling of hands and feet	42 (4.7)
Others	38 (4.3)

Table 4. Severe withdrawal symptoms reported by participants (n=891).

Symptom	Participants, n (%)
No severe withdrawal symptoms	770 (86.4)
Increased depression or anxiety	90 (10.1)
Severe headaches or migraines	23 (2.6)
Severe insomnia	22 (2.5)
Severe dizziness or nausea or weakness	19 (2.1)
Strong chest pain	16 (1.8)
Others	10 (1.1)

Factors Contributing to Success

To assess whether quitting smoking via QuitSure is independent of demographic variables, 2 chi-square tests of independence were conducted as shown in Table 5. The χ^2 value for the impact of gender and age on the efficacy of the program was found to be $\chi^2_2=3.8$ ($P=.09$) and $\chi^2_4=5.9$ ($P=.20$), respectively. This indicates that smoking cessation via QuitSure was not dependent on the gender or age of the participants. Smoking behavior prior to starting the program, however, did affect the program's efficacy. The value was found to be $\chi^2_1=20.3$ ($P<.001$),

indicating a significant impact of smoking behavior on the quit rate. The 30-day prolonged abstinence of heavy smokers was significantly lower than that of those who smoked <20 cigarettes a day (relative risk=0.91; 95% CI 90.0%-96.2%). Country of residence also had a significant impact on program effectiveness with a value of $\chi^2_4=9.8$ ($P=.04$) when comparing the 5 countries with the most participants. Residents of Australia had the highest 30-day prolonged abstinence rates (relative risk compared to all other participants=1.08, 95% CI 44.0%-83.0%), while residents of the United Kingdom had the lowest (relative risk for 30-day prolonged abstinence compared to all other participants=0.87, 95% CI 84.0%-99.2%).

Table 5. Factors affecting smoking cessation rates.

Factor	Chi-square (df)	P value
Gender	3.8 (2)	.09
Age groups	5.9 (4)	.20
Smoking behavior	20.3 (1)	<.001
Country of residence	9.8 (4)	.04

Factors Contributing to Failure and Relapse

Table 6 shows the reasons given for failure among participants for whom the program did not work at all (n=35), with fear of quitting (n=15, 42.9%) and lack of belief (n=11, 31.4%) being the most common reasons given. Table 7 shows the major

reasons for relapse among participants who quit successfully at first but then relapsed at some point before filling out the survey (n=296). The most likely reasons for relapse were cravings for cigarettes (n=101, 34.1%) and alcohol consumption (n=91, 30.1%).

Table 6. Reasons for failure (n=112).

Reason for failure	Participants, n (%)
I was afraid of quitting	15 (42.9)
I did not believe that I could quit	11 (31.4)
I do not know	9 (25.7)
I rushed through the program and may have missed some concepts	7 (20)
I did not do all the steps of the final cigarette transformation ceremony	6 (17.1)
I smoked less than 10 cigarettes mindfully	6 (17.1)
I did not follow all the instructions	5 (14.3)
I took a break >2 days while doing the program	5 (14.3)
I did not believe in the content of the app	2 (5.1)
I did not like the content of the app	2 (5.1)

Table 7. Reasons for relapse (n=296).

Reason for relapse	Participants, n (%)
I still had bad cravings and I was unable to resist	101 (34.1)
I gave in while drinking alcohol	91 (30.1)
I faced a tragedy (eg, death of a loved one and bad breakup)	71 (24)
I became overconfident of my success	69 (23.3)
I felt self-destructive	47 (15.9)
I still believe smoking has some benefits	24 (8.1)
I did not do the program properly	18 (6.1)
My physical withdrawal symptoms were very bad	17 (5.7)
I gained a lot of weight	14 (4.7)
Other reasons (stress, peer pressure, etc)	27 (9.1)

Among those who relapsed or were unable to quit after completing the program (n=410), 80.7% (n=331) had a moderate to high motivation to quit at the time of submitting the survey. In total, 91% (n=377) said that they would consider using QuitSure for their next quitting attempt, while 46.1% (n=189) said that they will definitely use QuitSure to quit in the future.

Survey for Noncompleters of the Program

In total, 19,873 users had dropped off after starting the program and were sent the S-Incompleters survey, of which only 126

(0.6%) consented to participate in the study and submitted the survey.

Table 8 shows the reasons submitted for not completing the program (n=126). The most common reasons given for dropping off midway were a busy schedule (n=51, 40.5%), not enjoying the content of the program or having too much to read (n=25, 19.8%), and lack of belief that the program will work (n=20, 15.9%).

Table 8. Reasons for not completing the program (n=126).

Reason for not completing the program	Participants, n (%)
Busy	51 (40.5)
Did not enjoy content or too much reading	25 (19.8)
Lack of belief in the program	20 (15.9)
Quit smoking midway or cut down	16 (12.7)
Had to pay	14 (11.1)
Technical issues	11 (8.7)
Felt program was not working	9 (7.1)
Others	6 (4.7)
Was not ready	5 (4)

Discussion

Principal Findings

The purpose of the study was to understand whether the QuitSure program is an effective intervention for smoking cessation and can be implemented at scale to counteract the health and economic consequences of the tobacco epidemic. It was conducted via 2 web-based surveys. In total, 1299 participants submitted the S-Completers survey for program completers. A majority of 80.9% (1040/1286) maintained prolonged abstinence for 30 days after program completion, and 72.4% (725/1002) maintained 6-month prolonged abstinence after program completion. In total, 86.4% (770/891) of participants reported no severe withdrawal symptoms, while 41.9% (373/891) reported no withdrawal symptoms at all. Only 18.5% (165/891) experienced more than 5-kg weight gain after completing the program. Demographic variables such as gender and age did not significantly impact the program's success, but smoking quantity prior to doing the program and country of residence did have a significant impact on program efficacy. For those who relapsed, cravings and alcohol consumption were major factors, while program noncompletion was attributed to busy schedules or lack of belief in the program by the participants.

The program was able to achieve extended cessation for every category of smoker, from light to heavy with high efficacy rates, and low withdrawal symptoms after quitting. It is easy to navigate and uses simple language. The low price makes it affordable for smokers across most socioeconomic strata, and the easy-to-understand content makes it usable by anyone with a basic understanding of English. The fact that most participants who relapsed, or for whom the program did not work, continue believing in the program's potential is also a point in its favor. The difference in cessation rates in different countries indicates that the program requires some adaptations to be contextually and culturally relevant to the residents of certain countries.

When it comes to the feasibility of the program to be distributed to the population at large, the dropout rates of the program, at 59.4%, did not show improved program adherence and engagement compared to other health care apps [32]. While the very short 6-day length of the program likely increases completion rates, it requires approximately 1 hour of daily use. This high engagement requirement could be the reason why 40.5% (51/126) of participants who dropped off the program midway state being busy as the reason for noncompletion. The other major reason for dropping off the program was the length and style of the content. QuitSure could break down the program into a 30-day version with just 10-15 minutes of content per day for people who are busy or for whom the content seems too much. They could also add more graphics, videos, and design elements in the content to make it more appealing to users than plain, simple text. Lack of belief in the program's techniques was also shared as a reason for dropout. The makers of the app can thus focus on informing the users about the scientific underpinnings of the techniques used in the program as well as include relevant references for their claims throughout the program.

The app is attempting to standardize and replicate an in-person deaddiction counseling program into a do-it-yourself app and uses many of these same psychological tools to achieve success for its users as in-person counseling [33-35]. The efficacy for those who completed the program and participated in the study seems high, indicating some degree of success. However, the program is of the do-it-yourself type and long enough that it requires high self-motivation and high intent to quit on the part of the user to complete the entire program. We do not have data on how many people dropped off even before starting because of the quantity of self-driven work required. A pre-post study analyzing dropout rates at every stage in the user journey will be required to evaluate the true feasibility of the app.

Limitations

The study had several limitations. A selection bias was created because the base sample selected was solely those who had already signed up for and completed the program, creating a closed cohort and a higher-than-normal intent to quit. Another limitation was the low response rate. Only 24.8% (1332/5365) of those who opened the email chose to submit the survey, allowing for a significant bias toward those for whom the program was successful. If we consider the program to have failed for all those who opened the email but did not submit the survey, the quit rate of QuitSure at the 30-day postprogram time point becomes just 19.4%. A recall bias may have resulted in false memories of withdrawal symptoms during the initial postprogram phase. The single measurement taken eliminates long-term cessation data of participants who only recently completed the program. Finally, the reward for filling out the survey may have motivated participants to give a false-positive response, based on an assumption that it would increase their likelihood of receiving the reward.

Ultimately, the obtained sample is not representative of the smoker population at large. To be able to understand the true feasibility and efficacy of the QuitSure program and counteract the above limitations, we would need to conduct a randomized controlled trial where the self-reported cessation of participants is confirmed via biochemical verification.

Comparison With Prior Work

Studies have shown that 46.3% of smokers who quit experience significant withdrawal symptoms ranging from anxiety, depression, irritability, and other physical symptoms [36,37]. The biggest strength of the QuitSure program is that only 13.6% (121/891) of the study participants faced severe withdrawal symptoms. Of the remaining participants, only around half faced even the milder withdrawal symptoms such as coughing and mild sleep disturbance, which are usually seen among all smokers upon quitting [38]. This could be a reflection of the program's focus on the psychological aspect of nicotine addiction via mindfulness, CBT, and reframing mental sets and beliefs, which have previously shown to reduce withdrawal symptoms after quitting [39,40]. Withdrawal symptoms are known to be a key contributor to relapse [36,37]. Therefore, it is likely that the increased effectiveness of the program and higher prolonged cessation rates are a result of these reduced withdrawal symptoms. However, QuitSure does not include any sort of NRT in its protocol. NRT is recommended by the

WHO, US Centers for Disease Control and Prevention, as well as the National Institute for Health and Care Excellence, United Kingdom [22,41,42] as an important complement to counseling and has been shown to significantly increase the success rates in psychology-based smoking cessation programs [34,43,44]. The hypothesis given is that NRT reduces withdrawal symptoms and craving levels. QuitSure could include a phased-out nicotine replacement regimen after the program to further increase its efficacy. This is especially important for heavy smokers, for whom the program was less effective.

The primary reason for relapse was due to still experiencing strong cravings for smoking. In fact, 75% (21/28) of participants who experienced greater than moderate levels of cravings after completing the program eventually relapsed. Currently, the QuitSure program does not address cravings management in any specific way after program completion, relying on the program itself to prevent the appearance of cravings at all. To address them and prevent their relapse, QuitSure can monitor craving levels after the program, with additional content and counseling for those who are struggling.

The second reason for relapse was alongside alcohol consumption. The app already recommends users not to drink any alcohol for the first week after quitting. It can extend this further and also give more guidelines on how to handle cravings when drinking alcohol.

Weight gain after quitting is another big concern among smokers, as there is evidence that nicotine reduces appetite, increases metabolism, and reduces food cravings [45,46]. Previous studies have shown that after quitting smoking, 35.4% of quitters had a weight gain over 5% of their body weight [47]. Of the study participants who were able to quit for even a brief period, 58.1% (518/891) had some weight gain. The QuitSure program should do more to specifically address the maladaptive

thought patterns and beliefs connecting food, hunger, and smoking.

Previous studies have found that the higher an individual's app engagement is, the more they are likely to be able to quit smoking [19]. Thus, the QuitSure app needs to improve its engagement rates to increase program completion rates. Some tools the app developers can use to increase engagement that have previously demonstrated success are (1) gamification techniques like leaderboards, progress bars, and levels [19,48,49]; (2) small rewards to participants for every engagement milestone [48]; (3) personalizing notifications and reminders [49]; as well as (4) inclusion of a peer support group to improve program adherence and navigate postquitting withdrawal symptoms and cravings [50].

Overall, within the limitations of the study, the program shows high smoking cessation rates, low rates of withdrawal symptoms and cravings, and a generally positive experience for its users.

Conclusions

In total, 80.9% (1040/1286) of the survey respondents were able to achieve 30-day prolonged abstinence from smoking after program completion. The program also adheres to the WHO's 5As guideline for smoking cessation and includes psychological tools used in evidence-based in-person counseling protocols. However, there are many improvements in app engagement, program adherence, and postprogram support that can be made by the app developers. The high success rates, including prolonged cessation rates, among study participants are an indicator that QuitSure could be a useful tool for achieving smoking cessation at scale. Despite the severe limitations and selection biases of the study, the results make the QuitSure program a strong contender for further investigation. Health care institutions should consider and study the program's feasibility and efficacy in a more controlled setting.

Acknowledgments

The authors thank the users of the QuitSure app, whose participation and feedback played a pivotal role in this study. Their willingness to engage with the program and share their experiences provided valuable insights and enriched the findings.

Authors' Contributions

GMG and KB worked on the experimental design, data analysis, and paper writing. SM worked on data analysis and paper writing. All 3 authors reviewed the final paper.

Conflicts of Interest

GMG has no conflicts of interest. KB is a cofounder and equity holder in QuitSure. SM is an employee of QuitSure.

Abstract

Background: Complementing digital adherence technologies (DATs) with mobile money incentives may improve their utility in supporting tuberculosis medication adherence, yet the feasibility and acceptability of this integrated approach remain unclear.

Objective: This study aims to describe the feasibility and acceptability of a novel DAT intervention called My Mobile Wallet composed of real-time adherence monitoring, SMS text message reminders, and mobile money incentives for tuberculosis medication adherence in a low-income setting.

Methods: We purposively recruited people living with tuberculosis from the Mbarara Regional Referral Hospital in Mbarara, Uganda, who (1) were starting tuberculosis treatment at enrollment or within the past 4 weeks, (2) owned a mobile phone, (3) were able to use SMS text messaging, (4) were aged ≥ 18 years, and (5) were living in Mbarara district. At study exit (month 6), we used interviews and questionnaires informed by the unified theory of acceptance and use of technology (UTAUT) to collect feasibility and acceptability data, reflecting patients' experiences of using each component of My Mobile Wallet. Feasibility also included tracking the functionality of the adherence monitor (ie, an electronic pillbox) as well as SMS text message and mobile money delivery. We used a content analytical approach to inductively analyze qualitative data and Stata (version 13; StataCorp LLC) to analyze quantitative data.

Results: All 39 participants reported that the intervention was feasible because it was easy for them to use (eg, access and read SMS text messages) and worked as expected. Almost all SMS text messages (6880/7064, 97.4%) were sent as planned. The transmission of adherence data from the monitor worked well, with 98.37% (5682/5776) of the data transmitted as planned. All participants additionally reported that the intervention was acceptable because it helped them take their tuberculosis medication as prescribed; the mobile money incentives relieved them of tuberculosis-related financial burdens; SMS text message reminders and electronic pillbox-based alarms reminded them to take their medication on time; and participants perceived real-time adherence monitoring as "being watched" while taking their medication, which encouraged them to take their medication on time to demonstrate their commitment. The intervention was perceived as a sign of care, which eventually created emotional support and a sense of connectedness to health care. Participants preferred daily SMS text message reminders (32/39, 82%) to reminders linked to missed doses (7/39, 18%), citing the fact that tuberculosis medication is taken daily.

Conclusions: The use of real-time adherence monitoring linked to SMS text message reminders and mobile money incentives for tuberculosis medication adherence was feasible and acceptable in a low-resource setting where poverty-based structural barriers heavily constrain tuberculosis treatment and care.

digital adherence technologies; real-time monitoring; SMS text message reminders; mobile money; financial incentives; tuberculosis; medication adherence; user-centered approach

Introduction

Background

Tuberculosis treatment adherence remains challenging in Uganda. Constraints to tuberculosis medication adherence include a lack of transport to the clinic to pick up the drugs and forgetfulness [1]. Digital adherence technologies (DATs) are being explored to encourage adherence to tuberculosis medication [2,3]. Recently, we showed that real-time adherence monitors linked to SMS text message reminders were potentially useful in reminding patients to take their medication and encouraging tuberculosis medication adherence in rural Uganda [4]. However, tuberculosis is well known to be a disease of poverty [5], and the lack of money may potentially limit the usefulness of DATs (eg, the inability to afford transport to pick up the medications) [6]. Although effective tuberculosis treatment has existed since the 1940s and is available for free, many people delay seeking treatment, struggle with medication adherence, or do not complete their treatment because of poverty [1]. This is because tuberculosis leads to the loss of productivity of patients and their caregivers, resulting in additional costs for patients in the form of transport to and from the clinic and may lead to loss of employment for fear of spreading the disease to other people [7]. Currently, in Uganda, 53% of patients living with tuberculosis take loans or sell property to meet the costs of their tuberculosis care [8]. Interventions are necessary to overcome the poverty-based structural barriers to tuberculosis treatment, including unconditional transport to and from the clinic. According to the End TB strategy of the World Health Organization (WHO), the use of social protection schemes (such as transport to the clinic and meals) could lower the financial burden of tuberculosis [9]. A recent systematic literature review and meta-analysis by Richterman et al [10] defines cash transfers as cash payments provided to specific beneficiaries. The review indicates that cash transfer interventions may improve treatment success among patients with pulmonary tuberculosis, although the review expresses the need for more research regarding the effectiveness of sensitive cash transfers for tuberculosis care, especially in low-income countries [10].

The use of mobile money technology (money sent, received, or saved on mobile phones) is a promising tool for delivering health-related cash transfers; for instance, mobile money enabled pregnant women to save for maternal health care in Kenya [11], while a progressive incentive scheme to reward private physicians and community health care workers enhanced identification and referral of suspected tuberculosis cases and treatment tracking in Pakistan [12]. The use of mobile money transfers to incentivize patients living with tuberculosis to take

their drugs may potentially improve their adherence to medication [13]. However, the use of mobile money services in the context of health care is still in its infancy, and the limited research in this area reports mixed results [14].

My Mobile Wallet

My Mobile Wallet is a DAT intervention composed of a real-time adherence monitor, SMS text message reminders, and mobile money incentives (known as WiseCash). The financial incentives are meant to motivate participants to take their medication as well as enable them to attend their clinic appointments for pill refills. The intervention was developed through user-centered approaches [15], and we previously published formative qualitative findings indicating the anticipated benefits and challenges of using the intervention for tuberculosis medication adherence in rural Uganda [13]. In brief, participants reported that the intervention could remind them to take their medication as well as support, and motivate tuberculosis medication adherence. However, they expressed concerns about the possible unintended tuberculosis status disclosure as well as the possibility of using the money for other competing demands. This information was then used to refine and improve My Mobile Wallet.

This paper presents the feasibility and acceptability of a pilot study implementing My Mobile Wallet. Specifically, we present the practical experiences of people living with drug-sensitive tuberculosis who used the intervention during their 6-month tuberculosis treatment period.

Methods

Study Design and Setting

This study used a convergent mixed methods study design. The study recruited people living with tuberculosis from the tuberculosis clinic at the Mbarara Regional Referral Hospital (MRRH) in Mbarara in southwestern Uganda. The tuberculosis clinic provides care to an estimated 600 people living with tuberculosis annually. All newly diagnosed people living with tuberculosis receive free tuberculosis medication and are counseled about the benefits of tuberculosis medication at the tuberculosis clinic. At the MRRH, the recommended directly observed therapy approach (which advises that patients should take their medication as they are watched by a health care provider or treatment supporter) is not used for monitoring medication adherence due to the costs involved for both people living with tuberculosis and the health care workers. Instead, people living with tuberculosis are treated with the 2HRZE regimen (isoniazid, rifampin, pyrazinamide, and ethambutol for 2 months) in the initiation phase, with clinic visits every 2

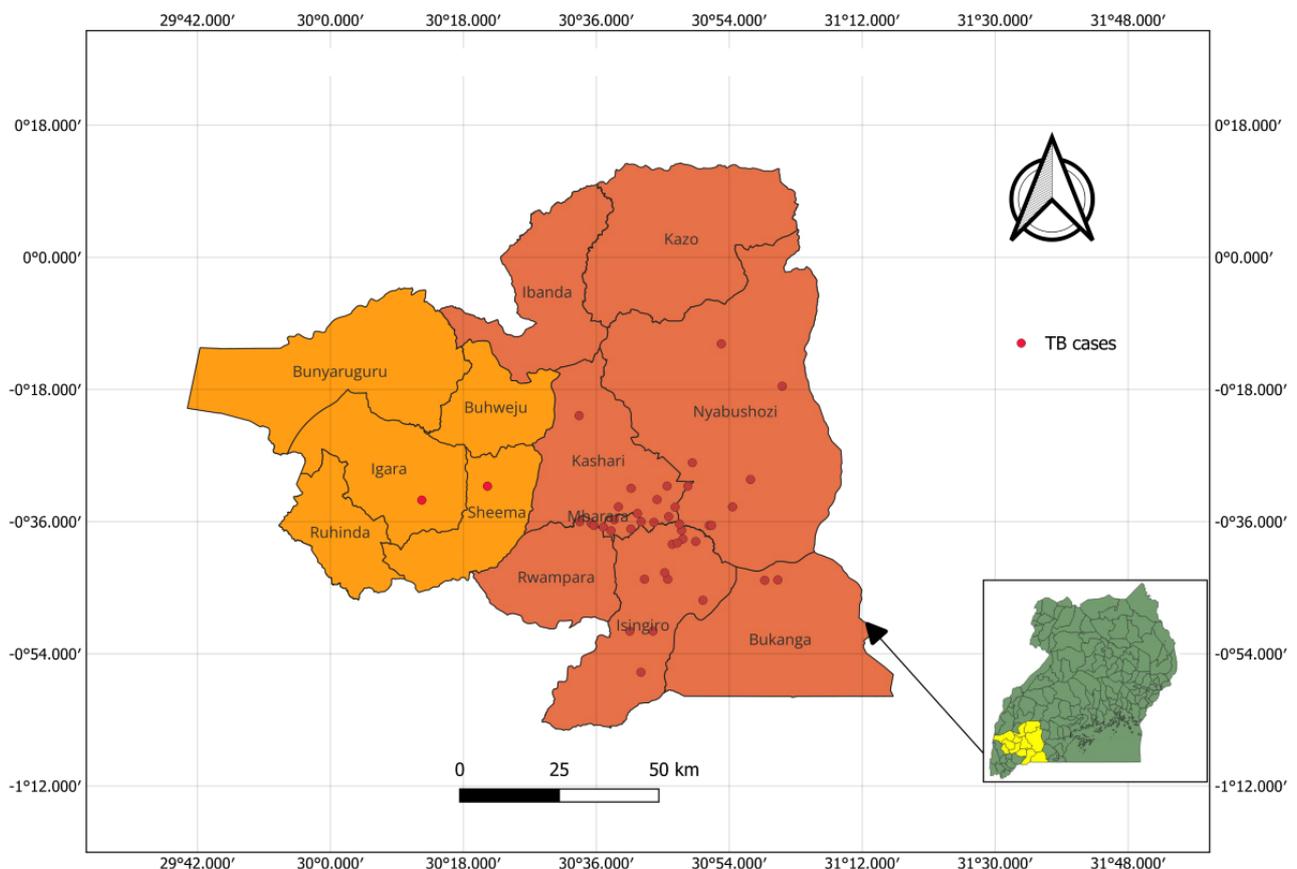

weeks. At the end of the 2-month period, they return to the tuberculosis clinic for a sputum conversion check. Those who become smear negative continue with the 4HR regimen (isoniazid plus rifampin for 4 months) in the continuation phase, with monthly clinic visits. Those with positive test results receive GeneXpert to exclude rifampicin resistance; subsequent treatment is then individualized. Treatment may be extended up to a full year to compensate for missed medication pick-ups or doses.

Selection of Study Participants

Between July 2022 and October 2022, we recruited participants at the MRRH according to the following inclusion criteria: (1)

newly diagnosed with tuberculosis per the clinic records and starting tuberculosis treatment at enrollment or within the past 4 weeks, (2) owning a mobile phone, and (3) living in Mbarara district (Figure 1). We excluded individuals who were unwilling or unable to provide informed consent due to severe mental conditions per the clinical records and those unable to use mobile money-based SMS text messaging (we trained potential participants and tested this skill at recruitment). We purposively sampled patients to achieve relatively balanced representation by HIV status and sex to solicit diverse perspectives.

Figure 1. The study area map and geographic distribution of participants. TB: tuberculosis.

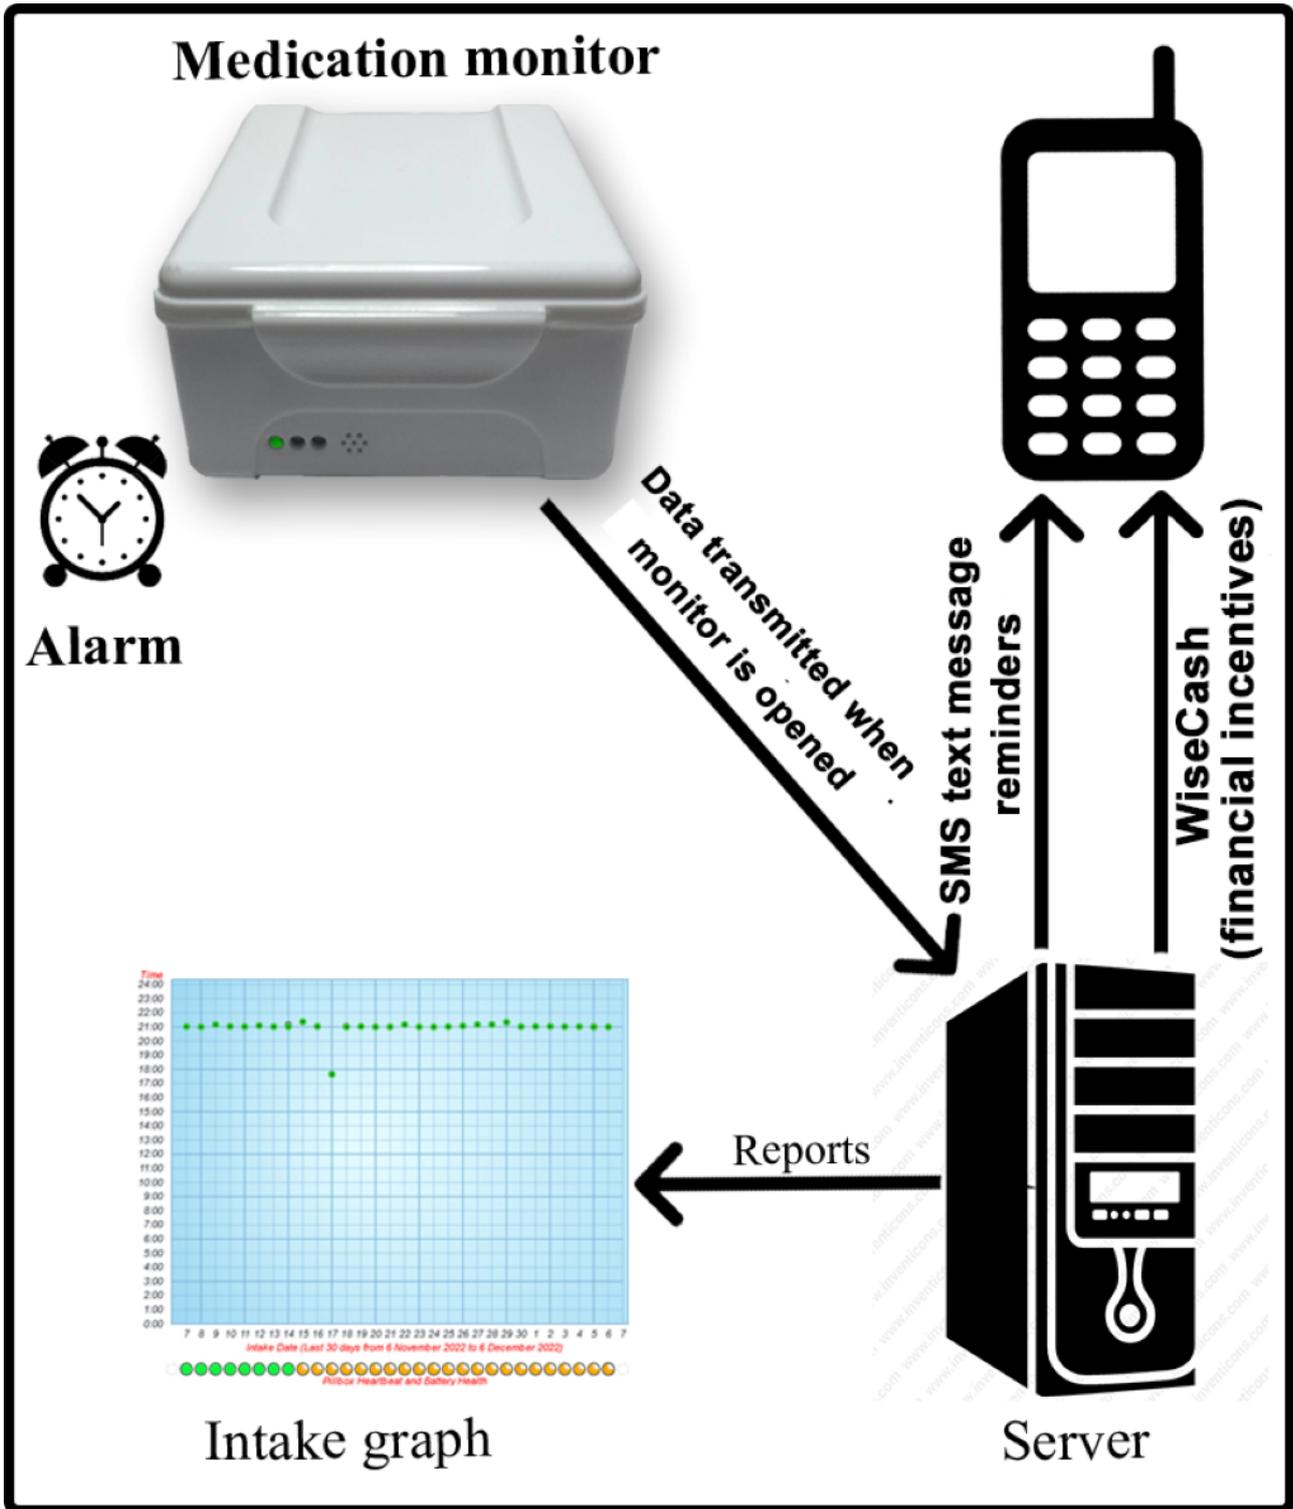

Intervention Technology

Details of the My Mobile Wallet intervention are described elsewhere [13]. Briefly, as shown in Figure 2, the intervention is composed of the following 3 components: a real-time medication monitor (Wisepill evriMED1000) to monitor medication adherence by sending signals when opened (the monitor records a date-and-time stamp as a proxy for taking

medication, and it has an option to set an alarm sound to remind patients to take their medication); SMS text message reminders sent to users' mobile phones to remind them to take their medication as prescribed (reminders are sent daily for 2 months, after which they are triggered as needed by missed or delayed doses); and the WiseCash app, which uses a tailored mobile money platform for sending financial incentives for transport to the clinic and motivating medication adherence.

Figure 2. The My Mobile Wallet intervention diagram.

Study Procedures

We first oriented each participant to the My Mobile Wallet intervention components. We explained and demonstrated how the real-time adherence monitor (Wisepill) works, including how it monitors medication adherence and sends a signal to researchers every time it is opened, how the monitor makes an alarm sound to remind patients to take their medication, and how to open and close the monitor to put in or retrieve medication. Participants were then asked to demonstrate how

the monitor works. Next, we explained to them how the intervention sends daily SMS text message reminders (30 minutes before medication-taking time) to remind participants to take their medication for the first 2 months. We also explained how the intervention sends SMS text message reminders for the next 4 months only if the monitor is not opened within an hour of the expected time (known as triggered SMS text message reminders). We then explained how the intervention transfers USh 28,000 (approximately equivalent to US \$8; we decided upon this amount based on the transport costs, which had

increased during the COVID-19 pandemic and had not reduced at the time of implementing this intervention) as an unconditional monthly mobile money incentive to mobile phones belonging to people living with tuberculosis for facilitating transport to the clinic (Figure 1 shows a visual representation of the geographic distribution of the participants) from the date of study recruitment until the end of their 6-month treatment period; furthermore, the participants were informed that US\$ 5250 (approximately equivalent to US \$1.50) would be transferred as a monthly conditional medication adherence incentive to those with a medication adherence rate of $\geq 90\%$ as ascertained from the real-time adherence monitor. The transfer of the transport incentives required patients to inform the research staff about their next date of appointment so that it could be input into the WiseCash application to allow automatic triggering of the transfer of the transport incentive a day before their next visit. We decided upon the medication adherence rate of $>90\%$ because evidence shows that adherence below this level does not yield favorable treatment outcomes [16].

Data Collection

We administered a baseline demographic and sociobehavioral questionnaire to participants at enrollment, which included age, sex, tuberculosis medication specifications (drugs and planned dosing times), and mobile phone number and use. We used the interviewer-administered approach for administering questionnaires to elicit quantitative data orally from the participants (ie, closed-ended questions read out in the participants' local language by the researcher, with participants answering the questions orally). Several validated surveys were adopted and included in this questionnaire (eg, the Duke-UNC Functional Social Support Questionnaire for measuring social support [17], the asset index scale to assess socioeconomic status [18], the depression section of the Hopkins Symptom Checklist for assessing depression [19], the Household Food Insecurity Access Scale for measuring food insecurity [20], the Alcohol Use Disorders Identification Test for assessing alcohol consumption [21], and the Internalized AIDS-Related Stigma Scale for assessing stigma [22]). Feasibility was ascertained by tracking the functionality of the monitor and SMS text message and mobile money delivery. The unified theory of acceptance and use of technology (UTAUT) model [23], given its track record of predicting a substantial portion of the acceptance of digital health interventions, provided a basis for developing surveys and interview guides for capturing participants' views on feasibility and acceptability at study exit (month 6). The UTAUT model asserts that the adoption of technology is influenced by four major constructs as perceived by an individual user: (1) performance expectancy or perceived usefulness of the intervention (in this case, My Mobile Wallet) (2) effort expectancy or perceived ease of use of the intervention, (3) social norms (how others perceive the individual's use of the intervention), and (4) facilitating conditions (the availability of technical and organizational infrastructure to support the use of the intervention). A structured exit questionnaire aimed at eliciting closed-ended information from participants regarding their experiences of using My Mobile Wallet was administered. This was a Likert scale questionnaire that sought to explore the extent to which participants liked or disliked the functionalities

of the intervention. Qualitative open-ended interviews, by contrast, elicited in-depth information about participants' experiences using each component of My Mobile Wallet (the real-time monitor, SMS text message reminders and monitor alarms, and the WiseCash application), including benefits and challenges related to the technologies. Authors WT and ATM (who are trained in qualitative research and research ethics) conducted the semistructured in-depth interviews with participants in a private space at a research office near the MRRH until thematic saturation was reached at the 30th participant interview. Each interview lasted between 30 and 60 minutes and was conducted in the local language (Runyankole), digitally recorded, transcribed, and translated into English. After each interview, author AM reviewed the transcripts for quality, clarity, and detail.

Data Analysis

We followed the UTAUT model [23] to review transcripts for content related to acceptability. We then developed a coding scheme, used it to code the data, and reviewed the coded data to develop descriptive categories. We mapped the descriptive categories onto the domains of the UTAUT model's four major constructs that influence technology adoption: (1) performance expectancy or perceived usefulness, (2) effort expectancy or perceived ease of use, (3) social norms, and (4) facilitating conditions. Illustrative quotations were then selected from the coded data. After the completion of the codebook, we applied the codes using NVivo 11 (Lumivero). We followed the COREQ (Consolidated Criteria for Reporting Qualitative Research) [24] checklist in reporting qualitative results. Feasibility metrics and the quantitative assessment of acceptability were analyzed descriptively by WT and ATM using Stata 13.

Ethical Considerations

The institutional review committees of Mbarara University of Science & Technology (MUST-2021-102) and the Uganda National Council for Science and Technology (HS1688ES) approved this study. All participants provided signed informed consent before study participation.

Results

Demographic Characteristics

Of the 54 screened participants, we excluded 5 (9%) for not owning a mobile phone, 5 (9%) for not living within 60 kilometers of Mbarara district, and 4 (7%) for having mobile phone numbers that were not registered for mobile money service. Thus, 40 (74%) of the 54 screened participants were enrolled in the study and used the intervention for 6 months. Of these 40 participants, 1 (2%) was lost to follow-up (her mobile phone was unreachable). As indicated in Table 1, of the 40 participants, 24 (60%) were female, 27 (68%) had coinfection with HIV, 34 (85%) had no regular or fixed income, 18 (45%) did not study beyond primary level (typically attended by children aged 6-12 years), 40 (100%) perceived their social support to be insufficient, and 21 (53%) reported severe food insecurity. The participants' median age was 38 (IQR 28-54) years, and, before joining the study, they were on medication for a median of 4 (IQR 2.5-8) weeks.

Table 1. Baseline demographic characteristics of participants (n=40).

Characteristics	Values

^aIn the Ugandan education system, primary school (P1-P7) is often attended by children aged 6 to 12 years.

^bIndex was measured using the measure proposed by Filmer and Pritchett [18].

As indicated in [Table 2](#), at baseline, half of the participants (20/40, 50%) did not share their mobile phones with anyone, 85% (34/40) checked their SMS text messages more frequently than *often* in a week, 75% (30/40) *often* used mobile money, 88% (35/40) preferred receiving SMS text message reminders daily because medication taking is a daily activity, 68% (27/40)

preferred SMS text message reminders that are not easily related to tuberculosis (eg, “Hello today”) to avoid unwanted tuberculosis status disclosure, and 38% (15/40) preferred receiving mobile money incentives for transport to the clinic a day before the clinic visit to avoid using the money for other competing needs.

Table 2. Mobile phone use and intervention preferences at baseline (n=40).

Questions	Participants, n (%)

^bTB: tuberculosis.

Exit Survey Results

All participants self-reported that it was easy for them to access and read the mobile money SMS text messages as well as the medication-taking reminders (39/39, 100%) and open the Wisepill device to retrieve their medication (39/39, 100%). In addition, all participants (39/39, 100%) received the mobile money incentive for transport to the clinic as expected, received the medication adherence incentives as expected, and reported that the real-time adherence monitor worked as expected. All participants (39/39, 100%) additionally reported that the mobile

money incentives, the Wisepill device, and the SMS text message reminders helped them take their tuberculosis medication on time or as prescribed.

The average adherence rate ascertained from the real-time monitors was 90.4% (SD 8.6%), and 24 (60%) of the 40 participants had an adherence rate of >90%.

As indicated in Table 3, almost all participants (38/40, 95%) opted to be reminded by both SMS text message reminders and alarms from the real-time monitor. Of the 40 participants, 2 (5%) requested study staff to switch off the alarms on their

monitors at enrollment because they anticipated being inconvenienced by the sound. Participants preferred daily SMS text message reminders (32/39, 82%) to reminders linked to missed doses (7/39, 18%), citing the fact that tuberculosis medication is taken daily. All participants reported that the mobile money incentives were sent as expected. However, 4 (10%) of the 40 participants received cash (once during the study period) as refund for the transport fare instead of being sent the mobile money incentive for transport to the clinic. These

participants did not inform the study staff on time about their next clinic visit date, which had to be input into the WiseCash application to allow automatic triggering of the transfer of the incentive a day before the clinic visit. Almost all the SMS text messages (6880/7064, 97.4%) were sent as planned. The transmission of adherence data from the monitor worked well, with 98.37% (5682/5776) of the data transmitted as planned. No real-time adherence monitor malfunctioned during the study period.

Table 3. Feasibility and acceptability of the My Mobile Wallet intervention.

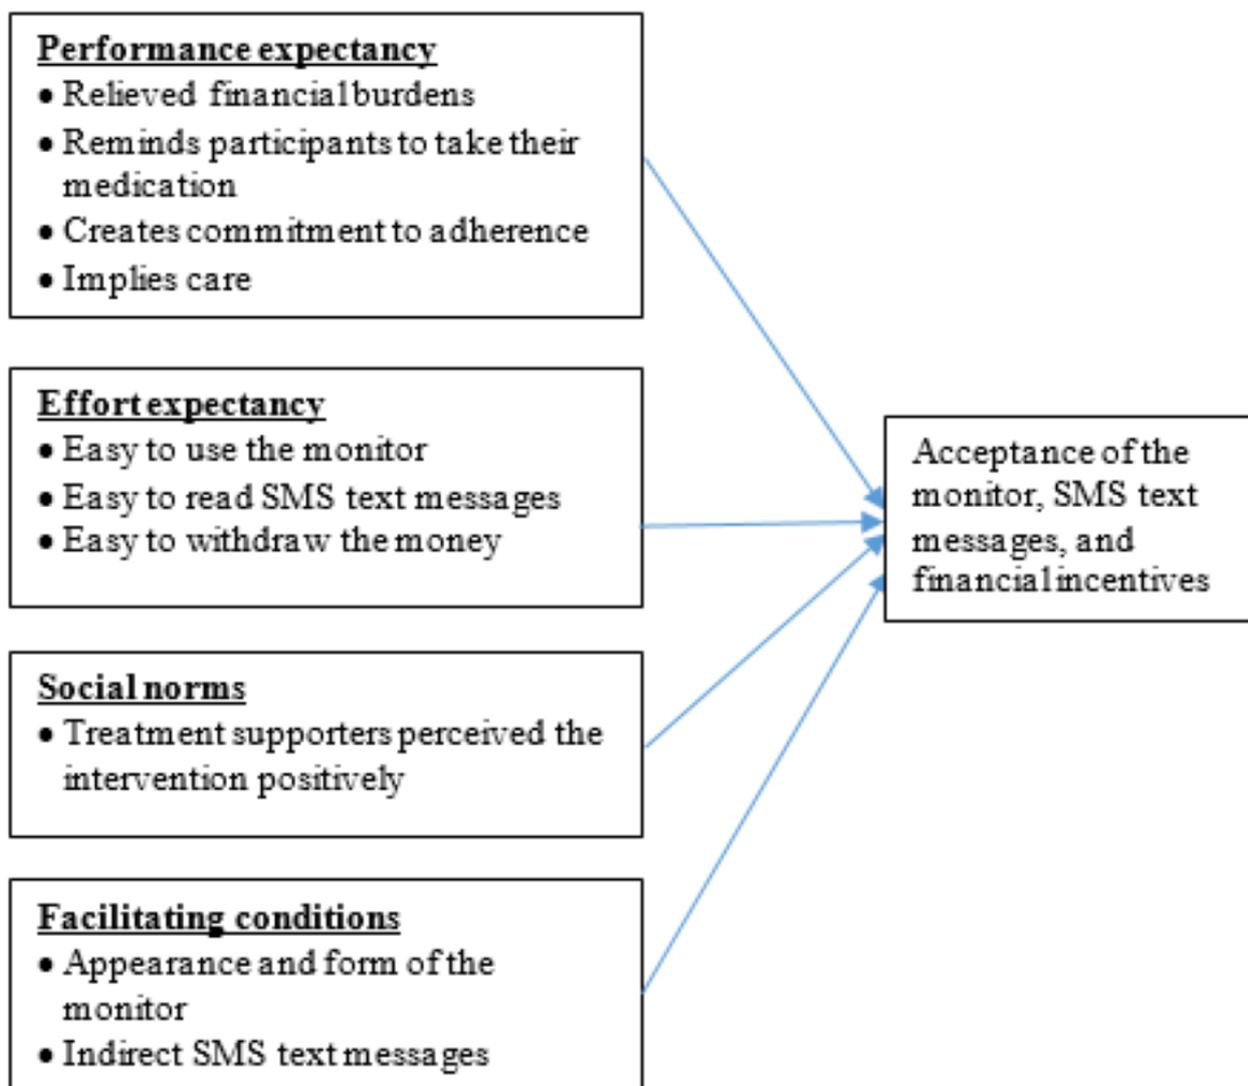

Feasibility and acceptability of SMS text messages	Values
Preference of SMS text message reminders versus device-based alarms (recorded at recruitment; n=40), n (%)	
Participants who opted to be reminded by SMS text message reminders only	0 (0)
Participants who opted to be reminded by Wisepill device alarm only	2 (5)
Participants who opted for SMS text message reminders plus Wisepill device alarm	38 (95)
SMS text message reminders (automatically ascertained from the intervention; N=7064), n (%)	
Total number of SMS text message reminders sent	6880 (97.4)
SMS text message reminders not sent due to technical challenges (eg, poor network)	184 (2.6)
Mobile money incentives (automatically ascertained from the intervention; N=40), n (%)	
Transport incentives not sent	0 (0)
Transport incentives sent unnecessarily	0 (0)
Adherence incentives not sent	0 (0)
Adherence incentives sent unnecessarily	0 (0)
Feasibility and acceptability of the real-time adherence monitor, n (%)	
Data loss due to technical issues with the real-time monitors (days when the monitor was not opened; automatically ascertained from the intervention; N=5776)	94 (1.63)
Device malfunction (N=40; devices that malfunctioned and were replaced)	0 (0)
Devices successfully returned by participants (N=40; the device used by the participant who was lost to follow-up was later recovered from her treatment supporter)	40 (100)

Interview Results: Intervention Acceptability

Acceptability is presented following the constructs of the UTAUT model (Figure 3) of the performance expectancy, effort

expectancy, social norms, and facilitating conditions associated with the intervention.

Figure 3. Organization of the qualitative data on acceptability following the unified theory of acceptance and use of technology (UTAUT) model.

Performance Expectancy or Perceived Usefulness

Mobile Money Incentives Relieve Participants of Tuberculosis-Related Financial Burdens

Before being enrolled in the study, some of the participants struggled to meet the basic costs of their tuberculosis care, including transport to the tuberculosis clinic and the cost of food and drinks needed to take the medication. These were mainly participants with no regular source of income, as well as those staying far from the tuberculosis clinic. They described relying on begging and borrowing money to meet their tuberculosis treatment costs. Unfortunate instances where begging and attempts to borrow money were not successful resulted in missed clinic appointments for pill refills due to lack of transport, which consequently resulted in missed medication. Others reported not taking their medication due to lack of food and drinks because they feared becoming weaker after taking their medication on an empty stomach. Participants reported that the mobile money transport incentives enabled them to meet the cost of transport to the clinic (eg, for pill refills) as well as the costs of meeting the basic tuberculosis treatment needs, such as food and drinks for taking their medication,

thereby relieving them (as their treatment supporters) of the financial burdens associated with tuberculosis treatment and care. One participant stated as follows:

Before you started sending me mobile money, there were times when I would request people to borrow me money or help me with transport to the hospital, but sometimes they would also not be in a position to give me money, so I would miss picking my medication from the hospital...I stopped working when I got sick. I stay far from the hospital. This study helped a lot by sending me [money for] transport to the hospital so that I don't miss taking my medication on time. [Male patient, aged 61 years]

Participants narrated how medication adherence incentives encouraged them to take their medication on time to meet the monthly target of $\geq 90\%$ medication adherence, which in turn helped them meet the cost of the basic food and drinks they needed for taking medication:

I knew that I would be given money after getting $\geq 90\%$ medication adherence, so I made sure that I was taking my medication well in order to be sent the

money. This disease made me too weak to work; yet, I needed money to buy food and porridge. [Female patient, aged 51 years]

Whenever I would receive a message about my adherence percentage, and it's below, it would motivate me to be serious so that next time I don't miss out again. [Male patient, aged 39 years]

SMS Text Message Reminders and the Real-Time Adherence Monitor Enabled Participants to Take Their Medication on Time

Participants reported that the SMS text message reminders and monitor-based alarms enabled them to take their medication on time. These technologies served as medication reminders, thereby addressing forgetfulness, which was common in participants who were not yet used to taking medication regularly. They were also useful for busy participants who could easily forget their medication-taking time due to other competing demands on their time. Participants reported being able to make the necessary preparations (eg, obtaining food and drinks and going back home in case the medication had been left behind at home) after receiving the daily SMS text message reminders (which were sent 30 minutes before their medication-taking time), thereby enabling them to take their medication on time:

The SMS [text message] reminders were very helpful because I was still learning how to take medicine in time, so they helped me in getting used to medication taking because they were coming every day, so my body eventually got used to the time. [Female patient, aged 35 years]

At times, I would get too busy at my video library and forget taking my medication, but whenever I would receive the message, I would close the business immediately, go home, eat some food, prepare a drink, and use it to take my medication on time. [Male patient, aged 27 years]

Using a Real-Time Adherence Monitor Creates Commitment to Medication Adherence

Participants perceived real-time adherence monitoring as “being watched” while taking their medication. This perception was welcomed and encouraged them to take their medication on time to demonstrate their commitment to the health care providers who they felt were concerned about their health and would not be happy with nonadherence:

When I started using the device, I felt touched knowing that there are people who are concerned about my life to the extent of using the device to watch me take medication yet they are not even my relatives or friends or people I knew before. This gave me morale to swallow my medication to play my part especially because they would be seeing whether or not I am taking my medication and they would probably feel bad if I miss taking [it]. [Female patient, aged 40 years]

Whenever I felt like not taking the medication, I always got motivated me to take medication because I knew that you people cared for me so much to the

extent that you gave me this monitor and kept texting me to remind me to take medication and even sent me money to go to the clinic. I felt encouraged because you were really interested in seeing my health condition improve. [Female patient, aged 26 years]

Although monitoring created commitment to medication adherence, it is noteworthy that the primary motivation for taking medication on time as reported by participants was the need to recover their good health and live longer. A participant stated as follows:

Whenever I saw it [the device], I knew it was going to report me, so I chose to take the commitment of swallowing the medication. But, the main issue was, I really needed to recover from this disease because I loved my life and wanted to save it by getting well as soon as possible. [Male patient, aged 57 years]

Receiving Financial Incentives and Reminders and Being Monitored Implies Care

Overview

Receiving the mobile money incentives and SMS text message or alarm reminders and being monitored via the real-time adherence monitor was perceived by participants as signs that the health care providers cared about them, which eventually created emotional support and a sense of connectedness that countered depressive feelings. A participant describes how she changed her mind about committing suicide as a result of using the technologies:

I was about to stop taking the medication and die because I developed self-rejection. I was in pain, and I had no one to help me, but you people encouraged me to take the medication when you put me in this study and started sending me texts, alarms, and mobile money to support me to take my medication. I dropped the idea of suicide because you people cared for me and loved me even more than I loved myself. Thank you for saving my life because I would be dead by now. [Female patient, aged 33 years]

Effort Expectancy or Perceived Ease of Use: The Intervention Was Easy to Use

After the participants' initial orientation to using the real-time adherence monitor, they found it easy to use for taking their medication. Participants, including a few (3/40, 8%) who never went to school, reported finding it easy to read the SMS text messages sent to them. In addition, they reported that it was easy to withdraw money from mobile money agents because the agents are readily available:

It was very easy to use the container [the real-time adherence monitor]; you open it the same way a food box is [opened], put your medication [in], and start using it; that is all. I did not have to charge it or do any other thing with it. [Male patient, aged 42 years]

Although I did not go to school, I can read messages written in my local language, so, reading the messages on [the mobile] phone was not a problem at all. [Female patient, aged 28 years]

There are so many mobile money agents around. It was easy for me to withdraw my money from them.
[Male patient, aged 35 years]

Social Norms or Other People's Perceptions of the Intervention

Positive Perceptions From Treatment Supporters

Participants reported that their treatment supporters approve of them using the intervention to support their medication adherence to get well. In addition, participants stated that because of the financial incentives, their treatment supporters were relieved of the financial burden of having to take care of the financial needs of the participants:

When my wife saw the container and the messages, she was happy knowing that I was being supported by the hospital; she believed the support would help [me] get well soon. It was also a relief for her when you sent me money; I stopped working when I got sick, and before your assistance, I was only relying on getting money from her small shop for transport to the hospital and getting other basic needs like food.
[Male patient, aged 32 years]

Possibility of Inappropriate Use of the Financial Incentives

One participant reported how her husband initially misappropriated the financial incentives intended to pay for her transport to the clinic. Although the participant did not miss visiting the clinic, she had to keep begging her husband for money for transport to the clinic. Sometimes she would have to walk part of the distance due to insufficient transport funds provided by her husband:

My husband never wants me to own any money and always forces [me] to give him my money. So, whenever you would send me money on the [mobile] phone, he would force me to give him the whole of it. I would then have to go through the hassle of begging him to give me the money for my hospital visit, and sometimes the money he would give me for transport would not be enough.... But after giving you my new SIM card [details], which he did not know [about], I started receiving and using the money for transport to the hospital. [Female patient, aged 33 years]

Facilitating Conditions: Appearance and Form of the Monitor

Participants reported that they liked the appearance and form of the real-time adherence monitor. Specifically, they liked the monitor's design, which resembled a food box, and its size, which they thought was reasonable because it accommodated all their pills; the absence of tuberculosis-related labels that could link them to the disease; and the hard outer cover that kept their medicines safe and clean, all of which motivated them to use the monitor:

The container looks like a food bowl, so people can easily think you have carrying some food in it; it is

also big enough to carry all my medicine, and has no any TB-related word. [Female patient, aged 35 years]

Indirect SMS Text Messages

To avoid unwanted status disclosure, participants preferred SMS text messages that could not easily link them to tuberculosis:

I chose the message "come and eat" because for me I knew what it reminded me to eat, but other people even if they saw it on my [mobile] phone would not know what I was going to eat. [Male patient, aged 38 years]

Discussion

Principal Findings

Drawing on the UTAUT model, this paper describes the feasibility and acceptability of My Mobile Wallet, a DAT intervention composed of a real-time adherence monitor, SMS text message reminders, and mobile money incentives (WiseCash) for tuberculosis medication adherence in rural southwestern Uganda. Generally, we found that the intervention was technically feasible because it functioned as expected. All participants reported that it was easy for them to use the intervention; they could access and read the mobile money SMS text messages as well as the medication reminders, and they were able to open the Wisepill device to retrieve their medication. Participants reported receiving the mobile money incentives for transport to the clinic and the medication adherence incentives as expected. The SMS text messages and real-time adherence monitor also worked as expected: the SMS text messages were sent as planned, the transmission of adherence data from the monitor worked well, and no monitor malfunctioned for the entire period of the study.

Concerning acceptability, participants reported being relieved of tuberculosis-related financial burdens as a result of receiving the mobile money incentives. SMS text message reminders and real-time monitor-based alarms reminded participants to take their medication on time. Daily SMS text message reminders were preferred to reminders triggered by missed doses. Participants' preference for daily SMS text message reminders even in the treatment continuation phase (from month 4 onward) was surprising because one would assume that during this phase, they were nearly getting used to taking their medication and therefore did not require to be reminded daily. Patients' preference for daily SMS text message reminders (for taking their medications) over weekly SMS text message reminders was also reported in our previous tuberculosis study [4] and HIV study [25]. As tuberculosis medications are taken daily, daily SMS text message reminders are preferred because they are aligned with the medication-taking frequency.

Participants perceived real-time adherence monitoring as "being watched" while taking their medication, which was welcomed and encouraged them to take their medication on time to demonstrate their commitment. Receiving the mobile money incentives and SMS text message or alarm reminders and being monitored via the real-time adherence monitor was perceived by participants as signs that the health care providers cared about them. Their experiences with the intervention eventually

created emotional support and a sense of connectedness that countered depressive feelings among the participants. Inappropriate use of the mobile money transport incentives was reported only rarely.

Limitations

The main limitation of this study is the possibility of social desirability bias in the data collected from interviews and surveys. The mobile money incentives in particular may have influenced participants, given the prevalence of poverty-based structural barriers to tuberculosis treatment in Uganda, a low-resource setting.

Comparison With Prior Work

We are not aware of any study that reports the impact of a DAT intervention composed of a real-time adherence monitor, SMS text message reminders, and mobile money incentives on tuberculosis medication adherence. However, it should be noted that some studies using some components of this intervention exist; for instance, a recent systematic review and meta-analysis on cash interventions to improve tuberculosis outcomes concluded that these interventions could improve tuberculosis treatment success and completion among patients in low- and middle-income countries [10]; in this review, only 1 randomized control trial in Peru [26] was identified, and the authors of the review noted that the evidence is still weak. In addition, the use of face-to-face cash transfers or transport vouchers as incentives has been reported to be acceptable in facilitating adherence to tuberculosis diagnostic evaluation in Uganda [27]. Furthermore, receiving monthly financial incentives face-to-face enabled patients living with tuberculosis in Nigeria to purchase food and get transport to the clinic [28], while, in Uganda, receiving a one-time cash transfer upon sputum submission supported tuberculosis testing completion among patients [29]. Although the receipt of unconditional cash transfers through a direct benefit scheme supported registered patients living with tuberculosis to meet their nutrition requirements in India, the scheme had no significant effect on treatment outcome [30]. In our study, individuals with no regular source of income and those living far from the clinic benefited most from the mobile money incentives; participants used the transport incentives to cover the cost of transport to the clinic, while they used the financial incentives conditional on high medication adherence to buy food and drinks required to take their medication. This approach could potentially address the financial insecurities that continue to constrain medication adherence [4]. In Uganda, 53% of the patients living with tuberculosis take loans or sell property to meet the costs of their tuberculosis care [8]. Although there is limited research in this area, our study indicates that mobile money incentives can potentially relieve the financial burden that tuberculosis places not only on patients but also on their treatment supporters. An incentive as small as US \$1 can increase the tuberculosis cure rate and reduce treatment loss to follow-up in Uganda [31]. Although this study estimated an average transport cost of US \$8 (based on the COVID-19-pandemic-induced transport cost increases) and provided the same amount for transport to all participants, using GPS information to estimate and provide transport costs

according to each participant's distance from their home to the clinic could be a better option.

The reported practice of a husband taking the mobile money transport incentive from the wife shows the effects of poverty as well as the complexity of implementing mobile money incentives in low-resource settings and cultures where some people still believe in male-exclusive ownership of resources [32]. This scenario could result in an inappropriate use of the incentives, thus limiting the impact of the intervention. An inclusive approach that engages men in the implementation of such an intervention (eg, through awareness creation) might mitigate the risk of the incentives being misappropriated.

This is the first study to report on the feasibility of real-time monitoring linked to SMS text message reminders and mobile money incentives for tuberculosis medication adherence. In the same setting, we had previously reported that using SMS text message reminders linked to real-time monitoring is feasible and acceptable for supporting tuberculosis medication adherence [6]. This study provides insights regarding the integration of financial incentives with these technologies to support access to tuberculosis medication from the hospital and motivate medication adherence.

Participants' medication adherence ascertained from the real-time adherence monitor was quite high. The receipt of financial incentives that was conditional upon a particular adherence target ($\geq 90\%$) resulted in participants taking their medication on time in order to hit the target for financial incentives. In addition, participants' awareness of the fact that their medication adherence was being watched or monitored through the real-time monitor motivated them to take their medication well in order not to disappoint those monitoring them. Notably, the reported adherence was ascertained from the monitor in the form of the monitor being opened, which was used as a proxy for medication taking. Overall, the real-time monitoring approach can potentially be more reliable than participant self-reports, which are highly subject to social desirability bias. However, although it was not reported in our findings, instances of opening the monitor without taking medication (such as accidental openings or opening the monitor to increase the chances of getting incentives) may constrain the feasibility of the intervention. In the ongoing phase of the study, we are supplementing the real-time adherence monitoring with hair analysis (assessing tuberculosis drug levels in participants' hair) to improve objectivity.

Although a few SMS text messages (184/7064, 2.6%) and some adherence data (94/5776, 1.63%) could not be sent by the SMS text messaging application and the real-time adherence monitor, respectively, mainly due to technical issues such as poor network, the intervention was otherwise feasible. The feasibility of this intervention could be attributed to the rapid evolution and adoption of mobile phone technologies in Uganda, including among populations based in rural areas and considered economically marginalized [33]. The applications for the SMS text message reminders and mobile money incentives were tailored from the existing mobile phone infrastructure, which likely facilitated use by participants who were already familiar using SMS text messaging and mobile money services in their

regular routines. By leveraging the existing mobile phone infrastructure, these technologies can potentially bridge the current gaps in access to health care services between economically advantaged populations and populations considered disadvantaged, consequently contributing to equitable access to health care. In addition, the fact that all participants owned personal mobile phones, had the ability to read SMS text message reminders and mobile money SMS text messages, and had reliable mobile network (per the enrolment criteria) could have contributed to the feasibility of the intervention. Different feasibility results may be yielded if this intervention is implemented in populations with fewer resources or in privileged populations.

Concerning acceptability, participants perceived the intervention's functionalities of sending timely medication-taking reminders (through SMS text messages and monitor-based alarms), financially supporting medication adherence (through mobile money incentives), and monitoring medication taking (through the adherence monitor) as supportive and taking care of them. For the participants, this perception created a sense of connectedness with health care providers and countered depressive feelings after their tuberculosis diagnosis. It also encouraged them to adhere to taking their medication as a way of appreciating the care and proving their commitment to taking an active role in their own health with the ultimate goal of regaining their health. Such emotional support can also potentially empower patients to cope with the stigma and discrimination that are often associated with tuberculosis [34]. Importantly, there is evidence that emotional and social support can improve tuberculosis treatment success rates [35]. The use of various tuberculosis medication adherence technologies (including SMS text messages and real-time adherence monitors) was perceived by participants to reduce visits to clinics and increase access to social supporters in a variety of settings [36].

In South Africa, the use of a real-time adherence monitor (Wisepill evriMED1000) was acceptable for prompting a stepwise differentiated care approach for tuberculosis medication adherence, composed of SMS text messages, telephone calls, home visits, and motivational counseling, in response to missed doses ascertained from the monitor [37]. Other studies referencing patient experiences of using real-time adherence monitoring linked to SMS text message reminders for antiretroviral adherence support among people living with HIV in Uganda also reported perceptions of being cared for as a result of using the technologies [25]. Although there are differences between HIV and tuberculosis, they are both diseases of poverty, and result in stigma, and discrimination. The findings regarding the adherence monitor and the SMS text message aspects of the intervention were indeed similar in this and another [25] study, indicating the strong potential of the intervention in this and potentially other similar settings.

Conclusions

In sum, we found the My Mobile Wallet intervention (composed of real-time adherence monitoring linked to SMS text message reminders and mobile money incentives) for tuberculosis medication adherence to be feasible and acceptable in a low-resource setting where poverty-based structural barriers heavily constrain tuberculosis treatment and care. The intervention worked as expected, and participants found it easy to use. The intervention relieved participants of the burden of tuberculosis treatment costs, reminded them to take their medication on time, and provided emotional support that made them feel connected to care.

On the basis of the findings from this study, we are now planning a randomized controlled trial (registered on ClinicalTrials.gov; NCT05656287) for assessing the full-scale feasibility, acceptability, and impact of My Mobile Wallet.

Abstract

Background: Increased pre-exposure prophylaxis (PrEP) use is urgently needed to substantially decrease HIV incidence among Black sexual minority men. Low perceived risk for HIV (PRH) is a key unaddressed PrEP barrier for Black sexual minority men. Peers and smartphone apps are popular intervention tools to promote community health behaviors, but few studies have used these together in a multicomponent strategy. Therefore, we designed a multicomponent intervention called POSSIBLE that used an existing smartphone app called PrEPme (Emocha Mobile Health, Inc) and a peer change agent (PCA) to increase PRH as a gateway to PrEP.

Objective: This paper aims to describe the feasibility and preliminary impact of POSSIBLE on PRH and willingness to accept a PrEP referral among Black sexual minority men.

Methods: POSSIBLE was a theoretically guided, single-group, 2-session pilot study conducted among Black sexual minority men from Baltimore, Maryland between 2019 and 2021 (N=69). POSSIBLE integrated a PCA and the PrEPme app that allows users to self-monitor sexual risk behaviors and chat with the in-app community health worker to obtain PrEP service information. PRH was assessed using the 8-item PRH scale before and after baseline and follow-up study visits. At the end of each study visit, the PCA referred interested individuals to the community health worker to learn more about PrEP service options.

Results: The average age of participants was 32.5 (SD 8.1, range 19-62) years. In total, 55 (80%) participants were retained for follow-up at month 1. After baseline sessions, 29 (42%) participants were willing to be referred to PrEP services, 20 (69%) of those confirmed scheduled appointments with PrEP care teams. There were no statistically significant differences in PRH between baseline and follow-up visits ($t_{122}=-1.36$; $P=.17$).

Conclusions: We observed no statistically significant improvement in PRH between baseline and month 1. However, given the high retention rate and acceptability, POSSIBLE may be feasible to implement. Future research should test a statistically powered peer-based approach on PrEP initiation among Black sexual minority men.

Introduction

Increased pre-exposure prophylaxis (PrEP) use is urgently needed to substantially decrease HIV incidence among Black sexual minority men who have an estimated 50% lifetime risk of HIV acquisition [1]. Data show racial inequities in uptake and adherence among sexual minority men who meet PrEP indications [2]. Socioecological factors such as side effect concerns, stigma, low health care access, and poor clinical experiences including patient-clinician communication remain substantial PrEP barriers for this community [3-5]. Low perceived risk for HIV (PRH) is also a key unaddressed PrEP barrier [6-9]. Some Black sexual minority men have low concerns about HIV acquisition because they think their current behaviors are lower risk than their past or their peers' behaviors and they do not associate HIV status with quality of life [6,10]. Other reasons for low PRH include being in a monogamous relationship and limited sexual activity [6,9,11]. However, low PRH inadequately reflects objective risks and disease severity for Black sexual minority men, given the high-community HIV incidence, suboptimal HIV care outcomes, and negative health consequences of long-term infection [7,8]. Therefore, multicomponent interventions that address PRH and other known barriers are needed to improve PrEP uptake.

Some HIV prevention interventions leverage in-group members as peer change agents (PCAs) to disseminate health-related information within the community for behavior change [12-15]. Peers are considered a valuable resource in marginalized communities to obtain health information, discuss taboo experiences, and help group members understand why behavior change could be beneficial [6,16,17]. Peers can facilitate behavior change because they have similar experiences, can address social barriers, and can improve health literacy [12,13,16,18]. PCAs are uniquely positioned to influence health behaviors because their roles as community members, patients, and health care paraprofessionals can build trust and lead others to credible information or clarify the information [17]. PCAs have improved behavioral health [12], HIV testing [19], medication adherence, and PrEP [13-15] for HIV prevention and could be effective interventionists among Black sexual minority men.

Other interventions have used smartphone apps as electronic diaries to reduce sexual risks through self-monitoring behaviors, which facilitates reflection [20-22]. Technology-based interventions could also be effective for Black sexual minority men because many of them use apps and other mobile devices for several purposes, including partner seeking, social network development, and health information [23,24]. Using apps for interventions could help Black sexual minority men circumvent the social and structural barriers to PrEP such as perceived judgment, stigma, and discrimination from clinicians. Since peers and smartphone apps are typically used independently in interventions, they could have a stronger impact if combined

into a multicomponent health communication strategy because they could hypothetically reduce socioecological barriers for Black sexual minority men simultaneously.

Motivational interviewing (MI) is a communication approach in which a professional collaborates with individuals to activate their motivations to change behavior [17,25]. Some studies use "motivational interview consistent" interventions for HIV prevention because of their cost-effectiveness, brevity, and use of client interests for behavior change [26]. However, existing MI-based interventions to improve PRH or PrEP among Black sexual minority men are limited [18]. Additionally, factors known to drive PRH or PrEP use among Black sexual minority men by PCAs may not be fully leveraged in traditional MI-based interventions [27].

We designed a multicomponent intervention called POSSIBLE that used a PCA and an existing smartphone app called PrEPme (Emocha Mobile Health, Inc) [25] to increase PRH as an important cognitive gateway to PrEP uptake among Black sexual minority men. The intervention was guided by life course theory [28,29], the health belief model [30,31], and possible selves [6,32]. Life course theory suggests that timing, major life events, and age-related vulnerabilities impact sexual health behaviors [28,33]. The health belief model posits that risk perceptions catalyze behavior change [9,30]. Possible selves suggests that ideas of what individuals could or want to become can influence behavior [6,32,34]. Taken together, we hypothesized that a PCA who represented a "future self" could influence PRH at particular points along the life course of Black sexual minority men by cueing individuals to action through a review of their sexual risks in PrEPme and successfully encourage others to use PrEP having navigated similar social challenges [6].

This paper describes the feasibility and preliminary effects of POSSIBLE on PRH and subsequent willingness to accept a PrEP referral among Black sexual minority men. More information on the feasibility and effects of a multicomponent strategy using a PCA and smartphone app is needed to advance the promise of their combined effectiveness. Given the extreme racial disparity in PrEP use among sexual minority men [35,36], strategies that can increase PrEP uptake are still needed. Findings will provide insights into the usefulness of combining 2 popular HIV prevention interventions into a multicomponent strategy and elucidate the cognitive and cultural aspects of health decision-making among this vulnerable community.

Methods

Ethical Considerations

All study procedures were approved by the Johns Hopkins School of Medicine Institutional Review Board (IRB00241244). Oral informed consent was audio-recorded and documented in study folders prior to conducting baseline study visits. Participants were given study ID numbers, and identifiable

information (ie, names and data) was stored on private, password-protected servers. Participants were provided a US \$50 electronic Amazon gift card for the baseline visit.

Study Design

POSSIBLE was a single-group, 2 session pilot intervention conducted between 2019 and 2021 that was refined using the ADAPT-ITT (Assessment, Decision, Administration, Production, Topical Experts, Integration, Training, and Testing) model [37]. Formative research was conducted to refine key aspects of the intervention approach such as the usefulness of the app-based diary and PCA characteristics among Black sexual minority men of different age groups [6].

Peer Change Agent

POSSIBLE incorporated a PCA who was matched with participants' key demographic and cultural characteristics as guided by theory, previous studies, and formative research identifying preferences among Black sexual minority men [6,38]. Specifically, studies suggested that the PCA should have similar experiences as Black sexual minority men (eg, navigating interactions with romantic or sexual partners, clinicians, and health insurance) and be a "future self" to whom they could aspire [6,38]. Therefore, the principal investigator (PI to DTD), used Descovy for PrEP and served the intervention as the PCA. Further details regarding the experience and dual role of the PI serving as a PrEP-using PCA have been published in an autoethnography [17].

PrEPme Smartphone App

PrEPme was designed for Maryland users to obtain statewide PrEP service information and navigation support from an app-based community health worker (CHW) [25]. PrEPme also allows users to self-monitor sexual risk behaviors, view a graph of sexual risk behaviors by week and month, and chat with the CHW in the app to obtain PrEP service information [6].

Linkage to PrEP Care

A CHW supervised by a nurse case manager within the Center for Infectious Disease and Nursing Innovation at the Johns Hopkins School of Nursing (previously known as the REACH Initiative) provided navigation services including reviewing eligibility for or access to medical insurance, identifying preferred clinic locations, and arranging appointment and scheduling activities. Occasionally, the PCA referred participants or helped schedule appointments at PrEP service organizations for individuals who wanted to avoid interfacing with additional staff associated with a medical research institution.

Study Procedures

Study Enrollment

A research assistant screened individuals who were interested in the study for eligibility via phone. Eligible individuals were emailed an informed consent form, details regarding their scheduled web-based baseline appointment, and an electronic survey assessing demographic and behavioral characteristics and PRH. Individuals were given the opportunity to ask the

research team (including the PI) questions regarding the study via phone or email prior to their baseline visit.

Web-Based Baseline Study Visit

Due to COVID-19, baseline and follow-up study visits were conducted via Zoom (Zoom Video Communications). Prior to the baseline visit, the PI or PCA provided participants an additional opportunity to ask questions regarding the study and obtained oral informed consent via Zoom [39]. The script guided the PCA to obtain information regarding participants' lifestyles, personal goals and values, relative HIV risks, and PRH, then tailor health communication based on their responses to influence PRH and encourage PrEP use regardless of participants' reported behaviors [16,26,27,29]. Example questions included, "How would being diagnosed with HIV impact your goals?" and "Given that research suggests that 50% of Black sexual minority men will get HIV despite the fact that they use condoms more than other people, how likely do you think you will get it?" [6,40]. The script also provided opportunities for the PCA to address HIV or PrEP misinformation and disclose PrEP use to share experiences managing potential side effects, challenges disclosing use to romantic or sexual partners, and empathy regarding participants' stigmatizing clinical experiences [17,40].

At the end of the session, the PCA referred interested individuals to the CHW as described earlier. Individuals who declined referrals to the CHW were provided alternative service locations for PrEP care and referred upon request. Baseline visits lasted between 45 and 60 minutes (accounting for informed consent, rapport building, 15- to 20-minute conversation, and PrEP navigation for those who were interested), at the end of which participants were asked to download PrEPme to record their sexual risk behaviors in its app-based diary for 1 month. Baseline study visit procedures and effects have been published [40].

Web-Based Follow-Up Visit

In the second session, the PCA reviewed the PrEPme diary with participants and conducted another MI-consistent conversation to explore relative HIV risk behaviors, review behavioral alignment with goals and values, and reassess their PrEP interests. At the end of the session, the PCA referred interested individuals to the CHW as described earlier. Individuals who declined referrals to the CHW were provided alternative service locations for PrEP care and referred upon request. Follow-up visits lasted between 20 and 30 minutes, and participants were provided another US \$50 electronic Amazon gift card for completing follow-up visits regardless of reported app use.

PrEP Referral

All participants were first referred a CHW at the Johns Hopkins School of Nursing who could help navigate them to PrEP services. Participants who were interested in case management from the CHW were linked to services of their choice. Individuals who declined referrals to the CHW were offered direct referrals by the PCA who reached out to the requested case management services to help schedule appointments.

Satisfaction Surveys

Participants completed a satisfaction survey that also assessed their PRH at the end of the baseline session prior to downloading PrEPme, then again at the end of their follow-up appointment.

Participants

Participants were recruited using a combination of active and passive strategies [39,41] in Baltimore, Maryland, and were eligible based upon the following self-reported criteria: Black or African American race, identifying as a cisgender person, being 18 years and older of age, same-sex attraction to men, HIV-negative, and having oral or anal sex with ≥ 1 male partner in the previous 6 months.

Measures

This concept was assessed using the 8-item PRH scale from Napper et al [42] before and after the baseline visit. Sample questions included items assessing concerns about HIV and perceived likelihoods of infection. Total possible scores ranged from 10 to 40, higher scores indicate greater PRH. The scale was found to be reliable (8 items, $\alpha=.78$).

Data Analysis

Paired 1-tailed *t* tests were used to examine changes in PRH after the end of the study. Descriptive statistics were used to explore the proportion of participants who were referred to services and scheduled a PrEP appointment after baseline.

Results

A total of 291 individuals were screened for the study, 93 of whom were eligible. Among eligible individuals, 69 participated and 55 (80%) were retained for follow-up at month 1. Table 1 describes the sociodemographic characteristics and PrEP referral willingness among participants. The average age of participants was 32.5 (SD 8.1, range 19-62) years. Additionally, 52 (75%) identified as gay, 11 (16%) identified as bisexual, 51 (74%) reported being employed full-time or part-time at baseline, 58 (84%) reported having insurance coverage, 54 (78%) reported being single, and 32 (47%) reported ever having a sexually transmitted infection. After baseline sessions, 29 (42%) participants were willing to be referred to PrEP services, and 20 (69%) of them confirmed scheduled appointments with PrEP care teams.

Regarding the use of the mobile app-based diary, 17 (31%) follow-up participants reported recording an entry every week prior to their follow-up appointment, 3 (5%) reported using the app for half of the weeks, and 6 (11%) reported that they did not use the app at all. In total, 11 (20%) reported initiating PrEP prior to follow-up, and 15 (27%) of follow-up participants were willing to be referred to PrEP services. There were no statistically significant differences in mean PRH scores between baseline (21.2, SD 5.5) and follow-up (23.6, SD 5.7) visits ($t_{122}=-1.36$; $P=.17$).

Discussion

Principal Findings

This study explored the feasibility and preliminary effectiveness of POSSIBLE, a multicomponent intervention using a PCA and mobile app-based diary to improve PRH among Black sexual minority men. Given the high retention rate, POSSIBLE may be a feasible multicomponent strategy to implement among Black sexual minority men. We found improvements in PRH after baseline sessions [40]. However, we observed no statistically significant improvement in PRH after intervention from baseline to month 1.

We observed relatively low PRH scores at baseline and month 1 follow-up. Analyses showed that the PCA increased baseline PRH scores [40]. The effects of the intervention may have been maximized in the baseline session such that the addition of the app for reflexivity could not increase scores from baseline to month 1. Other studies have found that competing survival priorities supersede HIV-related concerns in the lives of Black sexual minority men. The shift from HIV as a “death sentence” in the early days of the epidemic to its positioning as a manageable chronic health condition could be a key reason for low PRH and for why perceived risk did not change from baseline to month 1. Black sexual minority men may also consider their current behaviors relatively safer than their past or their peers’ behaviors as found in previous studies [6,10]. Some may appraise their vulnerability based upon their most recent behaviors, which may not have involved condomless sex or drug use in the month of the intervention, which was conducted partly during the height of the global COVID-19 pandemic.

We also observed relatively low use of the app-based diary in PrEPme. Mobile health interventions have been successful largely because of the convenience of the intervention within smartphone apps. However, PrEPme seemingly did not add value to the PCA intervention component. Studies suggest that aspects such as aesthetics, social networking ability, and gamification impact Black sexual minority men’s use of app-based HIV prevention apps [24,43]. The self-monitoring feature of the app-based diary could be refined for gamification and cultural responsiveness. PrEPme also did not maximize the power of health communication to tailor messaging. However, we are unable to identify reasons for nonuse. Qualitative insights or participant feedback could help in identifying barriers to app use. In light of previous analyses showing baseline effects on PRH [40], adding the mobile app-based diary may not be necessary in the presence of an effective PCA.

The intervention did observe relatively high proportions of willingness to accept PrEP referral and initiation, which could be attributed to the interpersonal dynamics between participants and the PCA [17]. Studies consistently show that peers and social networks are important, trusted sources of health

information and effective interventionists among marginalized communities, including Black sexual minority men [16,38,44,45]. Studies also show that Black sexual minority men are more willing to initiate PrEP if their peers are using it. The usefulness of communicating with a PCA may not have been outweighed by the convenience of technology. PRH may not necessarily be the primary motivation for PrEP referral willingness or initiation among Black sexual minority men.

Despite the feasibility of this intervention, using a PCA to catalyze PRH and PrEP initiation among Black sexual minority men is not without challenges. DTD described internal conflicts regarding honoring participants’ disinterest in PrEP versus professional goals to increase uptake for HIV prevention in an autoethnography [17]. Additionally, managing discussions regarding side effects with Black sexual minority men whose health histories the PI or PCA was unfamiliar with or unqualified to discuss is important to consider in this peer-based approach. Concerns that being a PCA could overshadow professionalism as a researcher and health care professional were also salient [17]. PCAs should be trained to manage insider-outsider dynamics as an interventionist among Black sexual minority men, engage in active listening, and communicate with care [17,46]. Some qualities may not be able to be provided in training such as the shared social experiences and vulnerabilities of being Black sexual minority men.

Limitations

Study limitations include insufficient sample size to detect effect sizes. Causal inferences cannot be drawn, and effectiveness cannot be established with a pre-post single-group design. It is also possible that unstudied external factors could have produced the changes observed. All data were self-reported. A larger trial is needed to definitively establish the effects of the intervention, including biological confirmation of PrEP use beyond self-report.

Conclusions

Future research should test a statistically powered peer-based approach on PrEP initiation among Black sexual minority men. Psychometric tests should also be conducted to identify culturally relevant concepts of HIV risk and PrEP motivation for Black sexual minority men. Qualitative research should also clarify how app-based sexual risk diaries have unintended consequences of triggering self-stigma and shame versus informed decision-making [6]. Targeted studies among young Black sexual minority men younger than 35 years of age should be conducted, given their high HIV incidence and low PrEP uptake. Studies show age cohort differences regarding the needs and vulnerabilities among Black sexual minority men such that peers may be a more effective behavior change mechanism for younger men [33,47,48]. If effectively implemented, the person-centered approach of a PrEP-using PCA approach could lead to substantial community-level impact for Black sexual minority men because their needs are not the same.

Acknowledgments

This research was supported by the National Institute of Mental Health Grant (#K01MH11849; principal investigator to DTD). This research has been facilitated by the infrastructure and resources provided by the Johns Hopkins University Center for AIDS Research, a National Institutes of Health (NIH) funded program (1P30AI094189), which is supported by the following NIH cofunding and participating institutes and centers: the National Institute of Allergy and Infectious Disease, the National Cancer Institute, the National Institute of Child Health and Human Development, the National Health, Lung, and Blood Institute, the National Institute on Drug Abuse, the National Institute on Aging, the National Institute of General Medical Sciences, the National Institute of Diabetes and Digestive Kidney Diseases, and the National Institute of Minority Health and Health Disparities. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. PrEPme was developed with funding from several sources including The Johns Hopkins School of Nursing REACH Initiative, the Gilead Science Unrestricted Educational Grant, and the Baltimore City Health Department.

Conflicts of Interest

JEF holds the technology transfer license with Johns Hopkins University for PrEPme. The app was developed in collaboration with Emocha Mobile Health, Inc.

Abstract

Background: In children with autism spectrum disorder (ASD), problem behaviors play a dysfunctional role, causing as much difficulty with daily living and adjustment as the core symptoms. If such behaviors are not effectively addressed, they can result in physical, economic, and psychological issues not only for the individual but also for family members.

Objective: We aimed to develop and evaluate the feasibility of a mobile app–assisted parent training program for reducing problem behaviors in children with ASD.

Methods: This open-label, single-center, randomized controlled trial was conducted among parents of children with ASD aged 36–84 months. Participants were recruited from the Department of Psychiatry at Seoul National University Hospital. Participants were randomly assigned (1:1) by a blinded researcher. Randomization was performed using a stratified block randomization (with a block size of 4). Parents in the intervention group completed the mobile app–assisted parent training program at home over a 12-week period. They continued to receive their usual nondrug treatment in addition to the mobile app–assisted parent training program. The control group continued to receive their usual nonpharmaceutical treatment for 12 weeks without receiving the parent training program intervention. The primary outcome measure was the median change in the Korean Child Behavior Checklist (K-CBCL) scores from before to after the intervention. Lower scores on the K-CBCL indicated a decrease in overall problem behavior.

Results: Between November 9, 2022, and December 8, 2022, 64 participants were enrolled. Overall, 42 children (intervention group median age: 49, IQR 41–52.5 months; control group median age: 49, IQR 42–58 months) of the participants joined the program. The intervention group included 20 (48%) participants and the control group included 22 (52%) participants. In the intervention group, the K-CBCL total scores showed a decrease after the intervention, with a median difference of –0.5 (95% CI –4.5 to 3). Pervasive developmental disorder scores also showed a decrease, with a median difference of –2.1 (95% CI –8.5 to 2.5). However, there was no significant difference in Clinical Global Impression–Severity of Illness scores after the intervention for both the control and intervention groups. Scores on the Korean version of the Social Communication Questionnaire showed a further decrease after the intervention in the intervention group (median difference –2, 95% CI –4 to 1). Caregivers' stress

evaluated using the Korean Parenting Stress Index Fourth Edition–Short Form did not show any significant differences between the control and intervention groups. There were no adverse events related to study participation.

Conclusions: The findings demonstrated the feasibility of using mobile devices for evidence-based parent training to reduce problem behaviors in children with ASD. Mobile devices' accessibility and flexibility may provide a viable alternative for offering early intervention for problem behaviors in children with ASD.

Introduction

Autism spectrum disorder (ASD) is a condition that affects how a person interacts with others, communicates, and behaves. It is characterized by social interaction difficulties, communication impairments, repetitive behaviors, and limited attention [1]. The prevalence and economic cost of ASD have been gradually increasing in recent years in Korea and worldwide [2,3]. Facilities for psychological evaluation and treatment, including consultation with a pediatric psychiatrist and testing for ASD, are concentrated in metropolitan areas, making them inaccessible to children in rural areas [4,5]. Additionally, even when a diagnosis is made, treatment centers for speech therapy, psychotherapy, acceptance and commitment therapy, music therapy, and occupational therapy are equally concentrated in metropolitan areas; the high cost of treatment makes it difficult for low-income children to receive appropriate treatment [4,6]. Given its enduring consequences and significant socioeconomic burden, ASD is emerging as a priority for intervention efforts.

In individuals diagnosed with ASD, problem behaviors play a dysfunctional role, causing difficulties in daily living and adjustment as much as the core symptoms [7,8]. Problem behaviors can be defined as any behavior that is aggressive toward the self or others, causes damage to the physical environment or objects, interferes with acquiring new skills, or isolates the person from society [9]. Problem behaviors that are not effectively addressed can cause physical, economic, and psychological distress to primary caregivers and other family members [10,11]. Various nonpharmacologic treatments are available to address these problems in children with ASD. Among them, nondrug treatments such as acceptance and commitment therapy and music therapy have shown promising results in addressing emotional problems and improving overall well-being, but they are limited in their ability to directly target problem behaviors [12-16]. Applied Behavior Analysis (ABA) refers to evidence-based interventions that are applied to the education of children with ASD to increase desirable behaviors and decrease or eliminate undesirable behaviors [17,18]. ABA is the science of learning and behavior; to effectively intervene and change problem behaviors, it focuses on identifying the exact cause of the behavior and implementing interventions that target that cause [19,20]. ABA-based parent training is reportedly effective in reducing problem behaviors in children developing from preschool through adolescence in general.

Parent training for children with ASD is practical as a treatment model, can be used in various settings, and empowers parents to be change agents themselves [21-23].

Digital therapeutics are advanced software technologies that deliver evidence-based therapeutic interventions to patients to prevent, manage, and treat diseases or disorders [24,25]. Korea's high mobile phone use rate of 94.8% [26] highlights the potential for increasing accessibility to mobile app-assisted digital therapies. These therapies, with their scalability, accessibility, and low cost, offer the convenience of accessing treatment anytime, anywhere, making them particularly relevant for children in rural areas and low-income communities with limited access to hospitals and treatment centers [25,27].

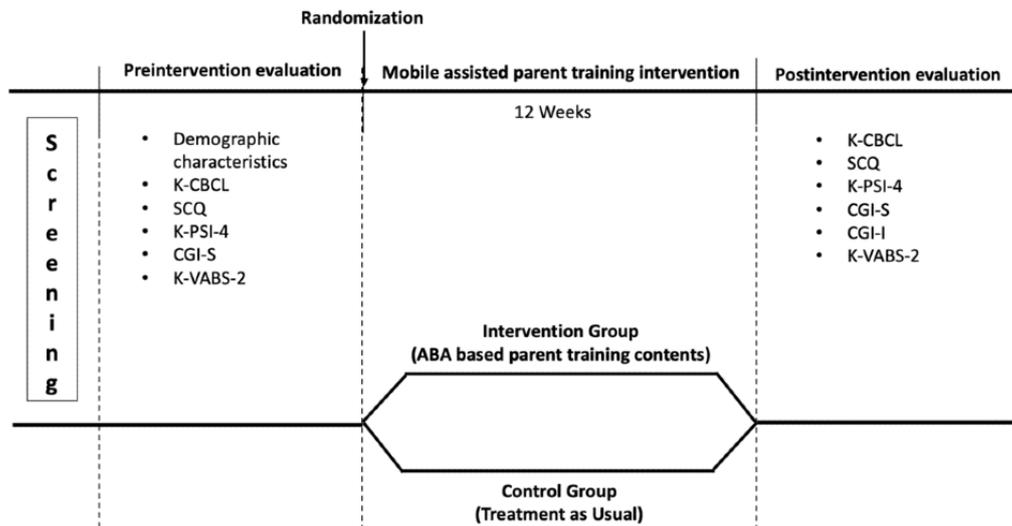

This study aimed to (1) create a mobile app-assisted parent training program using digital technology to decrease problem behaviors in children with ASD, and (2) evaluate the effectiveness of the training program in reducing problem behaviors in children with ASD by comparing pre- and postintervention outcomes.

Methods

Study Design

This study was a parallel-group, open-label, single-center, randomized controlled trial to test the effectiveness of a mobile app-assisted parent training program for reducing behavior problems in children with ASD aged 36-84 months. It followed the CONSORT (Consolidated Standards of Reporting Trials) guidelines. A parent training program based on ABA [17,18] was delivered via mobile devices. For inclusion criteria, children of participants were recruited from the Department of Psychiatry at Seoul National University Hospital and underwent the Autism Diagnostic Observation Schedule-2 (ADOS-2) and Korean Childhood Autism Rating Scale-2 (K-CARS-2), provided demographic information, and completed before the evaluation. Parenting stress levels of the parents and caregivers were also measured. The eligible participants were randomly assigned to either the intervention group or the control group at a 1:1 ratio for 12 weeks. The intervention group received a mobile app parent training program for 12 weeks, while the control group continued with their usual treatment but received no intervention. Both groups were assessed before and after the 12-week period (Figure 1).

Figure 1. Study design. ABA: Applied Behavior Analysis; CGI-S: Clinical Global Impression–Severity of Illness; K-CBCL: Korean Child Behavior Checklist; K-PSI-4: Korean version of the Parenting Stress Index 4th Edition; K-VABS-2: Korean Vineland Adaptive Behavior Scale-2; SCQ: Social Communication Questionnaire.

Participants

Participants with eligible children were recruited from November 9, 2022, to December 8, 2023, at the Department of Psychiatry at Seoul National University Hospital. The inclusion criteria for the children were as follows: (1) being aged between 36 and 84 months of age; (2) meeting the criteria for “autism” or “autism spectrum” classification according to the ADOS-2; and (3) having as a primary caregiver an adult aged at least 19 years. The following were the exclusion criteria for this study: (1) the child was currently taking psychiatric medication for behavioral regulation or similar purposes; (2) the child had a history of congenital or acquired brain damage, such as cerebral palsy; (3) the child had a history of seizure disorders or other neurological conditions; (4) the child had an uncorrected sensory impairment (eg, vision or hearing deficits); (5) the child’s primary caregiver did not possess a smartphone or lacked access to smartphone apps; and (6) the primary caregiver either did not give their consent to join the study or opted to withdraw during the course of the study. All participants provided written informed consent.

Randomization and Masking

The children were divided into low- and high-severity autism groups according to ADOS-2 criteria and randomized into intervention and control groups for each severity group. Randomization was performed using a stratified block randomization method (with a block size of 4) with 1:1 assignment to either the intervention or control group. The randomization list was created using the PROC PLAN method (SAS Institute Inc) in SAS (version 9.4; SAS Institute Inc) software. The randomization process was managed and operated by an independent third party, the Medical Statistics Team of Asan Medical Center.

Sample Size

As this was an exploratory clinical trial, a formal calculation for sample size was not necessary; however, we followed the method described by Julious [28] to calculate the sample size for the pilot trial. The recommended sample size for such pilot studies is 12 persons per group. Considering the possibility of lower compliance with the use of digital therapeutics compared with taking conventional medicines, this study was conducted with a total of 60 participants, 30 in the intervention group and 30 in the control group.

Mobile App–Assisted Parent Training Program

The mobile app–assisted parent training program aims to improve the behavior of children with ASD by identifying the causes of problem behaviors through a self-report questionnaire and providing digital content about it. Previous studies have shown that mobile app or telehealth-enabled ABA interventions can be effective in managing and reducing problem behaviors and increasing parent engagement in children with autism [29-31]. The program was developed in the form of a mobile app to help parents apply ABA-based therapy to their children in their daily lives to reduce their problem behaviors [32-34]. The mobile app–based training program lasted 10-15 minutes per session and was conducted 2-5 days a week for 12 weeks. It covers topics such as an introduction to ABA, identifying the underlying reasons for problematic behavior, creating a behavioral support plan, implementing behavior intervention, practicing in different situations, individualized learning opportunities, and crisis management (Table 1). To further validate our approach and differentiate it from previous studies, we included a system in the mobile app that allows parents to record and monitor their child’s behavior and progress. This real-time data collection allows for continuous monitoring and adjustment of the intervention to ensure responsiveness and effectiveness. Program content was developed with the consultation of 2 ABA experts and 1 child psychiatry specialist.

Table 1. Overview of the program curriculum of the mobile app–assisted parent training intervention for behavioral problems in children with autism spectrum disorder.

Session	Learning objectives	Description of the lesson
1	Orientation and introduction to ABA ^a	<ul style="list-style-type: none"> • Orientation: Introducing good time • ABA: definition, characteristics, and recent trends • Defining objective behavior and collecting data
2	Identifying the reasons behind problematic behaviors	<ul style="list-style-type: none"> • Functions of problem behaviors • Methodology of functional assessment: indirect functional assessment, observational functional assessment (ABC^b functional assessment)
3	Creating a BSP ^c	<ul style="list-style-type: none"> • Create a BSP according to ABC functional assessment: antecedent intervention; consequences intervention; behavior intervention
4	Antecedent intervention 1: Situation (background) event intervention	<ul style="list-style-type: none"> • Finding and structuring environments that cause problematic behavior • Finding and structuring time environments that cause problematic behavior
5	Antecedent intervention 2	<ul style="list-style-type: none"> • Stimulus control • Motivating operation
6	Consequences intervention 1: Reinforcement	<ul style="list-style-type: none"> • Reinforcement and differential reinforcement • Behavior contract and token reinforcement

^aABA: Applied Behavior Analysis.

^bABC: antecedents-behavior-consequences.

^cBSP: behavior support plan.

^dFCT: functional communication training.

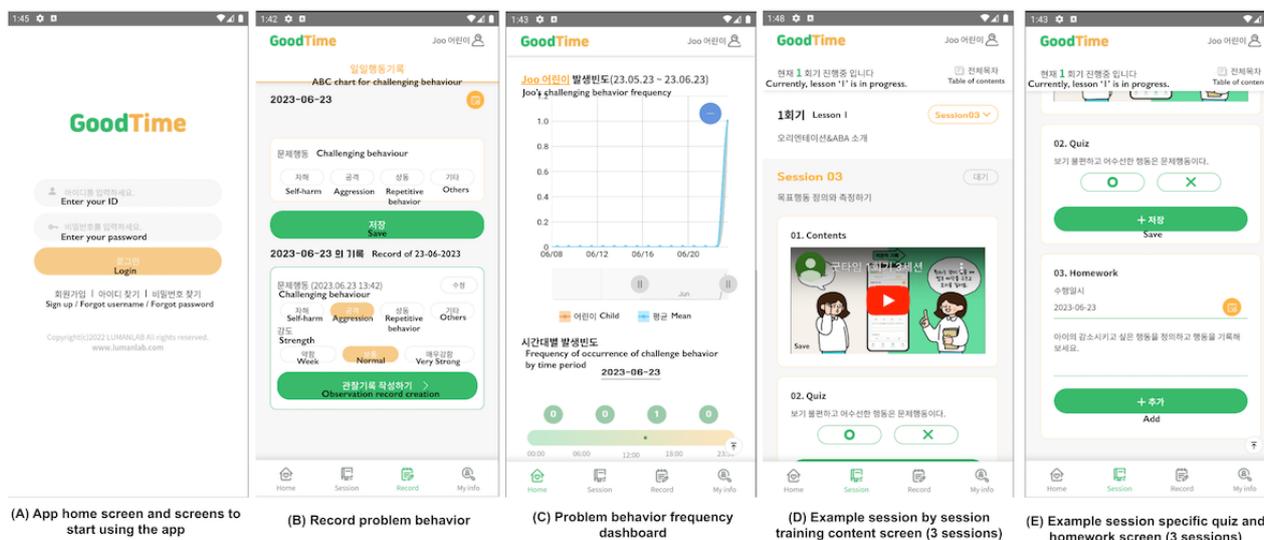

^eDTT: discrete trial training.

Procedure

The mobile app–assisted parent training program was available for download from a mobile app store, and participants accessed this study’s intervention using a unique, preannounced username and password. Parents in the intervention group completed the mobile app parent training program at home over a 12-week period, during which they continued to receive their usual nondrug treatment in addition to the training program. The

mobile app included recording problem behaviors and viewing the frequency of child problem behaviors, education, and homework assignments to help caregivers generalize skills in a real-world setting (Figure 2). All sessions included instruction on the parent training program, video content with case examples to help parents understand the program, and quizzes and homework to check for understanding of the session. Participants could access the app at any time, and all programs delivered were relearnable.

Figure 2. Mobile app platform example. (A) App home screen and screens to start using the app; (B) record problem behavior; (C) problem behavior frequency dashboard; (D) example session by session training content screen (3 sessions); and (E) example session-specific quiz and homework screen (3 sessions).

Control Group

The control group continued to receive their usual nonpharmaceutical treatments, such as behavioral therapy, speech therapy, and play therapy, for 12 weeks, without receiving the mobile app-assisted parent training program intervention.

Measures

About ADOS-2

The ADOS-2 is a tool used to help diagnose ASD by observing children's social interactions and behaviors through play or conversation [35]. It is administered by a qualified evaluator and takes approximately 45 minutes to complete. It is used to set standards for participating children and is a semistructured tool for directly observing children [36].

About K-CARS-2

The K-CARS-2 is a tool used to differentiate between autism and other developmental disorders, and to determine the severity of autism disorders [37,38]. It can be completed in a relatively short amount of time, typically taking 20-30 minutes.

Korean Child Behavior Checklist

The Korean Child Behavior Checklist (K-CBCL) is an evaluation tool used to assess the impact of overall problem behaviors, adaptation, and social performance in children [39]. It is a standardized checklist completed by parents, who describe their child's behavioral and emotional problems. The K-CBCL comprises a social ability scale and a syndrome and total problem scale, taking 15-20 minutes to complete. It is suitable for infants and toddlers aged 18 months to 5 years and can be administered to children aged up to 6 years in kindergarten.

About K-SCQ

The Korean Version of the Social Communication Questionnaire (K-SCQ) is a useful screening tool for identifying a range of

symptoms related to ASD in a short amount of time (approximately 15 min) and can be used with people of any age and language level. It comprises 2 types of tools, each containing 40 questions that ask parents or guardians about their child's symptoms related to autism (such as communication, interaction, and limited and repetitive behaviors and interests) [40]. The Social Communication Questionnaire (SCQ) current type focuses on behavior over the past 3 months, while the SCQ lifetime type focuses on behavior over a lifetime. This study used the Korean translation of the SCQ current type [41].

About Korean Vineland Adaptive Behavior Scale-2

The Korean Vineland Adaptive Behavior Scale-2 (K-VABS-2) is an evaluation tool used to assess the impact of overall problem behaviors, adaptation, and social performance in individuals of all ages. It comprises 4 areas (communication, daily life technology, socialization, and exercise functions) and 11 subareas (including language skills, coping abilities, and small muscle control). The K-VABS-2 can be administered in the form of a survey interview, taking 20-60 minutes, or a guardian rating, taking 30-60 minutes. It is suitable for individuals of all ages [42].

Clinical Global Impression–Severity of Illness

In the Clinical Global Impression–Severity of Illness (CGI-S), a physician uses a scale of 1-7 points to evaluate the severity of a disease based on the symptoms experienced by past patients diagnosed with the same disease. This scale is used to determine the degree of symptoms in currently diagnosed patients [43].

Clinical Global Impression Global Improvement

In the Clinical Global Impression Global Improvement (CGI-I), a physician uses a scale of 1-7 points to evaluate the effectiveness of therapeutic intervention in a patient with a mental disorder. The scale is used to determine whether the patient's condition has improved or worsened compared with before the intervention was initiated [43].

Korean Parenting Stress Index Fourth Edition–Short Form

The Parenting Stress Index is a self-report test used to measure the stress experienced by parents of children aged 1-12 years. It evaluates the characteristics and situational factors of children that affect parenting stress as perceived by the parents [44] and comprises 2 main areas: child and parent. The child area is further divided into 6 subscales: distraction or excessive behavior, adaptation, compensation, demand, mood, and acceptance. The parent area comprises 7 subscales: competence, isolation, attachment, health, role restriction, depression, and spouse or parenting partner relationship. The test also includes a life stress scale that measures events that can affect parenting stress. The Parenting Stress Index is available in both a general form and a short form (Korean Parenting Stress Index Fourth Edition–Short Form [K-PSI-4-SF]); the latter was used in our study [45].

Data Management

Research data were stored in a secure laboratory and personal information was stored in a separate file to ensure that personal identification is not possible through the research data. Enrollment logs were used to maintain personal identification information separately; the case report form did not include personal information except for initials and case numbers. This helped to protect participants' privacy.

Statistical Analysis

All outcomes were analyzed in participants who completed the program period and assessments at baseline and after the intervention. The analysis included participants who did not violate the protocol (per-protocol analysis set). Owing to the nonnormal distribution, nonparametric methods were used in this study. All baseline demographic variables and evaluation outcomes at baseline and after the intervention were summarized by randomized groups using the median (IQR) for continuous data or count (%) for categorical data. We estimated the median values and IQRs for each group and time point using the pre- and postintervention evaluation scores for the intervention and control groups. Before testing the effectiveness of the program, the Wilcoxon signed rank test was performed to determine whether there were differences in demographic and baseline variables between the groups. The Wilcoxon signed rank test was used to compare the effects of all outcomes. To evaluate the intervention effects between the 2 groups, the Kruskal-Wallis test was performed by judging the rejection range based on a significance level of 0.05. To assess differences in session completion rates within the intervention group, we estimated medians and IQRs and used Wilcoxon signed rank tests. To examine the correlation of completion rates with evaluation outcomes, Pearson correlation coefficient was used. Data analysis was performed using the R software (version 4.1.0; R Foundation) and Python (version 3.9.12; Python Software Foundation).

Ethical Considerations

Written informed consent was obtained from all participants. This study was approved by the Seoul National University Hospital Institutional Review Board (H-2205-158-1329).

All data were stored in a locked laboratory, and participants' personal information was stored in a separate file from the research data to prevent identification through the research data. Enrollment logs were maintained to keep personal information separate and to ensure that personal information was not exposed. Only initials and case numbers were used on case report forms to further protect participant identity.

The tests administered as part of this study were provided free of charge. Compensation was not contingent on the participant completing this study, and pretest results were provided even if the participant did not complete this study. The posttest was only administered if the participant completed this study. No other monetary compensation, including transportation, was offered.

Results

Participant Characteristics

Between November 9, 2022, and December 8, 2022, a total of 64 participants were enrolled. Further, 56 participants who met our inclusion criteria were randomly assigned into the intervention and control groups; however, after randomization, 8 participants in the intervention group and 3 in the control group declined to participate, resulting in 20 participants receiving the intervention and 25 participants in the control group. In the control group, 3 participants were excluded from the analysis; these included children who started a new treatment during the intervention period. Finally, a total of 42 participants were included in the data analysis (Figure 3).

Demographic and baseline variables were compared between the intervention and control groups before the intervention. Of the 42 participants, 20 (48%) were in the intervention group and 22 (52%) in the control group. There were no significant differences in sex, age, severity, or ethnicity between the 2 groups. Demographic variables, including the K-CARS-2 and ADOS-2, did not differ significantly between the groups. The current treatment also did not differ significantly between the intervention (n=17, 85%) and control (n=18, 81.8%) groups. Neuropsychological testing showed no significant differences between the 2 groups. The demographic and baseline variables of both groups are summarized in Table 2. Complete information is presented in Table S1 in Multimedia Appendix 1. Table S2 in Multimedia Appendix 1 provides demographic and baseline information for the full sample using an intention-to-treat (ITT) analysis approach. The results of this ITT analysis revealed a significant difference between the intervention group (14.5, 95% CI 12.5 to 16) and the control group (12, 95% CI 10 to 15) on social effect, a subscale of the ADOS, compared with the results obtained from the per-protocol analysis ($P=.045$). Except for this item, no significant differences were found for the remaining items. Multimedia Appendix 1 provides more details.

Primary Outcome

The results for the K-CBCL scores are shown in [Table 3](#). According to the K-CBCL, lower scores indicate a decrease in overall problem behaviors. The K-CBCL total score for the intervention group decreased from baseline to after the intervention (median difference -0.5 , 95% CI -4.5 to 3). In

comparison to the control group, the intervention group's median withdrawn score difference reduced to -2 (95% CI -8 to 4), median difference of attention decreased by -1 (95% CI -6 to 4), and median difference in pervasive developmental disorder exhibited a -1 (95% CI -5 to 2) decrease. The full table is shown in [Table S3](#) in [Multimedia Appendix 1](#).

Secondary Outcomes

Overview

A lower CGI-S score indicates less severe symptoms, a lower K-SCQ score indicates better social communication ability, a lower K-PSI-4-SF score indicates less stress, and a higher K-VABS-2 score indicates better adaptation and social

performance. The results for the secondary outcomes are shown in [Table 3](#), [Table S3](#) and [Figure S1](#) in [Multimedia Appendix 1](#) show the full table and plots.

Clinical Global Impression

There was no median difference between baseline and after the intervention for the intervention and control groups on the CGI-S (0, 95% CI 0 to 0.5). On the CGI-I, the number of participants

who improved after the intervention was 17 (77.3%) in the control group and 17 (85%) in the intervention group.

Social Adoption and Emotional and Behavioral Problems

K-SCQ scores in the intervention group decreased further after the intervention (median 15, IQR 9.5-20) compared with baseline (median 18, IQR 13-20). The median difference in communication on the K-VABS-2 exhibited a 4 (95% CI 0 to 8) increase after the intervention compared with the baseline, and socialization (7, 95% CI 2 to 13; P value <.01) increased more in the intervention group compared with the control group. Daily living skills also showed a significant difference when comparing the pre-post difference in the intervention group to the pre-post difference in the control group (6, 95% CI 1 to 13; P value .02).

Caregiver's Stress

Caregiver's stress was evaluated using the K-PSI-4-SF. The median difference between the intervention and control groups showed that the total stress scale (4, 95% CI -3 to 11), parental distress (2, 95% CI 0 to 6), parent-child dysfunctional interaction (1, 95% CI -2 to 4), and difficult child (0.5, 95% CI -3 to 3) were not statistically different between the intervention and control groups.

Comparison Values Based on Session Completion Rate

The mean number of sessions completed by participants in the intervention group was 13.4 of 26 (51.5%) sessions. The median pre- and post difference for K-CBCL total was -3.5 (95% CI -12 to 5) for 100% completion and -3.5 (95% CI -8.5 to 3) for 40% completion. The median difference in withdrawn was -4.5 (95% CI -14 to 5) for 100% completion and -3.1 (95% CI -11 to 6) for 40% completion, indicating a decrease in the intervention effect. For sleep problems, the median difference was -12 (95% CI not available) for 100% completion and -8.3 (95% CI -12 to -1.5) for 40% completion, indicating a decrease in the intervention effect. Communication and motor skills in the K-VABS-2 also increased from 8 (95% CI -8 to 24) and 10.8 (95% CI 2 to 22) at 100% completion to 3 (95% CI -4 to 11) and 5.5 (95% CI -0.5 to 17.5) at 40% completion, respectively. The total stress scale on the K-PSI-4-SF was 9.5 (95% CI 1.5 to 17) at 100% completion and 1.5 (95% CI -6.5 to 12) at 40% completion, indicating that higher session completion rates were associated with higher caregiver stress. All results for pre- and post median differences in evaluation scores by session completion rate are shown in [Table 4](#) and [Table S5 in Multimedia Appendix 1](#), and correlations for pre- and post median differences in evaluation score by session completion rate are shown in [Figure S2 in Multimedia Appendix 1](#).

Table 4. Differences in pre- and postevaluation values by session completion rate.

Characteristics	Session completion rate				
	100% ^a (n=5), median difference, median (95% CI)	90% ^b (n=6), median difference, median (95% CI)	80% ^c (n=7), median difference, median (95% CI)	60% ^d (n=8), median difference, median (95% CI)	40% ^e (n=9), median difference, median (95% CI)

^jK-SCQ: Korean versions of the Social Communication Questionnaire.

^kK-VABS-2: Korean Vineland adaptive behavior scale-2

^lHigher score indicates increased ability.

^mK-PSI-4-SF: Korean Parenting Stress Index 4th Edition-Short Form.

Statement on Harm

There were no serious intervention-related adverse events that led to treatment discontinuation in either group (Table 5).

Table 5. Summary of any adverse events during the trial.

Adverse events	Intervention group (n=20), n (%)	Control group (n=22), n (%)
Yes	0 (0)	0 (0)
No	20 (100)	22 (100)

Discussion

Principal Findings

This study tested the feasibility of a mobile app–assisted parent training program by comparing pre- and postintervention outcomes over a 12-week intervention to evaluate the effectiveness of the program in reducing behavioral problems in children with autism. Specifically, this study demonstrated the potential for a mobile app–based intervention to reduce behavioral problems in children with ASD. These findings can help in the planning of early interventions and high accessibility of mobile app–assisted parent training programs for children with ASD who have behavioral issues. Problem behaviors in children with ASD cause additional challenges for parents and create uncertainty about how to manage these behaviors. Given these challenges, parents of children with ASD can handle behavioral issues through parent training [46].

Regarding this study’s primary outcome, we found no clinically important differences between the intervention and control groups. A possible explanation for these results is that both groups maintained their existing treatments, such as ABA therapy, sensory integration therapy, and language therapy, which may have provided an indirect pathway for improving problem behaviors in children with ASD. However, the results can still be considered clinically significant. The pre- and posttreatment K-VABS-2 scores for the intervention group showed clinically significant effects for both communication and socialization. Daily living skills also showed clinically significant effects when comparing the intervention and control groups (Table 2). These scores represent the impact of overall problem behaviors, adaptation, and social performance in children, with similar results to previous studies [47,48]. Considering the exploratory nature of this study, we used the K-CBCL as the primary outcome measure, which provides subscale scores across various measurements. However, the actual significant effects were observed in core areas wherein individuals with ASD face difficulties, such as socialization, as was evident in the K-VABS-2, a widely used measure of adaptive behaviors in children with developmental disorders. These findings suggest the potential for conducting a confirmatory study using more focused outcome measurements.

Results on parenting stress showed that, within the intervention group, caregivers who used the training program the most reported higher levels of parenting stress (Table 3 and Figure S2 in Multimedia Appendix 1). This may imply that the more

parenting stress a caregiver has, the more extensively they use the program.

Analyzing the results based on session completion rates, a more pronounced difference was observed between K-CBCL and K-VABS-2. While the scores measured by K-CBCL did not exhibit significant variations based on different completion rates, a notable difference was found in the K-VABS-2 scores. One of the key advantages of digital interventions is their relative freedom from constraints such as time, space, and cost. Therefore, a higher session completion rate would have been expected. However, considering that the session completion rate in this study was not as high as anticipated, our data suggest the need for complementary strategies to enhance user engagement. In doing so, if parental participation in this training program increases, our study’s findings indicate the potential for further improvements in the K-VABS-2 scores.

Ongoing research suggests that a significant number of parents are interested in mobile app–based, evidence-based parent training programs, which do not rely on therapists because the content is standardized and can be easily accessed by parents anytime and anywhere [49]. Using these mobile app technologies can help bring key elements of evidence-based interventions to populations that may not otherwise be able to receive them.

This study had several limitations. First, it relied on parental opinions to assess children’s behavior. Although the CGI-S and CGI-I were assessed by a physician, as the physician’s evaluation relied on parental reports regarding the child, it was also influenced by the parents’ opinions. Second, we observed a nonsignificant clinical effect of the treatment group on the primary outcome, which we attribute to indirect effects from other treatments the child was already receiving owing to this study’s nature. Third, our study had low program participation rates. For studies based on mobile app interventions, there are challenges in promoting participant engagement in the program.

Conclusions

This study demonstrated the feasibility of using mobile devices for evidence-based parent training to reduce problem behaviors in children with ASD. In addition to the high prevalence of ASD and the high cost of treatment, there is a significant shortage of people to provide treatment, which is a barrier to treatment delivery. The accessibility and flexibility of mobile devices may make them a viable alternative as a parent education tool in providing early intervention for problem behaviors in children with ASD.

Acknowledgments

This work was supported by the Information & Communications Technology (ICT) research and development program of Ministry of Science and ICT/Institute for Information Communication Technology Planning and Evaluation (MSIT/IITP; 2022-0-00297, development and clinical validation of digital therapeutics for problematic behavior in children with autism).

Data Availability

The datasets produced or examined during this study are not openly accessible owing to the sensitivity of the information they contain and the potential risk of identifying individuals involved. Nonetheless, researchers who meet the necessary qualifications

may be able to access these data following a structured request procedure that necessitates ethical clearance. Inquiries for data access should be directed to the corresponding author and will be evaluated individually.

Authors' Contributions

YRP and SBH were the chief investigators responsible for this study's design and execution and the decision to submit the results for publication. This study design was developed and approved by J Lee, J Lim, SBH, and YRP. J Lee, SBH, and YRP wrote the paper with approval from all authors and developed the statistical analysis plan. J Lee, SYJ, S Kim (LumanLab), J Lim, and YRP designed and wrote the delivery of the therapy. S Kang, S Kim (Seoul National University College of Medicine), and SBH ensured that the investigation was conducted per the institutional review board approval and plan. J Lee and S Kang accessed and verified the underlying data. All authors critically reviewed the paper for important intellectual content and read and approved the final paper.

Abstract

Background: There are no uniform regulations for the osteopathic profession in Europe. It is subject to country-specific regulations defining who shall be allowed to practice osteopathy and which qualification shall be required. In recent years, legal regulations have been established in several European countries for the profession of osteopathy; however, these are also still pending for Austria. Currently, physiotherapists and physicians with osteopathic training are practicing osteopathy in Austria.

Objective: This study aims to examine the characteristics, challenges, and opportunities of osteopaths in Austria.

Methods: Guideline-based interviews with osteopaths (N=10) were conducted. The different research questions were examined using a qualitative content analysis.

Results: The study provided a differentiated insight into the professional situation of osteopaths in Austria. The most important result was that all interviewees unanimously supported a legal regulation of their profession. However, owing to their different professional self-image—on the one hand, individuals working on a structural basis, and, on the other hand, individuals working on a cranial or biodynamic basis—they were able to imagine a uniform professional regulation only to a limited extent. Additional topics for the interviewed osteopaths in Austria were the quality assurance of training and the urgent need for scientific research. Furthermore, the study also dealt with the influence of the COVID-19 pandemic on daily practice and on education and training in osteopathy.

Conclusions: This study is a pioneering study with regard to systematic basic research on osteopathy in Austria. The obtained results and the newly acquired research questions not only have the potential to serve as a basis for further studies but also provide insight into the working and professional situation of osteopaths in Austria for universities, schools, professional associations, politics, and—last but not least—all interested parties.

KEYWORDS

osteopathy; osteopath; osteopaths; osteopathic profession; health care system; Austria

Introduction

Osteopathy is a manual treatment method, the principles of which are based on its own philosophy and the consideration and treatment of special structure-function relationships in the human body [1]. Since osteopathy was established and as long as it has been applied, both its methods and the professional competence of osteopaths have been the subject of controversy among medical and therapeutic specialists. The European Committee for Standardization has defined osteopathy as a holistic, patient-centered, manual treatment method based on the interactions between the structure and function of the body and the body's self-healing ability [2].

There is no uniform European or international regulation regarding who is allowed to practice osteopathy and which qualifications are required. However, an increasing number of European countries are developing occupational laws for osteopaths. So far, 12 European countries including Cyprus, Denmark, Finland, France, Iceland, Liechtenstein, Luxembourg, Malta, Norway, Portugal, Switzerland, and the United Kingdom have adopted legal regulations regarding the practice of osteopaths [3].

In the German-speaking countries, there is no uniform picture of the profession. In contrast to Switzerland, a legal basis for the profession of osteopathy does not exist in Germany or Austria. In Austria, physicians and physiotherapists trained in osteopathy practice as osteopaths. Physicians are allowed to practice osteopathy without any restrictions, whereas physiotherapists are only allowed to practice osteopathy upon medical assignment [4]. According to the Austrian Society for Osteopathy (Österreichische Gesellschaft für Osteopathie; OEGO), approximately 2000 osteopaths practiced in Austria in 2022.

Studies about osteopathic identity are progressing internationally. However, the various legal regulations and intraprofessional conflicts make it difficult to perceive a collective identity [5]. Especially in countries where osteopathy is not regulated by law, the data about osteopathic practitioners are considered to be weak. However, quantitative studies that have surveyed the population of osteopaths with regard to work status, training, professional identity, or characteristics of clinical practice such as the typical patient profile and the use of diagnostic and treatment modalities exist already. In Austria, 2 surveys of osteopaths have been conducted in the past as part of final theses [6,7]. In 2022, the results of the Osteopathic Practitioners, Estimates, and Rates survey were also published for Austria, thus creating a solid data basis about osteopathic practitioners in Austria for the first time. The typical osteopath was defined as female, aged between 40 and 49 years, self-employed, worked before as a physiotherapist, trained in osteopathy part time, and successfully completed a master's degree [8]. However, there is a lack of studies with qualitative

designs to capture and examine the work of osteopaths in German-speaking countries in more detail.

The overall aim of this study was to make a substantial contribution to the largely unexplored profession of osteopathy in the German-speaking countries. Structured, basic research was necessary to implement this project. The first steps were taken in the framework of the study, "Characteristics, Opportunities, and Challenges of Osteopathy (COCO) in the Perceptions of Osteopaths in Germany, Austria, and Switzerland: Protocol for a Comprehensive Mixed Methods Study." The study protocol was published in *JMIR Research Protocols* in 2019. The Characteristics, Opportunities, and Challenges of Osteopathy (COCO) project investigates how osteopaths in Germany, Austria, and Switzerland distinguish themselves from other medical professions and the characteristics of their work.

This study is a partial study of the COCO project, with a focus on the situation of osteopaths in Austria. Osteopaths practicing in Austria were asked about their professional profile and their professional practice. The following questions were of particular interest: (1) How do osteopaths from Austria describe osteopathy? (2) What are the challenges faced by osteopaths in Austria? and (3) What opportunities do the interviewees see for osteopathy in Austria?

Methods

Design

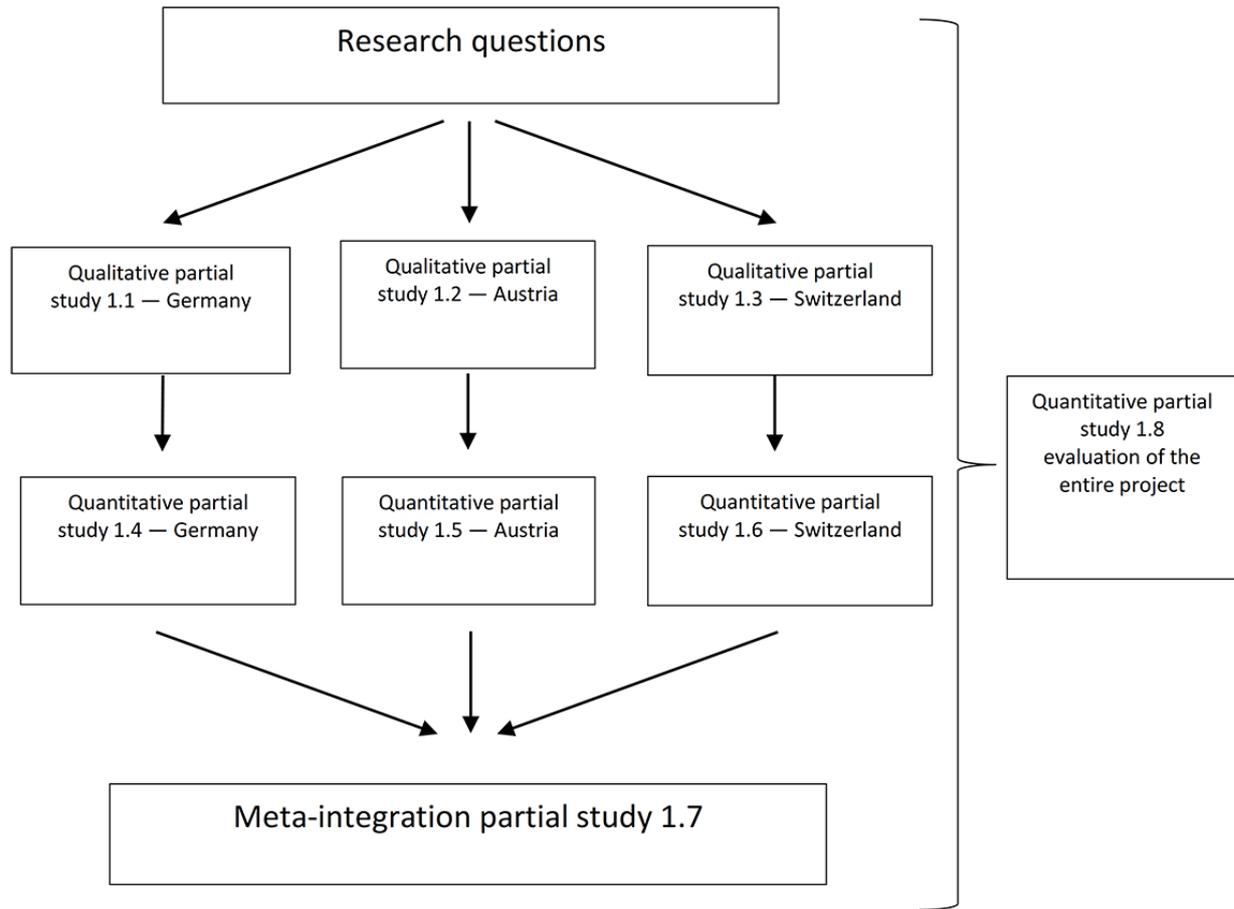

This qualitative study included the planning and implementation of guideline-based interviews with osteopaths practicing in Austria. Subsequently, a qualitative content analysis was performed according to Mayring [9]. A qualitative research design was selected to obtain questions relevant to the project that had not been considered before and views about the topic that had not yet been taken into consideration. The target of this qualitative partial study was the development of hypotheses. Accordingly, a relatively small sample of 8 to 10 participants could be used, because the results obtained shall be examined in subsequent studies with respect to their general validity using a quantitative study design [10].

To ensure the reporting quality regarding the research methodology of this qualitative study, COREQ (Consolidated Criteria for Reporting Qualitative Research) was used [11]. A checklist including the COREQ items taken into consideration has been attached to the paper ([Multimedia Appendix 1](#)). The registration identifier of the study is the International Registered Report Identifier: PRR2-10.2196/15399.

Ethical Considerations

This study (corresponding to partial study 1.2 in [Figure 1](#)), led by DM, has received ethics approval (S-287/2020) from the ethics committee of the University of Witten/Herdecke, Germany. Participants were not compensated for their participation.

Figure 1. Characteristics, Opportunities, and Challenges of Osteopathy project flowchart.

Setting and Sampling

Related to the research topic, osteopaths in Austria were questioned through guideline-based interviews. All the interviewed osteopaths (10/10, 100%) had completed at least 4 years of training as osteopaths and practiced as osteopaths in Austria. Instead of asking individual osteopaths to participate, OEGO was contacted with the study project itself, thus avoiding cold-calling. In this way, the criterion of comprehensive training in osteopathy was fulfilled, because otherwise, the participants could not be members of the professional association. This procedure ensured that the participants had provided evidence of their competence. To obtain the widest range of views, the sample was intended to show a high degree of diversity among the participants. Therefore, a further criterion for the whole group of participants was sex distribution according to the population of osteopathic practitioners in Austria. According to the OEGO’s membership register, two-thirds of practicing osteopaths in Austria are female and one-third are male. Moreover, care was taken to ensure that the residences and workplaces of the participants were subject to as wide a geographical distribution as possible, so that district-specific phenomena could be excluded. As osteopathy is not an independent profession in Austria, the participants should

include the different occupational groups that practice osteopathy. Inclusion and exclusion criteria were subsequently formulated (Textbox 1).

OEGO forwarded the contact details of 11 osteopaths. Appointments for an interview were made with 8 (73%) of the 11 osteopaths. No appointment could be made with 1 osteopath during the study period. From 1 other osteopath, no response to the request was received. Another 1 osteopath did not want to participate in the study; 2 new osteopaths were suggested by the osteopaths themselves. A total of 10 interviews were thus conducted.

All the participants were contacted via email and received a letter containing information about the course of the study, declaration of consent to participate in the study, and data protection declaration. The entire participation in the research project and the answering of individual questions was on a voluntary basis; nonparticipation did not lead to any disadvantages for the participants. The participants always had the option to end the survey (eg, in the case of unexpected, stressful questions). Through the format of web-based survey, any increased risk of infection for the participants owing to the COVID-19 pandemic could be excluded. Explicit cancellation criteria for the project were not set.

Textbox 1. Inclusion and exclusion criteria.**Inclusion criteria**

- The individual has completed 4 years of osteopathic training.
- The individual is currently practicing osteopathy.
- The individual has provided consent to participate in the study.

Exclusion criteria

- The individual cannot be interviewed within the examination period.
- The individual does not have the technical equipment required for participation in a web-based survey.
- The individual demands compensation.

Development of the Interview Guidelines and Data Collection

The guideline-based interview was chosen as a suitable research tool, because the aim of the data collection was to obtain concrete statements about the practice of osteopathy in Austria. In addition, the use of a guideline increased the comparability of the individual data sets [12]. Furthermore, this procedure avoided the possibility that essential aspects of the research question might be overlooked in the interviews [13]. The interview guideline was developed by JM on the basis of the research questions and 2 previous qualitative, partial studies of the COCO project [14,15]. The interview guideline was

developed by JM on the basis of the research problem and 2 previous qualitative, partial studies of the COCO project [14,15].

The questions were formulated as open questions (Textbox 2) and arranged according to the groups of topics (Textbox 3). In addition, sociodemographic data about the participants were collected. Alternative questions were prepared to be able to react flexibly to the course of the interview and to respond to the potential needs of the participants. To maintain the flow of the conversation, additional questions were developed in advance. Before beginning the interviews, a test interview was conducted with a German osteopath to test the interview guideline in practice and to improve the interview technique. Finally, the questionnaire was discussed and adapted together with JP, an osteopath with experience in qualitative research.

Textbox 2. Example interview questions.

- Where did you first hear about the osteopathic profession?
- How would you define osteopathy?
- In your opinion, what differentiates osteopathy from other professions?
- What does a typical osteopathic treatment look like for you?
- Should osteopath be its own profession?
- Are there any difficulties or problems that you face in your daily work life as an osteopath?
- Has the corona pandemic changed anything in your daily practice?

Data Collection

Data were collected from November 29, 2021, to January 26, 2022. In total, 10 interviews were conducted. The interviews were conducted using the Zoom software (Zoom Video Communications; audio and video were recorded). Apart from research economy and temporal and local flexibility, interviews were primarily conducted on the web to protect the participants from infection during the COVID-19 pandemic. No other individuals were present during the interviews. No interview was repeated. The interviews were recorded as a video file for transcription. The participants agreed in writing to the archiving of the files until the end of the publication activities or up to a maximum of 5 years after data collection. The files were protected against unauthorized access and stored and evaluated on local data carriers of a password-protected computer. Only encrypted files were transferred among the study colleagues. Upon completion of the study project, the recordings of the interviews shall be deleted irrevocably. All the interviews were conducted by JM in German. The interviewer is male, holds a master of science degree, and has already published in 2019 within the COCO project. At the time of the survey, he worked independently as a physiotherapist in his own practice in

Germany and was a doctoral student at the University of Witten/Herdecke. For this research project, JM was trained within a 3-part seminar at the Freie Universität Berlin regarding the collection and evaluation of qualitative data and the conduction of interviews. There was no previous personal relationship with any of the interviewees. The recordings were transcribed by JM. Transcription was performed according to pre-established rules, which were consistently observed, as there are no generally accepted transcription rules [16]. The rules were based on the transcription rules of Kuckartz and Rädiker [17] for computer-assisted evaluation. The participants were sent the transcript to gather their comments, if any, and to receive their final approval.

Data Analysis

On the basis of the results of the interview studies already conducted within the COCO project, deductive (ie, indirectly theory-driven) categories were formed first. It is indirect because the categories are descriptive and their definition is not the basis of a theory-driven description. As a first step, classical deductive codes were derived from the interview guideline (deductive category application). The transcripts were analyzed in the original language by means of content structuring. With the

help of the MAXQDA 2022 software (VERBI Software) [18], quotations that were relevant for the abovementioned research questions were categorized. Owing to an extensive interest in further knowledge, the preselected segments were expanded or specified by means of inductive categorization to deduce further

important aspects (deductive-inductive categorization) [17]. The quotations were summarized in categories, which were subsequently grouped into high-level categories. The main strategies of data analysis are described in [Textbox 4](#).

Textbox 4. Data analysis strategies.

Coding

- After developing an initial category system together (first, deductive; second, inductive), 2 complete material iterations were performed by 2 separate evaluators

Discussion

- Comparison and discussion of the results, with the main focus on the integration of different perspectives and the elimination of ambiguities

Quality control

- To check the quality of the category system (intercoder reliability) with its coding rules by means of the Cohen κ coefficient

Final iteration

- After the quality control step, a final, complete material iteration was performed by an evaluator using the final category system

Shared Coding

A first interview was coded by 2 evaluators together (JM and UW), and the category system was inductively expanded. An initial category system was developed, and coding rules were determined on the basis of 2 partial studies (eg, [Figure 1](#)—partial studies 1.1 and 1.3) [14,15] and the interview questions and guidelines developed specifically for this partial study. The result was an initial, deductive category system, and the first coding rules were defined. The deductively determined categories were based on the research questions and increased based on inductive subcategories during the evaluation. Then, the first iteration was run with the entire material, followed by further inductive categorization (UW). A second evaluator (JM) ran the second iteration of the entire material based on the category system resulting from the first material iteration. The results were then compared and discussed, with the main focus being on the integration of different perspectives and the elimination of ambiguities. The code definitions and anchor examples were also revised in this step. Finally, the category system was standardized. This shared coding from the beginning of the study was intended to increase the intersubjectivity of the statement.

Quality Control

Subsequently, of the 10 interviews, 3 (30%) were selected via lot procedure as a subsample to check the quality of the category system with its coding rules by means of the Cohen κ coefficient. The determination of the Cohen κ coefficient is a method for checking the intercoder reliability [19]. UW received the 3 allotted coded interviews from JM. The segment boundaries of the encodings were retained during this iteration. In this way, the evaluator was able to recognize which text parts were encoded and arrange these according to the categories. Without random adjustment, a match of 62.1% between the 2 encodings of this subsample was reached. The randomly adjusted coefficient was 0.61. Pursuant to Altman [20], accordance is considered as “good” in the case of a κ coefficient

of 61-80. After this quality control, as there was good accordance; a final complete material iteration was performed by an evaluator (JM) using the final category system.

Results

Overview

The result of this study was a system of categories in which the statements of the participants were classified and subcategorized according to the research questions regarding the groups of topics, such as characteristics, challenges, and opportunities of the osteopaths practicing in Austria. Sociodemographic data and more general statements about the practice of osteopathy were also classified in the main category, “training and work in osteopathy.” Out of current concern, the osteopaths were also asked about the influence of the COVID-19 pandemic on their work. On the basis of the interesting statements, we decided to dedicate a special category to this topic.

The final category system consists of 71 categories with a total of 783 encoded text passages. A definition was created for each individual category, and a quotation was recorded as an anchor example.

Only a part of these results could therefore be described in this paper. The printed quotations have been translated into English and serve for illustration purposes only. The question whether individual statements of the participants (O1 to O10) represent the entire population of osteopaths practicing in Austria shall be subject to further investigation.

Training and Work in Osteopathy

A total of 10 osteopaths practicing in Austria were interviewed—6 (60%) women and 4 (40%) men. Of the 10 osteopaths, 3 (30%) were physicians and 7 (70%) were physiotherapists. Of the 10 interviewees, 9 (90%) worked independently in their own practices and 1 (10%) had an employment relationship at the time of the interview. Only 10% (1/10) had other employees. The longest interview lasted 61

minutes, and the shortest interview lasted 29 minutes. The average duration of the interviews was 46 (SD 9.2) minutes.

The participants' characteristics are described in Table 1.

Table 1. Participants' characteristics (N=10).

Characteristics of Osteopathy

On the basis of the descriptions provided by the participants regarding the properties of osteopathy, the following categories were developed: "definition of osteopathy," "patient profile," "anchor personalities and literature," and "limits of the treatment technique."

Definition of Osteopathy

When asked about the definition of osteopathy, several participants had difficulties in explaining the concept:

Yes, it's really a difficult question. [O1; item 35]

The explanation of the term was mostly based on the manual work, origin of the word, differentiation or overlapping with other professional groups, or citation of definitions of third parties. Often, reference was made to the philosophy of osteopathy, holism of the treatment method, and activation of self-regulating forces. There was no uniform definition of osteopathy among the answers of the interviewees.

Patient Profile

Most of the interviewed osteopaths treat patients of all ages:

Oh, everything actually, there are patients of all ages. From...three-month-old babies to over 90-year-old men, women, so I couldn't paint a typical picture. [O2; item 54]

Common indications for child treatments mentioned by the interviewed osteopaths are sleep disorders, torticollis, scoliosis,

asthma, abdominal colic, and plagiocephaly. The treatment of adults was mainly based on the diagnosis or leading symptoms from the orthopedic area: back and neck pain and joint pain. Neurological diseases such as Parkinson disease were also mentioned. Moreover, patients were regularly treated for headache, migraine, tinnitus, chronic pain, craniomandibular dysfunction, abdominal pain, and hormonal imbalances or if wishing to become pregnant. However, internal diseases such as sinusitis, bronchitis, and cystitis were also treated by the physician O2 on the basis of osteopathic methods.

The indication of the treatment was usually given by the patients' treating physician:

Patients are often assigned by the doctors, meaning that the doctor writes a prescription with a recommendation to contact a certain therapist. [O8; item 51]

A participant working as a general practitioner in addition to his osteopathic activity also acquired patients during his regular consultation as a physician:

And actually, many of those who go to the general practitioner's clinic in the village, they come to me, too. [O2; item 54]

It appears that, in general, a broad medical field was covered by osteopathy. The selection of the appropriate therapist seemed to depend on personal recommendations of others, on the therapeutical possibilities in the patients' vicinity, and on the training or specializations of the osteopaths:

Because the patients who come to me come by word of mouth, yes. [O5; item 47]

Everything else is, I think, very average, that is, all the people who come to me do so because I am in their vicinity. [O3; item 38]

Patients who travel a long way mainly come because of endocrinological, metabolic problems..., gynaecological problems..., that is to say, where...the focus of my...training has mainly been during recent years. [O3; item 38]

Anchor Personalities and Literature

It was noticeable that many participants referred to other individuals when answering questions about osteopathy in theory and practice. These “anchor personalities” seem to have a great influence on the self-image of osteopaths in Austria and have therefore been included in a separate category. Both historical personalities from the history of osteopathy and currently active osteopaths were repeatedly mentioned:

But there will always be people who really care about this innermost quality of osteopathy... And just as osteopathy has developed from Still to Sutherland, Becker, Viola Frymann...and all their names..., or Mitchell and Jim Jealous now..., so it will continue to develop. [O5; item 84]

With regard to the self-study of osteopaths, primarily only the German-language journals of osteopathy were mentioned as reading material. Of the 10 participants, only 1 (10%) indicated that they regularly read an English journal:

Yes, I regularly read the two journals, DO and Osteopathische Medizin. [O5; item 88]

Limits of Osteopathy

There was agreement regarding the limits of osteopathy. The primary treatment of structural injuries or the care of patients with cancer without medical supervision were clearly mentioned by the interviewees as limits of osteopathic activity. However, patients were given osteopathic treatment nevertheless:

Yes, of course I see the limits in the pathologies that are there. If there is actually...an osteoarthritis that is simply there and will not vanish, osteopathy shall certainly have its limits; one can perhaps relieve the pain, but the osteoarthritis cannot be cured by osteopathy, now can it. I also see limits in some diseases. [O7; item 56]

O9 differentiated upon request that it is not the diagnosis that is decisive for the objective of treatment when it comes to whether osteopathic treatment is indicated or contraindicated:

Well, that depends on the objective.... It all depends totally on the objective. If I say that I want to treat coxarthrosis curatively, I think that we shall soon reach our limits with osteopathy; if we do a control X-ray after six months, we shall see that it is still coxarthrosis.... But if I say that I want to improve the quality of life, I would treat them nevertheless. The question is what the objective is. [O9; item 41]

O4 brought another aspect to mind:

We must not exceed the limits...of our own competence. That is very important. Unfortunately, many colleagues do this by suddenly giving dietary recommendations, by suddenly recommending medicines...or by talking patients out of taking medicines. Especially now when it comes to vaccination. [O4; item 75]

Challenges of Osteopathy

The challenges mentioned for the field of osteopathy can be classified mainly into the categories, “identity problem,” “disagreements within the osteopath community,” “research,” “training quality management,” and “conflicts and difficulties.”

Identity Problem

One of the great challenges of osteopathy is its unclear definition and lack of differentiation from other professional groups. As O6 clearly pointed out, osteopathy has an identity problem:

I would say that the identity problem is the most important issue...The definition is the most difficult question and no one can answer that. And if we can't answer that and don't deal with it, how can we argue what we are if we ourselves don't know exactly what we are. [O6; item 49]

Disagreements Within the Osteopathic Community

The identity problem or the problem of missing a uniform professional self-image might be based on disagreements within the osteopathic community described by several participants. Overall, 2 groups can be identified among practicing osteopaths: on the one hand, the structurally working osteopaths and, on the other hand, the cranially or biodynamically working osteopaths:

Yes, there is really a gap between biodynamic osteopathy and structural osteopathy. [O7; item 104]

This conflict might be decisive not only in terms of a common definition but also with respect to a possible recognition of osteopathy in terms of professional policy. O9, who was involved in professional policy, feared that these disputes might even prevent recognition:

The problem concerning regulation is - and that's simply the case now and that's also the elephant in the room about which no one is talking -...the problem with regulation has always been cranio.... You cannot say it openly, but it was always the problem of craniosacral therapy, no matter who I talked to. [O9; item 93]

Those participants who worked biodynamically were more critical toward regulation:

If one tries now to take this out of this mental...source,... I see the risk that it is practically shifted into evidence-based, as important as that is, well, but only into evidence-based, visible and perceptible dimensions, then osteopathy shall lose its

soul from my point of view.... And that's actually the greatest threat to osteopathy for me. [O5; item 64]

Research

In this context, O1 pointed out that evidence-based research can only substantiate a certain part of osteopathy scientifically, whereas other aspects might be lost:

A good scientific basis in order to argue how...many benefits osteopathy has...- in the end,... academisation probably cannot be avoided and will certainly be necessary. Even if all these developments are not entirely without risks. That is, the risk of losing sight of the holistic aspects of osteopathy. [O1; item 81]

Training Quality Management

Many osteopaths considered existing weaknesses in the training courses and their structures as a further obstacle. According to O4, a central aspect is the inadequate teaching of the skills for scientific work at osteopathy institutes and, thus, the lack of evidence-based research in osteopathy:

[Oh my] the training...We should learn from the beginning, not only during the last year when we have to write a Master Thesis, we should learn from the beginning what it means to work in an evidence-based way, to do research...It works in physiotherapy and is continuously getting better there, but in osteopathy...At the beginning, we never learn to deal with available studies, it is a matter of training. From the beginning, not only during the fifth year shortly before the Master Thesis, we should have the first lessons in statistics. [O4; item 113]

Conflicts and Difficulties

The lack of clarity regarding the profession is evident in the differentiation with respect to other professional groups. With regard to the settlement for osteopathic treatment with health insurance providers, several participants also reported potential for conflicts. Osteopathic treatment is often provided on the grounds of a physiotherapeutic prescription by the physician. The reasons are the economic pressure on the practices or the social situation of the patients:

Many colleagues work as physiotherapists, they also charge for osteopathy as physiotherapy, and yes, they are refunded in this way. And as a result,...osteopathy is also a little...less in the focus than it should be. I've been working for 20 years now, I'm only writing osteopathic invoices.... But...of course...I understand the problem. If somebody has fewer patients...and...has to charge for...physiotherapy, I absolutely understand the situation.... But...these problems are of course...long-burning issues. [O5; item 78]

No, [the bill] of course says physiotherapy and remedial massage, because otherwise the patient doesn't get his/her money from the insurance company. For the insurance company, well, this is ok or it is tolerated. I have already received the feedback from many patients that they told the company that

they went to an osteopath, and the health insurance said that of course that can't be billed, [but] we shall write physiotherapy and remedial massage and then that's it. [O8; item 55]

When asked about the challenges for osteopaths in general, the physicians working as osteopaths did not report any difficulties related to their practice. A physician and osteopath, in contrast, was aware of the potential for conflict:

Yes, of course I know that. I have a bonus, because I'm simply a doctor. And of course, osteopaths that aren't doctors have greater difficulties and are often rejected,...well,...because they are no medical doctors in a manner of speaking and...there are obviously difficulties. [O1; item 101]

Another participant stated it even more clearly:

No, I'm a doctor, I have...no restrictions. [O9; item 85]

Opportunities in Osteopathy

Regarding the questions about the opportunities and chances in osteopathy, most of the statements could be classified into the categories "professional profile" and "position in the health care system." A central opportunity in osteopathy is the installation of an independent profession. Almost all the osteopaths explicitly formulated the desire for their own professional profile. However, there was disagreement about the questions regarding where and how this profession should be integrated into the health care system or which competences it should include:

In the midst of the other health professions..., well, I don't see us as special consultants, as it is now in America, for example. But I see us as a health profession next to physiotherapists, occupational therapists... [O4; item 81]

In this context, many possible applications were mentioned for the field of osteopathy. An osteopath saw a great opportunity in the prevention of diseases:

Concerning also prevention..., I believe that osteopathy has an enormous potential for people's health by simply doing something really good and also really preventing things,...follow-up problems or operations or God knows what...I see a huge opportunity there. [O10; item 107]

O2 also attributed the potential for cost reduction to preventive osteopathy. From his point of view, examinations and medical consultations might be reduced:

I see a huge and very central importance of osteopathy in primary care...and I am convinced...from my daily experience that an incredible number...of diagnostic measures or specialist care...might be avoided if people were primarily also treated by osteopaths. [O2; item 68]

Whether osteopathy actually contributes to disease prevention and can thus also lead to cost reduction or relief for the health care system is to be investigated using clinical study designs

on the effectiveness of the treatment method itself. The position of osteopathy in the health care system and its differentiation from other professional groups have also not been uniformly described by practitioners in other countries.

The COVID-19 Pandemic

For current reasons, the participants were questioned about the effects of the COVID-19 pandemic, existing since March 2020, on their professional activities. Similar to a magnifying glass, crises very often reveal the weaknesses and failures of structures and concepts; however, they can also show their viability and strengths. Most respondents described the time of the COVID-19 pandemic with the lockdowns and the associated measures as a turning point in their practice. However, none of the participants described economic losses or existential fear:

Well, the time during Covid-19 wasn't easy at all. [O5; item 75]

At the time of the survey, everybody had to wear a face mask, patients and osteopaths alike. The interviewees not only described the difficult communication with the patients because of the mask but also mentioned limitations during examination and treatment. Certain treatments, for example, techniques relating to the mandibular joint, could not be performed for patients wearing a face mask:

I believe that a lot of communication is lost through the mask, because you don't see the whole face of the patient. Of course, you have communication through the eyes, but there is still a barrier, a lot is lost...It already starts with and continues during inspection: you only see half of the face and in the case of jaw problems, I have to take down the mask first. [O8; item 107]

Almost all the interviewees described a change in the clientele of their patients. Stress, sleep disorders, headaches, and dysfunctions of the mandibular joint were increasingly mentioned:

Psychosocial stress is increasing immensely...This in turn results...in sleep disorders...Mandibular joint problems due to stress, but also - and this is my own observation - because you constantly want to push around this mask if you have to wear it all day...I think that this has a huge influence...[O6; item 79]

Teaching also seemed to be affected by the protection measures for pandemic control. An osteopath reported that teaching on inpatients at the hospital ceased. The question of whether the osteopathic treatment of inpatients in institutions was disturbed by a lack of external osteopaths remained unanswered:

Prior to the lockdown, our osteopathic child centre also paid visits to the neonatal ward...where we treated premature babies. Unfortunately, this is not possible at the moment. [O1; item 47]

Owing to the cancellation of congresses and courses or their transfer to the digital world, interviewees experienced a gap in their personal training plans:

Of course, I...repeatedly attended courses. However, I scarcely did so in the last two years, actually...[O5; item 88]

This can only be a small insight into the impact of the pandemic in the field of osteopathy. The effects of the COVID-19 pandemic on osteopathic care should be investigated systematically in the next few years.

Discussion

Principal Findings

This study identified numerous aspects, possibilities, and opportunities in osteopathy in Austria from the point of view of the osteopaths practicing in Austria.

In our survey, the typical osteopath presents as female and has previously worked as a physiotherapist, as previous studies have found [8]. This is consistent with other surveys from Europe regarding osteopathy. Moreover, in accordance with a study from Italy, the typical osteopath practicing in Austria works independently in their own practice and without employees [21].

The osteopaths interviewed usually found it difficult to define osteopathy. The respondents were not able to provide a uniform definition of osteopathy. Many respondents even expressed difficulties in precisely describing their profession. Nevertheless, recurring patterns can be recognized in the explanations given by the respondents.

The participants attempted to define osteopathy by drawing a distinction or differentiation from other professions and using third-party definitions. Furthermore, the philosophy of osteopathy, various osteopathic concepts or models of thought, the holistic nature of the treatment method, and activation of the patient's self-healing powers are often referred to. A possible reason for the heterogeneous attempts at explanation may lie in the difference in training and previous education. A recent study showed that only 17% of osteopaths surveyed in Austria identified themselves "exclusively" as osteopaths [8]. Therefore, there is a suspicion that, as our study also showed, the basic profession and nonregulation have a major influence on self-image. We observed a fundamental distinction between therapeutic and medical osteopaths.

From our point of view, the clear statements regarding the disagreements within the osteopath community were surprising. The conflicts do not remain in the specialist circles of osteopathy, but they even extend to the level of professional policy. The question is whether this is a country-specific observation for Austria. In their study in Australia in 2018, for example, Blaich et al [22] found disagreement about the specialization of osteopaths; however, it did not result in the splitting of osteopaths into 2 separate groups. The belief patterns and paradigms of individual treatment techniques that influence professional identity are not new in osteopathy [23]. The fact that, according to the osteopaths interviewed, these intraprofessional conflicts exist even on the political level or are the reason for nonregulation is remarkable. An increasing number of European countries regulate the professional practice of osteopathy. Therefore, it remains to be investigated whether this dispute itself has an influence on the nonregulation of

osteopathy in Austria. However, conflicts and different opinions within a professional group are not inherent in osteopathy; these also exist in other medical professions such as chiropractic [24,25].

The general development of a profession is not only subject to cultural, historical, and social influences but also to the question of gender [26]. In this context, this study indicates a large influence of anchor personalities on the self-image of the interviewed osteopaths. It is remarkable that the anchor personalities mentioned are almost exclusively men. The historical context is worth noticing here, because Andrew Taylor Still, the founder of osteopathy, explicitly promoted equality between men and women already in the 19th century, in contrast to many other universities or teaching institutes during that time. He expressly included women in his courses [27]. In this context, it should be noted that in other health professions, although the practitioners are predominantly women, the leadership positions are often mainly occupied by men [28]. It is therefore not surprising that most users and practitioners of alternative medicine are women if their health needs are not being met by scientific medicine [29]. This becomes problematic when these professions are or become patriarchally dominated to match scientific standards [30].

To answer the questions about the origin of these conflicts and to deal with these in the future, we believe that a systematic and country-specific scientific analysis will be required. Conflicts in the health care system not only have the potential to weaken a profession but can also have a stimulating influence if understood as an opportunity [31].

Most of the osteopaths surveyed were in favor of a legal regulation of the profession. Under certain circumstances, osteopathically trained physiotherapists could benefit more from this, as they currently still need a physician's order to be able to practice with legal certainty.

However, nonregulation also has some advantages—no applications for licenses, no obligation for regular further training, and unregulated pricing for treatment. With integration into the health care system, some participants fear deterioration owing to possible low or lower payment by health insurance companies.

Training quality management and studies in the subarea of osteopathy were also mentioned as challenges in this context. In Italy, Sweden, and Australia, the transfer of scientific results to the practical work of osteopaths has already been systematically investigated in a country-specific manner [32-34]. The openness to evidence-based practice (EBP) appears to exist among practicing osteopaths on a transnational basis, but the skills in dealing with the former vary from country to country. A study of EBP from Spain characterized the skills of the participants to deal with EBP as being rather low. This might be related to the lack of legal regulations and the inadequate transfer of knowledge in the training institutions [35]. The situation regarding osteopathy is similar in Austria. Additional country-specific studies are required to identify conclusions and connections.

The different situation in everyday practice owing to the COVID-19 pandemic and the respective infection protection measures also had an influence on the daily work of osteopaths. Several interviewees realized an evident change in the patients' profile. Although economic damage or fear for their professional existence were not explicitly described, most osteopaths working independently were themselves responsible for the implementation of the legal measures in their practices. The impact of the pandemic on the daily work in practice seems to have been less considerable than the impact on the field of training in osteopathy. As a large part of practical teaching occurs with patients under supervision, it is difficult to implement in a web-based format. The impact of the pandemic on clinical research at universities or universities of applied sciences remains to be examined.

In the case of further investigations in this area, we recommend a specific distinction of the participants between physicians and physiotherapists practicing as osteopaths. As there is no uniform training or legal regulation of osteopathy in Austria, only physicians and physiotherapists trained in osteopathy exclusively practice osteopathy. The results of this study suggest that there are evident differences between these 2 professional groups regarding, for example, patient acquisition, conflict management, and cooperation with other professional groups.

The extent to which the individual statements made by the interviewees represent the entirety of osteopaths practicing in Austria will be further investigated. The protocol of the COCO project describes the further procedures. The results of the qualitative partial studies (studies 1.1, 1.2, and 1.3 in Figure 1) will be combined in a following study to verify the results of the qualitative partial studies in relation to the population [36]. We will develop a standardized questionnaire as a measuring instrument.

An important feature of this study is the methodology, including 2 evaluators who completed the entire evaluation process. Through this approach, intersubjectivity increased and new, inductively formed categories were created. During this phase, many aspects of the research problems could be identified and categorized. The intercoder reliability was tested and found to be viable within this study. With another material iteration, the category system can be further refined, and the intercoder reliability can be further increased by optimized code definitions.

Limitations

First, it should be noted that the results of this study do not necessarily allow conclusions to be drawn about the entirety of osteopaths in Austria, as this is not an evaluation of representative surveys with large numbers of participants. Nevertheless, certain tendencies seem to emerge when statements by osteopaths appear to be congruent, that is, confirm each other or complement each other in a meaningful way. The sample represents the entirety of osteopaths in Austria well. Most respondents were women and physiotherapists [8]. Nevertheless, bias cannot be dismissed with such a specific sample. However, they give an idea about how osteopaths in Austria think, and the results obtained can serve as a hypothesis for large quantitative studies to test.

Conclusions

It is difficult to characterize the community of osteopaths in Austria conclusively. On the one hand, there is a great deal of agreement about the urgency regarding regulatory legislation for their profession, a necessary revision of training structures, and the specific promotion of scientific studies of osteopathy. However, when it comes to the concrete practice of osteopathy, deep trenches and even strong disputes have occurred among osteopaths.

The following question remains to be answered: what is “correct” or “true” osteopathy? If we consider that osteopathy has derived from various sources; that its founder did not give a final answer to the question about what he understood by osteopathy; and that each discipline is constantly developing, solely through the different osteopaths practicing, it appears that this question cannot be answered completely.

Apart from this issue, there is another and equally sensitive question, that is, whether and how the different parties can or even must be brought together for the regulation of their profession, which is desired by most of them. The different professional origins of osteopaths should also be considered. With regard to binding legal regulations, which would not least strengthen the professional image, mutual understanding seems to be imperative. Perhaps such an understanding might also lead

to greater political weight for osteopathy, which it urgently needs, not only in terms of legal regulations but also to be able to promote important research projects.

The question arises as to whether the conflicts within osteopathy, in particular, with their possible professional-political consequences and the immense influence of the basic profession in the practice of osteopathy, are a country-specific phenomenon for Austria. However, there is a lack of studies in German-speaking countries with comparable qualitative designs to assess the work of osteopaths in more detail. We are therefore planning a meta-synthesis of qualitative studies with the aim of generating new theoretical insights from the accumulation of study results. Both the studies from the COCO project itself and other relevant literature can be used for the meta-synthesis.

To the best of our knowledge, the COCO project is the largest mixed methods study project on the osteopathic profession in German-speaking countries. The category system with its reliability check can be used as a basis for a repetition of the study. Such a research project would also be interesting if the profession was regulated formally and substantially in the near future. The results presented in this paper are not only intended to serve as a basis for further studies but also to provide universities, schools, professional associations, and politicians with an insight into the situation of osteopaths in Austria.

Abstract

Background: Digital interventions are gaining increasing interest due to their structured nature, ready availability, and self-administered capabilities. Perinatal women have expressed a desire for such interventions. In this regard, behavioral activation interventions may be particularly suitable for digital administration.

Objective: This study aims to exploratorily investigate and compare the feasibility of the internet-based self-help guided versus unguided version of the Brief Behavioral Activation Treatment for Depression-Revised, an empirically supported in-person behavioral activation protocol, targeting pregnant women with subclinical depression symptoms. A user-centered design is used, whereby data are collected with the intent of evaluating how to adjust the intervention in line with pregnant women's needs. Usability and user engagement were evaluated.

Methods: A total of 11 Italian pregnant women with subclinical depressive symptoms based on the Patient Health Questionnaire-9 (scoring < 15) participated in this study; of them, 6 (55%) women were randomly assigned to the guided group (age: mean 32.17, SD 4.36 years) and 5 (45%) to the unguided group (age: mean 31, SD 4.95 years). The Moodle platform was used to deliver the interventions in an e-learning format. It consisted of 6 core modules and 3 optional modules; the latter aimed at revising the content of the former. In the guided group, each woman had weekly chats with their assigned human guide to support them in the homework revisions. The intervention content included text, pictures, and videos. Semistructured interviews were conducted, and descriptive statistics were analyzed.

Results: Collectively, the data suggest that the guided intervention was better accepted than the unguided one. However, the high rates of dropout (at T6: guided group: 3/6, 50%; unguided: 4/5, 80%) suggest that a digital replica of Behavioral Activation Treatment for Depression-Revised may not be feasible in an e-learning format. The reduced usability of the platform used was reported, and homework was perceived as too time-consuming and effort-intensive. Moreover, the 6 core modules were deemed sufficient for the intervention's goals, suggesting that the 3 optional modules could be eliminated. Nevertheless, participants from both groups expressed satisfaction with the content and found it relevant to their pregnancy experiences.

Conclusions: Overall, the findings have emphasized both the intervention's merits and shortcomings. Results highlight the unsuitability of replicating an in-person protocol digitally as well as of the use of nonprofessional tools for the implementation of self-help interventions, ultimately making the intervention not feasible. Pregnant women have nonetheless expressed a desire to receive psychological support and commented on the possibilities of digital psychosocial supports, particularly those that are app-based. The information collected and the issues identified here are important to guide the development and co-design of a more refined platform for the intervention deployment and to tailor the intervention's content to pregnant women's needs.

Introduction

Background

Peripartum depression refers to an episode of depression that meets the criteria for persistent or major depressive disorder, with onset occurring during the peripartum period [1]; this definition highlights the direct link between the development of the depressive condition and the bodily changes and overall characteristics inherent to the perinatal period [2]. A distinction should also be made with regard to antenatal and postnatal depression, since antenatal depression is recognized as one of the main predictors of postnatal depression, with the latter then aggravating the repercussions on the mother as well as on the child and the whole family [3]. In Europe, antenatal depression counts a mean prevalence of 17.9% [4], while postnatal depression ranges from an average of 12.91% to 16.62% [5]. In Italy, specifically, the literature highlights a prevalence ranging from 6% to 22% for antenatal depression [6-9] and from around 13% to 23% for postnatal depression [5,7,9,10]. Such percentages emphasize the necessity for early detection and the implementation of prevention programs to alleviate depression symptoms already during pregnancy. Notably, women have expressed a desire for perinatal support programs and have reported benefiting from them, both in terms of symptom reduction and increased sense of agency [11]. However, barriers to help seeking, in the context of perinatal care, have been widely recognized (*knowledge barriers*, eg, difficulty in recognizing health needs and distinguishing emotional difficulties as well as not knowing the services available; *practical barriers*, eg, time and economic constraints; and *attitudinal barriers*, eg, stigma, guilt) [11-13], contributing to the still limited availability of the services to support perinatal women's mental health [14].

Within this context, digital solutions might be particularly valuable. A recent review that specifically focused on the application of eHealth in perinatal care [15] highlighted the potential of these solutions as alternatives or supplements to standard mental health practices, both for screening and intervention. A subsequent review [16] also emphasized the beneficial role of digital solutions in addressing perinatal depression by enhancing accessibility to psychological interventions, thus promoting scalability, which could ultimately allow to work around the abovementioned barriers to help seeking. Digital interventions could thus be valuable solutions to fill in the gap between what is asked and desired by women and the logistic and economic limits on both clinical professionals and health institutions part. Notwithstanding, despite the increasing focus on peripartum depression, there is currently a scarcity of digital psychological interventions aimed at alleviating depression symptoms, particularly those grounded in empirically validated intervention protocols [16-18]. Furthermore, the prevailing focus appears to lean more toward treating rather than preventing perinatal depression. This is evident in the dearth of studies investigating digital interventions during pregnancy and exemplified by the lack of studies

investigating digital interventions deployed during pregnancy and to women with subclinical depression symptoms [17,18]. In light of this, there is a need to develop theoretically grounded digital interventions tailored to pregnant women with subclinical symptoms needs and characteristics, ultimately preventing the development or worsening of clinically relevant depression symptoms during the postpartum.

Evidence-based interventions that are brief and structured such as behavioral activation (BA) interventions might be especially helpful to this end, as providing pregnant women with concrete strategies will be useful to support their adjustment. BA is an empirically supported behavioral intervention created to lessen depression symptoms [19-22]; it is based on the idea that a greater awareness of the mutual influence between behavior and emotion can ultimately encourage behavioral change by increasing participation in joyful and adaptive activities while reducing participation in maladaptive behaviors that maintain or exacerbate the depressive symptoms [19,23]. However, a recent scoping review [18] highlighted a gap in the literature: there are few digital BA interventions available during the perinatal period, and none have been specifically deployed during pregnancy. Furthermore, their usability has only been marginally evaluated.

Usability refers to the quality of the interaction occurring between the user (eg, pregnant women) and the tool used (eg, website, smartphone app, etc) [24]; a subcomponent of usability that is more specific is the *user engagement*, which includes the user's cognitive, behavioral, and affective reaction to the tool [25]. These factors are instrumental in supporting user compliance and adherence, and they should be carefully considered and addressed in the development of feasible and acceptable digital interventions [26]. The limited evaluation of these factors in the context of digital mental health solutions may be attributed to the novelty of the field, which has yet to establish a comprehensive understanding of design methods for such tools [27]. When designing these digital solutions, four components should be kept in mind: (1) the design issue and solution, (2) the context in which the design occurs, (3) the dynamics and organization of the design activity, and (4) the actors contributing to the design [28-30]. However, a recent review [27] investigating the design methods and approaches used for the design and development of digital tools for mental health stressed that *human-centered design methods* (ie, the design of digital tools not considering the engineering design and including user-centered approaches, co-design, participatory design, etc) are not yet fully integrated within the field and that reported design approaches are still mainly external, thus excluding the perspective of those for whom the tool is created.

This Study

This study aimed to investigate the feasibility of the Brief Behavioral Activation Treatment for Depression-Revised (BATD-R) [31] protocol that was structured as an internet-based self-help intervention and deployed to pregnant women with subclinical depression symptoms. Compared with other BA

protocols, the BATD-R protocol specifically targets subclinical depression symptoms, is flexible (in terms of both its structuring and the population it is administered to), and can be self-administered or deployed by both specialists or nonspecialists [31].

Given that no previous study has used the BATD-R protocol for this purpose, the intervention developed and evaluated in this study serves as digital “replica” of the in-person BATD-R protocol. By adopting a *user-centered* approach, this study not only aimed to assess its initial feasibility but also sought to gather valuable feedback directly from pregnant women. This feedback will guide the adjustment of the intervention’s content and thus its structure, without making assumptions beforehand about the changes required. Indeed, a user-centered design “is an approach to product development that grounds the process in information about the people who will ultimately use the product” [32]; as such, to create a well-accepted, engaging, and effective digital intervention in perinatal care, subsuming the intervention content and the mean through which it is deployed, pregnant women should be consulted in each stage of the intervention’s creation and refinement, thereby ultimately allowing the co-design of the final intervention. In this regard, this study relied on the Obesity-Related Behavioral Intervention Trials model [33], which provides an iterative progressive framework guiding the development, testing, and refinement of the behavioral intervention. More specifically, it uses a user-centered design that relies on a data-driven approach to iteratively test and revise the intervention, up until it is deemed appropriate to move to further phases of development and testing, thereby going from the intervention design, its preliminary testing to investigating its efficacy and effectiveness [33].

As previously reported, no digital BA intervention targeting subclinical or clinical depression symptoms among pregnant women has been developed [18]. Nonetheless, it is worth noting

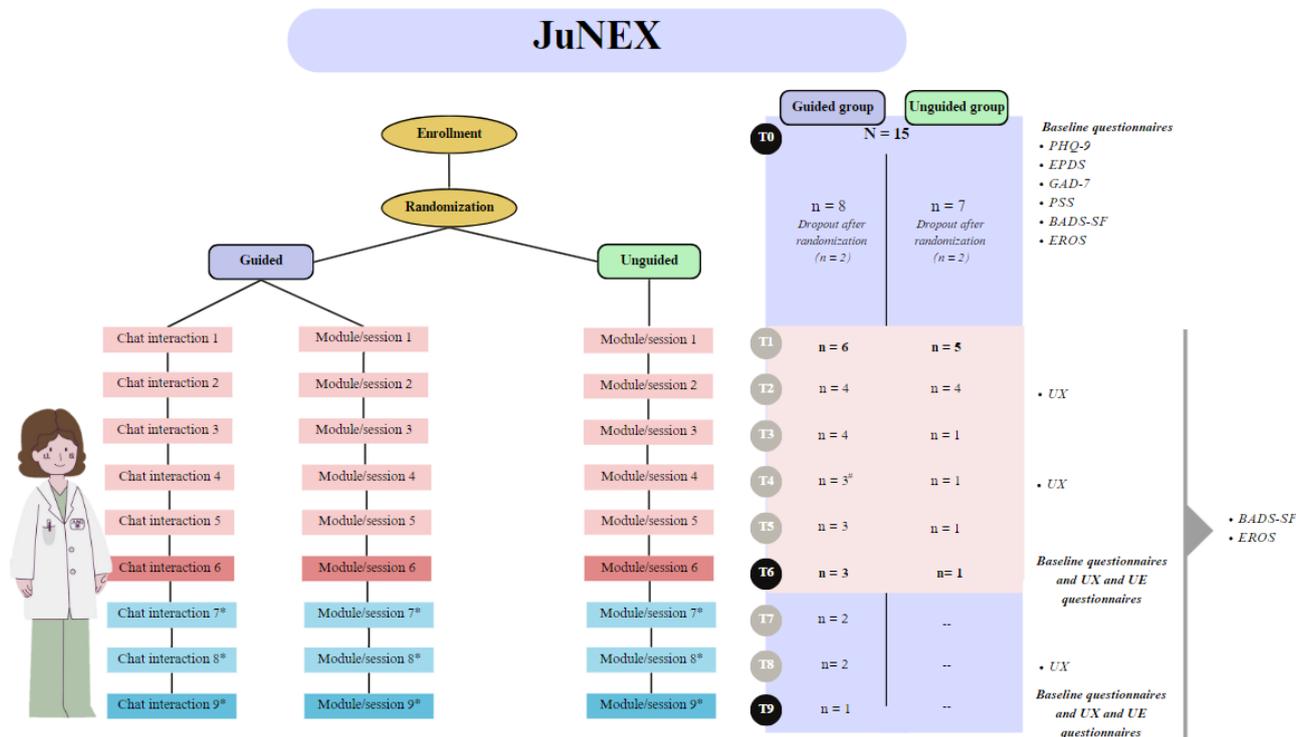

that among the existing digital BA interventions, many are guided interventions [18]. The guides, most often mental health specialists or trained professionals, provide additional support to women throughout the intervention, by addressing concerns or supporting them on intervention-related tasks. Mindful of this, a further aim of this study was also to explore and evaluate the role and potential benefits of including a guide as additional support in the self-help intervention. As such, the study also aimed to compare the feasibility of the guided versus unguided version of the intervention.

Methods

Recruitment

Recruitment was done through snowball sampling, using social media platforms (eg, Facebook). A Google Form survey was developed containing the informed consent and the questions and questionnaires needed to evaluate the women’s eligibility for participating in the study. Specifically, eligible women complied with the following inclusion criteria: they (1) had physiological pregnancy, (2) were aged ≥ 18 years, (3) were between the 12th and 30th week of gestation, and (4) had subclinical depression symptoms (Patient Health Questionnaire-9 [PHQ-9] score < 15) [34]. By contrast, women were excluded when (1) presenting a history of past or current mental disorders; (2) exhibiting clinically significant psychological symptoms (ie, depression symptoms: PHQ-9 ≥ 15) and suicidal ideation (PHQ-9 item 9); (3) having an obstetrically at-risk pregnancy; (4) presenting medical conditions, pregnancy-related and otherwise; (5) experiencing an artificially induced pregnancy. A total of 15 women had filled in the web-based questionnaire; all were deemed eligible, and thus none reported any of the exclusion criteria. Following randomization in either the guided or unguided group, 4 (27%) women dropped out (Figure 1) before starting the intervention. As such, the final sample is composed of 11 (73%) women.

Figure 1. Study structure and study adherence flowchart. *Indicates optional modules and # indicates that 1 participant had stopped interacting with the guide but had continued viewing the Moodle content. BADS-SF: Behavioral Activation for Depression Scale–Short Form; EPDS: Edinburgh Postnatal Depression Scale; EROS: Environmental Reward Observation Scale; GAD-7: Generalized Anxiety Disorder-7; PHQ-9: Patient Health Questionnaire-9; PSS: Perceived Stress Scale; T: time point; UE: user engagement; UX: user experience.

Procedure and Study Structure

This study is structured in 4 main phases (Figure 1). Phase 1 corresponds to time point 0 (T0), which encompasses the recruitment, enrolment (including the assessment of inclusion and exclusion criteria), and randomization processes. At this time, anamnestic information (reported in the *Recruitment* section) was collected, and standardized questionnaires were administered measuring depression and anxiety symptoms, perceived stress, current activity level, and perceived environmental reward. Phases 2 and 3 of the study correspond to T1-T6 and T7-T9, respectively. During these phases, the baseline questionnaires, along with one questionnaire assessing user engagement (UE) and another assessing user experience (UX; explained in the *Measurement Tools* section) were administered. In addition, the UX questionnaire was also administered during T2, T4, and T8. Questionnaires assessing the level of activity and related reward (explained in the *Measurement Tools* section) were administered each week, from T0 to T9. The final phase 4 involved conducting semistructured interviews that were created ad hoc, and participants who had participated up to at least T6 were interviewed. The semistructured interviews were conducted to qualitatively evaluate the women’s experience with the intervention and gather further feedback necessary for refining the intervention. All questionnaires administered between T1 and T9 were created using Google Forms. Links to access these questionnaires were made available within the intervention platform and were accessible to both groups in the same manner.

The participants were informed that they could leave the study at any moment without having to provide an explanation and

without incurring in any penalty. Each was assigned an alphanumeric code to ensure confidentiality.

Randomization

Alphanumeric codes were generated and allocated to each participating woman to guarantee confidentiality throughout the study. The process of creating these codes was carried out using Microsoft Excel and further randomized through a Google software [35], ensuring the unbiased assignment of participants to either the guided or unguided group before the commencement of recruitment. The results of random code assignment were kept aside, and women were only provided with their designated code once their eligibility for the study had been established. Only when eligibility was confirmed, participants were given specific information on the intervention they had to follow. The group assignment was single blinded.

The Intervention’s Content

This internet-based self-help intervention originates from the BATD-R [31] protocol. Originally, this protocol consisted of 10 sessions, which included 5 main sessions and 5 additional sessions aimed at reviewing and maintaining the benefits achieved; nevertheless, it is possible to reduce the number of sessions to 5 or even expand beyond 12 sessions. However, past studies advise against exceeding 10 weeks of intervention, reporting that BATD-R interventions of up to 6 or 8 weeks allow for a significant reduction in depression symptoms [36,37]. BATD-R can be self-administered or administered by both trained and untrained staff, further emphasizing its adaptability and flexibility. The protocol begins with a psychoeducation phase focused on understanding the characteristics of depression symptoms. Furthermore, it includes

homework assignments to be completed between sessions, which form the core content of the 5 main sessions. These assignments involve filling out 5 forms (refer to the original protocol by Lejuez et al [31]). The first form, called the “daily monitoring form,” should be completed throughout the intervention and requires participants to continuously evaluate their daily activities, in terms of behavioral patterns, the pleasantness of activities, and the importance of each daily action. Subsequently, the person is required to identify through a second form, called “life areas, values, and activity inventory,” what their values are within important areas of life (ie, important relationships; pleasurable activities and hobbies; work and study; mind, body, and spirituality; and daily responsibilities). This would then allow the person to identify (form 3, called “activity selection and ranking”) and plan daily activities (form 4, called “action plan”) that help them live in accordance with their values in the mentioned life areas. In this regard, it is worth noting that although the BATD-R does not include a complete functional analysis due to the brevity of the treatment approach [38], Lejuez et al [31] stressed that several components of treatment fit into a functional analytical framework. This is most noticeable when choosing activities that are closely related to values, given the dual goals of identifying the factors that maintain or reinforce depressive behavior (both positive and negative reinforcement) and the positive reinforcers that could support or strengthen healthy behavioral patterns. Along with the critical assessment of dysfunctional behavioral patterns, the BATD-R protocol includes a final form called “contracts,” which focuses on strategies to request social support. To create these “contracts,” the person is required to identify (1) an activity to perform, (2) up to 3 support persons who may be able to assist or support them, and (3) how and when each person can specifically provide said support. This activity allows the patient to identify their needs and provides a specific plan on how to seek the help they need by making concrete requests for obtaining assistance and social support to reinforce adaptive behaviors.

In this study, the intervention closely follows the structure of the original protocol but is adapted to fit a digital format. The intervention was divided into 6 weekly sessions or modules, which include the core content of the intervention. In addition, 3 optional “bust” sessions were included to reinforce and consolidate the information from previous weeks. The entire intervention spanned 9 weeks, with participants completing weekly homework assignments between sessions. While the intervention content and homework remained unchanged, it was adapted for digital delivery using text, video, and images. Information related to depression symptoms was contextualized for the pregnancy period to cater to the specific needs of the target population.

The Platforms

Overview

In this first evaluation of the intervention, the Moodle e-learning platform (Moodle 3.11; 2021) was used as the delivery method. This platform was accessible via both the web and the Moodle app on smartphones. Both the web and app versions of Moodle included a chat feature, which was exclusively used by the guided group to interact with their assigned guides. Specifically,

in the guided group, guide-woman dyads were created, and they interacted once a week for the homework revision. For the unguided group, homework revision was facilitated through a written self-guide available within the Moodle platform. The forms representing the homework were structured on Google Docs, with links to access them made available within the Moodle platform so that women could directly access them both on the web and the smartphone app.

Both intervention groups were presented with the intervention as an e-learning Moodle course; the sole difference in the intervention’s content between the groups lay in the reference to the guides. The intervention was structured into modules (6 core modules and 3 optional modules), and each module could be consulted only after completing the previous one. The content of each module was delivered using illustrative videos and images, complemented by brief text information. After viewing each section within a module, participants were presented with a brief quiz comprising 3 true-or-false questions related to the content they had just reviewed. These quizzes were incorporated with the intention of fostering UE. They encouraged participants to actively engage with the material rather than to passively view it. In addition, the quizzes served as a means of assessing participants’ comprehension of the content. On the basis of the accuracy of their responses, participants received reinforcing or motivating feedback after completing each quiz.

The Guides

In the guided group, specific guide-woman dyads were randomly created. All the guides were recognized psychologists who had been trained to become psychotherapists. They underwent comprehensive training, which included the provision of detailed written information and a 2-hour in-person meeting. This training covered the intervention’s content and structure and their role as guides. The training aimed to ensure that all the guides had a consistent understanding of the intervention and its content, thus maintaining uniformity across the interactions between the guides and participants. The guides adhered to a partially defined conversational protocol, which consisted of fixed messages and information to be delivered, as well as “free” parts where they had the freedom to phrase sentences as they saw fit. This flexibility in the “free” parts allowed guides to respond adaptively to women’s answers and feedback, particularly during the homework revision part of the intervention. Furthermore, it enabled guides to support participant compliance and adherence based on their perceived motivation levels. Supervision for the guides was provided by the first author (EM) of the study, who oversaw the technical aspects of the intervention. In addition, an expert psychotherapist, the third author (SS), provided supervision for clinical matters.

To ensure a consistent participant experience, all the guides were assigned the same name, “Joy.” This uniformity aimed to minimize any potential biases that could arise from variations in the perception of the different guides. Moreover, guides were not provided with any information about the women they were assigned to, ensuring privacy and confidentiality for the participants.

Measurement Tools

PHQ-9 Tool

The PHQ-9 [34] is a unidimensional self-report tool that is widely used in the Italian context [39]. It assesses the severity of depression symptoms during the previous 2 weeks, based on the diagnostic criteria of the *Diagnostic and Statistical Manual of Mental Disorders (Fourth Edition; DSM-IV)* [40]. It consists of 9 items measured on a 4-point Likert scale (0="not at all"; 3="almost every day"). Item 9 assesses suicidal ideation. A score of ≤ 9 indicates mild or no symptoms of depression, and a score between 10 and 14 indicates moderate symptoms, while a score of ≥ 15 indicates severe symptoms of depression. The instrument shows excellent internal consistency at $\alpha=.92$ [41].

Edinburgh Postnatal Depression Scale

Edinburgh Postnatal Depression Scale [42] is a unidimensional self-report tool, validated in Italy [43], which assesses the severity of depression symptoms during the previous week. Albeit developed to assess depression symptoms during the postpartum period, it is often used throughout the perinatal period. It consists of 10 items measured on a 4-point Likert scale (0="no, not at all"; 3="yes, always"). The instrument shows good internal consistency at $\alpha=.79$ [43].

Generalized Anxiety Disorder-7

Generalized Anxiety Disorder-7 [44] is a unidimensional self-report tool that assesses the severity of anxiety symptoms during the previous 2 weeks. It consists of 7 items measured on a 4-point Likert scale (0="never"; 3="almost every day") and shows good psychometric indexes in the Italian context as well [41]. The instrument shows excellent internal consistency at $\alpha=.92$ [41].

Perceived Stress Scale

Perceived Stress Scale [45] is a unidimensional self-report tool, validated also in Italy [46], which assesses the severity of stress symptoms in the previous month. It consists of 10 items measured on a 4-point Likert scale (0="never"; 3="quite often"). The instrument shows good internal consistency at $\alpha=.74$ [46].

Behavioral Activation for Depression Scale—Short Form

Behavioral Activation for Depression Scale—Short Form [47] is a self-report tool designed to measure changes in avoidance and activation during BA interventions for depression during the previous week. It consists of 9 items measured on a 7-point Likert scale (0="not at all"; 6="completely"). The scale provides 2 scores, the first score referring to the level of BA (5 items) and the second one to the level of behavioral avoidance (5 items). Manos et al [47], the authors of the tool, advise considering the total score instead of the subscales. This questionnaire has not been translated into Italian and was therefore translated through the back translation procedure. Example items are "I am content with the amount and types of things I did" (item 2) and "Most of what I did was to escape from or avoid something unpleasant" (item 5). The instrument shows good internal consistency (total scale $\alpha=.82$) [47].

Environmental Reward Observation Scale

Environmental Reward Observation Scale [48] is a unidimensional self-report tool designed to measure the level of environmental reward perceived in recent months. It consists of 10 items rated on a 4-point Likert scale (0="strongly disagree"; 4="strongly agree"). This questionnaire has not been translated into Italian and was therefore translated through the back translation procedure. Example items are "It is easy for me to find enjoyment in my life" (item 4) and "I wish that I could find more hobbies that would bring me a sense of pleasure" (item 7). The instrument shows good internal consistency ($\alpha=.87$) [48].

UX Measure

Mobile Application Rating Scale (MARS) [49] is a self-report tool consisting of 23 items scored on a 5-point Likert scale (1="poor"; 5="excellent"), which assesses the quality of the app and its features (ie, the Moodle app) on 4 dimensions of objective quality: engagement (5 items), functionality (4 items), aesthetics (3 items), and information (7 items); a final scale assesses the subjective quality (4 items). The average of the scores of the 4 dimensions of objective quality provides the total scale score. The questionnaire also contains an "application-specific" section (6 items) to assess the potential impact of a particular app on domains such as users' knowledge and intentions. The total and subscale scores of the MARS have high internal consistency coefficients ($\alpha=.90$ and $\alpha=.80-.89$, respectively). The scale has been validated in the Italian context [49]. For this study, only the subscales related to "information," "subjective app quality," and "app-specific" sections were considered, totaling to 17 items.

Together with the MARS items, only at T6 and T9, women were also asked to prove their overall subjective opinion on the platform ("Please write below your personal opinion with respect to your experience [pros and cons] while using the platform").

UE Measure

UE Scale—Short form [25] is a short self-report tool designed to assess UE with a digital solution. It consists of 12 items based on a 5-point Likert scale (1="strongly disagree"; 5="strongly agree"). The questionnaire consists of four factors: (1) focused attention, which indicates the feeling of being immersed in the interaction; (2) perceived usability, which is the negative effect experienced due to the interaction and the effort expended; (3) aesthetic attractiveness, which represents the graphical and visual appeal concerning a digital solution; and (4) the reinforcement (reward) factor, which regards the perceived involvement and enjoyment with the digital solution. This questionnaire was not translated into Italian and was therefore translated through the back translation procedure. The 4 scales have good internal reliability, as follows: focused attention, $\omega=0.75$; perceived usability, $\omega=0.70$; aesthetic attractiveness, $\omega=0.88$; and reinforcement, $\omega=0.79$ [25].

Semistructured Interview

The semistructured interviews were conducted by the first author (EM) and featured 15 main questions developed specifically for the study, 3 (20%) of which were asked only to the guided

group. This interview was conducted approximately 10 days after each woman had finished the intervention. It lasted between 15 and 20 minutes, and following the woman's consent, it was audio recorded to allow for its transcription and evaluation. For both the guided and unguided groups, the interviews investigated women's personal experience (7 questions) with the intervention and the experience (5 questions) specifically related to the use of the platform. In the guided group, women's experience with their guide and the overall chat interactions were investigated.

Data Analysis

Statistical analyses were performed using RStudio (R Foundation for Statistical Computing) [50]. Descriptive data for both categorical (n, %) and continuous (mean and SD) variables were analyzed separately for the guided and unguided groups, considering the different time points. Given the preliminary nature of the study and the small sample size, no further analyses were performed. The interviews were individually and qualitatively analyzed through thematic analysis, following the predefined semistructured interview's

3 broader themes. Thematic analysis was conducted following a modified version of the guidelines proposed by Braun and Clarke [51], which has already been used in other co-design studies [52].

Ethical Considerations

The study was conducted in compliance with the ethical guidelines of the Declaration of Helsinki [53] and the European Union law for data protection (EU General Data Protection Regulation 679/2016). The study was approved by the Ethical Committee of the Psychology Department of the University of Padova (number 4820/2022).

Results

Descriptive Information and Adherence

A total of 11 women participated in the study; 6 (55%) were part of the guided group and 5 (45%) were part of the unguided group. Descriptive information is reported in Table 1 separately for the 2 groups.

Table 1. Descriptive information (n=11).

^aPHQ-9: Patient Health Questionnaire-9.

^bEPDS: Edinburgh Postnatal Depression Scale.

^cGAD-7: Generalized Anxiety Disorder-7.

^dPSS: Perceived Stress Scale.

^eBADS-SF: Behavioral Activation for Depression Scale-Short Form.

^fEROS: Environmental Reward Observation Scale.

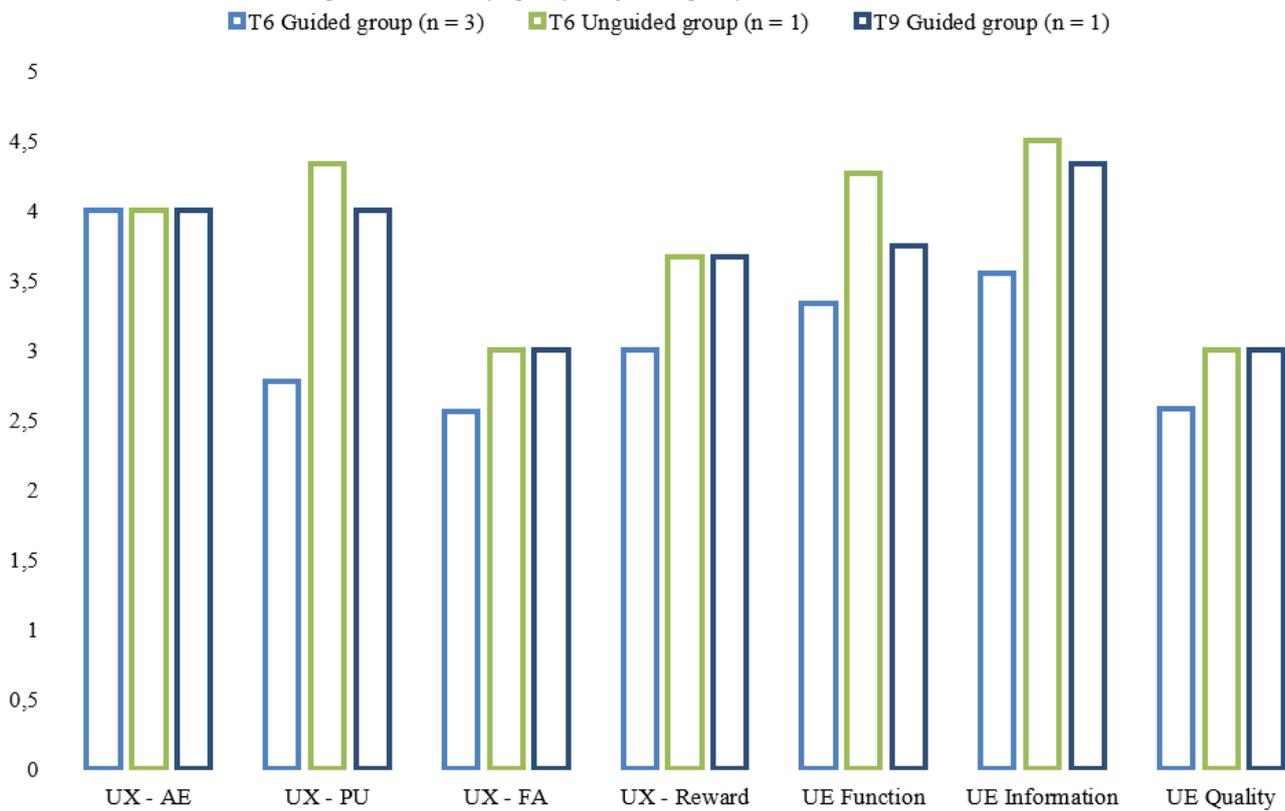

Regarding dropout rates, it was higher in the unguided group (n=5), with most participants (n=4, 80%) dropping out after completing the second module. In contrast, the dropout pattern in the guided group (n=6) was more gradual. Overall, 1 (9%) participant had dropped out because of health reasons and 3 (27%) because of the amount of time and effort (particularly related to the homework) required by the intervention, while 3 (27%) did not provide a reason for dropping out. Accordingly, 3 (50%) participants from the guided group reached T6, thereby completing the 6 core modules in Moodle, while only 1 (20%) in the unguided group reached T6. However, among the 3 participants from the guided group who reached T6, 1 (33%) ceased interactions with her guide after T3 but continued viewing the material on Moodle up to T6; the other 2 (67%) continued until T9. One of them stopped viewing the Moodle content at T8 but continued with the chat interactions with the guide.

Regarding homework completion, it is not possible to quantify adherence specifically, as, for instance, among the participants that had completed at least until T6 some (2/4, 50%) decided to handwrite the homework, instead of using Google Docs because of the low usability of the latter (ie, too many steps to go from Moodle to Google docs, which were also not well perceived and difficult to use within the smartphone). Moreover, it was considered cumbersome to write within the Google Docs.

UX and UE Measures

Descriptive statistics for UX and UE assessed at T6 and T9 are illustrated in [Figure 2](#). At T6, when the participants were asked whether they had used primarily the app or web version of Moodle, 2 (67%) participants of the guided group and the only 1 participant of the unguided group reported using the app version, while 1 (33%) of the participants of the guided group used primarily the web version because of difficulties with using the app.

Figure 2. User experience (UX) and user engagement (UE) at time point 6 (T6) and T9. All scales' response range was from 1 to 5. AE: aesthetic appearance; FA: focused attention; PU: perceived usability; quality: subjective quality.

Participants' subjective opinion on the platform, assessed through one open question, is reported in Table 3.

Table 3. Answers to the open question "Please, write below your personal opinion with respect to your experience (pros and cons) using the platforms."

Time points and group	Participants' feedback
Time 6	
Unguided group, n=1	<ul style="list-style-type: none"> "I am in my second pregnancy so I have been using the platform with a one-and-a-half-year-old [taking care of them] and I must say that being able to subdivide the time has been helpful even on an organizational level. If one fills out the daily forms from day to day it is not challenging, I must say that filling them out [the daily forms] from your cell phone though is quite inconvenient because the app [Google Docs] that opens the forms and allows you to fill them out does not always work well, so I then preferred to print them out and fill them out by hand."
Guided group, n=3	<ul style="list-style-type: none"> "I think it is still very cumbersome as a platform [Moodle], not easy to use and the interaction with the Guide [was] too dry. Some things need to be revised." "Using the platform on a practical level was quite intuitive and easy. The project itself involves a lot of effort and concentration, but it helps to feel a greater physical and psychological well-being." "It was intuitive and fast."
Time 9	
Guided group, n=1	<ul style="list-style-type: none"> "My experience in using the platform has been positive."

Semistructured Interviews Results

A total of 3 participants agreed to participate in the semistructured interview; 2 (67%) were from the guided group and had continued the intervention till T9, while 1 (33%) was from the unguided group and had participated till T6.

During the semistructured interview, all 3 (100%) participants reported that they had come to know of the study through a friend. As motivation for participating, all 3 reported "curiosity"

as the main reason because they did not have specific expectations before starting.

Overall, participants expressed that the intervention helped them find a moment for themselves and provided them with a method or strategy to change their perspective on how they viewed and performed their daily activities. Furthermore, they noted the positive effects of engaging in more rewarding activities. All 3 (100%) participants emphasized that the intervention supported their overall well-being rather than reduced negative feelings

per se. However, they also mentioned that the effort required by the intervention, particularly in terms of time and dedication, was substantial, especially regarding the homework assignments. While they appreciated the meaningful content of the homework, they found it burdensome to complete. It is important to note that part of the difficulty with homework completion was related

to the reduced fluidity and usability of Google Docs on smartphones. A more thorough explanation of the findings that emerged from the semistructured interviews with verbatim examples of participants' answers has been discussed as follows, and the specific themes and subthemes that emerged are reported in [Table 4](#).

Table 4. Semistructured interview (n=3): themes, subthemes, and examples.

Theme and subtheme	Example quotes
Personal experience with the intervention	
Self-observation and activities evaluation	<ul style="list-style-type: none"> “[...]you realize things that by not doing it [the intervention] you wouldn't have realized you could have done, how you could have also handled the pregnancy period better” [Unguided group participant] “It definitely helped me understand what are [...] let's say, [which is] the focus, where to aim to get better. I discovered some things that I had set aside[...] it helped me to not be so focused on negative things, which is kind of my problem, but more to identify something positive to do day-by-day, to be able to accomplish little goals that [might not be important for others] but for me at that moment they were important” [Guided group participant] “[...]most definitely [I appreciated] focusing my attention on some positive activities that I had somewhat set aside and forgotten[...] when I focused on those saddest moments and I [then] realized that they were not most of my days as one thinks when one is in the sad mood. Instead, I saw that most of my days were good moments” [Guided group participant]
Effort	<ul style="list-style-type: none"> “As the weeks went on, maybe even as the pregnancy progressed[...] I found it more 'burdensome.' The fact of filling out the daily forms [daily monitoring form] every day[...] as time went on, it was challenging, in the sense that one has to stop and really take [their] time and be consistent, when as the pregnancy progresses maybe other thoughts take over and you can't quite be that consistent all the time[...]” [Guided group participant] “[...]the part, let's say the most obnoxious, difficult, whatever we want to call it, is definitely the material to fill out during the last weeks. I have to tell you the truth, I didn't even finish them because I didn't have time[...]” [Guided group participant] “In my experience[...] I felt the fatigue more, maybe, here. Let's say that at the end of the six (sixth module), for myself, I felt that the intervention was -in quotes- “finished.” [Guided group participant] “[In reference to the intervention length] it probably depends on what stage of the pregnancy one is[...] I started it toward the end of my pregnancy, it would probably be better to start it before[...]” [Unguided group participant]
Learning the “method” and its application in the future	<ul style="list-style-type: none"> “[...]It might be a good method at other times in life when one may experience difficulties” [Guided group participant] “[...]mentally, I got into this mode of planning something nice to do, to be able to have that weekly commitment that I like, to ask somebody to do it with me. Maybe small things, but I'm sure it helped me for the future as well.” [Guided group participant]
User experience and user engagement	
Managing issues and learnability	<ul style="list-style-type: none"> “[...]when I had to write [for the homework], there was the transition from the daily monitoring [form] rather than very often I had trouble writing things down[...] I mean, I had to print them out [the forms] basically, if not I couldn't record [write] them [down].” [Unguided group participant] “[A]t first maybe you kind of have to learn the mode of, yeah, that you get the materials out[...] It wasn't easy to tell when it saved what you had done, because it was a little dubious, sometimes[...] it was easy to use once you had gotten the hang of it, going into the week, looking at the material...” [Guided group participant]
Multimedia material	<ul style="list-style-type: none"> “[...]the videos etc. were very effective in passing the message, both in terms of explanations and content, and the images, they were[...] they caught the attention[...]” [Guided group participant] “[T]he videos[...] they are very clear, well done, they are cute” [Unguided group participant]
App interventions in the future	<ul style="list-style-type: none"> “[...]with the current use of the phone and the computer in general, in my opinion an app is useful” [Unguided group participant] “[...]the app that you have on your phone is the most useful thing. You consult it wherever you want and whenever you want” [Guided group participant]
The experience with the guide	

Theme and subtheme	Example quotes
Support	<ul style="list-style-type: none"> “[...]the interaction itself was effective in the sense that it explained things to me when I had doubts, that it directed me, maybe, when I didn't quite understand the task, it directed me well[...].” “[...]giving me suggestions, helping me even on how not to give up-because maybe there were also harder moments-thus also giving me alternatives and suggestions to see the path in a different way, make it lighter[...] I had a great time”
Personalization of the conversation	<ul style="list-style-type: none"> “[...]the redundancy of the messages[...] sometimes it almost felt like a copy and paste of the messages and not an actual interaction[...] I found it a little depersonalized[...] I would have found it more enjoyable if it was personalized[...].” “I saw that the person who was on the other side—I don't like to say ‘Joy the guide!’—I still found her to be a person who each time, with respect to my mood, to how my week had gone, has put herself into my shoes, into my being, into my experience[...].”

Participant's Personal Experience With the Overall Intervention

Coherent with the *self-observation and activities evaluation* subtheme reported in Table 4, participants reported a positive personal experience as they seemed aligned with the content of the intervention, thus learning to appreciate the value of self-observation (regarding behavior and emotions) and how this can influence how they feel. For instance, the participant from the unguided group reported as follows:

[...]it [the intervention] was helpful, because it may not seem like it but by writing down daily what you do... you notice things that maybe normally you wouldn't notice, or [discover] free time that you can spare, which maybe you didn't even think about...

Coherently, a participant from the guided group affirmed as follows:

[...]in relation to well-being, it definitely helped me understand[...] where to aim to get better... being at home during pregnancy, I rediscovered some hobbies that helped me... it helped me to not be so focused on negative things[...] to identify something positive to do day-by-day, to be able to accomplish little goals that [might not be important for others] but for me at that moment were important.”

Participants seem to have internalized the “message” that the intervention wanted to transmit. When asked whether they believed what they had done during the intervention could be useful to them in the future, participants reported already having integrated what they have learned into their daily life, for instance, by starting “[...]to keep a journal[...].” (a participant from the unguided group), even after pregnancy. Notably, a participant from the guided group reported as follows:

[E]ven in conditions of not pregnancy... it might be a good method at other times in life when one may experience difficulties.

Referring to the subtheme of *learning the “method” and its application in the future*, this highlights that the intervention content was able to provide the participants with a broader method useful to support their psychological adjustment and well-being both during pregnancy and in the future:

[...]it's like, mentally, I got into this mode of planning something nice to do, to be able to have that weekly commitment that I like, to ask somebody to do it with me. [These] may be small things, but I'm sure it will help me in the future as well. [Guided group participant]

In this regard, and referring to the *effort subtheme*, participants reported that 6 weeks of intervention were enough to this end, while the subsequent optional 3 weeks were perceived as a bit redundant and excessive. In addition, they stressed the effort required by the intervention overall, affirming, for instance, as follows:

[A]s the weeks went on[...] I found it more burdensome[...] filling out the daily form chart [daily monitoring form] every day with the activities perhaps, as time went on, was challenging, in the sense that you have to stop and really take [your] time and be consistent, when as the pregnancy progresses maybe other thoughts take over and you can't quite be that consistent all the time[...] [Guided group participant]

On a similar note, another participant reported as follows:

[...]the part, let's say, the most obnoxious, difficult... is definitely the material to fill out during the last weeks. I have to tell the truth; I didn't even finish them because I didn't have time[...] [Guided group participant]

Finally, coherent with the emerging subthemes, a further comment made by a participant from the guided group ought to be reported; she stressed that women would need to be already motivated to be able to appreciate the intervention. Indeed, she mentioned a key point, which is the need to have an adequate capacity for insight, as it might otherwise be difficult to autonomously notice the maladaptive behavioral patterns and switch to more positive ones. In this regard, the participant reported as follows:

[...]they [those following this intervention] must be people[...] who are capable of introspection... I imagine people who don't have so much of a way of knowing themselves[...] it's not so easy to start on such a path if you haven't done some work on yourself first[...] also, just to have self-knowledge and say

“what are my weak points?” and say “where can I go with that?”

UX and UE Themes

Regarding UX and UE, the *managing issues and learnability* subtheme was quite prominent. All 3 (100%) women agreed that the Moodle app was not so easy to use overall, as some participants' approach has been that of learning how to work around what was not working to be able to continue the intervention. For instance, within an otherwise positive experience, a participant reported as follows:

...maybe the only thing that I would change, which is not really of the intervention though, [regards] more the use of the platform, is just that[...] I had trouble writing things down [for the homework...] even [the speed of the] connection when it makes you log back in to do the quiz, the page has to reload[...].
[Unguided group participant]

Similarly, a participant from the guided group reported as follows:

[Although she was a] geeky chick [as regards to the use of technology], it was not easy [to use the Moodle platform]. It took me a while to find the material[...] I had even emailed you [the researcher conducting the interview]... I couldn't really understand how it worked, where they [the materials] were[...] I always used it from the smartphone, only a couple of times I used it from my computer[...] maybe you kind of have to learn first [how to use the platform][...] then I had that glitch with the quiz, and that one I found a little obnoxious, because I thought I had done the quiz[...]. it had not saved nothing. It wasn't easy to tell when it saved what you had done, because it was a little dubious, you know, sometimes[...] it was easier to use once you had gotten the hang of it[...].

Altogether, this stresses the importance of the platform's simplicity, ease of use, and related learnability regarding UX and UE. However, it should be noted, referring to the *multimedia material* subtheme, that the aesthetic of the material present, and particularly the videos and images, were much appreciated and perceived as informative.

Furthermore, coherent with the *app interventions in the future* subtheme, all 3 (100%) participants reported that they did believe that a smartphone app, being readily available, could be a valuable tool to administer this sort of intervention saying, for instance, that “...with the current use of the phone and the computer in general...an app is useful” (the participant from the unguided group) as one can “...consult it wherever and whenever...” (a participant from the guided group). Indeed, albeit reporting difficulties with the platform, all 3 (100%) participants had already autonomously recommended the intervention to fellow pregnant women. However, the moving force, coherent with what is reported earlier, was the intervention content:

[Although deployed through a portable tool, interventions] help in times of transition or change. This tool [the present digital intervention] helps because it focuses on pleasant activities, and in such a long waiting time [the pregnancy], with the

struggles to organize exams, visits, what's going to happen tomorrow[...] it helps you a little bit to[...] focus on simpler thing, that then in itself just help you every day. So yes, I would recommend it for that [Guided group participant]

The Experience With the Guide

Regarding the role of the guide and the guided group's overall experience with the chat interactions, the *support* subtheme has emerged, as both participants reported the positive value of having this sort of support, whether it be practical or affective. However, intersecting with this support subtheme, the *personalization of the conversation* subtheme seemed to have weighted on participant perception of the quality of the support perceived. In particular, it seems plausible to hypothesize that as participants knew that the guide was an actual person, the way of talking of the guide in the free sections of their protocol guided the participants' perception of their capacity for empathy and perception of getting in tune with them. Indeed, while 1 (33%) of the 3 participants reported the intervention to be not personalized enough, 1 (33%) reported almost the opposite. More specifically, a participant reported as follows:

[...]the interaction itself was effective in the sense that it explained things to me when I had doubts, that it directed me, maybe, when I didn't quite understand the task, it directed me well. Um, the part that I definitely didn't like was the redundancy of the messages because sometimes it almost felt like a copy and paste of the messages and not an actual interaction[...] I found it a little depersonalized[...] I would have found it more enjoyable if it was more personalized.

The other, instead, reported expecting from the beginning a set of predetermined questions from the guide, particularly as some questions were indeed repeated each week; however, the participant reported about the guide as follows:

[S]aw that the person who was on the other side, I don't like to say “Joy the guide”- I found them to be a person who each time, with respect to my mood, to how my week had gone, has put herself into my shoes, into my being, into my experience, giving me suggestions, helping me even on how not to give up-because maybe there were also harder moments-thus also giving me alternatives and suggestions to see the path in a different way, to make it lighter. So, I had a great time!

Such difference in the perception of the guide and of their helpfulness seems even more plausible when considering that a participant (who did not agree to the semistructured interview) had finished viewing the modules on Moodle until T6 but did not continue with interactions with the guide after T3.

Discussion

Principal Findings

This study aimed to investigate the feasibility of the BATD-R protocol [31] that was structured as an internet-based self-help intervention and deployed to pregnant women with subclinical depression symptoms, while further comparing its guided versus

unguided versions. Such evaluations had the associated purpose of collecting the feedback needed to refine the intervention, thereby allowing its co-design and adaptation; moreover, it represents the first instance where the replication of the in-person BATD-R into a digital format has been empirically measured and evaluated, yielding valuable insights and shortcomings useful for future research.

Overall, results showed that this first version of the digital BA intervention, JuNEX, as a “replica” of the original BATD-R protocol [31], is not feasible to be implemented in a digital e-learning format. Specifically, data have highlighted the need to lighten the intervention and reduce the effort required for homework. Despite the perceived excessive effort, participants appreciated the content and purpose of the intervention, which allowed them to “take a moment” for themselves and understand “where to aim to get better.” Indeed, albeit the intervention protocol originated from a behavioral framework, its focus on the person’s everyday activities, the evaluation of one’s own experiences, and how these are linked to how behaviors and emotions mutually influence each other configure in line with third-generation cognitive behavioral therapies [54]. These therapies prioritize holistic enhancement of psychological and behavioral processes related to health and well-being [55], emphasizing adaptive coping methods and increasing experiential and contextual awareness [55,56]. Such an approach is particularly relevant for nonclinical populations (which are more diverse than clinical populations), as they allow for a more transversal relevance and application of the coping methods promoted, thus making the intervention especially valuable in preventive terms. Given that this study focused on women with subclinical depression symptoms, interventions emphasizing the awareness of psychosocial functioning and the interplay between emotions and behaviors may be more beneficial than targeting specific, limited areas of functioning and distress. This broader approach could enhance women’s capacity for adjustment and could be applicable to difficult situations beyond pregnancy-related challenges.

Such explanations serve to emphasize that consistent with women’s feedback, the intents of the intervention per se, and thus its content as well as homework purposes, ought to be maintained as they were found pertinent to the pregnancy situation and were appreciated by women; however, data also stress the need to structure the intervention so that it can be deployed with greater ease and the need to shorten it to maximum of 6 weeks. In this regard, the data do point to satisfactory usability and UX as pivotal aspects of the intervention feasibility, which was not provided either by the Moodle platforms or the Google Docs used. These platforms were used in line with the preliminary and exploratory nature of this study, allowing the first structuring of the BATD-R protocol in a digital setting in a time- and cost-efficient manner; this has favored the co-design of the future development of the intervention by developing a more advanced and refined application after having collected some initial pregnant women’s feedback.

When evaluating the usability of a digital solution, 5 main aspects are to be considered as follows [57]: (1) the simplicity of use experienced by users when learning how to use a digital

tool, (2) the number of mistakes they make to do a certain action correctly, (3) the effectiveness with which users interact with a digital tool, (4) the perceived satisfaction with the UX, and (5) the memorability of how to use a digital tool after having been exposed to it. In addition to this, and particularly linked to both the effectiveness and perceived satisfaction just mentioned, is the more specific UE, thus linked to the subjective experience of the user and subsuming affective, cognitive, and behavioral components [25]. Considering the UX and UE evaluated in this study, data suggest that usability and UE were mediocre, yet not scarce. Thus, there was some appreciation for the tools used by the participants who had completed the interventions; however, the simultaneous high dropout and overall low recruitment of participants strengthen the idea that the more positive feedback given is somewhat linked to the a priori internal motivation of the participants in following the intervention. Participants themselves have indeed underlined that to follow the intervention as it is, to be able to bear the effort required by it, and to work around the limits of the platform used, women would need to be highly motivated on their own.

Coherent with the importance of the users’ motivation to properly follow such interventions, data do suggest that the guided group showed greater adherence and were overall more willing to finish the intervention compared to the unguided group. A part of the guides’ job was indeed to motivate women to favor compliance and adherence, and as women knew that they were interacting with a psychologist, this can be thought to have further increased their motivation. However, the practical challenges of having to set a date and time for the interactions are the limiting factors and so are the individual differences related to the guides’ different writing modalities. In this regard, a step further in this direction might be the design and inclusion of a conversational agent to provide guidance and support during the digital intervention. Conversational agents can greatly favor the personalization of the user-system interactions while fostering scalability by requiring a much-reduced workforce for the intervention administration [58]. Existing literature has highlighted that conversational agents might be valuable tools to foster intervention adherence by favoring engagement and involvement, thereby supporting the overall UX [58,59] and allowing for a more immersive experience. Using a conversational agent is expected to further reduce time constraints for both patients and clinical professionals while also reducing health care costs in the long run. Within the perinatal context, future studies should thus evaluate the potentiality of including a conversational agent within digital interventions to ultimately support women’s motivation and engagement as well as their compliance and adherence to the intervention, allowing them to use such digital solutions more freely while still giving the feeling of a more personalized experience.

Coherently, and in line with past evidence [60-62], women have expressed a desire for web-based solutions that support their psychological well-being. Furthermore, the data in this study seem to suggest that women might prefer app-based solutions, as almost all (3/4, 75%) participants that completed at least up to T6 used the app version instead of the web version to follow

the intervention. Compared with web-based programs, interventions deployed through a smartphone app are much more readily available wherever and whenever, thus being overall easier to use and access.

Limitations

This paper reports the first-phase study's findings, highlighting valuable insights and several limitations that can guide future research and the development of digital interventions. First and foremost is the inherent challenge of having endeavored to replicate or simulate an in-person intervention digitally, a task that resulted in an ineffective outcome in our case. It is crucial to acknowledge that digital solutions offer a unique environment and set of possibilities that distinguish them from face-to-face interactions. Attempting to mirror traditional methods within this digital landscape may fall short of fully capitalizing on the advantages that digital interventions can bring. With our findings, we thus strengthened the idea that digital interventions should not be mere replicas of their in-person counterparts; rather, they should harness distinctive strengths and capabilities. This challenge underscores the need for innovation and adaptation, as well as a recognition that a direct translation of traditional methods may not always yield optimal results in the digital sphere. Future studies should first try to conduct workshops with end users in which the in-person protocol is administered to discuss feasible changes to the intervention, thus singling out the intervention's main principle and appreciated practices and then adapting them to the digital format. Furthermore, a subsequent limitation of the study overall is the limited sample size, which has prevented the possibility of computing any statistical comparisons between the 2 groups as well as generalizing findings. Nonetheless, given the preliminary and exploratory nature of this study, aimed at setting the base for the co-design of the final intervention, the data collected were still able to provide valuable insights directing

the refinement and future developments of the intervention. Further limitations are attributed to the platforms used, as they are created with different purposes than what they were used for in this study. This has warranted structuring the intervention content based on the functionalities of this platform instead of creating a tool tailored to the intervention requirements; therefore, future studies are advised to avoid using such tools to administer and evaluate digital intervention, even in the first-phase studies such as this one. However, it should still be emphasized that such platforms (ie, Moodle and Google Documents) have allowed to "prototype" the intervention in a time- and cost-efficient manner while collecting the information needed to refine the intervention and to create a specific app that can meet the requirements and preferences of the users.

Conclusions

This study had the purpose of evaluating the feasibility of the BATD-R protocol [31] structured as an internet-based self-help intervention among pregnant women with subclinical depression symptoms while comparing its guided versus unguided versions. A subsequent goal was the collection of women's feedback and perceptions of the intervention content through a prototyped version based on an e-learning platform to allow the co-design of the final intervention.

Overall, the ease with which the intervention can be followed has emerged as a central component to account for in the future developments of the intervention, in terms of the intervention itself as well as the platform used to administer it. The greater effort perceived was related to the homework, whereby women did emphasize that performing them was effortful and time-consuming. Even so, comparing the 2 versions of intervention, the guided version was more well-received than the unguided version. Nonetheless, both groups expressed satisfaction with the intervention's content and felt that it was relevant to their personal experiences with pregnancy.

Acknowledgments

The authors would like to thank the University of Padova and the Scuola di Specializzazione in Psicologia del Ciclo di Vita (Specialization School of Life Cycle Psychology, Padova, Italy) for allowing the inclusion of their psychotherapist in training to work as guides in the guided intervention. Moreover, the authors would like to thank the Artigianelli Institute (Trento, Italy) for creating the videos' illustrative content.

Abstract

Background: Artificial intelligence (AI)-powered technologies are being increasingly used in almost all fields, including medicine. However, to successfully implement medical AI applications, ensuring trust and acceptance toward such technologies is crucial for their successful spread and timely adoption worldwide. Although AI applications in medicine provide advantages to the current health care system, there are also various associated challenges regarding, for instance, data privacy, accountability, and equity and fairness, which could hinder medical AI application implementation.

Objective: The aim of this study was to identify factors related to trust in and acceptance of novel AI-powered medical technologies and to assess the relevance of those factors among relevant stakeholders.

Methods: This study used a mixed methods design. First, a rapid review of the existing literature was conducted, aiming to identify various factors related to trust in and acceptance of novel AI applications in medicine. Next, an electronic survey including the rapid review-derived factors was disseminated among key stakeholder groups. Participants (N=22) were asked to assess on a 5-point Likert scale (1=irrelevant to 5=relevant) to what extent they thought the various factors (N=19) were relevant to trust in and acceptance of novel AI applications in medicine.

Results: The rapid review (N=32 papers) yielded 110 factors related to trust and 77 factors related to acceptance toward AI technology in medicine. Closely related factors were assigned to 1 of the 19 overarching umbrella factors, which were further grouped into 4 categories: human-related (ie, the type of institution AI professionals originate from), technology-related (ie, the explainability and transparency of AI application processes and outcomes), ethical and legal (ie, data use transparency), and additional factors (ie, AI applications being environment friendly). The categorized 19 umbrella factors were presented as survey statements, which were evaluated by relevant stakeholders. Survey participants (N=22) represented researchers (n=18, 82%), technology providers (n=5, 23%), hospital staff (n=3, 14%), and policy makers (n=3, 14%). Of the 19 factors, 16 (84%) human-related, technology-related, ethical and legal, and additional factors were considered to be of high relevance to trust in and acceptance of novel AI applications in medicine. The patient's gender, age, and education level were found to be of low relevance (3/19, 16%).

Conclusions: The results of this study could help the implementers of medical AI applications to understand what drives trust and acceptance toward AI-powered technologies among key stakeholders in medicine. Consequently, this would allow the implementers to identify strategies that facilitate trust in and acceptance of medical AI applications among key stakeholders and potential users.

Introduction

Artificial Intelligence

Artificial intelligence (AI) is commonly defined as a computer system that uses statistical models, diverse algorithms, and self-modifying systems to make predictions and decisions based on its own aggregated experience. It can therefore perform tasks that usually require or even surpass the human level of intelligence [1,2]. AI has been increasingly integrated in the health care sector, where it helps with administrative workflows, diagnostic image analysis, robotic surgery, and clinical decision-making. Consequently, medical AI applications allow, amongst other things, earlier disease detection, patient-tailored treatments, and more efficient follow-ups, which should drive the health care costs down upon implementation [3]. Although medical AI applications provide various advantages to the current health care system, such as increased efficiency and improved workflows [4], there are also various challenges associated with AI implementation. For instance, a large share of potential users has concerns over privacy issues [5,6]. Equity and fairness are other important concerns, since there is a risk of perpetuating bias within data sets being adopted by AI technology [5,7,8]. Further, the implementation of AI into medical practice raises the question of accountability, since it is currently unclear whether technology developers, hospitals, or regulators should be responsible for mistakes or undesirable outcomes from the use of an AI application.

Trust and Acceptance

To ensure successful implementation of medical AI applications, it is essential to build trust in and acceptance of AI technology among its users [9,10]. In this study, a model of key drivers of trust in and acceptance of AI systems was used [11]. According to this model, trust is influenced by 4 drivers: current safeguards, job impact of AI, familiarity of AI, and AI uncertainty. Current safeguards indicate the belief that current regulations and laws are adequate for ensuring the safety of AI and the protection of people who use it. Job impact refers to the belief that there will be more jobs generated than eliminated due to AI implementation. Familiarity with AI is the level of understanding of how AI technology works and how AI applications are used. These 3 drivers have a positive influence on trust, with current safeguards being its strongest driver. The fourth driver, AI uncertainty, impacts trust in a negative way. It implies the belief that the impact of AI on society is unpredictable and the technology is still not fully explored. Overall, these drivers influence the extent to which people trust the AI system and believe it to be trustworthy. Trust, then, is a large contributor to the level of acceptance, which is the extent to which people accept or approve of AI and are willing to use it without resistance [11]. In the scientific literature, trust can be defined in different ways. In this study, we used literature-derived definitions of trust and acceptance in the context of AI implementation, namely:

- Trust is the belief of an individual that an AI application will do what it promises [12,13].
- Acceptance is the willingness of an individual to use the AI application in medicine [14].

Therefore, it can be argued that acceptance of an AI application depends on trust people have toward this technology [11,15,16]. At the same time, people can often accept their usage of technologies without necessarily trusting them [17]. Therefore, it is important to consider the 2 concepts separately as well as together.

Overall, widespread trust in and acceptance of an AI application is crucial for successful introduction and implementation of the technology. Failure to ensure trust in and acceptance of AI technology would pose the risk of “stifling innovation” and causing unnecessary “opportunity costs” [18]. The lack of trust in AI applications in medicine impedes their adoption in health care, compounded by inadequate public assurance and attention to concerns, thereby exacerbating these challenges. In addition, the anticipated benefits of AI-based innovations can coexist with significant acceptance barriers [15,18-21].

Investigating what factors contribute to trust in and acceptance of AI technology in medicine would help us understand how to make the implementation and regulatory approval of AI-powered advanced therapy manufacturing systems as efficient as possible. This can be achieved by collecting insights into stakeholders’ perspectives with regard to trust and acceptance toward medical AI applications [2,22]. Factors contributing to trust and acceptance toward medical AI applications can be attributed a different weight by various groups of stakeholders with distinct roles in AI.

Study Objectives

Since AI applications are still relatively new, users and providers are hesitant to trust and accept this new technology without restrictions. As for the future implementation of AI applications in treatment centers, it is essential that stakeholders (eg, clinicians, researchers, hospital staff) accept and trust the innovative AI-based manufacturing platform. Therefore, the aim of this study was first to identify the factors related to trust in and acceptance of AI technology in medicine and second to assess the relevance of those factors among relevant stakeholders in medicine.

Methods

Study Setting

This study is part of the European Union’s (EU) Horizon 2020 project AIDPATH (AI-driven Decentralized Production for Advanced Therapies in the Hospital; grant agreement number 101016909) [22,23]. It is an upcoming state-of-the-art AI application in hospitals, which aims to develop an AI-driven, automated chimeric antigen receptor T cell (CAR-T) manufacturing platform at the point of care as a treatment for acute leukemia and lymphoma. In CAR-T therapy, the patient’s

own T cells are removed, genetically modified, and reinfused into the patient in order to find and eliminate tumour cells. Current production is characterized by laborious manual process steps, complex logistics, and a lack of process understanding. This results in long delivery times (up to 21 days) and high costs (approx €320,000, or US \$347,890, per treatment) [24,25]. For this reason, AIDPATH is developing a system to fully automate the manufacturing process, from the provision of patient cells to the injection directly in the hospital. An important building block for effective and equitable manufacturing is AI. AI can provide essential process insights into the cell's characteristics and behavior. This offers a significant benefit for adaptive control of the whole process and the design of personalized process protocols. Furthermore, AI can assist cost-effective platform operation in a smart manufacturing hospital by improving manufacturing schedules and resource management [26]. In general, successful implementation of AIDPATH would serve as an example of an effective AI technology that automates the production and delivery of advanced therapy medicinal products (ATMPs). Furthermore, AI-powered technology can form the basis for a deployable platform for further pilot trials in multiple hospitals and would create a model innovation system for smart manufacturing hospitals [2,22].

In this study, to meet the study objectives, a rapid literature review was conducted, followed by a survey.

Rapid Literature Review

A rapid literature review of peer- and non-peer-reviewed publications was conducted to identify factors related to trust in and acceptance of AI applications used in medicine. As an alternative method to systematic reviews, a rapid review allows for accelerated synthesis of up-to-date evidence, while efficiently informing latest findings in recent health care research [27]. The peer- and non-peer-reviewed literature needed to be published between 2012 and 2022 in English. Data on attitudes toward AI in relation to prognosis, diagnosis, treatment, and care were included. The search was performed in PubMed/MEDLINE with the following search syntax: ((trust) OR (acceptance) OR (attitude) OR (perspective) OR (perception)) AND ((AI) OR (artificial intelligence) OR (machine learning) OR (deep learning)) AND (((prognosis) OR (diagnosis) OR (treatment) OR (care)) OR ((clinic*) OR (hospital) OR (smart hospital) OR (health care)) AND ((survey) OR (questionnaire) OR (interview))). The reason for inclusion of only survey-, questionnaire-, or interview-based research in the search terms was due to their direct relevance to our research objectives.

In the non-peer-reviewed literature search, similar terms and time frame of publication were used and the first 10 pages on the Google Search engine were examined to identify other relevant papers and reports by (non)governmental and research organizations. This allowed the study findings to be applicable to a broad range of medical AI applications. Papers were screened, and data were extracted by 2 authors (DS and AA). The selected literature was analyzed to identify key trends and explanatory factors related to trust and acceptance toward medical AI applications. The factors were then grouped into 4 categories: human-related, technology-related, legal and ethical,

and additional factors. These factor groups formed the basis of the survey designed to investigate factor relevance. This was performed independently by 2 authors (DS and AA).

Survey

The survey was reported in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) guidelines [28]. The survey in English assessed the relevance of the factors related to trust in and acceptance of novel AI applications in medicine. The survey started with an introduction to AI applications in medicine and AIDPATH, followed by 7 general questions on each participant's background, including gender, age, the country they worked in, years of experience, the stakeholder group they belonged to, their familiarity with AI applications in medicine, and their general view on AI. In the last question, the following distinction was made between the answer options: "I embrace AI" meant welcoming and using AI as a constituent part of their work or life, "I approve of AI" implied that the participant agreed with the use of AI in their work or life but did not use it themselves, and "I accept AI" referred to acknowledging the use of AI in work or life but not being ready to fully approve it.

In the core section of the survey, the definitions of trust and acceptance were provided as a reference for participants. The core part also consisted of 2 identical lists of 19 factors related to trust and acceptance toward AI applications in medicine. Each factor was categorized into human-related, technology-related, legal and ethical, or additional factors. Human-related factors were linked to AI professionals assessed the relevance of the type of organization the AI professionals were affiliated to and the purpose to innovate with a specific AI application. With respect to health care professionals, the factors were related to the knowledge of AI applications and the attitude toward AI application usage in medicine. In relation to patients, the relevance of the following factors was assessed: general knowledge of AI applications in medicine, the attitude toward AI application usage in medicine, and the patient's age, gender, and level of education. Furthermore, participants were asked to evaluate the relevance of transparency between all parties involved in AI application use. Technology-related factors related to the performance of AI applications in medicine, the possibility of their integration into existing clinical workflows, a clear balance of risks and benefits of the AI applications, and the explainability and transparency of processes and outcomes. The legal and ethical factors were related to the adequacy of regulations and governance of AI applications in medicine, data use transparency, and clear accountability and responsibility for an AI application. The additional factors were concerned with the environmental sustainability of AI applications and AI's impact on job availability. For each factor, participants could indicate each factor's relevance to trust in and acceptance of AI applications from their stakeholder perspective using a Likert scale of 1-5, where 1 stood for "not relevant," 3 for "not irrelevant, nor relevant," and 5 for "relevant." Throughout the survey, "relevant" meant being highly significant for ensuring trust in or acceptance of AI applications, while "irrelevant" meant no significance. The N/A (not applicable) option was available as well for each factor. Open questions at the end of both sections

allowed participants to suggest other relevant factors related to trust in or acceptance of AI applications that were not mentioned in the survey. Furthermore, the participants were invited to suggest any other factors, different from trust, deemed important for acceptance of AI applications in medicine.

Sampling

Using the convenience sampling method [29], AIDPATH Consortium members were requested to invite stakeholders in their network but outside the AIDPATH Consortium to fill in the survey on the SurveyMonkey platform. The survey was distributed by email to members of relevant stakeholder groups to capture their professional perspectives (eg, clinicians, scientists, and policy makers). Data were collected from April to May 2022 and analyzed using Microsoft Excel.

Data Collection and Analysis

After participants were asked to rate the relevance of each factor from 1 (irrelevant) to 5 (relevant), the mean score of each factor was determined by assigning each response a weight from 1 to 5. Next, means scores were calculated by finding an average of the sum of response values for each question. To visualize the survey responses and compare the mean scores for each factor included in the survey, a spider diagram was charted. This provided an overview of the factors' relevance and their relative importance in influencing both trust and acceptance toward AI applications in medicine. In addition, a scatter plot was created to obtain an overview of the interrelationship between the relevance to trust (x axis) in and acceptance (y axis) of AI applications in medicine. The plot allowed us to identify the degree of relevance of each factor in relation to both trust and acceptance. To classify the factors based on their relevance, score ranges were established. Factors with mean scores from 1 to 3 were considered to be of low relevance, while factors from 4 to 5 were deemed of high relevance. The open-question responses were considered when interpreting numerical data.

Ethical Considerations

Under Dutch law, no ethical approval was required according to Article 1b of the Dutch Medical Research in Human Subjects Act [30]. However, all participants were informed about the study objectives, their verbal consent was obtained, and all data were processed anonymously. All responses were recorded anonymously. Participants were informed of their right to withdraw from the study at any time without any consequences. They were not financially compensated.

Results

Rapid Literature Review

The literature search (Figure 1) yielded 301 hits in the PubMed database and 105 hits through gray literature search and snowballing. After screening titles and abstracts, 284 (70%)

records were excluded. After full-text screening, 90 (73.8%) records were excluded primarily due to the absence of concepts of trust or acceptance and a lack of factors related to trust or acceptance in the main text or data-containing figures. As a result, 32 (26.2%) papers and reports [7,9-12,15,16,19,21,31-53] were included in the data analysis.

Overall, the rapid review identified a total of 110 factors related to trust and 77 factors related to acceptance toward medical AI technology. The full list of factors identified through the rapid review with corresponding studies can be found in [Multimedia Appendix 1](#). [Tables 1-4](#) show all factors from the rapid review, each with the frequency of its appearance in the literature and the corresponding overarching umbrella factors. Some factors from a single study are repeated in the same category in [Tables 1 and 2](#) on trust and [Tables 3 and 4](#) on acceptance or within the same category (eg, health care professionals and patients subsections of the human-related factors section). The most frequently reported factors related to trust ([Tables 1 and 2](#)) in medical AI applications were knowledge and understanding of AI by health care professionals and knowledge and education of AI among patients. In terms of technology-related factors, accuracy, transparency, reliability, safety, and explainability of medical AI applications and their functioning appeared most often in the literature. Regarding legal and ethical factors, the most frequently occurring factors included fairness and equity of medical AI technology and the privacy and security of personal data handled by the AI systems. The most frequently presented human-related factors related to acceptance ([Tables 3 and 4](#)) of medical AI technology were the perceived usefulness and provision of better medical services by the AI technology. Regarding technology-related factors linked to acceptance, performance expectancy, design and output quality, and transparency were stated in the literature most often. A wide range of legal and ethical factors were mentioned in the literature, including adequate regulations of medical AI technology, protection and security of patients' data, and the allocation of accountability and responsibility for the (mal)functioning of an AI application. There were additional factors related to trust in and acceptance of medical AI technology ([Tables 1-4](#)). These included replacement of doctors by machines that lack a human touch and moral support, labor market implications, and environmental sustainability. Three studies also highlighted that acceptance of a medical AI application is directly related to trust in the AI application. Overall, there were fewer factors related to acceptance than those related to trust, whereas most of the overarching umbrella factors were fully represented in both tables. Therefore, an identical list of umbrella factors allocated within the 4 categories (human-related, technology-related, legal and ethical, and additional factors) was used in the survey for investigating the relevance of factors for both trust in and acceptance of AI applications in medicine.

Figure 1. PRISMA flow diagram of the rapid review literature screening. AI: artificial intelligence.

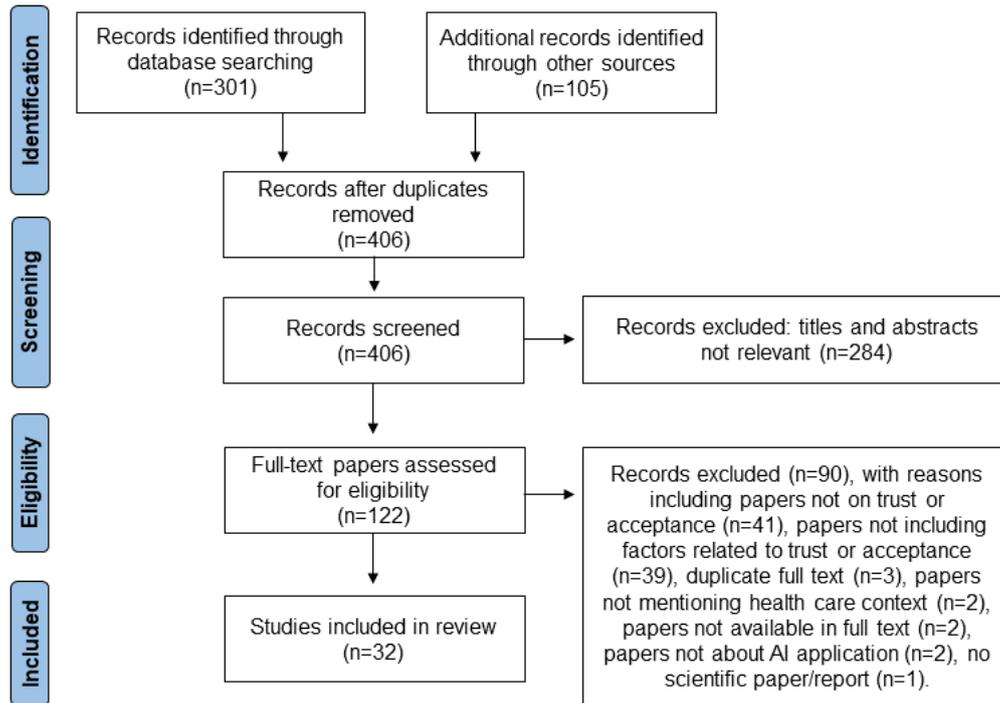

Table 1. Human-related factors related to trust (N=110) in medical AI^a applications (22/32, 68.8%, studies).

Factor category and factors from the rapid review	Umbrella factors used in the survey
AI professionals	
AI company/provider (n=2, 9.1%)	Type of institution/organization of AI professionals (eg, university, technology company, commercial organization)
AI role (n=1, 4.5%); perceived helpfulness (n=1, 4.5%)	The purpose to innovate with a specific AI application in medicine (eg, financial vs societal)
Health care professionals	
Knowledge and understanding of AI (n=6, 27.3%); education (n=3, 13.6%)	Knowledge of AI applications in medicine (eg, by means of training and education)
Expectation of AI (n=1, 4.5%); perceived actionability (ie, clear recommendation for action; n=1, 4.5%); user’s social network (n=1, 4.5%); user’s media consumption (n=1, 4.5%)	Attitude toward AI application usage in medicine (eg, agreeableness, openness, conscientiousness, engagement)
Patients informed about AI application usage in the hospital	
Knowledge/education about AI (n=5, 22.7%); awareness of AI (n=2, 9.1%)	General knowledge of AI applications in medicine
Openness (to AI health care technologies and to judgments of potential benefits and harms; n=1, 4.5%); perceived benefit and lower concern (n=1, 4.5%); user’s social network (n=1, 4.5%); user’s media consumption (n=1, 4.5%)	Attitude toward AI application usage in medicine (eg, agreeableness, openness, conscientiousness)
Gender (n=2, 9.1%); age (n=1, 4.5%); type of user (n=1, 4.5%)	Age, gender, level of education
All parties	
Clinicians and patients interaction during AI integration (n=1, 4.5%); human agency and oversight (n=1, 4.5%)	Transparency between all involved parties (AI professionals, health care professionals, patients)

^aAI: artificial intelligence.

Table 2. Other factors related to trust (N=110) in medical AI^a applications (22/32, 68.8%, studies).

Factor category and factors from the rapid review	Umbrella factors used in the survey
Technology-related factors	
Accuracy (n=7, 31.8%); reliability (n=5, 22.7%); safety (n=4, 18.2%); design and output quality (n=2, 9.1%); performance expectancy (n=2, 9.1%); ability (n=1, 4.5%); perceived functionality (n=1, 4.5%); self-efficacy (n=1, 4.5%); tool itself (n=1, 4.5%)	Performance of AI applications in medicine (reproducibility of outcomes, accuracy)
Auditability (n=1, 4.5%); customizability (n=1, 4.5%); understandability (n=1, 4.5%); ease of integration into clinical workflows (n=1, 4.5%); convenience of use (n=1, 4.5%); usability (n=1, 4.5%); (over)alerting and excessive false-positive rate (n=1, 4.5%)	Possibility of integration of AI applications into existing clinical workflows
Risk and impact mitigation (n=1, 4.5%)	Clear balance of risks and benefits of the AI application
Transparency (n=6, 27.3%); explainability (n=5, 22.7%); evidence strength (n=2, 9.1%); benevolence (n=2, 9.1%); complexity (n=2, 9.1%); interpretability (n=2, 9.1%); integrity (n=1, 4.5%); predictability (n=1, 4.5%); trialability (n=1, 4.5%); trustworthiness (n=1, 4.5%)	Explainability and transparency of the processes and outcomes
Legal and ethical factors	
Fairness and equity (n=8, 36.4%); adequate regulations, legislation, and governance (n=3, 13.6%); ethical/legal implications (n=1, 4.5%)	Adequacy of the regulations and governance of AI applications in medicine
Personal data privacy and security (n=8, 36.4%); data used to train AI/cognitive bias (n=2, 9.1%); data sensitivity (n=1, 4.5%); respect and preservation of human dignity (n=1, 4.5%)	Data use transparency
Accountability (n=3, 13.6%); power-control balance (n=1, 4.5%)	Clear accountability and responsibility of the AI application (machine vs human responsibility)
Additional factors	
Environmental sustainability (n=1, 4.5%)	Environment-friendly AI application
Replacement of doctor/lack of human touch and moral support when evaluated by AI alone (n=1, 4.5%); labor market implications (n=1, 4.5%)	Impact on job availability (machines replacing humans)

^aAI: artificial intelligence.

Table 3. Human-related factors related to acceptance (N=77) of medical AI^a applications (14/32, 43.8%, studies).

Factor category and factors from the rapid review	Umbrella factors used in the survey
AI professionals	
AI company/provider (n=1, 7.1%); brand impact (n=1, 7.1%)	Type of institution/organization of AI professionals (eg, university, technology company, commercial organization)
Perceived usefulness (n=3, 21.4%); better medical services/ understanding of disease (n=3, 21.4%); improve the quality of people's lives (n=2, 14.3%); medical costs (n=2, 14.3%); AI role (eg, saving patients' time; n=1, 7.1%); miniaturization of hardware (n=1, 7.1%)	Purpose to innovate with a specific AI application in medicine (eg, financial vs societal)
Health care professionals	
Knowledge and understanding of AI (n=1, 7.1%)	Knowledge of AI applications in medicine (eg, by means of training and education)
Behavioral intention to use (n=2, 14.3%); effort expectancy (n=2, 14.3%); perceived ease of use (n=2, 14.3%); perceived usefulness (n=2, 14.3%); intrinsic motivation (n=1, 7.1%); interest in AI (n=1, 7.1%); professional identity (n=1, 7.1%); concerns about benefit to patient care (n=1, 7.1%); general impression of AI (n=1, 7.1%)	Attitude toward AI application usage in medicine (eg, agreeableness, openness, conscientiousness, engagement)
Patients informed about AI application usage in the hospital	
Knowledge/education about AI (n=1, 7.1%); awareness of AI (n=1, 7.1%)	General knowledge of AI applications in medicine
Behavioral intention to use (n=2, 14.3%); general impression (n=1, 7.1%); Interest in topic (n=1, 7.1%)	Attitude toward AI application usage in medicine (eg, agreeableness, openness, conscientiousness)
Age (n=1, 7.1%)	Age
All parties	
Expectations of others (n=2, 14.3%)	Transparency between all involved parties (AI professionals, healthcare professionals, patients)

^aAI: artificial intelligence.

Table 4. Other factors related to acceptance (N=77) of medical AI^a applications (14/32, 43.8%, studies).

Factor category and factors from the rapid review	Umbrella factors used in the survey
Technology-related factors	
Performance expectancy (n=4, 28.6%); design and output quality (n=4, 28.6%); accuracy (n=2, 14.3%); efficiency (n=1, 7.1%)	Performance of AI applications in medicine (reproducibility of outcomes, accuracy)
Perceived ease of use (n=2, 14.3%); user-friendliness (n=2, 14.3%); actual system use (n=1, 7.1%); compatibility (n=1, 7.1%); facilitating conditions (n=1, 7.1%)	Possibility of integration of AI applications into existing clinical workflows
Perceived risk (n=1, 7.1%)	Clear balance of risks and benefits of the AI application
Transparency (n=3, 21.4%); explainability (n=2, 14.3%); evidence strength (n=1, 7.1%); trustworthiness (n=1, 7.1%)	Explainability and transparency of the processes and outcomes
Legal and ethical factors	
Adequate regulations, legislation and governance (n=2, 14.3%); ethical risks (n=1, 7.1%); political support (n=1, 7.1%)	Adequacy of the regulations and governance of AI applications in medicine
Data protection/security (n=2, 14.3%); patients' consent to the continuous collection and processing of data (n=1, 7.1%)	Data use transparency
Accountability and responsibility (n=2, 14.3%); tort liability (n=1, 7.1%)	Clear accountability and responsibility of the AI application (machine vs human responsibility)
Additional factors	
Replacement of doctor/lack of human touch and moral support when evaluated by AI alone (n=1, 7.1%)	Impact on job availability (machines replacing humans)
Trust in AI applications (n=3, 21.4%)	Acceptance emerging from trust

Survey

Participants

A total of 22 respondents participated in the survey, of which 18 (82%) completed the questions on trust and 15 (68%) completed the questions on acceptance. No reasons were provided for not completing the survey. [Table 5](#) shows the characteristics of the survey participants, the majority (n=21, 95%) of whom came from European countries, were aged from

40 to 60 years, and had 0-10 or 21-30 years of professional experience.

Participants were mainly slightly (n=7, 32%) or moderately (n=8, 36%) familiar with AI-based devices used for clinical purposes ([Figure 2](#)). In thinking about AI, 9 (41%) of the participants indicated that the statement “I accept AI” best represents their view, followed by “I approve of AI” (n=6, 27%) and “I embrace AI” (n=5, 23%); see [Figure 3](#).

Table 5. Characteristics of the participants (N=22).

Characteristic and type of participant	Participants, n (%)
Stakeholder group^a	
Researchers	18 (82)
Technology providers	5 (23)

Relevance of Factors for Trust in and Acceptance of AI

In Table 6, the mean scores per factor for its relevance to trust and acceptance are shown. Figure 4 demonstrates a spider diagram with the 19 summarized statements and the corresponding mean scores of relevance to trust in and acceptance of AI applications in medicine. The degrees of relevance of the factors related to trust and to acceptance closely followed each other for all but 1 (5.3%) of the 19 factors. Only

the type of AI organization was slightly more relevant to trust than to acceptance toward AI applications in medicine. In Figure 5, a scatter plot displays the combined relevance of the factors related to trust (x axis) and acceptance (y axis) toward medical AI applications. Of the 19 factors included in the survey, 3 (16%) were found to have, on average, low relevance, while the other 16 (84%) had high relevance. There were no factors relevant to acceptance and irrelevant to trust (upper-left section in the plot) and vice versa (bottom-right section in the plot).

Table 6. Mean (SD) factor relevance to trust and acceptance (N=22).

Factor	Trust	Acceptance
Type of AI ^a organization	4.72 (0.75)	4.27 (0.88)
Purpose to innovate with AI	4.33 (0.84)	4.47 (0.64)
Clinicians' knowledge about AI	4.50 (0.51)	4.73 (0.46)
Clinicians' attitude towards AI	4.50 (0.51)	4.47 (0.64)
Patients' knowledge of AI	4.17 (0.62)	4.20 (0.68)
Patients' attitude toward AI	4.28 (0.57)	4.47 (0.64)
Patients' age	3.17 (1.04)	3.47 (1.19)
Patients' gender	2.61 (1.14)	2.67 (1.05)
Patients' education level	3.50 (0.99)	3.53 (1.19)
Transparency between all parties	4.61 (0.50)	4.47 (0.64)
Performance of AI	4.83 (0.38)	4.67 (0.62)
Possibility of AI integration into existing workflows	4.56 (0.62)	4.53 (0.83)
Clear balance of AI risks and benefits	4.67 (0.49)	4.60 (0.63)
Explainability and transparency of AI processes	4.78 (0.43)	4.60 (0.63)
Adequacy of AI regulations	4.72 (0.57)	4.60 (0.83)
Data use transparency	4.61 (0.50)	4.67 (0.49)
Clear accountability and responsibility of AI	4.61 (0.61)	4.80 (0.41)
Environmental friendliness of AI	3.83 (0.79)	3.87 (0.92)

^aAI: artificial intelligence.

Figure 4. Mean scores of factors' relevance to trust in and acceptance of AI applications in medicine (N=19). Score=1 means irrelevant; score=3 means not irrelevant, nor relevant; and score=5 means relevant. AI: artificial intelligence.

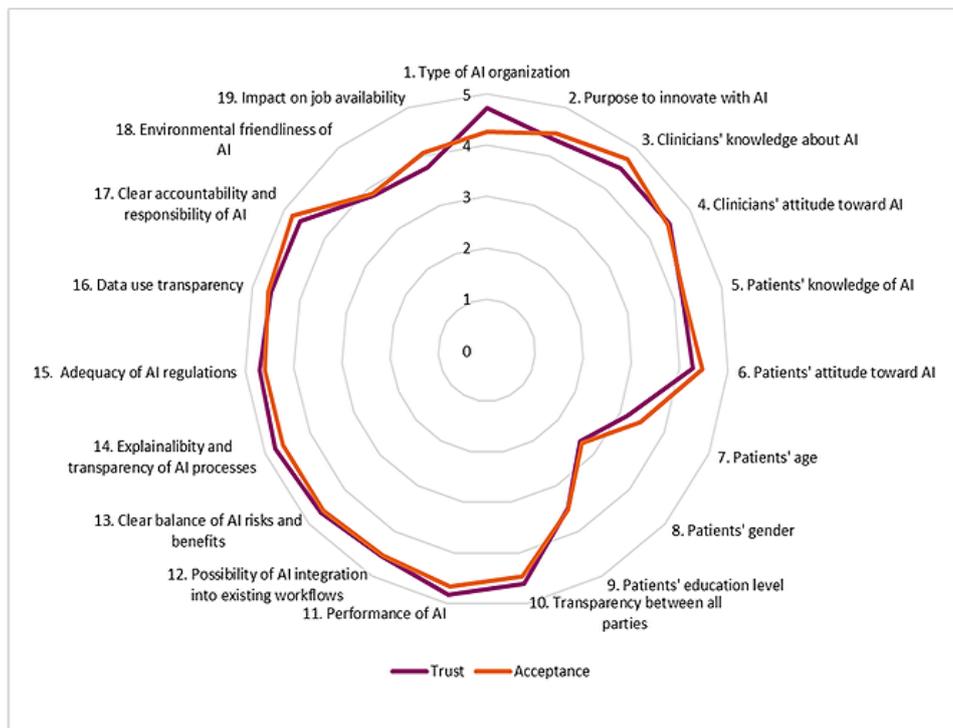

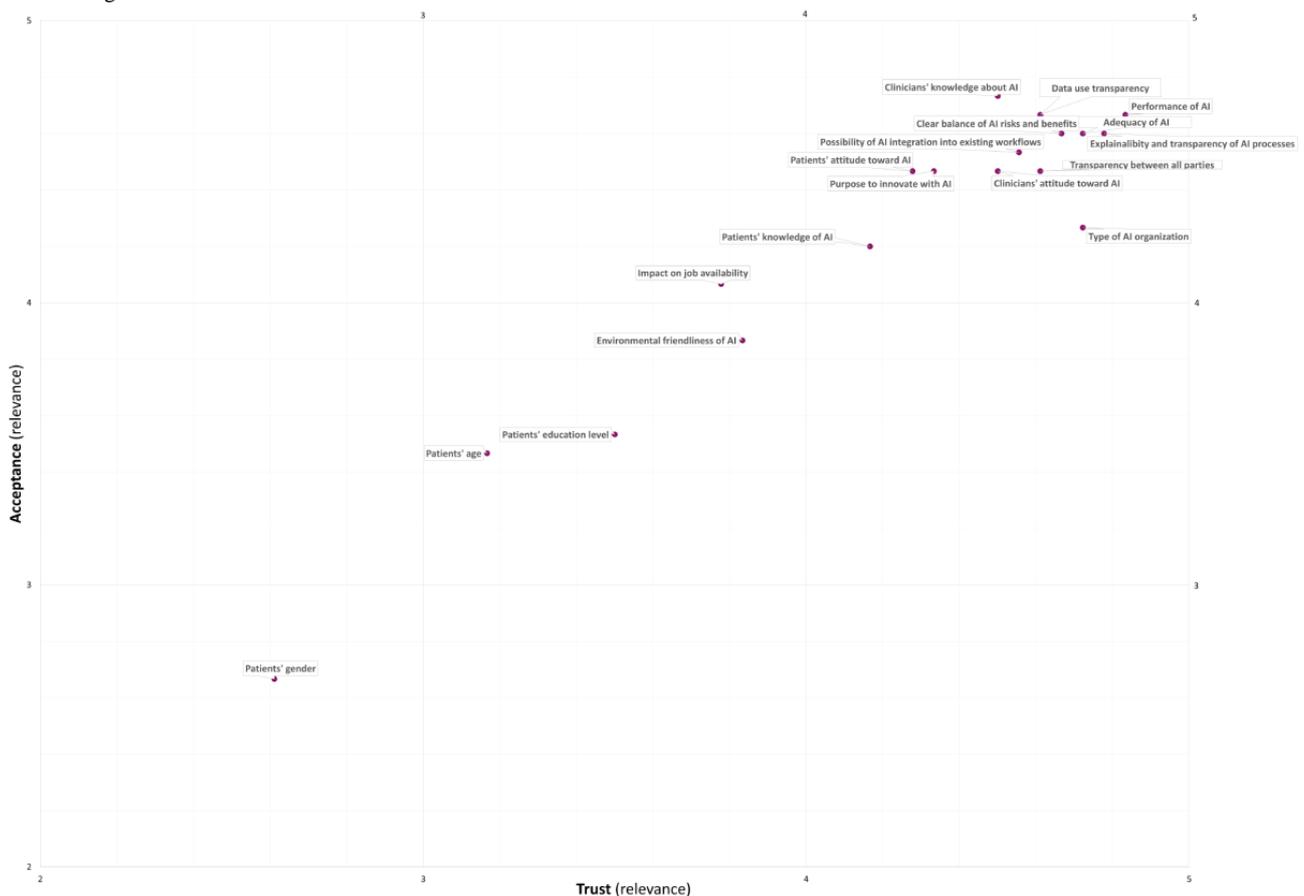

Figure 5. Overview of the relevance of factors related to trust in and acceptance of novel AI applications in medicine (1=not relevant, 5=relevant). AI: artificial intelligence.

Factors of Low Relevance

With regard to patients informed about AI application usage in the hospital, participants deemed the patient's gender, age, and educational level to be of low relevance to trust in and acceptance of novel AI applications in medicine.

Factors of High Relevance

The majority of factors were deemed highly relevant to trust in and acceptance of novel AI applications in medicine by participants. Regarding AI professionals, it was observed that the type of institution or organization where AI professionals originated from (eg, university, technology company, commercial organization) and the purpose to innovate with a specific AI application in medicine (eg, financial, societal, or clinical purpose) were considered relevant. Participants reported that the involvement of health care professionals having knowledge of the AI application (eg, by means of training and education) is highly relevant to trust and acceptance. The health care professionals' attitude toward AI application usage in medicine, comprising their agreeableness, openness, conscientiousness, and engagement, was found to be equally important. Likewise, the patients' general knowledge of and attitude toward AI application usage in medicine were found to be relevant. The transparency between all involved parties (AI professionals, health care professionals, and patients) was also deemed highly relevant. Technology-related factors were found to be highly relevant, too, in particular the performance of AI applications in medicine (eg, reproducibility and accuracy

of outcomes), the possibility of integration of the AI applications into existing clinical workflows, having a clear balance of risks and benefits of the AI applications, and the explainability and transparency of the processes and outcomes. Legal and ethical factors were also considered of high relevance and concerned the adequacy of the regulations and governance of AI applications in medicine, data use transparency, and clear accountability and responsibility of the AI applications (machine vs human responsibility). Additional factors, such as AI applications being environment friendly and the impact of medical AI on job availability (eg, machines replacing human beings), were viewed as factors of high relevance.

Other Factors

Participants were able to share other factors that were not mentioned in the survey questions. Factors related to trust included solidarity and understanding the bias and interdomain knowledge of AI in software development, data science, and medicine. Other factors related to acceptance were the extent to which alternatives to AI applications are available, the length of experience, transparency about limitations, reproducibility, risks evaluation, resources, and the fear to use an AI application (ie, fear of making the wrong decision or fear of losing control).

Discussion

Principal Findings

This study aimed to identify factors related to trust and acceptance toward medical AI applications by means of a rapid

review and to assess their relevance by conducting a survey. Through the rapid review, 19 key factors related to trust in and acceptance of AI-powered medical technologies were identified and subsequently grouped into 4 categories. Our survey results highlight that of all examined factors, 84% (16/19) were considered highly relevant to trust in and acceptance of novel AI applications in medicine. Only the patient's gender, age, and education level (3/19, 16%) were deemed to be of low relevance by participants.

Comparison With Prior Work

Previous studies have reported that trust in technology is mainly determined by human characteristics [54], technology-related factors [55], and environment-related factors [56], which is in line with the findings of our survey. According to Tran et al [57], who investigated patients' perceived benefits and risks of using digital and AI technology in health care, the important factors to consider are the new technologies requiring an overhaul of the current health care system as human care is being replaced by machines and health care professionals becoming sufficiently equipped with increasing knowledge of AI technology. This highlights the importance of several survey factors, including the possibility of AI integration into existing clinical workflows. Therefore, setting features such as understandability, usability, and user-friendliness (factors that frequently appeared in the rapid review) by AI professionals as key goals in the development of novel AI applications would increase the chances of successful integration of AI technology into health care systems. Tran et al [57] also highlighted the increasing importance of data use transparency toward patients and the acute need for clear accountability and responsibility (machine vs human responsibility) concerning the new technology, which also goes hand in hand with the findings from the rapid review and the survey [57]. The patient data handling must be organized in accordance with the existing data protection regulations in respective countries, with additional precautionary measures due to the sensitive nature of such medical data [57]. Shin et al [58] demonstrated that explainability of AI plays a big role in user trust and attitude toward AI. Explainability, along with transparency, was also found to be highly relevant in our study, especially in relation to the AI application processes and outcomes. In addition, Vourgidis et al [59] recommended that AI systems be regularly checked for being up to date, since today's technology is continuously evolving. This again highlights the relevance of the education of health care professionals, since they are the primary users of medical AI technology and hence need to follow the developments in the field. Yang et al [49] found that gender is not relevant to trust in AI technology in medicine. This agrees with our finding that a patient's gender has low relevance to trust in and acceptance of AI technology in medicine. Contrary to our findings, it has been reported that younger generations in general have more trust and are more likely to accept AI systems compared to older generations [11]. In our survey, the majority of participants were aged 40–60 years and above and they exhibited a solid awareness of and a positive attitude toward AI technology. Gillespie et al [11] also stated that highly educated people (university level) are more likely to trust and accept AI systems compared to those without a

university degree. However, our survey showed that a patient's educational level has low relevance to trust in and acceptance of medical AI applications.

Strengths and Limitations

To the best of our knowledge, this is the first study to use a rapid review of the latest literature to identify factors related to trust in and acceptance of AI applications in medicine in order to create a survey to evaluate their relevance and the attitudes of health care stakeholders toward implementation of medical AI applications. However, the study has several limitations. Since a large number of papers and reports in the rapid review did not provide sufficient context for the factors for trust or acceptance, there could have been an increased risk of personal bias during interpretation and categorization of those factors. Furthermore, some studies did not clarify whether the reported factors were related to only trust or only acceptance, which could also lead to possible misinterpretation. To minimize the effect of such bias and misinterpretation, a third reviewer (author HJMV) was consulted in such cases. Another limitation is the relatively small number of papers included in the rapid review, given the breadth of the topic. However, this rapid review was intentionally conducted focusing on the most relevant and recent literature to provide an initial overview and highlight key themes in a time-efficient manner. We aimed to provide a starting point that formed the basis for the survey. In addition, the number of participants included in the survey can be considered relatively low, which was caused by difficulties in recruiting participants and the time-constrained nature of the study. However, sufficient diversity in participant characteristics (ie, gender, age, country of work, and years of professional experience) was achieved, which could be considered more important in terms of validity of the study findings. Even though the survey benefited from a sample with a wide diversity in participant characteristics, one of the limitations to consider is the underrepresentation of certain stakeholder groups, in particular technology providers, policy makers, and hospital staff members other than clinicians. If these groups had been included in the survey, different patterns in factor relevance might have been observed, potentially shedding light on additional concerns or challenges associated with AI applications in medicine. Moreover, when considering the relevance of factors assessed through the survey, which were predominantly highlighted by researchers, it is important to note that these factors might be readily attainable or already well established within this specific stakeholder group. As a result, these factors may not necessarily represent challenges or barriers for this particular group, as they are already well versed in the aspects related to trust and acceptance.

Recommendations for Future Research

The results of this study can be valuable for various stakeholders involved in the implementation of novel AI applications, since trust and acceptance building remains a focus point throughout the different stages, including the pilot, implementation, evaluation, and monitoring phases of the process. In the survey, participants shared other factors related to trust in and acceptance of AI applications in medicine that were not included in the survey. However, due to a lack of context, it is not entirely clear what was meant by some of these factors; since these are

open to interpretation, follow-up research is required to better understand this. In addition, further research is needed to gain insight into the reasons participants considered factors to be of low or high relevance. Regarding the currently underrepresented stakeholder groups in the survey, more research is required to gain insight into the perspectives of policy regulators, technology providers, and hospital staff members. Next, once the implementation of a novel AI technology, such as the AIDPATH system, becomes clear from the trust and acceptance point of view, it would be beneficial to conduct a workshop with experts from the AI and biotechnology fields to identify technical challenges of implementation. This is crucial since, according to the survey results, the technical robustness and clarity of AI applications is a prerequisite for trust and acceptance exhibited toward this technology by stakeholders.

Recommendations for Implementation

By considering the factors that are most relevant in the AI technology adoption process, the implementers can facilitate trust in and acceptance of medical AI applications among their users and other stakeholders. Furthermore, the knowledge of the factors with high relevance to stakeholders can predict concerns the potential users might have regarding the new AI technology and act upon these concerns to implement the AI application efficiently and in a timely manner. There are several ways in how the results of the survey could be used by AI implementers, such as smart hospitals, to build trust and acceptance among various stakeholder groups. For instance, the highly relevant factor of knowledge and understanding of AI among health care professionals could be addressed by providing information about medical AI to clinicians in the form of conferences and educational workshops. These initiatives can ensure that health care professionals remain updated on significant changes in AI technology, facilitating its accurate utilization. Similarly, patients could be informed of medical AI

technology through patient information initiatives in (smart) hospitals and within patient communities. The highly relevant technology-related factors could be used by technology developers and scientific researchers as guidance in the development of novel AI technology. For regulators and policy makers, it is crucial to know that users and other stakeholders consider data use transparency and fairness and equity to be of utmost importance regarding novel medical AI technology. Indeed, data privacy is a crucial and ever-so-present topic in legislation and regulations, but it needs to be constantly reviewed by policy makers due to the newness of AI in health care and the speed of its development. The legal aspects of software containing AI have been subjected to the Medical Device Regulation (MDR) [60]. For the acceptance of AI, its implementation in MDR-compliant solutions is invaluable. The tasks of policy makers could involve the risk assessment of various data breaches related to AI in medicine with continuous updating of regulations related to data security and privacy within the field of medical AI. Furthermore, both policy makers and AI professionals have to ensure the maintenance of fairness and equity of AI technology usage.

Conclusion

This study identified and assessed the relevance of factors for trust in and acceptance of AI applications in medicine. The survey demonstrated that the majority of the identified human-related, technology-related, and legal and ethical factors for trust in and acceptance of novel AI applications in medicine were considered by stakeholders to be of high relevance. Taken together, these findings and subsequent recommendations could be used by any implementers of medical AI, such as (smart) hospitals, AI technology organizations, biotechnology research institutes, and policy makers, to facilitate smooth and timely adoption of novel AI applications in medicine.

Acknowledgments

Our gratitude goes out to the AIDPATH (artificial intelligence [AI]-driven Decentralized Production for Advanced Therapies in the Hospital) Consortium partners, the Fraunhofer Institute for Cell Therapy and Immunology IZI, University College London, the Foundation for Research and Technology (FORTH)-Hellas, SZTAKI, Aglaris Cell SL, Sartorius Cell Genix GmbH, the Fundació Clínic per a la Recerca Biomèdica, IRIS Technology Solutions, Red Alert Labs, and ORTEC b.v. We would also like to thank the advisory board members of AIDPATH for providing feedback on the survey. Lastly, we thank the survey's responders.

The paper was written within the framework of the European Union's (EU) Horizon 2020 research and innovation program project AIDPATH (grant agreement number 101016909). All mentioned colleagues/companies are part of AIDPATH and therefore received funding from the EU within the scope of AIDPATH.

Data Availability

The data used and analyzed in this study are available from the corresponding author upon reasonable request.

Authors' Contributions

DS was responsible for methods design, search strategy design, data acquisition, data extraction, data analysis, interpretation of data, and design and writing of the manuscript; AA, methods design, search strategy design, data acquisition, data extraction, data analysis, interpretation of data, regularly reviewing the work, design and writing of the manuscript, and providing feedback on the manuscript; IWAB, methods design, data acquisition, and providing feedback on the manuscript; CS, methods design, regularly reviewing the work, and providing feedback on the manuscript; MH, providing feedback on the manuscript and funding acquisition; JLLJ, reviewing the work and providing feedback on the manuscript; SH, contributing to the Introduction chapter,

providing feedback on the manuscript, project administration, and funding acquisition; and HJMV, concept and design of the overall study, quality assessment, interpretation of data, regularly reviewing the work, providing feedback on the manuscript, and manuscript final approval.

Conflicts of Interest

MH reports speaker honoraria from Novartis, Janssen, and Celgene/BMS and has participated in scientific advisory boards for Janssen and Celgene/BMS. MH is also listed as an inventor on patent applications and has been granted patents related to chimeric antigen receptor (CAR) technologies and CAR T cell therapy that have been filed by the Fred Hutchinson Cancer Research Center and the University of Wurzburg and that have been, in part, licensed to industry. In addition, MH is a cofounder and equity owner of T-CURX GmbH, Wurzburg, Germany. The remaining authors declare that they have no competing interests.

Abstract

Background: Adverse events refer to incidents with potential or actual harm to patients in hospitals. These events are typically documented through patient safety event (PSE) reports, which consist of detailed narratives providing contextual information on the occurrences. Accurate classification of PSE reports is crucial for patient safety monitoring. However, this process faces challenges due to inconsistencies in classifications and the sheer volume of reports. Recent advancements in text representation, particularly contextual text representation derived from transformer-based language models, offer a promising solution for more precise PSE report classification. Integrating the machine learning (ML) classifier necessitates a balance between human expertise and artificial intelligence (AI). Central to this integration is the concept of explainability, which is crucial for building trust and ensuring effective human-AI collaboration.

Objective: This study aims to investigate the efficacy of ML classifiers trained using contextual text representation in automatically classifying PSE reports. Furthermore, the study presents an interface that integrates the ML classifier with the explainability technique to facilitate human-AI collaboration for PSE report classification.

Methods: This study used a data set of 861 PSE reports from a large academic hospital's maternity units in the Southeastern United States. Various ML classifiers were trained with both static and contextual text representations of PSE reports. The trained ML classifiers were evaluated with multiclass classification metrics and the confusion matrix. The local interpretable model-agnostic explanations (LIME) technique was used to provide the rationale for the ML classifier's predictions. An interface that integrates the ML classifier with the LIME technique was designed for incident reporting systems.

Results: The top-performing classifier using contextual representation was able to obtain an accuracy of 75.4% (95/126) compared to an accuracy of 66.7% (84/126) by the top-performing classifier trained using static text representation. A PSE reporting interface has been designed to facilitate human-AI collaboration in PSE report classification. In this design, the ML classifier recommends the top 2 most probable event types, along with the explanations for the prediction, enabling PSE reporters and patient safety analysts to choose the most suitable one. The LIME technique showed that the classifier occasionally relies on arbitrary words for classification, emphasizing the necessity of human oversight.

Conclusions: This study demonstrates that training ML classifiers with contextual text representations can significantly enhance the accuracy of PSE report classification. The interface designed in this study lays the foundation for human-AI collaboration in the classification of PSE reports. The insights gained from this research enhance the decision-making process in PSE report classification, enabling hospitals to more efficiently identify potential risks and hazards and enabling patient safety analysts to take timely actions to prevent patient harm.

Introduction

Since the publication of the seminal report on patient safety—*To Err Is Human* [1], the importance of preventing adverse events in health care has been widely recognized. Adverse events refer to unintended or unexpected incidents that occur during hospital care that cause harm to a patient [2]. Common adverse events include complications, falls, and medication errors. These events can lead to prolonged hospital stays, permanent harm to patients, life-saving interventions, or even contributing to patient deaths [2,3]. Unfortunately, adverse events remain one of the top 10 leading causes of death and disability worldwide, resulting in 251,454 deaths annually in the United States alone [4]. In Organization for Economic Cooperation and Development (OECD) countries, 15% of total hospital activity is the direct result of adverse events [5]. The global cost of adverse events has been estimated at 42 billion USD annually [6].

Patient safety event (PSE) reporting systems, also called incident reporting systems, have been widely adopted in hospitals across the world as part of their efforts to mitigate adverse events and improve patient safety [7,8]. Multiple nations, including Canada, Japan, England, and Norway, have made it mandatory for hospitals to establish and maintain a PSE reporting system, either with individual health care systems or through centralized national incident reporting platforms [9]. The primary purpose of the PSE reporting system is to provide health care organizations with a centralized system for tracking and analyzing PSEs, thereby facilitating continuous learning and maintaining a record of PSEs for risk assessment and prevention [7,10]. PSE reporting systems are tools that allow frontline health care personnel to voluntarily report adverse events, near-misses, and unsafe conditions [11]. Each PSE report includes structured data, such as event types, patient harm level, date, and location of the event, as well as unstructured data, including a free-text section that contains the factual description of the event and the patient's outcome [12]. Following submission, PSE reports are reviewed by relevant hospital staff, such as risk managers, patient safety analysts, nurse managers, physicians, and biomedical engineers, to identify areas for patient safety and quality improvement within the hospital [13].

Accurately classifying PSE reports into their appropriate event type is crucial to ensure that these reports are directed to the relevant patient safety analyst, support organizational learning, identify patterns and trends in adverse events, and ultimately prioritize measures to reduce adverse events [14,15]. An event type refers to a specific class of events that share common characteristics [16]. Examples of event types include falls, medication-related issues, and diagnosis errors [17,18]. PSE reporting systems may have upwards of 20 categories of events. The formulation of these classification taxonomies generally involves systematically grouping PSE reports based on common characteristics [19]. The descriptions of event types are not

always readily accessible to PSE reporters and patient safety analysts [15]. Previous studies have found that the classification of PSE reports is inconsistent depending on the reporter's profession, interpretation of the adverse event, and understanding of the PSE classification taxonomy [15,20]. Furthermore, 25% of PSE reports are labeled with vague or nonspecific categories such as "miscellaneous" and "other" and require time-consuming retrospective analysis for reclassification [21]. These problems are further exacerbated by the growing volume of PSEs reported [18,22]. For instance, hospitals in the state of New South Wales in Australia reported close to 195,000 PSEs in 2020 [23], while there were approximately 2.3 million PSEs reported to the National Reporting and Learning System in England from April 2021 to March 2022 [24].

In light of these challenges, it is imperative to find an efficient solution to ensure the reliable classification of PSE reports. Recent studies have used static text representations and supervised machine learning (ML) techniques to automate the PSE report classification [17,25,26]. However, static text representations ignore the ordering of the words and do not account for the differences in word meaning across different contexts. These limitations may result in suboptimal classification performance. With the emergence of deep learning, contextual text representation produced from transformer-based deep learning models has achieved state-of-the-art performance on a wide range of natural language processing tasks, including text classification [27]. The contextual representation of each word is based on its surrounding context within the text, allowing for a more accurate understanding of its usage across different contexts and facilitating knowledge transfer across languages [28]. Therefore, using contextual text representation in training ML classifiers presents a promising opportunity for achieving a more precise classification of PSE reports.

The integration of ML models into PSE reporting systems has important implications for human-artificial intelligence (AI) collaboration, given the roles of the incident reporter (front end) and patient safety analyst (backend). Various approaches for using ML classifiers can be developed, including at different levels of automation; however, unifying the strengths of both human expertise and AI offers the most promising route for effective implementation [29-31]. A crucial determinant for successfully implementing the human-AI collaboration approach is decision transparency [32,33], which is often referred to as explainability. Explainability is the concept that an ML model's prediction can be explained in a way that human operators can comprehend and reconstruct the model's reasoning [33]. Incorporating explainability techniques in human-AI collaboration is paramount as it facilitates a deeper understanding of the factors influencing the predictions, thereby fostering trust and understanding between human experts and AI systems. Therefore, embedding explainability into the

human-AI collaboration holds significant potential for enhancing PSE report classification.

The main aim of this study is to examine the efficacy of contextual text representation in improving the accuracy of PSE report classification. To accomplish this, we trained, evaluated, and compared various ML classifiers with both static and contextual text representations. Additionally, we developed an interface to illustrate the integration of the ML classifier in an event reporting system to support human-AI collaboration for PSE report classification. Moreover, we enhanced the explainability of the ML classifiers by using an explainable AI technique. Furthermore, we have investigated the ML classifier's performance under 2 conditions, differentiated by whether the explanation is valid for the predicted event type. Based on this analysis, we offer recommendations for optimizing human-AI collaboration in the context of PSE report classification.

Methods

Data Collection

The data set for this study was obtained from a large academic hospital located in the Southeastern United States. A total of 861 PSE reports from the labor and delivery and mother-baby units were extracted from the PSE reporting system from January 1, 2019, to December 31, 2020. Each PSE report was assigned to a single event type from a set of 25 classes, such as complication of the surgery, fall, medication-related, and supply issues. The ML classifiers were trained exclusively on PSE reports from the 7 most frequently occurring event types. This selection was intended to create a more balanced training data set to reduce sampling bias and the risk of overfitting. The selected PSE reports used for training ML classifiers constitute approximately 72.8% (627/861) of the extracted reports (Table 1).

Table 1. Prevalence of patient safety event reports by event type in this study.

Event type	Extracted reports (n=861), n (%)
Care coordination or communication	186 (21.6)
Laboratory test	122 (14.2)
Medication related	89 (10.3)
Omission or errors in assessment, diagnosis, and monitoring	67 (7.8)
Maternal	58 (6.7)
Equipment or devices	56 (6.5)
Supplies	49 (5.7)
Total	627 (72.8)

Data Preprocessing

The free-text section of PSE reports was preprocessed before feeding into ML classifiers as input features. The preprocessing procedures include text normalization, feature extraction, data splitting, and data augmentation (Multimedia Appendix 1 [28,34-39]).

Classifier Training

A range of ML classifiers, including multinomial logistic regression (MLR), support vector machine (SVM), extreme gradient boosting, light gradient boosting, random forest (RF), *k*-nearest neighbor (KNN), and multilayer perceptron, were used for the classification of PSE reports. While SVM is a binary classifier, it is also capable of performing multiclass classification using the one-versus-one strategy. This involves treating the multiclass classification problem as a series of binary classification problems, creating $n \times (n - 1) / 2$ binary classifiers for each pair of classes, where *n* represents the total number of classes, and the final classification is based on the majority vote of all binary classifiers. Extreme gradient boosting, light gradient boosting, and RF are tree-based ensemble algorithms that are commonly used in text classification tasks [17,40]. The KNN classifier predicts the class of a data point based on the majority class among its nearest neighbors in the training data set. Multilayer perceptron is a feedforward neural network consisting

of multiple layers of interconnected neurons and trained using backpropagation.

To optimize the performance of ML classifiers, we used the 5-fold cross-validation grid search technique to identify the best combination of hyperparameters. During this process, a range of values of important hyperparameters (ie, regularization strength) is assessed with 5-fold cross-validation. For each combination of hyperparameters, the training set is randomly split into 5 distinct folds, and then the ML classifier is trained and evaluated 5 times, picking a different fold for evaluation every time and training on the remaining 4 folds. The optimized combination of hyperparameters is determined based on the average performance of the classifier on the F_1 -score across the 5-fold cross-validation runs.

Classifier Evaluation

We evaluated the performance of the trained classifiers on the testing set with standard classification metrics, including accuracy, precision, recall, F_1 -score, and area under the receiver operating characteristic curve. We also evaluated classifiers on top-2 accuracy, which measures the proportion of predictions where the correct event type is among the top 2 highest probability event types predicted by the classifier. The definitions and mathematical formulas of the evaluation metrics are shown in Multimedia Appendix 2. Each of these metrics provides a distinct perspective on the performance of the

classifier, and collectively, they offer a comprehensive understanding of how well the classifier is functioning. Since we framed PSE report classification as a multiclass text classification problem, the precision, recall, F_1 -score, and area under the receiver operating characteristic curve are computed for each class and combined using a weighted average where the weights correspond to the number of data points in each class.

Development and Assessment of Explainability

As the contextual text representation is generated from transformer-based neural network, which has a black box nature, we used the local interpretable model-agnostic explanations (LIME) technique to analyze the top-performing ML classifier trained with the contextual text representation. LIME is a post hoc, local perturbation technique that provides the explanation for a single prediction. LIME generates perturbed data by randomly removing words from a text document and trains a locally explainable model with perturbed data to simulate the original classifier's prediction [41]. By measuring how the classifier's prediction changes under these perturbations, LIME reflects the contributions of each word to the prediction. The importance of each word can then be assessed for a single prediction, revealing whether the ML classifier has learned to use relevant words for classifying PSE reports. We used LIME to generate explanations for the top-performing classifier's prediction, specifically by highlighting the words that the classifier deems influential for the prediction. We presented 3 distinct cases: one where the classifier effectively leveraged relevant words for accurate prediction, another where it failed to do so, and a final case that illustrated the explanation for a misclassification. In addition, we analyzed the top 5 most prevalent words identified by LIME for each event type.

A total of 2 human factors graduate students were recruited to assess the quality of the LIME explanations. For each PSE report in the test data set, the reviewers were asked to determine independently if any of the highlighted words were relevant to the predicted event type. Based on these evaluations, the reports were then categorized into 2 distinct groups: those in which the highlighted terms were deemed relevant to the predicted event types and those where they were deemed irrelevant. Discrepancies were resolved through discussions. The interrater reliability index (Cohen κ) was calculated to quantify the level of agreement between the reviewers. The ML classifier's accuracy and F_1 -score were evaluated for these 2 groups of PSE reports. A subsequent comparison will explore the influence of explanation quality on prediction reliability.

Interface Development

In the typical workflow of PSE report classification, reporters need to provide a narrative description of the event as well as key attributes such as the event type, level of harm, date, and location of the event. Subsequent to this initial classification, the patient safety analyst will review the submitted report and decide if it needs to be recategorized to better reflect the nature of the event [17,42]. To support efficient and reliable categorization, the classifier will need to provide reporters with real-time support during the reporting process. We developed a PSE reporting interface to illustrate the integration of the ML classifier and the LIME explainability technique. In the design, the ML classifier provides multiple high-probability event types along with explanations for its prediction and allows the user to select the most appropriate event type. The interface was developed in Figma [43] and designed using guidance from previous research on incident reporting systems, including question type, mandatory and optional questions, and taxonomy for event type and harm level [44,45].

Ethical Considerations

The study was approved by the Medical University of South Carolina Hospital's institutional review board (Pro00105892). Following data extraction, PSE reports were anonymized in accordance with privacy regulation guidelines.

Results

Performance Comparison

We evaluated the trained ML classifier's classification performance on both static and contextual text representations (Multimedia Appendix 3). The performance of the top-performing ML classifier trained with static and contextual text representations is shown in Table 2. Our results showed that for static text representation, the MLR classifier trained with term frequency-inverse document frequency (TF-IDF) achieved the best performance, with an F_1 -score of 0.631 and an accuracy of 66.7% (84/126). On the other hand, for contextual text representation, the SVM classifier trained with RoBERTa-base outperformed others, with an F_1 -score of 0.753 and an accuracy of 75.4% (95/126). The SVM classifier trained with RoBERTa-base showed a 19.3% relative improvement in F_1 -score and a 13% (11/85) relative improvement in accuracy compared to the MLR classifier trained with TF-IDF for contextual text representation. In addition, we compared the accuracy (95/126, 75.4%) and top 2 accuracy (107/126, 84.9%) of the SVM classifier trained with RoBERTa-base and observed that 9.5% (12/126) of PSE reports' true event type was predicted as the second highest probability event type by the classifier, which represents 39% (12/31) of misclassified PSE reports.

Table 2. Performance of top-performing ML classifiers trained with static and contextual text representations.

Metric	Top-performing ML ^a model trained with the static text representation			Top-performing ML model trained with the contextual text representation		
	Performance	ML classifier	Text Representation	Performance	ML classifier	Text Representation
Accuracy (%)	66.67	MLR ^b	TF-IDF ^c	75.40	SVM ^d	RoBERTa-base

^eMLP: multilayer perceptron.

^fKNN: k -nearest neighbor.

Performance on Classifying Individual Event Types

We analyzed the performance of the SVM classifier trained with RoBERTa-base on individual event types (Table 3). The

F_1 -score measure for different event types ranged from 0.958 (laboratory test) to 0.400 (omission or errors in assessment, diagnosis, and monitoring).

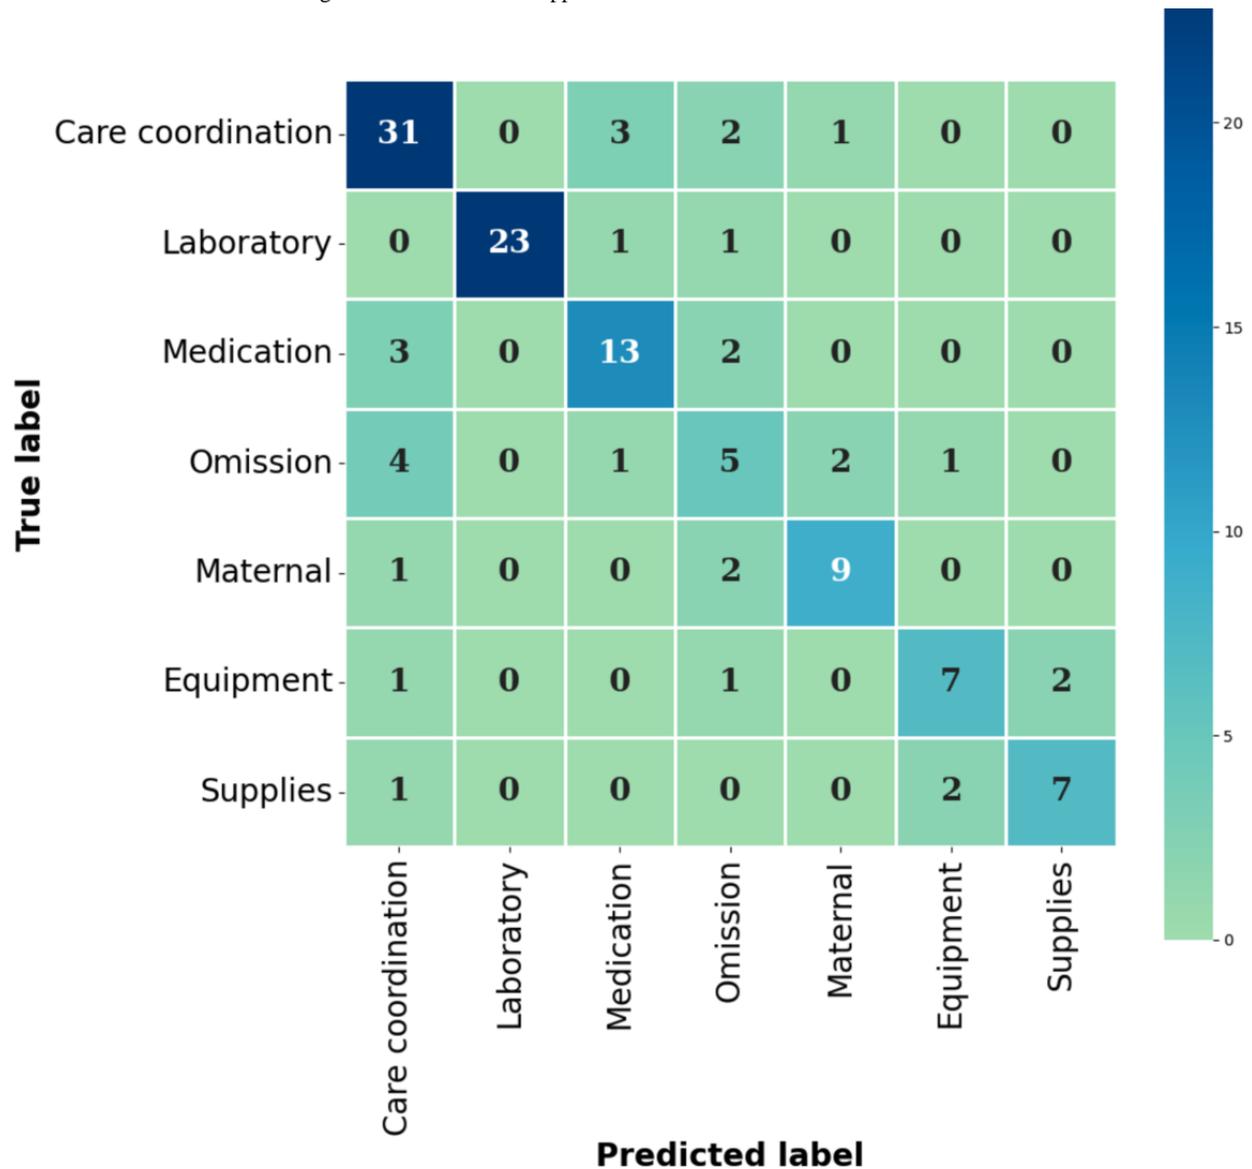

Table 3. Performance of support vector machine+RoBERTa-base on the individual event type.

Event type	Precision	Recall	F_1 -score
Care coordination or communication	0.721	0.838	0.775
Laboratory test	1.000	0.920	0.958
Medication related	0.765	0.722	0.743
Omission or errors in assessment, diagnosis, and monitoring	0.417	0.385	0.400
Maternal	0.750	0.750	0.750
Equipment or devices	0.700	0.636	0.667
Supplies	0.778	0.700	0.737

Figure 1 shows the confusion matrix for the SVM classifier trained with RoBERTa-base evaluated on the test set. A confusion matrix is a table that visualizes the performance of a classifier. The main diagonal value is the number of PSE reports that have been classified as true event types, whereas off-diagonal values are the number of PSE reports that have

been wrongly classified. While the classifier was able to classify the majority of event types of PSE reports correctly, there is a consistent misclassification of the omission or errors in assessment, diagnosis, or monitoring PSE report as the care coordination or communication (coordination) event type.

Figure 1. Confusion matrix for the testing set evaluation with a support vector machine classifier trained with RoBERTa-base.

LIME-Based Explainability Analysis

We used LIME to evaluate whether the SVM classifier trained with RoBERTa-base has leveraged informative words for classification. Figure 2 presents 3 examples of explanations for the classifier’s predictions. At the top of Figure 2, LIME identified “ketorolac,” “ibuprofen,” and “doses” from the PSE report as important words for classifying the report into the medication-related event type, which is reasonable given the report’s association with incorrect medication doses. Conversely, in the middle of Figure 2, LIME highlighted “our,” “handle,” and “or” from the text as important words for classifying the report into the equipment or device event type. Although the

predicted event type was correct, the classifier relied on irrelevant words for the classification. At the bottom of Figure 2, a case of misclassification is shown. LIME highlighted “pitocin,” “pump,” “available,” and “use” as influential words for classifying the PSE report into medication-related event type when it belongs to the equipment class. In addition, for each event type, we extract the 5 most prevalent words that were deemed important for the classifier’s prediction across the whole data set (Table 4). This inclusion of stop words (ie, “was,” “not,” and “till”) among influential terms, as shown in Table 4, demonstrated that the classifier does not always rely on relevant words for making classifications.

Figure 2. Local interpretable model-agnostic explanations of support vector machine classifiers trained with RoBERTa-base. MD: medical doctor; PSE: patient safety event; pt: patient.

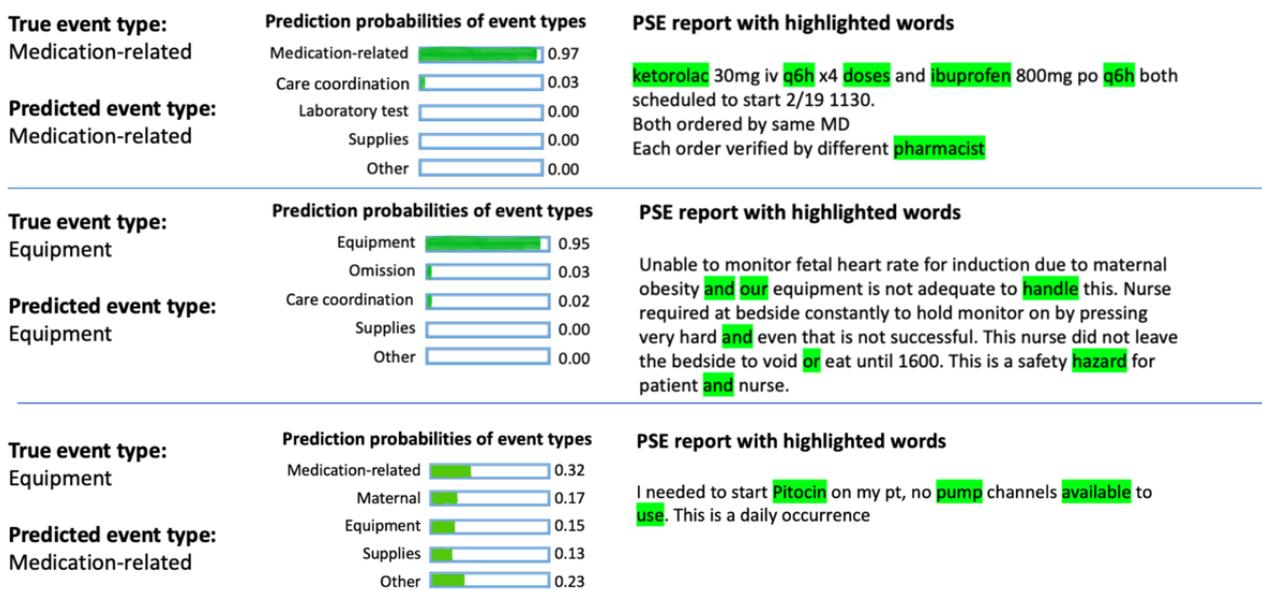

Table 4. The 5 most prevalent and important words for each event type were derived from the support vector machine classifier trained with RoBERTa-base.

Event type	Prevalent influential words highlighted by local interpretable model-agnostic explanations
Care coordination or communication	requested, delayed, patient, not, follow
Laboratory test	specimen, lab, labels, collection, results
Medication related	patches, doses, orders, medication, pitocin
Omission or errors in assessment, diagnosis, and monitoring	warning, patient, was, till, late
Maternal	baby, hysterectomy, stable, pumping, hemorrhage
Equipment or devices	instruments, trays, notified, malfunctioning, faulty
Supplies	vendor, sterile, available, needed, OR

After reviewing the LIME explanations for each PSE report in the test data set, 73.8% (93/126) of the reports were categorized into a subset where at least 1 highlighted word was deemed relevant to the predicted event type. The remaining reports comprised a second subset where no highlighted words were relevant. The interrater reliability index measured by Cohen κ

between the 2 reviewers was 0.83, indicating substantial agreement. Table 5 presents the performance of the top-performing ML classifier for both subsets. For the first subset, the classifier achieved an accuracy of 84% (78/93) and an F_1 -score of 0.825. In contrast, the second subset showed a classifier accuracy of 52% (17/33) and an F_1 -score of 0.549.

Table 5. Performance of a top-performing machine learning classifier on reports that have relevant words highlighted and reports with irrelevant words highlighted.

Metric	PSE ^a reports with relevant words highlighted	PSE reports with irrelevant words highlighted
Number of PSE reports, n	93	33
Percentage of test data set (%)	73.81	26.19
Accuracy (%)	83.87	51.51
F_1 -score	0.825	0.549

^aPSE: patient safety event.

PSE Reporting System Interface

We designed an event reporting interface that integrates both the ML classifier and the LIME explainability technique. Figure 3 shows the event classification screen, where reporters enter a narrative description of the event after providing the details

of the event, including date, time, unit, and information about the patient and reporter. Before describing the event in narrative form, reporters also choose among factors that contributed to the incident and the level of harm experienced by the patient. Once the reporter enters their narrative and selects the “classify” button, the system activates the ML classifier. Subsequently,

the interface displays the top 2 most probable event types, along with their associated probability distributions, in the lower left section. Simultaneously, the LIME technique will identify influential words that significantly contributed to the predicted event type, highlighting these words in green in the upper section of the dashboard. Based on the predicted event types and words

highlighted for their influence on the prediction, the reporter may select the most suitable event type from a drop-down menu located in the lower-right section of the dashboard. Following this selection, reporters are queried on whether they agree with the classifier's prediction, and the collected data can be used to guide subsequent refinement of the ML classifier.

Figure 3. Interface visualization of a patient safety event report classifier coupled with the local interpretable model-agnostic explanations technique. MD: medical doctor.

Patient safety event description:
Please specify the details of what happened and how it may have happened.

ketorolac 30mg iv q6h x4 doses and ibuprofen 800mg po q6h both scheduled to start 2/19 1130.
Both ordered by same MD
Each order verified by different pharmacist

Discussion

Overview

PSE event reporting systems are commonly used in health systems and hospitals across the world [46]. Data collected in PSE reporting systems drive quality improvement and patient safety efforts and supports regulatory reporting requirements for hospitals. The erroneous classification of PSE reports can impede the learning capabilities of the PSE reporting system, leading to suboptimal performance in detecting and preventing potential patient safety hazards [20]. It can also result in a substantial time cost for reclassifying PSE reports and compromise the integrity of a PSE database when analysts are investigating trends in events to develop effective solutions [17]. Previous studies have trained ML classifiers with static text representations for automatic PSE classification [12,17,25,26]. This study aimed to investigate whether using contextual text representations can further improve the accuracy of classifying PSE reports. We trained and evaluated a range of ML classifiers using both static and contextual text representations. To the best of our knowledge, this is the first time that contextual text representation has been used for training ML classifiers for PSE report classification. We analyzed the confusion matrix of the top-performing classifier to identify prevalent misclassified event types. Furthermore, aiming for more accurate and reliable PSE report classification, we incorporated an explainability technique to support human-AI collaboration and designed an interface to illustrate

the possible integration of the ML classifier in PSE reporting systems.

Principal Findings

In this study, we extensively investigated the potential of using contextual representation for improving PSE report classification. The leading classifier trained with the static text representation (MLR trained with TF-IDF) was able to achieve an accuracy of 66.7% (84/126). This accuracy considerably exceeds the baseline accuracy of 29.4% (37/126), which involves classifying all PSE reports into the majority event type. However, using contextual text representation proved more efficacious. The SVM trained with contextual text representation (RoBERTa-base) was able to achieve an accuracy of 75.4% (95/126), reflecting a 13% (11/84) relative improvement in accuracy compared to the best-performing classifier trained with static text representation. While the achieved accuracy of 75.4% may not appear outstanding in isolation, it represents a significant advance compared with static text representations and exceeds the baseline, given the limited size of the data set. The improvement in classifier performance can be attributed to the use of contextual text representations, which can capture not only the meaning of individual words but also the complex and subtle ways in which words interact with each other in a specific context. Therefore, contextual text representation overcomes some limitations of static text representation, which relies primarily on word frequency and co-occurrence to represent text. Moreover, contextual text representation does not require explicit text normalization while also avoiding issues associated with high-dimensionality and sparsity commonly found in static

text representations. Hence, when training ML classifiers for PSE reporting systems, contextual text representation should be prioritized over static text representation to ensure the highest level of accuracy in classifying PSE reports.

As part of our investigation, we evaluated the performance of the top-performing classifier trained with contextual text representation on individual event types. While the classifier demonstrated impressive performance in accurately classifying laboratory test PSE reports (F_1 -score=0.958), it struggled with classifying omissions or errors in assessment, diagnosis, and monitoring PSE reports, resulting in an unsatisfactory F_1 -score of 0.400. To investigate this discrepancy, we analyzed the confusion matrix for the classifier and discovered that omissions or errors in assessment, diagnosis, and monitoring PSE reports were frequently misclassified as the coordination event type. This misclassification can be attributed to the multiclass nature of PSE reports. For example, a failure to document the removal of a patient's epidural catheter (omission or errors in assessment, diagnosis, and monitoring) could lead to a medication ordered by a physician (such as Lovenox) being withheld by the pharmacy due to a complication risk (coordination). On the other hand, the laboratory test is a more distinct event type in comparison to the other event types, and the classifier was able to correctly classify the majority of these reports. The observation obtained from the confusion matrix implies that PSE reports can potentially have more than 1 event type. This finding is consistent with previous studies [25,26]. The finding also underscores the need for further refinement in the development of the PSE taxonomy to create more distinctive event types. Another potential solution for addressing the multiclass nature of PSEs is to enable multiple event-type assignments [47]. Alternatively, the ML classifier can provide several probable event types, allowing the user to select the most appropriate one. We evaluated the top 2 accuracy of the top-performing ML classifier trained with contextual text representation and observed that 39% (12/31) of misclassified PSE reports' true event type was predicted as the second-highest probability event type by the classifier. The finding suggests that there is a greater chance for the ML classifier to provide the correct event type when considering multiple options. As event reporting systems usually encompass over 20 event types, which can be difficult to memorize or access [17], narrowing down the PSE report's potential event types to a smaller range also reduces the cognitive workload for PSE reporters during the classification process [48] and enhances the efficiency of reclassifying PSE reports for patient safety analysts.

We used LIME to showcase 3 predictions' explanations and demonstrated cases where the ML classifier used informative words for classifying the PSE report and where it used irrelevant words for classification. These results highlight the importance of not solely relying on the ML classifier's prediction and underscore the need for explainability and transparency in using the ML classifier for PSE report classification. Additionally, we showed the top 5 most prevalent words the ML classifier deemed important in the PSE reports for each event type. These words are indicative of the prevalent themes and issues within specific event types. Understanding the context and relationships between these prevalent informative words and specific event

types can potentially provide valuable insights into the factors contributing to different types of PSEs. Furthermore, we have evaluated the top-performing ML classifier's performance on 2 subsets of PSE reports, differentiated by whether the highlighted word by LIME is relevant to the predicted event type. Our findings reveal that the majority of PSE reports (93/126) have at least 1 relevant word highlighted, with the classifier achieving an accuracy of 84% (78/93) on these reports. Conversely, accuracy drops to 52% (17/33) when irrelevant words are highlighted. Such a disparity in performance emphasizes the necessity for additional scrutiny from reporters and patient safety analysts, particularly when dealing with PSE reports that have irrelevant words highlighted.

While previous research has focused on the development of ML classifiers, none of these previous works have investigated the potential integration of the classifier within the PSE reporting system in a manner that aligns with the workflow of the front-end reporter. We designed an interface to demonstrate the feasibility of a collaborative human-AI approach for event categorization. The interface provides the PSE reporter with multiple probable event types and associated explanations for the ML classifier's prediction. This approach aligns with the principles of level 2 automation, where ML classifiers aids human decision-making rather than fully automating it [49]. This collaboration optimally combines human expertise with ML capabilities, potentially reducing cognitive workload and memorization of the taxonomy while also reducing the risks associated with overreliance on automation. Numerous studies have shown that the human-AI collaboration approach can improve the decision-making process [50-52], indicating its potential for enhancing PSE report classification. Furthermore, the interface also integrates the LIME explainability technique, which offers real-time insights into the rationale for the probable event types. Given the role of reporters and patient safety analysts in the incident reporting process, the use of explainability techniques can also increase trust in the recommendation provided by the ML classifier as it provides transparent and interpretable reasoning for the classification decisions [50,51]. Using LIME to highlight top informative words in real time for a PSE report can assist PSE reporters by emphasizing keywords in their narratives that are linked to the proposed classification. Highlighting informative words can also facilitate patient safety analysts working at the back end by providing insights into why a specific event type was chosen for classification. Such transparency not only clarifies current recommendations but also guides analysts in identifying influential terms for future report classifications. Previous research has illustrated the value of automation transparency in supporting appropriate levels of trust in the system, including decision support systems [32]. Additionally, regularly checking the explanations of the ML classifier's prediction enables continuous monitoring of the classifier's performance, identification of issues, and refinement [52]. As we have only designed the interface, additional research is needed to test the effectiveness of this approach in PSE report classification. Assessing the interface's impact on cognitive workload and decision-making accuracy is essential for ensuring its usability and adoption in the event reporting system. We plan to undertake

a usability testing study with health care professionals in a subsequent study.

Comparison With Previous Work

Research into the use of ML classifiers for the automation of PSE report classification has been relatively scarce. Wang et al [26] used logistic regression and SVM with the binary count, term frequency, and TF-IDF text representation to classify ten types of PSE reports, reaching an F_1 -score as high as 0.783. However, they used a considerably larger data set ($n=2860$). Fong et al [17] achieved an accuracy rate of 92.0% (284/309) when they examined the usage of an ML classifier for classifying miscellaneous PSE reports using SVM, RF, and logistic regression with TF-IDF [17]. They also used a much larger data set ($n=70,051$). Ong et al [12] investigated the feasibility of using an ML classifier to automatically classify 2 types of PSE reports, including inadequate clinical handover and incorrect patient identification. They used Bag of Words model for text representation and trained both SVM and naive Bayes on classifying PSE reports, reaching accuracy as high as 98% (364/372). However, they framed the problem as a binary classification problem, which inherently has a higher baseline accuracy compared to our investigation. In this study, we've performed an in-depth comparative analysis with the available PSE data set and compared the established methods of classifying PSE reports and our novel method of using contextual text representations for classification. Our findings reveal that our proposed method outperforms the traditional models in terms of accuracy (ie, 84/126, 66.7% vs 95/126, 75.4%) and F_1 -score (ie, 0.631 vs 0.753). This underlines the significance of our approach and its potential to advance the field of using ML classifiers for PSE report classification.

Limitations

There are several limitations to this study. First, the PSE reports used to train the ML classifiers were obtained from the maternal care units of a single hospital in the United States; therefore, the classifier might not generalize well to other settings. Second, this research's scope was constrained by the limited amount of PSE report data, and only 7 prevalent classes were incorporated for training the ML classifiers. The restricted quantity of PSE

reports might also result in an underestimation of the ML classifier's actual capabilities [12]. Third, the quality of the LIME explanations was assessed by 2 graduate students; thus, further investigation is needed for a more robust validation of explanation quality. Furthermore, we have not yet empirically tested the interface for potential decision-making biases it may introduce.

Future research should investigate the performance of ML classifiers trained with contextual text representations on a larger and more diverse data set. Additionally, while we plan to refine the interface and test whether it supports event classification, future research can continue to investigate the appropriate way of incorporating the ML classifier into the reporting and reviewing workflow of PSE report classification and examine various human-AI collaboration approaches. Future studies should explore the potential biases (ie, automation bias) that the interface may introduce into the analysts' decision-making process.

Conclusions

Improving the precision of PSE report classifications is a multifaceted task, involving both the refinement of the event type taxonomy and adequate training of hospital staff on the event reporting system. Despite these challenges, ML classifiers offer substantial potential to support accurate classification throughout the reporting and reviewing process. The findings of this study contribute to the advancement of ML classifiers for PSE report classification by demonstrating the superior performance of contextual text representation over static text representations in achieving more accurate classification outcomes. The integration of explainability techniques in ML classifiers fosters trust in their usage and provides valuable insights for informed decision-making and potential adjustments to the classifier. An event reporting interface that integrates an ML classifier with collaborative decision-making capabilities offers the potential to achieve an efficient and reliable PSE report classification process. These approaches can ultimately help hospitals identify risks and hazards promptly and take timely and informed actions to mitigate adverse events and reduce patient harm.

Abstract

Background: The HIV epidemic continues to grow fastest among men who have sex with men (MSM) in Malaysia in the presence of stigma and discrimination. Engaging MSM on the internet using chatbots supported through artificial intelligence (AI) can potentially help HIV prevention efforts. We previously identified the benefits, limitations, and preferred features of HIV prevention AI chatbots and developed an AI chatbot prototype that is now tested for feasibility and acceptability.

Objective: This study aims to test the feasibility and acceptability of an AI chatbot in promoting the uptake of HIV testing and pre-exposure prophylaxis (PrEP) in MSM.

Methods: We conducted beta testing with 14 MSM from February to April 2022 using Zoom (Zoom Video Communications, Inc). Beta testing involved 3 steps: a 45-minute human-chatbot interaction using the think-aloud method, a 35-minute semistructured interview, and a 10-minute web-based survey. The first 2 steps were recorded, transcribed verbatim, and analyzed using the Unified Theory of Acceptance and Use of Technology. Emerging themes from the qualitative data were mapped on the 4 domains of the Unified Theory of Acceptance and Use of Technology: performance expectancy, effort expectancy, facilitating conditions, and social influence.

Results: Most participants (13/14, 93%) perceived the chatbot to be useful because it provided comprehensive information on HIV testing and PrEP (*performance expectancy*). All participants indicated that the chatbot was easy to use because of its simple, straightforward design and quick, friendly responses (*effort expectancy*). Moreover, 93% (13/14) of the participants rated the overall chatbot quality as high, and all participants perceived the chatbot as a helpful tool and would refer it to others. Approximately 79% (11/14) of the participants agreed they would continue using the chatbot. They suggested adding a local language (ie, Bahasa Malaysia) to customize the chatbot to the Malaysian context (*facilitating condition*) and suggested that the chatbot should also incorporate more information on mental health, HIV risk assessment, and consequences of HIV. In terms of *social influence*, all

participants perceived the chatbot as helpful in avoiding stigma-inducing interactions and thus could increase the frequency of HIV testing and PrEP uptake among MSM.

Conclusions: The current AI chatbot is feasible and acceptable to promote the uptake of HIV testing and PrEP. To ensure the successful implementation and dissemination of AI chatbots in Malaysia, they should be customized to communicate in Bahasa Malaysia and upgraded to provide other HIV-related information to improve usability, such as mental health support, risk assessment for sexually transmitted infections, AIDS treatment, and the consequences of contracting HIV.

Introduction

Background

HIV continues to be a global health concern causing approximately 630,000 deaths yearly worldwide [1]. In 2019, approximately 62% of the new HIV infections among adults worldwide occurred within key populations and their sexual partners [2]. Men who have sex with men (MSM) accounted for 23% of new infections of HIV, which was much higher than the percentage of new infections in other key populations, such as people who used drugs (10%), sex workers (8%), and transgender people (2%) in 2019 [3]. Malaysia is a Southeast Asian country with a population of 33.5 million, with 1 in 5 MSM living with HIV [4]. Over the past 2 decades, the mode of HIV transmission in Malaysia has shifted from needle sharing to sexual transmission, particularly among MSM [5].

HIV testing is a prerequisite to effective HIV prevention and early treatment initiation [6]; people at risk for HIV or seropositive individuals need to be tested for HIV before being linked to health care services [7]. Despite the importance of HIV testing, it is disproportionately lower among MSM in Malaysia [8]. New HIV testing guidelines recommend that MSM at high risk for HIV should be tested every 3 to 6 months, but most MSM in Malaysia do not test optimally. Studies in Malaysia have found that only 9.5% of MSM tested more than once a year. In Malaysia, engaging in same-sex sexual behavior is prohibited by both secular and Sharia laws, leading to significant levels of stigma and discrimination within society [9]. As a result, many MSM may be hesitant or unwilling to engage with health care providers and outreach workers. Therefore, designing new strategies to promote HIV testing among MSM in Malaysia is urgently needed [10].

Using portable electronic devices with software programs to deliver health care services and manage patient information is known as mobile health (mHealth) [11]. mHealth interventions could reduce barriers to HIV testing for MSM by reducing in-person contact and offering internet-based platforms for HIV testing [12,13]. Studies have demonstrated that mHealth interventions using smartphones and apps could increase the uptake of HIV testing while protecting the privacy of MSM [14-16], and MSM in Malaysia have a high acceptance of the use of mHealth for HIV testing and prevention [13,17,18]. Recent breakthroughs in artificial intelligence (AI) and machine learning can potentially automate and scale up these mHealth

interventions through chatbots, a computer program that can mimic human conversation [19]. However, leveraging chatbot technology to promote HIV testing and prevention is in its infancy [15,20]. Although chatbot technology holds immense potential to prevent HIV, a lack of research in this field undermines its significance. The creation of ChatGPT has brought attention to the significance of studying chatbot technology for health care.

Our team has conducted formative research to understand HIV prevention chatbots in Malaysia and has identified the perceived benefits, limitations, and preferred features of AI chatbots for HIV testing and prevention among MSM [13]. On the basis of the study findings, we developed an HIV prevention AI chatbot prototype named Haris (a common Malaysian name) and a website called MYHIV365 (*MY* symbolizes Malaysia, *HIV* implies health care services aimed at preventing HIV, and *365* indicates the services are available every day of the year). Haris was hosted on MYHIV365 and could provide information on the 3 themes most needed by MSM: HIV testing, mental health, and pre-exposure prophylaxis (PrEP). PrEP is a highly effective HIV prevention method that involves the use of antiretroviral medication by at-risk individuals to prevent getting HIV from sex or injection drug use. Haris imitates human intelligence and can interact with users to provide support, including ordering free HIV self-testing kits, screening for depression, and recommending MSM-friendly clinics where individuals can get tested for HIV and receive PrEP.

Objectives

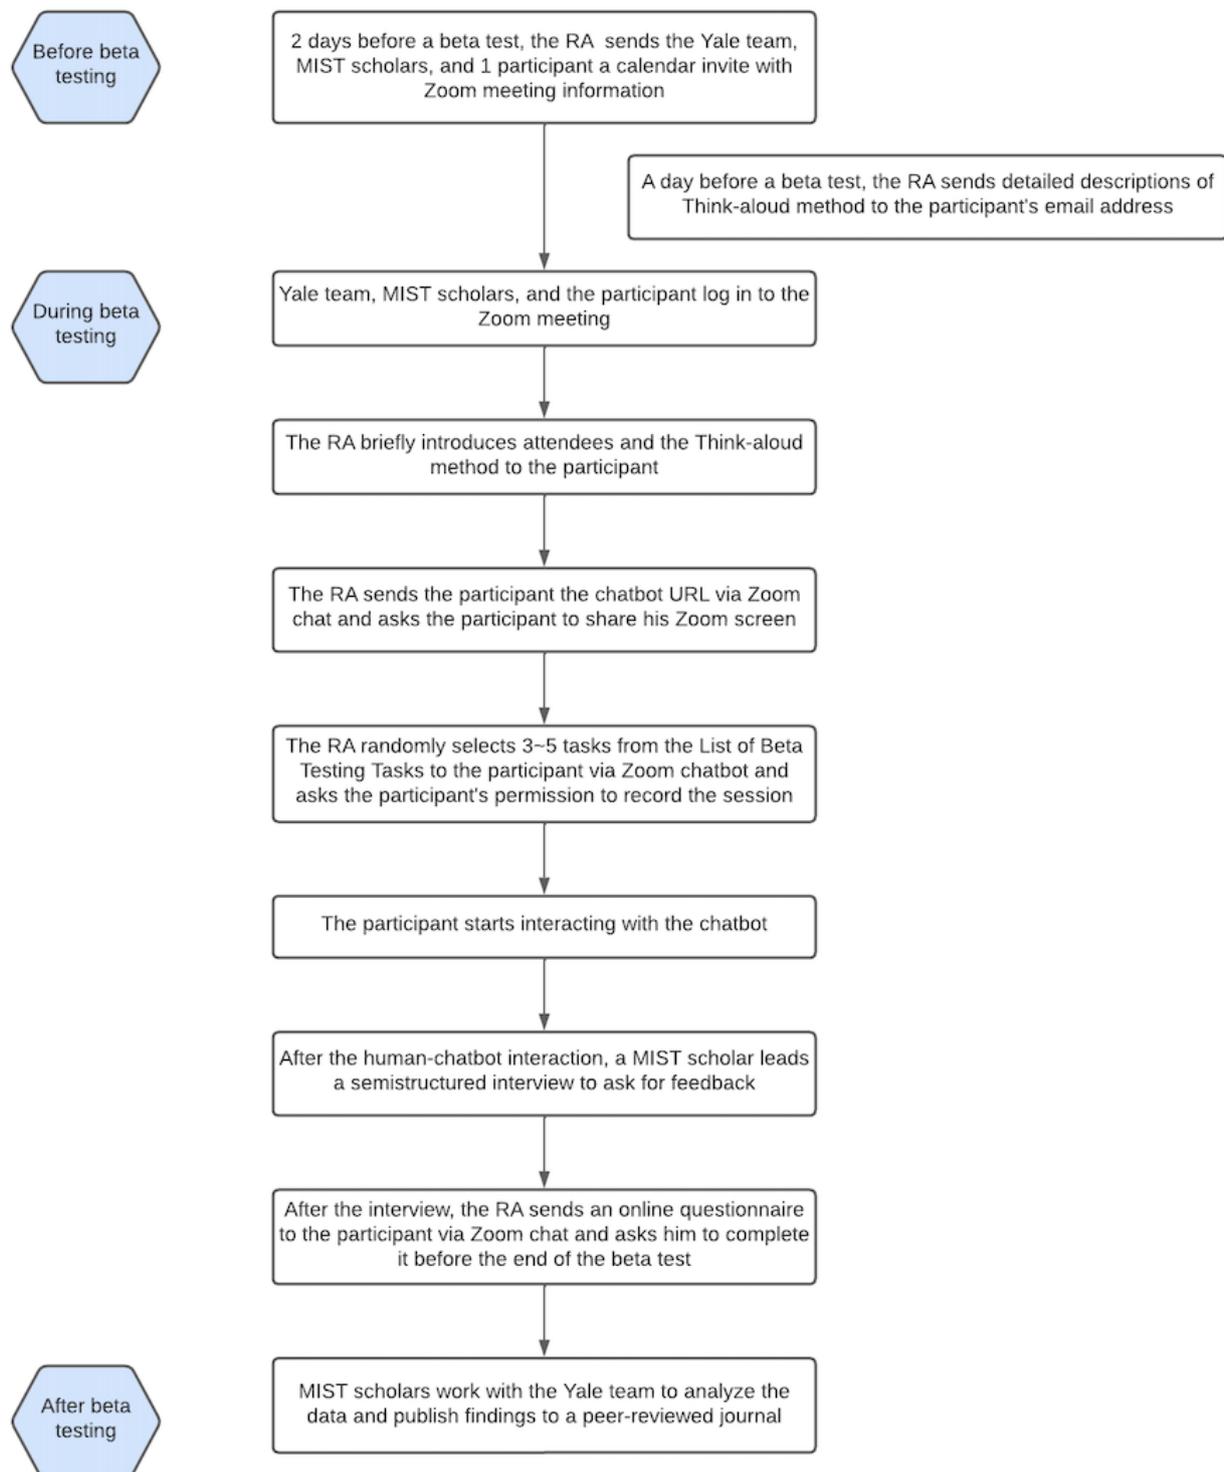

Despite the meticulous design and alpha testing (internal testing) of Haris among professors, experts, and community advisory board members, its feasibility and acceptability in preventing HIV among MSM is still unknown. Therefore, we conducted beta testing (testing in a real-world environment by actual users) of Haris among 14 MSM in Malaysia to address this knowledge gap. Specifically, we examined the use of the AI chatbot for delivering health information and improving linkage to HIV testing, PrEP, and care. We also investigated key strategies to refine the feasibility and acceptability of the AI chatbot in this study.

Methods

Study Design and Participants

Beta testing of the AI chatbot prototype was conducted with 14 MSM by an experienced qualitative interviewer (ZN) with expertise in chatbot development and HIV prevention in Malaysia and 4 trainees in the Malaysian Implementation Science Training program (Fogarty International Center, D43TW011324). Participants were recruited in Malaysia from February to April 2022 via social networking apps commonly used by MSM, including Grindr, Hornet, Blued, and WhatsApp. The procedures for participant recruitment have been published elsewhere [13]. A web-based screener including questions on demographic characteristics and HIV prevention practices was used. The eligibility criteria included (1) self-identification as a cisgender man, (2) age ≥ 18 years, (3) condomless sex with another man in the past 6 months, and (4) being HIV negative or of unknown status.

Each beta test involved the following three steps: (1) a 45-minute human-chatbot interaction using the think-aloud method [21]; (2) a 35-minute semistructured interview; and (3) a 10-minute web-based survey. The first 2 steps were conducted via Zoom (Zoom Video Communications, Inc), recorded, and transcribed verbatim. Specifically, 2 days before the test, a research assistant sent a calendar invite with Zoom meeting information to the interviewer and participant. One day before beta testing, the research assistant emailed the participant a detailed description of the human-chatbot interaction (Multimedia Appendix 1). During the human-chatbot interaction, participants were asked to share their screen via Zoom and access the chatbot through a URL sent by the research assistant. After the participants obtained access to the chatbot, the research assistant randomly selected 3 to 5 tasks from the list of beta testing tasks (Multimedia Appendix 2) and asked the participants to complete them through the chatbot. Some examples of the tasks include “find a clinic that can provide HIV testing service in Kuala Lumpur” and “find out the common symptoms of depression through the chatbot.” The study procedure is described in Figure 1.

Figure 1. Study procedure. MIST: Malaysian Implementation Science Training; RA: research assistant.

After the human-chatbot interaction, we conducted a semistructured interview (Multimedia Appendix 3 [22]) soliciting participants' feedback on two themes: (1) experience navigating the chatbot and (2) how the chatbot should be made available to a wider audience. During the interview, participants were asked several questions regarding their experience with the chatbot, such as "How was your experience with the AI chatbot?", "What feature of the AI chatbot do you like the most?", and "What information needs to be added to the AI

chatbot to increase its popularity among MSM?" After the interviews concluded, the participants were provided with a survey link to assess the feasibility and acceptability of the AI chatbot. The feasibility of the chatbot was measured through 4 outcomes, including participants' ratings of the chatbot's quality, satisfaction, intention to continue using the chatbot, and willingness to refer it to others. The outcomes were measured using a 10-point rating scale, with higher scores indicating more favorable outcomes (Multimedia Appendix 4). For example,

participants' satisfaction with the chatbot was measured by using the question, "How satisfied were you with the experience of interacting with the chatbot?" The score of "0" stands for not satisfactory at all and "10" stands for extremely satisfactory. The acceptability of the chatbot was measured using the standardized System Usability Scale [23] and an adjusted Chatbot Usability Scale [24]. The combination of the 2 scales provided a comprehensive evaluation of the acceptability of our chatbot.

Ethical Considerations

The participants provided electronic consent before initiating the beta testing. This study was approved by the institutional review board of Yale University (approval #2000027864) and Medical Research Ethics Committee of the University of Malaya (approval #2021112-10729). This research was conducted in accordance with the ethical standards of the 1964 Helsinki Declaration and its later amendments or comparable ethical standards.

Conceptual Framework for Analysis

The Unified Theory of Acceptance and Use of Technology (UTAUT) was used as a conceptual framework to guide the analysis of the experience of MSM using the AI chatbot for HIV testing and prevention in Malaysia. UTAUT consists of four domains: (1) performance expectancy, (2) effort expectancy, (3) facilitating conditions, and (4) social influence [25]. The definitions of these 4 domains have been published elsewhere [13]. UTAUT was chosen for the following reasons. First, this AI chatbot was developed based on the findings from a formative research project that was analyzed using UTAUT [13]. Therefore, using the same theory, we can compare the results of the 2 studies on the 4 domains and are more likely to find out the feasibility and acceptability of the AI chatbot.

Second, UTAUT emphasizes user-centered perspective, which allows researchers to assess the acceptance of the AI chatbot from the users' perception. Third, UTAUT has been extensively used to identify users' acceptance of technology and was reported to be effective and of high validity [26,27].

Analyses

All transcripts were cross-checked for accuracy and completeness by 7 researchers (MHC, YNG, NAMS, KSN, ZN, and 2 research assistants). Each of the 7 researchers independently coded 2 transcripts using NVivo 10 software (QSR International), compiled codes, and mapped the emerging themes from the qualitative data on the 4 domains of UTAUT, including performance expectancy, effort expectancy, facilitating conditions, and social influence. Discrepancies in codes and themes were addressed in group discussions where there was discordance in coding. We ceased the qualitative analysis when the results reached saturation, and no new themes emerged. The participants' quotes are presented throughout the results with additional quotes given in [Multimedia Appendix 5](#). Quantitative data from the survey were analyzed using SAS (version 9.4; SAS Institute) and are presented as descriptive statistics.

Results

Participant Characteristics

The 14 participants were on average in their mid-20s (mean 25.6, SD 4.2 years), and most of them (13/14, 93%) used smartphones as the primary means to access the internet. Most participants (10/14, 71%) were Malay, followed by Chinese (3/14, 21%) and Indian (1/14, 7%). About one-third of the participants (5/14, 36%) had taken PrEP previously, and only 14% (2/14) of them were currently taking PrEP. The demographic characteristics are summarized in [Table 1](#).

Table 1. Participant demographic details (N=14).

Characteristics	Values
Age (y), mean (SD)	25.6 (4.2)
Ethnicity, n (%)	
Malay	10 (71)
Chinese	3 (21)
Indian	1 (7)
Sexual orientation, n (%)	
Bisexual	3 (21)
Gay	11 (79)
Employment status, n (%)	
Student	6 (43)
Working full time	8 (57)
Highest level of education, n (%)	
Diploma or bachelor degree	8 (57)
Master degree or PhD	3 (21)
Secondary school	3 (21)
Average monthly income (MYR^a; 1 MYR=US \$0.21), n (%)	
<2000	6 (43)
2000-4000	5 (36)
>4000	3 (21)
Daily access to the internet, n (%)	
Yes	14 (100)
Primary device for accessing the internet, n (%)	
Smartphone	13 (93)
Laptop computer	1 (7)
Had ever taken PrEP^b, n (%)	
Yes	5 (36)
No	9 (64)
Currently taking PrEP, n (%)	
Yes	2 (14)
No	12 (86)

^aMYR: Malaysian Ringgit.

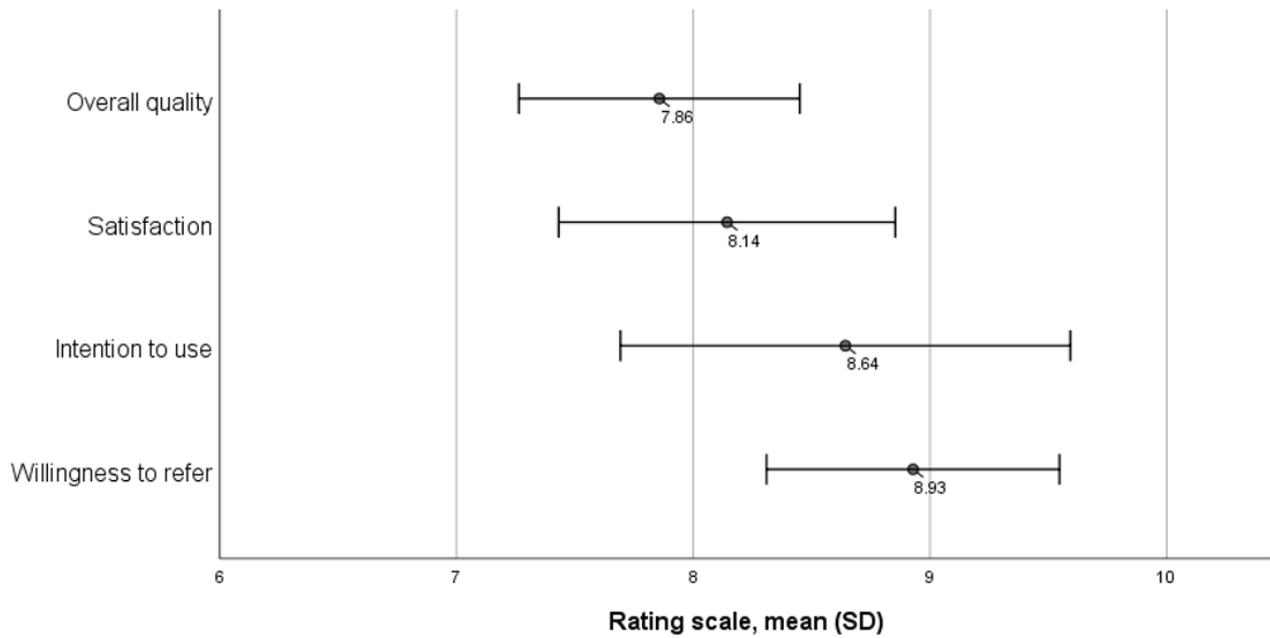

^bPrEP: pre-exposure prophylaxis.

Feasibility

The mean scores on the 4 metrics of the feasibility of the chatbot, overall quality, satisfaction, intention to continue using,

and willingness to refer to others were 7.86 (SD 1.03), 8.14 (SD 1.23), 8.64 (SD 1.65), and 8.93 (SD 1.07), respectively, on a scale from 0 to 10 ([Figure 2](#)).

Figure 2. Feasibility ratings of the chatbot.

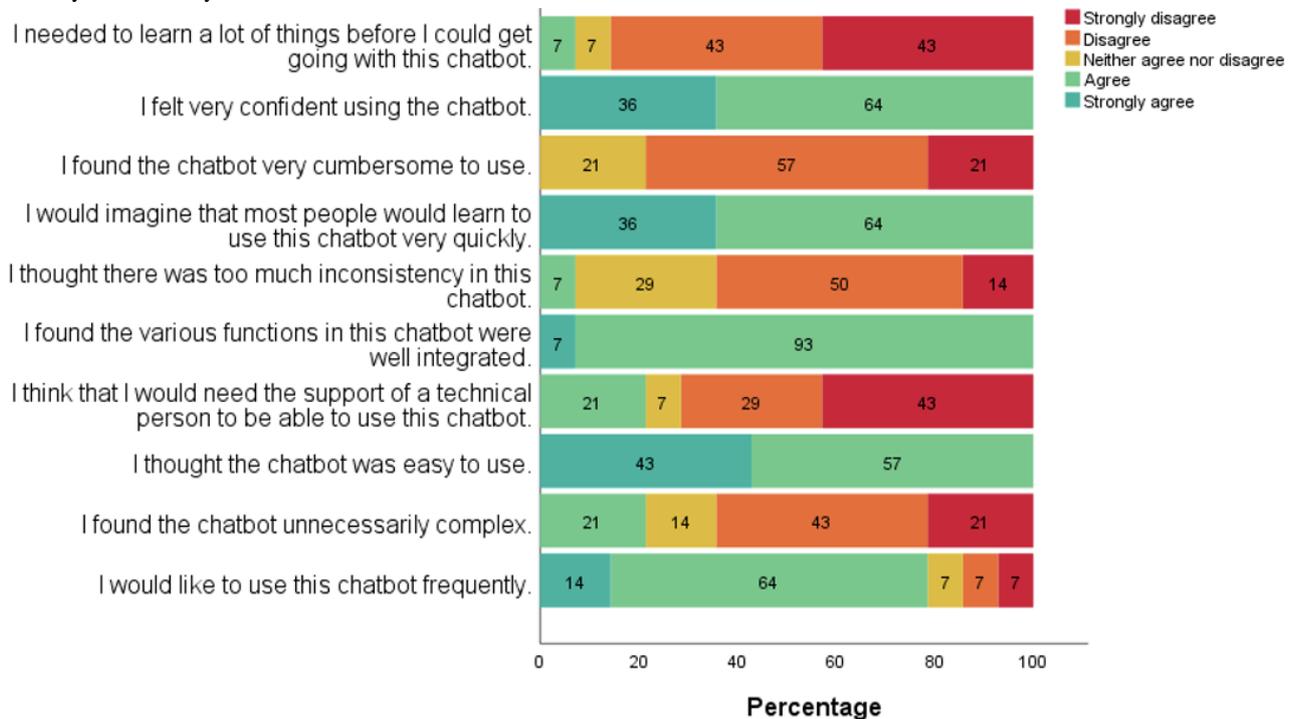

Acceptability

The participants found the chatbot acceptable, as it was perceived as easy to navigate and capable of providing valuable information (Multimedia Appendix 6). Specifically, all

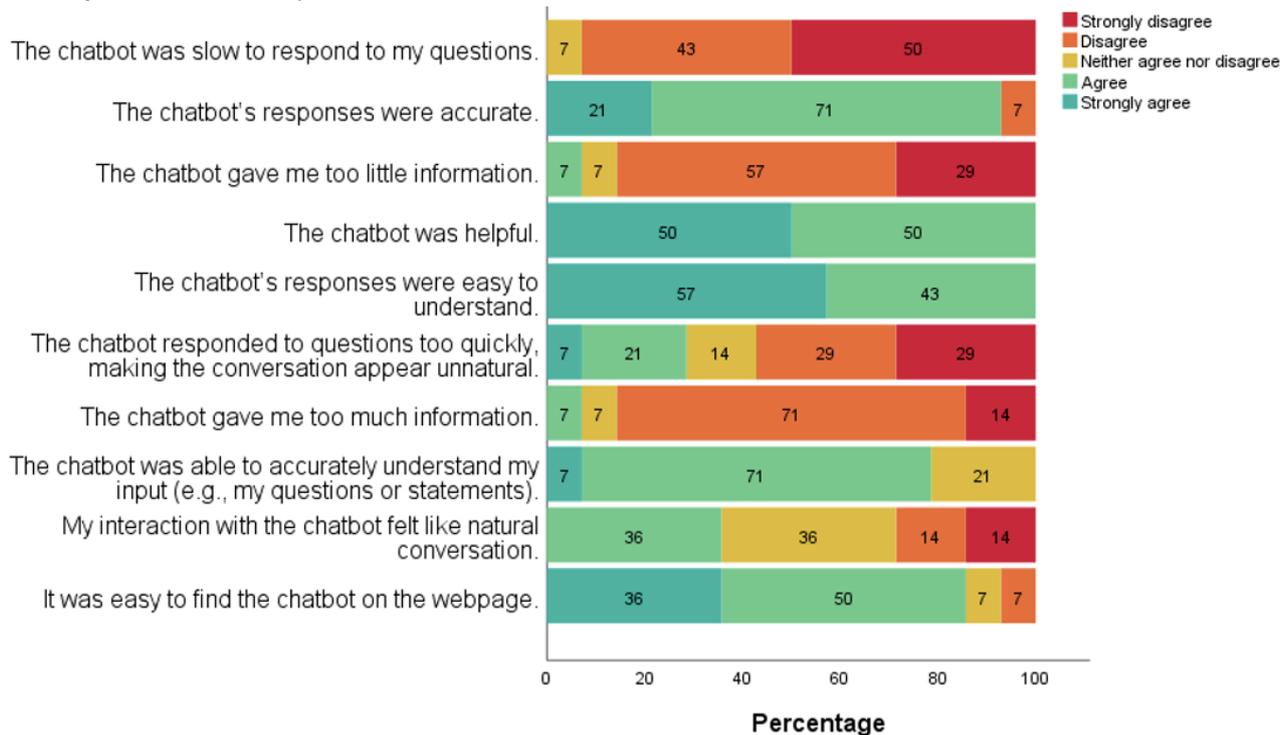

participants (14/14, 100%) expressed confidence in using the chatbot, believing that others could also quickly master its use (Figure 3). The overall mean (SD) score of the System Usability Scale was 76.07 (SD 8.19), which is greater than the recommended acceptable cutoff score of 68 [23].

Figure 3. System Usability Scale outcomes.

Moreover, 78% (11/14) of the participants agreed that the chatbot could understand their inputs accurately (Figure 4).

However, only 36% (5/14) of the participants agreed that their interaction with the chatbot felt like a natural conversation.

Figure 4. Adjusted Chatbot Usability Scale outcomes.

In addition to measuring feasibility and acceptability, we summarized the study findings based on the 4 domains of UTAUT: performance expectancy, effort expectancy, facilitating conditions, and social influence.

Performance Expectancy

Overall Perception

Participants responded positively about the performance of the AI chatbot. Quantitative data analysis revealed that all participants (14/14, 100%) perceived the chatbot as a helpful tool, they would refer it to others, and 93% (13/14) of them highly rated the overall quality of the chatbot. These results were consistent with the qualitative finding that participants were satisfied with the information provided by the chatbot and deemed it a trustable source.

Contributors to Positive Performance Expectancy

The chatbot served as a reliable source of information. Participants expressed their trust in this chatbot as they believed it was developed to help people learn more about HIV. For instance, one participant stated that he trusted the chatbot more than other internet-based platforms as the following:

I can actually trust, trust this chatbot more than I can trust the Internet. [Interview E]

Most participants expressed that the information provided by the chatbot was comprehensive and satisfactory. The same participant highlighted the following:

...everything is there, everything is informative... [Interview E]

Participants described the chatbot's function of ordering free HIV self-test kits as one of the most useful functions. The simple and straightforward instructions from the chatbot significantly

encouraged participants to perform HIV self-testing and helped prevent misuse of the self-test kit. A participant elaborated on the following:

...it never crossed my mind that you can do HIV self-test just using it (test stick) over the gums and without blood... [Interview G]

In addition to the positive feedback on the chatbot's ability to order free HIV self-test kits, participants also expressed appreciation for the information provided by the chatbot on MSM-friendly local clinics where they could test for HIV and receive PrEP consultation. For example, the participant stated the following:

That was beyond amazing...they give [me] the addresses, contact numbers. So, I would say, if a person really needs to do the [HIV] testing, essential information like that would be very useful, so I think it's more than helpful. The options [of HIV testing clinics] are not just [limited to] one or two [clinics], you know, so that's good. [Interview G]

The other participants stressed that the chatbot's features related to HIV self-testing and venue-based HIV testing were complementary and appreciated having access to both options through the chatbot. Although performing self-testing at home may be convenient, it may lack the human interaction that some MSM need for support during the testing process. By offering both self-testing and venue-based testing options, the chatbot gave MSM the flexibility to choose the option that best suited their individual needs and preferences. For example, a participant emphasized that the chatbot could enable his MSM friends to conduct HIV self-testing and then see a health care professional for advice on complex and sensitivity issues:

...the reason why [they] went to a health care facility was [that they] can have someone tell them that you know, "Being tested positive for HIV [was] not the end of the world. To reduce the [HIV] symptoms, to reduce the [HIV] effect, to reduce [their HIV] viral load... [they] can still live a normal life and so on," which might be something that the self-test kits [were] lacking. [Interview C]

Along with the positive feedback on the chatbot's features relevant to HIV testing, the participants also expressed their favorable feelings toward the PrEP information provided by the chatbot. For example, a participant mentioned that the chatbot could send him introductory information to allow him to comfortably assess his risk level and help him decide if he needed to take PrEP. Another participant reiterated the first participant's point by emphasizing the difficulties that MSM in determining if they should take PrEP, stating the following:

A lot of people [MSM] are always asking themselves, "Should I get PrEP? Am I at risk? Do I need to take PrEP as a precautionary measure?"... So these are [questions] that MSM usually a bit too scared to ask the doctors. [Interview C]

Major Concerns

Participants suggested that the chatbot would be improved if it could provide more information and resources relevant to mental health, as mental health issues were the prominent problems that MSM faced in Malaysia. Participants wanted the chatbot to provide information on strategies for managing stress, statistics about depression among MSM, peer consultation for depression, and professional health care services to prevent and treat depression. The participants also highlighted that the MYHIV365 website, where the chatbot was embedded, should provide more resources related to mental health. For example, one participant described this problem as follows:

The website did not have links to any information regarding mental health issues, and that is a glaring issue for it to be left out like that. [Interview A]

The same statement was echoed by another participant, who stressed the following:

I just find that for the mental health, it's kind of short. [Interview G]

Relevant Features Suggested by Participants That Are Needed to Improve the Chatbot

Although the chatbot made it easy for participants to receive an HIV self-test kit, one participant suggested that a step-by-step video demonstrating how to use the kit could be helpful for MSM who were testing for HIV. The participant stated the following:

If the self-test kit has got like an instructional video or something like that to kind of guide the users along the way of getting [themselves] tested, I think that'd be great because not everyone knows how to use a kit successfully. [Interview C]

Although the AI chatbot was developed primarily for HIV prevention and to assist with HIV testing and access to PrEP, the participants pointed out that some participants may test positive for HIV and would benefit from learning more about accessing HIV care and related antiretroviral therapy services. In addition, participants suggested that the chatbot should provide more information about antiretroviral therapy so that users could better manage HIV by knowing potential drug interactions and side effects. The participants also recommended providing more information about high-risk behaviors and sexually transmitted diseases to help increase awareness about HIV and sexually transmitted diseases among MSM. One participant stated the following:

I think [providing more information about] HIV treatment would [be] very helpful because those who might be exposed to HIV would definitely want to know what the treatment is all about. [Interview E]

This participant's statement was echoed by another participant, who stated the following:

...HIV and STDs...[are] not the same, but...I thought [they were] the same...I thought HIV and STDs were not curable...so I think it will be great if you can add STDs [to the chatbot]. [Interview E]

Effort Expectancy

Overall Perception

All surveyed participants (14/14, 100%) agreed that the chatbot was easy to use, and 86% (12/14) of the participants were satisfied with the chatbot. In the qualitative interviews, participants reported consistent feedback that the chatbot was user friendly and convenient to use, and they were satisfied with the chatbot because of its simple, straightforward design and quick, friendly responses. However, they were concerned about the technical issues, including the address input and text alignments (refer to the *Major Concerns* section). The participants also felt that tailoring the chatbot to the local context and adding a "human touch" would be helpful.

Positive Contributors to Low Effort Expectancy

Many participants expressed satisfaction with the chatbot because of its prompt response, expert information, and plain interface. Two participants commented the following:

...white and blue colors [are] neutral, and it [the chatbot] takes into account [of] color blindness as well, so that's great. [Interview C]

...[I] got a quick response [from the chatbot]. [Interview I]

The individualized and user-centered features of the chatbot, which cater to users with different levels of communication skills, were highlighted among the participants. For instance, one participant stated that the chatbot offered an ideal platform for MSM who are less comfortable interacting with others. A participant stated the following:

As we all know, some of us didn't have the skills to communicate, so I think...[the] chatbot... will definitely help. I think it was great. [Interview E]

Moreover, participants thought the chatbot was useful as it facilitated them to obtain culturally tailored health information. The chatbot met users' needs by providing a menu of options for users to choose from. Compared with obtaining health information in clinical settings in Malaysia, the chatbot was much simpler. A participant elaborated on the following:

When [the chatbot] come[s] up with three options like that, I can explore myself...I would say that [the chatbot] is more precise; it gets to the point directly. [Interview G]

The health intervention being tailored to the local setting was highly valued by the participants. Responses from the AI chatbot that contained localized features, specifically the use of "Manglish," a less formal form of Malaysian English, were appreciated by several participants. The feature of "Manglish," which was not in the standardized form of English, has added a local flavor to the AI chatbot, which some participants found amusing. A participant stated the following:

The impression that this chatbot...probably comes from America. It's in English, so the moment it puts up a Malaysian style saying "Boleh"... I'm very amused with this [style]. [Interview G]

Major Concerns

Some participants spoke about the difficulty in filling in their home addresses using the current prompts on the AI chatbot when they needed to order an HIV self-test kit; the chatbot required a step-by-step input of addresses, which was counterintuitive and inefficient. Participants preferred the standard address format in Malaysia over the step-by-step input format, in which incomplete addresses would triage further prompts to ask participants to refill the HIV self-test order. For example, one participant stated the following:

In Malaysia, we don't use the term "line address" or "street address". We usually enter the full address with the postcode and then the city and state. The one on the chatbot seems to be how addresses are filled in the United States. That part needs to be tweaked slightly based on Malaysian cities. [Interview C]

In addition, participants expressed that the address of the clinics provided by the chatbot needed to be tailored to Malaysian culture. For example, the district options may only be needed for certain states in Malaysia. A participant stated the following:

I think depends on the size of the state...we don't have to call out (provide choices for) all the districts because Perlis is already small enough, and I think...people can just go easily from one place to another in Perlis. But if...it is a big state...we need to divide it using district. [Interview I]

Relevant Features Suggested by Participants That Are Needed to Improve the Chatbot

Although participants were satisfied with the AI chatbot, 2 participants suggested that the chatbot's interface could be improved by adding more spaces between sentences, and the alignment of sentences should be adjusted to make the chatbot

look more professional. Two participants described the following:

...everything is tightly together with very little gap...there should be proper spacing... [Interview L]

The text is not properly centered in some of the boxes, and I feel like it could [be] a better design to make it look more professional. [Interview A]

The use of English as the only language of the AI chatbot was perceived by participants as a barrier to implementing the chatbot in Malaysia. Although all participants were proficient in English, concerns arose for the communities where English was not widely spoken. Participants suggested that the chatbot should be able to communicate in Bahasa Malaysia or Mandarin, given that the 2 languages are widely spoken in Malaysia. A participant stated the following:

...perhaps to have another option of language...I think that would be able to cover more people within the local population. [Interview C]

Adding a "human touch" to the chatbot can create a more engaging and user-friendly experience for the users interacting with the chatbot. The participant described the following:

...ideally, we would want [the chatbot's response] to be as human as possible, and not so robotic in its responses...a nice touch to make someone feel slightly comfortable. [Interview C]

Facilitating Conditions

Overall Perception

Participants reported 2 major facilitating conditions for the use of the AI chatbot. First, the social distancing policy adopted by the Malaysian government during the COVID-19 pandemic significantly increased the use of internet-based platforms to seek health information and consult about health issues among MSM. The participants expressed that the AI chatbot was a novel tool to promote HIV testing and prevention among MSM in Malaysia. A participant highlighted the convenience of using the chatbot as an alternative to meeting health care workers during the COVID-19 pandemic as follows:

...because now it's COVID, everyone is doing it in IT (information technology) format. Having an AI chatbot is definitely much more convenient than meeting people... [Interview G]

Second, the AI chatbot's capability of referring webpages to participants where they could find mental health information, community support, and counselors was a significant facilitator for them to accept the chatbot. Many participants stated that it was much easier to obtain information through the links provided by the chatbot than searching for information via websites or mobile apps. A participant stated the following:

When you interact with it (the chatbot), it throws out links to you. It's easier to navigate to the particular links from there. [Interview G]

Relevant Features Suggested by Participants That Are Needed to Improve the Chatbot

Participants suggested that the chatbot could be promoted through social media platforms, such as Facebook, Twitter, Instagram, YouTube, TikTok, and Telegram because these platforms were widely used by MSM as sources of information. Among all social networking apps, participants stated that Twitter was the best platform to advertise the AI chatbot because Twitter enabled users to post clickable links in the comments section where other users could access the chatbot. Participants further reported that Telegram was a more suitable platform for hosting the chatbot than the most popular text messaging app in Malaysia, WhatsApp. Telegram offers a more private and secure environment for MSM to ask questions or express concerns about HIV and AIDS. Participants also suggested that building a trustable relationship between the AI chatbot and the MSM community is key to implementing the AI chatbot in Malaysia. Given that there were many scams through pop-up advertisements on social media platforms, a participant described the following imagined scenario:

...if we play our Facebook, Twitter, Instagram, or YouTube, there are always mini advertisements, so who knows, [whether we] can add this [AI chatbot]?...I need to know about this [chatbot], and I hope this [chatbot] is not a scam. [Interview B]

Social Influence

In terms of *social influence*, the chatbot was perceived as helpful in avoiding HIV stigma and thus could increase the HIV testing rate and PrEP uptake frequency. Quantitative data analysis found that 79% (11/14) of the participants agreed to continue using the chatbot. During the interviews, these participants reported that societal stigma and discrimination related to HIV and AIDS would make them more likely to use the chatbot. They expressed discomfort in asking people questions about HIV and AIDS as they were afraid of encountering stigma and negative attitudes from others. MSM often preferred to seek information through internet-based platforms, and the chatbot was helpful, particularly for people living in small social circles. A participant elaborated on the following:

...this topic [HIV] is quite sensitive to most people, it will create like a negative energy around you...personally I don't go and ask people what HIV is, I will search myself maybe on the Internet... [Interview E]

The societal stigma and discrimination toward HIV and AIDS also facilitated participants to select HIV self-testing at home rather than testing in a clinical setting. Many participants appreciated that the chatbot offered them an opportunity to receive free HIV self-test kits while protecting their privacy. Two participants who used to be shy about discussing HIV described the following:

Because from the MSM community, some of us are not very comfortable of getting [HIV] test kits on site, because like...fear of the stigma, that the society will judge. [Interview D]

I can directly book the test kit through the chatbot, which is very useful and informative...my identity will remain anonymous, so people don't know me. [Interview E]

Participants deemed the AI chatbot useful and expressed their willingness to recommend the AI chatbot to others. Some participants suggested that the chatbot should be promoted among MSM who frequently use social networking apps, such as Grindr, Hornet, and Blued, to find sexual partners because those MSM were at higher risk for HIV and had greater need for HIV information. A participant stated the following:

I have the impression that anyone would actually need it [HIV testing]. But if we look at it from another angle, people on hookup apps like Grindr have a high tendency to hook up using those apps compared to those who don't use them...we need to introduce the chatbot to them because...they...[have] been highly exposed [to HIV]. [Interview G]

Discussion

Principal Findings

The feasibility and acceptability of leveraging AI chatbots to promote HIV testing and PrEP among MSM in Malaysia is high. Discrimination and stigma toward HIV and AIDS are major barriers for MSM to access high-quality HIV testing and prevention services in Malaysia, and they are also primary facilitators for MSM to seek health information via internet-based platforms. Our AI chatbot prototype provides a platform for MSM to order free HIV self-test kits in an MSM-friendly environment and to empower them with resources and instructions. MSM who prefer to interact with health care providers in person can also locate HIV testing clinics or PrEP clinics through the AI chatbot. MSM highlighted these functions of the AI chatbot as very useful.

Similar to other studies, AI chatbots were well received by users [28,29]. An AI chatbot could enhance engagement with the key population [30]. As contemporary social patterns increasingly involve the integration of AI into everyday routines, AI chatbots could contribute to delivering precise details regarding HIV testing to individuals actively seeking such information. A chatbot named Eli, developed by the United Nations Educational, Scientific, and Cultural Organization, received highly favorable user feedback and was widely acclaimed [29]. Eli offers a range of services, including details on HIV prevention, testing, and treatment and assistance in overcoming fears and concerns. Compared with Eli, our AI chatbot did not have information on treatment for AIDS and provided limited mental health support. Integrating these functions into our AI chatbot may support its usability. Nevertheless, our AI chatbot offers free HIV self-test kits and locates local clinics in Malaysia for HIV testing, PrEP consultation, and mental health care.

From our previous formative research, we know that factors facilitating the acceptance of an HIV prevention AI chatbot include providing useful information and having the capacity to solve problems [13]. In this study, participants reported that our AI chatbot was able to provide useful information and help

solve problems. This was indicated by the results that all participants perceived this chatbot as a helpful tool, and most participants deemed the chatbot a reliable source of information with a high satisfaction score. However, one area that required significant improvement in the chatbot was its conversation flow, as only 36% (5/14) of the participants felt that their interaction with the chatbot resembled a natural conversation. This was similar to another study where the quick response of the chatbot was deemed not humanlike and perceived as a disadvantage [28]. To address this issue and advance the chatbot, improving its algorithm and continuing training it using AI and machine learning techniques based on feedback from a larger sample size is crucial. Considering that the use of AI chatbots in health care is still in its early stages, this finding holds particular significance for designing AI chatbots. To enhance usability and promote the implementation of AI chatbots in health care, the chatbots must possess the ability to initiate natural conversations with humanlike characteristics. In addition, they should be equipped to effectively address users' questions and concerns while ensuring the security and safety of users' information.

The chatbot's plain interface and simple design were popular among MSM. Digital health interventions are useful, but knowing how to navigate a digital system sometimes could be daunting for users. Through this study, we are clear that accurate and simple responses without errors and redundant information were key to the acceptability of AI chatbots among MSM. Our participants reported that the AI chatbot helped them avoid societal stigma and protected their privacy, which increased their acceptability of using the chatbot to test for HIV. This finding is consistent with our previous formative research finding that addressing sociocultural barriers can facilitate the acceptance of an AI chatbot [13]. The chatbot does not require users to provide registration information. Therefore, it can maintain participants' anonymity. However, it is still necessary for the chatbot to clarify to users that the backend researchers and engineers who have access to users' conversations and information will not expose users' information to others. This suggestion is consistent with our study findings and some previous studies showing that mHealth interventions could improve HIV testing rates if users' anonymity were guaranteed [14,17].

Some technical-related issues negatively affected the participants' experience of navigating the chatbot. The inconvenient address input process and repeated steps owing to incomplete information contributed to the inconsistency and complexity of the chatbot, prompting participants to seek technical assistance. Many of these resulted from cultural differences, as the address options were designed based on overseas settings. This signifies the importance of tailoring the chatbot to the local context to improve usability. In addition, using localized language could also enhance the participants' satisfaction with the chatbot. Despite the challenges inherent in adopting novel technology, the advantages of using chatbots to connect with high-risk populations could significantly impact the efforts to address public health emergencies.

In line with other studies conducted in Malaysia, MSM are keen to peruse the information on PrEP and mental health, particularly

the information on where the PrEP and mental health clinics are located [14]. Most participants in our study felt that they would like to see more information through the chatbot introducing AIDS, its treatment, mental health issues, and sexually transmitted infections to better understand and manage AIDS, including how to prevent high-risk behaviors and where to seek timely help [12]. In Malaysia, professional and MSM-friendly care for mental health needs to be developed as most MSM reported that culturally sensitive information and resources regarding mental health issues were difficult to obtain. Interestingly, researchers have identified several obstacles to the adoption of AI chatbots for mental health care among users [31]. These include concerns related to privacy risks, restricted conversational engagement, negative user perceptions of personality traits (such as rudeness, lack of empathy, patronization, and being judgmental), and a lack of trust in the app's creators. Nevertheless, Eli chatbot overcame all these challenges by having a language that merges expertise and respect for the user, ensuring speech that is gender neutral and devoid of stigmatizing elements [29]. Our AI chatbot also had a similar language as Eli, which warrants future support on mental health issues.

To increase the use of the AI chatbot, it needs to be embedded in social media platforms that MSM frequently use. The geosocial networking apps where MSM find sexual partners, such as Grindr, Hornet, and Blued, and websites owned by nongovernmental organizations and MSM-friendly clinics are important venues to advertise the AI chatbot. MSM preferred these platforms because they are trusted and frequently used by MSM. Dissemination of the AI chatbot should be promoted among young MSM who use geosocial networking apps to find sexual partners because they are at a higher risk for HIV. Through this study, we found that to embed an AI chatbot into an internet-based platform for health promotion, researchers and engineers must consider the platform's characteristics, including its target population, level of privacy, and user-friendliness. Findings from this study will be used to improve the AI chatbot before testing on a larger scale through a national observational study in Malaysia. AI chatbots are a promising tool for promoting HIV testing and prevention. The AI chatbot must be made visible to MSM to increase its usability among MSM. Adopting the right dissemination strategies is key to increasing the visibility of AI chatbots and bringing significant impact to the MSM community. In addition, it is important for researchers to consider the sustainability of AI chatbots for MSM care in a context where sex-same sexual behaviors are criminalized. The policies and laws in Malaysia pose significant challenges on the sustainability of leveraging AI and securing funding for MSM care research. In such a political environment, it is crucial for researchers to collaborate with local nongovernmental organization and MSM-friendly clinics that operate within the existing Malaysian legal framework. Future research should focus on developing innovative and culturally tailored AI interventions to combat HIV among MSM, promote public health in Malaysia, and advocate for changes in discriminatory policies and laws to enhance the testing, implementation, and sustainability of these AI interventions.

Limitations

Testing the AI chatbot among its end users (ie, MSM) was an important step in determining its feasibility and acceptability in Malaysia and collecting feedback to improve the chatbot further. Although this study contributed important scientific knowledge, it had several limitations. One of the limitations is that we only included MSM who can read English, as the AI chatbot is currently only available in this language. Thus, the reach of the AI chatbot may be limited only to those fluent in English, which is not the case for most MSM in Malaysia. Therefore, our findings may not be generalizable to MSM who cannot read English. Considering that Malaysia is a multilingual country with Bahasa Malaysia as the official language, the chatbot must be improved to communicate in Bahasa Malaysia or Mandarin to reach a wider audience and promote greater access to HIV self-testing and PrEP. In addition, our participants were highly educated; this may lead to bias as they might possess a certain level of knowledge and health literacy, thus facilitating their interactions with the chatbot. Therefore, the findings may differ in the less educated or literate group. In

addition, our study only included MSM aged ≥ 18 years; therefore, the study findings do not capture the perceptions of younger MSM who are typically more tech-savvy and susceptible to HIV. Although obtaining consent from younger MSM in Malaysia for HIV-related research is a significant challenge, future studies should consider conducting surveys and interviews with MSM aged < 18 years who can provide insights into the experiences and needs of the younger MSM.

Conclusions

The AI chatbot was found to be feasible and acceptable among MSM, highlighting features, such as being informative, being able to respond to users' questions, and having a simple and user-friendly interface. Adapting the AI chatbot to local cultures, including support for other languages, and providing additional information such as mental health support, risk assessment for sexually transmitted infections, AIDS treatment, and the consequences of contracting HIV would contribute to the successful implementation and dissemination of the AI chatbot in Malaysia.

Acknowledgments

This work was supported by research grants from the National Institutes of Health (R21TW011663 and R33TW011663 for ZN and FLA; R21AI152927 for JAW, FLA, and ZN; and D43TW011324 for FLA) and the Fund for Lesbian and Gay Studies Research Award from Yale University for ZN.

Authors' Contributions

MHC and ZN wrote the first draft of the manuscript. YNG, NAMS, and KSN assisted in both developing the qualitative analysis and writing the qualitative results. All authors contributed to the development of the study protocol, revised the subsequent version of the manuscript, and approved the submitted version.

Abstract

More clinicians and researchers are exploring uses for large language model chatbots, such as ChatGPT, for research, dissemination, and educational purposes. Therefore, it becomes increasingly relevant to consider the full potential of this tool, including the special features that are currently available through the application programming interface. One of these features is a variable called temperature, which changes the degree to which randomness is involved in the model's generated output. This is of particular interest to clinicians and researchers. By lowering this variable, one can generate more consistent outputs; by increasing it, one can receive more creative responses. For clinicians and researchers who are exploring these tools for a variety of tasks, the ability to tailor outputs to be less creative may be beneficial for work that demands consistency. Additionally, access to more creative text generation may enable scientific authors to describe their research in more general language and potentially connect with a broader public through social media. In this viewpoint, we present the temperature feature, discuss potential uses, and provide some examples.

Introduction

ChatGPT [1] is a large language model developed by OpenAI that currently has over 100 million users [2]. As its popularity continues to grow, clinicians and researchers are among many considering its potential applications in health care and academia. In a short time, ChatGPT has been extensively published [3], with clinical researchers exploring its potential utility for a variety of tasks, including answering patient questions [4,5], generating clinical summaries [6], and

abstracting data from important documentation (eg, computed tomography reports) [7].

When using ChatGPT, one can interact through the website by providing a single prompt or engaging in a conversation. In addition to this more well-known web-based version of ChatGPT, there is also an application programming interface (API) that allows for more customization and flexibility. With the API, users can programmatically interact with ChatGPT and modify features for their specific use case. Although this approach may currently require more technical expertise for clinicians to use, its features may become available on the web

interface in future iterations of the tool. Therefore, these features are important to understand and relevant to discuss in terms of their meaning for clinicians and researchers in advance of their more widespread use. Additionally, they have direct implications for introducing greater reproducibility in use cases where this matters.

The Temperature Feature of ChatGPT

ChatGPT generates text through a probabilistic language modeling approach, where it writes responses word by word, calculating the most likely next word in the sequence. A key feature that influences this behavior is called temperature [8, 9]. In this context, temperature is a value from 0 to 2 that adjusts how random each subsequent word in the chat output is. A value of 0 will give the most probable word and, thus, the least variability. As the value increases toward and beyond 1, the next word becomes less probable, leading to more randomness and “creativity” in the response. This feature can currently be adjusted in the API, where the default value is 1 [9].

The ability to adjust the “creativity” of ChatGPT output should also be of interest to clinicians and medical researchers using the tool. By accounting for temperature, large language models such as ChatGPT can be tailored for different use cases. Lowering ChatGPT’s creativity level would be preferable for tasks that require more consistent outputs; for clinicians and researchers, tasks of this sort may include summarizing patient data (eg, symptoms and medications) or streamlining administrative tasks (eg, billing inquiries and patient registrations). Alternatively, increasing the creativity level may provide better outputs for less structured tasks and may

specifically hold relevance for improving clinicians’ and researchers’ digital communication with other health care workers, patients, and a wider audience.

Currently, many clinicians may find it difficult to engage with the broader public when it comes to disseminating findings. A lack of public accessibility can limit the impact of research. Creativity proves to be a powerful ally in communication, as it simplifies complex concepts, fosters critical thinking, and enhances the accessibility of intricate information. These factors collectively contribute to increased audience engagement and more effective message transmission. This feature has value for developing patient education materials, medical courses, science communication, and public research dissemination [10]. Increasing the creativity level could be useful when trying to report research results on social media [11], at conferences, or in scientific publications. Among other things, researchers could use a more creative ChatGPT to help come up with tags that apply to their work, brainstorm analogies or metaphors for scientific concepts, and check the tone of their writing.

Illustrating This Feature: Example

As an illustration of the “creativity” feature in ChatGPT, we have provided ChatGPT with the abstract of a recently published article on the development of a keyword library for capturing symptom talk in oncology [12]. While setting the temperature to low (0.0), medium (0.5), and high (1.0), we asked ChatGPT to create a tweet for a public audience, a title for a scientific journal article, and a title for a keynote address. Example ChatGPT-generated responses can be found in Table 1.

Table 1. ChatGPT-generated responses on the prompts for the different temperatures. For each temperature level, the same prompts were run 10 times in a ChatGPT model (text-davinci-003).

Temperature	Low (0.0)	Medium (0.5)	High (1.0)
Tweet for public audience	We developed a keyword library to detect symptom talk in transcribed clinical conversations. Our findings suggest that physical symptoms are more easily detected than psychological symptoms, and that more advanced computational models are needed to detect symptom expressions. #AI #Healthcare #SymptomDetection	Have you heard about the new study that developed and evaluated a natural language processing keyword library to detect symptom talk in oncology conversations? The findings highlight the need for more advanced computational models to detect symptom expressions in transcribed clinical conversations. #Oncology #SymptomTalk #NLP #ComputationalMethods	Check out how computational methods can help us detect patient symptoms in clinical conversations! A recent study developed & evaluated a keyword library for capturing expressed symptoms, highlighting the need for more advanced models for real-time detection of symptoms at scale. #AI @healthinformatics
Title for scientific journal	Detecting Symptom Talk in Transcribed Outpatient Oncology Conversations: Developing and Evaluating a Natural Language Processing Keyword Library	Keyword-Based Detection of Symptom Talk in Oncology Conversations: Developing a Natural Language Processing Library and Exploring Opportunities for Advanced Computational Models	Unlocking the Ambiguity of Symptom Talk: Developing and Evaluating a Natural Language Processing Library for Detecting Outpatient Oncology Conversations
Title of a keynote address	Unlocking the Potential of Computational Methods for Detecting Symptoms: Achieving Better Patient Care Through Natural Language Processing	Harnessing the Power of Computational Methods to Detect Patient Suffering: A Study of Symptom Talk in Oncology Conversations	The Ambiguity of Symptom Expressions: Utilizing Computational Methods to Better Attend to Patient Suffering

The examples shown in Table 1 illustrate that when the creativity level in ChatGPT is adjusted, slightly different responses are generated; these different creativity levels may provide more useful output depending on the task at hand. For example, a tweet created with a high level of creativity includes

an exclamation mark and directly addresses the audience. Therefore, it may be more engaging compared to tweets with a low or medium creativity level. The title of the article and keynote generated with high “creativity” were more surprising and potentially less useful for these tasks, although this may

depend on the context, setting, and personality of the user. For these tasks, the low- and medium-creativity titles were more straightforward. Importantly, these lower values do translate to more consistent responses. We ran each of these prompts 10 times, and at a temperature level of 0, all responses were identical. Given ChatGPT's normally variable output, this feature holds exciting implications for scenarios where consistency and reproducibility are preferred.

In addition to the results reported above, we have also experimented with adjustments in temperature level using other ChatGPT models (ie, gpt-3.5-turbo-1106, gpt-3.5-turbo-instruct, and gpt-4-1106-preview). All outputs appear in [Multimedia Appendix 1](#). In contrast to what we found when using the ChatGPT model "text-davinci-003," some other models showed some variability, even at a temperature level of 0. Regardless, the relative variability of outputs is still modified by temperature, with a higher temperature increasing creativity. Users should consider and test how temperature impacts outputs within the model they are using.

In the examples provided above, we have demonstrated how adjusting the level of creativity can enhance science communication, making it more engaging. However, it is crucial to also acknowledge the potential risks associated with increasing creativity, especially for clinical cases. Using ChatGPT with high creativity settings in clinical contexts, such as for summarizing patient medical data, can be problematic. Excessive creativity might lead to the embellishment or misrepresentation of crucial information, either by omitting vital details or interpreting data too liberally. Such inaccuracies

could impact patient treatment and outcomes. Therefore, it is advisable to lower the creativity level of ChatGPT in clinical applications. By doing so, we ensure that the summarized information remains faithful to the original data, thereby prioritizing accuracy and reliability over creative expression.

In summary, the temperature feature of ChatGPT allows users to adjust the level of "creativity." Although no previous articles have discussed or investigated this feature for its use in clinical research, it shows promising potential for clinicians and researchers. Both high and low creativity levels could have interesting applications for health care and may broaden the ways clinicians and researchers consider using artificial intelligence (AI) tools to close gaps in areas such as digital communication. ChatGPT documentation suggests using a temperature value of 0 to 0.2 for more focused (less creative) tasks and 0.8 to 1 for more random (more creative) tasks [9]. As large language models are variable and use case dependent, we strongly suggest testing and validating the proper temperature level for your specific use case. While this feature is a powerful tool that could be useful for creating easy-to-understand summaries, captivating social media posts, or making complex information more accessible to a wider audience, the parameters need to be carefully tweaked to find a balance between coherence and creativity and to tailor to specific needs. Looking ahead, as AI continues to advance in the health care sector, the temperature feature can play a pivotal role in health care applications in generative AI, unlocking the potential for more accurate, empathetic, or creative interactions between AI and health care stakeholders.

Acknowledgments

This work was supported by the Research Foundation Flanders (FWO; grants 1159522N and K210723N to LVB) and by the National Institutes of Health, National Institute on Aging Medical Student Training in Aging Research Program (grant 5T35AG038027-13 to JD). The funding sources had no involvement in the study design, analyses, or interpretation of the data; writing of the report; or decision to submit the paper for publication. During the preparation of this work, the authors used ChatGPT in order to generate the examples reported in the paper and to assist with the writing process. The use of a large language model has greatly assisted us in rephrasing and ensuring the clarity and effectiveness of our language. After using this tool, the authors reviewed and edited the content as needed and take full responsibility for the content of the publication.

Data Availability

All data generated or analyzed during this study are included in this published article and [Multimedia Appendix 1](#).

Authors' Contributions

JD and LVB contributed equally and share first authorship. LVB, JD, and BND contributed to the conception and design of the study and drafted the paper. CL critically revised the paper. JD and LVB both accessed and verified the underlying data reported in the manuscript. All authors approved the final version of the manuscript and had full responsibility for the decision to submit for publication.

Conflicts of Interest

None declared.

Multimedia Appendix 1

All data presented in this article, ChatGPT outputs for tests of 3 prompts across 3 temperature values for 3 different models (gpt-3.5-turbo-1106, gpt-3.5-turbo-instruct, and gpt-4-1106-preview; 100 runs for each test), and a summary document describing the multiple model tests.

Abstract

Background: ChatGPT (OpenAI) is a powerful tool for a wide range of tasks, from entertainment and creativity to health care queries. There are potential risks and benefits associated with this technology. In the discourse concerning the deployment of ChatGPT and similar large language models, it is sensible to recommend their use primarily for tasks a human user can execute accurately. As we transition into the subsequent phase of ChatGPT deployment, establishing realistic performance expectations and understanding users' perceptions of risk associated with its use are crucial in determining the successful integration of this artificial intelligence (AI) technology.

Objective: The aim of the study is to explore how perceived workload, satisfaction, performance expectancy, and risk-benefit perception influence users' trust in ChatGPT.

Methods: A semistructured, web-based survey was conducted with 607 adults in the United States who actively use ChatGPT. The survey questions were adapted from constructs used in various models and theories such as the technology acceptance model, the theory of planned behavior, the unified theory of acceptance and use of technology, and research on trust and security in digital environments. To test our hypotheses and structural model, we used the partial least squares structural equation modeling method, a widely used approach for multivariate analysis.

Results: A total of 607 people responded to our survey. A significant portion of the participants held at least a high school diploma (n=204, 33.6%), and the majority had a bachelor's degree (n=262, 43.1%). The primary motivations for participants to use ChatGPT were for acquiring information (n=219, 36.1%), amusement (n=203, 33.4%), and addressing problems (n=135, 22.2%). Some participants used it for health-related inquiries (n=44, 7.2%), while a few others (n=6, 1%) used it for miscellaneous activities such as brainstorming, grammar verification, and blog content creation. Our model explained 64.6% of the variance in trust. Our analysis indicated a significant relationship between (1) workload and satisfaction, (2) trust and satisfaction, (3) performance expectations and trust, and (4) risk-benefit perception and trust.

Conclusions: The findings underscore the importance of ensuring user-friendly design and functionality in AI-based applications to reduce workload and enhance user satisfaction, thereby increasing user trust. Future research should further explore the relationship between risk-benefit perception and trust in the context of AI chatbots.

Introduction

ChatGPT (OpenAI) [1] is a powerful tool for a wide range of tasks, from entertainment and creativity to health care queries [2]. However, there are potential benefits associated with this technology. For instance, it can help summarize large amounts of text data [3,4] or generate programming code [5]. There is also the notion that ChatGPT may potentially assist with health care tasks [6-9]. However, the risks associated with using ChatGPT can hinder its adoption in various high-risk domains. These risks include the potential for inaccuracies and lack of citation relevance in scientific content generated by ChatGPT [10], ethical issues (copyright, attribution, plagiarism, and authorship) [11], the risk of hallucination (inaccurate information that sounds plausible scientifically) [12], and the possibility of biased content and inaccurate information due to the quality of training data sets generated prior to the year 2021 [4].

In the discourse concerning the deployment of ChatGPT and similar artificial intelligence (AI) technologies, it is sensible to recommend their use primarily for tasks a human user can execute accurately. Few studies have advocated using the technology under human supervision [13,14]. Encouraging users to rely on such tools for tasks beyond their competence is risky, as they may need help to evaluate the AI's output effectively. The strength of ChatGPT lies in its ability to automate more straightforward, mundane tasks, freeing human users to invest their time and cognitive resources into critical tasks (not vice versa). This approach to technology use maintains a necessary balance, leveraging AI for efficiency gains while ensuring that critical decision-making remains within the purview of human expertise.

As we transition into the subsequent phase of ChatGPT deployment, establishing realistic performance expectations and understanding users' perceptions of risk associated with its use are crucial in determining the successful integration of this AI technology. Thus, understanding users' perceptions of ChatGPT becomes essential, as these perceptions significantly influence their usage decisions [2]. For example, suppose users believe that ChatGPT's capabilities surpass human knowledge. In that case, they may be tempted to use it for tasks such as self-diagnosis, which could lead to potentially harmful outcomes if the generated information is mistaken or misleading. Conversely, a realistic appraisal of the limitations and strengths of technology would encourage its use in low-risk, routine tasks and foster a safer, more effective integration into our everyday lives.

Building upon the importance of user perceptions and expectations, we must also consider that the extent to which users trust ChatGPT hinges mainly on the perception of its accuracy and reliability. As users witness the technology's ability to perform tasks effectively and generate correct, helpful information, their trust in the system grows. This, in turn, allows them to offload routine tasks to the AI and focus their energies on more complex or meaningful endeavors. Similarly, instances

where the AI generates inaccurate or misleading information can quickly erode users' perception of the technology. Users may become dissatisfied and lose trust if they perceive the technology as unreliable or potentially harmful, particularly if they have previously overestimated its capabilities. This underlines the importance of setting realistic expectations and accurately understanding the strengths and limitations of ChatGPT, which can help foster a healthy level of trust and satisfaction among users. Ultimately, establishing and maintaining trust and satisfaction are not a onetime event but an ongoing process of validating the AI's outputs, understanding and acknowledging its limitations, and making the best use of its capabilities within a framework of informed expectations and continuous learning. This dynamic balance is pivotal for the effective and safe integration of AI technologies such as ChatGPT into various sectors of human activity.

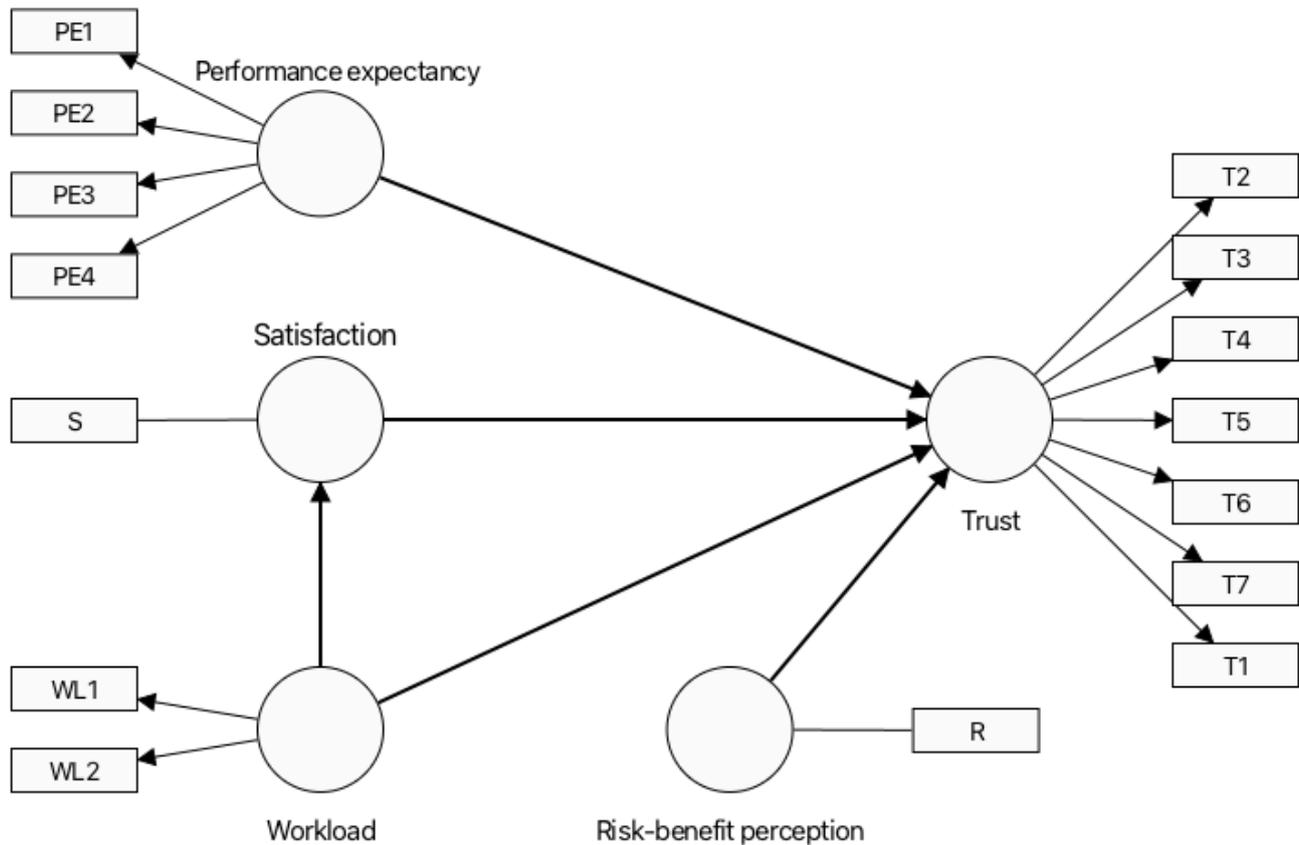

In our prior work, we explored the impact of trust in the actual use of ChatGPT [15]. This study aims to explore a conceptual framework delving deeper into the aspects influencing user trust in ChatGPT.

As shown in [Figure 1](#), the proposed conceptual model is grounded in the well-established theories of technology acceptance and use, incorporating constructs such as performance expectancy, workload, satisfaction, risk-benefit perception, and trust to comprehensively evaluate user interaction with technology. Performance expectancy, derived from the core postulates of the technology acceptance model (TAM) [16] and the unified theory of acceptance and use of technology (UTAUT) [17], posits that the perceived use of the technology significantly predicts usage intentions. Workload, akin to effort expectancy, reflects the perceived cognitive and physical effort required to use the technology, where a higher workload may inversely affect user satisfaction—a construct that encapsulates the fulfillment of user expectations and needs through technology interaction. The risk-benefit perception embodies the user's assessment of the technology's potential advantages against its risks, intricately influencing both user satisfaction and trust. Trust, a pivotal determinant of technology acceptance [15], signifies the user's confidence in the reliability and efficacy of the technology. This theoretical framework thus serves to elucidate the multifaceted process by which users come to accept and use a technological system, highlighting the critical role of both cognitive appraisals and affective responses in shaping the technology adoption landscape.

We explore the following hypotheses:

- Hypothesis 1: Perceived workload of using ChatGPT negatively correlates with user trust in ChatGPT.
- Hypothesis 2: Perceived workload of using ChatGPT negatively correlates with user satisfaction with ChatGPT.
- Hypothesis 3: User satisfaction with ChatGPT positively correlates with trust in ChatGPT.
- Hypothesis 4: User trust in ChatGPT is positively correlated with the performance expectancy of ChatGPT.
- Hypothesis 5: The risk-benefit perception of using ChatGPT is positively correlated with user trust in ChatGPT.

Figure 1. A conceptual model of technology acceptance illustrating trust (T) as the dependent outcome variable, with performance expectancy (PE), workload (WL), and risk-benefit perception (R) as direct predictors. Satisfaction (S) is depicted as a mediating variable that moderates the impact of workload on trust.

Methods

Ethical Considerations

The study obtained ethics approval from West Virginia University, Morgantown (protocol 2302725983). The study was performed in accordance with relevant guidelines and regulations. No identifiers were collected during the study, and all users were compensated for completing the survey through an audience paneling service. In compliance with ethical research practices, informed consent was obtained from all participants before initiating the survey. Attached to the survey was a comprehensive cover letter outlining the purpose of the study, the procedure involved, the approximate time to complete the survey, and assurances of anonymity and confidentiality. It also emphasized that participation was completely voluntary, and participants could withdraw at any time without any consequences. The cover letter also included the contact information of the researchers for any questions or concerns the participants might have regarding the study. Participants were asked to read through the cover letter information carefully and were instructed to proceed with the survey only if they understood and agreed to the terms described, effectively providing their consent to participate in the study.

Study Design

A semistructured, web-based questionnaire was disseminated to adult individuals within the United States who engaged with ChatGPT (version 3.5) at least once per month. Data collection took place between February and March 2023. The questionnaire

was crafted using Qualtrics (Qualtrics LLC), and its circulation was handled by Centiment (Centiment LLC), a provider of audience-paneling services. Centiment's services were used due to their extensive reach and ability to connect with a diverse and representative group via their network and social media. Their fingerprinting technology, which uses IP address, device type, screen size, and cookies, was used to guarantee the uniqueness of the survey respondents. Prior to the full-scale dissemination, a soft launch was carried out with 40 responses gathered. The purpose of a soft launch, a limited-scale trial of the survey, is to pinpoint any potential problems, such as ambiguity or confusion in questions, technical mishaps, or any other factors that might affect the quality of data obtained. The survey was made available to a larger audience following the successful soft launch.

Table 1 shows the descriptive statistics of the survey questions used in this study. We developed 3 latent constructs based on the question: trust, workload, and performance expectancy, and 2 single question variables: satisfaction and risk-benefit perception. Participant responses to all the questions were captured using a 4-point Likert scale ranging from 1=strongly disagree to 4=strongly agree. These questions were adapted from constructs used in various models and theories such as the TAM, the theory of planned behavior, UTAUT, and research on trust and security in digital environments.

- Trust: Questions T1-T7 related to trust in AI systems were adapted from the trust building model [18].

- Workload: WL1 and WL2 questions from the National Aeronautics and Space Administration Task Load Index for measuring perceived workload [19].
- Performance expectancy: PE1-PE4 are about the perceived benefits of using the system, which is a central concept in TAM and UTAUT.
- Satisfaction: The single item relates to overall user satisfaction, a common measure in information systems success models [20].
- Risk-benefit perception: Question addresses the user's assessment of benefits relative to potential risks, an aspect often discussed in the context of technology adoption and use [21].

These references provide a starting point for understanding the theoretical underpinnings of the survey used in this study. They are adapted from foundational works in information systems, human-computer interaction, and psychology that address trust, workload, performance expectancy, satisfaction, and the evaluation of benefits versus risks in technology use.

Table 1. Study variables and latent construct (N=607).

Survey items	Value, mean (SD)
Trust (T)	
T1: ChatGPT is competent in providing the information and guidance I need	3.20 (0.83)
T2: ChatGPT is reliable in providing consistent and dependable information	3.16 (0.80)
T3: ChatGPT is transparent	3.12 (0.86)
T4: ChatGPT is trustworthy in the sense that it is dependable and credible	3.17 (0.84)
T5: ChatGPT will not cause harm, manipulate its responses, or create negative consequences for me	3.10 (0.88)
T6: ChatGPT will act with integrity and be honest with me	3.19 (0.82)
T7: ChatGPT is secure and protects my privacy and confidential information	3.27 (0.81)
Workload (WL)	
WL1: Using ChatGPT was mentally demanding	3.21 (0.75)
WL2: I had to work hard to use ChatGPT	2.20 (0.98)
Performance expectancy (PE)	
PE1: ChatGPT can help me achieve my goals	3.24 (0.77)
PE2: ChatGPT can reduce my workload	3.22 (0.78)
PE3: ChatGPT improves my work efficiency	3.21 (0.84)
PE4: ChatGPT helps me make informed and timely decisions	3.26 (0.79)
Satisfaction (S)	
S: I am satisfied with ChatGPT	3.24 (0.76)
Risk-benefit perception (R)	
R: The benefits of using ChatGPT outweigh any potential risks	3.20 (0.80)

Statistical Analysis and Model Validation

To test our hypotheses and structural model, we used the partial least squares structural equation modeling (PLS-SEM) method, a widely used approach for multivariate analysis. PLS-SEM enables the estimation of complex models with multiple constructs, indicator variables, and structural paths, without

making assumptions about the data's distribution [22]. This method is beneficial for studies with small sample sizes that involve many constructs and items [23]. PLS-SEM is a suitable method because of its flexibility and ability to allow for interaction between theory and data in exploratory research [24]. The analyses were performed using the *SEMInR* package

in R (R Foundation for Statistical Computing) [25]. We started by loading the data set collected for this study using the *reader* package in R. We then defined the measurement model. This consisted of 5 composite constructs: trust, performance expectancy, workload, risk-benefit perception, and satisfaction. Trust was measured with 7 items (T1 through T7), performance expectancy with 4 items (PE1 through PE4), and workload with 2 items (WL1 and WL2), while risk-benefit perception and satisfaction were each measured with a single item. We also evaluated the convergent and discriminant validity of the latent constructs, which we assessed using 3 criteria: factor loadings (>0.50), composite reliability (>0.70), and average variance extracted (>0.50). We used the Heterotrait-Monotrait ratio (<0.90) to assess discriminant validity [26].

Next, we defined the structural model, which captured the hypothesized relationships between the constructs. The model included paths from risk-benefit perception, performance expectancy, workload, satisfaction to trust, and a path from workload to satisfaction. We then estimated the model's parameters using the partial least squares method. This was done with the *estimate_pls* function in the *semr* package. The partial least squares method was preferred due to its ability to handle complex models and its robustness to violations of normality assumptions. We performed a bootstrap resampling procedure with 10,000 iterations to obtain robust parameter estimates and compute 95% CIs. The bootstrapped model was plotted to visualize the estimates and their 95% CIs.

Results

Of 607 participants who completed the survey, 29.9% ($n=182$) used ChatGPT at least once per month, 26.1% ($n=158$) used it weekly, 24.5% ($n=149$) accessed it more than once per week, and 19.4% ($n=118$) interacted with it almost daily. A substantial portion of the participants held at least a high school diploma ($n=204$, 33.6%), and the majority had a bachelor's degree ($n=262$, 43.1%). The primary motivations for participants to use ChatGPT were for acquiring information ($n=219$, 36%), amusement ($n=203$, 33.4%), and addressing problems ($n=135$, 22.2%). Some participants used it for health-related inquiries ($n=44$, 7.2%), while a few others ($n=6$, 1%) used it for miscellaneous activities such as brainstorming, grammar verification, and blog content creation. Table 2 shows the factor loading of the latent constructs in the model.

The model explained 2% and 64.6% of the variance in "satisfaction" and "trust," respectively. Reliability estimates, as shown in Table 3, indicated high levels of internal consistency for all 5 latent variables, with Cronbach α and ρ values exceeding the recommended threshold of 0.7. The average

variance extracted for the latent variables also exceeded the recommended threshold of 0.5, indicating that these variables are well-defined and reliable. Based on the root mean square error of approximation (RMSEA) fit index, our PLS-SEM model demonstrates a good fit for the observed data. The calculated RMSEA value of 0.07 falls below the commonly accepted threshold of 0.08, indicating an acceptable fit. The RMSEA estimates the average discrepancy per degree of freedom in the model, capturing how the proposed model aligns with the population covariance matrix. With a value below the threshold, it suggests that the proposed model adequately represents the relationships among the latent variables. This finding provides confidence in the model's ability to explain the observed data and support the underlying theoretical framework.

Table 4 shows the estimated paths in our model. Hypothesis 1 postulated that as the perceived workload of using ChatGPT increases, user trust in ChatGPT decreases. Our analysis indicated a negative estimate for the path from workload to trust (-0.047). However, the T statistic (-1.674) is less than the critical value, and the 95% CI straddles 0 (-0.102 to -0.007), suggesting that the effect is not statistically significant. Therefore, we do not have sufficient evidence to support hypothesis 1.

Hypothesis 2 stated that perceived workload is negatively correlated with user satisfaction with ChatGPT. The results supported this hypothesis, as the path from workload to satisfaction showed a negative estimate (-0.142), a T statistic (-3.416) beyond the critical value, and a 95% CI (-0.223 to -0.061).

The data confirmed this relationship for hypothesis 3, which proposed a positive correlation between satisfaction with ChatGPT and trust in ChatGPT. The path from satisfaction to trust had a positive estimate (0.165), a T statistic (4.478) beyond the critical value, and a 95% CI (0.093-0.237).

Hypothesis 4 suggested that user performance expectations of ChatGPT increase with their trust in the technology. The analysis supported this hypothesis. The path from performance expectancy to trust displayed a positive estimate (0.598), a large T statistic (15.554), and a 95% CI (0.522-0.672). Finally, we examined hypothesis 5, which posited that user trust in ChatGPT increases as their risk-benefit perception of using the technology increases. The path from risk-benefit perception to trust showed a positive estimate (0.114). The T statistic (3.372) and the 95% CI (0.048-0.179) indicating this relationship is significant, but the positive sign suggests that as the perceived benefits outweigh the risks, the trust in ChatGPT increases. Therefore, hypothesis 5 is supported. Figure 2 illustrates the structural model with all path coefficients.

Table 2. Bootstrapped loadings: model analysis estimates the relationship between various constructs and their indicators.

Bootstrapped loadings	Loadings	T statistic	95% CI
Trust (T)			
T1	0.788	41.998	0.750-0.823
T2	0.753	33.795	0.706-0.794
T3	0.773	40.293	0.733-0.808
T4	0.732	28.772	0.679-0.779
T5	0.673	21.066	0.607-0.732
T6	0.799	46.065	0.763-0.831
T7	0.779	38.088	0.736-0.816
Performance expectancy (PE)			
PE1	0.809	49.231	0.775-0.839
PE2	0.733	29.360	0.681-0.779
PE3	0.802	44.968	0.766-0.835
PE4	0.777	34.198	0.729-0.818
Workload (WL)			
WL1	0.856	28.883	0.789-0.905
WL2	0.913	44.872	0.869-0.950

Table 3. Convergent reliability.

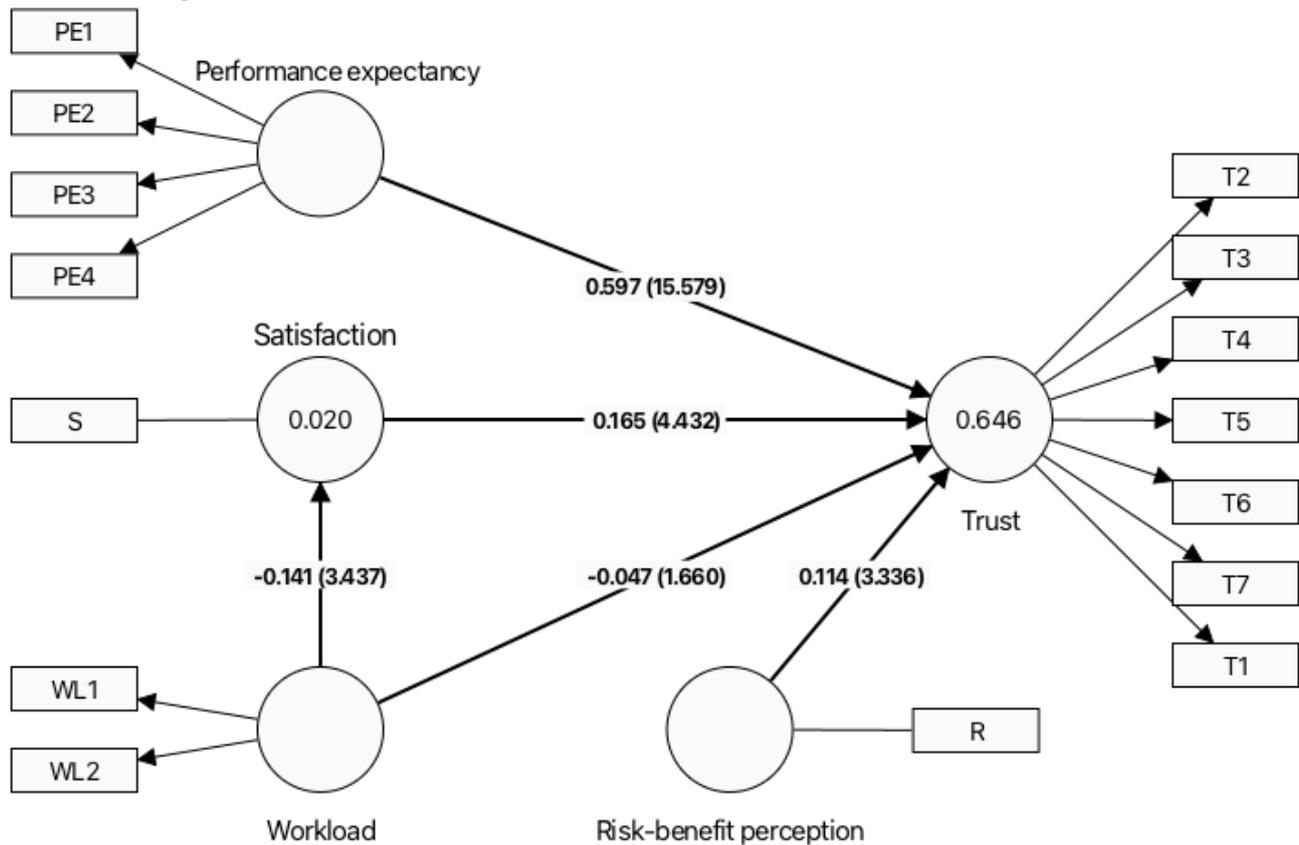

Construct	Cronbach α	ρC	AVE ^a	ρA
Performance expectation	0.787	0.862	0.610	0.610
Workload	0.729	0.870	0.771	0.968
Trust	0.876	0.904	0.575	0.880

^aAVE: average variance extracted.

Table 4. Bootstrapped structural path estimates.

Direct path	Bootstrap mean standard estimate (SD)	T statistic	95% CI
Risk-benefit perception→trust	0.114 (0.034)	3.372	0.048 to 0.179
Performance expectancy→trust	0.598 (0.038)	15.554	0.522 to 0.672
Workload→satisfaction	-0.142 (0.041)	-3.416	-0.223 to -0.061
Workload→trust	-0.047 (0.028)	-1.674	-0.102 to 0.007
Satisfaction→trust	0.165 (0.037)	4.478	0.093 to 0.237

Figure 2. The significant paths connecting trust (T) in ChatGPT, performance expectancy (PE), satisfaction (S), workload (WL), and risk-benefit perception (R). T1 through T7: factors for trust; PE1 through PE4: factors for performance expectancy; and WL1 and WL2: factors for workload. The inner model shows the path coefficient and T statistic values.

Discussion

Main Findings

This study represents one of the initial attempts to investigate how human factors such as workload, performance expectancy, risk-benefit perception, and satisfaction influence trust in ChatGPT. Our results showed that these factors significantly influenced trust in ChatGPT, with performance expectancy exerting the strongest association, highlighting its critical role in fostering trust. Additionally, we found that satisfaction was a mediator in the relationship between workload and trust. At the same time, a positive correlation was observed between trust in ChatGPT and the risk-benefit perception. Our findings align with the May 23, 2023, efforts and initiatives of the Biden-Harris Administration to advance responsible AI research, development, and deployment [27]. The Administration recognizes that managing its risks is crucial and prioritizes protecting individuals' rights and safety. One of the critical actions taken by the administration is the development of the artificial intelligence risk management framework (AI RMF). The AI RMF builds on the importance of trustworthiness in AI systems and is a framework for strengthening AI trustworthiness and promoting the trustworthy design, development, deployment, and use of AI systems, contributing to the need for our research [28]. Our findings reveal the importance of performance expectancy, satisfaction, and risk-benefit perception in determining the user's trust in AI systems. By addressing these factors, AI systems can be designed and developed to be

more user-centric, aligning with the AI RMF's emphasis on human-centricity and responsible AI.

Workload and Trust in ChatGPT

Moreover, we found that reducing user workload is vital for enhancing user satisfaction, which in turn improves trust. This finding aligns with the AI RMF's focus on creating AI systems that are equitable and accountable and that mitigate inequitable outcomes. Additionally, our research emphasizes the need for future exploration of other factors impacting user trust in AI technologies. Such endeavors align with the AI RMF's vision of managing AI risks comprehensively and holistically, considering technical and societal factors. Understanding these factors is crucial for fostering public trust and enhancing the overall trustworthiness of AI systems, as outlined in the AI RMF [28].

This study also extends and complements existing literature. Consistent with the observed patterns in studies on flight simulators, dynamic multitasking environments, and cyberattacks [29-31], we also found that higher perceived workload in using ChatGPT led to lower levels of trust in this technology. Our findings align with the existing research indicating a negative correlation between workload and user satisfaction [32]. We observed that as the perceived workload of using ChatGPT increased, user satisfaction with the technology decreased. This outcome echoes the consensus within the literature that a high workload can lead to user dissatisfaction, particularly if the technology requires too much effort or time [33]. The literature reveals that perceived

workload balance significantly influences job satisfaction in work organizations [25], and similar patterns are found in the well-being studies of nurses, where perceived workload negatively impacts satisfaction with work-life balance [34]. While this study does not directly involve the workplace environment or work-life balance, the parallels between workload and satisfaction are evident. Furthermore, our research parallels the study suggesting that when providing timely service, AI applications can alleviate perceived workload and improve job satisfaction [35]. ChatGPT, as an AI-powered chatbot, could potentially contribute to workload relief when it performs effectively and efficiently, thereby boosting user satisfaction.

Satisfaction and Trust in ChatGPT

Our findings corroborate with existing literature, suggesting a strong positive correlation between user satisfaction and trust in the technology or service provider [23,24,26,36-38]. We found that the users who expressed higher satisfaction with ChatGPT were more likely to trust the system, strengthening the premise that satisfaction can predict trust in a technology or service provider. Similar to the study on digital transaction services, our research indicates that higher satisfaction levels with ChatGPT corresponded with higher trust in the AI system [37]. This suggests that when users are satisfied with the performance and results provided by ChatGPT, they tend to trust the technology more. The research on mobile transaction apps mirrors our findings, where we also discovered that satisfaction with ChatGPT use was a significant predictor of trust in the system [36]. This showcases the importance of ensuring user satisfaction in fostering trust using innovative technologies like AI chatbots. The study on satisfaction with using digital assistants, where a positive relationship between trust and satisfaction was observed [26], further aligns with our study. We also found a positive correlation between trust in ChatGPT and user satisfaction with this AI assistant.

Performance Expectancy and Trust in ChatGPT

Our findings concerning the strong positive correlation between performance expectancy and trust in ChatGPT serve as an extension to prior literature. Similar findings have been reported in previous studies on wearables and mobile banking [39,40], where performance expectancy was positively correlated with trust. However, our results diverge from the observations of a recent study that did not find a significant impact of performance expectancy on trust in chatbots [41]. Moreover, the observed mediating role of satisfaction in the relationship between workload and trust in ChatGPT is a notable contribution to the literature. While previous studies have demonstrated a positive correlation between workload reduction by chatbots and trust,

as well as between trust and user satisfaction [42-44], the role of satisfaction as a mediator between workload and trust has not been explored. Finally, the positive correlation between the risk-benefit perception of using ChatGPT and trust aligns with the findings of previous studies [45-47]. Similar studies on the intention to use chatbots for digital shopping and customer service have found that trust in chatbots impacts perceived risk and is affected by the risk involved in using chatbots [46,47]. Our study adds to this body of research by confirming the same positive relationship within the context of ChatGPT.

Limitations

Despite the valuable insights provided by this study, limitations should be acknowledged. First, our research focused explicitly on ChatGPT and may not be generalizable to other AI-powered conversational agents or chatbot technologies. Different chatbot systems may have unique characteristics and user experiences that could influence the factors affecting trust. Second, this study relied on self-reported data from survey responses, which may be subject to response biases and limitations inherent to self-report measures. Participants' perceptions and interpretations of the constructs under investigation could vary, leading to potential measurement errors. Third, this study was cross-sectional, capturing data at a specific point in time. Longitudinal studies that track users' experiences and perceptions over time provide a more comprehensive understanding of the dynamics between trust and the factors investigated. Finally, the sample of participants in this study consisted of individuals who actively use ChatGPT, which may introduce a self-selection bias. The perspectives and experiences of nonusers or individuals with limited exposure to AI-powered conversational agents may differ, and their insights could provide additional valuable perspectives.

Conclusions

This study examined the factors influencing trust in ChatGPT, an AI-powered conversational agent. Our analysis found that performance expectancy, satisfaction, workload, and risk-benefit perceptions significantly influenced users' trust in ChatGPT. These findings contribute to understanding trust dynamics in the context of AI-powered conversational agents and provide insights into the factors that can enhance user trust. By addressing the factors influencing trust, we contribute to the broader goal of fostering responsible AI practices that prioritize user-centric design and protect individuals' rights and safety. Future research should consider longitudinal designs to capture the dynamics of trust over time. Additionally, incorporating perspectives from diverse user groups and examining the impact of contextual factors on trust would further enrich our understanding of trust in AI technologies.

Data Availability

The data sets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

AC, the lead researcher, was responsible for the study's conceptualization, the survey's development, figure illustration, data collection and analysis, and manuscript writing. HS, the student author, was responsible for manuscript writing and conducting

the literature review. Both authors collaborated throughout the research process and approved the final version of the manuscript for submission.

Conflicts of Interest

None declared.

Abstract

Background: Artificial intelligence (AI) has the potential to enhance physical activity (PA) interventions. However, human factors (HFs) play a pivotal role in the successful integration of AI into mobile health (mHealth) solutions for promoting PA. Understanding and optimizing the interaction between individuals and AI-driven mHealth apps is essential for achieving the desired outcomes.

Objective: This study aims to review and describe the current evidence on the HFs in AI-driven digital solutions for increasing PA.

Methods: We conducted a scoping review by searching for publications containing terms related to PA, HFs, and AI in the titles and abstracts across 3 databases—PubMed, Embase, and IEEE Xplore—and Google Scholar. Studies were included if they were primary studies describing an AI-based solution aimed at increasing PA, and results from testing the solution were reported. Studies that did not meet these criteria were excluded. Additionally, we searched the references in the included articles for relevant research. The following data were extracted from included studies and incorporated into a qualitative synthesis: bibliographic information, study characteristics, population, intervention, comparison, outcomes, and AI-related information. The certainty of the evidence in the included studies was evaluated using GRADE (Grading of Recommendations Assessment, Development, and Evaluation).

Results: A total of 15 studies published between 2015 and 2023 involving 899 participants aged approximately between 19 and 84 years, 60.7% (546/899) of whom were female participants, were included in this review. The interventions lasted between 2 and 26 weeks in the included studies. Recommender systems were the most commonly used AI technology in digital solutions for PA (10/15 studies), followed by conversational agents (4/15 studies). User acceptability and satisfaction were the HFs most frequently evaluated (5/15 studies each), followed by usability (4/15 studies). Regarding automated data collection for personalization and recommendation, most systems involved fitness trackers (5/15 studies). The certainty of the evidence analysis indicates moderate certainty of the effectiveness of AI-driven digital technologies in increasing PA (eg, number of steps, distance walked, or time spent on PA). Furthermore, AI-driven technology, particularly recommender systems, seems to positively influence changes in PA behavior, although with very low certainty evidence.

Conclusions: Current research highlights the potential of AI-driven technologies to enhance PA, though the evidence remains limited. Longer-term studies are necessary to assess the sustained impact of AI-driven technologies on behavior change and habit formation. While AI-driven digital solutions for PA hold significant promise, further exploration into optimizing AI's impact on PA and effectively integrating AI and HFs is crucial for broader benefits. Thus, the implications for innovation management

involve conducting long-term studies, prioritizing diversity, ensuring research quality, focusing on user experience, and understanding the evolving role of AI in PA promotion.

Introduction

Physical activity (PA) has been recognized as a cornerstone of a healthy lifestyle since it has demonstrated numerous benefits for both physical and mental well-being [1,2]. Engaging in regular PA has been associated with preventing and managing a range of health conditions, including obesity, diabetes, cardiovascular disease, and multiple sclerosis [2,3]. However, the global population's engagement in regular PA is often low, with many individuals failing to meet the recommendations necessary for health benefits. This persistent challenge necessitates innovative approaches to motivate and facilitate increased PA participation, and mobile health (mHealth) technologies have emerged as a promising avenue for intervention [4].

The availability of mobile devices and the increasing mobile penetration provide an unprecedented opportunity to leverage mHealth solutions to promote PA [5,6]. Mobile technologies offer persuasive and ubiquitous systems. Equipped with built-in sensors that can monitor and encourage PA in real time, they can facilitate sending personalized reminders and motivational messages [7-10], which have been proven to significantly increase PA [10-12]. However, the effectiveness of mHealth interventions in promoting PA has been limited by the challenge of sustaining engagement over the medium and long term. Mönninghoff et al [13] found that mHealth “can foster small to moderate increases in PA,” and the effects are even maintained long-term, but “the effect size decreases over time.” This is where the integration of artificial intelligence (AI) holds immense promise. AI technology has the potential to deliver effective interventions to promote PA [11,14].

AI can enrich mHealth solutions by offering personalized, adaptive, and tailored interventions that cater to individual preferences and needs. For example, an optimal exercise plan for an individual can be suggested by AI algorithms to help maximize the long-term health utility of the user [15]. This level of customization has the potential to enhance user experience (UX), which in turn could result in increased motivation to engage in PA. Motivation is a critical factor in driving behavior change, especially when adopting and maintaining a physically active lifestyle. AI can also gamify fitness by setting challenges, goals, and rewards, motivating users to increase PA through points, competition, and achievements [16]. Moreover, research indicates that the human-likeness of conversational agents increases adherence to chatbots [17] and compliance with their recommendations [18].

In this context, human factors (HFs) play a pivotal role in the successful integration of AI into mHealth solutions aimed at promoting PA. Understanding and optimizing the interaction between individuals and AI-driven mHealth apps is essential for achieving the desired outcomes [19]. HFs, in the context of AI, involve considerations related to human cognition, behavior, and ergonomics, which are crucial for designing effective and user-friendly mHealth interventions. Bergevi et al [20] explored users' perceptions of acceptability, engagement, and usability of mHealth solutions that promote PA, healthy diets, or both. They concluded that mHealth services targeting increased PA “should be personalized, dynamic, easily manageable, and reliable.” This study is distinguished from their work by focusing on AI-driven digital solutions.

This research underscores the critical role of PA in promoting overall health and well-being while highlighting the persistent challenge of low engagement in regular PA globally. It emphasizes the potential of mHealth technologies, augmented by AI, to effectively motivate and facilitate increased PA participation. By leveraging AI, mHealth solutions can offer personalized, adaptive interventions tailored to individual preferences and needs, thereby enhancing the UX and motivation. However, the successful integration of AI into mHealth solutions relies on understanding and optimizing HFs, encompassing cognition, behavior, and ergonomics, to ensure effective and user-friendly interventions. Specifically, this study aims to address the following research question, what are the key HFs influencing the effectiveness and adoption of AI-driven digital solutions aimed at promoting PA? Our objective is to review and describe the current evidence on the HFs in AI-driven digital solutions for increasing PA.

Methods

Overview

We have conducted a scoping review to capture current evidence on HFs in AI-driven digital solutions for increasing PA. A scoping review is a systematic approach used to map and synthesize existing literature on a broad topic, providing an overview of key concepts, sources, and knowledge gaps. Our review followed the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [21].

Search Strategy

We have searched for publications including keywords related to PA (ie, “physical activity;” “exercise;” “active lifestyle;” “sedentary behaviour;” “inactivity;” “resistance training;”

“exergaming;” “walking;” “swimming;” “jogging;” “climbing”), artificial intelligence (ie, “artificial intelligence;” “AI;” “machine learning;” “deep learning;” “natural language processing;” “neural networks;” “sentiment analysis”), and human factors (ie, “usability;” “task performance;” “satisfaction;” “workload;” “human errors;” “user perception;” “cognitive factors;” “mental model;” “context awareness;” “automation bias;” “teamworking;” “user experience;” “acceptance;” “acceptability;” “task analysis;” “handover;” “patient interaction;” “human factors;” “ergonomics”) in their titles and abstracts. No language or year limitations were used. The full search strategy can be found in [Multimedia Appendix 1](#).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Primary studies that described an artificial intelligence (AI)-based digital solution
- AI-based digital solutions aimed at increasing physical activity
- Publications that reported results from testing the AI-based solution related to physical activity behavior

Exclusion criteria

- Publications that did not meet all 3 inclusion criteria

All references were uploaded to EndNote (version 20.6; Clarivate) [22] and Rayyan (Qatar Computing Research Institute) [23]. After duplicates were removed, 2 authors (EG and DL) independently assessed the eligibility of the remaining publications by checking their titles and abstracts. Two additional authors (KD and OR-R) checked the full text of the eligible papers after the title and abstract screening. After the full-text screening, the selected papers were included in a qualitative synthesis.

Data Items and Data Extraction

Two authors (KD and OR-R) extracted the following data: bibliographic information (publication year and country); study characteristics (study design, type of evaluation, research methods, primary and secondary measures, materials, and theoretical foundations); population (number of participants, age, and gender); intervention (intervention design, duration, and follow-ups); comparison (control group or groups and pre-post evaluation or other); outcomes (primary and secondary outcomes); and AI-related information (technology type, main purpose, platform, and HFs).

OR-R identified and assigned codes representative of the main purpose of the AI model implemented in each of the systems studied. The 3 main purposes of the AI models implemented in the studied systems were identified as personalization, communication, and human activity recognition. Personalization

The data search was performed on August 29, 2023. The database search was done by a single author (EG) and covered PubMed, Embase, and IEEE Xplore. Another author (DL) carried out a search on Google Scholar and selected the first 100 entries. Finally, DL used a snowballing approach to identify additional relevant studies cited in only the included publications.

Eligibility and Selection Process

Inclusion and exclusion criteria are presented in [Textbox 1](#).

includes all AI models analyzed whose main purpose was to adapt the digital solution or intervention to the patient’s needs, conditions, and preferences. The second group includes models that enabled a communication pathway with patients. Finally, human activity recognition includes all models that enable the detection of user behaviors, particularly PA. OR-R and KD reviewed the assigned codes and created a classification of these by consensus.

Certainty of the Evidence

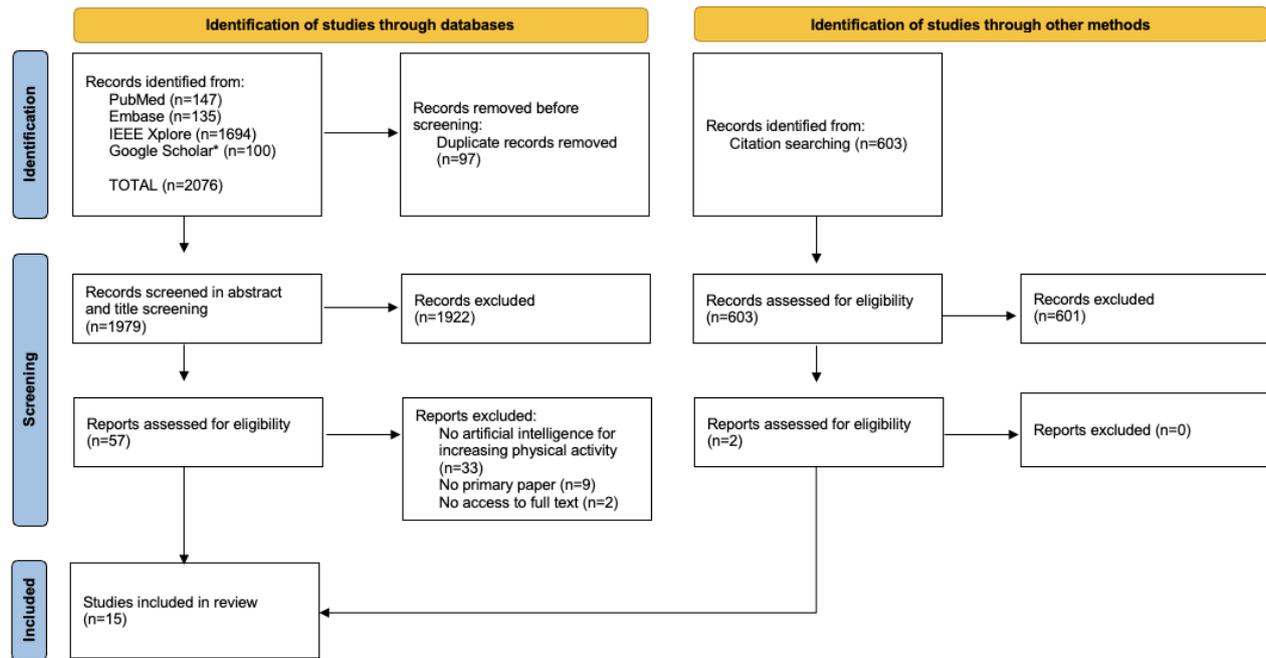

The certainty of the evidence on the outcomes was assessed by a single author (EG) by drawing on the GRADE (Grading of Recommendations Assessment, Development, and Evaluation) criteria [24] and verified by the rest of the coauthors.

Results

Study Selection

A total of 2076 articles were identified in the data search. After removing duplicates, 1979 titles and abstracts were screened for eligibility. Of those, 13 publications met the inclusion criteria [25-37]. The snowballing approach identified 2 additional publications [38,39]; therefore, the final number of publications included in this review was 15 ([Figure 1](#) shows the PRISMA [Preferred Reporting Items for Systematic Reviews and Meta-Analyses] flowchart).

Figure 1. Flowchart diagram of the selection process.

* Only 100 first entries chosen

The list of publications excluded during the full-text search and the reasons for their exclusion are reported in [Multimedia Appendix 2](#).

Description of the Included Publications

The 15 included articles were published between 2015 and 2023. Countries of origin of these studies were: United States (n=3) [25,26,36], Australia (n=2) [32,38], South Korea (n=2) [29,35], the Netherlands (n=1) [31], Italy (n=1) [27], Belgium and Italy (n=1) [30], Thailand (n=1) [37], and Taiwan (n=1) [33]. A total of 3 publications did not specify in which country the study was performed [28,34,39].

Regarding the study design, 8 publications followed a quasi-experimental approach [26-29,32,35,38,39], 5 were randomized controlled trials [25,30,33,36,37], and 2 were exploratory studies [31,34].

Only 4 of the 15 included publications explicitly mentioned their theoretical foundations. The following theoretical approaches were cited in these 4 publications: the Fogg Model for behavior change [25,31], Capability, Opportunity, and Motivation model of Behavior [32]; learning theory [25], social cognitive theory [25], and the Transtheoretical Model [39].

The main technical characteristics of the 15 included publications are presented in [Table 1](#).

Table 1. Main technical characteristics of the included artificial intelligence (AI)-based solutions.

^aRS: recommender system.

^bHAR: human activity recognition.

^cCA: conversational agent.

^dAIoT: artificial intelligence of things.

AI-Driven Technology and HFs

The most common AI technology type was recommender systems, described in 10 of the 15 included publications [25,26,29-31,33,35-37,39]. In addition to the recommender system, one of these publications also included computer vision [29]. Conversational agents were the second most used AI technology, as described in 4 publications [27,28,32,38]. One

of them was integrated into a social media platform, namely Slack [28]. One study tested human activity recognition [34]. Details of the AI technology, systems, or platforms used in the included studies are summarized in Table 1.

Regarding the considered HFs, the most commonly evaluated were acceptability [26,32,34,38,39] and satisfaction [29,34-37], both reported in 5 publications. Usability was the next most

considered and evaluated HF, as reported in 4 papers [29,31-33]. Usefulness was assessed in 2 publications [26,29]. Other considered and evaluated HFs were engagement [38], UX or individual perception [25], and task performance [34].

The studies that resulted in increased PA and had a moderate certainty of evidence were chatbot systems with integrated recommender systems. Although the usability of some of those systems was considered poor [32], they were perceived positively. Several papers gained interesting results regarding HFs. Given the variety of systems, a generalization for all 15 studies is difficult.

The automated collection of data needed for personalization and recommendation is an important aspect. In total, 5 systems involved fitness trackers [26,30,32,35,38] to enable automated data collection. They can be grouped into mobile-based activity tracking using movement sensors in the phone [25], dedicated fitness trackers [30,32,38], specifically an accelerometer in the wristband [30], Fitbit Flex 1 activity tracker (Fitbit LLC) [32], and Garmin Vivofit4 tracker (Garmin) [38], and smartwatches [35]. Rabbi et al [25] concluded that automated data collection would be useful. The studies involving chatbots concluded that users have high expectations regarding the chatbot’s knowledge and capabilities [28]. Human likeness is reported as a success factor of such systems. Relevant aspects leading to the efficacy of the system include the human-like qualities of the chatbot and the personalization of the suggestions [28,32,39], that is, chatbots or digital assistants should have a personality, have humor, be able to act with spontaneous behavior, and in a diverse, nonrepetitive manner [28,32]. They should provide the correct answers. For successful recommendations, it is essential to learn the personal preferences of users so that suggestions can be made that fit into personal routines and lifestyles [39].

Even a combination of human agents and digital agents was reported to be better accepted than pure virtual support [27]. Beyond that, access to a system anywhere and anytime is well

perceived [31]—and this is reflected by the fact that most systems included in this study are delivered as mobile apps (instead of desktop apps). Exercises and recommendations are successful in this setting when they can be easily integrated into the daily lives of the users [31].

Population, Interventions, and Comparison

A total of 899 individuals participated in the included publications. Of those, 60.7% (546) were female participants. The reported average ages of these participants ranged from 18.7 to 84.4 years. In total, 6 out of the 15 studies tested their solutions on participants with mean ages of around 50 years or older [28,31-33,37,38], while 6 studies predominantly included participants with a mean age of 40 years or younger [25,27,29,34,36,39]. Two studies did not specify the gender or age of participants [30,35].

The intervention of the included studies lasted between 2 and 26 weeks.

Prepost evaluations were carried out in 6 of the publications to evaluate the impact of the AI-driven intervention [26,29,32,35,38,39]. In 4 publications, control groups were used to assess the impact [25,30,34,36]. In 5 of the publications, the comparison methods used to assess the impact of the AI-driven intervention on increasing PA were not clearly reported [27,28,31,33,37].

Outcomes and Certainty of the Evidence

The effectiveness of AI-driven technologies for increasing PA was shown in 5 publications [28,32,36,38,39]. Three of these publications tested conversational agents [28,32,38], while the other 2 focused on recommender systems [36,39]. The analysis, based on GRADE guidelines, found moderate certainty in the evidence supporting this statement. Further details about the proven effect of these studies and the certainty of the evidence on these findings are reported in Table 2.

Table 2. Certainty of the evidence (artificial intelligence for increasing physical activity [PA]).

Outcome	Effect	Participants (studies)	Certainty of the evidence (GRADE ^a) ^b	Comment
<ul style="list-style-type: none"> Increased number of steps, distance walked, or time spent on PA Follow-up: mean 9.4 weeks 	<ul style="list-style-type: none"> Increased walked distance [36] exceeded step goal [28] more steps [32] increased walking minutes [39] increased time spent on PA [38] 	<ul style="list-style-type: none"> n=260 (3 pre-post studies, 1 RCT^c, and 1 observational study) 	B: moderate	We have a moderate level of confidence that the actual impact closely aligns with the estimated effect.
<ul style="list-style-type: none"> Change in PA behavior and abilities to perform behavior Follow-up: mean 13.3 weeks 	<ul style="list-style-type: none"> Feeling more stimulated to engage in PAs [30] change in walking behaviors [25] improved behaviors related to PA [35] improved ability to do sports [37] 	<ul style="list-style-type: none"> n=98 reported (number not explicitly reported in 2 studies) 3 RCTs, 1 pre-post study 	D: very low	We have a very low level of confidence in the estimated effect.

^aGRADE: Grading of Recommendations Assessment, Development, and Evaluation.

^bScale of 4 degrees, where A denotes the highest quality and D denotes the lowest quality.

^cRCT: randomized controlled trial.

In total, 4 of the included articles also showed that AI technologies have an effect on changing PA behavior (ie, feeling

more stimulated to engage in PAs, change in walking behavior, improved behavior related to PA, or improved ability to perform

PA) [25,30,35,37]. All these publications were recommender systems [25,30,35,37] and found a positive effect of AI-driven technology on changing PA behavior. However, the analysis, based on GRADE guidelines, found very low certainty evidence supporting this statement.

Discussion

Principal Results

In this scoping review, we aimed to identify and describe the current evidence on HFs in AI-driven digital solutions for increasing PA. The results showed that the most common AI technology used in digital solutions for PA was recommender

systems, followed by conversational agents. User acceptability and satisfaction were the most commonly evaluated HFs in the included studies. Some studies also evaluated the usability of AI-driven digital solutions for PA.

We have identified studies that provide evidence that AI-driven digital technologies have the potential to increase PA (eg, number of steps, distance walked, or time spent on PA). Furthermore, AI-driven technology, particularly recommender systems and chatbots, seems to have the potential to influence changes in PA behavior. Although these studies offer valuable insights by demonstrating positive outcomes through various AI-driven technologies for enhancing PA, the evidence is still very limited. The main findings are presented in [Table 3](#).

Table 3. Summary of main findings.

Included in review	Findings (N=15 studies; covering a total of 899 study participants)
Interventions duration	<ul style="list-style-type: none"> Interventions lasted between 2 and 26 weeks
Used AI ^a technologies	<ul style="list-style-type: none"> Recommender systems (described in 10/15 studies) Conversational agents (described in 4/15 studies) Human activity recognition (described in 1 study)
Human factors	<ul style="list-style-type: none"> Acceptability (evaluated in 5/15 studies) Satisfaction (evaluated in 5/15 studies) Usability (evaluated in 4/15 studies) Usefulness (evaluated in 2/15 studies) Engagement (evaluated in 1 study) User experience (evaluated in 1 study) Task performance (evaluated in 1 study)
Effectiveness of AI-driven technologies for increasing PA ^b	<ul style="list-style-type: none"> Moderate evidence: AI-driven digital technologies have the potential to increase PA (eg, number of steps, distance walked, or time spent on PA) Very low evidence: Recommender systems and chatbots, seems to have the potential to influence changes in PA behavior

^aAI: artificial intelligence.

^bPA: physical activity.

Comparison With Previous Work

In the included studies, we recognized several benefits of AI integrated into digital solutions for increasing PA, such as the ability to adapt the solution to the patient's physical capacity, current activity, and psychological profile [8,11,30]. AI can monitor activity and inactivity and predict bodily occurrences, which is especially relevant for older people [40]. AI can also simulate the role of a personal trainer, provide guidance, form correction, and motivation [37] through voice- or text-based interactions. Users can receive real-time feedback and support during their workouts [8,10] which would be difficult to achieve with non-AI digital solutions. AI algorithms can analyze user data such as fitness levels, health conditions, and preferences and provide personalized exercise recommendations [11]. The activities or other suggestions are tailored to the specific needs and goals of the user, increasing the likelihood of adherence. Real-time feedback can be shared with the user. Previous studies found that activity tracking combined with real-time, personalized text messages can significantly increase PA and further affirm text messaging as an effective health behavior modifier [10-12]. However, in our review, researchers concluded that their solution did not achieve sufficient adherence to the

exercise program [28,30]. The entire potential of personalization techniques has not yet been implemented in the solutions, as Luštrek et al [30] concluded that personalization, simplicity, ease of use, and avoiding information overload could be improved.

AI algorithms can continuously learn from user interactions and feedback to refine and improve the UX. This iterative process leads to more effective and engaging solutions over time. For example, the continuous interaction that chatbots can provide was reported to be useful in helping users increase regular PA and in helping them stay motivated to participate in PA [32]. Studies have already found that the human-likeness or anthropomorphisms of a chatbot increase the likelihood that users comply with the chatbot's recommendations [18]. Roy and Naidoo [17] found that human qualities like warmth and competence are contributing to a positive UX and possibly to an increased adherence to the digital solution [17].

We only found 5 studies involving sensors to measure PA [26,30,32,35,38]. Dedicated fitness trackers seem to be more prominent to be involved in solutions increasing PA. Mobile-based activity tracking and smartwatches were only implemented in one solution. A reason might be that users prefer

to use systems they already use; that is, integration with existing tools like fitness trackers is desired by users, as found by Wang et al [41]. The landscape of wearables and sensors that could be used for PA tracking is much larger than was found in our research [42]. The integration of sensors with AI could help analyze the data streams and promote an increase in PA [43]. Additionally, it could assist in monitoring PA among individuals affected by health conditions [44-46]. We hypothesize that existing research focuses on sensors that are well-known, not very intrusive, and therefore probably more accepted by users of solutions for increasing PA.

AI can gamify the fitness experience by setting challenges, goals, and rewards. Users are motivated to increase PA by earning points, competing with friends, or unlocking achievements. Xu et al [16] found in their review that gamification interventions could increase PA participation. Interestingly, none of our included studies explicitly reported about gamification elements.

Do We Have Enough Evidence on AI's Effectiveness in Increasing PA?

In total, 5 of the included studies provide moderate evidence of AI's effectiveness for increasing PA [28,32,36,38,39]. However, these studies involve short interventions lasting from 6 to 12 weeks. Hence, the significant effect might be influenced by this brief follow-up period, similar to other mHealth interventions [13]. The estimated time needed to form habits of complex behaviors such as exercise behavior is 12 weeks [47]. Thus, longer intervention studies are needed to assess the potential long-term effectiveness of AI-driven technologies for increasing PA.

Out of the 260 participants in these 5 studies [28,32,36,38,39], 72.3% (188) of them were women, and the majority were aged between 40 and 50 years. Further studies are needed to investigate the effects of these AI-driven technologies on participants with different sociodemographic characteristics, as well as those with health conditions for which exercise aids in managing the disease and preventing complications [1,2,4].

There is very limited and low-quality evidence supporting the impact of AI-driven technologies on changing PA behavior and the ability to perform such behavior [25,30,35,37]. In these cases, the durations of the interventions varied, ranging from as short as 3 to 4 weeks [25,37], to as long as 20 to 26 weeks [30,35]. Similar to previous cases, the majority of participants in these 4 studies were women, comprising 83.7% (82/98) reported participants. While research indicates that gender is one of the factors influencing the use of health-related technologies [48,49], technologies aimed at increasing PA should be tested, personalized, and accessible for all demographic groups.

What Is the Role of HFs on the AI-Based PA Solutions?

Most of the included AI-based PA systems showed positive results in terms of HFs related to their use. However, no study aimed to evaluate how the AI component could independently influence HFs such as user acceptance, perceived ease of use, or perceived usefulness. Many studies used AI techniques to personalize the PA system based on the authors' assumptions

about the persuasive power of personalization that could lead to greater motivation and thus result in greater intention to use, adoption, and engagement. However, no study has tested these hypotheses. In this regard, more research is still needed to identify the role of AI components in HFs affecting PA systems. In addition, no study has focused on whether the inclusion of AI could lead to a change in the role of HFs, as has been the case with traditional technologies.

Limitations

There were some identified limitations in this scoping review. Even though we did not have a language limitation in the search strategy, all the included studies were in English. Therefore, we could have missed relevant AI-driven solutions published in other languages. The included studies were mainly from diverse high-income countries, restricting generalization to low- and middle-income countries. In addition, the studies included in the scoping review had an intervention period of a maximum of 26 weeks, showing only the short-term effect of the AI-driven solutions. All studies were included in the review, irrespective of the assessed quality of the evidence. However, the results of the included studies were reported separately according to the quality of the evidence, minimizing misinterpretation of the data.

Conclusions

This study synthesized current evidence on the effectiveness and potential of AI-driven digital solutions for increasing PA. Although the included studies offer valuable insights by demonstrating positive outcomes through various AI-driven technologies for enhancing PA, the evidence is still very limited. While some studies demonstrated moderate evidence of AI's effectiveness in increasing PA, these interventions were typically short-term. Longer-term studies are necessary to assess the sustained impact of AI-driven technologies on behavior change and habit formation. Additionally, further research is needed to investigate the effects of AI-driven interventions on diverse populations, including individuals with varying sociodemographic characteristics and conditions. Moreover, the evidence regarding the impact of AI-driven technologies on changing PA behavior remains limited and of low quality. There is a need for rigorous studies to evaluate the effectiveness of these interventions, particularly in terms of their ability to induce long-term behavior change. Furthermore, while most AI-based PA systems demonstrated positive results in terms of UX, there is a lack of research focusing on the independent influence of AI components on HFs, such as user acceptance and perceived usefulness. Additionally, more investigation is required to understand how the inclusion of AI may alter the role of HFs in PA systems compared to traditional technologies.

In conclusion, while AI-driven digital solutions hold significant promise for promoting PA and improving public health outcomes, addressing these limitations and challenges will be crucial for maximizing their effectiveness and accessibility. Continued research efforts in these areas are essential for advancing our understanding of the role of AI in PA promotion and ensuring the development of evidence-based interventions that benefit diverse populations.

Abstract

Background: Self-management is endorsed in clinical practice guidelines for the care of musculoskeletal pain. In a randomized clinical trial, we tested the effectiveness of an artificial intelligence–based self-management app (selfBACK) as an adjunct to usual care for patients with low back and neck pain referred to specialist care.

Objective: This study is a process evaluation aiming to explore patients' engagement and experiences with the selfBACK app and specialist health care practitioners' views on adopting digital self-management tools in their clinical practice.

Methods: App usage analytics in the first 12 weeks were used to explore patients' engagement with the SELFBACK app. Among the 99 patients allocated to the SELFBACK interventions, a purposive sample of 11 patients (aged 27–75 years, 8 female) was selected for semistructured individual interviews based on app usage. Two focus group interviews were conducted with specialist health care practitioners (n=9). Interviews were analyzed using thematic analysis.

Results: Nearly one-third of patients never accessed the app, and one-third were low users. Three themes were identified from interviews with patients and health care practitioners: (1) overall impression of the app, where patients discussed the interface and content of the app, reported on usability issues, and described their app usage; (2) perceived value of the app, where patients and health care practitioners described the primary value of the app and its potential to supplement usual care; and (3) suggestions for future use, where patients and health care practitioners addressed aspects they believed would determine acceptance.

Conclusions: Although the app's uptake was relatively low, both patients and health care practitioners had a positive opinion about adopting an app-based self-management intervention for low back and neck pain as an add-on to usual care. Both described that the app could reassure patients by providing trustworthy information, thus empowering them to take actions on their own. Factors influencing app acceptance and engagement, such as content relevance, tailoring, trust, and usability properties, were identified.

Trial Registration: ClinicalTrials.gov NCT04463043; <https://clinicaltrials.gov/study/NCT04463043>

Introduction

Low back pain and neck pain are the main causes of disability worldwide [1]. Up to 30% of patients with acute or recurrent disability develop persistent pain [2,3]. Patients with persistent pain are often work-disabled and might need specialist assessment, which further increases health care and societal costs [4]. Given the highly prevalent and costly nature of low back and neck pain, enabling patients to self-manage constitutes an important strategy for reducing the individual and societal burden.

Self-management is commonly defined as an individual's ability to actively monitor own health condition, adapt to physical and psychological demands, and implement lifestyle changes [5]. While self-management is endorsed in clinical practice guidelines to manage musculoskeletal pain [6], self-management support offered in clinical practice, for example, primary and specialist care, remains suboptimal [7,8]. Digital interventions such as smartphone apps can be a viable mode for delivering self-management support as an add-on to usual care due to their accessibility and possibility of making evidence-based advice easily available to patients.

We recently reported results from a randomized clinical trial (RCT) testing the effectiveness of an artificial intelligence (AI)-based self-management app (selfBACK) as an adjunct to usual care for patients with low back and neck pain in specialist care [9]. The app uses the case-based reasoning methodology, which is a branch of knowledge-driven AI [10] providing individually tailored self-management recommendations to users. Although individual tailoring is considered as an important feature for engagement in self-management interventions [11], the RCT did not show the SELFBACK app to be more effective than usual care alone or a web-based self-management intervention in improving self-reported musculoskeletal health. The aim of this study was to explore patients' engagement and experiences with the selfBACK app and specialist health care practitioners' views on adopting such digital self-management tools in their clinical practice.

Methods

Study Design and Context

This study is a process evaluation carried out in parallel with the RCT [9]. The qualitative part of the study is reported according to the consolidated criteria for reporting qualitative research (COREQ) [12].

Recruitment for the RCT took place at the multidisciplinary outpatient clinic for back-, neck-, and shoulder pain at St Olavs Hospital, Trondheim, Norway. Patients with low back and neck

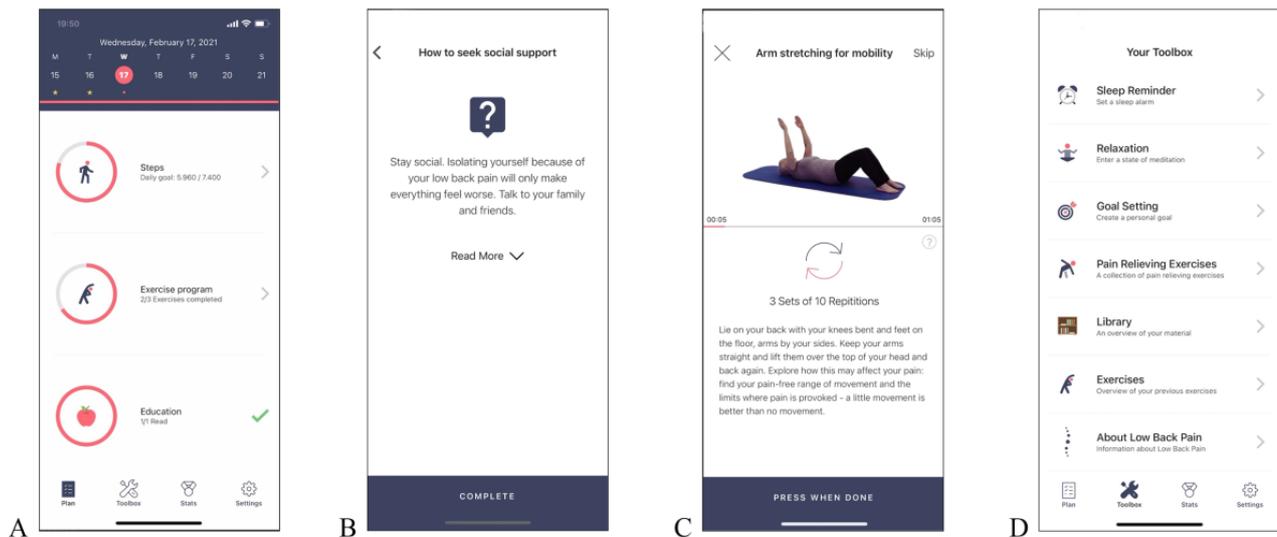

pain who were referred and on a waiting list for a consultation at the clinic were invited to the study via SMS text message. Interested and eligible patients were subsequently randomized to (1) the selfBACK app adjunct to usual care (99/294, 33.7%); (2) the e-Help (a self-management website) adjunct to usual care (98/294, 33.3%); and (3) usual care only (97/294, 33.0%). Usual care consisted of a waiting period of approximately 6-8 weeks before a consultation, including a clinical examination, followed by recommendations for suitable treatment. The recommendations could vary from no further treatment and adjusted recommendations for primary care treatment to outpatient multimodal rehabilitation or referral for surgery.

The process evaluation consisted of descriptive data analytics on app usage and semistructured interviews involving patients allocated to the selfBACK intervention. In addition, health care practitioners at the outpatient clinic were invited to participate in focus group interviews with the purpose of exploring their views on adopting digital tools for self-management support in their clinical practice. While health care practitioners were aware of the trial, they were not provided any specific instructions in relation to the trial conduct.

SELFBACK App as an Adjunct to Usual Care

The SELFBACK intervention was developed using intervention mapping [13] and underwent iterative pilot-testing before the final version was released [14,15]. The SELFBACK is an AI-based self-management app that provides users with weekly and individually tailored plans encompassing physical activity recommendations, strength and flexibility exercises, and educational messages (updated daily). In addition, the app contains a toolbox, which is a static component of the app containing, for example, goal-setting tool, mindfulness audios, pain-relieving exercises, and sleep reminders that patients can access at their own convenience [16] (Figure 1). The tailoring of patient recommendations delivered via the app relies on the application of case-based reasoning [10], a knowledge-driven AI methodology. In this methodology, knowledge from previous similar successful patient cases is reused to offer patient-centered and tailored recommendations. Thereby, new and similar patient cases receive recommendations based on what has or has not been successful in previous patient cases [17]. The AI system uses weekly reports (eg, symptom progression) and information collected through the app (eg, exercise completion and number of steps) to personalize the self-management recommendations. Patients can collect badges and rewards within the app by adhering to weekly recommendations. Push notifications are triggered by patients' self-management behavior (eg, completion of exercises) and sent via the app to motivate and reinforce the desired self-management behavior.

Figure 1. SELFBACK app screen views. (A) Home screen containing the 3 main components of the app, that is, steps achieved, exercise completion, and educational messages read. (B) Example of an educational message. (C) Example of exercise. (D) Toolbox screen containing additional resources.

The selfBACK app was offered as an adjunct to usual care. Patients randomized to the SELFBACK group were sent an SMS with a link to download the app. They were also provided with an installation guide and contact information of the research team if they had any access issues. Instructions on how to use the app and its content was provided within the app and patients had unrestricted access throughout the 6-month study period.

App Usage Data Analytics

Data on app usage consisted of information about number of weekly plans generated, number of app access per week, and specific content visited. For weekly plans to be generated, the patient needed to access the app and complete the weekly short-tailoring questionnaire (eg, questions on pain intensity, self-efficacy level, and fear avoidance level). The number of weekly plans generated was used to dichotomize patients into moderate or high users and low users as basis for a purposive recruitment for interviews. Moderate or high use was defined as generating at least 6 plans during the first 12 weeks after first access of the app, while low use was defined as generating less than 6 plans as described previously [9]. This information together with the number of app access per week was retrieved from the back end of the AI system, which has information when users actively interact with the app (completing exercises, tailoring sessions, or similar). Information about number of days a specific content was visited per week (eg, exercises, educational component, and toolbox) was retrieved from Matomo [18], a free and open-source software that records whenever a user accesses a screen of the app.

Interviews With Patients and Health Care Practitioners

A purposive sample of 15 patients was contacted by phone and invited for interviews according to their app usage (ie, number of weekly plans generated). Of these, 3 declined participation and 1 did not answer. A total of 11 patients were interviewed (aged 27-75 years, 8 female), of whom 7 were moderate or high app users and 4 were low users.

Health care practitioners from the multidisciplinary outpatient clinic (n=11) were informed about the study during a regular

staff meeting and invited to participate in focus group interviews. Overall, 9 health care practitioners expressed an interest in participating and were included. Two focus groups were formed based on the role the health care practitioners had at the clinic. One focus group (focus group 1) included 3 physiotherapists and 2 social workers (aged 32-51 years, 4 female) with 5-13 years of working experience at the outpatient clinic. The other group (focus group 2) included 4 physicians (aged 32-42 years, 3 female) with working experience at the outpatient clinic ranging from 1 week to 7 years.

The interviews with patients and health care practitioners were performed by a research assistant with prior experience of conducting qualitative interviews and no prior relationship with patients or health care practitioners. Patients were interviewed individually via Skype between January and February 2021. The interview guide was semistructured and developed using the Normalization Process Theory [19,20]. The questions included background information, the motivation to join the study, how pain was managed before the study, what facilitated or hindered the use of the app, how the app was integrated in daily life, future intentions to use the app, and general thoughts about self-management. Questions were adapted when needed and follow-up questions added where appropriate. Each interview lasted approximately 45 minutes and was recorded with the patient's permission. One interview was repeated due to failure of the recording.

The focus groups took place digitally via the Zoom (Zoom Video Communications) platform in February 2021. Prior to the focus groups, health care practitioners were provided with an overview of the selfBACK app by the research team and access to the app. They were asked about their initial impressions of the selfBACK app, their views on digital tools to support self-management, whether and how they would use them in clinical practice, what potential benefits and risks such tools entailed, whether they believed that using them could affect their professional autonomy, and whether such digital tools could be trusted. Each focus group lasted approximately 90 minutes and was facilitated by 2 research assistants (one

acting as an observer). At the end of each focus group, the 2 researchers exchanged experiences on the interaction among health care practitioners and these were annotated. Both interviews and focus groups were audio recorded with the permission of all participants and transcribed verbatim. Data were de-identified during transcription and used thereafter for data analysis.

Data Analysis

Baseline characteristics of all patients were reported descriptively. Interviews and focus groups data were analyzed using thematic analysis [20]. First, ALN and AM read and coded the interview transcripts with the support from the research assistant who transcribed the interviews to ensure that coding was reflective of the material. The codes were then grouped into themes by a process of constantly deliberating their content and boundaries, resulting in 2 coding trees for the patients and health care practitioners, respectively. These were subsequently discussed with 2 researchers in the team (NK and LA) who had read all the interview transcripts. As the 2 coding trees were found to largely contain complementary themes, they were combined before writing up the results. Quotations were added to either exemplify or nuance the analytic text.

Ethical Considerations

The RCT was registered in ClinicalTrials.gov (NCT04463043), and the protocol, including the description of the process evaluation, was published [21]. Ethics approval was granted by the Regional Committee for Medical and Health Research Ethics in Central Norway (reference 64084) and the Norwegian Medicines Agency (reference 20/10329-10). All patients provided written informed consent before entering the study.

Health care practitioners were provided with oral information about the study and verbal informed consent was obtained from them before the focus groups were conducted.

Results

App Usage

The demographic and clinical characteristics of the 99 patients allocated to the selfBACK intervention stratified by app usage are shown in [Table 1](#). Overall, patients' characteristics were similar across groups, although a greater proportion of patients who never accessed the app or who were low users reported having daily pain as well as having both neck and back pain compared with moderate or high users who reported pain less frequently and predominantly pain at the lower back ([Table 1](#)).

Table 1. Demographic and clinical characteristics of the 99 patients allocated to SELFBACK intervention, stratified by app usage.

	Never accessed app	Low usage group ^a	Moderate or high usage group ^b
Participants, n (%)	29 (29.3)	32 (32.3)	38 (38.4)
Age (years), mean (SD)	52.3 (11.5)	47.8 (14.2)	50.8 (16.4)
Women, n (%)	17 (58.6)	19 (59.4)	24 (63.2)
Education (years), n (%)			
>12	16 (26.2)	19 (31.2)	26 (42.6)
10-12	9 (32.1)	10 (35.7)	9 (32.1)
<10	4 (40.0)	3 (30.0)	3 (30.0)
Full-time or part-time employment, n (%)	19 (65.5)	25 (78.1)	26 (68.4)
Married or living with partner, n (%)	20 (69.0)	23 (71.9)	29 (76.3)
Pain localization, n (%)			
Low back pain	13 (25.0)	16 (30.8)	23 (44.2)
Neck pain	6 (24.0)	11 (44.0)	8 (32.0)
Neck and low back pain	10 (45.5)	5 (22.7)	7 (31.8)
Days with pain past year, n (%)			
≤30 days	3 (42.9)	1 (14.2)	3 (42.9)
>30 days but not every day	7 (18.4)	10 (26.3)	21 (55.3)
Every day	19 (35.2)	21 (38.9)	14 (25.9)
Use of pain medication (days per week), n (%)			
None	8 (28.6)	9 (32.1)	11 (39.3)
1-2 days	8 (40.0)	5 (25.0)	7 (35.0)
3-5 days	7 (31.8)	6 (27.3)	9 (40.9)
Daily	6 (20.7)	12 (41.4)	11 (37.9)
Musculoskeletal Health Questionnaire (score range 0-56), mean (SD)	30.9 (9.0)	28.4 (8.6)	30.8 (9.6)
Average pain intensity level past week ^c (score range 0-10), mean (SD)	5.7 (2.4)	5.5 (1.6)	4.8 (2.0)
Worst pain intensity level past week ^c (score range 0-10), mean (SD)	6.9 (2.3)	7.3 (1.6)	6.3 (2.1)
Health-related quality of life ^d (score range 0-100), mean (SD)	52.7 (20.6)	56.3 (14.1)	57.5 (19.2)
Pain Self-Efficacy Questionnaire (score range 0-60), mean (SD)	37.8 (13.7)	36.5 (14.0)	39.3 (12.1)

^aLow usage group comprises patients who generated less than 6 of 12 weekly plans.

^bModerate or high usage group comprises patients who generated 6 of 12 weekly plans.

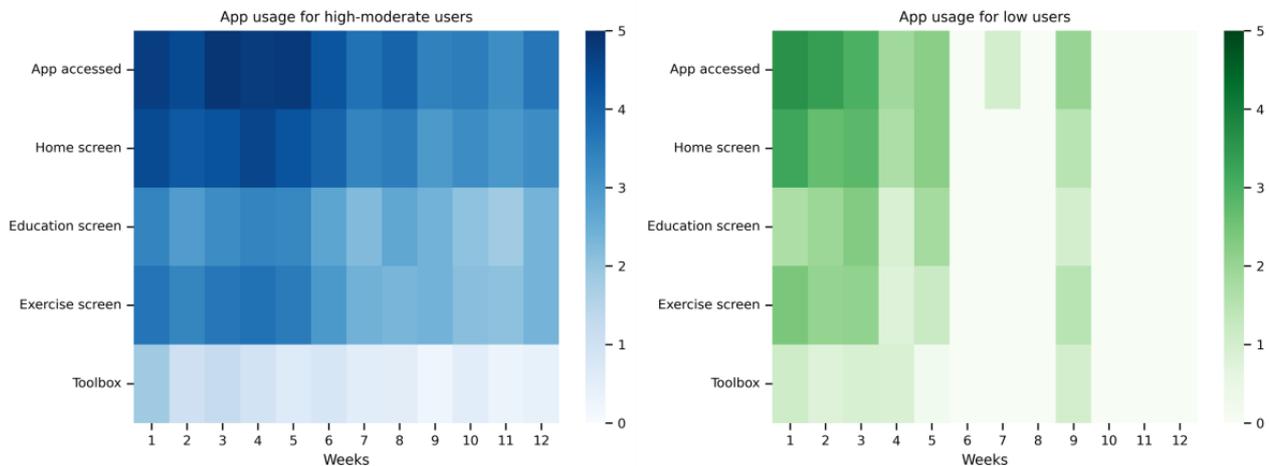

^cMeasured by the Numeric Rating Scale.

^dMeasured by the Visual Analogue Scale in the EQ-5D.

Figure 2 shows usage of each app components in the first 12 weeks stratified by usage group. Patients in the moderate or high usage group accessed the app, on average, most days of the week (ie, 4-5 days) for the first 5 weeks and somewhat reduced the frequency of weekly app access thereafter. The most visited content was the exercises, followed by the

educational messages which were accessed, on average, more than once a week throughout the 12 weeks. The toolbox (ie, the static component of the app) was visited the least (Figure 2). Patients in the low usage group accessed the app, on average, fewer days per week from the beginning and mostly discontinued use after 5 weeks (Figure 2).

Figure 2. Average number of days each app component was visited in the first 12 weeks. Moderate or high users are shown on the left and low users are shown on the right. The bar to the right of each graph indicates the shading according to the average number of days each component was visited. App-accessed row shows any interaction with the app. Home screen, education screen, exercise screen, and toolbox rows represent the main components of the app shown in Figures 1A-D. Only those users who accessed the app at least once (n=70) are shown.

Interviews With Patients and Health Care Practitioners

We found that the interviews with patients and health care practitioners generated valuable information on their overall impression of the app, its perceived value, and suggestions for future use.

Theme 1: Overall Impression of the App

Patients discussed the interface and content of the app, reported on usability issues, and described their app usage.

App Interface and Content

Most patients described the app's user interface as simple and intuitive, with a user-friendly layout that was easy to navigate. Both patients and health care practitioners appreciated how the information was presented, for example, short and structured, and receiving a weekly plan was a convenient feature some patients valued.

You get a full program. You don't have to make it yourself. You are reminded and guided through the exercises so that you do not have to think and remember and count. [Female, 50 years, low user]

When describing the content of the app, patients in both usage groups talked extensively about the exercise component. Indeed, being instructed on specific exercises was one of the main motivations for joining the study for most, and the integrated exercise videos were a feature they highly valued. Many also described that while they were often familiar with the educational content in the app, this nevertheless served as valuable reminders in their daily life. However, being familiar with the exercises and the educational content in the selfBACK app also resulted in some patients becoming unmotivated. In addition, some patients found the app's content to be tailored to their individual needs, while others believed that the content was of low relevance to them.

I thought that the exercises were very neutral, and I didn't get an exercise that suited my injury. [Female, 46 years, low user]

Usability

Many patients in both user groups reported various technical problems when using the app. In the low usage group, some found the onboarding procedure burdensome and lost motivation to use the app. Several patients also had technical difficulties with step synchronization (ie, between the selfBACK app and health apps registering steps), which made them frustrated as notifications encouraging physical activity felt inappropriate when they had been active, and since they did not get validation when achieving their goals. In addition, some patients mentioned difficulties in scoring the weekly questions about their symptoms and function or not finding them relevant, although this issue did not prevent them from using the app. One patient also reported that the audio in the mindfulness section was difficult to hear due to a hearing impairment, and even though this feature felt relevant, they could not use it.

Usage Behavior

When describing how they used the app, most patients in the high usage group said that they used it regularly at the beginning and then gradually discontinued use. Some reported that, over time, they felt less need to access the app content and register their activity, mainly since their pain symptoms subsided.

My back improved, and I don't have the same need to use it and getting that recognition for progression and so on. [Male, 27 years, high user]

Some patients commented that they performed the exercises in the app in combination with other exercises they already knew from before or with pain-relieving exercises in the toolbox (a static library of exercises within the app).

Theme 2: Perceived Value

Patients and health care practitioners described the primary value of the app as providing reassurance to patients by offering trustworthy information, thereby empowering them to self-manage. They also described the potential of the app to supplement usual care.

Providing Reassurance

Several patients described feeling reassured by the information in the app and experiencing exercises as manageable and not harmful.

These three things [components on the main page of the app] together give you some input at least during a period where you're unsure of what you can do, because it hurts really bad. And then the app comes with a little advice: okay, even if you're in pain then it doesn't get worse or, yes, it's unlikely to get much worse. And I believe that has helped. [Female, 54 years, high user]

Most patients reflected on how recommendations encouraging activity in the selfBACK app also aligned with advice from chiropractors and physiotherapists they had consulted previously. As such, the coherence between the information in the app and health care personnel reassured them that the information and exercises could be trusted. On the contrary, 1 patient experienced that her health care practitioner did not endorse the advice provided by the app and, as a result, she discontinued using it, feeling insecure about its appropriateness for her situation.

I showed my therapist [chiropractor] the exercise, and he said right away: "you shouldn't do that exercise. Because then you make it worse for yourself". [Female, 46 years, low user]

Health care practitioners underlined the need to present patients with reassuring language. The app was described as an opportunity to prevent patients from getting information from unreliable sources on the internet and provide patients with up-to-date, reliable, and consistent information that reinforced their message.

Knowing that the information is given via the health service can be reassuring, and they [the patients] may be more confident that it is nuanced and correct. They can go back and see "yes, that's consistent with what the doctor said". [Female, focus group 2]

In line with this, some patients also described how their confidence in digital tools would increase if a health care practitioner or other trustworthy sources had developed or endorsed them in contrast with commercial parties.

One patient also described valuing how an app was made specifically for her health condition and that digital tools in general made her feel taken care of and included.

You can say that even if it's a robot, just the fact that you get a message, one feels taken care of in some way. And feeling like you're not alone in what you're struggling with, the app becomes a symbol that there are many others who are struggling with it [musculoskeletal pain]. [Female, 50 years, low user]

Empowering Patients to Self-Manage

Some patients described that using the app supported them on the road to becoming more active and that their confidence and thoughts about self-management increased while using it.

I'm just going to have to try on my own now. What's working and what's not working. It's not that I'm afraid something's dangerous anymore. [Female, 44 years, high user]

Some also pointed out that although the information about self-management was perhaps well known to them, it nevertheless encouraged the thought of being able to act on one's own.

It has helped to think a little more positively and, yes, that you can do a lot yourself. This kind of things you know deep down, but it's about getting a little help to put your thoughts on the right track. [Female, 54 years, high user]

Some patients described features such as reminders and activity tracking as positive influences on motivation to be active, and these also served as a reminder of how much they achieved. Health care practitioners similarly believed that digital tools such as the selfBACK app could help encourage patients' active participation in rehabilitation. The interactive features (eg, goal setting) and accessibility of the app were also mentioned as elements that can promote and reinforce self-management behaviors.

A nice thing is that you could make your own personal goal [...], you have to take a position on some questions. For example, you are asked a lot about this goal, whether it is realistic, how long it should last. So, you have to make some active choices. [Male, focus group 1]

One physiotherapist described this active approach as taking responsibility instead of clientification, a point also reflected in the statements of many patients.

There is something that we hope [to achieve] in collaboration with the patient, which is to make them accountable, so that the patient sits in the driver seat. [Female, focus group 1]

Supplementing Usual Care

Both patients and health care practitioners believed that the selfBACK app could be a valuable supplement to usual care. When reflecting on how digital tools can help in taking responsibility for one's health, several described it as a necessity and solution to the increasing pressure on health care services.

Adopting an app such as selfBACK in clinical practice was described by both patients and health care practitioners as valuable to compensate for current organizational constraints (eg, long waiting time for the first consultation at the clinic, short consultations, limited service for people living in remote areas, and as a supplement to the physiotherapy service). One physician added how being active in advance could be helpful during consultations since the patients would then find it easier to explain their difficulties. Another physician described how the app positively impacted patients' health while awaiting health care assessment.

There is a long waiting time to get an appointment with us. Some patients have already gotten much better when they meet at the first appointment with

me because they have started with physical activity and exercises on their own through the app [...]. I think it is a great way to get them started. [Female, focus group 2]

Others underlined how the app could also help maintain continuity for patients between consultations or cut down on the number of consultations, and some described the app as a way to support patients benefitting from less-intensive treatment. Therefore, the app was seen as a potential aid in allocating health care resources more appropriately to those needing it the most.

We have talked a lot about who is the right patient for us. And then we concluded that the so-called simple patients, those who can get help, for example, from an app by taking some steps in their lives that enable them to function, might not be the right patients for us. [...] So, if we have a tool that we feel is good and can help some of these patients, it is fantastic. Then we handle the more complex cases, where an app is not sufficient. [Female, focus group 1]

However, patients and health care practitioners emphasized that digital tools such as the selfBACK app should be regarded only as a supplement to usual care and not as a replacement. One patient explained how she believed that severe conditions should be ruled out first, which 1 physician also underlined when describing how many patients are not reassured by solely receiving information, for instance, when experiencing radiating pain. Another physician also described how normalizing pain in some, yet very few cases, can be inappropriate, and that the app should be combined with a health care consultation in such cases.

Several patients also underlined how their trust in and enthusiasm for technological tools did not imply that it could substitute the human contact offered by consultations with health care practitioners due to the value such interpersonal relationships represent. Similarly, the health care practitioners commented that they did not feel that the selfBACK app would interfere with their professional autonomy, seeing their role as essential.

Even if the app, based on how the patients respond to questionnaires, is customised and makes individual adaptations, it will never be able to do what a physician might do, see the patient in a larger perspective. [Female, focus group 2]

Theme 3: Suggestions for Future Use

Although patients and health care practitioners felt positive about the possibility of adopting tools such as the selfBACK app and making progress on their own, they addressed several aspects they believed would determine acceptance. Many suggestions for change aligned with the difficulties described in the overall impression of the app regarding usability and content.

Some health care practitioners mentioned that the start-up process should be made more efficient if patients were to adopt the selfback app. Although patients and health care practitioners highlighted the possibility of replacing exercises as a valuable

feature, some patients wished for an opportunity to provide feedback or point out the issues they experienced. Some patients also felt that they would have benefitted from more instructions within the app, for example, describing the frequency and purpose of the exercises, a point also reflected on by some physiotherapists.

Physiotherapists also said that the extensive focus on exercises was less beneficial than instructing patients to find an activity they liked to start being active. In addition, they pointed out that some exercise descriptions potentially undermined the main message of the app that activity is not harmful by communicating the opposite impression.

It [the app] uses words like “careful, controlled movement”. Then you are communicating that you can potentially destroy something. [Female, focus group 1]

Some physiotherapists and social workers also suggested that information on how other aspects, such as anxiety and depression, contribute to the feeling of pain should be highlighted within the app. In addition, 1 physiotherapist found the goal setting in the app so important to patients' rehabilitation processes that they suggested that it should be made mandatory to fill it in to proceed further.

Health care practitioners also reflected on aspects facilitating implementation in clinical practice. One stated how it would be beneficial to refer patients to something specific, such as the app, instead of a general call for “being active.” Physiotherapists and social workers commented that having access to patients' interaction with the app would enable them to integrate it into their clinical routine. This point was also reflected by a statement from a patient.

It's nice if you have such an app, which you can choose to get and use yourself. Then you might get a follow-up with a doctor by phone or something like that asking: “What is the status now?”. And the doctor might also be able to see the updates in the app and what you have posted. It is a tool for both the doctor and the patient if both have access to the results of such an app. [Female, 59 years, low user]

Discussion

Principal Findings

This study explored the engagement and experiences with an app-based self-management support system (selfback) for patients with low back and neck pain referred to specialist care, and health care practitioners' views on adopting such digital tools in their clinical practice. Overall, patients' experiences and health care practitioners' perception of the app largely overlapped. Both had a positive attitude toward adopting app-based self-management support in this setting and saw a large potential in the selfback app to supplement usual care. Both described how the app can reassure patients by providing trustworthy information, thereby empowering them to take action on their own. Usability properties, content relevance, and the role of health care professionals were identified as

important elements influencing acceptance and further engagement with the app.

While patients and clinicians were positive about the adoption of app-based self-management support for low back and neck pain as a supplement to usual care, the uptake of the intervention across patients enrolled in the RCT was relatively low. This somewhat differed from the SELFBACK trial in primary care, where nearly two-thirds of patients sustained use throughout 12 weeks [22,23]. Such differences might be partly explained by the onboarding procedures used, as well as by the study setting, that is, patients waiting for further consultation after referral to specialist care might be less prone or motivated to explore self-management interventions. Furthermore, low or nonusers in our study reported greater pain frequency and more widespread pain than moderate or high users. More burdensome health conditions, for example, having comorbidities or high symptom severity, have been suggested to be a barrier for engaging with self-management interventions [24,25]. Thus, understanding how the heterogeneity in clinical features might affect the uptake and engagement of self-management interventions should be explored further, particularly since greater symptom burden does not seem to modify the effect of such interventions [26-28].

Successful implementation of digital interventions relies, at least in part, on patients' acceptance of the intervention. Patients indicated that factors promoting the app's adoption included that it was easy to use, convenient, and provided structured and tailored information (eg, weekly plans). Furthermore, some patients described that knowing that the app was coming from a trustworthy source (ie, health care system or university) facilitated acceptance. On the contrary, technical difficulties, perceiving the content as irrelevant or not new, and lack of endorsement from the health care practitioner hindered some users from adopting the app. These elements are in line with existing acceptance models positing that perceived ease of use, perceived usefulness, and trusting beliefs in health care providers (or vendors) are, among other factors [29], significant predictors of behavioral intention in digital interventions [30,31].

Ensuring adequate engagement is a prerequisite for the effectiveness of app-based interventions [32]. Some patients described how notifications, activity tracking, and rewards helped them stay engaged with the app's content, emphasizing the importance of interactive, tailored support for sustaining self-management behaviors [11]. Such reminders seemed particularly relevant in the first phase of use, as some patients reported not having the need to log their activities or getting the recognition of achievements once the symptoms subsided. This use pattern has been described in previous digital interventions for low back pain [22,25]. The fact that some patients perceived the app as a supporter and tailored to one's individual needs suggests a form of therapeutic alliance with the digital interaction [33], which is an important enabler of self-management [24] and has been linked with increased engagement [34]. Conversely, perceiving the app as too general and irrelevant to one's health condition, as reported by other patients, might prevent the establishment of such a bond [33]. Technological and human-like design features, for example, AI chatbot, avatars, social forums, and peer support, can potentially

foster digital therapeutic alliance further [35,36], which could be interesting to explore in future developments.

While the selfBACK app was designed to be self-explanatory, some patients indicated the need for more instructions. This was partly reflected by the fact that the exploration of the app was mostly limited to the main components of exercises and physical activity (ie, step count). Other components in the toolbox (static component within the app) containing additional self-management resources (eg, goal setting, pacing, relaxation techniques, and mindfulness) were less explored, as reflected by the usage data and the interview data. Although suggestions to access these resources were somewhat integrated into the educational content, they were not very prominent in the design of the weekly plan algorithm compared with the exercises. This might have limited the exposure and practice of relevant self-management skills linked to the promotion of self-efficacy, in turn influencing long-term behavioral change [24]. A few patients also mentioned the necessity of customizing some elements within the app (beyond changing exercises) and the ability to provide feedback. This need for greater self-tailoring of the content aligns with the concept of autonomy support, whereby taking individual preferences into account and enabling patients' perceived active control foster autonomous motivation, which is important for the maintenance of behavior change [37].

Offering a self-management app for patients on a waiting list for specialist care can be an easy and inexpensive approach to initiate cognitive and behavioral processes by providing evidence-based and tailored content. Some patients described being reassured by the educational content and exercises and developing greater awareness and confidence about the possibility of self-managing while using the app. As such, the app can increase patients' feeling of empowerment, which is important to achieve competence to manage pain and enable lifestyle changes [38]. The clinical value of embedding a self-help intervention in this phase was further highlighted by health care practitioners who stated that priming patients with such content would enhance patient-clinician communication, thus facilitating shared decision-making during the clinical encounter. However, both patients and health care practitioners often mentioned the need for clinical involvement to enable engagement with self-management advice, mostly due to diagnostic uncertainty in this patient group. Previous research has shown that health care professional support, even when remote or minimal, can increase the effectiveness of self-management interventions [39]. Thus, combining digital and human support could be a useful approach to enhance adoption of self-management, particularly in the specialist health care setting with long waiting time.

Both patients and health care practitioners widely emphasized the necessity for taking responsibility for one's own health conditions, indicating that digital interventions such as the SELFBACK app hold a large potential in mitigating current health care shortage challenges. However, while digital interventions are useful and wanted by many patients, our findings suggest that not all patients can benefit from such interventions. Since the patient group in this study is highly heterogeneous and pain management styles and preferences vary, further research should look into how to further optimize

tailoring of self-management support to increase patients' feeling of relevance and usefulness over time. In addition, patients' needs, abilities, and preferences for autonomy should be considered when implementing digital interventions within the health care setting [40]. This should come with the awareness that assuming patients' responsibility for self-management could lead to stigmatization of some patients, potentially those with higher needs for health care services [41].

Strengths and Limitations

While our findings might not be generalizable to other contexts (eg, different health care systems) or patient groups with other chronic health challenges, they nonetheless provide useful insights into patients' and health care practitioners' experiences with digital self-management interventions. Since back pain complaints are one of the main causes of years lived with disability worldwide [42] and practitioners' acceptance of app-based interventions has been recognized as a global tendency [43], the need and value of digital self-management support transcend the regional setting of this study.

A strength of this study was that researchers from different backgrounds, that is, physiotherapy, medicine, anthropology, and exercise physiology read the interviews, and results were discussed thoroughly among them. Another strength was the inclusion of patients with different levels of app usage (ie, the number of plans generated), ensuring a balanced view of patients' experiences with the app, including those who might have been less satisfied with it. In addition, data on how much the users accessed different content in the app were available for all patients allocated to the SELFBACK app. Integrating the views of health care practitioners with patients' experiences

allowed a better understanding of acceptability and needs from both sides, which are important for future implementation. However, some limitations need to be considered. Although health care practitioners were invited to get acquainted with the app for some weeks prior to the focus groups in addition to receiving an overview of its functionality, only a few tried the app and were familiar with the entire content. A greater firsthand experience could have increased the specificity of their views regarding adopting selfBACK in this context. Furthermore, patients were most likely interviewed when they already received first consultation and initiated treatment in specialist care (ie, 3-4 months after inclusion), and this might have affected their views on self-management and the use of digital interventions. Finally, while we interviewed patients with different app usage levels, we did not interview patients who had never accessed it. This could have provided better insight into factors related to the onboarding procedure and uptake of digital interventions in this setting.

Conclusions

Both patients and health care practitioners supported the adoption of app-based self-management support for low back and neck pain in specialist care. The selfback app was reported by some patients and health care practitioners to provide reassurance and empowering patients to take actions for their health problem on their own. Acceptance and engagement with the app-based intervention can be influenced by various factors, such as content structure and relevance, tailoring, trust, and usability properties. Digital self-help combined with human support might be necessary to enhance adoption of self-management, particularly in specialist health care settings.

Acknowledgments

This study was supported by the European Union's Horizon 2020 research and innovation program (grants 777090, Back-UP; and 689043, SELFBACK) and innovation funding allocated to St Olavs Hospital by the Central Norway Regional Health Authorities (grant 2019/34-629/2020; the e-Help project).

Conflicts of Interest

The authors declare that no conflicts of interest exist. The overall aim of this project was to test a digital decision support system and a smartphone app to support patients to self-manage their low back and neck pain. The results and experiences from this project will inform further developments of the app, which may be introduced into a commercial market.

Abstract

Background: Emerging technologies such as artificial intelligence (AI) require an early-stage assessment of potential societal and ethical implications to increase their acceptability, desirability, and sustainability. This paper explores and compares 2 of these assessment approaches: the responsible innovation (RI) framework originating from technology studies and the co-design approach originating from design studies. While the RI framework has been introduced to guide early-stage technology assessment through anticipation, inclusion, reflexivity, and responsiveness, co-design is a commonly accepted approach in the development of technologies to support the care for older adults with frailty. However, there is limited understanding about how co-design contributes to the anticipation of implications.

Objective: This paper empirically explores how the co-design process of an AI-based decision support system (DSS) for dementia caregivers is complemented by explicit anticipation of implications.

Methods: This case study investigated an international collaborative project that focused on the co-design, development, testing, and commercialization of a DSS that is intended to provide actionable information to formal caregivers of people with dementia. In parallel to the co-design process, an RI exploration took place, which involved examining project members' viewpoints on both positive and negative implications of using the DSS, along with strategies to address these implications. Results from the co-design process and RI exploration were analyzed and compared. In addition, retrospective interviews were held with project members to reflect on the co-design process and RI exploration.

Results: Our results indicate that, when involved in exploring requirements for the DSS, co-design participants naturally raised various implications and conditions for responsible design and deployment: protecting privacy, preventing cognitive overload, providing transparency, empowering caregivers to be in control, safeguarding accuracy, and training users. However, when comparing the co-design results with insights from the RI exploration, we found limitations to the co-design results, for instance, regarding the specification, interrelatedness, and context dependency of implications and strategies to address implications.

Conclusions: This case study shows that a co-design process that focuses on opportunities for innovation rather than balancing attention for both positive and negative implications may result in knowledge gaps related to social and ethical implications and how they can be addressed. In the pursuit of responsible outcomes, co-design facilitators could broaden their scope and reconsider the specific implementation of the process-oriented RI principles of *anticipation* and *inclusion*.

Introduction

Background

In the long-term care for older adults with frailty, caregivers and clients are increasingly being assisted by artificial intelligence (AI)-based technologies [1-5]. AI-based technologies can, for a given set of human-defined objectives, make predictions, recommendations, or decisions influencing real or web-based environments, thereby using machine or human-based data and input [6]. For instance, AI is being used in decision support systems (DSSs) that acquire relevant data about care needs or processes; present the relevant data to users (eg, caregivers); and translate raw data into actionable information, such as alerts, risk assessments, or recommendations about care strategies [7-10]. Notwithstanding the opportunities and advantages, it is broadly acknowledged that the use of AI-based technologies entails societal and ethical implications. The long-term data collection in the context of monitoring older people's health and well-being and the mediating or even leading role of algorithms in interpreting these data to arrive at care-related decisions pose implications related to, among others, undermining people's privacy, autonomy, and self-determination; the discrimination and stigmatization of old age; and surveillance capitalism [1,11-15].

Due to the impact technologies such as DSSs have on people's lives and the potential resistance that might emerge during implementation, an early-stage assessment of their implications is called for. This paper explores and compares 2 of these assessment approaches: the responsible innovation (RI) framework originating from technology studies and the co-design approach originating from design studies. The term RI refers to the aim to ensure the ethical acceptability, societal desirability, and sustainability of innovation processes and outcomes [16,17]. To guide RI into practice, Owen et al [17] suggest that four process-oriented principles should guide technology research and development: (1) anticipation of the potential positive and negative implications; (2) inclusion of users and other stakeholders; (3) reflexivity of actors upon their own practices, assumptions, values, and interests; and (4) responsiveness to insights that emerge during the innovation process.

Co-design can be used as an umbrella term for approaches that actively involve users and other stakeholders of innovations in any stage of the design process to ensure that the outcomes meet their needs [18,19]. It is a commonly accepted approach in the development of technologies to support the long-term care for older adults [20-22]. On a conceptual level, co-design resonates with RI. Both approaches share a focus on developing technologies to match human needs and abilities, similar to research fields such as human factors, human-computer interaction, and cognitive engineering. In fact, co-design has increasingly received attention as a way to support RI [23]. Similar to RI, the co-design approach describes a research and

development process in which innovators *inclusively deliberate* and *reflect* on the needs and values of different stakeholders and *iteratively* design and *adapt* innovations based on these insights [23]. However, in contrast to RI, co-design does not explicitly impose on innovators the need to *anticipate* potential societal and ethical implications (henceforth, abbreviated as "implications"). Co-design can yield insights into potential unintended side effects and value creation that stakeholders do not want from innovation, but this is generally not an explicit aim in co-design. Against this background, this paper empirically explores how the explicit *anticipation* of implications can complement co-design.

More specifically, this paper presents a case study on an international collaborative project that focuses on the development of a DSS to support formal caregivers involved in long-term dementia care. A co-design process involving intended users and other stakeholders (henceforth, abbreviated as "users") is central to the development of the DSS. In addition, a separate line of research of the project under investigation explicitly anticipated implications of using DSSs in dementia care, along with strategies to address these implications, thereby fostering RI in AI-assisted decision-making. This so-called RI exploration largely took place in parallel to (ie, not as part of) the co-design activities and focused on soliciting the perspectives of project members (PMs) rather than those of users. This paper describes the empirical exploration of how the co-design process of an AI-based DSS for dementia caregivers is complemented by the explicit anticipation of implications.

The Healthy Ageing Eco-System for People With Dementia Project

The case presented in this paper is the Healthy Ageing Eco-system for People With Dementia (HAAL) project, which is part of the European Active and Assisted Living (AAL) program (AAL Europe, 2021; project AAL-2020-7-229-CP). In HAAL, an international consortium comprising care organizations, research institutes, and commercial firms from the Netherlands, Italy, Taiwan, and Denmark collaborates on the co-design, development, testing, and commercialization of a DSS that is intended to provide actionable information to formal caregivers of people with dementia, with the aim of reducing their workload and increasing the quality of care [24]. The DSS developed in HAAL concerns a dashboard that integrates various types of data about the physical activity, eating and sleeping patterns, cognitive functioning, mood, social contact, and medication intake of people with dementia. These data can be collected via several digital technologies (henceforth, "HAAL technologies") throughout various stages of dementia. Besides integrating the data from HAAL technologies into 1 dashboard, possibilities to provide caregivers only the most relevant data in the form of summary overviews, alerts, predictions about emergency situations, and recommendations about care strategies were explored. To this end, both

preprogrammed, rule-based algorithms and data-driven algorithms rooted in machine learning are used to process data.

With these predefined directions as a starting point, a series of iterative co-design activities involving dementia caregivers, or more correctly “proxy users” who represent these eventual users (see the study by Stewart and Hyysalo [25]), and other stakeholders were organized to feed the actual design and development of the dashboard. The co-design activities focused on exploring the relevance and possibilities of translating the data from HAAL technologies into useful information and prioritizing data that are relevant to be presented in the dashboard [24,26]. In addition, the co-design activities focused on determining functionalities of the dashboard and designing and evaluating different pages of the dashboard’s user interface.

The RI exploration in HAAL, which took place largely in parallel to the co-design activities, initially focused on raising PMs’ general awareness about RI and exploring their

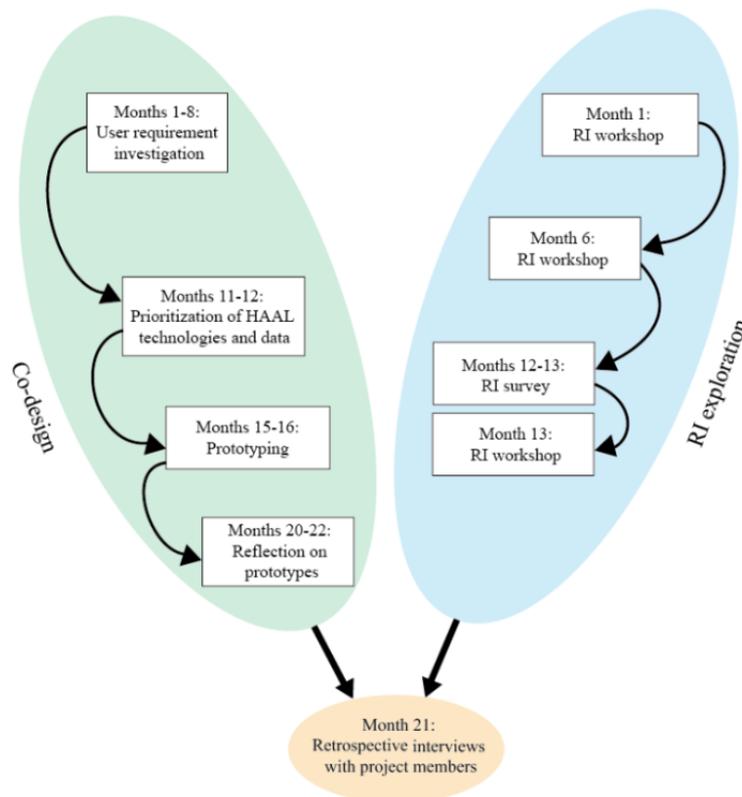

perspectives on both positive and negative implications of using the HAAL dashboard, along with strategies to address these implications.

Methods

Overview

For this case study, results from the co-design process and RI exploration within the HAAL project were incorporated and analyzed. In addition, retrospective interviews were held with individual PMs to reflect on the co-design process and RI exploration. Because the co-design process and RI exploration were largely organized in parallel, the HAAL project provided sufficient data within a specific time and context to perform a retrospective analysis on how the explicit anticipation of implications can complement co-design. Figure 1 shows a timeline of activities.

Figure 1. Timeline of the co-design process, responsible innovation (RI) exploration, and retrospective interviews. "Month" refers to the month (count in project) in which the activity took place. HAAL: Healthy Ageing Eco-system for People With Dementia.

Co-Design Process

Table 1 describes the 4 specific steps taken in the co-design process. The co-design activities in HAAL were conducted in 4 countries: the Netherlands, Italy, Taiwan and Denmark. The organizations from Denmark are unsubsidized partners in the HAAL project and did not participate in co-design steps 3 to 4. Despite differences in dementia care systems across these countries, such as types of caregivers involved in home-based and institutionalized care settings, formal caregivers of people with dementia were perceived as the primary target group for (using) the dashboard in all countries. Hence, a variety of formal caregivers of people with dementia, such as (homecare) nurses,

case managers, psychologists, psychotherapists, social workers, and specialists in the care of older adults, were involved in the co-design activities. In addition, other stakeholders, such as innovation staff, data analysts at care organizations, and people working in (care) alarm centrals, were involved in some steps of the co-design process to broadly explore requirements for the dashboard. As indicated in Table 1, two intermediate steps were taken without the direct involvement of users. Further, at the end of step 4, participants were implicitly asked about RI-related themes (autonomy and transparency). Throughout the co-design activities, data were collected in the form of notes, audio and video recordings, photos, drawings, and (web-based) canvasses and by conducting surveys.

Table 1. Steps taken in the co-design process.

Step	Methods	Research focus	Participants
1 ^a	Focus group sessions (3 web based, 1 hybrid, and 16 physical)	<ul style="list-style-type: none"> User requirement investigation: insights were gathered into different stakeholders' attitudes toward the HAAL^b technologies, their ideas about the added value and functionalities that are envisioned in the integration of these technologies in 1 dashboard, and for which stakeholders such a dashboard may be most relevant. 	Nurses, day-care workers, psychologists, physiotherapists, technical stakeholders, innovation managers and directors of care organizations, representatives from various municipalities, people with dementia, and informal caregivers (n=146; the Netherlands: n=18, 12.3%; Italy: n=18, 12.3%; Taiwan: n=108, 74%; Denmark: n=2, 1.4%).
2	Demonstration, try-outs, and survey (7 physical and 1 hybrid)	<ul style="list-style-type: none"> Prioritization of HAAL technologies and data: based on the MoSCoW^c technique, all HAAL technologies and corresponding data were categorized into 4 ascending categories (must have, should have, could have, and won't have this time), indicating what best fits the needs of people with dementia and their caregivers [27,28]. After a demonstration and try-outs of the HAAL technologies, participants completed a digital prioritization survey. 	Nurses, day-care workers, psychologists, physiotherapists, data specialists, and innovation staff and directors from care organizations (n=48; the Netherlands: n=6, 12%; Italy: n=9, 19%; Taiwan: n=30, 62%; Denmark: n=3, 6%).
3 ^d	Co-design sessions (3 physical and 2 web based)	<ul style="list-style-type: none"> Prototyping: three dashboard pages were preselected to be co-designed with participants: (1) client profile with detailed information on specific clients, (2) overall list of clients, and (3) an overview of urgent situations. This resulted in insights (ie, through sketches and design by participants) into the kind of information to be displayed in the dashboard and how the information could be visualized. Finally, the results were compared with those of the preliminary mock-up. 	Data specialists and innovation staff, including part-time nurses (n=21; the Netherlands: n=6, 29%; Italy: n=4, 19%; Taiwan: n=11, 52%).
4	Usability study (8 physical sessions, including survey)	<ul style="list-style-type: none"> Reflection on prototypes: insights were gained into the usability and heuristics of the clickable mock-up. More specifically, after first performing 6 tasks in the mock-up, participants completed a survey. In the survey, the HUBBI^e questionnaire [29] was used to determine usability, and heuristics were evaluated using the issue categories of Bastien and Scapin [30] and Nielsen's severity ranking [31]. After completing the survey, participants engaged in a group discussion on the overall added value and functioning of the dashboard. At the end of the discussion, participants were also asked to reflect on 2 RI^f themes: <ul style="list-style-type: none"> Autonomy: do you think the degree to which the dashboard guides your decision-making as a caregiver is adequate, too low, or too high, and why do you think so? Transparency: what would you choose, if you had to choose between either the accuracy of the information (ie, recommendations) provided by the dashboard or the understandability of the information, and why would you choose it? 	Formal caregivers, digital care ambassadors, alarm centralists, and innovation staff (n=33; the Netherlands: n=9, 27%; Italy: n=14, 42%; Taiwan: n=10, 30%).

^aIntermediate step: after analyzing results from step 1, user personas and desired dashboard functionalities were defined and translated into a preliminary mock-up for the dashboard (iteration 1). The motivational goal model of Taveter et al [32] was used for this translation.

^bHAAL: Healthy Ageing Eco-system for People With Dementia.

^cMoSCoW: must have, should have, could have, and won't have this time.

^dIntermediate step: after analyzing results from step 3, insights about user requirements were again plotted on the motivational goal model to define design requirements. These design requirements were used to translate the preliminary mock-up into a clickable mock-up (iteration 2).

^eHUBBI: eHealth usability benchmarking instrument.

^fRI: responsible innovation.

RI Exploration

The RI exploration was primarily based on a qualitative survey among PMs, which was preceded by 2 workshops and followed by a third workshop with PMs. The first 2 workshops with PMs were held in a hybrid setting (web based and physical) during collective consortium meetings. The goal of the first workshop was to explain the notion of RI to PMs and discuss their thoughts about the relevance of and ways to address RI in HAAL. In the second workshop, based on the guidance ethics approach of Verbeek and Tijink [33], potential positive and negative implications of using the envisioned HAAL dashboard were explored, along with ways to address these implications.

Next, a dedicated qualitative RI survey was developed and conducted among PMs (Multimedia Appendix 1). The goal of the RI survey was to reveal PMs' viewpoints on how to responsibly develop AI-based analytical functionalities and the dashboard user interface in the HAAL project. The survey first explained that AI, as in the HAAL dashboard, provides opportunities for descriptive, diagnostic, predictive, and prescriptive analyses with differing levels of complexity and automation [34,35]. Next, questions were asked in relation to 2 distinct imaginary scenarios that outline different roles for AI within the HAAL dashboard. The first scenario (A) described a descriptive and largely rule-based dashboard through which users can assess the data from HAAL technologies and how the situations of clients have changed over time. This scenario was inspired by the dashboard that was aimed to be developed in the HAAL project. The second scenario (B) took a more speculative turn and described a proactive and partially self-learning dashboard that automatically translates the data into diagnostic, predictive, and prescriptive information to prompt caregivers to take certain actions. The scenarios were used as input to inspire respondents about directions the project could take in terms of developing AI and to enable them to articulate their expectations and considerations regarding the opportunities and implications of an advanced AI-based DSS (see also the study by Noortman et al [36]). After presenting each scenario, questions were asked about the positive and negative implications of using the respective dashboard. Thereafter, respondents were asked which scenario they preferred in terms of ethical acceptability, societal desirability, and technical feasibility and why they preferred it. Next, the survey introduced six principles for responsible AI innovation, adopted from guidelines from the World Health Organization: (1) protecting human autonomy; (2) promoting human well-being and safety and the public interest; (3) ensuring transparency, explainability, and intelligibility; (4) fostering responsibility and accountability; (5) ensuring inclusiveness and equity; and (6) promoting AI that is responsive and sustainable [37]. Respondents were asked how these principles might be relevant to and could be applied in the HAAL project. The survey was completed by 12 respondents representing 7 different organizations from all 4 countries. In addition, 5 respondents partially filled in the survey anonymously.

Finally, the RI survey was followed by a third hybrid workshop in which PMs were invited to jointly discuss what they learned from answering the RI survey.

Retrospective Interviews With PMs

In addition to the co-design activities and RI exploration, semistructured interviews were held with 6 PMs: 4 co-design facilitators (n=1, 25% working in the Netherlands; n=2, 50% working in Taiwan; and n=1, 25% working in Italy) and 2 software developers (working in Italy). The goal of the interviews was to uncover possible rationales behind the co-design process, choices made throughout the co-design process, and input given by co-design participants. All interviews lasted between 30 and 40 minutes and were fully transcribed by a professional transcription service.

Analysis

The analysis of data was performed by DRML, SIA, NES, and BMH. The data collected during the co-design activities and RI exploration were first analyzed independently by these 4 researchers. While the co-design data were previously analyzed by HAAL PMs to learn about the dashboard requirements, they were analyzed again for the purposes of this paper. Taking the 6 responsible AI principles from the World Health Organization guidelines [37] as a starting point, the researchers performed an inductive thematic analysis [38] to uncover conditions for the responsible design and deployment of the HAAL dashboard, including potential negative implications and strategies to address them. In doing so, they examined how certain insights regarding these conditions emerged in the co-design activities, the RI exploration, or both. In other words, the analysis focused, first, on identifying themes common within and between the co-design and RI exploration results and, second, on examining how the results from the RI exploration complement those from the co-design activities, or vice versa, in terms of RI. Subsequently, the transcripts of the retrospective interviews were analyzed independently by DRML, SIA, and BMH to uncover new conditions for RI and explore the complementarity between the co-design process and RI exploration. An additional focus was on why certain insights about conditions for RI may have emerged less explicitly in either the co-design process or the RI exploration. While analyzing the data, the researchers applied open coding and kept track of their reflections by writing them down as memos. After the data were independently analyzed by the researchers, the findings and memos were regularly discussed and reviewed by the researchers to reconcile major discrepancies in the coding and to reach agreement on the final coding scheme. Both physical and digital meetings were held to ensure the consistency of the analysis and reach convergence.

Ethical Considerations

The authors of this study followed the guidelines in the Declaration of Helsinki and the Dutch code of conduct for scientific integrity. Ethical approval for the interviews, not subject to the medical scientific research act involving human subjects, was granted by an independent board of the lead author's department (Vilans), including a privacy officer and legal expert [39].

For each co-design step, general information about the goal and procedure was provided, and the participants were asked to read and sign an informed consent form. The original consent covers

secondary analysis of the data for the purposes of this study. The data gathered through the co-design steps and RI exploration were pseudonymized before analysis. Study participants did not receive any financial compensation.

Results

Overview

Seven overarching and interlinked themes representing conditions for the responsible development and deployment of

the HAAL dashboard were extracted: (1) develop a proactive dashboard, (2) prevent cognitive overload, (3) protect privacy, (4) provide transparency, (5) empower caregivers to be in control, (6) safeguard accuracy, and (7) train users. We explicate how insights related to each theme emerged in the co-design activities, the RI exploration, or both. In addition, insights from the interviews with PMs are provided. In doing so, for each theme, we discuss how the explicit anticipation of implications (ie, the RI exploration) complements the co-design process in the HAAL project. [Textbox 1](#) excerpts the results.

Textbox 1. Analysis of complementarities between the co-design process and responsible innovation (RI) exploration per theme.

1. Develop a proactive dashboard
 - The co-design results clearly indicate a perceived need for a proactive dashboard and provide concrete arguments to this end. The RI exploration also indicated the need for a proactive dashboard, albeit with less concrete arguments. Besides, limitations were raised regarding the short-term feasibility of a proactive dashboard.
2. Prevent cognitive overload
 - The co-design process and RI exploration yielded similar insights, that is, that too much data in one place would overload caregivers' cognitive workload and that focus of the dashboard should be on providing actionable and only the most relevant information. However, this insight only emerged late in the co-design process (step 4 of 4).
3. Protect privacy
 - The need for privacy protection emerged strongly in the co-design process, and participants clearly pointed to the need for a proactive dashboard in privacy terms. The theme was discussed only briefly in the RI exploration, although some practical suggestions were provided, such as the use of encryption and passwords.
4. Provide transparency
 - While the importance of the transparency of the dashboard's information emerged in the co-design process, practical suggestions on how to provide transparency (eg, training users in correctly interpreting information and explanations) were given only in the RI exploration.
5. Empower caregivers to be in control
 - The main contribution from co-design was the proposition to gradually expand the application of artificial intelligence (AI) functions in practice so that users can get used to an increasing role of AI. In comparison, the RI exploration yielded more in-depth insights and suggestions. The RI exploration stressed that it is important for caregivers not to become too reliant on the results of AI and to have a critical mindset and keep the context in mind.
6. Safeguard accuracy
 - During co-design, the importance of accurate dashboard information was mentioned but not discussed in depth. In the RI exploration, concrete suggestions were made to ensure accuracy, such as including feedback buttons for users.
7. Train users
 - The importance of training, also in relation to other themes such as empowering caregivers to be in control and safeguarding accuracy, frequently appeared in the RI exploration but was raised by only one of the participants in the co-design process. In the RI exploration, suggestions were also provided regarding the focus of training, for instance, on creating awareness about the mediating role of AI in decision-making.

Theme 1: Develop a Proactive Dashboard

The co-design participants generally agreed that the HAAL dashboard should support decision-making proactively, by actively generating and pointing users to relevant insights, rather than passively, by merely showing data from the HAAL technologies. In contrast, the results from the RI survey showed varying viewpoints among PMs regarding the dashboard's required level of proactiveness with regard to supporting decision-making.

Co-design steps 1 and 2 showed that the data from HAAL technologies could be potentially useful for both daily caregivers and caregivers who are less frequently involved (eg, general practitioners). In these co-design steps, there was limited reflection on the possibilities of a dashboard beyond data integration. However, in co-design steps 3 and 4, most participants expressed an interest in a dashboard that also interprets data to provide new information and inspire users. That is, participants suggested that the dashboard should provide insights into or predictions about outliers from usual patterns and distinguish between urgent (eg, a fall) and nonurgent (eg,

a deviation in sleeping pattern) outliers to prompt caregivers to take appropriate action. As one of the caregivers at a Taiwanese care center argued, “What I would like is an alert service, more centered on urgency than on daily, routine patient follow-up.” In addition, the dashboard was seen as a way to encourage caregivers to consider signs that might otherwise have been neglected or perceived too late. Besides, some participants of co-design steps 3 and 4 proposed that the dashboard could provide recommendations on how to prevent or address certain deviations from usual patterns.

In the RI survey, most PMs shared pros and cons related to both a descriptive dashboard (scenario A) and a proactive dashboard (scenario B). Most PMs argued that a proactive dashboard could potentially add the most value, especially in terms of enhancing prevention and reducing caregivers’ cognitive load (see also theme 2). At the same time, all PMs expressed doubts about the feasibility of developing a proactive dashboard due to the complexity and relatively limited time span of the HAAL project. Some PMs stressed that the initial acceptance and adoption of a proactive dashboard by caregivers might be low, arguing that the more proactive the dashboard is, the more it may infringe on job satisfaction. As one of the PMs explained, “Caregivers might enjoy the part in their work where they investigate the status of the client, and this is then (partially) taken over by machines.” However, although market introduction was questioned, some PMs advocated exploring possibilities for and experimenting with the more progressive concept of a proactive dashboard to iteratively learn and generate ideas and lessons for future research and development. In an interview, one of the PMs explained, “We know that we could do bigger, smarter things with AI, but you cannot start with high-level AI...But I think that these kinds of projects are useful also to build knowledge and literacy, by making people consider what technology and artificial intelligence could do.”

Theme 2: Prevent Cognitive Overload

The need to prevent cognitive overload was another recurring argument for developing a proactive dashboard in both the co-design process and RI survey. In co-design step 4, it was stressed by multiple participants that too much data or information in one place could exceed caregivers’ cognitive load and cause problems regarding the prioritization of which client, or what aspect of a client’s life, needs attention first. Similarly, in the RI survey, PMs suggested multiple times that a descriptive dashboard may require additional time for caregivers in terms of checking the data, rather than save time, and increase mental strain. As one of the PMs stated, “Adding more data in one place without elaborating on it would not really reduce the caregiver burden.”

Theme 3: Protect Privacy

While privacy was a prominent theme throughout all co-design steps, it was only briefly discussed in the RI exploration. During co-design step 3, multiple participants suggested that from a privacy perspective, a (proactive) dashboard that provides only the most relevant data patterns, notifications, and alerts may be preferred over a (descriptive) dashboard that directly discloses all data about the evolving status of clients in relation to various indicators. This link between the need for a proactive dashboard

(scenario B) and privacy concerns was not discussed in the RI survey.

Further, privacy concerns raised in the co-design activities were related to the storage of large amounts of data collected about people with dementia and how these data would be handled. As one of the participants stated, “A lot of personal information is gathered, so you can get to know a lot about people.” In line with this, most participants stated that compliance with the European General Data Protection Regulation should be ensured, and some practical suggestions were made, for instance, to show the client’s home address or room number in the dashboard rather than their names in case of alarms.

The importance of privacy protection was mentioned by various PMs in the first 2 RI workshops, but in the RI survey, only 3 (18%) of the 17 PMs provided input on privacy issues. One of the PMs stated that ways must be found to balance the benefits of large-scale and long-term data collection (eg, in terms of prevention) with downsides such as a feeling of intrusion. Complementary to the co-design process, PMs also provided practical suggestions on privacy protection in the RI survey, such as using a private log-in to the dashboard for caregivers, encryption, or even facial recognition to protect data.

Another privacy concern, raised during co-design step 3, was data accessibility. Several participants reported about who should have access to the dashboard. Some participants proposed that access should be limited to specific caregivers with the specific assignment to learn from the dashboard. In contrast, others reported that all caregivers, including informal carers (eg, family), should have access to the dashboard, if desired. There was no consensus among participants about whether a distinction should be made between different users who are able to see different client data.

Theme 4: Provide Transparency

In co-design step 4, participants proposed that a condition for the use of a proactive dashboard is that users need to understand the reasons (eg, data patterns) behind information provided by the dashboard. In this respect, one of the PMs discussed in an interview that caregivers should not be overloaded with too many details about how specific dashboard information comes about (see also theme 2). In contrast, some co-design participants stressed that users should always be able to examine all data from the different HAAL technologies. Hence, this could be in conflict with the previously discussed insight from co-design that making all data available may be less preferable from a privacy perspective (see also theme 3).

The co-design participants also made various remarks regarding the context specificity of transparency needs. Multiple participants expressed that a need for transparency may not always, or for every user, mean the same. For instance, in case of alarms about certain urgent situations, it may be irrelevant or even distracting to immediately show all data that triggered the alarm. However, users may want to view all the data at a later stage to gain insights into the context and possible causes for the urgent situation, for instance, for training and prevention purposes. A similar insight was raised in the RI exploration, where it was, for example, suggested that in-depth explanations

could be provided but only after users ask for it, for instance, by clicking through.

Further, during co-design step 4, it was suggested that once caregivers have built a certain level of trust in the dashboard, less detailed explanations clarifying how the dashboard reaches its conclusions might be sufficient. However, as one of the PMs added in an interview, in the long run, excessive trust might lead to caregivers making certain decisions too easily based on the dashboard's information without critical reflection: "The long-term risk is that users end up trusting the system too much" (see also theme 5).

Although co-design participants highlighted the importance of transparency in HAAL, they did not provide practical suggestions about ways to provide transparency. In the retrospective interviews, various possible explanations were given. For instance, 2 PMs argued that issues such as transparency may have been discussed with limited depth throughout co-design because they pertain more to the backend of the system (ie, algorithms and web services) than the front end (ie, interface) with which users directly interact and because participants may place a certain degree of trust in developers to deal with such issues. Besides, 2 PMs discussed that it may have been hard for co-design participants to formulate requirements regarding transparency during early phases of design because the dashboard concept was still relatively abstract. As suggested, gaining in-depth insights into issues such as these may be easier when practically demonstrating and testing the dashboard in field tests, as users can then actually experience the system and its limitations.

While practical suggestions on providing transparency in HAAL were absent in the co-design results, they were discussed in the RI survey. For instance, PMs suggested (1) showing which specific data were included by algorithms to provide certain information; (2) creating abstractions easy to understand for users to explain the logic behind data analyses, for instance, by giving explanatory examples of common use cases; and (3) training users in interpreting the information and their explanations (see also theme 7).

Theme 5: Empower Caregivers to Be in Control

It was raised in co-design step 4 that people should be in charge of decision-making, regardless of whether human decisions are in line with the dashboard's information. In the same line, multiple PMs argued in the RI survey that people (ie, caregivers) should always be making the final decisions, and they should make these decisions only after carefully valuing the dashboard's information in light of the specific context. It was also suggested during co-design that caregivers may at first instance not be ready yet to get extensive advice from a dashboard. A gradual expansion of AI-functions in real practice was suggested. For instance, in the beginning, the dashboard could provide only generic insights (eg, patterns), alarms, and predictions. In a later stage, when reliability has improved and trust in and experience with the system have been gained, recommendations or conclusions about follow-up steps could be provided. Apart from the above, the importance of people making the final decisions was not further reported by co-design participants.

In contrast, the importance of caregivers being and remaining to be in control of decision-making was more prominent in the RI exploration. In the RI survey, 3 PMs suggested that the long-term use of a proactive dashboard might slowly deprive the intuition of caregivers and maintain an automated and predefined focus whereby one might overlook the person (ie, person with dementia) behind the data. One of the PMs even stated, "There may be a tendency to rely more on AI than own observations and assessments because 'the computer is always right.'" To encourage caregivers to make autonomous decisions while using the dashboard, training was put forward as an important factor by several PMs (see also theme 7).

Theme 6: Safeguard Accuracy

The importance of accurate dashboard information was reflected to a limited extent in the co-design process. During all co-design steps, participants reported a couple of times that the accuracy of the data and data analyses should be regularly evaluated. However, in an interview, a PM suggested that co-design participants mainly shared this requirement as a general condition that must be met before the dashboard could be put into practice, rather than giving concrete ideas on how to achieve this.

The importance of accurate dashboard information and ways to achieve this were more prominently discussed in the RI survey. Multiple PMs argued that information provided by the dashboard should not lead to any faulty judgments by caregivers and that both the data and the algorithms processing data should, therefore, be accurate, without significant biases. For instance, one of the PMs stated, "The dashboard should not give unnecessary warnings to caregivers because the false warning could stimulate the caregivers to impose unnecessary boundaries to people with dementia." One of the PMs explicitly linked accuracy to being sensitive toward the diversity among clients and suggested that the dashboard be fed with data from heterogeneous clients to reduce bias. In contrast to the co-design process, PMs also provided practical suggestions about particular ways of involving users to safeguard accuracy, such as enabling users to (1) provide feedback on data or insights through a button, (2) personalize certain thresholds for alarms to the individual client, (3) keep track of their responses and follow-up actions on the dashboard's information, (4) report nonplausible suggestions and malfunctions, and (5) periodically evaluate the dashboard's functioning. Again, training was put forward as an important factor in this case for users to be able to be involved (see also theme 7).

Theme 7: Train Users

During the co-design activities, one of the participants commented that the proper use of the dashboard would require training and practical learning. In the RI survey, multiple PMs pointed out that training users is an important measure to tackle challenges related to the autonomy of users and the accuracy of the dashboard's information (see also themes 5 and 6). It was suggested that the training should focus on making the users become acquainted with the HAAL technologies; data types; and information provided by the dashboard, including underlying data analyses, and on understanding the impact that the use of the dashboard might have on decision-making. One

of the PMs said, “Caregivers should be taught that they will always in some degree be influenced by the information on the dashboard, and be recommended to make their own judgements first.” Another PM argued that training should prevent caregivers to become overreliant on the dashboard. In addition, training was suggested to prepare some users for active involvement in maintaining the accuracy of the dashboard information (see also theme 6).

Discussion

Principal Findings

This paper empirically explores how the co-design process of an AI-based DSS for dementia caregivers is complemented by the explicit anticipation of implications. A total of 7 overarching and interlinked themes representing conditions for the responsible development and deployment of the DSS were extracted: develop a proactive dashboard, prevent cognitive overload, protect privacy, provide transparency, empower caregivers to be in control, safeguard accuracy (eg, by reducing false positives), and train users. Because these conditions are interlinked, it is essential for various actors, including developers and users of the DSS, to work together to cohesively address them in practice. Moreover, some conditions, such as to develop a proactive dashboard and empower caregivers to be in charge or to provide transparency through detailed information and prevent cognitive overload, can be at odds with each other and need to be carefully balanced. To gain a deeper understanding about appropriate and responsible levels of proactivity by the DSS, where the contributions of AI and human input in decision-making are balanced, future studies could expand upon prior research in fields such as human factors by exploring and contextualizing notions such as automation bias [40,41] and human automation coordination [42,43] in the context of AI-assisted decision-making in long-term dementia care. Scenarios that may lead to excessive reliance on the automated execution of functions, such as AI-driven data interpretation, could be anticipated, and strategies could be devised to mitigate such scenarios [40].

As our analysis points out, the general expectation of both co-design participants and PMs was that a dashboard that proactively supports decision-making would be most valuable to dementia caregivers. To this regard, the perspectives of co-design participants were fairly aligned; there was a consensus that the dashboard should not show all available data from care technologies. Rather, it should focus on information about significant changes in the data that, for instance, indicate a deterioration of well-being. AI itself was positioned as a technical fix (see also the study by Wehrens et al [44]) to mitigate specific risks related to the remote technology-based monitoring of people with dementia, that is, the infringement of clients’ privacy and cognitive overload of caregivers. This is in line with previous studies that show that too much information [45-47] and insufficient time can lead to information overload [48]. The same suggestion of using AI to actually support the responsible embedding of technology in care practice was also found in a scoping review on practical approaches to responsible AI innovation in the context of long-term care [49].

In comparison to the co-design results, the perspectives of PMs in the RI exploration were less unanimous; some PMs shared doubts about the short-term feasibility and acceptance of a proactive dashboard. This discrepancy between results may have been owing to the co-design process being focused on exploring opportunities for innovation, while the RI exploration explicitly invited PMs to reflect on opportunities as well as risks of AI-based analytical functionalities.

Throughout both the co-design process and the RI exploration, various conditions were defined for the responsible development and deployment of a proactive DSS. Similar conditions emerged in the co-design process and RI exploration. However, despite considering and addressing usability requirements, such as minimizing memory load [31,50], in the co-design process, co-design participants generally went into less detail. Compared to PMs in the RI exploration, co-design participants provided fewer practical suggestions on how to meet the RI conditions, except for conditions related to privacy protection. In addition, multiple conditions (ie, preventing cognitive overload, empowering caregivers to be in control, and safeguarding accuracy) emerged in a relatively late stage of the co-design process, once prototyping and reflection on prototypes stood central. Relevant input on implications and conditions for RI emerged more naturally in these phases of co-design, regardless of 2 RI questions related to autonomy and transparency being asked at the end of the last co-design step. Again, these differences in results could potentially be explained by the focus of co-design activities being mainly on opportunities, while the RI exploration was focused on both opportunities and risks.

Hence, the explicit anticipation of implications (ie, the RI exploration) was found to complement the insights from the co-design process in the project under investigation. At the same time, a number of deficiencies can be mentioned regarding the insights that have been gained about social and ethical implications of the DSS. For instance, potential tensions were found between conditions set by different co-design participants. More specifically, to protect privacy, some co-design participants proposed to limit access to information provided by the DSS to specific caregivers. Other participants advocated more transparency and data availability. It is premature to draw conclusions from such contrasting insights. However, it can be stated that insufficient insights were gained into people’s individual views on such matters, the interrelatedness of conditions, and potential trade-offs between them. Further, it stood out that both the co-design process and RI exploration yielded limited insights into the dependency of different conditions on context (eg, time, place, and culture). Although it was indicated that trust in the dashboard and transparency needs may change over time, limited insights were gained into how conditions for RI may depend on other contextual factors, such as place and culture. Despite the co-design activities being carried out in multiple countries, no cross-country differences in conditions for the responsible design and deployment of the dashboard were found.

Practical Implications

As argued by Fischer et al [22], differences regarding who is involved in the co-design of care technologies, and how, when,

and why they are involved, result in different types of outcomes. To this respect, we discuss 4 considerations that designers and co-design facilitators could take into account to increase the potential for co-design processes to contribute to ethically acceptable, societally desirable, and sustainable deployments of AI-based care technologies.

First, one could strive for balanced attention on both positive and negative implications throughout co-design processes. The co-design process in this case study was focused mostly on functional (ie, what the technology must do) and nonfunctional (eg, usability and reliability) requirements. However, rather than merely eliciting information on the needs, preferences, and requirements of users, co-design processes should go back and forth between needs and opportunities for innovation on the one hand and associated implications on the other hand. In addition, RI necessitates striking a balance in co-design practices between focusing on design aspects, such as usability and esthetics, and considering ethical and social implications. Adhering to specific design standards holds importance to meaningful field tests and the implementation of innovations in practice. However, excessive emphasis on these aspects during early phases of innovation may detract from fostering the innovation's desirability and acceptability. Although research and development projects that *integrate* anticipatory elements into co-design may yield more in-depth insights and be able to more flexibly adapt to insights than projects that anticipate implications separate from the co-design process, a few remarks can be made here. For instance, implications of innovation may need to be anticipated and addressed not only as part of co-design but also in parallel to and beyond the co-design process through methods such as impact assessments, ethical reviews, and foresight exercises. Besides, caution should be exercised to prevent co-design processes from becoming dominated by the anticipation of long-term and wider societal implications, as this may go at the expense of fast iterative design cycles exploring and addressing requirements and direct benefits for users. Further, Sumner et al [21] argued that co-design may require the commitment of a significant amount of time and resources and that some projects may have to rationalize limited resources. Naturally, the same applies to anticipating implications as part of or in parallel to co-design.

Second, one could engage with the perspectives of people who are willing and able to imagine how their interests and their role as users of technology evolve over time (ie, future users), rather than merely involve people from contemporary care practices in co-design. Innovators should not just examine the needs of current users because they may then be insufficiently able to respond to future needs [51]. For instance, in the context of the HAAL project, which was investigated in this study, this could concern the involvement of progressive and technology-savvy dementia caregivers who reflect on how the adoption of increasingly advanced DSSs and other AI technologies will change their work.

Third, one could deliberate on which stakeholders, apart from users, should actually participate in co-design and regularly evaluate how their views guide the underlying direction of innovation. Due to the focus of co-design often being on the needs, expectations, and contexts of individual users, innovators

may fail to address potential negative implications, especially implications for other stakeholders or in the long run [52]. Accordingly, it might be relevant to involve certain stakeholders such as intermediary user organizations or social advocacy groups in co-design to articulate societal demands and consider societal implications from a systemic perspective [25,53,54]. For instance, in the context of the HAAL project, this could concern involving nongovernmental organizations that are committed to the privacy interests of older people.

Fourth, one could not only invite but also actively enable users to contribute to the anticipation of implications in co-design. As users are often no experts in (responsible) innovation, they may have difficulties in explicating implications and how they could be addressed, even if explicitly asked for. In this case study, it became more natural for co-design participants to come up with implications in the later phases of co-design (ie, steps 3 and 4) when the dashboard concept had become more tangible. To enable the anticipation of implications *early* in the co-design process, it may be useful to develop inspirational tools that use, for instance, examples of negative impacts of AI technologies [55], envisioning cards [56], or design fiction [36,57] to evoke consideration of the possible intended and unintended short- and long-term effects of future technologies. In addition, in the context of AI-based innovation, one could ensure through training that co-design participants have a basic understanding of what AI can do and how its behavior may be unpredictable and change over time while accumulating data [58,59].

In sum, for co-design processes to result in more RI outcomes, designers and co-design facilitators may need to broaden their scope and reconsider the specific implementation of the process-oriented RI principles of *anticipation* and *inclusion* [17,60]. Even though there are still many uncertainties about the potential uses and consequences of technology during early phases of co-design and before users can “experience” the technology in practice, the anticipation of implications with users ideally starts early, before the technology design has been locked in and change becomes difficult, time-consuming, and expensive [61]. Besides, anticipation should be a recurring element of the innovation process, as people's values and perspectives on what is *responsible* may evolve over time and under the influence of technological innovation [62].

Limitations and Suggestions for Future Research

Given that this paper studies merely a single case, our aim is not to generalize, but rather to illustrate a typical co-design process of an AI-based technology to support the care for older adults and contribute to building a nuanced view on the relation between co-design and RI [63]. Although we use a broad definition for co-design, we acknowledge that there are multiple ways, methods, and instruments to integrate users into the innovation process [21]. Therefore, our findings about the role of anticipating implications in co-design are not generally applicable to co-design. For instance, it is plausible that projects that adopt the value-sensitive design approach yield different results, as this approach aims to explicitly consider the values of users and other stakeholders and how these values are affected by the envisioned technology [64-66]. In other words, some approaches to co-design may in themselves impose on

facilitators to explore the values at stake and thereby the implications of innovation. Future research could examine to what extent such approaches support RI.

Further, we recognize that there are limitations to the RI exploration that was part of our study and thus to the insights gained into conditions for the responsible development and deployment of DSSs in dementia care. Our RI exploration initially focused on the perspectives of PMs to stimulate and facilitate whole-team participation in exploring how RI could be addressed throughout the HAAL project. The underlying assumption was that RI cannot be prescribed to innovators but needs to be conceptualized and addressed “in context” by those who actually perform the research, design, development, and testing with users [67,68]. However, soliciting PMs’ perspectives provided neither a complete nor necessarily an accurate picture about implications and ways they can be addressed. To this end, future studies could consider embedding trained ethicists in the research team who can provide *top-down* guidance and inspiration (eg, contextualized ethics principles) during *bottom-up* engagement with users and other stakeholders [49,69]. Besides, future research could explore the perspectives of users on RI in the context of AI-based care technologies, such as DSSs, for instance, what values come to matter most to them, what positive and negative implications they foresee, how they perceive the urgency of (other) known implications in their context, and how they look at certain strategies to address implications (eg, see the study of Lukkien et al [70]). In doing so, the perspectives of stakeholders from different care contexts (eg, care organizations or countries) can be captured with sufficient detail and be compared to learn how to account for the context specificity of values in technology design and deployment [71,72]. In addition, the perspectives of people with dementia should be clarified, even when they are only a passive user of the technology (as is often the case with DSSs), and despite these people often having difficulties in expressing their needs [73,74].

Finally, even though all co-design activities and the RI exploration had already been completed by the time the objectives for this case study were established, the RI exploration had a minor effect on the co-design process. For instance, some co-design researchers were also participants in

the RI exploration, which could have affected the co-design activities. Besides, at the request of DRML (who led the RI exploration), the usability study (co-design step 4) included 2 RI-related questions. In our results, we explicated that co-design participants already discussed more implications before these 2 questions were asked. Without this minor effect, there may have been a greater knowledge gap between the results from the co-design process and RI exploration in HAAL. However, to gain more robust results into the role of the anticipation of implications in co-design, future research could study co-design processes completely separately from an exploration of associated implications.

Conclusions

In this paper, we explored how the co-design process of an AI-based DSS for dementia caregivers is complemented by the explicit anticipation of social and ethical implications. Co-design is an essential means to feed the development and deployment of AI-based care technologies with insights about needs of targeted users and collectively translate these needs into requirements for technology design. Besides, as found in this empirical study, certain implications and strategies to address these implications may be naturally anticipated in co-design, even though users may not necessarily think in terms of implications or risks, but rather in terms of conditions before the technology can be used. At the same time, this case study indicates that a co-design process that focuses on opportunities rather than balancing attention for both positive and negative implications may result in knowledge gaps related to implications and how they can be addressed. In the pursuit of responsible outcomes, co-design facilitators could consider broadening the scope of co-design processes, for instance, by moving back and forth between opportunities and associated implications of innovation, involving future users and social advocacy groups in such an inquiry, and ensuring that co-design participants are provided with inspiration and have basic knowledge and skills to contribute to anticipating implications. Explicit *anticipation* of implications in co-design and broader *inclusion* of stakeholders in doing so increase opportunities for innovators to start addressing implications of innovation before the technology design has been locked in.

Acknowledgments

The authors gratefully acknowledge support from the Active and Assisted Living (AAL) program, cofinanced by the European Commission through the Horizon 2020 Societal Challenge Health, Demographic Change, and Wellbeing. In particular, the work reported here has been supported by the AAL Healthy Ageing Eco-system for People With Dementia (HAAL) project (AAL-2020-7-229-CP). In addition, the authors thank their HAAL project partners in the Netherlands, Italy, Taiwan, and Denmark for organizing and participating in the research activities that provided the basis for this study.

Authors' Contributions

DRML contributed to conceptualization, methodology, validation, investigation, formal analysis, writing the original draft, reviewing and editing the manuscript, and funding acquisition. SIA contributed to methodology, investigation, formal analysis, and reviewing and editing the manuscript. NES contributed to methodology, investigation, and reviewing and editing the manuscript. BMH contributed to formal analysis and reviewing and editing the manuscript. Abstract

Background: Artificial intelligence (AI) use cases in health care are on the rise, with the potential to improve operational efficiency and care outcomes. However, the translation of AI into practical, everyday use has been limited, as its effectiveness relies on successful implementation and adoption by clinicians, patients, and other health care stakeholders.

Objective: As adoption is a key factor in the successful proliferation of an innovation, this scoping review aimed at presenting an overview of the barriers to and facilitators of AI adoption in health care.

Methods: A scoping review was conducted using the guidance provided by the Joanna Briggs Institute and the framework proposed by Arksey and O'Malley. MEDLINE, IEEE Xplore, and ScienceDirect databases were searched to identify publications in English that reported on the barriers to or facilitators of AI adoption in health care. This review focused on articles published between January 2011 and December 2023. The review did not have any limitations regarding the health care setting (hospital or community) or the population (patients, clinicians, physicians, or health care administrators). A thematic analysis was conducted on the selected articles to map factors associated with the barriers to and facilitators of AI adoption in health care.

Results: A total of 2514 articles were identified in the initial search. After title and abstract reviews, 50 (1.99%) articles were included in the final analysis. These articles were reviewed for the barriers to and facilitators of AI adoption in health care. Most articles were empirical studies, literature reviews, reports, and thought articles. Approximately 18 categories of barriers and facilitators were identified. These were organized sequentially to provide considerations for AI development, implementation, and the overall structure needed to facilitate adoption.

Conclusions: The literature review revealed that trust is a significant catalyst of adoption, and it was found to be impacted by several barriers identified in this review. A governance structure can be a key facilitator, among others, in ensuring all the elements identified as barriers are addressed appropriately. The findings demonstrate that the implementation of AI in health care is still, in many ways, dependent on the establishment of regulatory and legal frameworks. Further research into a combination of governance and implementation frameworks, models, or theories to enhance trust that would specifically enable adoption is needed to provide the necessary guidance to those translating AI research into practice. Future research could also be expanded to include attempts at understanding patients' perspectives on complex, high-risk AI use cases and how the use of AI applications affects clinical practice and patient care, including sociotechnical considerations, as more algorithms are implemented in actual clinical environments.

Introduction

Background

The onset of the 2020 COVID-19 pandemic has particularly triggered health care organizations across the globe to consider transforming their health delivery models. According to the 2024 Global Health Care Sector Outlook report published by Deloitte, hospitals and health care organizations are addressing challenges by turning toward novel technologies such as cloud computing, artificial intelligence (AI), 5G telecommunications, and interoperable data and analytics to enable care via digital models [1]. It was not too long ago, in 2017, when the Canadian government created the Pan-Canadian Artificial Intelligence Strategy and announced an investment plan of CAD \$125 million (US \$96 million) for research in AI. The Canadian Institute for Advanced Research was mandated to lead this strategy forward with a 5-year plan to enhance Canada's AI innovation profile on the international stage. Health care is one of the 4 sectors on which the Canadian Institute for Advanced Research is focusing for the advancement of AI research [2]. However, health care has seen slow success in the implementation of AI use cases.

Objective

The objective of this review was to investigate what is known from existing literature about the barriers to and facilitators of AI adoption in health care and propose recommendations on approaches that would address barriers to adoption.

We begin this paper by (1) defining AI (before providing some context for AI's use in health care), (2) describing the most prominent applications of AI in health care, (3) outlining the value that AI is expected to provide, and (4) providing a rationale for this review.

History and Definitions

AI is not necessarily a new concept; rather, the exploration of this innovation goes as far back as 10th century China, when mechanical engineer Yan Shi presented to Emperor Zhou mechanical men capable of independently moving their bodies. In the 12th century, al Jazari, who was a polymath, an inventor, and a mechanical engineer, developed humanoid robots. Furthermore, in the 15th century European Renaissance, Leonardo da Vinci similarly developed a knight robot that was able to move different parts of its body on its own. The definition of AI has changed over time, from referring to robotic machines to much more sophisticated technologies capable of mimicking human decision-making processes and behaviors. The advancement of computer systems and languages in the more recent decades has made it possible to progress toward AI systems. The definition that most fits today's application of AI and is referenced in this paper was coined by John McCarthy in 1956. McCarthy defined AI as "the science and engineering of making intelligent machines" [3]. It is unclear what definition is consistently used; however, what is clear is that today's AI encompasses various techniques aimed at mimicking humanlike intelligence and behavior to allow for the emergence of intelligent technologies capable of problem-solving and decision-making. In this way, AI should be skilled at processing

large amounts of information, should arrive at a conclusion through reasoning, and have the ability to learn and solve problems on its own [4]. Various analytic techniques are used to allow for this, with the most prominent ones falling under machine learning (ML) and natural language processing (NLP) [5].

Large data sets are needed to develop effective AI algorithms and enable AI's maturity to arrive at intelligent outputs. In health care, the sources of data for NLP are primarily unstructured data, for example, free-text clinical notes from electronic medical records (EMRs). ML techniques use structured data such as diagnostic images and genomic data. ML uses two primary types of algorithms: (1) supervised and (2) unsupervised. Supervised learning provides more clinically relevant results; hence, AI applications mostly use supervised learning. There are several techniques in supervised learning, with neural networks and support vector machines being the most popular of the techniques [5]. The most modern extension of the neural network technique is called deep learning (DL). DL has been made possible due to the increasing availability of large amounts of complex data. This technique has become more popular because of the number of layers of data it can translate. NLP can be used to convert unstructured data into structured data. Therefore, both NLP and ML, along with additional data, are required to train the AI continuously. The more data that are fed into the AI, the "smarter" it becomes. In health care, data sets can be available from various sources, such as electronic health records (EHRs), laboratory tests, diagnostic imaging, electrodiagnosis, genetic diagnosis, and mass screening [5]. In 2022, the release of ChatGPT (OpenAI) brought to light the power of large language models. This type of chatbot-style generative AI is being considered to enable extracting data from EMRs and converting them into meaningful outputs that can be useful for clinicians by lowering their administrative burden [6].

Current State of AI Research and Health Care Use Cases

Research in AI has been exponentially increasing, with bibliometric reporting of published articles on the topic of health care having increased at an annual growth rate of 5.12% over the past 28 years. As of 2021, the most significant increases in bibliometric reporting took place in the 3 years before 2021 [7]. According to Tran et al [8], the disciplines with the highest number of publications at the intersection of AI and health include cancer, heart diseases and stroke, ophthalmology, Alzheimer disease, and depression. Most publications on the types of AI used reported on robotics, ML, and DL.

In health care, publications of AI applications are concentrated around operational or administrative efficiency as well as patient care improvement, including better outcomes through improved diagnosis and treatment [9]. AI enhances operational and administrative efficiency by providing administrative support to health professionals and improving performance across the organization. AI can achieve this through, for example, its ability to consolidate and provide the latest and most validated research findings that can support clinicians with up-to-date evidence-based decision-making while providing care and its

ability to leverage EHR data to predict data heterogeneity between various hospitals and clinics [7]. Emergency departments are largely found to have successfully applied AI to optimize resource planning and crowd management [10,11]; for example, the Hospital for Sick Children and Humber River Hospital in Ontario, Canada, are using AI to improve emergency department operations by predicting patient surges in the emergency waiting room [12,13].

Use cases aimed at improving care outcomes include predictive analytics around disease outcome prediction or prognosis evaluation and clinical decision support systems [7]. Examples of such cases are found in cardiology and include the early detection of atrial fibrillation via a smartphone-based electrocardiogram or cardiovascular risk assessment via patient records. Other promising areas include neurology, specifically stroke prediction and diagnosis [5]. Gastroenterology AI applications have also been successfully tested, where algorithms are used to predict outcomes in cases of esophageal cancer and metastasis in colorectal cancer [14]. Image-based diagnosis is considered the most successful use of AI applications in health care, largely supporting radiology, dermatology, ophthalmology, and pathology [15]. In a review conducted on the literature on AI use in the emergency department, Kirubarajan et al [11] reported that 50% of the studies found that AI interventions were better able to diagnose various ailments, such as acute cardiac events and hyperkalemia, among other health conditions.

As mentioned earlier, AI requires large amounts of data to learn and apply sophisticated reasoning and accurate problem-solving. In addition to the race toward researching AI use cases, a surge in health care data is further setting the stage to allow for accelerated AI innovations [16]. EMR data; wearable sensor technology; and genomic, pharmaceutical, and research databases offer opportunities to apply AI to the analysis of health data. Approximately 30% of the world's data volume is generated by the health care industry. The compound annual growth rate of data for health care is expected to reach 36% by 2025 [17]. This growth of data volume in health care is faster than that in manufacturing, financial services, and media and entertainment industries [18]. This sets the stage well for developing AI technologies that can be integrated into health care practice, as algorithms now have more data to provide increasingly sophisticated outputs.

Contributions of the Research

It is clear that the changing landscape, increasing evidence on AI use cases, and increasing availability of data in health care are setting the path toward realizing real-life applications of AI. However, successful utility requires successful adoption, and a number of studies have reported on the challenges encountered with implementing AI in health care [19-21]. Health care organizations are especially complex and can be resistant to change due to various reasons associated with legacy structures, a shortage of resources, and high demand. An estimated 70% of health IT projects fail [22], and an important characteristic of successful technological implementation is tied to its adoption, which is why adoption is a key component of frameworks such as the unified theory of acceptance and use

of technology and nonadoption, abandonment, scale-up, spread, and sustainability theory. These frameworks are used to evaluate and study the acceptance of technologies. For example, the unified theory of acceptance and use of technology framework, which integrates all the available theories about technology adoption, suggests several factors that help understand users' intention to adopt and use a technology. It looks at all the available theories about technology adoption to evaluate use of information systems [23]. Similarly, the nonadoption, abandonment, scale-up, spread, and sustainability framework has incorporated multiple theories to help study factors influencing "non-adoption, abandonment and challenges to scale-up, spread and sustainability of technology-supported change efforts" [24]. Both emphasize the importance of studying adoption to support the successful uptake of technologies beyond implementation. With these reasons in mind, it is important that organizations understand the barriers to and facilitators of AI adoption to ensure successful AI implementation. In reference to the widely known work of Everett Rogers, famously known as the Rogers diffusion of innovation theory, Cresswell and Sheikh [25] have defined implementation as "the consideration and the introduction of HIT applications," whereas adoption is defined as "the acceptance and incorporation of HIT applications into everyday practice."

An initial search was performed to identify whether any consolidated reviews, such as scoping reviews, were already conducted to understand the barriers to and facilitators of AI adoption in health care. During this search, it was found that a majority of the literature seemed to report on a specific area, such as radiology, in a specific setting (hospital or community), and a number of studies were reporting on implementation findings and not necessarily adoption. A few literature reviews on the determinants of and barriers to AI adoption have been conducted, such as the review by Radhakrishnan and Chattopadhyay [26]. However, these reviews span across multiple industries. For health care, 1 systematic review on the *barriers to AI adoption in health care* has been conducted by Assadullah [27]. However, there are no consolidated reviews that consider both the *barriers to and facilitators of AI adoption in health care at large*. Therefore, this review has attempted to explore the latter to provide considerations for health care organizations looking to successfully implement AI technologies via increased adoption.

Methods

Overview

This review was guided by the methodology and reporting structure outlined for scoping reviews by the Joanna Briggs Institute as well as Arksey and O'Malley [28]. The stages defined by Arksey and O'Malley [28] were followed to conduct this scoping review: (1) identifying the research question; (2) identifying relevant studies; (3) selecting studies for inclusion; (4) charting the data; and (5) collating, summarizing, and reporting the results

Stage 1: Identifying the Research Question

Because adoption is a key element of successful cost-benefit realization of technological investments, a general question was

formed using the “population, concept, and context” approach [29]. The first component, “population,” included users or potential users of the AI system, such as patients, providers, health care leaders, researchers, and those who were involved with implementing AI systems in various settings. The second component, “concept,” consisted of barriers to and facilitators of any AI technology. The third component, “context,” was centered on barriers to and facilitators of any AI technology in *any health care setting*, leaving this as broad as possible to maintain the paradigms of a true scoping review. A generic question developed was as follows: What are the barriers to and facilitators of AI adoption in health care?

Stages 2 and 3: Identifying Relevant Studies and Study Selection

In commencing the research, eligibility criteria were defined (as described in the Eligibility section). Once the eligibility criteria were defined, the search strategy was identified, and a search for articles was conducted in the selected databases.

Eligibility (Inclusion and Exclusion Criteria)

All published studies and gray literature that reported implementation findings related to adoption or reported factors impacting adoption were considered in this review. Therefore, studies with various designs, including quantitative and qualitative studies, literature reviews, thought articles,

Textbox 1. Search query.

Query

- “artificial intelligence” AND healthcare or health care or hospital or health services or health facilities AND adoption AND barriers or obstacles or challenges or facilitators or enablers
- “artificial intelligence” AND health AND adoption AND (Barrier OR Facilitator)

Study Selection

A total of 2 reviewers independently screened the articles from the initial search by reviewing their titles and abstracts. Articles meeting the inclusion criteria were identified. Articles that did not meet the inclusion criteria were excluded. Any discrepancies were resolved through discussion.

Of the articles identified, the full text of the semifinal set of articles was reviewed to further refine selected articles. This process was iterative, and some exclusions were made during the writing phase, as the findings evolved. An Excel spreadsheet (Microsoft Corp) was used to record the articles identified. Recordings included the following details: the name of the article, authors, journal, whether the article was peer reviewed, type of paper, discipline, country, region, method, population, end users, and type of AI application (if specified). Duplicate studies were identified and removed to ensure there was no overlap.

Stages 4 and 5: Charting the Data and Collating, Summarizing, and Reporting the Results

A conventional content analysis approach was used to review the articles, chart the data, and identify themes [30]. Publications meeting the inclusion criteria were reviewed in detail, and an inductive approach was used to identify themes. First, the

conference papers, and reports, were included in the initial search and review. “Health care organizations” were defined as organizations that are engaged in providing care to patients or involved in some aspect of providing agency to health care players. Health care players were defined as anyone involved in the process of providing or receiving care, including policy makers; administrative professionals; clinicians; physicians; and, most importantly, patients and their families. All types of AI technologies were considered in this review. Articles were not excluded based on variations in settings (hospital vs community setting) or countries where the research was conducted. Only articles in English were included. Due to the speed at which the landscape for AI is advancing, only articles that were published between January 2011 and December 2023 (when the search was conducted) were included.

Search Strategy

This review is intended to synthesize findings from publications that reported on the barriers to and facilitators of the adoption of AI implementations. A search was conducted on MEDLINE, ScienceDirect, and IEEE Xplore in December 2023. Keywords were selected in reference to the question identified to formulate the scope. Keywords included “artificial intelligence”; “healthcare” or “health care”; “hospital,” “health services,” or “health facilities”; “adoption”; “barriers”; “obstacles”; “challenges”; “facilitators”; and “enablers” (Textbox 1).

articles were read in full for the author to immerse into the content. This was followed by carefully reading each article and highlighting key concepts around barriers and facilitators that appeared to repeat across all the articles. These initial key concepts were recorded as themes, and this process helped identify many themes that were further categorized and grouped based on similarity. All data were charted in an Excel table to help with the analysis.

Ethical Considerations

This work received an ethics exemption from the University of Victoria ethics board due to the nature of research being a literature review.

Results

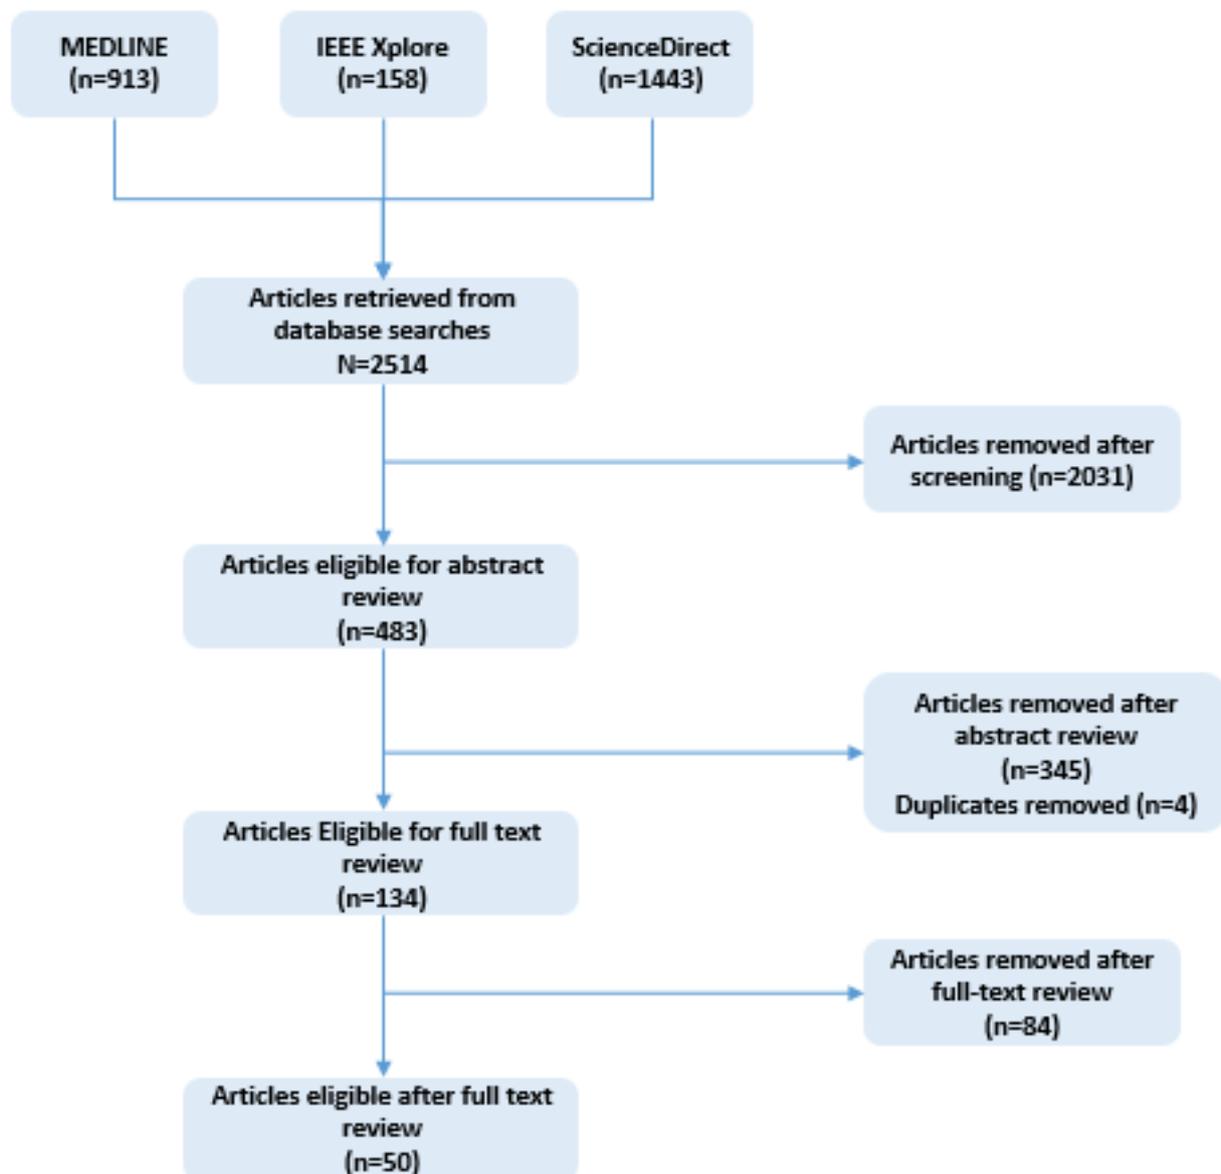

Overview

The initial search from MEDLINE, IEEE Xplore, and ScienceDirect provided cumulative results of 2514 publications. After screening the results, 483 (19.21%) publications were included for abstract review based on the title of the study. After abstract review, 134 (27.7%) publications were identified for further text review, further excluding 345 (71.4%) publications, including 4 (0.8%) duplicate articles. Out of the 134 studies, 50 (37.3%) went through a thorough and more detailed review

and thematic analysis. Figure 1 presents the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. The breakdown of studies is based on the country of origin, types of articles selected, and health care discipline or area covered. Overall, 11 articles were from the United States, 7 from China, 5 each from the United Kingdom and Canada, and 3 each from Germany and the Netherlands; the remainder of the articles were from Australia, France, Germany, India, Indonesia and Taiwan, Italy, New Zealand, Saudi Arabia, Singapore, Sweden, Switzerland, and other European countries. In some cases, multiple countries or regions collaborated to

publish the articles together, including different European countries or the United Kingdom and United States. A total of 13% of the articles were literature reviews and 8% were mixed methods studies. The rest of the articles were cross-sectional studies, ethnographic or qualitative studies, case studies, white papers, and thought articles. In terms of setting, the majority of the articles discussed AI in health care in general with a majority of the articles reporting from the field of radiology or oncology. The setting of the remainder of the articles were academic hospitals, ophthalmology clinics, hospital, primary care, and dermatology clinics.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram showing the study selection process.

Thematic Analysis

Overview

On the basis of the conventional content analysis approach used (as described in the Methods section), a total of 18 categories

of barriers and facilitators were identified (Figure 2). Interestingly, the themes were found to provide perspective on both facilitators and barriers. For example, if the theme explainability was identified as a barrier, the same theme was tabulated as a facilitator to capture what the articles

recommended for overcoming challenges with explainability to increase adoption. As such, the reporting of the results for each theme provided perspective on the theme being both a

barrier and facilitator, with the exception of governance, which was entirely noted as a key facilitator.

Figure 2. Themes identified. AI: artificial intelligence.

Transparency and Explainability

Explainability can be defined as the ability to deconstruct an algorithm to understand the mechanism by which it arrived at the output. Explainability has gained prominence due to the fast-paced growth of ML algorithms such as DL. These algorithms are labeled “black box” due to the difficulty in interpreting and tracing the techniques used by the AI models, thereby impacting trust and demanding the need for transparency [31,32]. According to Holzinger et al [33], “explainable AI deals with the implementation of transparency and traceability of statistical black-box machine learning methods, particularly deep learning.” While transparency has a wider definition and explainability is a component of transparency [34], most studies have noted explainability in the context of algorithmic transparency; therefore, findings from these 2 interrelated concepts have been discussed together.

Several studies noted a lack of explainability as a barrier to adoption. Baxter et al [35] reported concerns from adopters around the lack of explainability regarding the prediction of the AI algorithm embedded in the EHR to predict unplanned readmission; specifically, the lack of explainability regarding what features of the algorithm were driving the output was an impediment to trust among adopters. Other studies noted that the way the data were being used to train algorithms was not clear. The lack of traceability and logical understanding of how the algorithm arrived at a recommendation contradicted a key foundation of evidence-based medicine, which relies on high standards of explainability. Clinicians expressed the need to understand both the scientific and clinical bases of the recommendations provided by the AI to confidently validate and apply the decision [19,20,36–38]. Morrison [36] particularly quoted stakeholders seeking clarity on the extent to which there is a need to provide transparency on AI output to patients and how this is directed by legislation or data protection laws. In a study conducted by Nadarzynski et al [39], users of an AI-enabled chatbot reported hesitancy to use the technology due to a lack of transparency on how the chatbot accurately arrives at responses to health inquiries.

According to Holzinger et al [33], “explainability is an important element for consideration in order to enhance trust of medical professionals.” To facilitate adoption, improving algorithmic transparency will be a key consideration to change attitudes and build the trust of adopters [35,40]. Additional recommendations around facilitating adoption were to have processes in place to support clinicians in case of disagreements on decisions due to a lack of transparency and explainability [41]. Furthermore, revealing the process of how the algorithm was developed, who was involved in the development process, whether clinicians were consulted, and how the data were processed would enable acceptability [42,43].

In health care, causality is especially important when using automated decision systems; therefore, Holzinger et al [33] emphasized that AI systems should support the understanding and explanation of the causal models as opposed to simply solving through pattern recognition. Similarly, Gillner [44] also noted that this opacity of the output is not aligned with the “medical ethos.” Weinert et al [45] recommended that investing into explainable AI that produces a transparent and understandable AI could help address the issue of acceptability. Moorman [38] reported that successful adoption was achieved by publishing evidence on the algorithm’s underpinnings and providing clinicians with details on how data elements interacted within the algorithm to produce the predictive output.

Algorithm Bias, Equity, or Fairness

A prominent theme that came through was around the prevention of algorithm bias to ensure equity and fairness and avoid concealed discrimination. Algorithmic bias has been defined by Panch et al [46] as “the instances when the application of an algorithm compounds existing inequities in socioeconomic status, race, ethnic background, religion, gender, disability or sexual orientation to amplify them and adversely impact inequities in health systems.” Such biases have been visibly found in glomerular filtration rate and pulmonary function and have continued to persist despite efforts to address them. Inaccurate and underrepresentative training data sets for AI models can cause bias, misleading predictions, adverse events, and large-scale discrimination, causing barriers to adoption [32,41,47,48]. Baxter et al [35] and Chua et al [49] reported

clinical stakeholders' concerns around the relevance of the AI model's output, especially because the algorithm did not consider social determinants of health to predict risk outcomes for readmissions. Similar concerns were raised by participants from other studies around the risk of algorithm bias as a challenge for adoption. Others expressed dissatisfaction that the AI algorithm may not be representative of the patient population among whom it is implemented or may have been trained with a biased training data set that has been retrofitted to produce certain results, therefore not providing a representative outcome of interest [36,49-51]. AI not accounting for patients' health determinants was noted as a "grand challenge" [19].

Inadequate data from representative groups, algorithms designed to represent a majority, and missing variables that impact predictions are components that contribute to bias [21]. This can be addressed by engaging clinicians in the design and development of the algorithm to ensure that appropriate measures are taken to address bias before the AI algorithm is deployed.

Functionality (Accuracy and Usefulness)

One of the major themes that came through was around the value, usefulness, and accuracy of an AI algorithm. Accuracy and quality of the AI algorithm's output were primary reasons for adoption hesitancy in the context of the functionality of the AI. In some studies, patients reported the need to assess the usefulness of the AI before using it and had concerns around the quality and accuracy of the output, thereby questioning the value of AI as a whole [39,42,52-55]. Clinicians also reported concerns around the usefulness of the output based on the lack of accuracy and inactionable output contributing to a low likelihood of use. This also included dissatisfaction if recommendations were too similar, inappropriate, or not useful [35,37,38,40,56]. Ease of use; complex interfaces; and inconsistent performance, for example, due to false positives and negatives add burden to the workflow, creating more work for clinicians, thereby impeding adoption [42,52,57-59]. Morrison [36] identified a lack of an agreed standard and benchmark for accuracy (how accurate does an AI tool need to be before it is approved for clinical practice) as an impediment to implementation and, subsequently, adoption, as, if a standard existed, it could provide rationale for the accuracy. Temsah et al [60] recommend the application of evidence-based oversight mechanisms to ensure accuracy and dependability. Finally, Choudhury [61] noted that if an algorithm is not performing up to standards or adds more work to the clinicians, this can impact adoption, as clinicians perceive it as a high risk.

Perceived benefit, perceived usefulness, usability, ease of use, usefulness, accuracy, and reliability of the output of the AI are key contributors to adoption [19,45,62-67]. In particular, usability and acceptability should be assessed with the intended user in mind [41]. Perceived benefit is especially important when it contributes to improved efficiency in clinical processes [62].

From a patient's perspective, there is value if an AI technology can be used from home for minor consultations, such as skin cancer detection using an AI-enabled app [42]. Ease of use of

the technology and accessibility to information for minor health concerns [39] are especially seen as valuable, as they negate the need for a visit to the physician; however, in the event that a visit is required based on the AI's recommendation, then the integration of the technology with the health care system is considered beneficial [42]. It is essential that as the AI system matures, it is designed such that it can "adopt and challenge contradictory rules and behaviours" [43].

Risk of Harm

Patient safety concerns causing adverse effects were noted by Mlodzinski et al [48] and Vijayakumar et al [59]. The lack of accuracy of AI output was also considered to pose a potential risk of harm by both clinicians and patients, as, in some cases where the algorithm may output false negative results, it may provide an incorrect sense of reassurance and cause a delay in treatment. However, in cases where the algorithm is too sensitive, thereby providing false positive results, it may add work and costs to the treatment process [39,42,57,61,68]. The risk of harm can be lowered if AI algorithms are developed with the 5 rights (in the case of an automated decision system), similar to other clinical decision support tools [40]. In addition, Sangers et al [42] proposed that in some cases, AI applications should provide only risk indication instead of a diagnosis to reduce the risk of harm. Chen et al [68] reported that policies and mechanisms to safeguard professionals could address challenges associated with a potential risk of harm due to a lack of output accuracy.

Trust

Lack of accuracy; doubts about unsafe results; privacy breaches; patients' perceptions and acceptance of automation; and uncertainty about developers' reliability, availability, usability, and perceived usefulness were found to be obstacles to gaining trust [39,42,47,50,53,54,69,70]. Clinicians expressed fear around having to reframe their professional identity and responsibilities [57]. Fear around what AI really meant was noted as another barrier [36,42].

Facilitators of trust included the endorsement of the technology by experts as well as academically backed clinicians, including regulating bodies such as the government; evidence of output accuracy based on the evaluation of AI; and positive opinions from trusted thought leaders in the respective clinical fields [42,58,60]. Another facilitator of trust is the engagement of patients in the development of AI. This could facilitate trust in the public and address concerns around trust in data sharing [71]. Overall, trust was largely found to be associated with perceived usefulness; however, one study noted that "if peoples' confidence and beliefs are improved, they will use the product despite its usefulness" [52]. In addition, Fan et al [72] reported that initial trust is a key indicator of the intention to use the AI application and noted that if the confidence to use the AI application is high based on performance expectancy, then this will increase trust in using the AI.

Human-AI Teaming

The lack of human intervention was found to be a barrier to adoption for both clinicians and patients. From a clinician standpoint, physicians expressed that they would be less likely

to use an AI, given their familiarity with the patient's condition and the value of intuition in clinical decision-making [32,35]. Mlodzinski et al [48] reported concerns about potential systemic bias present in the AI that could impact the patient-provider relationship. From a patient standpoint, the lack of human presence was seen as a limitation due to a lack of empathy and emotional connectivity with another human or simply not having the presence of a human physician to verbally communicate and discuss, such as when using an AI app or chatbot [51,64]. By contrast, the lack of human presence was, in some cases, seen as a benefit due to the anonymity in sharing intimate or uncomfortable health concerns [39,42]. Hemphill et al [73] reported increased confidence in patients when AI was combined with clinical interpretation.

Aligning Strategic Components

Several studies particularly highlighted the importance of strategic alignment with initiatives. Baxter et al [35] reported on how a lack of alignment among different organizational initiatives led to varying outcomes and disjointed communication. Strohm et al [57], on the other hand, talked about how strategic alignment could lead to better dispersing of funds across different departments.

Sun and Medaglia [50] pointed out the necessity of outlining a comprehensive "top-down strategy" that would include organizations' goals and resource distribution for AI implementation. Weinert et al [45] elaborated that to overcome the barrier to including AI initiatives in the organizational strategy, the German government introduced a new law that supported organizations with financial assistance to implement innovative digital technologies such as AI, as there was hesitancy among organizations to include expensive AI implementations as part of their strategy due to a lack of funds.

Use Case-Driven or Problem-Driven AI

Several studies noted that to start the journey of implementing AI, there is a need to identify a problem and not merely use data to come up with a solution. Therefore, use cases should be identified based on notable problems that can be addressed by AI solutions. One particular study mentioned how the lack of a use case affected the implementation of the AI model [35,36].

End-User Engagement or Co-Design

A lack of sufficient buy-in from end users and a lack of endorsement from organizational leadership emerged as barriers, including not engaging stakeholders early in the process. It is critical to incorporate clinicians and other stakeholders, such as patients, in the development life cycle, especially the testing phase with the application of a user-centered design and testing approaches. This may be time intensive but proves to be an effective approach to enable adoption [39,40]. As Ongena et al [69] pointed out in their findings, patients should be involved when developing AI systems, specifically for diagnostic, treatment planning, and prognostic purposes. Pou-Prom et al [74] reported the usefulness of engaging end users in designing, deploying, and refining the AI solution. Moorman [38] recommended maximizing buy-in and engagement at all levels of stakeholders, from leadership to users, and especially engaging a clinician leader from the onset. Finally, Goldstein

et al [75] noted the inclusion of champions at the leadership and clinical levels to achieve successful implementation.

Workflow Integration

This review found that the lack of integration of the AI system into the workflow can be a barrier to successful implementation and adoption. For example, Baxter et al [35] reported impacts on success due to variations in existing workflows for risk assessments and readmission scores across different areas. Similarly, Strohm et al [57] mentioned how the lack of integration and standardization of workflows led to variations in workflows. For other types of AI solutions, such as apps, the data not being integrated into the health care system or workflow was seen as a barrier for patients to adopt the solution [42,53]. Helenason et al [58] and Schepart et al [56] both noted the importance of conformity with the workflow when integrating AI tools into the environment where they would be used.

Recommendations included the following: ensuring that AI applications easily integrate with existing IT systems, integrating data from patients' use of AI-enabled apps into the health care system and workflow, and considering the integration of the AI into the clinical workflow but maintaining autonomy for clinicians to have the final say [19,20,38,42,49,57,75]. In situations where the AI system is deployed in different areas, using a common model may improve alignment in workflows [35,36]. Chen et al [68] reported that clinicians saw AI integration into the workflow as a positive if the system was seen as potentially eliminating routine work, allowing them to focus on other tasks. Moorman [38] reported that it was helpful to assess existing unit workflows, communications, escalation, and event management processes before implementation to address challenges brought up by clinicians concerned about added work.

Awareness and Training

Training refers to educating the users on various aspects of the technology, such as the outcomes of the AI model, its benefits, and how it supports the clinical workflow, and providing new skills such as technical and data science skills to staff, especially laggards and champions, to assist with the adoption [36,41,57,62]. Kelly et al [21] particularly noted that to provide clinicians with clarity on how an algorithm could improve patient care, approaches such as using a decision curve analysis that would provide quantified benefits of using a model to inform actions that need to be taken would be helpful. Skepticism and a lack of understanding were seen as barriers to AI adoption [48,51]. Chen et al [68] found that AI adoption increased among radiologists who were more familiar with AI. Sun [76] recommended that implementation teams should consider influencing clinicians by sharing AI knowledge via more informal communications, such as social media communication or in-person communication. Moorman [38] found it helpful to develop educational material with input from clinicians to tailor it to the clinical role and hospital culture. Training and awareness should include building an understanding of the technology; providing clarity around language such as the definition of AI; education around data use in health care; and building awareness on the value of AI, including breaking down concepts that dispel fear

[36,37,39,42,50,52,71]. Clinicians' awareness and knowledge of AI before using it contributed to its successful acceptance [59,73]. In addition, users feel that the technology is "unqualified" based on their perception of the premature nature of the technology [39]. Misunderstanding of the capabilities of AI technologies in the general public and the health care sector is a challenge to adoption, with gaps in awareness around the value, advantages, and high expectations of AI [37,50]. Overall, Alsobhi et al [70] emphasized the urgency of accelerating AI adoption through the dissemination of AI training.

Resources and Infrastructure

Shortages of personnel with the required skills were reported as barriers, along with the quality of IT infrastructure available for AI implementation [32,35,36,40,45,50]. Hickman et al [71], in particular, noted the lack of technological (infrastructure) maturity to allow for the integration of AI. The presence of AI experts, perhaps a multidisciplinary team, particularly with clinical scientists, data science and subject matter experts with AI skills, an innovation manager, AI experts to provide training, and local champions within departments involved in the end-to-end process, was considered an important element for adoption [32,57,59,62,71]. Goldstein et al [75] noted that for scalability, where the AI application would be deployed in multiple sites, having designated resources from the onset of the project with clear roles and responsibilities was seen with success. Yang et al [77] recommended cultivating talent with both high-level medical and technology knowledge and understanding how the 2 domains can be used to meet patients' needs. In a different perspective on the shortage of resources, Chen et al [68] noted that radiographers and radiologists held more positive attitudes toward the adoption of AI, as it would help address workforce shortages in the radiology field in the United Kingdom.

Evaluation and Validation

The need for evaluation on multiple fronts was noted by various studies. Studies indicated that the technical evaluation of AI is necessary as a first step to validation. Technical evaluation must be followed by clinical validation (based on established methods in clinical research) and economic validation. Wolff et al [78] particularly noted the lack of clinical and economic measurements as a barrier to practical implementation. Evaluations should be tailored toward digital technologies to gather empirical evidence surrounding the value of AI's use [53,78]. However, the cost of conducting an empirical evaluation and a quantified clinical trial-type evaluation may be a deterrent to the pace of developing the technology. Therefore, this should be considered when selecting the type of evaluation to be conducted. A focus on assessing the effectiveness and accuracy was duly highlighted. Implementers should consider validating or testing the algorithm with synthetic data [40-42,57]. Establishing a standard methodology for the validation of AI algorithms and the overall evaluation of AI will be critical to gaining confidence from adopters [50]. Hickman et al [71] suggested that having structures in place for the continued monitoring of standards that impact AI (eg, regulatory standards) and ensuring that infrastructure is in place to evaluate and monitor algorithms continuously are necessary.

Data Security, Ownership, Quality, and Availability

Data quality, security, ownership, and storage were prominent themes in the reviewed studies. In terms of data quality and integrity, several issues were identified as barriers to developing good AI models that provide value to users. These were issues around variability, the nature of unstructured data, incompleteness of data, the data not representing the reality of clinical care, and the absence of data standards (specifically around how and what data are collected). Having metadata standards, terminologies, data quality metrics, and common data models were identified as facilitators in resolving some of these issues [40,43,45,50]. Fragmented access to data and limited sources, such as the availability of data only from EHRs or data silos, were also noted as barriers [78].

Data access, integrity, and provenance are key to the development of models. Institutions that were the most successful in implementing AI were thoughtful about how to guarantee data integrity [40]. Wolff et al [78] noted the challenges with data silos and fragmented access to medical data, including limitations on the availability of data only from the EHR, to enable the development of robust AI applications. In terms of data ownership, the dilemma around who owns the data, whether it would be the government, institution (eg, hospital), or patient, is a barrier to adoption, as it leaves questions around how data would be integrated or accessible for future AI advancement [37,50]. While this may not present a direct adoption challenge, it does indirectly impact the availability of data required for development and to produce meaningful outputs, which is an impediment to adoption, as identified earlier.

Data security was identified as a major contributor toward hesitancy, with concerns around cybersecurity relating to both training and testing data as well as fear of trackers and spyware obtaining unsolicited data [39,41,42,45,48,77]. Furthermore, the ability of deidentified data to be reidentified poses a major risk for the individuals and institutions providing their data. This further contributes to resistance to sharing the data that could help expand data sets for AI training. Several strategies for preventing security breaches have been proposed, and these could be helpful in securing data, especially health data that are accessible over the web [20,42].

Concerns around data processing include the lack of understanding of how data are stored, processed, and accessed; the establishment of protocols; and compliance with existing privacy policies, such as the General Data Protection Regulation and the Health Insurance Portability and Accountability Act [20,36]. A survey of patients conducted by Ongena et al [69] indicated the need for patients to be informed about how and specifically which data are processed. One study explicitly highlighted the issue of data ownership. Concerns over data ownership were particularly evident when patients linked data ownership to trust in the technology [47].

Ethics and Privacy

Concerns about privacy and ethics were focused on maintaining confidentiality, ensuring processes are in place to obtain consent, and having informed consent with clarity on how the data will

be processed [32,39,47,56]. Having clear consent processes related to how data are generated through the use of AI and how these data flow as well as defining the meaning of consent and transparency on strategies to maintain privacy are seen as facilitators of adoption. This is especially applicable to “clinical and epidemiological use cases of ML in both decision support and automation categories, as data from patients or the public are essential to train algorithms in these areas” [20]. In addition, Sun and Medaglia [50] particularly pointed out the unethical use of data, such as data being used by commercial organizations. Ensuring transparency to end users, especially patients involved in the ethical and legal frameworks that guide the development of AI systems, could be helpful [69,73]. Weinert et al [45] particularly identified ethical issues, specifically as they relate to liability, as a barrier to AI adoption. Wolff et al [78] noted that integrating “privacy-by-design” technologies into AI applications that incorporate advanced data protection features could mitigate such challenges.

Governance

Governance was primarily noted as a key facilitating factor, playing the role of enabling the full cycle of AI. It is critical to have a governance structure in place to oversee the development and rollout of AI from conception to implementation, with governance tools providing guidance on various stages of the process. Governance should include diverse professionals with clear articulation of accountability, including nuances in reactions to accountability [35,40,55,58,64]. Isbanner et al [64] noted the importance of articulating accountability. This is especially important in health care because “ethical and governance challenges matter to the public.” Wolff et al [78] recommended outlining specific responsibilities for different stakeholders to delineate accountability-based steps in the process, for example, identifying who would review an x-ray image analysis and identifying liability and culpability (eg, obligatory human check of a decision obtained by an AI application). According to Sunarti et al [47], the governance body should include “developers of software, government officials, health care, medical practitioners and advocacy for patients groups.” The lack of accountability in the decision-making process is a challenge; therefore, framing this in the governance model could be a way to address adoption issues related to accountability [37,50,73]. Other functions of the governance body would be to ensure funding and connectivity to the wider data science community, ensure alignment with strategic initiatives in the organization, and act as a long-term centralized knowledge repository for performance oversight. A governance model should have mechanisms and systems in place to facilitate changes impacting AI technologies in development or use based on cyclical changes in the technology or changes in the external landscape, such as the ones initiated by regulatory bodies [32,41,79]. Formalized analysis of ethical considerations in the development and use of AI should be a key component of governance. Governance should also be linked to the data governance committees for various data processing, quality, and integrity oversights [43]. One particular solution proposed by Morrison [36] was to have national-level governance templates that would facilitate national data protection via the implementation of impact

assessments. In contrast, governance can hinder data sharing. Therefore, governance bodies should maintain a rigorous process without becoming a constraint [36].

Regulatory and Legal Frameworks

A lack of regulation and policies from the government, including uncertainty around legal direction or law, was presented as a barrier to the application of AI technologies [37,45,57,60,77,78]. Other researchers noted that there was no clarity in the area of regulatory structures with regard to which regulatory body should be consulted for AI developments and deployments [36,53]. Therefore, it would be essential for governments to establish regulatory bodies and legal frameworks to provide guidance on various aspects of AI development and application [20,41]. In addition, ambiguity surrounding malpractice liability policy as it relates to physicians’ legal responsibilities, for example, in case of diagnostic errors, remains a barrier to AI adoption [49].

Funding and Cost

The lack of and uncertainty surrounding funding are presented as barriers to implementation [32,51,56]. Researchers have suggested that there is a need to have costs identified from the start-up stage all the way to scalability. Funding can especially be a barrier if an AI technology is lacking in evidence, with little to show for the value it provides. Sun and Medaglia [50] and Xing et al [53] reported that financial barriers in the context of cost and benefits, the lack of a sustainable business model, and insufficient funding to meet public demands should also be considered. Sun and Medaglia [50] additionally noted challenges associated with the adoption of IBM Watson in China due to patients having to pay high fees for the service. Finally, funding should be cohesively considered not only for the development of the technology but also for resources required to implement the technology, such as technical subject matter experts, project managers, and champions [36,40,41,51,57]. Weinert et al [45] noted that to overcome the barrier of lack of resources and meet the financial investment demands of AI implementations, the German government introduced a new law that could help organizations bridge funding gaps; however, they could not conclude whether this would facilitate any progress, as the announcement was just made.

Discussion

Principal Findings

The principal findings of this study imply several factors impacting the adoption of AI systems, and for each barrier identified, there are corresponding facilitators. Ethics, bias, and transparency or explainability are core considerations in developing trustworthy and adoption-centric AI systems. Furthermore, the barriers identified should be holistically synergized within a governance framework, one that ideally oversees the entire end-to-end process, from ideation to the implementation and sustainability of AI systems.

Trust emerged as one of the most critical elements of AI adoption. This review revealed that trust can either be facilitated or impacted by almost all the themes identified in this scoping review. More specifically, fairness, explainability, and ethics

seem to be the centerfold of barriers to AI adoption. Therefore, our discussions have focused on these 3 domains with recommendations on how organizations can address these domains to facilitate adoption.

Transparency and Explainability

Our findings revealed that explainability in the context of algorithmic transparency is a significant barrier to adoption. Various studies noted that limitations due to the opacity of an algorithm may inhibit clinicians from relying on ML outputs in clinical settings. This leads to ambiguity on whether the ML output can be trusted enough for the clinician to move forward with the clinical decision-making or should be overridden due to a lack of certitude or misalignment with traditional clinical judgment [80]. AI explainability (XAI) is an entire field dedicated to ensuring trustworthy and explainable AI. There are numerous publications from this field. For example, Markus et al [81] noted that explanations are crucial to involving a human in the process of verifying the decision of the algorithm, for example, by revealing what features were used in training the AI algorithm. Adadi and Berrada [82] have conducted a comprehensive review of existing evidence on explainability approaches and organized them from different perspectives. They specifically outline 4 guidelines for the need for explainable AI. Explain to justify: the decisions made by using an underlying model should be explained to increase their justifiability. Explain to control: explanations should enhance the transparency of a model and its functioning, allowing its debugging and the identification of potential flaws. Explain to improve: explanations should help improve the accuracy and efficiency of their models. Explain to discover: explanations should support the extraction of novel knowledge and the learning of relationships and patterns to manage social interaction and create a shared meaning of the decision-making process.

There are several techniques that organizations can adopt when aiming to achieve explainable AI. These include explainable modeling, evaluating for explainability, or following an explainability framework, as proposed by Markus et al [81]. Preece [83] and Vilone and Longo [31] have done a thorough analysis of evaluation approaches for explainable AI. The inclusion of the combination of these techniques from XAI could be useful for organizations to address adoption barriers associated with explainability. It is prudent that organizations developing and implementing AI incorporate various explainable modeling approaches, include explainability frameworks, and consider explainability evaluation in their AI life cycle. In addition, part of this process should include equipping clinicians with knowledge about what the AI takes as input, how the input is processed, and what the AI produces as output, along with the training process used. In this way, clinician engagement is essential to the process of developing and validating AI algorithms and outputs. This approach will also empower clinicians to discuss these transparencies with patients, thereby contributing toward building trust on all fronts.

Bias

In terms of equity and fairness, our findings have demonstrated that algorithm bias is a critical factor in not only gaining trust

but also having meaningful outputs that can be applied to diverse patients. Specific concerns related to adoption include models being trained on data not representative of the patient population or not containing diverse data as related to social determinants of health [19,35,36]. Bias in AI systems can be introduced due to biased data, algorithms being trained on the biased data, limitations in the model itself, small training size, lack of user participation, and other unseen factors [84]. There are a number of examples of specific issues related to bias in AI systems. Buolamwini and Gebru [85] reported that an artificial vision algorithm was unable to identify dark-skinned individuals, as >80% of the individuals in a reference data set were light-skinned individuals. Another failed case is found in the field of anesthesiology, where data from 40 institutions revealed that Black patients received inferior care (with respect to postoperative nausea and vomiting prophylaxis) at nearly every single center [86]. Seyyed-Kalantari et al [87] noted that convolutional neural networks will frequently underdiagnose Hispanic patients at a disproportionate rate due to the potential lack of access to health care and insurance type. In the field of mental health, specifically concerning schizophrenia, a meta-analysis found that risk-flagging models trained on European populations have reduced performance in East Asian populations [88].

According to Panch et al [46], several challenges need to be addressed when addressing algorithmic bias. They include a lack of clear definitions and standards of “fairness,” insufficient contextual specificity, and the “black-box” nature of algorithms. These can be addressed by developing algorithms based on where they will be deployed by first establishing and identifying these contexts and ensuring processes are in place to address these challenges. There are numerous solutions to address bias that emphasize the risk of bias mitigation techniques to be applied at each stage of model development. For example, Chen et al [89] and O’Reilly-Shah [90] recommend that at the preprocessing stage, where the data may have internalized biases, techniques such as reweighing data samples of marginalized groups or resampling based on the population that algorithm output would be applied to. These techniques could help address the adoption barriers identified in this review, particularly those around underrepresentative and inaccurate training data sets. Similarly, at the postprocessing stage, similar thresholds for different representative groups could be set for the model to be monitored, adjusted, and trained. The design of the algorithm should consider equity via training data sets that are either diverse or focused to fit the localized population. Another major concern is data set drift, which means that the data set the model was trained with is different from the test data set. There are various techniques to mitigate data set shift, and these techniques should be considered in model development. Another mitigation technique, as recommended by Chen et al [89], is federated learning, where a model is trained on a global server. This technique allows for models to be trained on large data sets without sharing sensitive information. Aside from more quantitative techniques to address the risk of bias, there are assessments available that can be used as a checklist during each stage of AI development. While these tools can address statistical bias, it is much more challenging to identify social bias that can intrude into the data. Frameworks

such as the one developed by Landers and Behrend [91] comprehensively outline questions that would be asked at each stage of AI development. These questions focus on information, perceptions, and other social and cultural components. Such tools, when integrated into the AI development process, would help gather evidence that could be shared with clinicians and patients on how bias mitigation has been considered in the end-to-end development process, thereby addressing adoption concerns around bias identified in this review.

Ethics

Gerke et al [92] have discussed four primary ethical challenges that need to be addressed to realize the full potential of AI in health care: (1) informed consent to use, (2) safety and transparency, (3) algorithmic fairness and biases, and (4) data privacy. These challenges resonate with our findings around barriers to adoption and, interestingly, tie in these elements of barriers to adoption under the ethics domain.

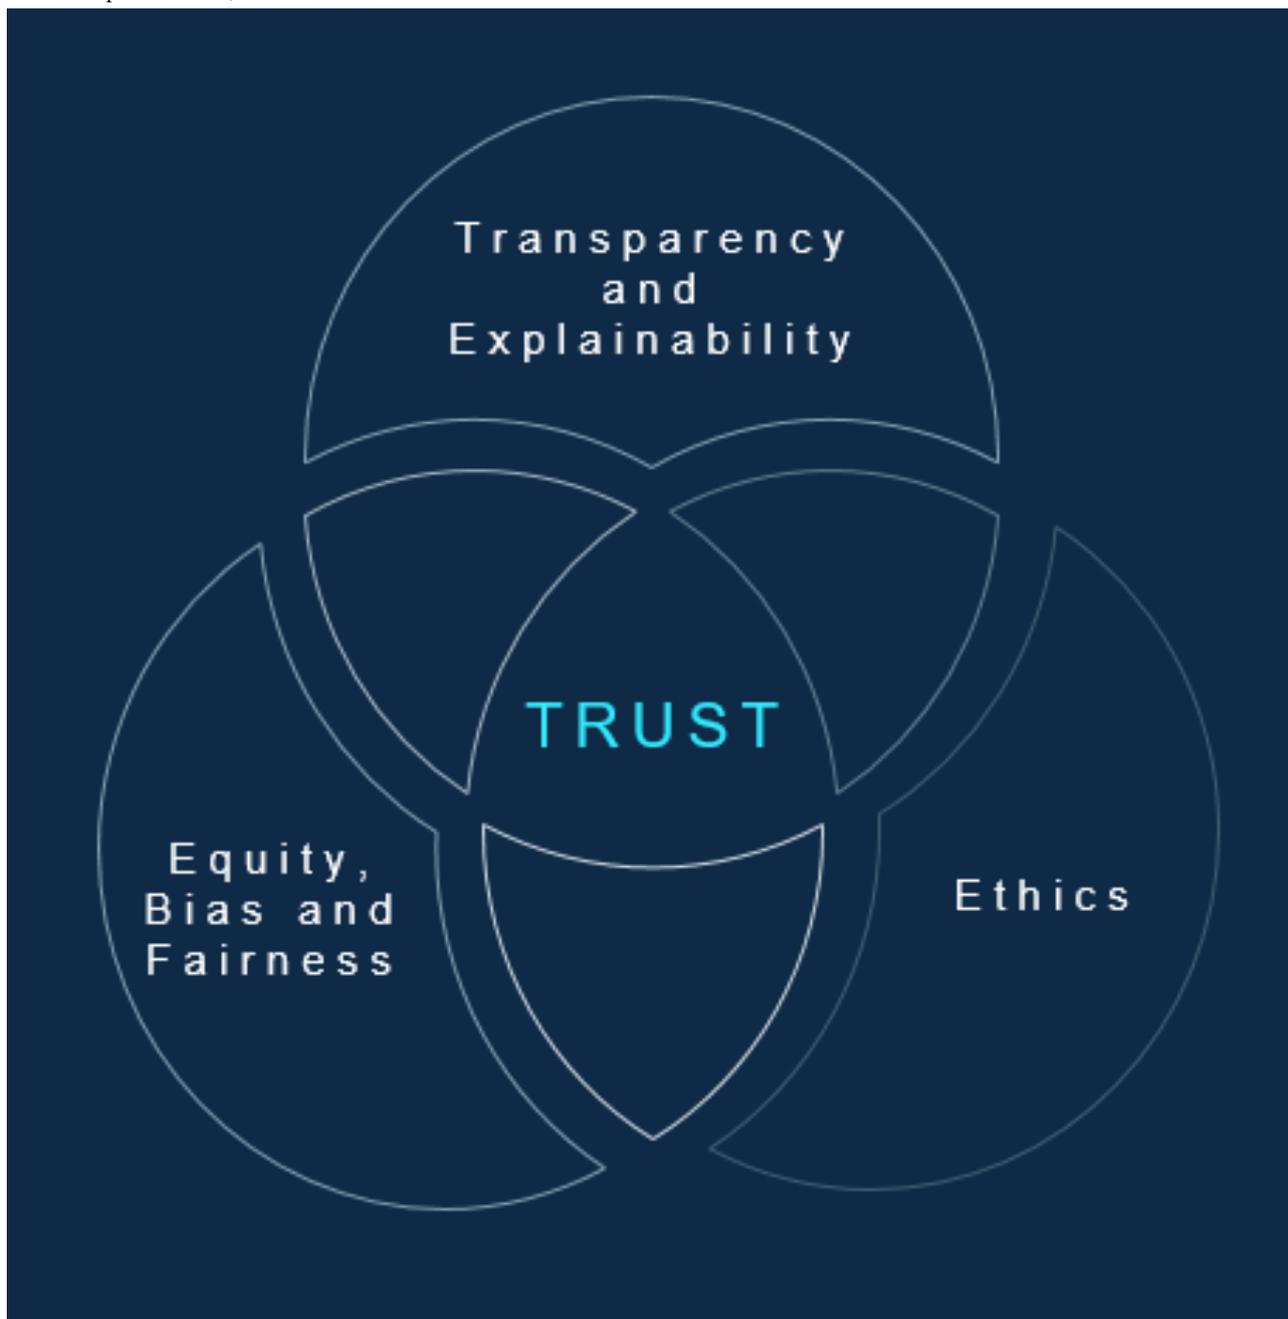

There are several cases of ethical concerns that highlight the need for ethics. In the context of ethical concerns around informed consent and data privacy, in 2017, the personal data of approximately 1.6 million patients were provided to Google DeepMind by Royal Free National Health Service Foundation Trust without the patients' consent. The data were to be used to test a new way of detecting kidney injuries [93]. From a clinician's perspective, there are concerns around what the clinician's responsibility is in informing patients about the use of AI in their care [92]. In the context of algorithmic safety and bias, Buolamwini and Gebru [85] and Liao [94] note ethical concerns around algorithms not detecting dark-skinned individuals for skin cancer detection due to the fact that the algorithm was trained on light-skinned individuals. Similarly, an algorithm that is widely used in US hospitals to identify patients who need additional care was found to use the cost expenditure by patients as a means to identify those who need extra care. This was discriminatory toward Black patients, as they generally spend less than White patients on health care, resulting in false conclusions [95].

In terms of safety and transparency, Liao [94] provides a good explanation as to why the lack of safety and transparency is an issue. They provide an example of a prediction of a 70% chance for a supposed patient's tumor to become malignant in 5 years; however, the algorithm does not necessarily provide detailed

reasons as to how it arrived at the conclusion. From an ethical standpoint, this is an issue because humans need to know how a decision is reached; specifically, in health care, not being able to understand and trust a decision is problematic.

Which and, more importantly, how can organizations address ethical concerns? According to Liao [94], there are >80 ethical frameworks that have been proposed for AI. Many of these draw on the 4 principles of biomedical ethics, namely, autonomy, beneficence, nonmaleficence, and justice. Some of these frameworks provide practical checklists that organizations can use to conduct an ethics deliberation. For example, Solanki et al [96] developed a comprehensive framework for AI developers that includes ethics oversight during different phases of the AI development life cycle. Similarly, Rogers et al [97] shared a very practical approach to how they evaluated an AI model for ethics. Such tools are practical methods of assessing AI algorithms for ethical principles. Despite these practical approaches, Goirand et al [98] note that operationalizing ethical frameworks for AI is challenging, as there is a need for contextualization due to different ethical issues present in different environments. Therefore, organizations have to consider these nuances and determine an ethics approach that would work best for their organization when evaluating each AI model.

These frameworks and tools to develop trustworthy AI by addressing various barriers to adoption are also just beginning to emerge and be applied in real-life cases; however, they are a good start to the implementation journey of AI, especially those applied in clinical settings. Overall, our findings demonstrate that the adoption of an AI system has to be considered from its onset, when the system is being conceptualized, to when it is implemented and sustained. The existing technology implementation and acceptance models may not be all encompassing of adoption factors; therefore, adding additional frameworks around trust, bias, explainability, and ethics will be necessary to foresee the success of an AI innovation. A governance model may address concerns around risk, safety, and adoption barriers identified in this paper by facilitating the overall development process of AI and ensuring various checks and balances are in place. Figure 3 is a visual depiction of the core elements that were found to impact trust, as discussed in this section.

Figure 3. Adoption barriers, as related to trust.

Limitations

Given the limited application of AI in health care at the time of this research, only a few number of papers that reported on implementation barriers and facilitators were reviewed to identify AI adoption barriers and facilitators. As the application of AI and types of AI systems in health care grows, a follow-up on adoption barriers and facilitators to assess for additional barriers and facilitators suitable to future environments may be necessary.

Comparison With Prior Work

At the time this search was conducted, a few literature reviews on the determinants of and barriers to AI adoption were conducted, such as the review by Radhakrishnan and Chattopadhyay [26]. However, these studies span across multiple

industries. For health care, one systematic review on the *barriers* to AI adoption in health care was conducted by Assadullah [27]. However, there is less work that considers both the *barriers to and facilitators* of AI adoption in health care at large. Therefore, this review has attempted to explore the latter to provide considerations for health care organizations looking to successfully implement AI technologies via increased adoption. Our findings are validated due to the replication of several themes identified in similar, previous research by Assadullah [27]. Common themes identified around barriers to adoption included explainability, trust issues centered on privacy, challenges around data ownership, lack of regulatory standards, issue of bias, and lack of accountability. Overall, the issue of trust was found to be centered on bias, ethics, and explainability, which led to a lack of accountability and an inability to evaluate. Other issues impeding trust included impacts on model

performance leading to inaccurate results. These findings around trust resonate with results from this research, reinforcing the barriers to adoption identified in both studies.

Conclusions

This literature review revealed that trust is impacted by a number of elements identified as barriers and that trust is a significant catalyst of adoption. A governance structure can be a key facilitator in ensuring all the elements identified as barriers are addressed appropriately. The findings demonstrate that the implementation of AI in health care is still in many ways

dependent on the establishment of regulatory and legal frameworks. Further research around the combination of governance and implementation frameworks, models, or theories to enhance trust that would specifically enable adoption is needed to provide the necessary guidance to those translating AI research into practice. Future research could also be expanded to include attempts at understanding patients' perspectives on complex, high-risk AI use cases and how the use of AI applications affect clinical practice and patient care, including sociotechnical considerations, as more algorithms are implemented in actual clinical environments.

Abstract

Background: A 2017 survey of patient perspectives showed overall willingness and comfort to use telemedicine, but low actual use. Given recent growth and widespread exposure of patients to telemedicine, patient preferences are likely to have changed.

Objective: This study aimed to (1) identify demographic trends in patient preferences and experiences; (2) measure ease of use and satisfaction of telemedicine; and (3) measure changes in telemedicine use, willingness, and comfort since 2017.

Methods: We replicated a 2017 study with a nationwide survey of US adults. The survey, an extended version of the previous study, measured patient health care access as well as knowledge, experiences, and preferences regarding telemedicine encounters. We recruited participants using SurveyMonkey Audience in July 2022. We used descriptive statistics and generalized estimating equations to measure change and identify trends.

Results: We accrued 4577 complete responses. Patient experience with telemedicine was substantially higher in 2022 than in 2017, with 61.1% (vs 5.3%) of participants aware that their primary care provider offered telemedicine and 34.5% (vs 3.5%) reporting use of telemedicine with their primary care provider. This study also reported ease of use and satisfaction rates to be similar to in-person visits, while overall willingness and comfort in using telemedicine increased from 2017. Individuals at the poverty line were significantly less likely to report satisfaction with telemedicine visits. We found increased interpersonal distance in a patient and health care professional relationship significantly reduced patient ease of use, willingness, and comfort in using telemedicine.

Conclusions: This study identified an association between income and patient satisfaction, conveying the importance of understanding telemedicine in relation to health care access and equity. Telemedicine ease of use and satisfaction were comparable to in-person visits. Individuals reported greater use and higher positive perceptions of telemedicine willingness and comfort since 2017.

telemedicine; survey; patient preferences; direct-to-consumer telemedicine; patient-provider relationship; inequity; consumer; patient experience; willingness; income; association; satisfaction; mobile phone

Introduction

Telemedicine has allowed for the growth of new technologies and platforms for asynchronous and synchronous health care.

Most patients, though, imagine direct-to-consumer, synchronous visits when considering “telemedicine” [1]. While lower costs and higher ease of access had long been recognized in the biomedical literature [2,3], telemedicine did not come into widespread use until the 2020 pandemic caused by

SARS-CoV-2. Public health recommendations to use telemedicine greatly expanded its use and created opportunities for expanded research measuring stakeholder satisfaction, as well as barriers and facilitators [4,5]. Given the profound increase in use, it is necessary to understand whether patient preferences, experiences, and needs related to telemedicine have changed. A current understanding of the patient experience can help us to effectively develop and implement telemedicine programs within health care, especially with the push toward hybrid care [6-8].

According to the 2021 National Center for Health Statistics survey, more than one-third (37%) of US adults had used telemedicine [9]. The same study showed demographic trends that may point to differences in preferences or even unequal access to telemedicine based on income, gender, and race [9]. Though studies generally show high satisfaction of telemedicine use among patients [10-12], specific measurement of patient comfort in using telemedicine and willingness to use telemedicine is difficult to find in literature, and most studies were conducted before widespread adoption of telemedicine in the year 2020 [13-15]. Our team, Welch et al [14], conducted a 2017 study measuring aspects of willingness and comfort in direct-to-consumer telemedicine. In a nationwide representative sample of over 4300 US adults, we found that only 5.3% of patients knew their primary care health care professional (PCP) offered telemedicine and 3.5% had ever used telemedicine for their PCP visits [14]. Overall, over 50% of patients were willing and comfortable to use telemedicine with their own PCP [14]. Health care professional scenario types appeared to affect patient willingness and comfort, though: for example, patients were mostly willing (51.9%) to see their own PCP using telemedicine but less so for a different PCP within the health organization (34.9%) or a different PCP from a different organization (18.6%). Similar results were seen regarding comfort with 53.7% of patients being comfortable in using telemedicine with their own PCP but only 18.6% with a different PCP from a different organization [14]. Additionally, over 56% of patients reported that having an established relationship with a health care professional before having a telemedicine visit is important [14]. While this survey study did not include direct measures regarding satisfaction and ease of use, it showed that patients in the United States had a positive disposition toward telemedicine, even with little direct telemedicine exposure. Inclusion of additional assessments within this survey, including measures of satisfaction, would have helped to determine a more holistic understanding of patient preferences and experiences in telemedicine.

Telemedicine satisfaction has been assessed in myriad ways, from brief questions to full-length, validated questionnaires [10,16-19]. Generally, literature shows telemedicine satisfaction can be reliably measured through survey research, comparing satisfaction of telemedicine and in-person visits [17,19]. This approach to understanding telemedicine preferences can reasonably be extended to determine satisfaction with telemedicine in a hybrid care environment. For example, while Welch et al [14] may have measured willingness and comfort in using telemedicine, the addition of specific patient satisfaction questions for both telemedicine and in-person visits would have

provided an additional dimension in assessing patient preferences [17]. While previous studies have shown little difference in satisfaction between in-person and telemedicine visits for specific types of visits or specialties [12,20,21], consumer experience with telemedicine has grown enormously in recent years, and their perspectives may have changed [22,23].

One of the largest changes to telemedicine occurred within the realm of compliance and regulation in 2020. With the public health emergency providing the flexibility necessary to implement telemedicine in a widespread fashion [24], telemedicine was provided to the US population in ways previously impossible. Patients could visit with health care professionals across state lines, use modes of telemedicine that were not necessarily Health Insurance Portability and Accountability Act (HIPAA)-compliant, and have the cost of telemedicine visits covered by insurance or other payors [24]. Indeed, with the new flexibilities and regulatory changes, many long-standing barriers to telemedicine usage were placed in the spotlight for public discussion. For example, 2015 guidelines from the American College of Physicians promoted that a patient first meets their health care professional in person prior to any telemedicine visits [25]. Loosened regulations in 2020 placed these expectations under debate [26]. With new flexibilities due to the public health emergency, patients could still access telemedicine if they were unable or unwilling to first meet a health care professional in person [26]. Compliance and regulatory shifts have resulted in critical changes to pathways of telemedicine implementation. As a result, revisiting patient experiences, preferences, and satisfaction with telemedicine is critical in determining ideal implementation strategies of telemedicine. Additionally, understanding patient perceptions of comfort and satisfaction regarding telemedicine may help identify needed changes to national and state policies relating to successful telemedicine practice within the United States.

In prior work, the 2017 Welch et al [14] study, we assessed patients' willingness and comfort to use telemedicine. The results may be used as a baseline to determine how patient willingness and comfort to use direct-to-consumer telemedicine have changed since 2017, and after large-scale population exposure to telemedicine. Here, we conducted a survey of the US population, replicating the items used in the prior study, to understand how comfort and willingness to use telemedicine has changed. This study aimed to (1) identify potential demographic trends in US patient preferences and experiences in telemedicine visits; (2) measure the current state of patient ease of use and satisfaction with using telemedicine; and (3) measure change regarding telemedicine use, comfort, and willingness among patients since 2017. By assessing the current patient experience in finer resolution, we can better understand patient needs, preferences, and potential barriers to successful use of telemedicine.

Methods

Sample and Procedures

We conducted a cross-sectional survey of a national sample of adults from July 1 to July 2, 2022, using SurveyMonkey

Audience, an online market research platform [27]. To emulate the Welch et al [14] study, we chose to recruit a similar sample size: we recruited 4500 adults (aged 18 years or older) representative of the US adult population based on age, gender, income, and regionality. Based on sample size calculations, we would be able to report results with a 99.99% confidence level and 2.75% margin of error. The anonymous survey was estimated to take 10 minutes. After providing informed consent, participants answered questions about their PCP, previous use of telemedicine, willingness to use telemedicine, and comfort using telemedicine. Participants received a US \$0.50 donation to a nonprofit of their choice in return for their participation. SurveyMonkey Audience uses fraud and bot detection to ensure the integrity of their survey results [27].

Ethical Considerations

Study procedures were approved as exempt by the Institutional Review Board at the University of South Florida (IRB#4255). Participants were provided with informed consent and were able to opt out of the survey if they chose.

Survey and Methods

See [Multimedia Appendix 1](#) for a complete list of survey questions and response options. We replicated and extended a previous 2017 survey, developed and reviewed by health care professionals and researchers, to directly compare results [14]. The adapted 10-minute survey comprised 13 multiple-choice questions, which included 7 Likert-scale matrix questions. The outcome measures included participant perceptions of willingness to use telemedicine, comfort in using telemedicine, ease of meeting with health care professionals, and satisfaction in meeting with providers. SurveyMonkey Audience provided 5 multiple-choice screening questions to ensure a representative US sample by gender, age, income, device type, and region.

We retained multiple-choice items from the 2017 survey related to duration (Q1) and frequency (Q2) of visits to a PCP, and added items asking participants of their level of use of telemedicine (Q3) [14]. Next, we asked participants, who responded to having used telemedicine with their PCP, about the satisfaction (Q4), ease of meeting with their health care professionals (Q5), and whether they would be disappointed if telemedicine were no longer offered (Q6). As an extension of the original study, the questions about satisfaction and ease of meeting with providers in person and via telemedicine were anchored on a 5-point Likert scale from 1=very unsatisfied or very difficult to 5=very satisfied or very easy. Additionally, the disappointment question was anchored on a 4-point scale from 1=very disappointed to 5=not disappointed. We then asked participants whether they have used telemedicine with any other health care professionals (Q7) following with the same set of questions regarding satisfaction (Q8), ease (Q9), and disappointment (Q10). All participants were asked about their willingness (Q11) and comfort (Q12) of using telemedicine in different scenario types related to their level of relationship with a PCP (own PCP, different PCP from the same health care organization, and different PCP from different health care organization). Willingness and comfort questions were anchored on 5-point Likert scales similar to the 2017 study from 1=very unwilling or very uncomfortable to 5=very willing or very

comfortable. Lastly, we asked participants of their level of agreement (Q13) regarding statements about the importance of (1) having telemedicine as an option, (2) switching to new health care professionals offering telemedicine, (3) having an established relationship with a telemedicine health care professional, and (4) one's health care professional having access to health records. These importance questions were anchored on a 5-point Likert scale from 1=strongly disagree to 5=strongly agree similar to the 2017 study [14].

Data Analysis

In order to directly compare the current survey results with the 2017 results, we replicated the analysis detailed in Welch et al [14], using SPSS (version 29; IBM Corp).

We measured each of the four outcomes by the self-reported, 5-point Likert scale; however, for the purposes of analysis, these variables were dichotomized in a similar fashion as seen in Welch et al [14] (eg, very willing, willing, and neutral grouped as willing; and unwilling and very unwilling grouped as unwilling). We reported all four outcome measures in relation to health professional scenario types, income, gender, and age. We determined a reference for each demographic or scenario type for the purposes of analysis (see *Results* section for references).

We computed descriptive statistics for demographic variables and generalized estimating equation (GEE) models for multivariate data modeling of parameter estimates [14,28]. A GEE shows how the average of a response variable of an individual changes with covariates. Additionally, a GEE allows us to view this correlation between repeated measurements on the same individual [29,30].

We used GEE models with the logit function and an exchangeable correlation matrix. For each GEE model, the four demographic predictors were used as independent variables. As the outcome measures were dichotomized, we used binomial logistic models. Independent variables included scenario type (ie, own PCP, different PCP from the same organization, and different PCP from a different organization), age, income, and gender. Each set of independent variables included a reference that yielded adjusted odds ratios (ORs), determining the odds of individuals responding other than the reference category, with the dependent variable in mind (see *Results* section). References were chosen based on the limiting impact of relationship for scenario types and impact of socioeconomic accessibility issues (eg, higher income and age).

Results

Overview

We conducted the survey from July 1 to July 2, 2022, and accrued a sample of 4639 participants, resulting in 4577 completed surveys (98.66% completion rate).

Patient Demographics and Preferences

We present complete descriptive statistics for survey items in [Table 1](#). Patient demographics were representative of the national population by gender and age. Household income

displayed a top-heavy trend with 31.07% (1422/4577) reporting they make more than US \$75,000.

Table . Sample characteristics (N=4577).

Demographics	Participants, n (%)
Age (years)	
18 - 29	1109 (24.2)
30 - 44	1076 (23.5)
45 - 60	1268 (27.7)
>60	1124 (24.6)
Sex

Patients reported a length of relationship with their current PCP of less than 6 months (424/4577, 9.26%), 6 months to a year (527/4577, 11.51%), 1 to 3 years (996/4577, 21.76%), 3 to 5 years (574/4577, 12.54%), or 5 years or more (1618/4577, 35.35%). Some patients (438/4577, 9.57%) reported not having

a PCP. Patients noted the frequency of visits to a PCP in the last 12 months: 1 time (1033/4577, 22.57%), 2 times (1197/4577, 26.15%), 3 times (752/4577, 16.43%), 4 times (422/4577, 9.22%), 5 or more times (459/4577, 10.03%), or none (714/4577, 15.6%).

Fewer than half of patients (1909/4577, 41.71%) agreed (1288/4577, 28.14%) or strongly agreed (621/4577, 13.57%) that it is important that their current health care professional offers telemedicine visits. Some (1286/4577, 28.10%) agreed (936/4577, 20.45%) or strongly agreed (350/4577, 7.65%) that they would consider switching to a new health care professional, who offers telemedicine. Most (2864/4577, 62.60%) agreed (1843/4577, 40.27%) or strongly agreed (1021/4577, 22.31%) that it is important to have an established relationship with the health care professional they are having a telemedicine visit with. Most patients (3235/4577, 70.68%) agreed (1706/4577, 37.27%) or strongly agreed (1529/4577, 33.41%) that it is important that their health care professional has access to their health records.

Measures of Satisfaction and Ease of Using Telemedicine

About 35% (1588/4577) of patients reported having had a telemedicine visit with their PCP and 26.59% (1231/4577)

reported that their PCP offers telemedicine, but they have not had a telemedicine visit. Of these, 70.34% (1117/1588) reported being satisfied (651/1588, 40.99%) or very satisfied (466/1588, 29.35%) with telemedicine for online video visits, and 77.83% (1236/1588) reported feeling satisfied (578/1588, 36.40%) or very satisfied (658/1588, 41.44%) with in-person visits at clinic (Figure 1). Regarding ease and difficulty of visits, 71.28% (1132/1588) reported telemedicine visits as being easy (612/1588, 38.54%) or very easy (520/1588, 32.75%), and 62.9% (999/1588) reported seeing their health care professional in person at a clinic as easy (581/1588, 36.59%) or very easy (418/1588, 26.32%; Figure 2). If they no longer had the option to meet with their PCP using telemedicine, 69.9% (1110/1588) reported that they would be somewhat to very disappointed (Figure 3). Some patients reported that their PCP did not offer telemedicine as an option (551/4577, 12.04%), or that they were not sure whether their PCP offered telemedicine (974/4577, 21.28%).

Figure 1. Satisfaction meeting with your PCP and other health care professionals. PCP: primary care health care professional.

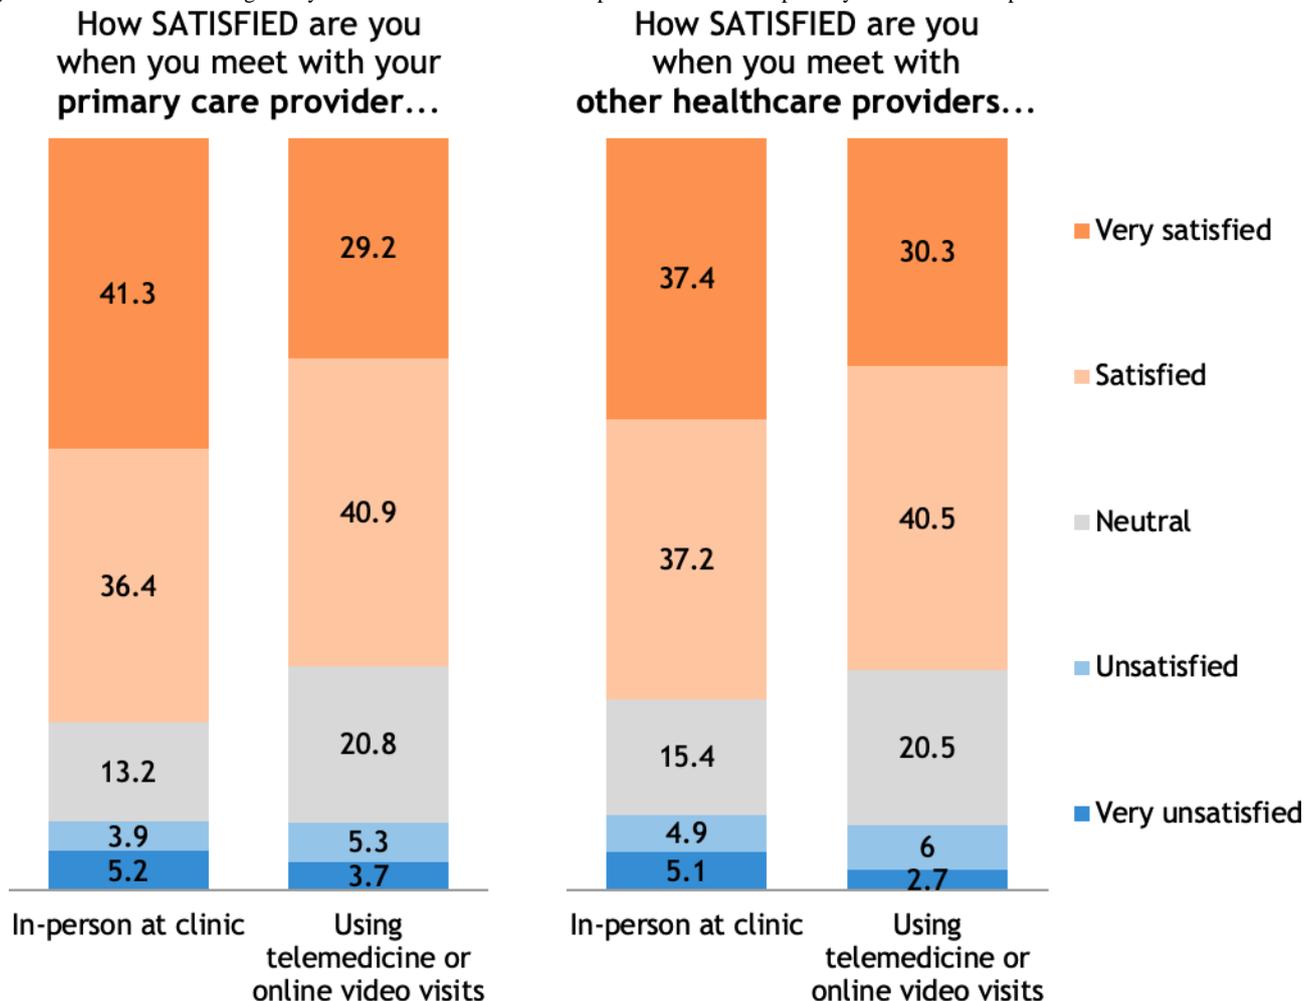

Figure 2. Ease of meeting with your PCP and other health care professionals. PCP: primary care health care professional.

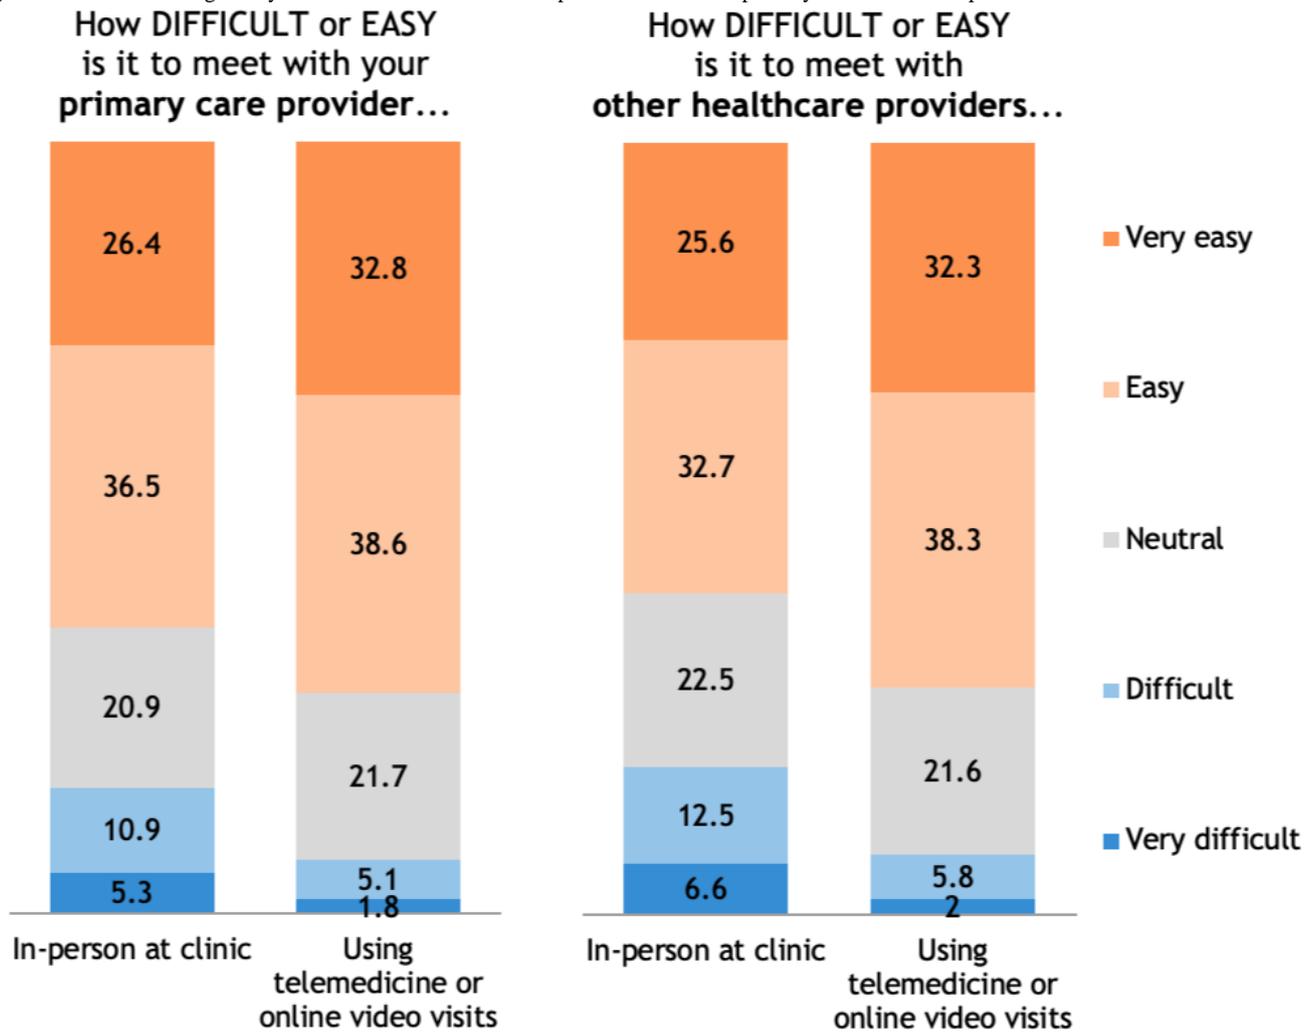

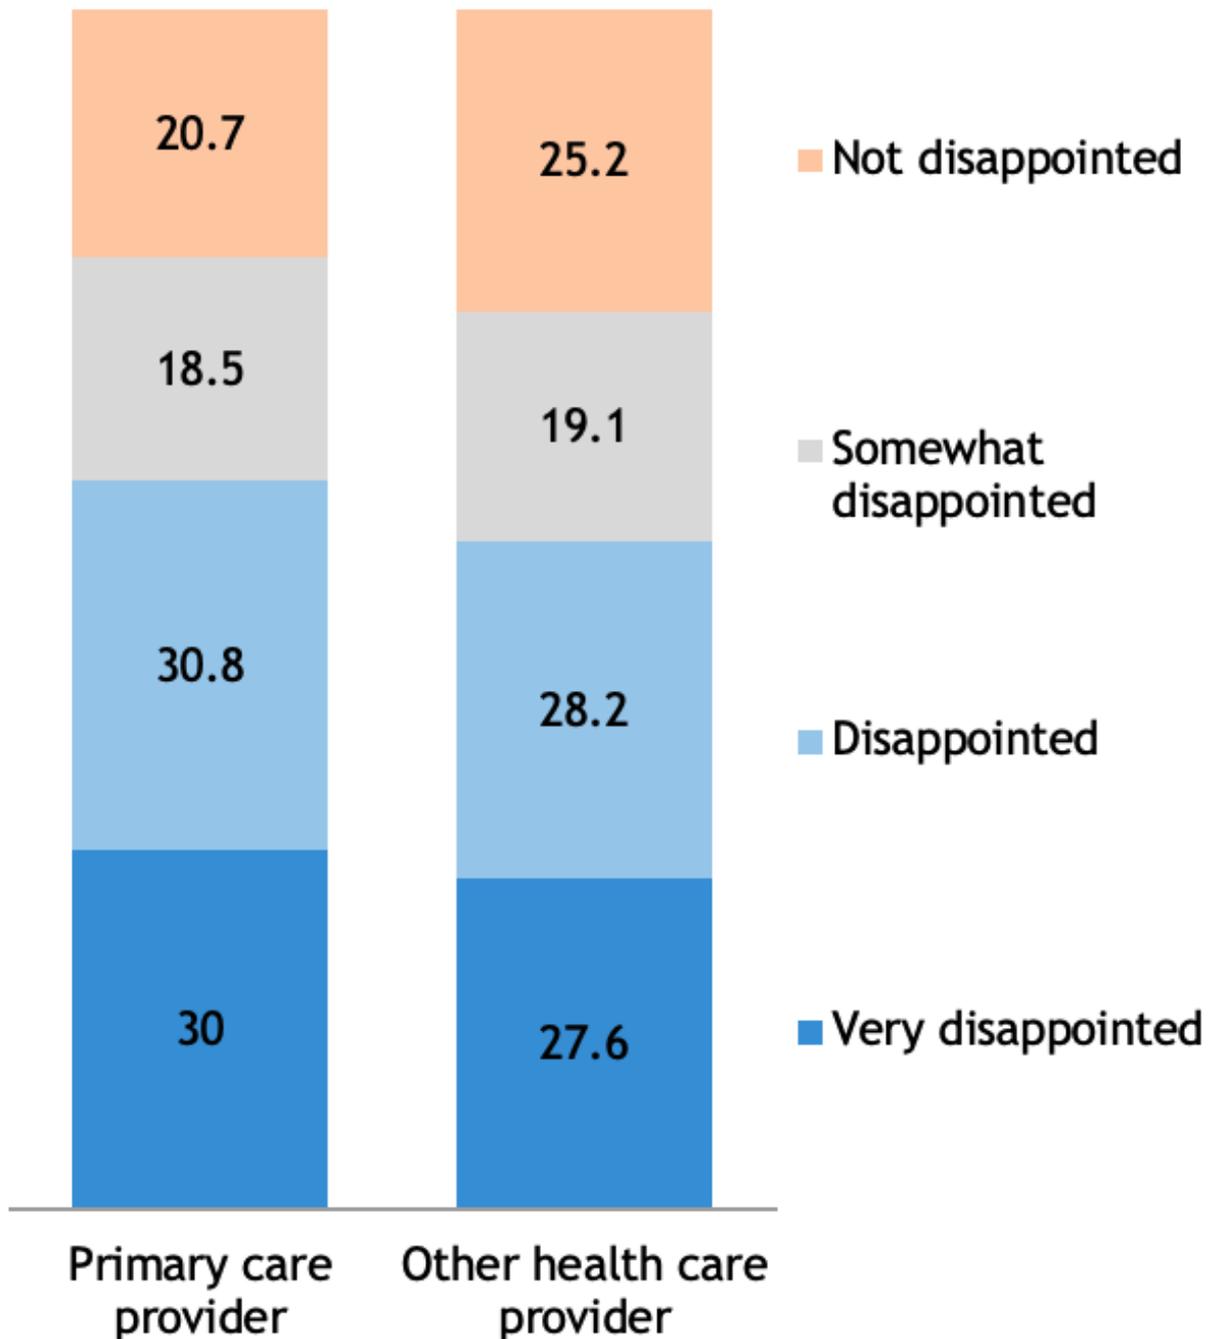

Figure 3. Disappointment if telemedicine was no longer an option to meet with your health care professional.

How DISAPPOINTED would you be if you no longer had the option to meet with your provider using telemedicine (online video) visits?

About one-third (1513/4577, 33.06%) of patients reported having had a telemedicine visit with any health care professional (eg, mental health professional, cardiologist, or dermatologist), while 25.54% (1169/4577) reported that their other health care professional offered telemedicine services, but that they had not had a telemedicine visit. Of the 33.06% (1513/4577) that have had a telemedicine visit, 70.79% (1071/1513) reported being satisfied (612/1513, 40.45%) or very satisfied (459/1513, 30.34%) with telemedicine visits, and 74.55% (1128/1513)

reported being satisfied (562/1513, 37.14%) or very satisfied (566/1513, 37.41%) with in-person visits at the clinic (Figure 1). Regarding ease and difficulty of visits, 70.65% (1069/1513) reported telemedicine visits with other health care professionals as being easy (581/1513, 38.40%) or very easy (488/1513, 32.25%), and 58.36% (883/1513) reported seeing their other health care professionals in person at a clinic as easy (497/1513, 32.84%) or very easy (386/1513, 25.51%; Figure 2). If they no longer had the option to meet with their other health care

professionals using telemedicine, 72.44% (1096/1513) reported that they would be somewhat to very disappointed (Figure 3). Some patients reported that other health care professionals did not offer telemedicine as an option (683/4577, 14.92%) or that they were not sure if their other health care professionals offered telemedicine (1255/4577, 27.42%).

We fitted GEE models for patients who had experienced telemedicine visits and considered scenario type, age, gender, and income. These models suggested patients had lower odds of reporting ease when meeting in person with an established health care professional or new professional from the same organization compared to a telehealth visit with a new provider from a different organization (Table 2). Patients aged between 18 - 29 years (OR 0.51, 95% CI 0.37 to 0.71, $P < .001$) and 30 - 44 years (OR 0.61, 95% CI 0.44 to 0.84, $P = .003$) had lower

odds of reporting ease when meeting in person with their PCP, when compared to patients aged 60 years and older. Individuals who reported an income of US \$0 - \$24,999 had lower odds of reporting ease when meeting in person with their PCP (OR 0.69, 95% CI 0.50 to 0.95, $P = .02$) as compared to those with an income of US \$100,000 or over. Gender did not appear to impact ease of meeting with a health care professional.

Patients reporting poverty-level income (US \$0 - \$24,999) had lower odds of reporting satisfaction with in-person health care professional meetings when compared to those with an income of US \$100,000 or more (OR 0.53, 95% CI 0.37 to 0.75, $P < .001$). Scenario type (eg, own PCP), gender, and age had no statistically significant impact on reported satisfaction in meeting with health care professionals.

Table 2. Odds ratios from generalized estimating equation models predicting ease to meet with health care professional and satisfaction of using telemedicine.

Scenario	Ease to meet with health care professional		Satisfaction meeting with health care professional

Measures of Telemedicine Use, Willingness, and Comfort

Over half (2836/4577, 61.96%) of patients would be willing (1573/4577, 34.37%) or very willing (1263/4577, 27.59%) to have a telemedicine visit with their health care professional. About half (2278/4577, 49.77%) would be willing (1645/4577, 35.94%) or very willing (633/4577, 13.83%) to have a

telemedicine visit with a different health care professional from the same health care organization. About one-third (1550/4577, 33.86%) would be willing (1037/4577, 22.66%) or very willing (513/4577, 11.21%) to have a telemedicine visit with a different health care professional from a different health care organization (Figure 4).

The odds of patients being willing to use telemedicine with their own PCP (OR 2.49, 95% CI 2.27 to 2.73, $P < .001$) or a different PCP from the same organization (OR 2.21, 95% CI 2.05 to 2.38, $P < .001$) were statistically significantly higher compared to a different PCP from a different organization (Table 3). Age showed an impact on willingness to use telemedicine, with the age group 30 - 44 years having the highest odds of willingness compared to those aged 60 and older (OR 2.33, 95% CI 1.96 to 2.76, $P < .001$). Income and gender did not appear to impact willingness to use telemedicine.

Most patients (2819/4577, 61.59%) reported being comfortable (1672/4577, 36.53%) or very comfortable (1147/4577, 25.06%) having a telemedicine visit with their health care professional. Most (2333/4577, 50.97%) would be comfortable (1729/4577, 37.78%) or very comfortable (604/4577, 13.20%) having a telemedicine visit with a different PCP in the same health care organization. Approximately one-third of patients (1533/4577, 33.49%) reported being comfortable (1050/4577, 22.94%) or

very comfortable (483/4577, 10.55%) having a telemedicine visit with a different health care professional from a different health care organization (Figure 5).

The odds of patients feeling more comfortable in using telemedicine with their own PCP (OR 2.72, 95% CI 2.47 to 2.99, $P < .001$) or a different PCP from the same organization (OR 2.56, 95% CI 2.37 to 2.77, $P < .001$) were significantly higher than those with a different PCP from a different organization (Table 3). Age had a significant effect on comfort in using telemedicine, with the age group of 30 - 44 years reporting the highest odds of comfort in using telemedicine compared to those aged 60 years and older (OR 2.35, 95% CI 1.98 to 2.80, $P < .001$). Individuals reporting an income of US \$0 - \$24,999 had lower odds (OR 0.81, 95% CI 0.67 to 0.97, $P = .02$) of being comfortable using telemedicine in reference to those who made US \$100,000 or more. Gender did not appear to affect comfortability in using telemedicine.

Figure 5. Comfortability having a telemedicine visit.

Discussion

Principal Results

This study aimed to assess demographic trends in patient preferences in telemedicine visits; measure patient ease of use and satisfaction in using telemedicine; and measure changes in patient use, willingness, and comfort with telemedicine since 2017. The results showed that telemedicine has become an accepted part of many people's health care. We found individuals reporting incomes at or below poverty levels tended to find telemedicine more difficult to use, were less comfortable using it, and were ultimately less satisfied with a telemedicine visit. The level of patient–health care professional relationship (scenario types) significantly affected willingness and comfort in using telemedicine, with closer relationships showing higher levels of comfort and willingness to use telemedicine. This study leveraged the baseline data from a study published in 2017 to understand current patient preferences and the potential impact of increased exposure to telemedicine [14].

Comparison With Prior Work

We compared public use, knowledge, and perceptions of telemedicine from 2017 and 2022. Importantly, patient telemedicine preferences and knowledge had changed dramatically with 61.1% of patients knowing their PCP offered telemedicine compared to 5.3% in 2017 and 34.69% had used telemedicine with their PCP as compared to only 3.5% in 2017

[14]. Interestingly, nearly a quarter (21.28%) and over a quarter (27.42%) of patients did not know whether their PCP or other health care professionals, respectively, offered telemedicine. While only 12.04% and 14.92% of patients had PCPs or other health care professionals not offering them telemedicine, these numbers contrast greatly when noting that 67.7% of patients in 2017 reported that their PCPs did not offer telemedicine at all. Though an increase was expected, these numbers highlight the drastic increase telemedicine use saw in a short period of time. To put these numbers in perspective regarding general health care visits, most (69.65%) individuals reported being with their PCP for at least one year, and nearly half (48.72%) went to their PCP annually or biannually. While little change was seen in general health care access from 2017, major changes were indeed visible in telemedicine knowledge and use [14].

Overall, satisfaction in the use of telemedicine was found to be comparable (70.34%) to visits in person (77.83%) with a PCP. While in-person visits trended to be higher in satisfaction, telemedicine visits trended to be higher (71.28%) in ease for visits with a PCP than in-person visits (62.90%). About 70% of patients reported they would feel some level of disappointment should their PCP no longer offer telemedicine options. These results conveyed that while people view telemedicine visits similarly to in-person visits regarding satisfaction and ease, having the option for telemedicine access is now expected. Patients and health care professionals now use

telemedicine as an additional feature, intervention mode, or aspect of treatment [31].

While the health care professional scenario type impacted the odds of individuals reporting higher ease of using telemedicine for visits, this study indicated patients also generally find telemedicine visits to be easier than in-person visits. Interestingly, a similar result is not seen for the satisfaction measure. Indeed, while age and income had a significant impact on whether patients found telemedicine easier or harder, GEE models showed that patients with an income of US \$0 - \$24,999 were the only group significantly more likely to report lower satisfaction with health care professional visits when compared to the reference group. Such a result is not unexpected, as those at or below the poverty line would have the most difficulty in accessing telemedicine for health care visits due to the costs associated with having the right hardware (computer, tablet, or smartphone), access to reliable internet, and availability of privacy for a visit [32,33].

Literature supports this study's results that patients at poverty level incomes are less comfortable using telemedicine, find telemedicine more difficult to use, and are less satisfied with telemedicine than those in higher income brackets. Though telemedicine increases access to health care for many [32], Curtis et al [33] show that digital access disparities can exacerbate current health care inequalities, leaving those most vulnerable even further behind. While telemedicine can be provided from the comfort and convenience of one's home [34], such a scenario does not explicitly mean a patient is comfortable to use telemedicine [35,36]. For example, a patient who may need to borrow a smartphone for a telemedicine visit may feel uncomfortable asking for the device. While some studies have shown that both health care professionals and patients feel telemedicine may improve access to care due to convenience, there is a need for better assessment of actual patient satisfaction, comfort, and willingness in using telemedicine [14,37]. Considering that the US \$0 - \$24,999 income group was significantly more likely to report difficulty in meeting with a PCP over telemedicine, this study clearly shows the limitations individuals face due to economic status. Understanding such patient preferences informs approaches to increase telemedicine accessibility [35].

While the development of the patient–health care professional relationship is a critical part of medicine, it is even more scrutinized in telemedicine [38-40]. Though federal laws allow health care professionals to establish a relationship with a new patient via telemedicine, some states pose specific stipulations that severely restrict this process [41]. The three scenarios used in the patient survey provide insight into key aspects of the patient–health care professional relationship—necessary insight for context of how telemedicine is provided in terms of visit environment and communication. The importance of the patient-provider relationship scenarios became evident when looking at reported willingness and comfort in using telemedicine by patients. The results highlighted that people are significantly more willing and comfortable in using telemedicine with their own PCP or at least a PCP from their health organization than an unknown PCP from a different organization altogether. Welch et al [14] found that patients

became less willing to use telemedicine as they became further detached from their own health care professional in 2017, our study showed a similar trend for both willingness and comfort. While trust in health care professionals may be measured in many ways, the Trust in Physician scale has shown that patient trust increased with length of relationship with a provider and that patients who were able to choose their providers exhibited higher trust scores [42]. One study by Orrange et al [43] surveyed 368 patients during March-April 2020 regarding satisfaction, trust, and concerns related to telemedicine visits. Patients reported being very satisfied (47.4%) or satisfied (35.3%) with their telemedicine visits, significant correlation with Trust in Physician scores and technical issues, concerns over privacy and cost, satisfaction with convenience, and the amount of time spent in a visit [43]. As the interpersonal patient–health care professional relationship becomes further scrutinized with the new era of telemedicine, knowledge of patient perceptions regarding satisfaction and trust are important for successful implementation of telemedicine and telemedicine policy. The future of health care seems to include a combination of telemedicine and in-person care access, which means improving telemedicine with such factors in mind are key for success.

Though general trends show that willingness and comfort in using telemedicine have increased since 2017, the level of change may provide insight toward actual telemedicine access. Individuals were more likely to report greater comfort and willingness to use telemedicine depending on their age, income, and scenario type. While income did not factor into willingness to use telemedicine, individuals reporting an income at or below poverty levels were significantly less likely to be comfortable using telemedicine. Some literature shows that income may not relate to certain aspects of comfort such as technological literacy; yet, there is a definite need in understanding how income inequalities may affect feelings of comfort [44]. Though all patients may be equally willing to try telemedicine based on income, differences in comfort highlighted current limitations for telemedicine visits in the United States. For example, while patients may want to use telemedicine, they may find themselves uncomfortable in using the technology or asking others for aid [45]. Such differences between willingness and comfort levels have become easier to see: in the 2017 study, willingness and comfort mirrored one another, while this study saw a distinct separation of the two when looking at the comfort of using telemedicine with a wholly new health care professional—18.6% for both comfort and willingness in 2017, and 33.49% comfort and 33.86% willingness now [14]. To implement telemedicine successfully, stakeholder experience and needs must be considered (eg, why is patient comfort lagging behind willingness to use telemedicine?) to make changes in policy and organizational processes.

Prior studies have shown the importance of the patient–health care professional relationship in patient satisfaction and trust [43]. This study showcased that satisfaction and willingness are affected by this relationship and bolstered prior findings. This knowledge is critical in developing successful telemedicine guidelines for health care professionals and patients. As changes to policy and regulation occur for telemedicine [46], a careful

consideration of patient preferences and needs would help develop more effective, timely policies. With the knowledge that health care is moving toward a hybrid care model, successful implementation of telemedicine requires that both patient and health care professional preferences are considered. The public health emergency gave telemedicine more regulatory flexibility for both stakeholders, thus helping to lead to the sustained use of telemedicine [47]. Now, policy makers are under pressure to ensure patient and health care professional needs are being met regarding telemedicine and ensuring patient safety and health information security. Understanding that more of the population feel telemedicine is important (41.71% from 19.8% in 2017) showed that telemedicine is now an expected and significant part of health care.

Limitations

We obtained a national sample using SurveyMonkey Audience, in part to emulate sampling from the 2017 study. However, the platform no longer includes race or education as part of reported demographics or as sampling criteria. Without data describing race and education, it is difficult to compare or fully understand socioeconomic differences between the original 2017 survey and this study. However, we remained able to examine age, gender, and income in relation to willingness, comfort, satisfaction, and ease of use of telemedicine within the United States. It is important to note that though sampling was carried out using the same methods for the purpose of consistency, bias

is possible in online survey recruitment platforms. For example, those surveyed already have access to technology in the forms of the devices used and internet. This study leverages the 2017 results as baselines where possible and relevant. As a result, not all methods and analyses reflect the prior study as descriptive and frequency statistics were determined to provide a satisfactory mode for comparison. Future work should include further measures of socioeconomic status, such as race, ethnicity, and education, to further understand how telemedicine is currently used and what can be carried out to improve its accessibility and levels of success.

Conclusion

With the increased public exposure to telemedicine, there has been a visible difference in telemedicine use and perceptions among the US population. Willingness and comfort to use telemedicine have increased since 2017. Further, the patient–health care professional relationship appears to influence willingness, comfort, and ease of using telemedicine. Additionally, this study highlighted the significant negative effect income has for individuals regarding comfort, satisfaction, and ease of use of telemedicine; this result is especially important when considering that telemedicine is touted as a breakthrough for health care access. Overall, there has been a large increase in telemedicine usage since 2017, with more finding telemedicine an important part of their health care.

Conflicts of Interest

FK, JH, NO, and JM have no conflicts to disclose. BW is a shareholder, and all other authors not listed earlier are employees of Doxy.me Inc, a commercial telemedicine company. The authors declare no other conflicts of interest.

Abstract

Background: Health-related quality of life (HRQoL) reflects an individual's perception of their physical and mental health over time. Despite numerous studies linking physical activity to improved HRQoL, most rely on self-reported data, limiting the accuracy and generalizability of findings. This study leverages objective accelerometer data to explore the association between physical activity and HRQoL in Korean adults.

Objective: The objective of this study is to analyze the relationship between objectively measured physical activity using accelerometers and HRQoL among Korean adults, aiming to inform targeted interventions for enhancing HRQoL through physical activity.

Methods: This observational study included 1298 participants aged 19-64 years from the Korea National Health and Nutrition Examination Survey (KNHANES) VI, who wore an accelerometer for 7 consecutive days. HRQoL was assessed using the EQ-5D questionnaire, and physical activity was quantified as moderate-to-vigorous physical activity accelerometer-total (MVPA-AT) and accelerometer-bout (MVPA-AB). Data were analyzed using logistic regression to determine the odds ratio (ORs) for low HRQoL, adjusting for socioeconomic variables and mental health factors.

Results: Participants with higher HRQoL were younger, more likely to be male, single, highly educated, employed in white-collar jobs, and had higher household incomes. They also reported less stress and better subjective health status. The high HRQoL group had significantly more participants meeting MVPA-AB ≥ 600 metabolic equivalents ($P < .01$). Logistic regression showed that participants meeting MVPA-AB ≥ 600 metabolic equivalents had higher odds of high HRQoL (OR 1.55, 95% CI 1.11-2.17). Adjusted models showed consistent results, although the association weakened when adjusting for mental health factors (OR 1.45, 95% CI 1.01-2.09).

Conclusions: The study demonstrates a significant association between HRQoL and moderate to vigorous physical activity sustained for at least 10 minutes, as measured by accelerometer. These findings support promoting physical activity, particularly sustained moderate to vigorous activity, to enhance HRQoL. Further interventional studies focusing on specific physical activity domains such as occupational, leisure-time, and commuting activities are warranted.

KEYWORDS

Health-Related Quality of Life (HRQoL); physical activity; Accelerometer; Korea National Health and Nutrition Examination Survey (KNHANES); mobile phone

Introduction

Physical activity (PA) is defined as any bodily movement produced by skeletal muscles that results in energy expenditure [1]. It includes all activities such as work, housework, commuting, and leisure. PA is widely recognized as a critical component of healthy lifestyle, contributing significantly to the prevention and management of various chronic diseases such as cardiovascular disease, diabetes, and obesity [2-4]. Despite various guidelines for PA based on many studies, the rate of aerobic PA in Korea has been continuously decreasing, with the rate among women being less than half (44%) [5].

Quality of life (QoL) is defined as an individual's perception of their position in life in the context of the culture and value systems where they live and in relation to their goals, expectations, standards, and concerns [6]. It is divided into health-related quality of life (HRQoL) and non-HRQoL [7]. As medical technology and accessibility advances, life expectancy increases, and major health problems become chronic diseases; not only the interest in treatment but also the management and prevention of diseases is increasing. HRQoL is a concept used to help determine an individual's physical and mental health to help prevent disease and make treatment decisions [8]. It is important because it can be applied to actual clinical treatment through research.

Previous studies have shown a positive association between PA and HRQoL, emphasizing the importance of maintaining active lifestyle for overall well-being. For instance, a study by Scarabottolo et al [9] found that different domains of PA (occupational PA and leisure-time sports practice) were significantly associated with improved HRQoL. Similarly, Puciato et al [10] reported that PA positively influenced the QoL in working-age people in Poland. However, most of the studies have predominantly focused on elderly populations or patients with specific diseases [11-15]. Furthermore, the majority of these studies have relied on self-reported questionnaires to measure PA [9,10,13,15-17].

In recent years, the use of accelerometers to objectively measure PA levels has gained popularity, offering more accurate and reliable data compared to self-reported measures [18-21]. This advancement provides deeper insights into the relationship between PA and various health outcomes. However, studies investigating the association between objectively measured PA using devices such as accelerometers and HRQoL are relatively scarce, especially in Korea.

Therefore, the aim of this study was to analyze the association between objective PA, as measured by accelerometers, and HRQoL in Korean adults using data from the Korea National Health and Nutrition Examination Survey (KNHANES). By analyzing this relationship, we anticipate to contribute to the development of evidence-based strategies to promote PA and enhance HRQoL.

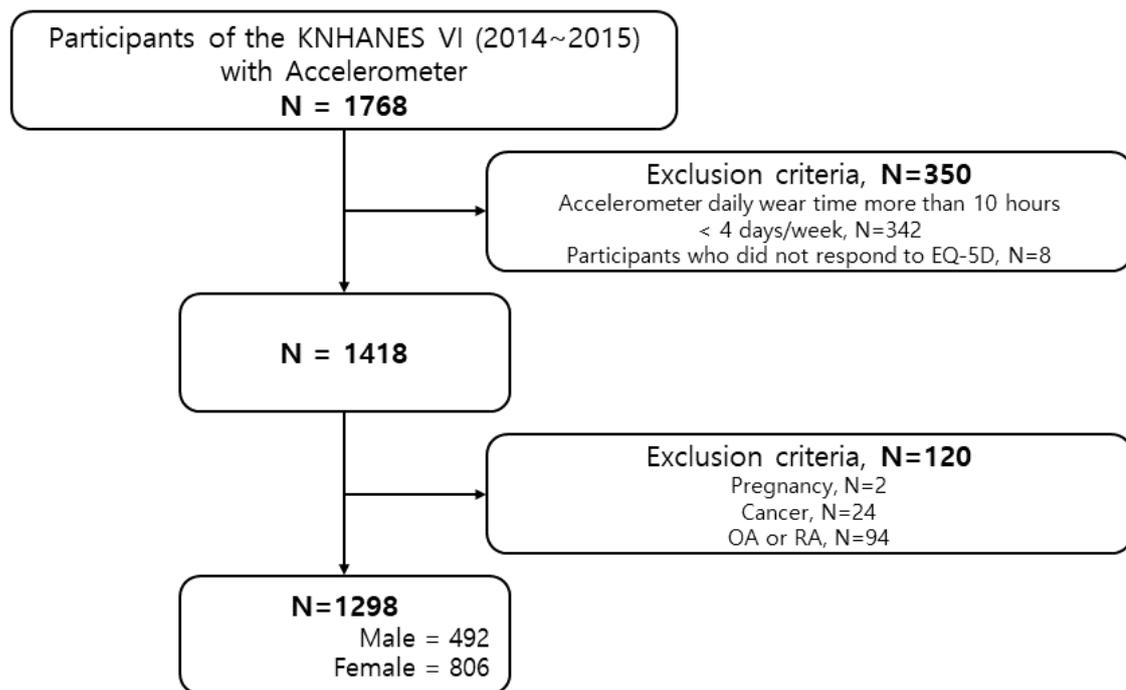

Methods

Data Source and Study Population

This study was based on data from the sixth KNHANES (KNHANES VI) conducted from 2014 to 2015 by the Korea Centers for Disease Control and Prevention (KCDC). KNHANES is a legal survey conducted annually on the level of health of the public, health-related awareness and behaviors, chronic diseases, and food and nutrition intake.

Among the participants of the KNHANES VI (2014-2015), 1827 people participated in the accelerometer survey, but 59 people were excluded due to loss of the accelerometer (9 people), nonwearers (47 people), and mechanical errors (3 people). A total of 1418 people were selected first, excluding 342 people who did not meet the minimum wearing time and number of days of the accelerometer used in the previous study for more than 10 hours a day, 4 days a week, and 8 people who did not respond to the health-related quality of life survey (EQ-5D). Among them, 1298 people were selected as participants for final analysis, excluding 2 pregnant women, 24 people receiving cancer treatment, and 94 people with osteoarthritis or rheumatoid arthritis that could affect their PA (Figure 1).

Ethical Considerations

It was approved by the Research Ethics Review Committee of the KCDC (Approval No. 2013-12 EXP-03-5C, 2015-01-02-6C).

Variables and Measurements: Health-Related Quality of Life

Tools to evaluate HRQoL include World Health Organization Quality of Life Brief Version (WHOQOL-BREF) [6], Quality of Well-Being Scale [22], 36-Item Short Form [23], and EQ-5D [24]. Among them, the reliability and validity of the Korean version of EQ-5D reliability and validity have been verified in several studies [25,26].

EQ-5D, a self-report questionnaire, was used for measurement of HRQoL. The survey questions were answered on a three-step scale (no problem, moderate problem, severe problem) with 5 questions: mobility, self-care, usual activity, pain/disability, and anxiety/depression. The KCDC calculated the EQ-5D index using the following formula to express it as a single index.

$$EQ-5D \text{ index} = 1 - (0.050 + 0.096 \times M2 + 0.418 \times M3 + 0.046 \times SC2 + 0.136 \times SC3 + 0.051 \times UA2 + 0.208 \times UA3 + 0.037 \times PD2 + 0.151 \times PD3 + 0.043 \times AD2 + 0.158 \times AD3 + 0.050 \times N3)$$

Based on previous research methods [8], the EQ-5D index was divided into 2 groups, below average (low quality of life, low QoL) and above average (high quality of life, high QoL).

PA

PA Measured by Accelerometer

The accelerometer used in KNHANES is the wGT3X+ (ActiGraph LLC), and it is a device that converts the acceleration of movement displayed by PA into an electrical signal. The accelerometer and a written consent form were

provided to adults 19-64 years old who consented to wear the accelerometer. Measurements were programmed to record from midnight (midnight) on the next day after delivery, and they were instructed to wear the accelerometer on the waist for 7 consecutive days except for swimming, showering, and sleeping.

The following criteria were applied with reference to previous studies [18,27]: (1) data summary cycle (60 seconds); (2) intensity of PA (count per minute [CPM], sedentary behavior <100; 2000 ≤ moderate PA ≤ 5998; vigorous PA ≥ 5999); (3) determination algorithm of accelerometer wearing or nonwearing time (If CPM is 0 and lasts longer than 60 minutes, it is considered nonwearing time. However, if CPM is less than 100 and lasts less than 2 minutes, it is acceptable); (4) accelerometer minimum wearing time and days (10 hours per day, 4 days per week); and (5) criteria for meeting PA guidelines (600 metabolic equivalent [MET]-minutes/week: [(moderate PA × 4 METs) + (vigorous PA × 8 METs)] ≥ 600 METs)

PA measured with an accelerometer was quantified in two ways: (1) Moderate to vigorous PA accelerometer-total (MVPA-AT, for at least 1 minute), and (2) Moderate to vigorous PA accelerometer-bout (MVPA-AB, for at least 10 minutes; if the time when the corresponding strength number of cutting points has not been reached is less than 2 minutes, it is acceptable). One minute of vigorous PA was counted as 2 minutes of moderate PA.

Self-Reported PA

Self-reported PA was collected by using the Global Physical Activity Questionnaire (GPAQ), divided into 3 categories: leisure, occupation, and commuting PA. Since the PA measured with the accelerometer was collected for most of the time while wearing the accelerometer, all 3 physical activities (leisure, occupation, commuting) were summed up. After that, the

same criteria for the PA measured by accelerometer were applied.

Covariates

Socioeconomic factors such as age, sex, marital status, education level, employment, household income, and residence were investigated. Employment was classified according to occupational reclassification and unemployment and economic inactivity status codes. After that, it was divided into 3 groups: white collar (managers, experts, related workers, and office workers), blue collar (service/sales workers, skilled workers in agriculture, forestry and fisheries, craftsmen, workers in machine operation/assembly, and simple labor workers), and unemployed (housewives, students, etc). Household income level was classified into 2 groups: the bottom 50% (Low) and the top 50% (High) of household income. Residence was classified into *dong* (urban) and *eup/myeon* (rural).

Health-related lifestyle factors including smoking, drinking, and average daily sleep time were investigated. Smoking was classified into 3 groups: nonsmoker (person who never smoked or smoked less than 5 packs or 100 cigarettes in their lifetime), past smoker (person who smoked in the past but not now), and smoker (person who currently smokes). Alcohol use was classified into 3 groups according to the WHO high-risk drinking standards: heavy drinker (14 or more drinks per week for men/10 or more drinks per week for women), adequate drinker (annual drinker, not heavy drinker), and abstainer (those who have not drunk alcohol in their lifetime).

Mental health factors including stress perception rate and subjective health status were investigated. Stress was classified into 2 categories with answers to the question "How much stress do you usually feel in your daily life?": Stressful (I feel a lot, I feel a little), little stress (I hardly feel it). Subjective health status was classified into 3 categories with answers to the question "How do you usually feel about your health?": good (very good, good), normal (average), and poor (bad, very bad).

Variables related to chronic disease, the prevalence of cardiovascular disease, diabetes, and depression was investigated. Cardiovascular disease includes stroke, angina, and myocardial infarction. The prevalence of each disease was classified into those diagnosed by a doctor.

Statistical Analysis

Data are presented as the mean (SD) for continuous variables, and presented as number and percent for categorical variables. We analyzed the study participants' characteristics according to the EQ-5D index, using *t* test to compare continuous variables, chi-square test for categorical variables.

Additionally, adjusted odds ratio (OR) and 95% CIs for the risk of low HRQoL according to PA measured by the accelerometer and GPAQ were calculated using logistic regression after adjusting the socioeconomic variables (age, sex, marital status, education, employment, and income) for model 1, covariates in model 1 plus mental health-related variables (stress, subjective health status, and depression) for model 2.

All statistical analyses were performed using STATA (version 18.0; StataCorp) and *P* values of <.05 were considered to indicate statistical significance.

Results

General Characteristics

Table 1 shows the baseline characteristics of the below-average (low QoL) and above-average (high QoL) groups of the EQ-5D index. Age was significantly lower in the high QoL group. In addition, males, singles, highly educated people, office workers, and high-income earners were more common in the high QoL group. Those who usually feel less stress and those whose subjective health was good were more common in the high QoL group. There was no significant difference between the 2 groups in some health-related lifestyle variables such as smoking, drinking, and average sleep time. Among chronic disease-related variables, cardiovascular disease and diabetes were not significantly different between the 2 groups.

^fMETs: metabolic equivalents.

Association Between the Domains of PA and HRQoL

In Table 3, logistic regression analysis was performed to determine the correlation between HRQoL and PA measured by the accelerometer and GPAQ, and marked with an OR and 95% CI. Compared with the low QoL group, the crude OR of the HRQoL was 1.55 (95% CI 1.11-2.17) in MVPA-AB ≥ 600

METs. After adjusting for the socioeconomic variables (model 1), the OR of the HRQoL was 1.60 (95% CI 1.13-2.27). After adjusting model 1 for the mental health-related variables (model 2), the OR was 1.45 (95% CI 1.01-2.09), which weakened the statistical significance compared with model 1. There was no statistical significance between the 2 QoL groups for MVPA-AT and self-reported PA.

Table 3. Association between domains of physical activity and health-related quality of life.

Domains of physical activity	Number	Crude OR ^a (95% CI)	Model 1 ^b (95% CI)	Model 2 ^c (95% CI)
MVPA^d-AB^e (10-min bouts)				
<600 METs ^f	1005	1	1	1
≥600 METs	239	1.55 (1.11-2.17)	1.60 (1.13-2.27)	1.45 (1.01-2.09)
MVPA-AT^g (Total bouts)				
<600 METs	527	1	1	1
≥600 METs	771	1.15 (0.89-1.51)	1.07 (0.82-1.41)	0.91 (0.68-1.22)
MVPA-S (Self-reported)				
<600 METs	574	1	1	1

^dMVPA: moderate to vigorous physical activity.

^eAB: accelerometer-bout.

^fMET: metabolic equivalent.

^gAT: accelerometer-total.

Discussion

Principle Findings

This study was designed to confirm the relationship between HRQoL and PA measured by an accelerometer using national survey data. As a result of the analysis, HRQoL was significantly associated with the group that engaged in more MVPA for at least 10 minutes, as measured by the accelerometer. However, there was no statistical significance with HRQoL for MVPA measured for at least 1 minute by the accelerometer. In the previous KNHANES, only self-report questionnaires were used to measure PA [8]. However, in the sixth KNHANES (2014-2015), PA measured with an accelerometer was provided, making it possible to conduct studies [28-30] like ours.

Our findings align with previous research demonstrating the beneficial effects of PA on HRQoL across various populations [31,32]. For example, multiple studies have reported that increased PA is associated with improved HRQoL. A study by Brown et al [16] found that adults who engaged in regular MVPA had significantly higher HRQoL scores compared to those who were inactive. Similarly, a review by Marquez et al [33] synthesized evidence from numerous studies and concluded that PA interventions can effectively enhance HRQoL across various populations. PA has been shown to enhance self-efficacy, physical self-esteem, and positive affect [32,34], which collectively contribute to improvements in HRQoL. Overall, our results are consistent with the majority of previous literature on the positive relationship between PA and HRQoL. This study further supports these findings by using objective measures of PA, thus providing a more accurate assessment of its impact on HRQoL.

This study can serve as a basis for recommending at least 10 minutes of MVPA to improve HRQoL. However, the phrase “at least 10 minutes” was deleted from the PA guidelines published by the US Department of Health and Human Services in 2018, as MVPA for less than 10 minutes can benefit health. Therefore, to compare this with other health-related variables not considered in this study, it is necessary to measure MVPA for at least 1 minute. Nevertheless, since the PA questionnaire used in the KNHANES specifies “usually continued PA for at least 10 minutes during a week,” it is more appropriate to compare it with PA for more than 10 minutes, as measured with an accelerometer in this study [35].

Earlier, it was mentioned that the GPAQ calculates PA that has been continued for at least 10 minutes, so it is appropriate to compare it with PA measured with an accelerometer for at least 10 minutes. However, previous studies [28,36-38] found no correlation between accelerometer data and the questionnaire's satisfaction with the PA guidelines, and the results were not consistent in this study as well. This inconsistency may arise because the questionnaire's criteria for “PA continued for at least 10 minutes” are subjective or may include PA lasting less than 10 minutes. Additionally, there is a possibility of bias in the self-report questionnaire, as people engaging in MVPA may over-report their activity levels [37-39]. Furthermore, since the accelerometer was provided after filling out the questionnaire, the data measurement periods differ, and the GPAQ may misclassify location movement PA as MVPA without considering movement speed. Therefore, to measure PA more accurately, a specific method that can complement both approaches is necessary.

In previous studies [40-42], stress and subjective health status perception had a negative correlation with HRQoL, and in 1 study [43]; it was reported that stress had the greatest influence on the deterioration of women's QoL. In this study, when

socioeconomic variables were corrected for the group with a lot of PA measured with an accelerometer, the statistical significance was stronger than before the correction. But when stress and subjective health status perception were additionally corrected, the degree of statistical significance decreased. Similar to previous studies, this can be interpreted as having a greater effect on stress and subjective health status perception on HRQoL.

Limitations

This study has the following limitations. First, it is difficult to generalize the study results since it is a nonprobability sample composed of study subjects selected through convenience sampling. Second, variables including EQ-5D are investigated through a self-report questionnaire, so there is a possibility of social desirability bias, misclassification bias, and recall bias. Third, since it was conducted as an observational cross-sectional study, it is not possible to know the causal relationship between HRQoL and variables. Nevertheless, it is significant that the study was conducted using national health and nutrition survey data of about 1300 adults aged 19-64. Also, since it is a study

using data obtained using an accelerometer, it has an advantage in being able to compare it with other domestic and foreign studies conducted in a similar way. Research using accelerometers began to increase in the 2000s, and since the beginning of 2010, nearly 100 related studies have been published annually [44,45]. In addition, the era has come when it is possible to measure PA using wearable devices such as smartphones and smart watches. It is thought that various follow-up studies using tools that can quantify PA are possible in the future. Based on this, we expect the growth of fields related to PA aimed at promoting health.

Conclusions

Our study shows the association between HRQoL and MVPA, which is significantly higher in the group with more PA for at least 10 minutes, using the KNHANES. The study emphasizes the need for promoting PA and interventions focusing specifically on continuing at least 10 minutes. We expect further interventional studies to focus on the specific PA time period such as occupational PA, leisure-time PA, and commuting PA.

Abstract

Background: Morning emotions can significantly affect daily wellness. While many studies have analyzed daily survey responses to identify factors influencing morning emotions, these methods require additional time and effort from individuals for emotional monitoring.

Objective: This study aims to identify daily alarm usage patterns related to morning emotions.

Methods: We recruited 373 users of the Alarmy app (DelightRoom) in the United States and South Korea and surveyed their demographics and usual behaviors related to morning emotions. Participants described their morning emotions over a 2-week period, during which we collected daily alarm app logs. We used a generalized estimating equation (GEE) method to identify factors affecting morning emotions.

Results: The findings indicate that varied alarm usage is related to morning emotions. Alarm set time was positively associated with feelings of peacefulness and refreshment in the morning, while task-based alarms were related to nervousness. The time taken to deactivate the alarm after it rang was negatively correlated with happiness. In addition, usual behaviors and demographic factors were found to be related to morning emotions, consistent with previous studies.

Conclusions: The study reveals that daily alarm usage is related to morning emotions, suggesting that daily alarm logs can supplement survey methods to facilitate daily emotion monitoring.

KEYWORDS

morning emotion; wake-up alarm usage; morning context; emotion monitoring; longitudinal observational study

Introduction

Background

The mental or emotional state of an individual in the morning significantly impacts daily wellness and is associated with 6 dimensions of holistic health: physical, mental, spiritual, emotional, social, and environmental health [1]. Rothbard and

Wilk [2] identified a correlation between employees' morning moods and their emotional states throughout the day. Employees who began their day with positive emotions tended to maintain those emotions, positively influencing their interactions with customers. Conversely, morning fatigue adversely affects daily life by reducing the quantity and intensity of physical activities [3]. Studies suggest that daily performance can be enhanced by

activities that positively influence one's morning emotional state, such as listening to music [4] or taking a shower [5].

Numerous studies have attempted to understand and modify morning emotions. For instance, Sonnentag et al [6] reported that evening relaxation could promote positive emotional states the following morning. Nandy et al [7] found that regular exercise can enhance positive morning emotions. Among the various factors influencing morning mood, sleep quality is paramount. High-quality sleep is significantly associated with the suppression of negative emotions and the maintenance of positive emotions into the next day [8,9]. Early bedtimes have been shown to improve social interactions and emotional experiences [10]. Furthermore, the mood experienced in dreams can affect the emotional state the next morning [11].

However, to our knowledge, previous studies have not sufficiently addressed the impact of morning context—specific circumstances and environments experienced during the morning hours—on morning emotions. The morning period possesses unique characteristics, such as sleep inertia and preparation for daily routines, distinguishing it from other times of the day. Therefore, understanding awakening contexts could provide deeper insights into morning emotions. Furthermore, contextual factors are generally recognized as important in understanding specific behaviors [12-14]. Similarly, Oh et al [15] highlighted the necessity of considering morning contexts to comprehend changes in morning behavior.

Objectives

This study aimed to explore the contextual factors that affect morning emotions. To achieve this, we analyzed alarm usage logs to evaluate the contextual information surrounding the moment of waking up. An alarm usage log reflects various aspects of waking behavior, such as the time and regularity of waking. In addition, monitoring and analyzing alarm usage logs is relatively easy because no additional user action is required. Previous studies to understand morning emotions have mainly relied on survey data that requires responses from the user. This study investigates the feasibility of a new method for monitoring morning emotions based on alarm logs by analyzing the relationship between alarm usage log data and morning emotions. If a significant relationship is found, this method could be expanded to monitor morning emotions using alarm usage log data. This approach could complement traditional methods that rely heavily on surveys, potentially providing a more efficient and unobtrusive way to understand and track morning emotions.

Methods

Participants

We recruited participants for this study from users of the Alarmy app (DelightRoom), focusing on the United States and South Korea, where the app is highly popular. Recruitment posts detailing the experiment's background, objectives, and procedures, along with a web URL for the application, were disseminated through the app's notice board and push notifications. In total, 373 subjects were recruited: 232 from the United States and 141 from South Korea.

The decision to use Alarmy as the focal application for this study was based on several compelling reasons. First, Alarmy is one of the most downloaded alarm apps globally, making it a widely used tool across diverse demographics and cultural contexts. Second, its unique features, such as mission-based alarms and loud alarm options, allow for a comprehensive analysis of wake-up behaviors and morning routines, providing insights that extend beyond basic alarm functions.

A key aspect of this study was to ensure that the findings were representative of the broader population of alarm users. To address potential concerns about generalizability, we compared the demographic characteristics of our sample to the larger Alarmy user population. The comparison revealed no significant differences in major usage statistics between our dataset and those used in previous studies analyzing large-scale Alarmy usage logs [16,17]. Furthermore, the age and gender distribution of our sample closely mirrored that of the overall Alarmy user base, suggesting that our findings are robust and applicable to a wide range of users.

Furthermore, a collaborative research agreement with Alarmy facilitated access to detailed log data, enhancing the robustness of the study. This agreement allowed us to leverage a large-scale dataset, ensuring that our sample was representative of the entire user base. Consequently, while the study exclusively recruited users of the Alarmy app, the demographic similarities between our sample and the broader population of Alarmy users support the generalizability of our conclusions.

All subjects participated voluntarily and received compensation of US \$43 for their commitment. The compensation amount was carefully chosen to reflect the effort needed for daily participation over 2 weeks and the specific requirement to respond during morning hours. This ensured adequate participant motivation while minimizing any potential bias due to compensation. The study's compensation strategy was designed to provide sufficient incentive to maintain participant engagement without compromising the integrity of the results. Evidence suggests that appropriately calibrated compensation is unlikely to bias experimental outcomes. According to a review by Singer and Couper [18], empirical studies typically find little evidence of payment influencing participants' behavior in a way that significantly affects the results, provided that the payment is not coercively large. Our compensation of US \$43 was benchmarked against typical study payments for similar durations and task demands, ensuring it was reasonable yet not overly influential.

Experimental Procedure

We conducted a longitudinal observational study to explore the relationship between daily waking behaviors and morning emotions. Given that an individual's demographics and characteristics could influence morning emotions, we categorized factors into three groups: (1) demographic, (2) usual, and (3) daily. Demographic factors included age and gender, while usual factors encompassed self-assessments of one's typical morning state. Daily factors were derived from analyzing alarm app usage. As dependent variables, we specified 9 emotions commonly experienced in the morning—hopeful, happy, peaceful, refreshed, annoyed, tired, depressed, nervous,

and neutral—along with a morning wellness score. These variables were measured through a presurvey, daily surveys, and alarm app usage logs.

The main experiment proceeded with participants first completing an 18-question presurvey covering demographics and their usual morning state. Over the course of 2 weeks, participants responded to daily surveys about their morning emotions and the time they went to sleep the previous night. These surveys were implemented and conducted using TypeForm, a web-based platform. To ensure accurate data collection on morning emotions, the initial survey link was sent 30 minutes after the participant's alarm was set. If there was no response, a follow-up link was sent at 10 AM. This method aimed to capture participants' emotions soon after waking while

providing a second opportunity for those who missed the initial prompt. Alarm app usage data during the study period was shared for analysis.

After 2 weeks, the experimental procedure concluded, and participants were compensated for their involvement. This comprehensive approach, combining presurvey data, daily surveys, and usage logs, allowed for an in-depth analysis of the relationship between waking behaviors and morning emotions.

Independent Variables

The independent variables in this study were classified into three categories: (1) demographic, (2) usual, and (3) daily. [Table 1](#) provides detailed descriptions of each independent variable within these categories.

Table 1. Descriptions of independent variables.

Factors	Variable	Description
Demographics		
Sex	demo_gender	Sex of the participant (male=0, female=1)
Age	demo_age	Age of the participant
Country	demo_country	Country of residence (United States=0, South Korea=1)
Usual		
Morning state	usual_state_alert	Degree of alertness after waking up (Not at all alerts=1, Slightly alert=2, Fairly alert=3, Very alert=4)
Morning state	usual_state_tired	Degree of tiredness after waking up (Very refreshed=1, Fairly refreshed=2, Slightly tired=3, Very tired=4)
Morning state	usual_state_score	Usual morning condition, rated on a 1-7 scale, assessed at the start of the experiment.
Habit	usual_habits_morningActivity	Habit of engaging in positive morning activities, such as exercise or meditation (No=0, Yes=1)
Theory of Planned Behavior	usual_tpb_attitude	Attitude toward morning waking (Strongly disagree=1, Strongly agree=7)
Theory of Planned Behavior	usual_tpb_subjectiveNorm	Subjective norm toward morning waking (Strongly disagree=1, Strongly agree=7)
Theory of Planned Behavior	usual_tpb_intention	Intention toward morning waking (Strongly disagree=1, Strongly agree=7)
Theory of Planned Behavior	usual_tpb_control	Control toward morning waking (Strongly disagree=1, Strongly agree=7)
Daily		
Alarm usage	daily_usage_dayOfWeek	Alarm usage on weekdays vs. weekends (weekday=0, weekends=1)
Alarm usage	daily_usage_ringCount	Number of alarms used to wake up in the morning
Alarm usage	daily_usage_ring2dismiss	Time elapsed from the alarm ringing to deactivation
Alarm usage	daily_usage_continuity	Number of days the alarm was used in the past week
Alarm usage	daily_first_ringTime	Time of the first alarm in the morning
Alarm usage	daily_last_typeInBed	Percentage of wake-up tasks performed in bed after the last alarm
Alarm usage	daily_last_typeOutOfBed	Percentage of wake-up tasks performed out of bed after the last alarm
Alarm usage	daily_last_isLoud	Use of a loud sound for the last alarm
Alarm usage	daily_last_isLabel	Use of a label for the last alarm
Time to sleep	daily_sleep_time	Bedtime the previous night

Demographic Factors

A total of 3 demographic variables were used: age, gender, and country, denoted as “demo_age,” “demo_gender,” and “demo_country,” respectively. Gender, being a categorical variable, was represented using a single dummy variable (male=0, female=1). Similarly, the participant's country was coded as a binary variable (United States=0, South Korea=1). All demographic variables were measured in a preliminary survey.

Usual Factors

We examined variables related to the usual morning state through a presurvey, assessing three types of individual characteristics: (1) usual morning state, (2) habits, and (3) planned behavior.

Participants' self-assessments of their usual morning state included aspects such as alertness and tiredness. These were measured using 4-point Likert scale questions adapted from the morning-evening wellness questionnaire [19]. Specifically, participants were asked, “How alert do you feel during the first half-hour after you wake up in the morning?” and “During the first half-hour after you wake up in the morning, how tired do you feel?” These responses were designated as “usual_state_alert” and “usual_state_tired,” respectively. In addition, participants rated their overall sense of well-being in the morning on a 7-point scale (“Rate your usual morning on a 7-point scale.”), which we denoted as “usual_state_score.”

We also considered the impact of participants' morning habits on their emotions, as indicated by previous studies [7]. Participants reported their engagement in frequent dynamic activities (eg, exercise) or static activities (eg, meditation) in the morning. These activities were recorded as “usual_habits_morningActivity.”

Finally, we explored behavioral factors based on the theory of planned behavior (TPB) [20]. TPB variables are widely used to describe purposive human behaviors [21-23]. We developed a questionnaire with 4 questions on a 7-point Likert scale to evaluate participants' usual target waking hours and morning behavioral patterns. The questions included: “Waking up on time in the morning is important to me,” “I intend to wake up on time in the morning,” “Other people think that I should wake up earlier in the morning,” and “I am confident that I am capable of waking up on time in the morning.” The responses to these questions were denoted as “usual_tpb_attitude,” “usual_tpb_intention,” “usual_tpb_subjectiveNorm,” and “usual_tpb_control,” respectively.

Daily Factors

In this study, we analyzed the Alarmy app usage logs of participants during the experiment period to track their daily morning behavior. Given the reported differences in sleep patterns between weekdays and weekends [24], we denoted the days of the week with the variable “daily_usage_dayOfWeek,” coding weekdays as 0 and weekends as 1. Holidays were excluded from this classification. To examine the continuity of alarm use, the number of days the alarm was used in the previous week was recorded as “daily_usage_continuity.” In addition,

we gathered information on how quickly users woke up in the morning. The number of alarms required to wake them up was denoted as “daily_usage_ringCount,” and the time from the ringing of the first alarm to its deactivation was denoted as “daily_usage_ring2dismiss.”

We further focused on the first and last alarms used in the morning. The time of the first alarm, indicating the targeted waking time, was marked as “daily_first_ringTime.” We also recorded the type of tasks required to dismiss the alarm. Alarms that could be deactivated without moving out of bed were indicated as “daily_last_typeInBed,” while those requiring movement out of bed were indicated as “daily_last_typeOutOfBed.” The use of a loud alarm sound for the last alarm was denoted as “daily_last_isLoud,” and the labeling of the last alarm was indicated by “daily_last_isLabel,” as the alarm label is the first text the user notices upon waking.

Finally, we included the time at which participants went to bed the night before. The ordinal variable “daily_sleep_time” was divided into 30-minute increments from 9 PM to 3 AM, with a total of 14 values numbered from 0 to 13.

Dependent Variables: Morning Emotions

We collected overall condition scores on a 7-point scale each morning using the question, “Rate your morning on a 7-point scale,” and used these responses as the variable “daily_overall_state.” In addition, we considered 9 specific categories for morning emotions. Previous studies have defined emotions in various ways. For instance, Ekman [25] identified 6 basic emotions, while Plutchik [26] presented a detailed diagram of 8 core emotions. Russell [27] developed a circular emotion model using arousal and valence as the two axes. To specify the emotions people feel upon waking, we conducted a pilot survey with 29 participants before the main experiments. Respondents were asked to describe their feelings in the morning hours, and their responses were classified into 9 representative emotions: 4 positive emotions (hopeful, happy, peaceful, and refreshed) and 4 negative emotions (annoyed, tired, depressed, and nervous). The ninth category was “no emotion” (none).

Analysis Methods

This study used generalized estimating equations (GEE) analysis [28] to effectively account for temporal changes in morning emotions. The GEE method is a widely used statistical technique for analyzing variables that are repeatedly measured over time [29,30]. While repeated-measures ANOVA is a common approach for analyzing repeated measurement data, the GEE method was deemed more appropriate for this study due to the presence of more than 2 independent variables.

Ethical Considerations

To ensure participant confidentiality, all study data were deidentified. In addition, the experiment received an exemption for informed consent from the institutional review board of Hanyang University (HYUIRB-202205-011).

Results

User Statistics

Table 2 presents the descriptive statistics of the independent variables. Initially, we collected demographic information from

participants based on 3 factors. The gender ratio was 49.6% (185/373 male participants). The average age of the participants was 23.94 (SD 9.65) years. Of the participants, 62.2% (232/373) resided in the United States, while the remainder lived in South Korea.

Table 2. Statistics of independent variables.

Factor	Variable	Mean (base)	SD
Demographic			
Sex	demo_gender	0.49 (male)	0.50
Age	demo_age	23.94	9.65
Country	demo_country	0.62 (US)	0.48
Usual			
Morning state	usual_state_alert	2.27	0.86
Morning state	usual_state_tired	3.30	0.68
Morning state	usual_state_score	4.29	1.39
Habit	usual_habit_morningActivity	0.60	0.48
Theory of planned behavior	usual_tpb_attitude	6.36	1.07
Theory of planned behavior	usual_tpb_subjectiveNorm	5.72	1.62
Theory of planned behavior	usual_tpb_intention	6.45	1.03
Theory of planned behavior	usual_tpb_control	4.43	1.86
Daily			
Alarm usage	daily_usage_dayOfWeek	0.79 (Weekday)	0.24
Alarm usage	daily_usgae_ringCount	1.72	1.46
Alarm usage	daily_usage_ring2dismiss	721.10	1496.27
Alarm usage	daily_usage_continuity	3.78	1.67
Alarm usage	daily_first_ringTime	25900.05	4570.43
Alarm usage	daily_last_typeInBed	0.51	0.46
Alarm usage	daily_last_typeOutOfBed	0.16	0.35
Alarm usage	daily_last_isLoud	0.05 (True)	0.18
Alarm usage	daily_last_isLabel	0.29 (True)	0.43
Time to sleep	daily_sleep_time	7.55	3.06

We then examined usual lifestyle factors related to the morning state using a 7-point Likert scale. In the self-assessment of their usual morning condition within 30 minutes of waking, the overall health condition averaged 4.29 out of 7. The scores for alertness and tiredness were 2.27 and 3.30 out of 4, respectively. In addition, 60.3% (225/373) of participants reported that they typically engage in active exercises in the morning. The average scores for the four variables in the TPB category were as follows: attitude, 6.36; subjective norm, 5.72; intention, 6.45; and control, 4.43.

We also collected data on daily user behavior based on alarm use. Overall, 79% of the total usage occurred on weekdays, with participants using alarms an average of 3.787 days per week. On days when alarms were used, an average of 1.7 alarms were set due to participants either snoozing or setting multiple alarms. Approximately 12 minutes passed before deactivating the alarm.

The average ring time of the first alarm of the day was 7:11:40 AM (25,900 seconds). The most commonly used alarm mission was the touch-a-button mission, with participants using this feature an average of 32.4% of the time. On average, 51.2% of wake-up tasks were performed in bed (eg, typing, math, memory, and shaking), while 16.3% of tasks required getting out of bed (eg, walking, squats, photo, and barcode). In addition, on average, participants selected loud alarm sounds 5.8% of the time and used alarm labels 29.9% of the time. Regarding usual bedtime, most respondents reported going to bed between 12 AM and 12:30 AM.

GEE Analysis Results

Our GEE analysis identified unique wake-up context factors for each emotion. The comprehensive results of the GEE analysis are presented in [Multimedia Appendix 1](#). In this section, we describe the variables that showed statistically significant

results, including the odds ratio (OR), 95% CI of the original GEE coefficient values, and *P* values.

Daily Overall State

Our analysis identified several variables significantly associated with the overall morning condition (daily_overall_state). Fewer alarms used per day (daily_usage_ringCount: OR 0.901, 95% CI -0.170 to -0.039; *P*=.002) and a greater number of days with alarm usage (daily_usage_continuity: OR 1.063, 95% CI 0.005-0.119; *P*=.03) were linked to higher overall scores. This suggests that consistency in alarm usage and reduced dependence on multiple alarms can enhance morning well-being.

The time of the first alarm (daily_first_ringTime) showed a positive correlation with the overall state (OR 1.133, 95% CI 0.052-0.199; *P*=.001), indicating that waking up later in the morning can contribute to a better overall morning state. Conversely, bedtime (daily_sleep_time) exhibited a negative

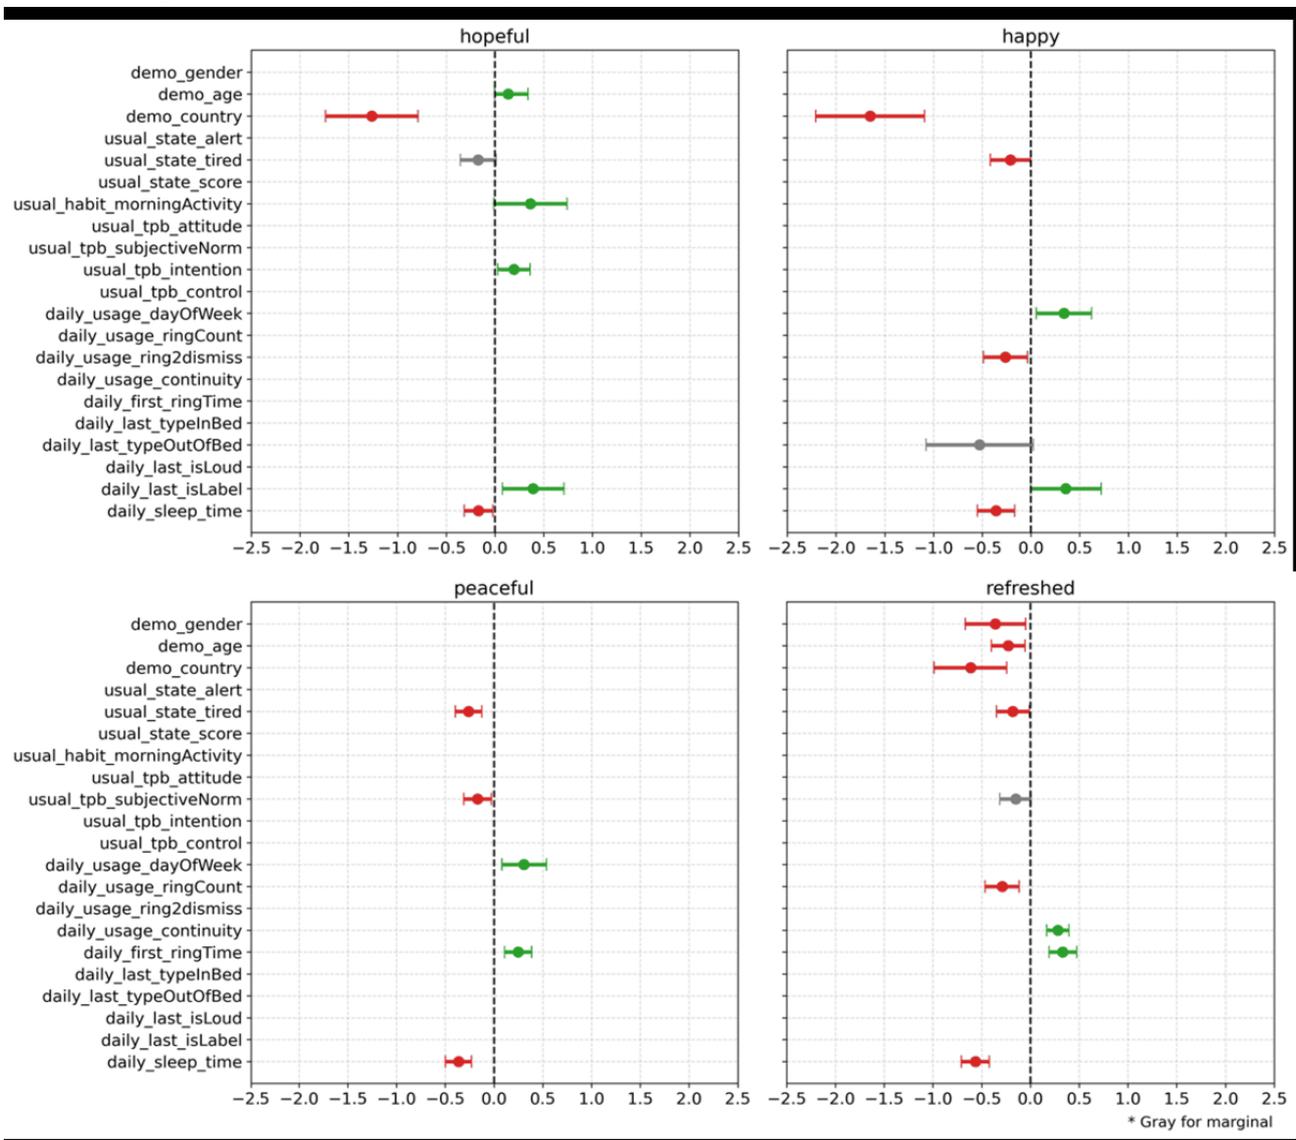

relationship with the overall score (OR 0.743, 95% CI -0.370 to -0.224; *P*<.001), suggesting that going to bed earlier significantly improves morning well-being.

Furthermore, individuals who perceived their usual morning state positively (usual_state_score) tended to have better daily morning states (daily_overall_state) (OR 1.437, 95% CI 0.208-0.519; *P*<.001), highlighting the importance of a consistently good morning routine. Among the TPB variables, only attitude (usual_tpb_attitude) showed a positive correlation with the overall morning state of the day (OR 1.202, 95% CI 0.050-0.319, *P*=.007), implying that a positive outlook toward waking up is beneficial for morning well-being.

Positive Emotions

Figure 1 displays the GEE analysis results for positive emotions, including the β coefficient and CI for each significant independent variable.

Figure 1. Results of generalized estimating equations analysis on positive emotions.

Hopefulness

We identified several significant factors influencing the emotion of hopefulness in the morning. Using a label on the last alarm

(daily_last_isLabel) increased the odds of feeling hopeful (OR 1.479, 95% CI 0.076-0.709; *P*=.01), suggesting that personalized alarm labels can positively impact morning emotions.

Conversely, a late bedtime (`daily_sleep_time`) the previous day decreased the odds of feeling hopeful (OR 0.845, 95% CI -0.313 to -0.023; $P=.02$), indicating the importance of an early bedtime for a positive morning start. Age was positively correlated with hopefulness (`demo_age`: OR 1.181, 95% CI -0.004 to 0.339], $P=.05$), and Korean users had significantly lower odds of feeling hopeful compared with American users (`demo_country`: OR 0.282, 95% CI -1.738 to -0.789; $P<.001$). Feeling tired after waking (`usual_state_tired`) negatively influenced hopefulness (OR 0.842, 95% CI -0.353 to 0.011; $P=.06$), whereas engaging in physical activities in the morning (`usual_habits_morningActivity`) tended to increase hopefulness (OR 1.437, 95% CI -0.013-0.740; $P=.05$). Among the TPB factors, only intention (`usual_tpb_intention`) significantly increased the odds of feeling hopeful (OR 1.215, 95% CI 0.028-0.362; $P=.02$).

Happiness

The use of alarms significantly affected morning happiness. The elapsed time from the first alarm ring to its deactivation (`daily_usage_ring2dismiss`) was negatively associated with happiness (OR 0.768, 95% CI -0.489 to -0.036; $P=.02$), suggesting that quicker responses to alarms may improve morning mood. Alarm use on weekends (`daily_usage_dayOfWeek`) was 1.4 times more likely to increase happiness compared to weekdays (OR 1.402, 95% CI 0.054-0.623; $P=.02$). This may be because individuals who maintain a regular rhythm without distinguishing between weekdays and weekends tend to feel happier. Performing wake-up tasks out of bed after the last alarm (`daily_last_typeOutOfBed`) marginally decreased happiness (OR 0.590, 95% CI -1.077 to 0.023; $P=.06$), implying that remaining in bed for initial tasks might contribute to better mood. Using a label on the last alarm (`daily_last_isLabel`) was positively correlated with happiness (OR 1.430, 95% CI -0.002 to 0.719; $P=.05$), while a late bedtime (`daily_sleep_time`) significantly decreased happiness (OR 0.699, 95% CI -0.548 to -0.166; $P<.001$), highlighting the importance of an early bedtime for positive morning emotions. Morning tiredness (`usual_state_tired`) significantly reduced happiness (OR 0.809, 95% CI -0.418 to -0.005; $P=.04$), indicating the negative impact of fatigue on morning mood.

Peacefulness

Using alarms on weekends (`daily_usage_dayOfWeek`) was more likely to result in peaceful emotions in the morning compared to weekdays (OR 1.360, 95% CI 0.080-0.538; $P=.008$). Setting the alarm for a later time (`daily_first_ringTime`) was associated with increased feelings of peace (OR 1.281, 95% CI 0.109-0.388; $P<.001$). Like other positive morning emotions, a late bedtime (`daily_sleep_time`) was positively and significantly correlated with peacefulness (OR 0.696, 95% CI -0.497 to -0.229; $P<.001$). Those who usually felt tired upon waking (`usual_state_tired`) experienced less peace (OR 0.770, 95% CI -0.396 to -0.126; $P<.001$). In addition, participants who were more conscious of the people around them (`usual_tpb_subjectiveNorm`) tended not to feel peaceful (OR 0.845, 95% CI -0.310 to -0.026; $P=.02$), suggesting that social pressures may detract from morning peace.

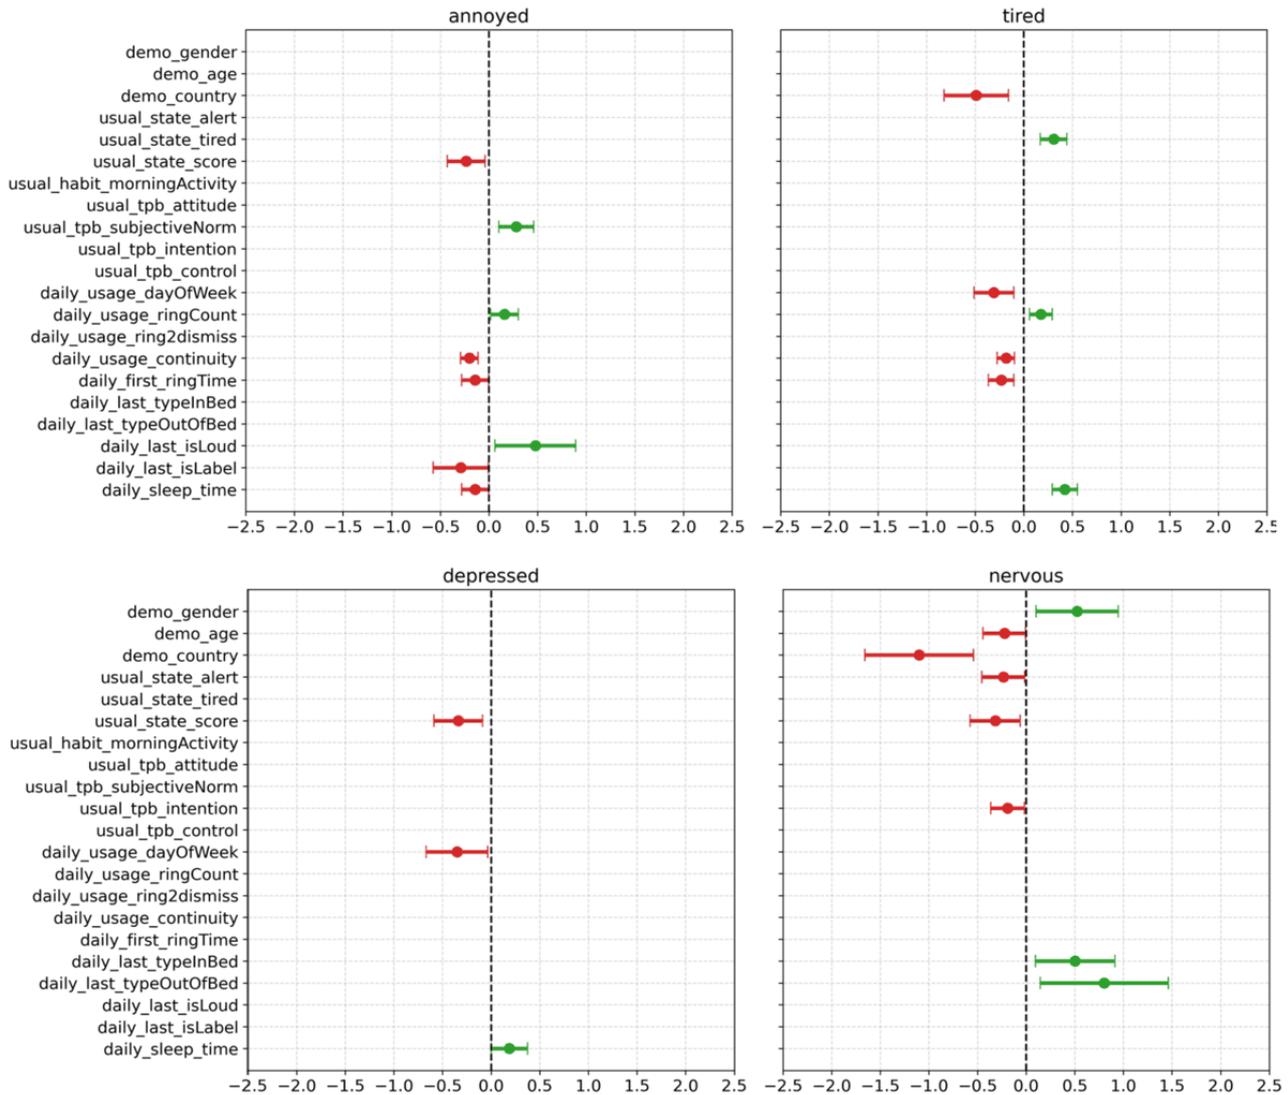

Refreshed

The number of alarms used in a day (`daily_usage_ringCount`) negatively affected the likelihood of feeling refreshed (OR 0.748, 95% CI -0.464 to -0.117; $P=.001$). Regular alarm use (`daily_usage_continuity`) positively influenced feelings of refreshment (OR 1.324, 95% CI 0.167 to 0.395; $P<.001$). Early bedtimes (`daily_sleep_time`: OR 0.568, 95% CI -0.708 to -0.421; $P<.001$) and later wake-up times (`daily_first_ringTime`: OR 1.392, 95% CI 0.190-0.474; $P<.001$) were significantly associated with feeling refreshed. Younger users (`demo_age`) felt more refreshed (OR 0.796, 95% CI -0.399 to -0.055; $P=.01$), as did males (`demo_gender`: OR 0.698, 95% CI -0.669 to -0.050; $P=.02$) and American users (`demo_country`: OR 0.541, 95% CI -0.988 to -0.242; $P=.001$). Usual tiredness after waking (`usual_state_tired`) was negatively correlated with feeling refreshed (OR 0.835, 95% CI -0.349 to -0.011; $P=.03$). The subjective norm in TPB (`usual_tpb_subjectiveNorm`) marginally decreased the feeling of refreshment (OR 0.858, 95% CI -0.313 to 0.008; $P=.06$), indicating that awareness of others can negatively affect the feeling of refreshment.

Negative Emotions

Our analysis identified several significant variables affecting negative morning emotions, as shown in [Figure 2](#).

Figure 2. Results of generalized estimating equations analysis on negative emotions.

Annoyance

Participants who used alarms more frequently in a day (daily_usage_ringCount) were more likely to feel annoyed (OR 1.173, 95% CI 0.018-0.303; $P=.02$). Conversely, a higher number of consistent alarm use days (daily_usage_continuity) reduced the tendency for annoyance (OR 0.817, 95% CI -0.293 to -0.11; $P<.001$). Setting an alarm for a later time (daily_first_ringTime) was associated with decreased annoyance (OR 0.868, 95% CI -0.279 to -0.004; $P=.04$), suggesting that waking up later can improve mood. Loud alarm sounds (daily_last_isLoud) increased annoyance (OR 1.611, 95% CI 0.062-0.892; $P=.02$), whereas using alarms with label texts (daily_last_isLabel) was negatively related to annoyance (OR 0.748, 95% CI -0.573 to -0.007; $P=.04$). The need to wake up earlier (daily_first_ringTime) also increased annoyance (OR 1.221, 95% CI -0.279 to -0.004; $P=.008$). Participants' usual morning state (usual_state_score) showed a negative correlation with morning annoyance (OR 0.791, 95% CI -0.427 to -0.041; $P=.01$). In addition, the subjective norm variable in TPB (usual_tpb_subjectiveNorm) was significantly and positively related to annoyance (OR 1.323, 95% CI 0.102-0.459; $P=.002$),

suggesting that social pressures contribute to feelings of irritation.

Tiredness

Alarms used on weekends (daily_usage_dayOfWeek) resulted in significantly lower tiredness than alarms used on weekdays (OR 0.734, 95% CI -0.513 to -0.103; $P=.003$). More frequent alarm use in a day (daily_usage_ringCount) increased tiredness (OR 1.190, 95% CI 0.058-0.291; $P=.003$), whereas regular alarm use throughout the week (daily_usage_continuity) was associated with reduced tiredness (OR 0.831, 95% CI -0.274 to -0.096; $P<.001$). Later bedtimes (daily_sleep_time) increased the likelihood of feeling tired (OR 1.523, 95% CI 0.295-0.550; $P<.001$), as did earlier wake-up times (daily_first_ringTime: OR 0.792, 95% CI -0.365 to -0.101; $P=.001$). Participants in the United States felt significantly less tired in the morning compared with those in South Korea (demo_country: OR 0.612, 95% CI -0.822 to -0.158; $P=.004$). Those who reported usually feeling tired in the presurvey (usual_state_tired) were more likely to feel tired during the experiment (OR 1.357, 95% CI 0.168-0.444; $P<.001$), indicating a consistent pattern of fatigue.

Depression

Participants with lower scores on the usual morning state in the presurvey (usual_state_score) were more likely to feel depressed during the experiment (OR 0.713, 95% CI -0.588 to -0.088; $P=.008$). Using alarms on weekends (daily_usage_dayOfWeek) was negatively related to morning depression (OR 0.703, 95% CI -0.669 to -0.035; $P=.02$). Later bedtimes (daily_sleep_time) increased the likelihood of feeling depressed the following day (OR 1.205, 95% CI 0.002-0.373; $P=.04$).

Nervousness

Morning nervousness varied depending on the type of wake-up tasks performed. In-bed wake-up tasks (daily_last_typeInBed: OR 1.655, 95% CI 0.096-0.912; $P=.01$) and out-of-bed tasks (daily_last_typeOutOfBed: OR 2.229, 95% CI 0.146-1.460; $P=.01$) were both associated with increased nervousness, suggesting that the nature of the wake-up activity impacts stress levels. Usual morning state (usual_state_score: OR 0.727, 95% CI -0.575 to -0.061; $P=.01$) and usual waking level (usual_state_alert: OR 0.776, 95% CI -0.456 to -0.015; $P=.03$) were negatively related to nervousness. Participants in the United States were significantly more likely to feel nervous compared with those in South Korea (demo_country: OR 0.333, 95% CI -1.657 to -0.542; $P<.001$). Men were 1.68 times less likely to feel nervous than women (demo_gender: OR 1.687, 95% CI 0.101 to 0.946; $P=.01$), and younger users tended to feel more nervous (demo_age: OR 0.800, 95% CI -0.442 to -0.005; $P=.04$). Among the TPB factors, only intention (usual_tpb_intention) significantly decreased nervousness in the morning (OR 0.826, 95% CI -0.364 to -0.019; $P=.02$).

No Emotions

Our analysis identified a single variable significantly related to the absence of emotions in the morning. South Korean participants were significantly more likely to report no specific emotions upon waking compared to participants in the United States (demo_country: OR 4.083, 95% CI 0.859-1.956; $P<.001$). This finding may be influenced by cultural differences, as previous research has indicated that Western individuals tend to express their emotions more openly than their Eastern counterparts [31].

Discussion

Daily Alarm Usage Related to Morning Emotions

The findings of this study provide insightful correlations between mobile alarm usage and morning emotions. Several key factors influencing morning emotions were identified, and these results can be interpreted and applied to improve daily wake-up experiences.

First, the significant influence of alarm set time on morning emotions can be explained by the alignment with natural circadian rhythms. Waking up later allows individuals to complete their sleep cycles, leading to feelings of peacefulness and refreshment. Conversely, a late bedtime disrupts these cycles, suppressing positive emotions and augmenting negative ones. This underscores the importance of maintaining consistent sleep and wake times for emotional well-being. Similar results

have been demonstrated in previous studies dealing with sleep duration and its effect on emotions. For example, Demasi et al [32] reported that sleep duration has a positive relationship with mental health. Insufficient sleep duration deteriorates emotional health conditions [33,34], such as depression [35]. Wrzus et al [36] identified the influence of the appropriate duration of sleep on mental health the following day by age. Also, a high quality of sleep fostered positive emotions on the morning of the next day [37].

Second, the method of alarm deactivation impacts morning emotions, likely due to the physical and cognitive demands placed on individuals immediately upon waking. Active wake-up tasks, such as taking pictures or performing squats, can induce stress and discomfort, resulting in nervousness and unhappiness. Previous study results show that those who do not wake up on time usually prefer hard alarms based on wake-up tasks [16]. These tasks are often preferred by individuals who struggle to wake up on time, further exacerbating their negative morning emotions.

Third, the detailed alarm settings, such as loudness and sound type, affect post-wake emotions due to their direct impact on sensory processing upon waking. Loud and jarring alarms can cause abrupt awakenings, leading to annoyance and a negative start to the day. Han et al [38] analyzed the effects of the types of alarm sounds on postwake emotions and noted that loud sounds could cause bad morning emotions. In contrast, using alarms with pleasant sounds and moderate volume can create a smoother transition from sleep to wakefulness. In addition, an alarm used on weekends had a significant effect on positive emotions, such as happiness and peace in the morning, while negative emotions, such as tiredness and depression, decreased.

Finally, the relationship between the wake-up process and morning emotions highlights the role of sleep inertia—a state characterized by reduced cognitive and sensory-motor performance after waking. A prolonged period between the alarm ringing and deactivation can prolong this inertia, decreasing morning happiness. Similarly, multiple alarms can increase annoyance and tiredness due to repeated disruptions in the waking process. This indicates that morning emotion can be related to sleep inertia [39], which refers to the transitional state experienced after waking and lowers cognitive and sensory-motor performance [40-42]. The findings of this study are consistent with previous study results that sleep inertia impairs positive emotions and encourages negative emotions [43,44]. In addition, using labeled alarms (eg, self-motivating to wake up on time or specifying the purpose) tended to induce feelings of hope and happiness and reduce annoyance in the morning.

Based on these interpretations, practical suggestions for optimizing alarm usage to improve morning emotions are as follows:

- Optimal alarm timing: Set alarms for later times in the morning, if possible, to align with natural circadian rhythms. Aim for consistent wake times that allow for the completion of sleep cycles, promoting peacefulness and refreshment.
- Consistent sleep schedule: Maintain a regular bedtime and wake time, even on weekends, to ensure sufficient sleep

duration and prevent the suppression of positive emotions. A consistent sleep schedule supports overall emotional health and well-being.

- Gentle wake-up methods: Choose alarm deactivation methods that require minimal physical activity and are less intrusive. Avoid active tasks like taking pictures or performing exercises immediately upon waking, as these can increase stress and negative emotions.
- Moderate alarm volume and pleasant sounds: Use alarms with moderate volume and pleasant sounds to avoid abrupt awakenings and reduce annoyance. Select sounds that are calming and conducive to a gentle wake-up experience.
- Labeling alarms for motivation: Use labeled alarms with motivational messages or specified purposes to foster feelings of hope and happiness. This can make the wake-up process more intentional and positive.
- Minimize multiple alarms: Limit the number of alarms used in the morning to reduce repeated disruptions and minimize sleep inertia. Aim to wake up with a single alarm to enhance morning happiness and reduce tiredness.

In conclusion, while this study provides valuable insights into the relationship between alarm usage and morning emotions, future research with extended durations could offer a more comprehensive understanding. By adopting these practical suggestions, individuals can improve their morning emotional states and overall well-being.

Nonalarm Factors Influencing Morning Emotions

Our study identified various nonalarm factors that influence morning emotions. First, demographic variables demonstrated significant differences in experiencing morning emotions. For example, male participants tended to be less nervous upon waking, consistent with previous studies indicating that females report more negative emotions than males [45,46]. In addition, significant correlations were found between age and feelings of nervousness and hope in the morning, aligning with previous findings [47]. Older participants reported lower levels of feeling refreshed upon waking, which may be related to decreased sleep quality with age [48]. Participants in the United States experienced a wider range of morning emotions compared to Korean participants, highlighting the need to consider cultural factors in studies of human emotion [47].

The usual morning states reported by participants also explained their morning emotions. For instance, alertness and tiredness within the first 30 minutes of waking were significantly related to negative emotions. Every negative emotion, except tiredness, tended to decrease when the usual morning score was higher. These findings align with previous studies [49,50], which show that individuals with low self-assessment scores tend to have lower quality of life in terms of physical and mental health, experiencing higher levels of pain, depression symptoms, and lower daily activity scores.

Previous research has emphasized the importance of behavioral patterns and lifestyles in understanding human emotions [51-53]. For example, Peluso and Guerra de Andrade [54] examined the relationship between emotion and physical activity in improving mental health, while Penedo and Dahn [55] explored the benefits of physical activity on emotional well-being. Studies have also

used apps or web-based services to investigate the effects of physical activity on emotions [56,57]. Similarly, our results indicated that participants who engaged in physical activities after waking experienced more positive emotions, such as happiness.

Finally, we found that TPB variables related to waking on time significantly affect morning emotions, corroborating previous studies on morning behavior change [15]. For example, a positive intention to wake up on time was positively related to hopeful emotions and negatively related to nervousness. This suggests that a strong willingness to wake up on time fosters feelings of hope and reduces nervousness in the morning. The subjective norm variable was significantly positively correlated with annoyance and negatively correlated with feelings of peace and refreshment. This indicates that relying on external cues to wake up can hinder positive morning emotions.

Unexplored Influences and Future Research

In our study, we ventured beyond traditional research paradigms by exploring how waking context, particularly alarm usage behaviors, influences morning emotions. This approach is significant as it sheds light on specific daily behaviors that can substantially impact emotional states at the start of the day. Notably, our research highlights the role of the Alarray app's various functions, such as mission-based alarms, in shaping individuals' initial emotional responses. These findings underscore the importance of considering practical daily interactions with technology when studying emotional dynamics.

However, our investigation did not encompass all possible variables that could influence morning emotions. Factors such as family relationships, work-life balance, and health conditions can significantly influence individuals' morning emotions [7,58]. Research indicates that behaviors like physical activity, social interactions, diet, and medication compliance play a crucial role in shaping morning emotional states, particularly in populations with mental health issues and histories of chronic homelessness [59]. In addition, loneliness has been associated with lower positive affect and higher distressed affect throughout the day, emphasizing the impact of social relationships on emotional well-being [60]. Furthermore, work-related stress and exhaustion can lead to physical and mental health problems, affecting overall living conditions and emotional states [61].

Cultural factors also play a significant role in influencing the positivity or negativity of morning emotions. For example, individuals from different countries exhibit distinct morningness patterns, highlighting strong national differences in morningness scores and factorial structures [47]. Cultural factors between the US and South Korea can significantly influence emotions, as evidenced in various studies. The emotional tendencies of Korean women in the US and Korea were influenced more by personal characteristics than cultural differences [62]. In addition, Korean American adolescents often face challenges due to the clash between traditional Korean culture and Americanization demands, impacting their emotional well-being and behavior in school settings [63]. Differences in aesthetic perceptions between US and South Korean participants highlight how cultural contexts shape emotional responses to website aesthetics [64]. Furthermore, US-aided construction projects in

South Korea post-Korean War influenced the sociopolitical context and emotional landscape of the region by promoting democratic citizenship, private enterprise, and the American way of life [65].

The cultural dimensions proposed by Hofstede [66] further illuminate the distinctions between collectivistic and individualistic societies, which can deeply influence emotional responses. In collectivistic societies, individuals prioritize social harmony and often avoid behaviors that might discomfort others. This cultural trait could influence morning emotions, as people may wake feeling more harmonious or stressed based on their perception of social obligations or conflicts. Conversely, in individualistic cultures, where personal autonomy and self-expression are valued, transgressions of social norms can induce feelings of guilt, impacting morning emotional states.

For future research, it would be pertinent to incorporate these variables into the study design. A broader examination that includes diverse family dynamics, parenting styles, and a more extensive cultural representation would likely enhance the understanding of morning emotional states. In addition, longitudinal studies could provide deeper insights into how consistent interactions with alarm features, like those offered by Alarmy, influence long-term emotional and psychological well-being.

Such an integrated approach would not only validate the findings from this initial study but also expand our understanding of the intricate web of factors that influence morning emotions. Future research could also explore the impact of technology-based interventions tailored to different cultural contexts to improve morning emotional states. This could lead to more targeted interventions aimed at enhancing emotional well-being right from the start of the day, considering both cultural and familial contexts.

Limitations

This study presents several limitations that should be considered when interpreting the overall findings within the specific context in which the research was conducted.

First, this research examined factors related to morning emotions by analyzing the usage logs of the Alarmy app from 373 users across two countries, emphasizing the significance of the wake-up context. Previous studies have seldom addressed app usage logs or waking conditions in relation to morning emotions, making the use of actual log data notably uncommon. However, other known factors, such as family relationships, work-life balance, and health conditions, which also influence morning emotions, were not included in this study. The practical constraints of conducting research in real-world settings, as opposed to a laboratory environment, limited the consideration and control of all variables. Future studies could benefit from

incorporating these additional factors to offer a more comprehensive understanding of morning emotions.

Second, this study used actual alarm usage logs and daily survey data collected over a 2-week period. Consequently, it did not capture long-term usage patterns. Further research is necessary to observe long-term effects or pattern changes. Despite the short duration, the study gathered daily data from 373 real users, yielding a substantial number of sample instances that reflect real-life scenarios. The findings from this study will be valuable for designing future long-term studies.

Third, while this study analyzed the relationships between various variables and morning emotions, it primarily focused on correlations rather than causations. This means that although significant associations between variables and morning emotions were identified, direct causal relationships cannot be conclusively determined. However, understanding these correlations can still be valuable. Depending on the nature of the variables, these correlations can provide useful insights for predicting morning emotions and potentially guiding interventions.

Finally, this study concentrated on the Alarmy app among mobile alarm applications. Alarmy is widely used globally and provides a variety of wake-up alarm functions, and its log data was accessible for analysis. Therefore, the findings of this study should be interpreted within the context of the Alarmy app. Future research comparing different types of wake-up alarm apps or methods could offer insights into varying user experiences and usage patterns.

Conclusions

This study aimed to comprehensively understand morning emotions by examining the context of morning waking through alarm usage. We categorized morning emotions into 9 distinct categories and identified factors affecting each. Specifically, we analyzed daily alarm usage logs, including ring times and deactivation types. The GEE analysis results revealed several factors related to each emotion. In addition to traditional factors such as demographics and usual state, daily alarm usage played a crucial role in understanding morning emotions.

This study demonstrates the feasibility of using waking alarms to monitor daily emotions. Existing methods for monitoring emotions primarily depend on explicit user data, such as survey responses [67,68]. While some studies have proposed monitoring methods based on implicit data from mobile sensors [69,70] or social activities from social media (eg, Twitter) [71-73], their practical application may be limited due to sensitive data collection and complex analyses. We believe that the findings of this study contribute to the improvement of future emotion monitoring by illustrating the relationship between waking alarm usage and specific emotions.

Acknowledgments

This work was supported by Culture, Sports and Tourism R&D Program through the Korea Creative Content Agency grant funded by the Ministry of Culture, Sports and Tourism in 2023 (Project Name: Cultivation of Next-generation Convergence Culture Technology [CT] Experts through Education, Developments, and Demonstration Projects for the Real-time Adaptive Performance

and Exhibition Technologies to the User Reactions in the Metaverse, Project Number RS-2023-00224524) and by the Ministry of Education of the Republic of Korea and the National Research Foundation of Korea (NRF-2020S1A5B8104091).

Conflicts of Interest

None declared.

Multimedia Appendix 1

Generalized estimating equations analysis results.

Abstract

Background: Many countries have introduced video consultations in primary care both inside and outside of office hours. Despite some relational and technical limitations, general practitioners (GPs) have reported the benefits of video use in the daytime as it provides faster and more flexible access to health care. Studies have indicated that video may be specifically valuable in out-of-hours primary care (OOH-PC), but additional information on the added value of video use is needed.

Objective: This study aimed to investigate triage GPs' perspectives on video use in GP-led telephone triage in OOH-PC by exploring their reasons for choosing video use and its effect on triage outcome, the decision-making process, communication, and invested time.

Methods: We conducted a cross-sectional questionnaire study among GPs performing telephone triage in the OOH-PC service in the Central Denmark Region from September 5, 2022, until December 21, 2022. The questionnaire was integrated into the electronic patient registration system as a pop-up window appearing after every third video contact. This setup automatically linked background data on the contact, patient, and GP to the questionnaire data. We used descriptive analyses to describe reasons for and effects of video use and GP evaluation, stratified by patient age.

Results: A total of 2456 questionnaires were completed. The most frequent reasons for video use were to assess the severity (n=1951, 79.4%), to increase the probability of self-care (n=1279, 52.1%), and to achieve greater certainty in decision-making (n=810, 33%) (multiple answers were possible for reasons of video use). In 61.9% (n=1516) of contacts, the triage GPs anticipated that the contact would have resulted in a different triage outcome if video had not been used. Use of video resulted in a downgrading of severity level in 88.3% (n=1338) of cases. Triage GPs evaluated the use of video as positive in terms of their decision-making process (n=2358, 96%), communication (n=2214, 90.1%), and invested time (n=2391, 97.3%).

Conclusions: Triage GPs assessed that the use of video in telephone triage did affect their triage outcome, mostly by downgrading the level of care needed. The participating triage GPs found video in OOH-PC to be of added value, particularly in communication and the decision-making process.

KEYWORDS

primary health care; after-hours care; referral and consultation; general practitioners; triage; remote consultation; telemedicine

Introduction

Health care systems are undergoing a digital transformation worldwide [1-9]. Studies on contact patterns in primary health care during the COVID-19 pandemic found an overall increase in digital consultations (e-mail, video, or telephone) [5,10,11]. A central part of this development is driven by the use of video consultations, which many countries have introduced in primary care both inside and outside office hours [2,5,6,10,12,13]. Video use in daytime general practice has been reported to range from

1% to 6.4% [14-18], but studies on video use in out-of-hours primary care (OOH-PC) are lacking.

Video use has been shown to be context dependent, such as daytime general practice versus OOH-PC setting [15,19-21]. Several studies have investigated the perspectives of general practitioners (GPs) on video use in daytime general practice [3,12,15,19-26]. The benefits of video use include faster access to health care compared to face-to-face consultations and flexibility in care delivery [3,21,22,25,26]. As drawbacks of video use, GPs have reported technical [12,20,22-25] and

relational limitations, such as lack of connection with the patient and of the feeling of presence and intimacy [12,24,26], and uncertainty about which patients are eligible candidates for video use [3,15,25,26]. Therefore, many GPs prefer face-to-face consultations over video consultations [12,19,21].

Limited knowledge exists on the user experiences of video in OOH-PC. In total, 2 qualitative studies found that the use of video adds value specifically in the context of OOH-PC services [19,27]. A focus group study among GPs in British OOH-PC conducted by Payne et al [27], showed that GPs used video to support their clinical decision-making. Furthermore, a questionnaire study conducted by Gren et al [28] among Danish triage nurses found that the use of video improved patient assessment and reassurance in calls related to young children. No quantitative studies on the GP perspective have been conducted, highlighting the need for additional insights into the added value of video use in OOH-PC, such as the effect on patient flows. This knowledge is essential to ensure optimal utilization and further implementation of video technology.

This study aimed to investigate triage GPs' perspectives on video use in GP-led telephone triage in OOH-PC by exploring their reasons for choosing video use and its effect on triage outcome, the decision-making process, communication, and invested time. Based on literature, we expected high satisfaction levels among GPs. In addition, we hypothesized a moderate effect of video use on triage outcomes, as video theoretically provides the triage GP with more information, enabling them to make a better-informed decision.

Methods

Design

We conducted a cross-sectional questionnaire study among GPs conducting telephone triage in the OOH-PC service in the Central Denmark Region from September 5, 2022, until December 21, 2022.

Setting

In Denmark, health care is publicly funded and free of charge for all residents, including all care delivered by GPs. The health care system is centrally regulated, but most services, including OOH-PC, are provided by the local governments of the 5 Danish regions. OOH-PC services are open on weekdays from 4 PM to 8 AM and for 24 hours during weekends and holidays. GPs and GP trainees (hereafter referred to collectively as triage GPs) are obligated to cover shifts in their regional OOH-PC service.

The study was conducted in the Central Denmark Region. This region has 2 call centers handling all telephone triage contacts, along with 13 locations for clinic consultations. The number of triage GPs present depends on weekday and time of day, ranging from 2 to 15 triage GPs. Patients are obligated to call the OOH-PC, being triaged by telephone. They cannot show up physically at the OOH-PC service without a prior telephone triage call. Triage GPs perform telephone triage with the use of video (video contact) or without the use of video (telephone contact), but without a clinical decision support tool. When answering a telephone triage contact, the triage GP gathers information about the reason for the encounter. Based on this

information and their clinical experience, the triage GP decides if the telephone triage contact is suitable for video use. If so, a video link is sent to the caller in an SMS text message, and, when activated by the caller, a one-way video connection is established. In Denmark, video contacts were rapidly implemented at the start of the COVID-19 pandemic, without clear guidelines for their use. Triage GPs are paid a fee-for-service through standardized remuneration codes for telephone contacts (€10, US \$10.89) or video contacts (€31, US \$33.76). Triage GPs also decide upon the triage outcome: self-care, referral to face-to-face consultation (clinic consultation or home visit), or referral to hospital. Out of 5 Danish regions, 3 are organized with GP-led triage (including the Central Denmark Region), whereas 2 regions have nurse-led or mixed triage.

Questionnaire Development

The development of the questionnaire followed a thorough process. The content was based on results from studies investigating video use in a general practice setting [1,3,4,7,8,12,15,16,22,25,29-35] and on experiences with video use shared by triage GPs and local stakeholders. The research group conducted several internal feedback rounds, which were followed by external feedback from 8 GPs with expertise in both research and triage in OOH-PC. Both internal and external feedback concerned the wording, construction, and clinical relevance of included items. In addition, short interviews were conducted with several triage GPs from the regional OOH-PC service to compile a comprehensive list of relevant response categories to the defined questions. Furthermore, cognitive interviews were conducted with 2 GPs from the external feedback panel to assure understanding of the meaning and relevance of the questions and answering categories. Finally, we performed a 1-day pilot test among triage GPs in the regional OOH-PC service, receiving responses from 19 different triage GPs, which resulted in 40 completed questionnaires. The test provided us with further information to consider before initiation of data collection (eg, relevance of response categories, response rate, and ceiling effect).

Final Questionnaire

The final questionnaire consisted of 7 questions. One question covered reasons for video use and offered predefined response categories with multiple responses possible as well as a free-text response option. One question covered the actual triage outcome (self-care, referral to face-to-face consultation, or referral to hospital), and one question covered the anticipated triage outcome without video use to assess if the use of video may influence the triage outcome. In total, 3 questions covered the added effect of video on the decision-making process (5-point Likert scale), communication (5-point Likert scale), and invested time (predefined response categories). One final question covered the reason for encounter (data not presented in this article). An English version of the questionnaire is available in [Multimedia Appendix 1](#).

Data Collection

The questionnaire was integrated into the electronic patient registration system of the regional OOH-PC service and was

set to pop-up after every third video contact. This setup automatically linked background data on the contact, patient, and GP to the questionnaire data (date and time of contact, and sex and age of both patient and triage GP). As the questionnaire was integrated into the electronic patient registration system, triage GPs had to answer the questionnaire between patient contacts. To affect the workflow and telephone waiting time as little as possible, answering the questionnaire should take no more than 1 minute, which was confirmed in the pilot test.

To investigate the representativeness of patients and triage GPs, we included data on all video contacts in the regional OOH-PC service in the study period. Triage GPs were invited to participate in the study when logging into the electronic patient registration system at the beginning of a telephone triage shift. Participation was voluntary, and the triage GPs were remunerated for participation (€4 [US \$4.36] per completed questionnaire). To avoid the sample being dominated by a few very active triage GPs, we allowed each individual triage GP to participate in a maximum of 5 telephone triage shifts.

Data Handling and Statistical Analyses

Contacts were categorized according to whether the triage GP participated in the study. Triage GPs who had already participated in 5 triage shifts were categorized as participating, since it is reasonable to assume that these triage GPs would also have accepted participation if they received an invitation for subsequent triage shifts.

On September 6, 2022, a server crash prevented questionnaire data generation. Therefore, all video contacts on this date were excluded from the analysis ($n=173$; 0.8%). Furthermore, 59 blank questionnaires were excluded from the analysis. In total, 5 questionnaires had missing answers to the question on estimated triage outcome without video use; these questionnaires were not excluded since the remaining parts had been completed ([Multimedia Appendix 2](#)).

Patient age and sex were calculated through the Danish personal identification number. A total of 28 (0.3%) video contacts had missing personal identification number and were excluded from the analysis. For the purposes of stratification, patient age was categorized in 3 groups: 0 - 4 years, 5 - 18 years, and >18 years. This stratification was chosen because of very few older adult patients receiving a video contact ([Multimedia Appendix 3](#)).

Descriptive analyses were used to describe the study population and the questionnaire data. We performed stratified analyses according to patient age and used the Pearson chi-square test to compare groups. To investigate possible selection bias, we compared contacts handled by participating triage GPs to contacts handled by nonparticipating triage GPs. The reasons for video use were presented with predefined response categories, and answers were stratified by patient age. To investigate the possible effect of video use on the actual triage outcome, we tabulated answers to the question regarding the anticipated triage outcome against answers to the question on the actual triage outcome. Finally, to present the triage GPs'

evaluation of video use, we tabulated the answers to the questions regarding the decision-making process, communication, and time invested.

Ethical Considerations

The Committee on Health Research Ethics in the Central Denmark Region approved the data collection from the electronic patient records in the OOH-PC registration system (1-45-70-15-22). All GPs taking shifts in the regional OOH-PC service were informed about the study prior to the beginning of the data collection. During the study period, all triage GPs were informed about the project and the ability to opt out in accordance with the General Data Protection Regulation of the European Union. Answering questionnaires was voluntary, and triage GPs gave their consent for participation at the beginning of every triage shift. Triage GPs were paid €4 (US \$ 4.24) per questionnaire. The study was listed in the record of processing activities at the Research Unit for General Practice in Aarhus, and data were anonymized in accordance with the provisions of the General Data Protection Regulation. Finally, the study was endorsed by the Danish Organization of General Practitioners in the Central Denmark Region.

Results

Participation and Questionnaire Completion Rates

In the study period, a total of 189,229 telephone triage contacts were conducted in the regional OOH-PC service. Of these, 22,093 (11.7%) were video contacts, of which 2456 resulted in a completed pop-up questionnaire ([Multimedia Appendix 2](#)).

In total, 649 different triage GPs were invited 2597 times when logging into the electronic patient registration system at the beginning of a telephone triage shift. Of these, 1330 invitations were accepted (participation rate: 51.2%), of which 430 invitations (32.3%) did not produce completed pop-up questionnaires as the triage GP used video less than 3 times during the triage shift. The remaining 900 accepted invitations resulted in 2456 completed questionnaires. The average number of questionnaires completed by a triage GP was 0.36 (IQR 0.14 - 0.50) questionnaires per hour, corresponding to 2.8 (IQR 1.12 - 4) questionnaires on an 8-hour triage shift.

Patient characteristics for all video contacts during the study period were stratified according to whether (or not) the contact resulted in a completed pop-up questionnaire. Patient characteristics were comparable for both groups ([Multimedia Appendix 3](#)).

Characteristics of Triage GPs

[Table 1](#) shows GP characteristics for all video contacts during the study period. Video contacts were stratified according to whether the contact was handled by a participating or a nonparticipating triage GP. Compared to nonparticipating triage GPs, participating GPs were significantly more often male (54.6% vs 65.1%) and under the age of 50 years (46.4% vs 63.5%) ([Table 1](#)).

Table . Distribution of triage GP^a characteristics in all video contacts, stratified for whether (or not) the triage GP participated in the study.

Triage GP characteristics	Video contacts (n=22,093), n (%)	
	Nonparticipating triage GPs (n=5802)	Participating triage GPs (n=16,291)
Sex^b		
Female	2634 (45.4)	5691 (34.9)
Male	3168 (54.6)	10,600 (65.1)
Age (years)^b		
31 - 40	968 (16.7)	4104 (25.2)
41 - 50	1722 (29.7)	6248 (38.4)
51 - 60	2000 (34.5)	4013 (24.6)
61 - 70	1083 (18.6)	1830 (11.2)
>70	29 (0.5)	96 (0.6)

^aGP: general practitioner.

^bSignificant difference between groups ($P<.001$) when using the Pearson χ^2 test.

Reasons for Video Use

The most frequent reasons for video use were to assess the severity (79.4%), to increase the probability of self-care (52.1%), and to achieve greater certainty in decision-making (33%) (Table 2). When stratifying for patient age, significant differences

between age groups were found; to assess the severity and to achieve greater certainty in decision-making were more often used for contacts concerning children, whereas to better understand what the encounter was about was more often used for contacts concerning adults.

Table . Triage GPs^a reasons for using video according to predefined response categories, stratified for patient age groups.

Reasons for using video ^b	Age groups, n (%)			Total (n=2456)
	0 - 4 years (n=974 ^c)	5 - 18 years (n=461 ^c)	>18 years (n=1021 ^c)	
To better assess the severity of the condition and the described symptoms ^d	821 (84.3)	365 (79.2)	765 (74.9)	1951 (79.4)
To increase the probability of being able to finish the patient by phone	490 (50.3)	251 (54.5)	538 (52.7)	1279 (52.1)
To achieve greater certainty in decision-making about the triage outcome ^d	364 (37.4)	144 (31.3)	302 (29.6)	810 (33.0)
To better understand what the encounter was about ^d	79 (8.1)	47 (10.2)	120 (11.8)	246 (10.0)
To meet the patient's needs (eg, long distance to consultation room, requested by the patient)	41 (4.2)	22 (4.8)	52 (5.1)	115 (4.7)
To ensure that the triage of the patient could be completed in shorter time	20 (2.1)	3 (0.7)	12 (1.2)	35 (1.4)

^aGP: general practitioner.

^bMultiple answers allowed (total number of answers: 4436).

^cn: number of completed questionnaires within the age group.

^dSignificant difference between age groups ($P<.001$) when using the Pearson χ^2 test.

Effect on Triage Outcomes

Of the 2456 included video contacts, triage GPs anticipated that the contact would have resulted in a different triage outcome if

video had not been used in 1516 contacts (61.9%) (Table 3). With the use of video, 1338 of these contacts (88.3%) were downgraded to a lesser severity level. Of the 650 contacts that triage GPs anticipated to have ended with self-care prior to

video use, 120 contacts were upgraded to either a face-to-face consultation (16.9%) or a hospital referral (1.5%). Additionally, video use changed the outcome of some of the 1719 contacts anticipated to end with a face-to-face consultation prior to video use; video downgraded 76.4% of these contacts to self-care, whereas 2.3% were upgraded to a hospital referral. Prior to video use, triage GPs would have ended 82 contacts with a

hospital referral, but video use downgraded 23.2% of these contacts to face-to-face consultation and 30.5% to self-care. When we stratified for patient age, we found that young children aged 0 - 4 years (974 contacts) were more often upgraded from self-care to a hospital referral (2.6%) compared to older children (461 contacts) (0%) and adults (1016 contacts) (1.2%) (data not shown in the table).

Table . Anticipated triage outcome (vertical) versus actual triage outcome (horizontal).

	Actual triage outcome (%)			Total ^a , n
	Self-care	Face-to-face consulta- tion	Hospital referral	
Anticipated triage outcome (%)				
Self-care	81.5 ^b	16.9 ^c	1.5 ^c	650
Face-to-face consulta- tion	76.4 ^d	21.4 ^b	2.3 ^c	1719
Hospital referral	30.5 ^d	23.2 ^d	46.3 ^b	82

^aTotal number of completed questionnaires (n=2451), as 5 questionnaires had missing data regarding estimated triage outcome without video use.

^bUnchanged triage outcome.

^cUpgraded triage outcome.

^dDowngraded triage outcome.

Effect on the Decision-Making Process, Communication, and Invested Time

According to triage GPs, video use contributed to a better decision-making process and better communication with the patient (Table 4). Only 5 questionnaires (0.2%) had a negative assessment (3 regarding the decision-making process and 2

regarding communication). Triage GPs generally assessed that video use was worth the time spent, but disagreement was reported in 49 questionnaires (2%). Triage GPs assessed that their decision-making process and the time spent on video use primarily benefitted the youngest patients (0 - 4 years) (data not shown in the table).

Table . Triage GPs^a assessment of video use regarding the decision-making process, communication, and invested time.

Question and response categories	Response, n (%) ^b
How did the use of video influence your decision-making process?	
It got much better	1349 (54.9)
It got better	1009 (41.1)
There was no difference	95 (3.9)
It got worse	2 (0.1)
It got much worse	1 (0.0)
How did the use of video influence your communication with the patient?	
It got much better	1143 (46.5)
It got better	1071 (43.6)
There was no difference	240 (9.8)
It got worse	2 (0.1)
It got much worse	0 (0)
Was the use of video worth the time spent?

Discussion

Principal Results

The most frequent reasons for video use were to assess the severity, to increase the probability of self-care, and to achieve greater certainty in decision-making. In 61.9% of contacts, the triage GPs anticipated that the contact would have resulted in a different triage outcome if video had not been used. Use of video resulted in a downgrading of severity level in 88.3% of cases. Triage GPs found the use of video to have a positive influence on the decision-making process, communication, and invested time.

Limitations

To our knowledge, our study is the first to quantitatively investigate GPs' perspectives on video use in OOH-PC. The study is based on a large dataset that combines data from questionnaires and register data. The risk of recall bias was reduced as triage GPs answered the questionnaire immediately after a video contact. Furthermore, the questionnaire was answered by many different triage GPs, which increased the representativeness of the results.

Our study also had some limitations. Selection bias may be present because triage GPs who declined participation may differ from participating triage GPs in their way of using and assessing video. Participating GPs were younger and more often male compared to those who declined. In addition, triage GPs conducting many video contacts were overrepresented in our data set, as they completed more questionnaires. These triage

GPs are likely to differ from triage GPs having only a few video contacts in terms of their attitude toward video use. Furthermore, we found a ceiling effect of answers regarding communication, the decision-making process, and time invested (with mainly very positive assessments). This ceiling effect points toward indication bias, as the triage GPs first decided if the use of video was suitable and then assessed the quality of this decision. Furthermore, the answering categories in the question regarding time invested do not have the same degree of differentiation as the other questions, which may have skewed the results in a positive direction. Telephone triage by GPs is uncommon in most countries with comparable OOH-PC services [36], and GPs may differ in their use and assessment of video. Finally, we investigated 1-way video, whereas 2-way video may have produced different findings.

Comparison With Prior Work

We found that triage GPs most often used video in telephone triage contacts to assess the severity, to increase the probability of self-care, and to achieve greater certainty in decision-making. These findings are in line with results from 2 qualitative studies investigating video use in OOH-PC [27,28]. Gren et al [28] interviewed triage nurses using video in contacts concerning young children and found that nurses identified several children who appeared more ill on video than presented by telephone. Payne et al [27] conducted a focus group study among GPs working in OOH-PC. They found that GPs used video to support decision-making about which patients could be managed safely with self-care advice and which patients were seriously ill and needed further care. Many contacts to OOH-PC concern

reassurance [28]. Seeing the patient, thereby not only relying on verbal information from the patient, is likely to increase reassurance and the likelihood of ending with self-care advice. In addition, a scoping review found that GPs in daytime general practice considered video to be effective in achieving successful decision-making [21].

In our study, the use of video appeared to improve the patient flow due to more self-care advice and direct referrals to the hospital. In line with our findings, the 2 abovementioned qualitative studies found that video facilitated more effective handling of calls [27,28]. Improving the call handling might offer substantial advantages to the health care system and clinicians, primarily by reducing the use of health care resources and optimizing resource allocation. More efficient call handling may also enhance patient safety through the facilitation of direct hospital referrals when needed [28].

Danish triage GPs found video to be valuable in communicating with the patient at OOH-PC. Similarly, Payne et al [27] highlighted that GPs experienced a closer personal connection with patients when using video compared to telephone contacts. In line with this, Gren et al [28] found that triage nurses assessed their interactions to become more humane when using video. However, findings from studies conducted in daytime general practice present a more negative picture. Some studies have indicated that GPs perceive relational limitations due to inaccurate reading of nonverbal signals and challenges with expressing emotions when not being physically present [12,24,26]. Yet, video use may also help build relationships with patients who might otherwise be reluctant to seek help [26]. The difference found between daytime general practice and OOH-PC could be due to many factors, including contextual factors and variations in patient population and reasons for encounter [37-40]. Furthermore, in daytime general practice, video consultations are often compared with in-clinic

consultations, whereas contacts in OOH-PC video are compared with telephone contacts [25,27]. This discrepancy could contribute to the difference in evaluation of video use between the 2 settings. At OOH-PC, video is used as an additional triage tool to assess the level of care needed.

Implications for Practice and Future Research

Our study suggests that great added value of video use in OOH-PC telephone triage. Using video may optimize the utilization of limited medical resources during periods of large demands by reducing the number of face-to-face consultations and increasing the number of self-care advices. However, the real potential of video use should be investigated, addressing the scope of use and the number of suitable telephone triage contacts. Further implementation of video in OOH-PC could be recommended, although future studies are needed to support our results.

Future studies should examine whether the outcomes of this study remain consistent across varying OOH-PC models and varying triage professionals. Moreover, the added value of 2-way video in OOH-PC should be investigated, specifically the quality of communication. Research on patient safety associated with the use of video in OOH-PC is also highly relevant, as we found a considerable level of downgrading of severity level.

Conclusions

Triage GPs assessed that the use of video in telephone triage did affect their triage outcome, mostly by downgrading the level of care needed. The participating triage GPs found video in OOH-PC of added value, in particular in the communication and in the decision-making process. However, future research is needed to assess the full potential of video use and to define the best scope of use.

Acknowledgments

We gratefully acknowledge the financial support provided by the Danish health insurance foundation Sygeforsikringen Danmark, the General Practice Research Foundation (Praksisforskningsfonden) of the Central Denmark Region, the Department of Public Health at Aarhus University, the Multipractice Study Committee (Multipraksisudvalget) of the Danish College of General Practitioners, and the Committee for Quality Improvement and Continuing Medical Education (Kvalitets- og Efteruddannelsesudvalget) of the Central Denmark Region. The funding bodies had no role in the study design, data collection, data analysis, data interpretation, writing of the manuscript, or submission of the final article.

Authors' Contributions

All authors contributed to the study design, interpretation of results, and drafting and revising of the manuscript. The first author (MAN) was responsible for data management and the statistical analysis. All authors agreed to the final submitted version of the manuscript.

Abstract

Background: Social robots are becoming increasingly important as companions in our daily lives. Consequently, humans expect to interact with them using the same mental models applied to human-human interactions, including the use of cospeech gestures. Research efforts have been devoted to understanding users' needs and developing robot's behavioral models that can perceive the user state and properly plan a reaction. Despite the efforts made, some challenges regarding the effect of robot embodiment and behavior in the perception of emotions remain open.

Objective: The aim of this study is dual. First, it aims to assess the role of the robot's cospeech gestures and embodiment in the user's perceived emotions in terms of valence (stimulus pleasantness), arousal (intensity of evoked emotion), and dominance (degree of control exerted by the stimulus). Second, it aims to evaluate the robot's accuracy in identifying positive, negative, and neutral emotions displayed by interacting humans using 3 supervised machine learning algorithms: support vector machine, random forest, and K-nearest neighbor.

Methods: Pepper robot was used to elicit the 3 emotions in humans using a set of 60 images retrieved from a standardized database. In particular, 2 experimental conditions for emotion elicitation were performed with Pepper robot: with a static behavior or with a robot that expresses coherent (COH) cospeech behavior. Furthermore, to evaluate the role of the robot embodiment, the third elicitation was performed by asking the participant to interact with a PC, where a graphical interface showed the same images. Each participant was requested to undergo only 1 of the 3 experimental conditions.

Results: A total of 60 participants were recruited for this study, 20 for each experimental condition for a total of 3600 interactions. The results showed significant differences ($P < .05$) in valence, arousal, and dominance when stimulated with the Pepper robot behaving COH with respect to the PC condition, thus underlying the importance of the robot's nonverbal communication and embodiment. A higher valence score was obtained for the elicitation of the robot (COH and robot with static behavior) with respect to the PC. For emotion recognition, the K-nearest neighbor classifiers achieved the best accuracy results. In particular, the COH modality achieved the highest level of accuracy (0.97) when compared with the static behavior and PC elicitations (0.88 and 0.94, respectively).

Conclusions: The results suggest that the use of multimodal communication channels, such as cospeech and visual channels, as in the COH modality, may improve the recognition accuracy of the user's emotional state and can reinforce the perceived emotion. Future studies should investigate the effect of age, culture, and cognitive profile on the emotion perception and recognition going beyond the limitation of this work.

Introduction

Background

During the last decade, there has been increasing interest in research on socially assistive robotics aimed at realizing intelligent robotic solutions for health care and social assistance. We experience an evolution of social robot applications; indeed, they moved from the role of *conciierge* and *helper* [1] toward the role of *companion* and *therapist* [2,3]. Social robots have the potential to contribute to the greater good of society; indeed, it has been demonstrated that they can support everyday life as companions and the health care system from *logistics* to *assistance and rehabilitation*. Thinking to include social robots in the care chain, they can be used to reduce stress, anxiety, and pain in children [4]; they can be integrated into conventional behavioral and cognitive therapies for both children and adults who struggle with social anxiety [5]; or they can be used to promote mental health [6]. A review by Hung et al [7] showed evidence that Paro robots can reduce negative emotions in patients, promoting a positive mood and improving social engagement. Rossi et al [8] demonstrated that social robots are effective in decreasing stress in children accessing the emergency room. As the complexity of the robot task increases, social robots are required to perform more complex perceptual, cognitive, and interactive functionalities. This is the case in long-term interactions in which robots and users should establish meaningful communication, emotional awareness, and reliable engagement.

In this context, the human-robot interaction (HRI) field has become crucial, and it is now compelling to better understand how humans perceive, interact with, or accept these machines in social and real contexts. Researchers are also debating on defining the factors that can influence the perceived social capabilities and intelligence of a robot [9,10]. De Graaf et al [11] highlighted the significance of the robot's social capability, emphasizing the importance of 2-way interaction where a robot is expected to respond to humans in a social manner. In addition, De Graaf et al [11] underlined that a social robot should *also display thoughts and feelings* and should be *socially aware of the environment*, among other issues. When a robot failed to perform this 2-way interaction, people were disappointed and experienced a sense of dissonance. In other words, when interacting with a social robot, especially a humanoid robot, we expect to use the same mental structure and social rules that guide us in human-human communication, expecting empathetic interaction because they are perceived as social actors [12].

From a roboticist or engineering point of view, these concepts are translated into the design and development of behavioral

models that can guarantee an efficient and reliable 2-way interaction [13,14]; they should *perceive* and *show* emotions (and social norms) and thus be understood by humans with whom they are interacting. The key challenge in this field is to provide robots with cognitive and affective capabilities, developing architectures that allow them to establish empathetic relationships with users, which can foster long-term and meaningful interactions. From an implementation perspective, the design and the deployment of a socially capable social robot comprises 2 essential parts. The first is devoted to designing and implementing a consistent and congruent emotional behavioral architecture that makes the robot react or act to the environment (ie, *display thoughts and feelings*). The capabilities of a user to understand the emotions displayed by a robot have been explored in different settings [15,16]. Examples of actions can include the expression of congruent cues such as facial expressions [17], changes in the color of the eyes, movement of the upper limbs [16,18], or smart navigation strategies [19]. In contrast, the other part is more focused on the robot's perception of the user's emotional response to these behaviors [20], with special attention to contextualizing its action and reaction according to the living contexts and habits or preferences of the person with whom it is interacting (ie, *being socially aware of the environment*) [21].

Related Work on Emotion and Social Robots

The ability of a robot to perceive the nonverbal cues of the user, which convey user emotion and intent, plays a key role in the development of social robots capable of performing meaningful interactions [22,23]. In this sense, humans' gaze, body posture, cospeech gestures, and facial expressions play a leading role in defining the context of the interaction, helping the robot to correctly classify the experience, and associating it with informative content [21]. The development of such abilities, for a researcher in the field of robotics, translates into the use of multimodal sensor modality and the implementation of several complex algorithms to endow robots with different cognitive and social capabilities. The visual modality is the most commonly used [24] because it can detect nonverbal behaviors that are representative of the emotional state of users without requiring them to wear any external sensor. Alternatively, wearable sensors [25] can be used, also using a multimodal approach, to overcome the problems related to occlusion and low light. Other algorithms or modules were implemented to perform multiperson tracking [26], speech recognition [27,28], and automatic engagement detection [29]. A recent review paper [24] provides a deep insight into the most used methods and approaches.

For the *showemotion* part, robots must exploit several channels (ie, auditory, visual, cospeech, and gestures) and mechanisms (eg, body posture, facial expressions, vocal prosody, touch, and gaze) to communicate their “internal emotional status” and intentions authentically and clearly [30]. Thus, the capabilities of a user to understand the emotions displayed by a robot have been explored in several settings [31]. Over the last few years, several attempts have been made using both video-simulated robots and real robots. Guo et al [20] showed participants 5 different emotions using the humanoid robot called Alpha2, and they were asked to rate the perceived emotion using the Self-Assessment Manikin questionnaire (SAM; only valence and arousal dimensions) [32]. In contrast, Barchard et al [33] conducted a web-based study to evaluate the perception of a robot’s social intelligence by showing videos of robot interactions. However, the embodiment and the appearance of social robots play important roles in the perception of the robot; therefore, video-based elicitation could introduce some bias in the analysis of perceived emotion. This is why other research has relied on investigating the emotion perceived during a real HRI. This is the case of Bagheri et al [34], who asked participants to watch 6 performances of America’s Got Talent Show on Pepper’s tablet that are expected to evoke the 6 basic emotions. Rossi et al [35] and Staffa et al [36] relied on movie trailers to evoke emotions. However, they used nonstandard videos, making it challenging to identify the target emotion in a recognized and standardized manner, as the elicited emotion through the video clips is not known a priori, and consequently, it is difficult to define the role of the robot (and its embodiment) in the elicitation process.

Research groups have recently begun to study the effects of multimodal channels on communication. Studies conducted with embodied conversational agents showed that incongruent emotional stimuli (eg, auditory and visual stimuli) can result in adverse consequences on user rating; conversely, congruent stimuli can facilitate the recognition of emotions [37]. Other researchers have also studied the role of nonverbal behavioral cues while interacting with robots. Movie clips showing coherent and incoherent robot behaviors are often used to elicit emotional responses from users with respect to those induced by movie clips [15,16,18,35]. For instance, Rossi et al [16] investigated how an incoherent nonverbal robot’s behavior with respect to the presented emotion can produce a type of humorous effect. Tsiourti et al [18] investigated how contextual incongruence (ie, a robot’s reaction conflicts with the socioemotional context) can confuse the observers, decreasing the accuracy of the perceived emotion. Nevertheless, such a cospeech robot’s behavior was used in addition to a nonstandard method of emotion elicitation, as previously remarked; thus, it is not easy to understand the role of the robot’s behavior with respect to the emotional context. Therefore, it is important to understand how the robot’s nonverbal behavior might shape the human perception of the showed emotion elicited through standard emotionally labeled visual data sets and, at the same time, observe the robot’s emotion recognition accuracy rate. Although previous studies have shown a correlation between the robot’s nonverbal action and perceived emotion, there is a lack of use of standard elicitation modalities.

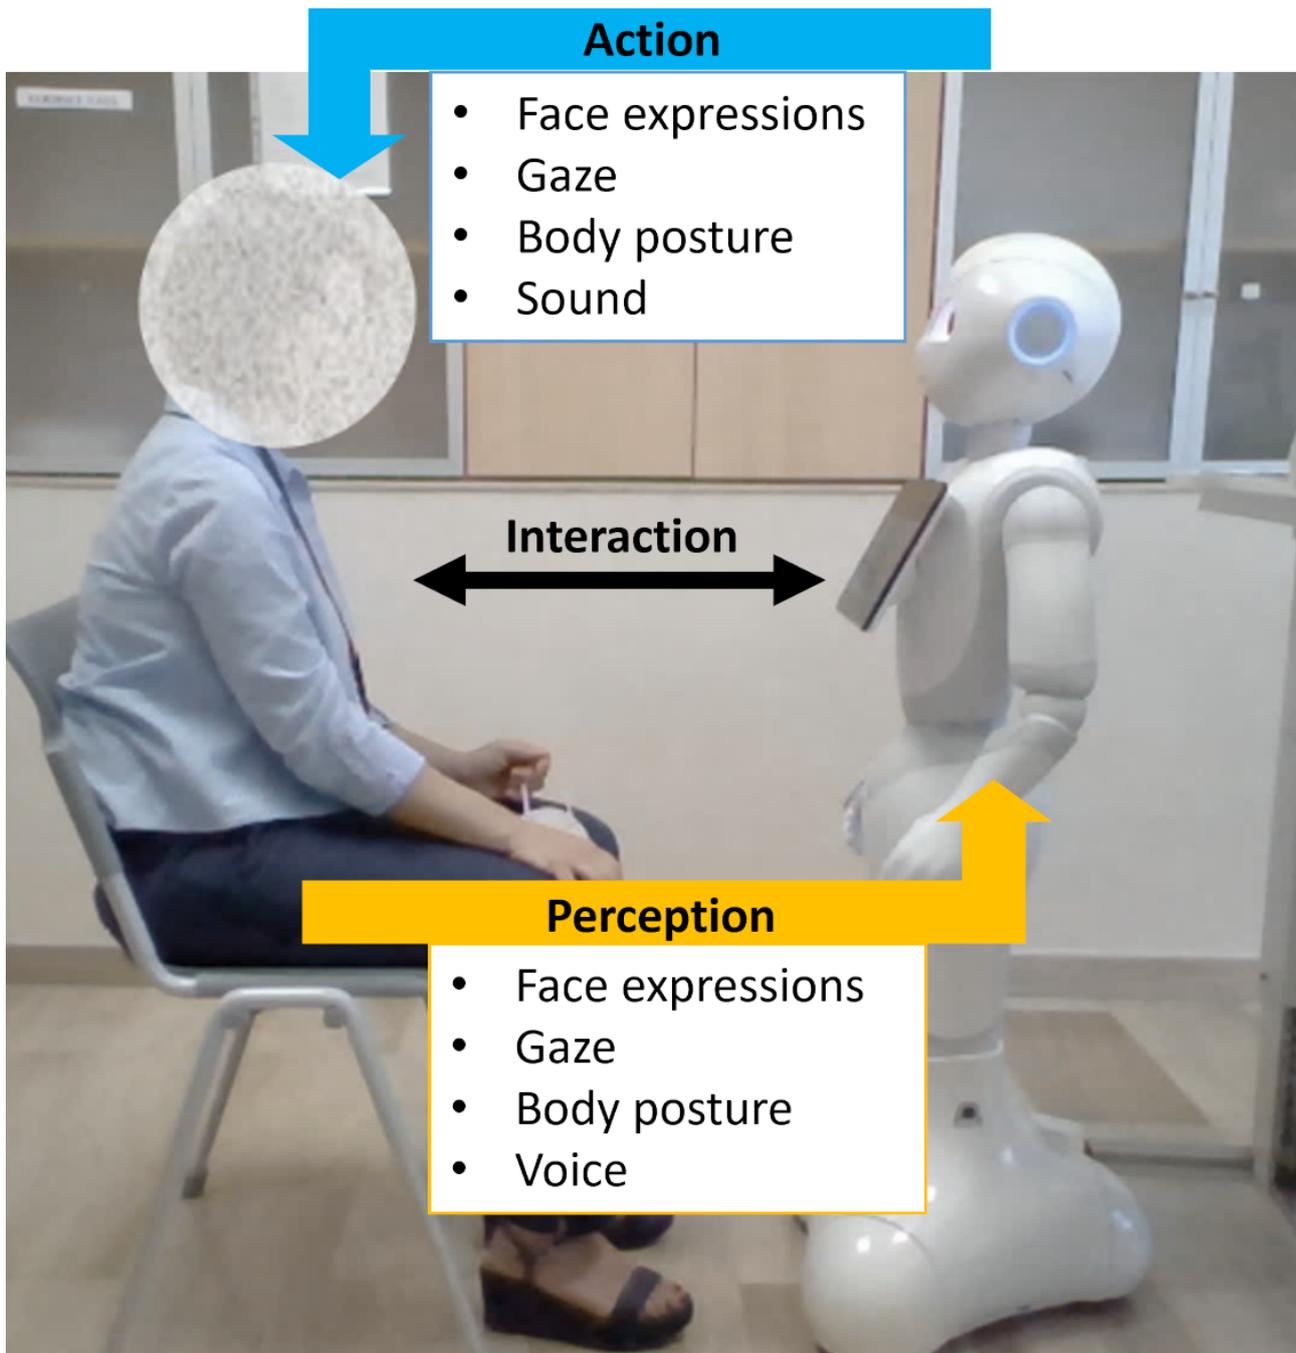

Therefore, in this work, we present the results of 3 experimental sessions to observe the performance of the robot in recognizing users’ emotions as well as to investigate the difference (if any) in eliciting emotions in humans when using a social robot (with or without coherent behavior) rather than a PC. We plan to use a standard data set of pictures, namely, the International Affective Picture System (IAPS) [38], to elicit emotions in users. Particularly, the robot will use a multimodal behavior (ie, head movements, vocal reinforcement, and body gestures) to interact with the participants while showing the graphical emotions by establishing social binding, whereas the PC will provide emotion elicitation only through a graphical interface. The 2 graphical interfaces have been designed to provide the same information to the user but using different communication channels. In this context, the aim of this work is dual. First, it aims to investigate the increase in the user’s emotional perception during the interaction with a robot with respect to a PC (Figure 1, blue arrow). In particular, this work investigates the role of the robot’s coherent nonverbal behavior in emotion perception by consequently assessing the impact of robot embodiment and, eventually, its coherent behavior. Robot nonverbal cues are manipulated with respect to a mapping between the main associated emotion and cospeech gestures that can be generated on the robot. At the end of each interaction, the participants were asked to self-assess their perceived emotions. In this study, we used the emotion classification proposed by Russel et al [39], which relies on 3 variables, namely, valence, arousal, and dominance. Valence describes the degree to which a stimulus causes a positive or negative emotion, arousal refers to the intensity or level of energy invested in the emotion, and dominance reflects the extent of perceived control over the emotional response when facing the stimulus. The collected answers were analyzed to answer the following research questions (RQs):

1. RQ1: Emotion elicited through a humanoid robot interacting with coherent emotional behavior is rated higher than emotions elicited by a web application in terms of emotional valence, arousal, and dominance.
2. RQ2: There are significant differences in terms of emotional valence, arousal, and dominance between a robot showing coherent behavior rather than a robot that it is not moving at all (static condition).
3. RQ3: The embodiment of the humanoid robot will not affect the emotion perception compared with the web application.

Second, this study aims to assess the accuracy of the robot in recognizing the elicited emotion in the participants (Figure 1, yellow arrow). The ability to infer and interpret emotions plays a key role in establishing intuitive and engaging HRIs. On the one hand, a robot endowed with emotion recognition skills can adapt its behavior based on the detected user emotion [22]. On the other hand, a robot expressing recognizable emotions positively influences the evaluation of its capabilities [40]. In particular, features related to facial expressions were extracted, preprocessed, and analyzed with 3 supervised machine learning techniques to verify the following RQ:

1. RQ4—There is no difference in the robot emotion recognition accuracy despite the elicitation modalities (robot or web application).

Figure 1. Two-way interaction proposed in this study. To improve the human-robot interaction, the robot should perceive the user's behavior (yellow arrow) and plan appropriate action (blue arrow).

In our previous studies [41,42], we evaluated the perceived acceptance and the recognition rate of having a robot that acts coherently and incoherently despite the standard emotion showed with respect to the standard elicitation modality. In contrast, in this study, we focus only on coherent behavior by comparing it with a standard web application that runs on a PC. In addition, instead of focusing on evaluating how the robot's acceptance is modulated according to the elicitation modality, we focused on the perceived emotion evoked.

Methods

Instrumentation

The instrumentation is composed of the following elements: (1) a Pepper robot (Aldebaran, United Robotics Group) or a PC, (2) the RoboMate (Behaviour Labs) interface for cospeech gestures, (3) a custom interface that contains pictures from the IAPS for eliciting emotion, and (4) an external camera placed on Pepper to record the participants' emotions during the interaction. Pepper is a humanoid robot that is widely used for experimentation in socially assistive robotics. It is 120 cm tall, weighs 28 kg, and has 20 df, including 1 head, 2 arms, and 1 wheeled base. In addition, it has a tablet on the front. Robot

coherent behavior was managed through the RoboMate interface [43] to animate Pepper, when necessary, selecting among the behaviors classified as “positive social stimulus” or “negative social stimulus.” The selected stimulus was modeled by a psychologist using 3 modalities: body gestures (upper limb and head), gaze, and sound. IAPS is a database of images devoted to eliciting standardized emotions [44]. It was developed by the Center for Emotion and Attention at the University of Florida. This database is commonly used in psychological studies on emotions and attention. Each image in the data set is labeled with the corresponding emotion, thus enabling researchers to properly select the stimulus. In this study, 60 images were selected from the team of psychologists of the hospital “Casa Sollievo della Sofferenza.” According to the IAPS valence dimension, 21 of the selected images were rated as positive, 19 as negative, and 20 as neutral. A customized web-based interface was developed to standardize the emotional stimulation when using 2 different communication channels (a robot and a PC).

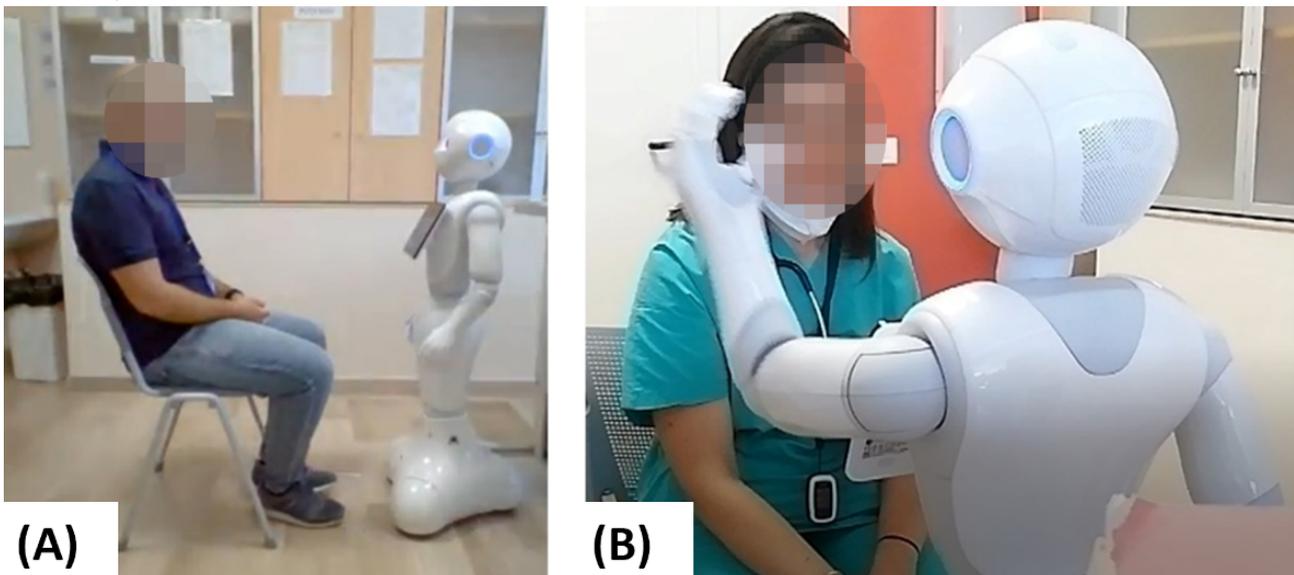

Experimental Setup

A psychologist welcomed the participant, briefly explaining the experimental setup, including how to use the evaluation tool. It is important to emphasize that the participant was not aware of the real objective of the experimentation, thus avoiding

interference with the experience. To properly investigate the RQs, each participant underwent 1 of the following elicitation modalities.

1. **Static (STA) behavior:** Pepper robot has its arms along the body in a neutral position (Figure 2A). Pepper’s face was looking at the participant but without any animacy. Pepper displayed IAPS images on its tablet through the customized web application.
2. **Coherent (COH) behavior:** Similar to the STA condition, the IAPS images were shown on Pepper’s tablet. Using the RoboMate application, the psychologist assigned a coherent behavior to Pepper with the shown images. In particular, the psychologist can choose and combine 3 modalities for elicited emotions: body gesture (upper limb and head), gaze, and sound, which are available on the RoboMate application (Figure 2B). For example, in the case of positive emotion, Pepper’s gestures were chosen to look friendly; it should look to the user direction, and the voice gave positive reinforcements.
3. **PC:** For this experimental condition, we used a PC instead of the Pepper robot. Participants were asked to evaluate the images shown on a PC through the customized web application.

Figure 2. Experimental setup. The participants were interacting with Pepper robot during the experimentation. (A) Participants were asked to sit in front of the robot and watch the images on its tablet. (B) If the participant belonged to the coherent elicitation modality group, the Pepper robot would move its arms, eyes, and head.

The participant was asked to sit in front of the technology (ie, Pepper robot or PC). If the user interacts with Pepper, Pepper is placed 0.5 to 0.6 m far from the user (ie, personal distances [45]); in the case of interaction with the PC, the user is requested to sit and interact with the computer as he or she will commonly do.

Each stimulus was shown for 7 seconds, and at the end, the participant was asked to fill out the SAM [32], as adapted in the study by Gatti et al [46] directly on the robot or on the computer after each picture. SAM is an emotion assessment tool that uses graphic scales, depicting cartoon characters expressing 3 emotional elements (valence, arousal, and dominance). Each participant was asked to rate the domains by

selecting an image that corresponded to a score between 1 and 9. A picture of the interface is presented in [Multimedia Appendix 1](#).

At the end of the experimental session, each participant completed 60 SAM questionnaires. The psychologist was present during the test, and she or he was ready to intervene in case of necessity. All the tests were performed at the “Casa Sollievo della Sofferenza” research hospital.

Ethical Considerations

The approval of the study for experiments using human participants was obtained from the local Ethics Committee on Human Experimentation (register code 3038/01DG). All

participants signed an informed consent form before participating in this study, and pictured participants provided written informed consent to allow their image to be published. The data were pseudoanonymized and stored on a GDPR-compliant server.

Participants

Participants were recruited from July 2020 to February 2021 from employees and staff of the “Casa Sollievo della Sofferenza” research hospital located in Apulia (San Giovanni Rotondo, Foggia) using convenience sampling. Participants were excluded if they had a hearing or visual impairment. Recruited participants were then randomly assigned to undergo 1 of the 3 experimental conditions (ie, STA, COH, and PC). Sociodemographic information (age, education, and sex) was collected to verify the similarities between the groups.

Data Analysis

Overview

Owing to the sample size of each cohort, the nonparametric statistic was used, particularly the Kruskal-Wallis test and chi-square test, to investigate significant differences between participants' groups in terms of age, sex, and educational level. The significance level was set at $P=.05$. The following paragraphs describe the analysis performed on the SAM questionnaires and the data collected from camera sensors.

Emotion Perception Analysis

A total of 60 SAM questionnaires were collected for each participant. The average values of the valence, arousal, and dominance domains were computed for each selected image of each group of elicitation modality (ie, STA, COH, and PC). Differences were analyzed with the Kruskal-Wallis test ($P<.05$) and post hoc evaluated with the Mann-Whitney U test (with Bonferroni correction) used to identify between which pair of elicitation modes the difference has occurred.

Emotion Recognition Analysis

Data from the camera were processed and examined offline. The recordings were initially analyzed [47] to ensure that only the frames featuring the face of the person performing the test were included in the study. Then the recordings were segmented, providing short videos that corresponded to the user's reaction to each image proposed, totaling 60 videos per user. The OpenFace toolkit [48] was used to extract 150 features related to gaze and facial expression from each video as well as the quality (ie, confidence) of the extracted features. The data were filtered according to the confidence score (frames with a confidence score <0.90 were discarded). The data were then labeled based on the IAPS-defined emotions (ie, positive, negative, and neutral). Data were normalized and selected. Only features with a correlation coefficient of <0.85 were picked

from the initial data set, avoiding those with a high correlation coefficient (which may represent redundant information). The data of the merged data set were then separated into sub-data sets (one for each participant), and emotion classification was performed using the selected features. In this study, we rely on state-of-the-art methods used for emotion recognition [24] to facilitate a comparison with other works. The 3 supervised classifiers used are support vector machine (SVM), random forest (RF), and K-nearest neighbor (KNN). To classify the data by participant, a 10-fold cross-validation procedure was applied, and the outputs were organized in a confusion matrix. The classification performance was assessed in terms of accuracy, precision, recall, and F-measure [49]. The calculations were computed using MATLAB 2020a. More details on emotion recognition analysis are available in [Multimedia Appendix 2 \[24,47-49\]](#).

Results

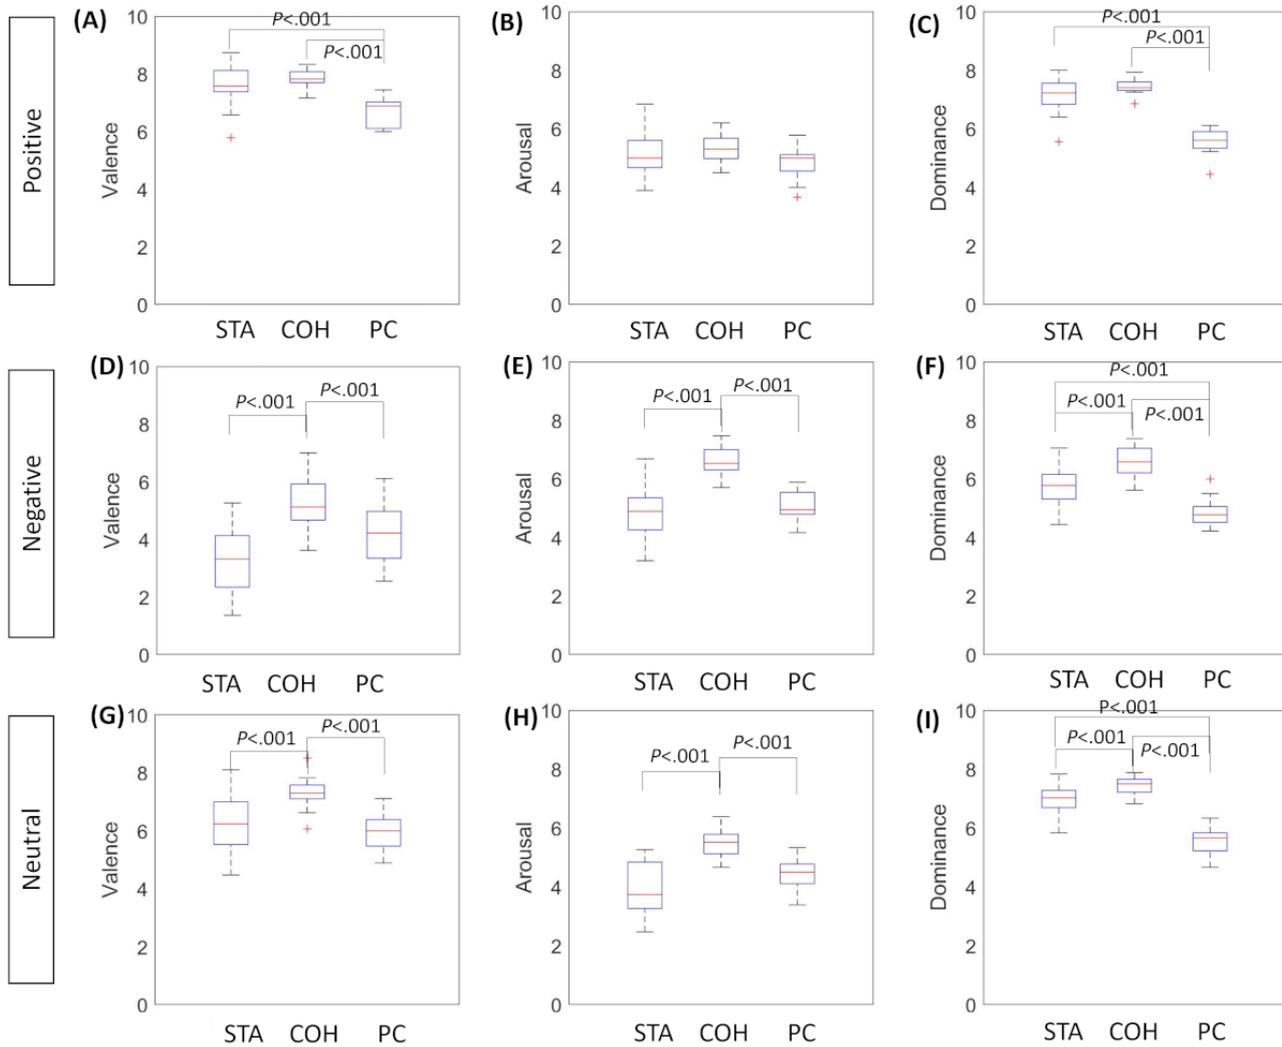

Description of the Participant Cohort

A total of 60 participants were involved in this study, 20 for each modality, resulting in 3600 interactions with technologies. In total, 3 participants were excluded from the analysis of perceived emotion because not all SAM evaluations were correctly saved after each elicitation. In case of missing SAM values, these ratings were removed from the analysis of average values. Finally, 57 participants were included in these subgroups of analyses linked to RQ1, RQ2, and RQ3. Regarding the recognition of emotion using machine learning techniques (linked to RQ4), a total of 53 participants were included in the analysis. A total of 7 participants were excluded because of technical problems related to the quality of the recorded images. The statistical tests did not indicate any difference between the 3 participant cohorts regarding age, sex, and educational level. The participant demographics and educational analyses are reported in [Multimedia Appendix 3](#).

Participants' Perceived Emotion Results

The results underline significant differences ($P<.001$) in the perceived emotions according to the different elicitation modalities, except for the arousal elicited with the positive images (Figure 3). The median and IQR values are fully reported in [Multimedia Appendix 4](#). As for valence, the robot with coherent behavior elicited significant differences ($P<.001$) and higher values in terms of valence, arousal, and dominance domains compared with the other 2 modalities for negative and neutral emotions. In terms of negative valence, the participants perceived fewer negative emotions with the coherent robot than with the other 2 modalities. For positive valence, elicitation with the web application is significantly different from that with the robot ($P<.001$).

Figure 3. Self-Assessment Manikin Questionnaire results for the 3 elicitation modalities. Boxplot matrix (A), (B), and (C) denote valence, arousal, and dominance for the positive elicitation, respectively; (D), (E), and (F) denote valence, arousal, and dominance for the negative elicitation, respectively; (G), (H), and (I) denote valence, arousal, and dominance for the neutral elicitation, respectively; asterisks on boxplot remark the significant differences evaluated with the Mann-Whitney post hoc test corrected with Bonferroni. COH: coherent; STA: static.

Regarding arousal, the coherent robot was rated higher than the other 2 modalities, but there were significant differences ($P < .001$) only for negative and neutral emotions, whereas for positive arousal, the results, depicted in Figure 3, highlight only a trend. All the P values are reported in Multimedia Appendix 4.

The participants stimulated using the robot rated significantly higher dominance across all 3 emotions rather than the cohort that used the PC in the test. As for positive elicitation, we found significant differences ($P < .001$) between the cohort stimulated with the PC and those stimulated with the robot (ie, static behavior and coherent behavior). Indeed, the participants rated the emotions (in terms of valence and arousal) elicited by the robot more than the ones elicited using the PC. All P values are reported in Multimedia Appendix 4.

Robot's Emotion Recognition Results

Because of technical issues 1848 frames pertaining to the PC modality were removed from the analysis during the

preprocessing. At the end, the total number of samples included in this study was 296,677 for the STA modality, 228,170 for the COH modality, and 103,758 for the PC modality. The number of columns in each data set corresponded to the number of features selected using the correlation analysis method. The following features were selected (Figure 4):

1. The x-, y-, and z-coordinates of the eye gaze direction vector for eye 0 (3 features).
2. The z-coordinate of the eye gaze direction vector for eye 1 (1 feature).
3. The x- and y-coordinates of the location of the landmark 8 (the leftmost in the image) of the eye 0 (2 features).

The 53 data sets were fed into 3 classifiers (SVM, RF, and KNN) [24]. The data sets were uniformly distributed across the 3 groups, as presented in Table 1.

Figure 4. Selected features. (A) Face and (B) eye landmarks extracted with OpenFace software. The landmark 8 in panel B was chosen after the feature selection.

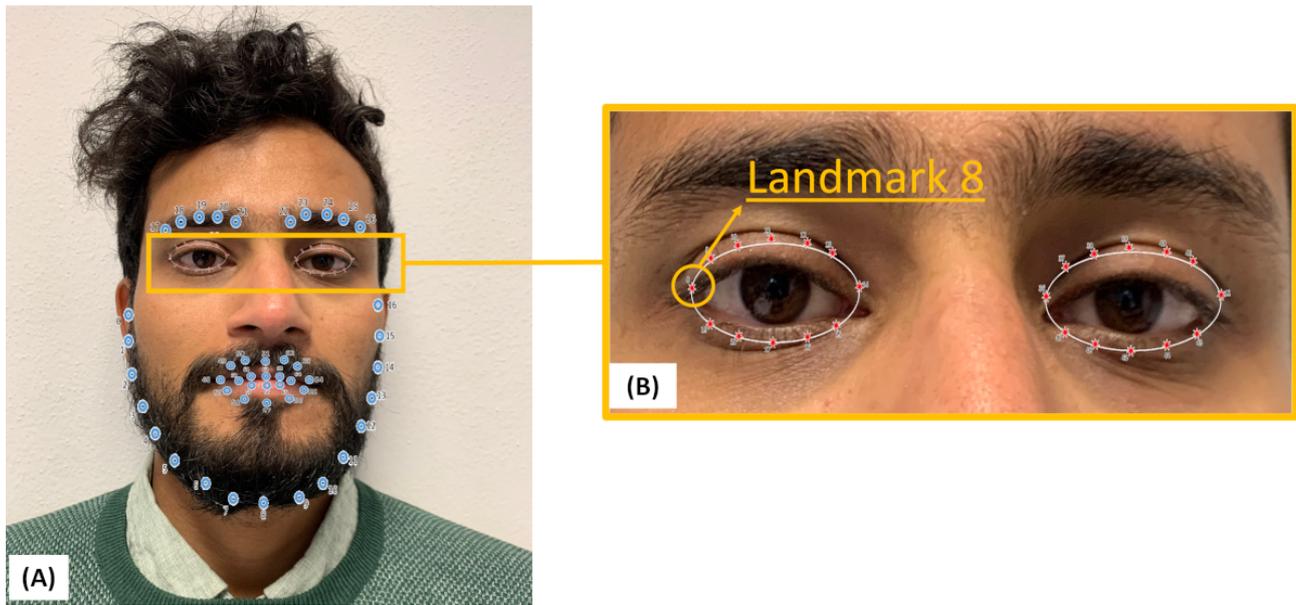

Table 1. Distribution of data set instances.

Group	Positive, n (%)	Negative, n (%)	Neutral, n (%)
Static (n=296,677)	103,992 (35.03)	94,257 (31.77)	98,499 (33.2)
Coherent (n=228,170)	70,710 (30.99)	74,383 (32.6)	83,077 (36.41)
PC (n=103,758)	35,195 (33.92)	32,072 (30.91)	36,492 (35.17)

Accuracy, precision, F-measure, and recall were calculated as the mean values from the participants in the same experimental cohort. According to the findings, the KNN classifier offers the best classification results, with an accuracy of up to 0.88 for STA behavior, 0.97 for COH, and 0.94 for PC. The SVM classifiers, in contrast, had the lowest results (accuracy of up to 0.57, 0.67, and 0.68 for STA, COH, and PC, respectively); hence, they were excluded from further research. Compared

with the RF classifier, the KNN classifier has the best F-measure (>0.88).

Table 2 presents the complete results for the KNN and RF classifiers, including the accuracy, F-measure, precision, and recall for each group. According to the overall trend, the COH modality achieves a high level of accuracy when compared with the STA and PC elicitations. In terms of the other indicators, the COH was better with the KNN classifier and slightly worse with the RF classifier when it came to elicitation with the PC.

Table 2. Performance of K-nearest neighbor (KNN) and random forest (RF) classifiers.

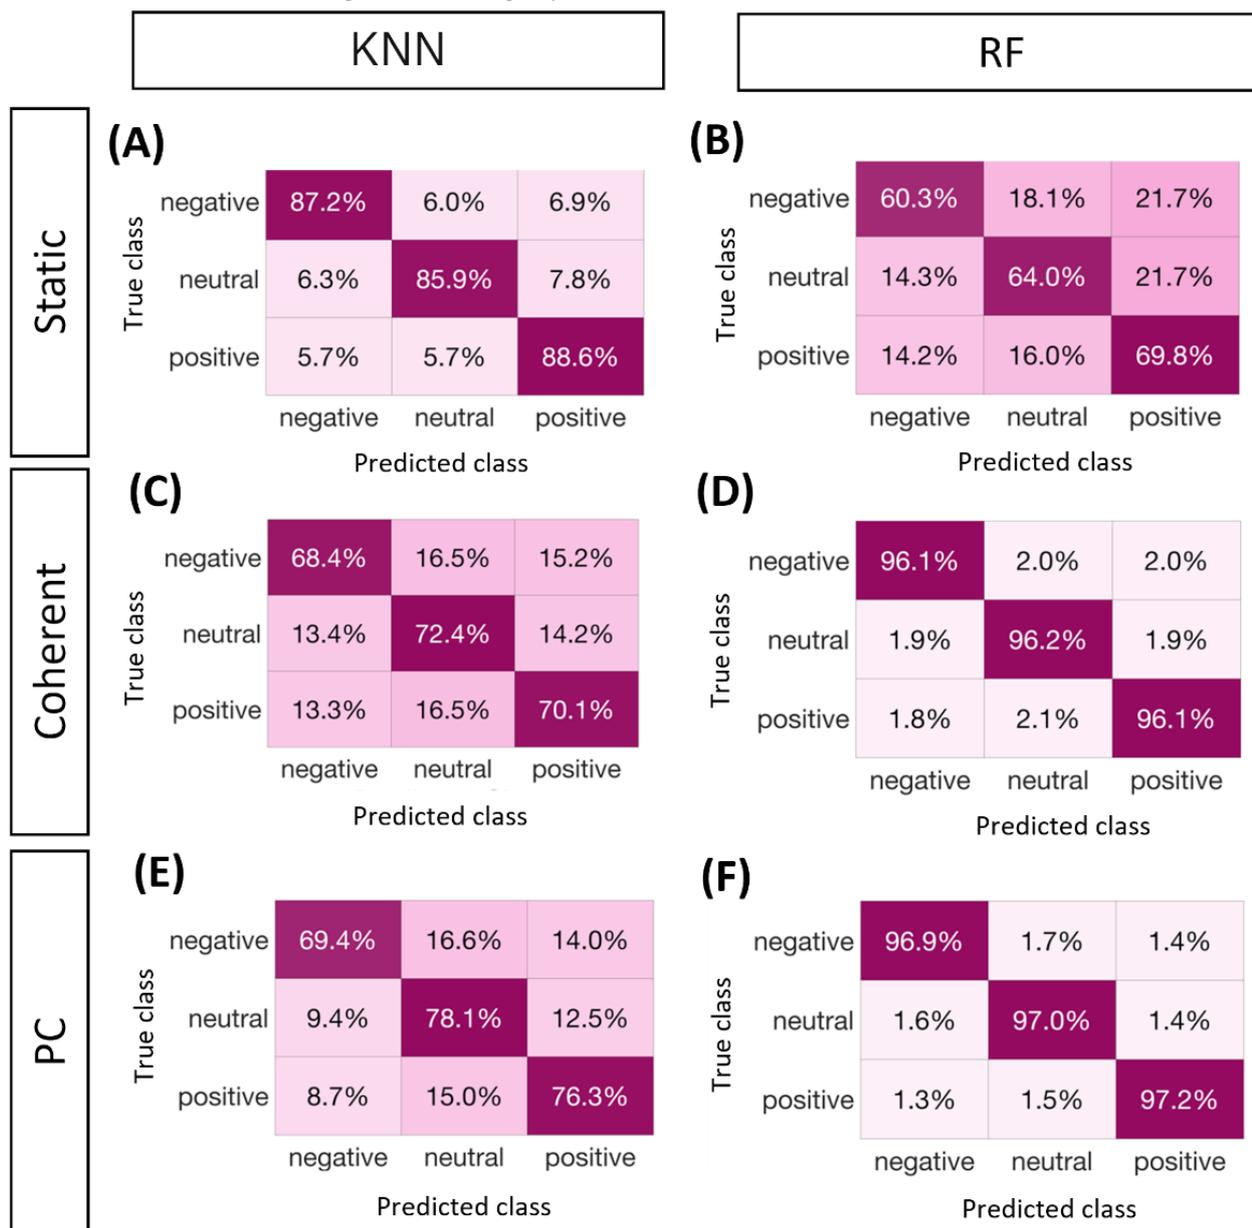

Group	Accuracy		Precision		F-measure		Recall	
	KNN	RF	KNN	RF	KNN	RF	KNN	RF
Static	0.88	0.65	0.88	0.65	0.88	0.65	0.88	0.65
Coherent	0.97	0.73	0.96	0.72	0.96	0.72	0.96	0.72
PC	0.94	0.74	0.94	0.74	0.94	0.74	0.94	0.74

^aMean values are used to calculate the results.

Confusion matrices (Figure 5) for the 3 elicitation modalities were generated to investigate the performance of the classifiers in recognizing the 3 selected emotions. The positive emotion was often better identified, whereas the negative emotion was the least recognized. When the user is stimulated with the robot

with coherent modality and the PC, the RF classifier performs better than the KNN classifiers in distinguishing emotions. The KNN classifier appeared to perform better in the static modality than in the other 2.

Figure 5. Confusion matrices for K-nearest neighbor (KNN) and random forest (RF) classifiers. The confusion matrices obtained for the 3 elicitation modalities (ie, static, coherent, PC) are reported considering only the KNN and the RF classifiers.

Discussion

Principal Findings

The results confirm RQ1 (“A humanoid robot interacting with coherent emotional behavior is rated higher in terms of emotional valence, arousal, and dominance compared to the web application”) because the COH robot is rated significantly higher for all SAM dimensions (except positive arousal) with respect to the PC condition (Figure 3). However, it is worth noting that when speaking of negative elicitation, receiving a higher rating of valence means that the stimulus with the COH condition was perceived less negatively than the ones elicited with the others. RQ2 (“There are significant differences in terms of emotional valence, arousal, and dominance between the static robot compared to the robot that shows movement”) is confirmed for the 3 dimensions for negative and neutral emotions (Figure 3). It is worth noting that these results confirm

that the robot’s movements cause the negative emotion to be perceived as less negative (STA valence median value=3.32; COH valence median value=5.13). As for the positive emotion, there were no significant differences, which could suggest that the robot’s behavior per se did not affect the perception of the positive emotion.

The presented results did not confirm the RQ3 (“The embodiment of humanoid robot will not affect the emotion perception compared to the web application”) for all elicited emotion and SAM constructs. Indeed, there were no significant differences between the STA and the PC elicitation for valence and arousal measured during negative and neutral elicitation (Figure 3). Conversely, COH and STA differed significantly from PC in terms of positive elicitation. These results suggest that robot embodiment per se has a role in the perception of dominance associated with negative and neutral emotions with respect to a standard web interface. On the contrary, as for the

positive emotion, embodiment seems to play a key role because both COH and STA elicitation differ from the web application in terms of valence and dominance.

The ability to recognize user emotions is a fundamental step in the development of socially aware robots (RQ4). The emotions were recognized with an average accuracy >0.88 over the 3 elicitation conditions. In addition, the amount of gaze also depends on the interpersonal dynamics between the partner and their personalities and on the intent of using gaze to communicate their internal state. Therefore, it is important to measure it during interactions. As shown in [Table 2](#), the accuracy of COH stimulation was higher than that of the other 2 methods. In addition, the results in the confusion matrices were aligned with the perceived emotion ([Figure 5](#)). According to the SAM results, the valence ratings for positive elicitation elicited with PC were significantly different from the other 2 with lower median values. This trend is reflected in the confusion matrices obtained using RF classifiers.

Comparison With Prior Work

Previous qualitative studies have pointed out how incoherent behavior can generate hilarious reactions in humans [16]. The presented results suggest that we can observe something similar, even if the stimulus is coherent. It appears that the robot's behavior somewhat distracts from perceiving negative emotions, even if the behavior is aligned with the shown emotion. In addition, as confirmation, positive emotion was perceived significantly more positively than the PC modality, suggesting that robot movements make the robot more positive. Consequently, these results suggest that it is important to tailor the reaction of the robot appropriately to elicit a specific emotion. Indeed, if we need to stimulate—for a certain reason—negatively the users, we need to reduce the robot's body expression because they can decrease the perception of negative emotions. Alternatively, if we need to provide positive feedback to users, the combined actions of both verbal and nonverbal communication can be used.

A previous study [36] compared robots and web applications that focused on investigating preferences and acceptance, and they did not find any significant deviation in the quantitative results. In contrast, in this study, we focus on human emotion perception, and this perception seems to be influenced or biased by the emotion itself and the robot's movement. This finding highlights the significance of not just robot embodiment but also its cospeech gestures in designing social agents, particularly when evaluating all dimensions of emotions. Methodologically, the presented findings carry significant implications for the design of experimental protocols. Evaluating HRI cannot rely solely on videos, as they overlook the importance of physical interaction. In the literature, some papers [33] provide a user impression without direct interaction with a robot; the collected results can be biased because the participant missed the contribution in the perception related to embodiment. Take, for instance, the scenario where you are testing a new game application or software on a tablet meant for eventual integration into a robot. Particularly when assessing emotions, it's crucial to approach the generalization of results with caution. In this sense, the result could be altered because the emotions elicited

could not be directly applicable when interacting with an embodied agent.

The results obtained for the STA robots with the KNN and RF classifiers were slightly improved with respect to the results obtained in our previous work [42] (average accuracy was equal to 0.85 with KNN and 0.98 with RF), where we used them in combination with encoders. It is also worth noting that after the feature selection process, only the features related to gaze were retained in the analysis. Gaze is extremely important in managing interpersonal interaction and also during human-robot conversation; indeed, it can be correlated with user engagement during conversation or mutual tasks [50,51].

Limitations of the Study

The limitations of this study were mainly related to the cohort of recruited participants. First, both cognitive and cultural backgrounds are factors that can influence the perception of emotions [52]. Some neurological pathologies (eg, Parkinson disease) can affect facial expressions, whereas others can affect body gestures and language (eg, autism spectrum disorders and apathy); consequently, emotion recognition accuracy in such cases can change. The RQs do not focus on investigating their role in emotion perception; consequently, we recruited cohorts of people comparable for cultural background and cognitive status to limit the impact of these factors. The second limitation of this study refers to how the emotion is evaluated; in this study, we evaluated each SAM dimension separately. The third limitation of this study relies on the supervised machine learning techniques used. In this study, we rely on standard supervised methods because our main RQs are not focused on learning methods; therefore, we apply the most used techniques.

Future Directions

In this context, by applying the findings and implications of this paper in the health care context, we can conclude that it is important to tailor the reaction of the robot properly; indeed, if we need to stimulate—for a certain clinical reason—the users negatively, we need to reduce the robot's body expression because they can decrease the perception of negative emotions. Alternatively, if we need to give positive feedback to the users, for instance, during an exercise, we can use the combined action of both verbal and nonverbal communication. To overcome the limitations of this study, future research can be planned to extend the study to include a different group of participants with some cognitive and physical disorders and different cultural backgrounds to evaluate the effect of these factors on emotion perceptions. Future studies should also investigate whether there are differences in combining valence-arousal domains, as proposed in other studies [16,53]. Finally, the data could be analyzed using also deep learning and reinforcement learning techniques.

Conclusions

This study aimed to investigate the role of robot embodiment and its behavior in emotion perception and recognition using a standard elicitation model. In total, 4 RQs were investigated to understand how the robot's nonverbal behavior might shape the human perception of the showed emotion elicited through a standard data set and, at the same time, to observe the robot's

emotion recognition accuracy rate. This study presents an experimental setup in which 60 participants were asked to interact with 2 embodied agents (ie, a robot or tablet) that acted as emotion facilitators by showing them 60 standard pictures. The results underline the good recognition accuracy of the perception modules of the robot. Indeed, we can correctly

classify the valence of the emotion (ie, positive, neutral, and negative) with an accuracy of up to 0.97 in the best case. According to the results, robot embodiment affects the perception of dominance significantly compared with web applications, which means that participants' emotions were less controlled when they were interacting with an embodied agent.

Acknowledgments

The authors would like to thank all the people involved in the study. This study was funded by “An adapted behavioral robot model with advanced cognitive/physical interaction capabilities for assessment and rehabilitation of neurodegenerative diseases (DESTINI)” founded by Unione Europea—NextGenerationEU (CUP: B55F21007810001).

Data Availability

The data sets generated and analyzed during this study are not publicly available because of the scope of the consent signed by the patient participating in the study but are in part (no video recordings) available from the corresponding author on reasonable request.

Authors' Contributions

The conceptualization was done by LF, GDO, and F Cavallo. Data curation was conducted by GDO, F Ciccone and AS. LF, FGCL, and AS were responsible for the data analysis. LF acquired the funding. The methodology was developed by GDO, LF, F Cavallo, and FG. The investigation was carried out by GDO and F Ciccone. AS and SR handled the software. DS, FG, and F Cavallo provided supervision. LF was responsible for the original draft of writing, while all authors contributed to the writing, review, and editing.

Abstract

Background: Frontline health care staff are frequently exposed to traumatic events as part of their work. Although this study commenced before the emergence of COVID-19, levels of exposure were heightened by the pandemic. Many health care staff members report intrusive memories of such events, which can elicit distress, affect functioning, and be associated with posttraumatic stress disorder symptoms in the long term. We need evidence-based interventions that are brief, preventative, nonstigmatizing, suitable for the working lives of frontline health care staff, and effective for repeated trauma exposure. A brief, guided imagery-competing task intervention involving a trauma reminder cue and Tetris gameplay may hold promise in this regard, given evidence that it can prevent and reduce the number of intrusive memories following trauma across various settings.

Objective: This case series aims to investigate the impact of a brief imagery-competing task intervention on the number of intrusive memories, general functioning, and symptoms of posttraumatic stress, anxiety, and depression, and examine the feasibility and acceptability of the intervention for UK National Health Service frontline health care staff. The intervention was delivered with guidance from a clinical psychologist.

Methods: We recruited 12 clinical staff from the UK National Health Service, specifically from emergency departments, the intensive care unit, and the ambulance service. We evaluated the intervention using an AB single-case experimental design, where the baseline (A) was the monitoring-only phase and the postintervention (B) period was the time after the intervention was first administered. Methods were adapted once the COVID-19 pandemic began.

Results: There was a decrease (59%) in the mean number of intrusive memories per day from baseline (mean 1.29, SD 0.94) to postintervention (mean 0.54, SD 0.51). There was a statistically significant reduction in the number of intrusive memories from baseline to postintervention, as shown by an aggregated omnibus analysis with a small effect size ($\tau-U=-0.38$; $P<.001$). Depression, anxiety, and posttraumatic stress symptoms all significantly reduced from preintervention to postintervention.

Participants also reported improvements in functioning based on both quantitative and qualitative measures. The intervention was feasible to deliver and rated as acceptable by participants.

Conclusions: These preliminary findings suggest that this brief therapist-guided imagery-competing task intervention offers a potential approach to mitigating the impact of work-related traumatic events in frontline health care staff, both during a pandemic and beyond. Randomized controlled trials will be an important next step.

Introduction

Background

Frontline health care staff, including emergency department (ED) staff, intensive care unit (ICU) staff, and paramedics, frequently encounter highly stressful and traumatic clinical events, such as patient death, resuscitations, and treating patients with severe injuries [1]. These experiences often lead to intrusive memories, which are involuntary sensory recollections, primarily visual but sometimes involving other senses, such as smell and sound [2-4]. These memories can evoke strong negative emotions [5], disrupt concentration [6], and impair daily functioning [7], making them a critical treatment target.

Intrusive memories are a core symptom of posttraumatic stress disorder (PTSD) and acute stress disorder [8], and they may drive posttraumatic stress symptomatology [9]. Reducing intrusive memories could lead to a broader reduction in PTSD symptoms [10], suggesting a potential “therapeutic cascade” [11].

PTSD rates were already high among National Health Service (NHS) health care staff before the COVID-19 pandemic and increased substantially during it, with prevalence ranging from 21% among health care workers across 21 countries to 40% among ICU staff in the United Kingdom [12-17]. Unrelenting workloads, burnout, and stress are major drivers of nurses leaving the profession [18]. Furthermore, investigating new initiatives to improve ED staff engagement, resilience, and retention has been highlighted as a research priority for emergency medicine in the United Kingdom [19]. Therefore, developing effective treatments to protect the mental well-being of frontline health care staff is essential [20].

Frontline health care staff may experience intrusive memories without meeting the full diagnostic criteria for PTSD. Many may prefer shorter, more targeted interventions due to the stigma surrounding mental health issues among health care professionals and the substantial workload imposed by the pandemic [21,22]. It is crucial to develop novel interventions that are effective, brief, accessible, scalable, and nonstigmatizing, and that can be used repeatedly to manage ongoing trauma exposure.

A novel, brief, low-intensity, imagery-competing task intervention has been developed to target intrusive memories of trauma [23-25]. The intervention, which lasts approximately 25 minutes, can be administered in a single researcher-assisted session and self-administered thereafter. It aims to reduce the

number of intrusive memories by using principles from cognitive science, specifically dual tasking, the properties of mental imagery [26], and the theories of memory consolidation and reconsolidation [27].

The intervention’s mechanism involves performing a visuospatial task while the trauma memory is still labile. This is theorized to interfere with the memory consolidation process and prevent the emergence of intrusive memories [28]. This approach for recent trauma has been supported by 3 randomized controlled trials involving women who experienced traumatic childbirth [29], motor vehicle accident survivors in the ED [30], and a mixed trauma sample of individuals presenting to the ED [25]. In these trials, participants who received the intervention reported significantly fewer intrusive memories in the first week after exposure to trauma compared with control groups, with effect sizes ranging from small to medium (Cohen $d=0.43$ to Cohen $d=0.67$) [25,29,30]. In addition, the intervention significantly reduced intrusion-related distress and vividness [25].

Evidence also supports that the intervention can reduce older, established trauma memories, with the effect informed by theories of memory reconsolidation interference. Promising results, including a decreased frequency of intrusive memories and improvements in functioning, have been shown in case series involving refugees [31], inpatients with complex PTSD [32], and women with childhood trauma [33,34].

A digital version of the intervention, delivered remotely with researcher support, was tested among health care staff members during the COVID-19 pandemic in a pilot study and was found to be feasible and acceptable [35]. This brief remotely delivered digital intervention was tested in a randomized controlled trial with the UK NHS ICU staff during the COVID-19 pandemic [36,37]. Participants who received immediate access to the intervention (with an initial guided session) reported significantly fewer intrusive memories at week 4 compared with those with delayed access. Intrusive memories also significantly decreased at week 8 (postintervention) compared with week 4 (preintervention) in the delayed access arm [37]. Furthermore, the immediate (vs delayed) intervention group reported reduced PTSD symptoms, insomnia, anxiety, posttrauma distress, and burnout, and improved work functioning and general well-being. Participants found the intervention to be acceptable and safe. The study provided strong evidence of the intervention’s efficacy for reducing intrusive memories among this group of health care staff [36]. While the intervention has been tested among hospital staff, its effectiveness among prehospital staff,

such as paramedics, who often face unpredictable, high-intensity trauma in chaotic and risk-prone settings, remains unknown [38-40].

Objectives

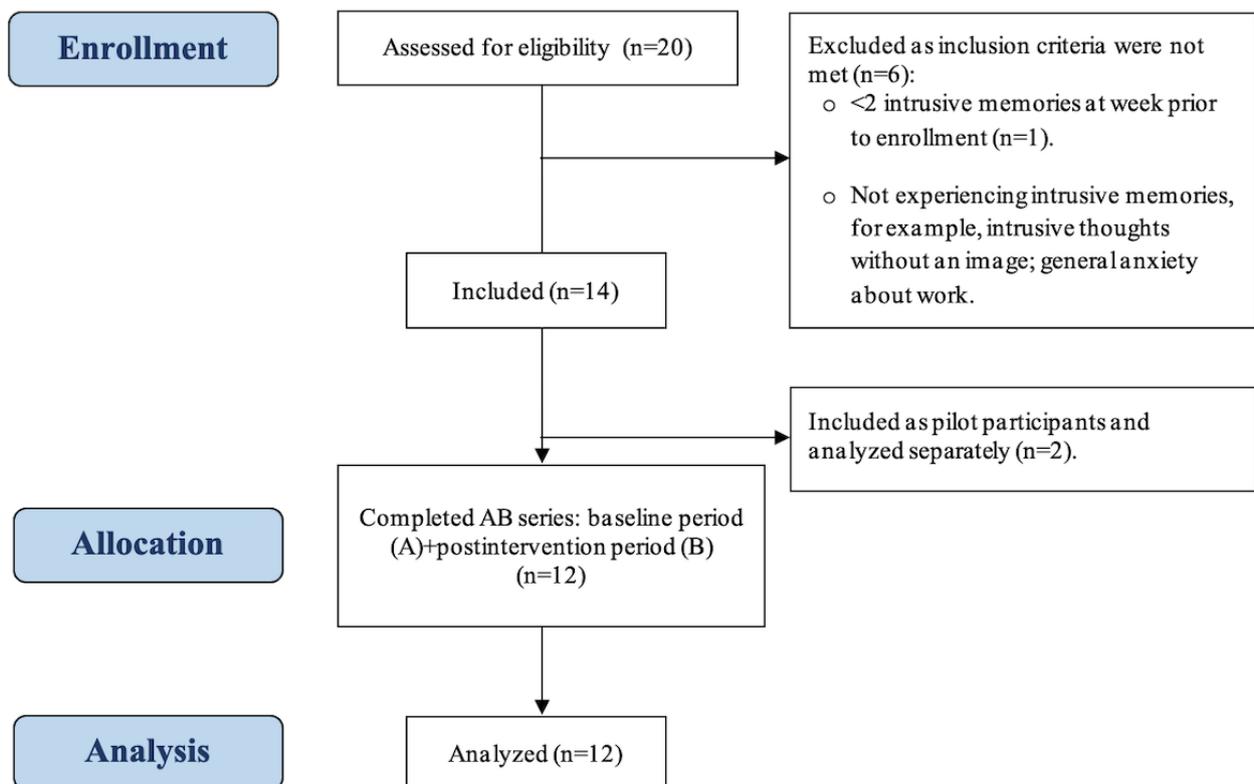

Given these promising findings and the need for novel approaches to support health care personnel beyond ICU staff, our study aimed to test the efficacy, feasibility, and acceptability of the brief guided imagery-competing task intervention in a sample of frontline prehospital and hospital NHS health care staff exposed to traumatic events in the course of their work. The primary aim was to determine whether the intervention reduced the number of intrusive memories of work-related traumatic events. We predicted a significant decrease in the number of intrusive memories from baseline to postintervention. Secondary aims included assessing changes in intrusive memory characteristics (eg, vividness and distress), their impact on daily functioning (eg, sleep and concentration), and other mental health symptoms (eg, posttraumatic stress, depression, and anxiety). In addition, we evaluated the intervention’s feasibility and acceptability among NHS health care staff.

Methods

Participants

In total, 12 frontline NHS health care staff members, including doctors, nurses, and paramedics, working in hospital (eg, ED and ICU) and prehospital departments (eg, ambulance services team) at Oxford University Hospitals, Royal Berkshire, and South Central Ambulance Service NHS Foundation Trusts participated in the study (recruited from February 2020 to September 2020). Inclusion criteria were aged ≥18 years; ability to read, write, and speak in English; being able and willing to provide informed consent and complete study procedures; employed as NHS hospital or prehospital clinical staff; having experienced at least 2 intrusive memories (self-rated as problematic) of a work-related traumatic incident in the previous 7 days; being able and willing to talk about the intrusive memories; ability to complete a web-based daily intrusive memory diary over a 2-to-3-week period; being capable of playing Tetris on a handheld device; and not currently undergoing treatment for PTSD. Participants were excluded if they had <2 intrusive memories per week during the baseline period or had started undergoing treatment for PTSD. The study was piloted on 2 participants (Multimedia Appendix 1). Figure 1 depicts an adapted CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the study.

Figure 1. Adapted CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the study.

Design

This case series used an AB single-case experimental design [41]. The primary outcome was the change in the number of intrusive memories of work-related traumatic events from baseline (A) to postintervention (B). The baseline was the period

before the first administration of the intervention, that is, monitoring-only, and the postintervention period was anytime thereafter. The study consisted of a 1-week baseline period, a 2-week postintervention period following a single

researcher-assisted intervention session, and a follow-up 4 weeks after the intervention session.

Following the single researcher-assisted intervention session, participants received instructions for using optional intervention boosters as needed in their daily lives. The intervention boosters could be researcher-assisted (ie, by scheduling a guided intervention session with the researcher) or self-administered (ie, playing Tetris for 25 minutes *immediately* after experiencing an intrusive memory, excluding a brief trauma reminder cue procedure required in the researcher-assisted intervention sessions). Participants were invited to use the intervention boosters for any new intrusive memories of work-related traumatic events they experienced after enrolling in the study; however, these were not included in the analysis. Participants could use the intervention boosters as many times as needed until week 4 (postintervention).

Due to COVID-19-related national restrictions, all participant interactions and intervention sessions were conducted remotely (ie, via videocall).

Procedure

Training to Deliver the Intervention

To ensure proper intervention delivery and protocol adherence, the primary researcher, VK (a trainee clinical psychologist in the final year of clinical training), received comprehensive training, feedback, and monitoring from clinical psychologists experienced in delivering the intervention. This training included a 1-day web-based workshop covering the theoretical foundations, key components, and wider protocol aspects of the intervention, including identifying and recording intrusive memories, the trauma reminder cue procedure, delivering “mental rotation” (that is, visualizing in the mind’s eye how to rotate and move the Tetris blocks to make horizontal lines) instructions for Tetris gameplay, and collecting primary outcomes. VK participated in role-playing sessions during the workshop and subsequently with LI and MK, with filmed role-plays evaluated for protocol fidelity by an independent rater.

A written standard protocol was used by the researcher in all researcher-assisted intervention sessions to ensure intervention fidelity. Criteria for intervention fidelity were completion of an arousal level manipulation check before and after the trauma reminder cue and after Tetris gameplay; administration of the trauma reminder cue and checks to ensure the visual or perceptual details were in the participant’s mind; delivery of Tetris gameplay instructions with an emphasis on mental rotation; ensuring participants played Tetris for at least 25 minutes with at least 1 continuous period of 10 minutes. For the pilot and the first study participants, LI provided supervision and protocol fidelity checks via phone or video call after each session.

Regular supervision meetings addressed protocol fidelity and adaptations. During recruitment and data collection, VK participated in fortnightly video calls with other researchers to share experiences, best practices, and receive feedback.

Eligibility and Baseline Assessment Meeting: Week 1 (Preintervention)

Potential participants met with VK to assess eligibility based on the inclusion and exclusion criteria. During this meeting, the study’s purpose, procedures, risks, and benefits were explained, and verbal informed consent was obtained due to COVID-19 social distancing measures. All participants were provided with information about local occupational and mental health support services.

After giving their informed consent, participants completed the baseline assessment, including self-report measures administered via Qualtrics [42], a web-based survey platform. The “hotspots” form was then used to gather information about the number and timing of traumatic events, as well as a brief description of participants’ intrusive memories. Participants were verbally given the following definition of intrusive memories: “vivid, emotional memories of the incident that ‘pop’ into mind without warning, often taking the form of visual pictures in the mind’s eye, for example, a snapshot image or a film clip.” Participants were also informed that intrusive memories can include other senses (such as sounds and smells), that they may or may not be triggered by something the person is aware of (eg, telling someone about the incident or being back at the scene), and that intrusive memories can be “very short, fleeting, and broken up.” Participants were told that deliberately thinking about an incident, mulling it over, or having general thoughts about it without an image did not constitute an intrusive memory. Participants identified the most frequent and bothersome intrusive memory to be targeted during the intervention. Participants were instructed on how to complete a web-based daily intrusive memory diary using Qualtrics and were given clear guidelines on how to document each occurrence of an intrusive memory.

Intrusive Memory Monitoring and Weekly Questionnaires

Participants were asked to complete the intrusive memory diary at least once daily for 3 weeks. They received automated reminders via email and text message to ensure compliance with daily diary entries. In addition to the daily diary, participants completed weekly secondary outcome measures from week 1 (preintervention) through to week 4 (postintervention). These measures assessed various aspects of participants’ mental health and functioning (Measures and Materials section).

Intervention Session: Week 2 (Preintervention)

The intervention, with guided delivery by VK, targeted the most frequent and bothersome intrusive memory identified during the baseline assessment. The brief single-session imagery-competing task intervention consisted of 3 components: (1) a trauma reminder cue to bring the specific trauma memory to mind; (2) engaging in a visuospatial interference task, that is, playing the computer game Tetris for 25 minutes; and (3) using specific mental rotation instructions to play the game to optimize visuospatial demand along set timing parameters.

The trauma reminder cue consisted of participants briefly bringing the targeted intrusive memory to mind and writing

down its contents (in the first person) on a blank piece of paper (similar to the method of Kessler et al [32], although with a briefer description). Participants were asked to write only as much detail as was necessary to briefly recall the memory to avoid it becoming too emotionally overwhelming. Of note, this brief trauma reminder cue is focused on specific sensory-perceptual aspects of the trauma memory, and contrary to reliving procedures included in exposure-based therapies for PTSD (eg, Shearing et al [43]), it does not include a focus on the details of the event or emotional and cognitive aspects. Furthermore, also in contrast to reliving procedures, it is brief, only just enough to bring the memory image to mind before engaging in the gameplay part of the intervention. To prevent unintended reminders, this written description was discarded by the participant immediately after the intervention session; its contents were not read by or discussed with VK, as the aim of the procedure was solely to bring the intrusive memory into working memory (ie, to activate it).

Participants then received instructions on how to play the computer game Tetris using mental rotation. To increase the visuospatial demands of the game, participants were asked to plan and work out where to place the next blocks coming up, as well as the block that was currently presented [7,24]. After receiving instructions and a demonstration from VK, participants were given the opportunity to practice the game by completing 1 or 2 lines of Tetris blocks using mental rotation before beginning the timed portion of the intervention. The intervention was delivered via the official Tetris website [44], accessed on participants' mobile phone, or tablet computer, and the game was set to "marathon mode" and "ghost piece" off.

Participants played Tetris for at least one uninterrupted period of 10 minutes and for approximately 25 minutes in total [25]. Participants were asked to restart the game if "game over" was reached [32]. VK was present for the duration of the 25-minute gameplay to encourage participants to maintain engagement with the game and occasionally remind them about the mental rotation instructions.

Follow-Up: Week 4 (Postintervention)

At week 4 (postintervention), participants completed the final set of secondary outcome measures. They also completed a feedback questionnaire assessing the acceptability and feasibility of the intervention and study procedures. Participants were provided with information about the study aims and reimbursed £50 (US \$65.3) for their time and effort in participating in the study.

Measures and Materials

Baseline Information Regarding Traumatic Events and Intrusive Memories

Participants' descriptions of their intrusive memories were recorded in a web-based "hotspots" form (Multimedia Appendix 2) in Qualtrics [42] using the "share screen" option.

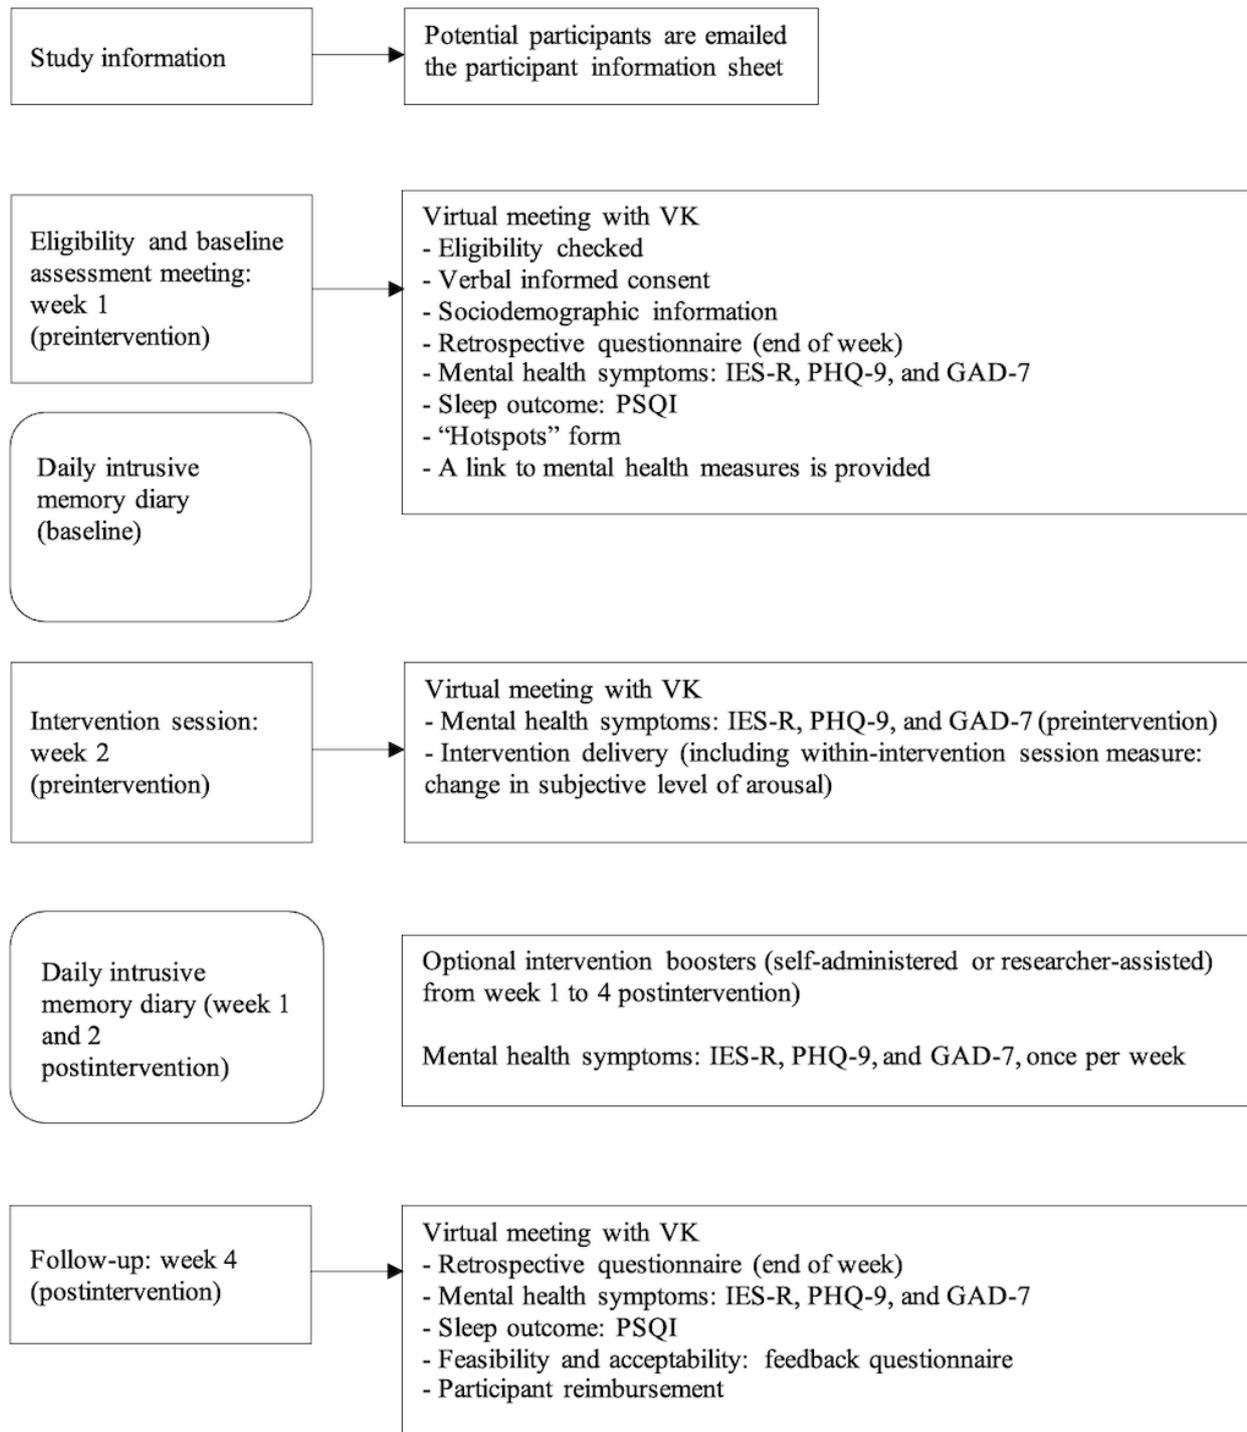

Participants indicated how many work-related traumatic events they were currently experiencing intrusive memories of and how long ago each event took place (ie, years and months). Participants were given the following verbal instruction: "Please briefly describe the worst moments of the traumatic event(s), e.g., an image or a sound. It is fine to summarize them in just a few words." These descriptions were then used to identify established intrusive memories, rather than only "hotspots" of trauma as in Kanstrup et al [25] and helped ensure that what participants noted were indeed intrusive memories (rather than ruminative thoughts, etc). We note that this process did not involve a detailed discussion of the traumatic event, or a focus on emotional aspects, but rather a brief description primarily focused on visuo-sensory content (ie, just a few words, such as "seeing the pattern on the cardiac monitoring machine," as per Hoppe et al [45]). Participants were asked to label each intrusive memory by selecting a few keywords (eg, "cardiac monitoring machine") to describe its content. These keywords were used to aid the intrusive memory diary completion as well as to identify which intrusive memory to target as part of the intervention procedure.

Primary Outcome Measure: Number of Intrusive Memories

Participants recorded the primary outcome, the number of intrusive memories experienced each day, in a diary, which was adapted from paper diaries used in previous studies [24,25,30,32] and here delivered using a web-based format (via Qualtrics [42]; Multimedia Appendix 3).

Participants received daily reminders through secure email links and automated text messages to ensure diary completion. In the diary, participants were instructed to select the intrusive memories they had experienced since their last entry from a drop-down menu populated with the intrusive memories they had previously identified on the "hotspots" form. They were also asked to indicate how many times they had experienced that intrusive memory by typing in the relevant number. If they experienced a new intrusive memory (ie, not one that was identified on the "hotspots" form), they had the option to select "other." Participants were asked to complete the diary as soon as possible after they experienced an intrusive memory, but at least once per day. If no intrusive memories were experienced that day, they were asked to indicate this by recording 0. Figure 2 depicts an overview of study meetings and when each measure was administered.

Figure 2. Overview of study meetings: the eligibility and baseline assessment occurred at week 1 (preintervention), followed by the intervention session at week 2 (preintervention). The final study meeting took place 4 weeks postintervention. Participants completed a daily diary for 3 weeks (1 week baseline and 2 weeks postintervention). GAD-7: Generalized Anxiety Disorder Scale; IES-R: Impact of Events Scale-Revised; PHQ-9: Patient Health Questionnaire Depression Scale; PSQI: Pittsburgh Sleep Quality Index.

Secondary Outcome Measures

Intrusive Memory Characteristics and Impact on Functioning: Daily Intrusive Memory Diary

In the intrusive memory diary, participants rated how vivid and distressing each intrusive memory was (0=not at all to 10=extremely), how much the intrusive memory disrupted their concentration and disrupted the task at hand (0=not at all to 10=a great deal), the length of time that the intrusive memory

bothered them (<1 min, 1-5 min, 6-10 min, 11-30 min, 31-60 min, and >60 min), and sleep quality over the past 24 hours (very good, fairly good, fairly bad, and very bad). Participants indicated whether they were at work when they experienced the intrusive memory, the approximate time at which this intrusive memory occurred, and how many times they used the intervention since the last diary entry (ie, to record the number of intervention booster sessions).

Mental Health Symptoms: Impact of Events Scale-Revised

PTSD symptoms were assessed with the Impact of Event Scale-Revised (IES-R) [46], a 22-item measure containing 3 subscales: intrusion, avoidance, and hyperarousal. Each item ranges from 0=not at all to 4=extremely. The IES-R has high internal consistency (Cronbach $\alpha=0.96$) [47] and good test-retest reliability (ranging from 0.89 to 0.94) [48] and is sensitive to a general construct of traumatic stress in populations with lower symptom levels [48].

Mental Health Symptoms: Patient Health Questionnaire Depression Scale

Depression symptoms were assessed with the Patient Health Questionnaire-9 (PHQ-9) [49], a 9-item self-report measure of depression symptoms severity. Each item ranges from 0=not at all to 3=nearly every day. A score of ≥ 10 has sensitivity of 88% and specificity of 88% for major depression. The PHQ-9 has excellent internal reliability (Cronbach $\alpha=0.89$) and test-retest reliability ($r=0.84$) [49], and its validity has been demonstrated in a nonclinical population [50].

Mental Health Symptoms: Generalized Anxiety Disorder Scale

Anxiety symptoms were assessed with the Generalized Anxiety Disorder-7 (GAD-7) [51], a brief self-report measure of symptoms of general anxiety disorder and their severity. Each item ranges from 0=not at all to 3=nearly every day. The GAD-7 has excellent internal consistency (Cronbach $\alpha=0.92$) and good test-retest reliability ($r=0.83$) [51].

Mental Health Symptoms: Pittsburgh Sleep Quality Index

Participants rated their sleep quality with the Pittsburgh Sleep Quality Index (PSQI) [52], a self-report measure of sleep quality over a 1-month time interval. The PSQI has good internal consistency (Cronbach $\alpha=0.83$) and test-retest reliability ($r=0.85$) [53].

Intrusive Memory Characteristics and Impact on Functioning: Retrospective Questionnaire (End of Week)

Participants rated the characteristics of their intrusive memories and their impact on functioning, retrospectively (ie, “over the past week;” [Multimedia Appendix 4](#)), using a 10-item rating scale. Participants provided ratings of the number of intrusive memories (none (0), some (1-4), quite a few (5-10), lots (11-20), very many (21-30), a large amount (31-50), and more than 50), as well as their vividness and associated distress (0=not at all to 10=extremely), the extent to which they disrupted concentration, interfered with the task at hand, affected night’s sleep, and impacted their ability to function in daily life (0=not at all to 10=a great deal). In addition, participants reported the duration of time the intrusive memories were bothersome (<1 min, 1-5 min, 6-10 min, 11-30 min, 31-60 min, and >60 min) and described how their ability to function in daily life was affected by intrusive memories.

Change in Subjective Level of Arousal: Within-Intervention Session Measure

Participants rated their subjective level of arousal before and after the trauma reminder cue and after playing Tetris during all researcher-assisted intervention sessions on an 11-point scale

(0=calm to 10=maximum arousal). This manipulation check was done to assess changes in arousal in response to the trauma reminder cue and to check for potential immediate effects of the intervention.

Acceptability and Feasibility: Feedback Questionnaire

Participants completed an 11-item feedback questionnaire (adapted from Iyadurai et al [30]) to assess the acceptability of the intervention and feasibility of the study procedures ([Multimedia Appendix 5](#)). The questionnaire included items assessing participants’ experience of the intervention (ie, how easy, helpful, and burdensome they found it), their willingness to use the intervention if it was offered to them in the future, and their confidence in recommending the intervention to a colleague who was experiencing intrusive memories (0=not at all to 10=extremely). Participants also described their experience of the intervention and taking part in the study (eg, suggestions for improvements; other comments about the intervention or the study).

Intrusive Memory Diary Adherence

Adherence to completing the daily intrusive memory diary was assessed with the rating, “How accurately do you think you completed the diary? (0=not at all to 10=extremely).”

Treatment Adherence

Adherence to treatment was assessed by recording whether participants completed the trauma reminder cue procedure, received mental rotation instructions, and the duration of Tetris gameplay during the researcher-assisted intervention sessions. Adherence to mental rotation and 25-minute gameplay in self-administered sessions was not assessed.

Data Analysis

Participant Characteristics

Sociodemographic data and baseline information regarding traumatic events and intrusive memories were summarized using descriptive statistics.

Primary Outcome Analyses

We calculated the mean number of intrusive memories per day for each participant to assess the change in the mean number of intrusive memories from baseline to postintervention. The per-day unit was chosen over per-week for greater measurement accuracy. Intrusive memories of new work-related traumatic events that occurred after participants enrolled in the study (marked as “other” in the daily intrusive memory diary) were excluded from the analyses and reported separately using descriptive statistics (Table S1 in [Multimedia Appendix 1](#)).

Baseline and postintervention daily intrusive memory means were calculated considering the exact timing of the intervention delivery within a 24-hour period. Baseline time was determined as the number of complete baseline days plus the number of hours before intervention delivery divided by 24. The baseline mean was the number of baseline intrusive memories divided by baseline time. The postintervention mean was the number of postintervention intrusive memories divided by postintervention time. The percentage change in intrusive memory frequency from baseline to postintervention was

calculated as $(1 - [\text{mean number per day postintervention} / \text{mean number per day at baseline}] \times 100)$ [32]. A “global” percentage change in intrusive memories was calculated across all participants.

Visual inspection of individual time-series graphs is fundamental to case series methodology [54]. The time-series graphs were created using a website for single-case data analysis [55]. Visual inspection was conducted to identify patterns of change in intrusive memory frequency from baseline to postintervention [54,56].

In addition, the τ - U statistic was used to analyze the intervention’s impact on between-phase differences (baseline vs postintervention) [57]. [Multimedia Appendix 1](#) gives further details regarding τ - U analyses.

Secondary Outcome Analyses

Changes in intrusive memory characteristics (ie, vividness and distress) and their impact on functioning (ie, concentration and task disruption) from baseline to postintervention were analyzed using means, tests of difference, and effect sizes. Categorical data (ie, sleep quality and length of time intrusive memories were bothersome) were presented using descriptive statistics.

We calculated means, tests of difference, and effect sizes from week 1 (preintervention) to week 4 (postintervention) to assess changes in depression, anxiety, and posttraumatic stress symptoms, global sleep, and overall sleep quality.

For retrospective ratings of intrusive memory characteristics and impact on functioning, we calculated means, SDs, and effect sizes for week 1 (preintervention) and week 4 (postintervention) ratings. Categorical data (number of intrusive memories in the past week and length of time intrusive memories were bothersome) were summarized using descriptive statistics. Qualitative data on the impact of intrusive memories on everyday functioning were presented as anonymized quotes.

Changes in subjective arousal levels (pre- to posttrauma reminder cue and pre- to post-Tetris gameplay) were reported as means and SDs, with tests of difference calculated. These findings are detailed in [Multimedia Appendix 1](#).

Feedback questionnaire ratings were summarized using descriptive statistics to assess the intervention’s acceptability. Open-ended responses regarding the acceptability and feasibility of the intervention and study procedures were analyzed for themes, with anonymized quotes presented as examples.

Treatment adherence, including the duration of Tetris gameplay, subjective accuracy ratings for intrusive memory diary completion, and outcome measure completion rates, was summarized using descriptive statistics ([Multimedia Appendix 1](#) provides further details).

Missing Data

Participants with missing data were excluded from the analysis for the specific outcome measure in which data were missing.

Data Accuracy Checks

Outcome data accuracy was verified by an independent rater.

Ethical Considerations

The study required ethics approval due to the involvement of NHS staff members as participants. Ethics approval was granted by the Health Research Authority and the University of Oxford Medical Sciences Inter-Divisional Research Ethics Committee (approval number R64738/RE001). An amendment to obtain verbal consent due to COVID-19 social distancing measures was approved on April 23, 2020 (approval number R64738/RE004). Trust management approval was provided by the Oxford University Hospitals NHS Foundation Trust, the Royal Berkshire NHS Foundation Trust, and the South Central Ambulance Service NHS Foundation Trust. For public record, the study was retrospectively registered on ClinicalTrials.gov (NCT04769999) following data collection but preanalysis ([Multimedia Appendix 1](#) provides further details).

Results

Intrusive Memory Diary Adherence

The mean subjective accuracy rating for daily intrusive memory diary completion across all entries and participants was 8.50 (SD 0.90; range 0-10).

Treatment Adherence

Treatment adherence was 100% for all researcher-assisted sessions: every participant completed all 3 components of the intervention protocol (trauma reminder cue, receiving mental rotation instructions, and playing Tetris for at least 25 minutes). In these sessions, all participants played Tetris for a minimum of 25 minutes (mean 25.17, SD 0.49 min; range 25-27 min).

Rates of Outcome Measure Completion

The completion rate for the primary outcome measure was 100%. For secondary outcome measures, the IES-R, PHQ-9, and GAD-7 completion rate was 99% (87/88; week 5 measures were missing for 1 participant). The PSQI completion rate was 96% (23/24; missing data for 1 participant). All participants completed the study feedback questionnaire.

Attrition

All participants remained in the study for its full duration.

Baseline Information Regarding Traumatic Events and Intrusive Memories

The mean number of work-related traumatic events reported at the week 1 preintervention meeting was 2.58. Of all reported work-related traumatic events, 39% (12/31) occurred between January and September 2020, during the COVID-19 pandemic. On average, participants reported 5.33 work-related traumatic event "hotspots." Participants reported a range of intrusive memory content; examples include patients with fatal injuries,

patients dying, extremely distressed family members, and medical procedures (Table S2 in [Multimedia Appendix 1](#) gives further details regarding baseline information).

Following the baseline period, 85 intervention sessions were delivered across all participants. Of these, 86% (73/85) were intervention boosters, with 14% (10/73) being researcher-assisted and 86% (63/73) self-administered. Table S3 in [Multimedia Appendix 1](#) gives details of the

researcher-assisted and self-administered booster sessions (ie, following the first researcher-assisted session).

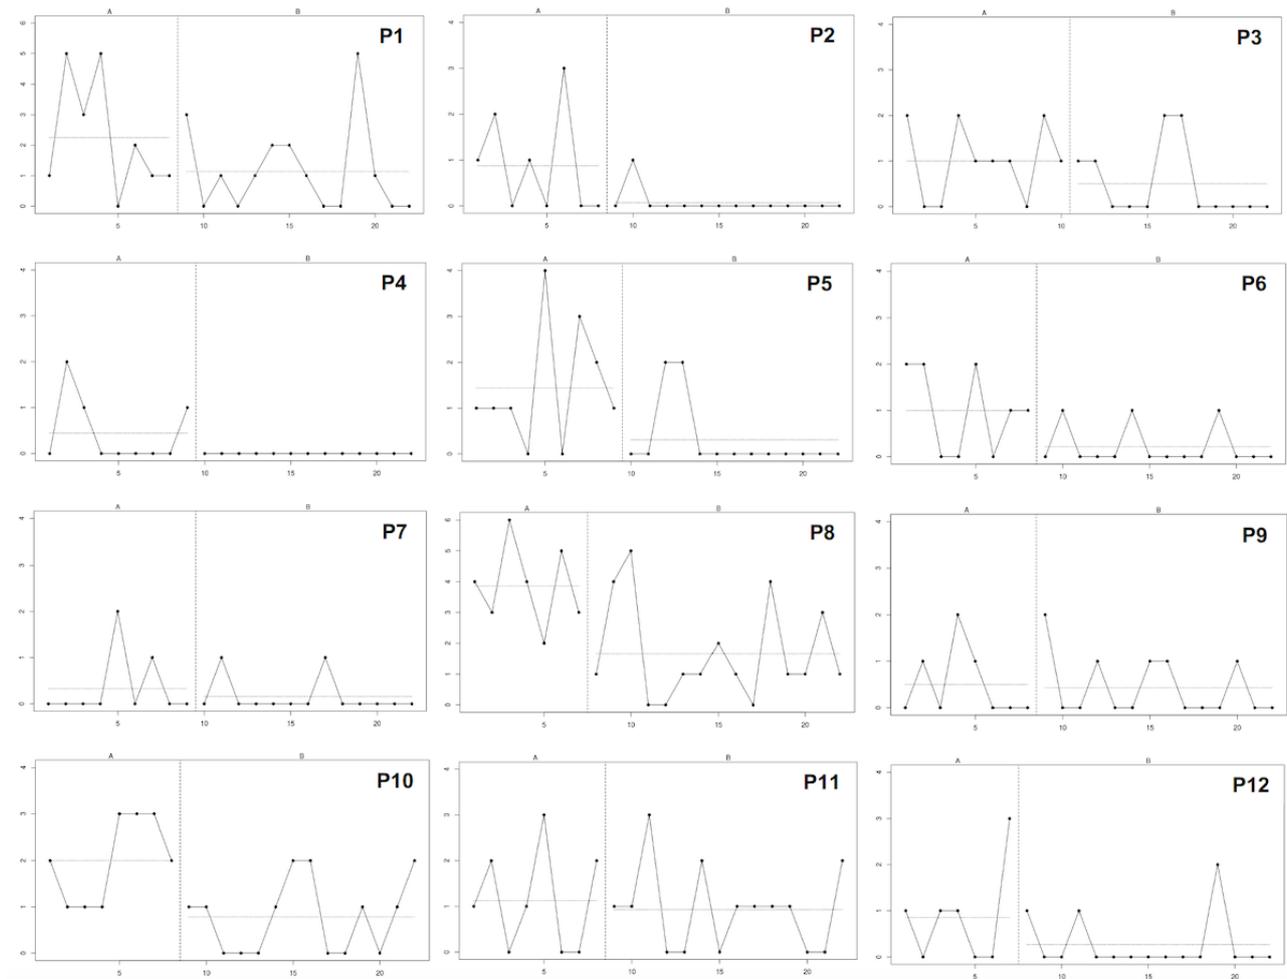

Primary Outcome Measure: Number of Intrusive Memories

Across all participants, the mean number of intrusive memories per day decreased by 59% from baseline (mean 1.29, SD 0.94) to postintervention (mean 0.54, SD 0.51). Individual-level data showed that 83% (10/12) of participants experienced reductions

between 51% and 100% (Table S4 in [Multimedia Appendix 1](#) gives individual percentage changes).

Visual inspection of individual time-series graphs [54,56] indicated a reduction in the number of intrusive memories following the intervention for all participants, as evidenced by overall lower measures of central tendency from baseline to postintervention ([Figure 3](#)). Generally, the number of intrusive memories decreased either immediately or soon after the initial intervention session.

Figure 3. Graphs showing the primary outcome data (number of intrusive memories) for all participants (N=12). The y-axis represents the number of intrusive memories per day, and the x-axis represents each day of the study period. The horizontal dashed lines represent a measure of central tendency for the baseline (A) and postintervention (B) periods.

Participants P2 to P5 maintained 0 intrusive memories for the final 5 consecutive days of the study. However, participants P1, P9, and P11 showed a reemergence of intrusive memories postintervention, similar to their baseline levels. Participant P1 reported several intrusive memories during a particularly stressful period at work, coinciding with the postintervention period. This period included a taxing day during the COVID-19 pandemic, including redeployment to a COVID-19 ward, associated with a sharp increase in intrusive memories on day 19. Participants P1 and P9 reported functional improvements at work and in their social lives, despite modest reductions in the number of intrusive memories.

τ - U analysis yielded significant ($P<.05$) medium effect sizes for 3 participants (P5, P8, and P10). The aggregated omnibus

analysis showed a significant ($P<.001$) small effect size (τ - $U=-0.38$; Table S4 in [Multimedia Appendix 1](#) gives individual participant-level data).

Secondary Outcome Measures

Intrusive Memory Characteristics and Impact on Functioning: Daily Intrusive Memory Diary

A total of 216 intrusive memories were recorded by participants in the daily intrusive memory diary during the study period, with 31.9% (69/216) occurring while they were at work.

There were no statistically significant reductions in any ratings of intrusive memory characteristics (ie, vividness and distress), functioning (ie, concentration and task disruption), length of time intrusive memories were bothersome, or sleep quality, as

recorded in the daily intrusive memory diary (Table S5 in [Multimedia Appendix 1](#)).

Mental Health Symptoms: IES-R, PHQ-9, GAD-7, and PSQI

Mental health outcomes, including depression, anxiety, and posttraumatic stress symptoms, showed significant reductions

from week 1 (preintervention) to week 4 (postintervention). However, global sleep and overall sleep quality scores did not change significantly over this period ([Table 2](#)).

Table 2. Mental health symptoms and continuous outcomes of the retrospective ratings of intrusive memory characteristics (end of week) at week 1 (preintervention) and week 4 (postintervention), with analyses and effect sizes (N=12).

	Week 1 (preintervention), mean (SD)	Week 4 (postintervention), mean (SD)	z score	t test (df)	P value	Effect size, Cohen d (95% CI)

^aIES-R: Impact of Events Scale-Revised (scores ranging from 0-88).

^bNot available.

^cPHQ-9: Patient Health Questionnaire (scores ranging from 0-27).

^dGAD-7: Generalized Anxiety Disorder Scale (scores ranging from 0-21).

^ePSQI global: Pittsburgh Sleep Quality Index (global PSQI scores ranging from 0-21).

^fn=11 (excluding P3 who had missing PSQI data for week 4 postintervention).

^gDuring the past month, how would you rate your sleep quality? very good=0, fairly good=1, fairly bad=2, and very bad=3.

^hFor continuous outcomes, N=8. Data at week 1 (preintervention) have been excluded for those participants who reported no intrusive memories at week 4 (postintervention). Night's sleep interference and daily functioning interference are missing for P1, hence N=7 for these items.

ⁱHow vivid were your intrusive memories? 0=not at all and 10=extremely.

^jHow distressing were your intrusive memories? 0=not at all and 10=extremely.

^kHow much did they disrupt your concentration? 0=not at all and 10=a great deal.

^lHow much did they disrupt the tasks you were doing? 0=not at all and 10=a great deal.

^mHow much did your intrusive memories interfere with your night's sleep? 0=not at all and 10=a great deal.

ⁿHow much have your intrusive memories affected your ability to function in your daily life? 0=not at all and 10=a great deal.

Intrusive Memory Characteristics and Impact on Functioning: Retrospective Questionnaire (End of Week)

All retrospective ratings of intrusive memory characteristics showed significant reductions from week 1 (preintervention)

to week 4 (postintervention), except for ratings of how much intrusive memories interfered with sleep. Participants reported fewer intrusive memories and a shorter duration of being bothered by them from week 1 (preintervention) to week 4 (postintervention; [Tables 2 and 3](#)).

Table 3. Discrete outcomes of the retrospective ratings of intrusive memory characteristics (end of week) at week 1 (preintervention) and week 4 (postintervention; N=12).

	Week 1 (preintervention), n (%)	Week 4 (postintervention), n (%)
Discrete outcome^a		
None	0 (0)	4 (33)
Some (1-4)	1 (8)	7 (58)
Quite a few (5-9)	4 (33)	1 (8)
Lots (10-20)	3 (25)	0 (0)
Very many (21-30)	2 (17)	0 (0)
A large amount (31-50)	2 (17)	0 (0)
More (>50)	0 (0)	0 (0)
Length of time that intrusive memories were bothersome^b (min)		
<1	3 (25)	4 (50)
1-5	5 (42)	3 (38)
6-10	2 (17)	1 (13)
11-30	1 (8)	0 (0)
31-60	0 (0)	0 (0)
>60	1 (8)	0 (0)

^aHow many intrusive memories did you have? None (0), some (1-4), quite a few (5-10), lots (10-20), very many (21-30), a large amount (31-50), more (>50).

^bApproximately how long did your intrusive memories bother you for? <1 minutes, 1-5 minutes, 6-10 minutes, 11-30 minutes, 31-60 minutes, and >60 minutes.

Responses to the open-ended question, “How have intrusive memories affected your ability to function in your daily life in the past week?” revealed that intrusive memories impacted various functional domains before the intervention, including occupational, cognitive, social and home life, and emotional functioning. For example, one participant stated:

I was previously reluctant to go to the next medical rotation when I have had memories about the event connected to the rotation, but now it's felt very much in my control. It couldn't have been a better timing to do the study.

Another participant reported, “I can focus on the tasks at hand whilst at work.” Another participant felt that they are “no longer struggling to get to sleep or waking up startled.” One participant explained, “I'm more conversive again with people; I'm more chatty with my colleagues.” Another reported:

The frustration within the family about my mentioning intrusive memories that I've been having...it's not happening anymore—I've not been needing to mention anything to my wife at all.

One participant noted, “[My] manager noticed a difference—I'm more myself now than at the beginning of the study.” One

participant observed global changes at work, “At work I'm less stressed, less moody, and happier.”

About 83% (10/12) of participants reported improved functioning at postintervention. For example, some indicated that when intrusive memories occurred, they no longer interfered with functioning. One participant noted, “The intrusive memories aren't as vivid and they don't last as long, so I can focus on the tasks at hand whilst at work.” Another said, “I'm still getting some of the intrusive memories, but they're a lot less bothersome, and I feel able to manage them better.” One participant noted global changes in the impact of intrusive memories, “I don't feel like [intrusive memories] are impacting me in any way now.”

Acceptability and Feasibility: Feedback Questionnaire

Participants generally found playing Tetris at work helpful and not very burdensome. There was considerable variability in participants' ratings of how easy they found playing Tetris at work. Overall, participants found taking part in the study easy and not burdensome and reported feeling confident in suggesting playing Tetris to another staff member (Table S6 in [Multimedia Appendix 1](#)).

Participants generally found taking part in the study helpful, describing the intervention as accessible. A common theme was

that playing Tetris enabled them to focus on something other than work: “It takes your concentration somewhere else.” Some found it a helpful “distraction” after an intrusive memory, “I play it from time to time following intrusive memories of other events in my life. It’s a massive distraction.”

Several participants noted a reduction in the emotional impact of their intrusive memories:

When I had the intrusive memory this week, it didn’t have such a strong emotional potency and didn’t have such a hold of me. You can deal with the memory better when it doesn’t have such a strong emotion attached to it. I can really see the benefits.

Regarding the feasibility of playing Tetris while at work, participants mentioned challenges, such as lack of time or opportunity, as for some, breacktimes were the only times they were able to access the intervention. Even then, it was sometimes perceived as antisocial:

During breacktimes is the only time that it’s possible [to play Tetris], however, even then, the staffroom is very busy and it’s hard to concentrate. You might have others asking you to join in a conversation, and you don’t want to be seen as antisocial.

Participants also highlighted potential challenges to the intervention’s acceptability in their work environments, such as: “I didn’t feel comfortable telling my nurse in charge that I need to go play Tetris,” and:

When colleagues describe intrusive memories, the expectation is that we sit there and listen. Culturally, we are not there yet to do something that might distract away from the memory. It might come across insensitive or that I’m not interested.

Finally, participants recommended improvements, such as having Tetris on an app, a version without advertisements, shorter play sessions, and regular reminders to play Tetris.

Discussion

Principal Findings

This single-case series examined the efficacy, feasibility, and acceptability of a brief imagery-competing task intervention to reduce intrusive memories in frontline NHS health care staff, including both prehospital and hospital staff, exposed to workplace trauma. Overall, participants reported a substantial reduction (59%) in the number of intrusive memories per day from baseline to postintervention. All participants experienced a decrease in daily intrusive memories from baseline to postintervention, with reductions ranging from 51% to 100% in 10 of 12 (83%) participants. In addition, there was a notable improvement in depression, anxiety, and posttraumatic stress symptoms over the intervention period, although no change in sleep patterns was observed. Qualitative feedback indicated enhanced cognitive, behavioral, and emotional functioning across social, home life, and work-related domains following the intervention, emphasizing its feasibility and acceptability. Adherence to treatment protocols was excellent.

This study supports previous findings that indicate the effect of the intervention in reducing intrusive memories among trauma-exposed populations (eg, inpatients with complex PTSD [32], refugees [31], and ICU staff [36,37]), extending to various frontline health care staff employed in prehospital contexts, such as ambulance services, as well as hospital staff (eg, in the ED and ICU). Alongside reduced intrusive memory frequency, improvements in psychopathology symptoms (eg, posttraumatic stress symptoms) and overall functioning were observed, in accordance with evidence that intrusive symptoms are centrally linked to other PTSD symptoms [10].

Participants also reported significant reductions in intrusive memory-related distress and vividness, along with positive changes in their appraisals of intrusive memories postintervention, as assessed by the retrospective questionnaire (end of week). For example, following the intervention, participants rated their intrusive memories as less “bothersome,” and in qualitative responses, some reported feeling better able to manage intrusive memories when they did come to mind. However, significant changes were not observed when the characteristics of intrusive memories were measured in the daily intrusive memory diary. The discrepancies between the daily and retrospective measures of intrusive memory characteristics may be due to differences in data collection methods. Daily diary entries capture immediate, specific experiences, while retrospective ratings reflect a broader, overall assessment of intrusive memories over the past week, potentially encompassing global changes in participants’ perceptions and impact on functioning. Thus, although the primary objective of the intervention is to reduce the number of intrusive memories, our findings suggest possible broader clinical impact. Future evaluations should consider measuring outcomes beyond the frequency of intrusive memories, such as their qualities, associated appraisals, symptoms of psychopathology, and functional impacts, to capture the broader potential effects of the intervention.

The COVID-19 pandemic had an unavoidable impact on this research, necessitating several modifications to the study design and procedures after the study had commenced. First, the study duration was reduced, and it was not possible to proceed with the originally planned randomization to a 3- or 5-week baseline, which we acknowledge as a limitation. Second, due to the national lockdown, study procedures were adapted for remote rather than in-person delivery. Nevertheless, delivering the intervention according to the protocol despite these modifications underscores its flexibility and potential for remote delivery—2 key features of a scalable intervention.

Study Limitations

We acknowledge some important limitations of the study that should be considered when interpreting the findings. First, we used an AB single-case experimental design. Further research has since included randomized procedures to test the effectiveness and feasibility of the intervention for NHS staff, as demonstrated by Ramineni et al [36] and Iyadurai et al [37] for ICU staff. In addition, future studies could benefit from incorporating additional time-related controls, such as the stability of daily intrusive memories over time, the typical

frequency of intrusive memories in the week before the study, and the long-term effects of the intervention. Finally, this study design does not allow us to distinguish the effects of specific intervention components, such as discarding the written descriptions of the intrusive memories. Further research with varied designs is needed to isolate and understand the impact of each individual component of the procedure.

Conclusions

In conclusion, this case series supports the efficacy of an imagery-competing task intervention in reducing the number

of intrusive memories and improving mental health and functioning among frontline NHS prehospital and hospital staff, aligning with findings in other populations. Important next steps have included further optimizing the digital delivery of the intervention across various NHS health care staff groups and settings, using rigorous randomized controlled designs (eg, with an active control), and investigating longer-term effects of the intervention [36,37]. These and similar future trials will further enhance the development of a remotely delivered, scalable intervention aimed at mitigating the impact of work-related traumatic events on health care staff globally.

Acknowledgments

The authors would like to thank the participants who gave their time to this study, as well as staff from the Oxford University Hospitals National Health Service (NHS) Foundation Trust, the Royal Berkshire NHS Foundation Trust, and the South Central Ambulance Service NHS Foundation Trust, who provided input in adapting study materials for frontline health care staff and assisted with the recruitment process. This project was mainly supported by a grant to LI from the University of Oxford John Fell Fund (grant 0006754). VK was supported by funding from the Oxford Institute of Clinical Psychology Training and Research, EAH receives grants from the Swedish Research Council (grant 2020-00873), the Oak Foundation (grant OKAY-18-442), AFA Insurance (grant 200342), and LI was supported by National Institute of Health Research Capability Funding. EAH's salary was part funded by Wellcome Trust (grant 223016/Z/21/Z) via consultancy to P1vital Products Ltd. Sponsorship was provided by the University of Oxford Clinical Trials Research Governance.

Authors' Contributions

LI conceived the study. VK and LI designed the study with substantial contributions from CS, EAH, SB, MD, and LK. SB, MD, and LK additionally facilitated recruitment. EAH, MLM, and MK contributed to interpretation of the data and supported intervention training and delivery. EAH developed the imagery-competing task intervention for intrusive memories and training in using it (ANEMONE). All the authors were involved in drafting or revising the work and have approved the final version.

Conflicts of Interest

EAH is on the board of trustees of the MQ Foundation. EAH receives book royalties from Guilford Press and the Oxford University Press and receives occasional honoraria for conference keynotes and clinical workshops.

Abstract

Background: To improve the engagement and effectiveness of traditional health programs, it is necessary to explore alternative models of health education including video-assisted lectures and peer education.

Objective: This study aimed to evaluate the effects of a combination of video-assisted lectures and peer education on health literacy related to infectious diseases among students.

Methods: Third-grade classes from 11 pilot schools in Longgang District of Shenzhen, China, were randomized to the intervention and control groups. In the intervention group, a video-assisted interactive health education program was conducted twice over a time span of 5 months. Each of the 2 sessions included a 40-minute lecture on COVID-19 and other common infectious diseases in schools and a 5-minute science video. In addition, 5 “little health supervisors” at the end of the first session were elected in each class, who were responsible for helping class members to learn health knowledge and develop good hygiene habits. Students answered the same quiz before the first and after the second session. Models based on item response theory (IRT) were constructed to score the students’ knowledge of infectious diseases based on the quiz.

Results: In total, 52 classes and 2526 students (intervention group: n=1311; control group: n=1215) were enrolled. Responses of the baseline survey were available for 2177 (86.2%; intervention group: n=1306; control group: n=871) students and those of the postintervention survey were available for 1862 (73.7%; intervention group: n=1187; control group: n=675). There were significant cross-group differences in the rates of correctly answering questions about influenza symptoms, transmission, and preventive measures; chicken pox symptoms; norovirus diarrhea symptoms; mumps symptoms; and COVID-19 symptoms. Average IRT scores of questions related to infectious diseases in the intervention and control groups were, respectively, -0.0375 (SD 0.7784) and 0.0477 (SD 0.7481) before the intervention ($P=.01$), suggesting better baseline knowledge in the control group. After the intervention, the average scores of the intervention and control groups were 0.0543 (SD 0.7569) and -0.1115 (SD 0.7307), respectively ($P<.001$), suggesting not only significantly better scores but also greater improvement in the intervention group.

Conclusions: After the health education project, the correct answer rate of infectious disease questions in the intervention group was higher than that of the control group, which indicates significant effects of the combination of video-assisted lectures and peer education for the promotion of health literacy. In addition, the intervention effect of the first session persisted for at least 4

months up to the second session. As such, the proposed program was effective in improving the health literacy of school children in relation to infectious diseases and should be considered for massive health promotion campaigns during pandemics.

infectious diseases; primary school students; quasi-randomized controlled trial; video-assisted health education; peer education; item response theory; IRT

Introduction

Primary school students are vulnerable to emerging and common infectious diseases such as COVID-19, influenza, mumps, and intestinal infectious diseases [1]. A survey on the reasons for sick leaves in primary and secondary schools in Shenzhen showed that the top 5 causes were common cold, gastrointestinal diseases, unexplained or other illness, influenza, and chicken pox [2]. In addition, the importance of acquiring essential knowledge regarding the prevention and control of COVID-19 cannot be overstated during the pandemic. Accordingly, it is critical to embed health promotion into the school education of primary school students. To that end, the outline of “Healthy China 2030” emphasizes the importance of fortifying health education among school children. In particular, primary schools were integral to the life cycle of the health education curriculum to the extent that early-life exposure to information on diseases and health behaviors is associated with improved future health outcomes [3].

Despite its importance, health education was highly restricted in its delivery forms. Conventionally, the most prevalent approach of health education of infectious diseases for school students was, arguably, classroom lectures aided with paper-based materials, in which the teaching contents are usually compiled by school teachers and researchers [4]. Traditional health education is also reported to have a limited duration of effects. Hampered by the collective challenges faced in traditional health education, most schools lack systematic health education programs [5]. To increase students’ interest in healthy behaviors and to extend the duration of education effects, researchers have been exploring alternative media for health education. Among the various new models, two of the prevailing approaches are video-assisted health education and interactional peer education [5,6].

In professional medical education, video-assisted lectures are useful tools for students to acquire basic clinical skills. When delivered in bundle with in-person lectures, video-based materials are often preferred by students [7]. In addition, video-assisted health education has been shown to be more effective than oral education in facilitating postoperative recovery of patients [8].

The effects of health education are not necessarily limited to the immediate recipients of the program themselves. Students may also help to shape the opinions and behaviors of their classmates by becoming peer educators of health and hygiene. Peer education is defined as “sharing experiences and learning among people with something in common,” such as a similar

age, living environment, and culture [9]. There is substantial evidence that peer education is highly effective in specific areas of medical and health education, including professional medical training, chronic disease prevention, and sexual health behaviors [6,10,11]. Incorporating peer effects into the design of health education programs could, therefore, strengthen the programs’ impacts on behavioral change.

However, evidence on the effects of video-assisted lectures and peer education on health literacy among school children is still lacking. Given its substantial potential for public health practice, we designed a health education package that combined video-assisted classroom teaching and peer education and tested the effectiveness of this program. This program, which we anecdotally refer to as the “Little Health Supervisors” project, was anticipated to improve the health literacy of students over an array of infectious diseases.

Methods

Trial Design

The “Little Health Supervisors” project is jointly enacted by the Longgang District Bureau of Health and the Longgang District Bureau of Education as an administrative task. Third-grade classes from 11 pilot schools in Longgang district of Shenzhen, China, were randomized to the intervention and control groups. Our aim was to allocate equal numbers of third-grade classrooms to the intervention and control groups within each school. However, schools with an odd total number of classes inevitably resulted in uneven groups; hence, one group might outnumber another eventually. This project enclosed 2 health education sessions 4 months apart in Dec 2021 and Apr 2022 in Longgang District, Shenzhen City in the Guangdong Province of China, which is a district with approximately 4 million residents and 0.4 million school students.

Ethical Considerations

The “Little Health Supervisors” project was launched by the district government as a public service project. The study protocol was approved by the Biomedical Research Ethics Review Committee, School of Public Health (Shenzhen), Sun Yat-sen University [2021(056)] and was registered with Longgang District Bureau of Health (Figure S1 in [Multimedia Appendix 1](#)). Informed consent was obtained from all students and their parents who met the inclusion criteria and were willing to participate. Confidentiality of information was maintained.

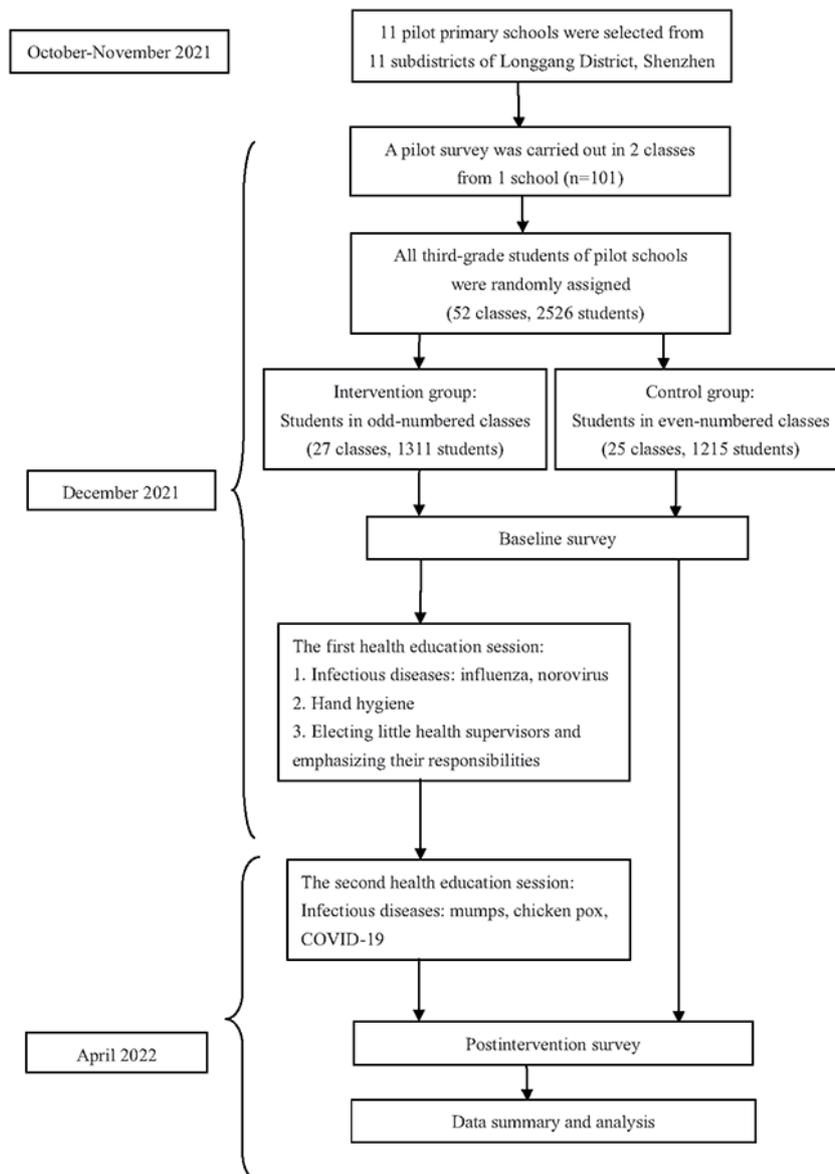

Recruitment

In the first step of sample enrollment, considering the feasibility of the project’s implementation, the Longgang District Bureau

of Health and the Longgang District Bureau of Education recommended 1 primary school based on the willingness to participate for each of the 11 subdistricts of this district. Second, all third-grade students in the 11 schools were eligible for participation if they met the following requirements: (1) they were not taking a leave of absence from school at the time of enrollment; (2) they agreed (or their guardians agreed) to spend time on attending lectures; (3) they had access to a computer, tablet, or smartphone with an internet connection; (4) they had

sufficient knowledge to use mobile devices or computers (assistance allowed); and (5) they were able to read and interpret Chinese characters. Next, as decided by the researchers, the eligible students were assigned to the intervention and control groups using the class number as the randomizer. Specifically, odd-numbered classes were assigned to the intervention group; even-numbered classes, the control group. The flowchart of participant enrollment is illustrated in Figure 1.

Figure 1. Flowchart of the "Little Health Supervisors" project (a cluster randomized controlled trial) from December 2021 to April 2022.

Data Collection

To standardize students' knowledge of infectious diseases both before and after the education program, a questionnaire containing a quiz on COVID-19 and selected infectious diseases with relatively high local incidences was curated, which included influenza, chicken pox, norovirus diarrhea, and mumps. The questionnaire also collected demographic characteristics (school, class, student number, sex, and date of birth) and COVID-19 vaccination status. In addition, we delivered a separate

questionnaire to a parent of each student who collected parental assent to vaccinate their children against COVID-19. Moreover, family socioeconomic information was also collected in the parent questionnaire, which included monthly household income and the parents' education level [12].

Questionnaires were distributed via a web-based survey platform (Wenjuanxing, Changsha Ranxing Information Technology Co, Ltd). In the baseline survey, students completed the questionnaires in a computer laboratory with the instructions of either the computer teachers or the class advisors. To collect

parents' responses, the teachers arranged a meeting with each family using previously connected social media to select a representative for questionnaire responses. Due to COVID-19 outbreaks during the planned time period of the second session, the postintervention survey was distributed on the web. Simultaneously, the researchers also collected the questionnaire from the control group.

Interventions

The intervention was developed by both researchers and the local health department. Details of the development process and the content of the intervention are provided in Table S1 and Figures S2-S3 in [Multimedia Appendix 1](#) [13,14]. Students randomized to the intervention group had access to 2 free sessions of health education during the study. Each session included a 40-minute lecture on the transmission and prevention of different infectious diseases, followed by a 5-minute science video. To incentivize learning, students were informed that there would be interactional question-and-answer sections during the lecture, for which the participating students were eligible for prizes.

In December 2021, the baseline survey and the first health education session were conducted, with the former preceding the latter. The in-person lecture and the videos of the first session pertained to influenza, norovirus diarrhea, and hand hygiene. At the end of this session, 5 little health supervisors were elected by the teachers from each class. They were naturally assumed as opinion leaders, showcasing their ability to effectively convey knowledge and could supervise the learning of health knowledge and the development of good hygiene habits of their classmates. The teachers also handed out brochures, armbands, and stickers to the 5 little health supervisors. In addition, the teachers encouraged all students to take health knowledge home and improve the family's health literacy by way of "small hands holding big hands," which aimed to exploit the power of two-step flow theory of communication for information transmission. Originating from political science, the two-step flow theory asserts that information can be conveyed through the chain of media-opinion leaders-audience. Students may also help to shape the opinions and behaviors of their family members by becoming an opinion leader of health and hygiene [15,16].

In April 2022, the second health education session and the postintervention survey were carried out. However, the order of education and survey was reversed in relation to the first session. The lecture and the videos of the second session pertained to chicken pox, mumps, and COVID-19 symptoms. Affected by a local COVID-19 outbreak, students had to take the web-based classes at home, so the health education sessions had to be conducted in the form of recorded course videos. In the intervention group, students were required to watch the video, and the teachers also encouraged all students to distribute health knowledge to the people around them.

As for the control group, the students only received routine health education at school, which included health tips on influenza from school doctors and 1 or 2 public welfare courses conducted by the local health department or hospitals every

semester. These routine health education sessions were balanced between the 2 groups.

Outcomes

The primary outcomes of this trial were the score in the original scale (hereafter referred to as "crude score") and item response theory (IRT) score of questions related to infectious diseases, the correct answer rates of questions related to infectious diseases, and the pre-post changes in the correct answer rates after the intervention. The secondary outcomes were the COVID-19 vaccination rates. For those who did not receive COVID-19 vaccines at baseline or at the end of the program, we also exploratively asked about their willingness to get vaccinated and the reasons for not being vaccinated.

Statistical Analysis

To gain an overview of students' characteristics, their families' demographic data were collected. Monthly household income (in ¥) was categorized into 4 levels (<¥5000 [US \$702.97], ¥5000 [US \$702.97]~¥10,000 [US \$1405.94], ¥10,000 [US \$1405.94]~¥20,000 [US \$2811.88], and ≥¥20,000 [US \$2811.88]). Parent's education was grouped into 3 levels (junior high or below, secondary school [including technical secondary school], and college and above). For the questions related to infectious diseases, multiple answers were regarded as correct only if all the correct answers were selected. Correctly answered questions contributed 1 point, and incorrectly answered questions contributed 0 points. The crude score of questions related to infectious diseases ranged from 0 to 7, with a higher score indicating higher knowledge of infectious diseases. For the item of willingness to be vaccinated against COVID-19, we assigned 1, 2, 3, 4, and 5 points respectively to the 5 options of very reluctant, reluctant, neutral, willing, and very willing. To comprehensively evaluate the students' knowledge of infectious diseases, IRT was used to fit the model of 7 items of the questionnaire. Frequently used in studies on education examinations, IRT is a set of psychometric models used to measure unobservable characteristics of the respondents and the development of scoring scales [17-19]. IRT can be used to explain the relationship between a latent trait (eg, the health literacy of school children related to infectious diseases) and observable characteristics and items (eg, questionnaire answers). IRT has at least 3 model specifications. The one parameter logistic model takes item difficulty into account when evaluating individual ability, whereas the two parameter logistic model additionally considers differential discrimination of items [19,20]. In addition to these 2 models, the three-parameter model (TPM) allows the possibility of guessing [19,20]. In this study, a TPM was selected to calculate the IRT score (Table S2 in [Multimedia Appendix 1](#)). To score the students' latent health literacy, we fitted TPM using the R package "ltm: Birnbaum's three parameter model" to the 7 questions related to the knowledge of infectious diseases [20]. A higher score meant higher health literacy. We plotted the estimated IRT score of questions related to infectious diseases to visualize the students' performance (Figures S4-S7 in [Multimedia Appendix 1](#)). Although not directly related to our main analyses, we also plotted the item characteristic curves, item information curves, and the test information curve to provide some information

regarding the difficulty of the test (Figures S8-S10 in [Multimedia Appendix 1](#)).

Finally, to summarize categorial sociodemographic characteristics, the correct answer rates of answering the questions, the pre-post changes in the correct answer rates after the intervention, the COVID-19 vaccination rate, the reasons for nonvaccination, and the percentages of the corresponding variables were calculated. We used mean and SD to describe the crude score, the IRT score of questions related to infectious diseases, and the willingness to vaccinate against COVID-19. We used *t* tests to compare the crude score, the IRT score, and the willingness to be vaccinated against COVID-19 across groups. Regarding the willingness to be vaccinated between 2 groups, we also conducted a stratified analysis based on the parents' sex. Chi-square tests were carried out on the basis of the correct answer rate, the COVID-19 vaccination rate, and the reason for nonvaccination to investigate differences between the 2 groups. The pre-post changes in the correct answer rates after the intervention were compared between study groups, using the *z* test. Furthermore, since we used class as our intervention unit, we also conducted an additional analysis using class as the primary unit of analysis. This was undertaken to ensure that our class-based examination would yield coherent findings as well (Tables S3-S5 in [Multimedia Appendix 1](#)). A *P* value less than .05 was considered significant. All data were analyzed using SPSS (version 26; IBM Corp) and R (version 4.2.0; The R Foundation).

Power

We calculated the power of this study on the basis of the sample size of the intervention and on the primary outcome. To calculate power, we used the sample size of 1862 (intervention group: *n*=1187; control group: *n*=675), an acceptable probability for type I error of .05, a pooled SD of 0.767, and a minimal difference in the infectious disease knowledge scores between the 2 groups of 0.166 (ie, $\mu_1 - \mu_2$). The power of this study was 99.43%.

Data Exclusion

First, when an intervention group student decided to quit or was lost to follow-up, the student was excluded from the primary analysis. Second, the researchers checked information such as IP address, birth date, sex, and school and class codes to identify duplicates.

Results

Study Population

In the baseline survey, 2177 (intervention group: *n*=1306; control group: *n*=871) student questionnaires and 2496 (intervention group: *n*=1430; control group: *n*=1066) parent questionnaires were collected, amounting to response rates of 86.2% and 98.8%, respectively. In the postintervention survey, 1862 (intervention group: *n*=1187; control group: *n*=675) student questionnaires and 1799 (intervention group: *n*=1076; control group: *n*=723) parent questionnaires were retrieved, yielding response rates of 73.7% and 71.2%, respectively (Tables S6-S9 in [Multimedia Appendix 1](#)). In the intervention group, 2493 (intervention group: *n*=1306; control group: *n*=1187) student questionnaires were collected, with a response rate of 95.1%. In the control group, 1546 (baseline survey: *n*=871; postintervention survey: *n*=675) student questionnaires were collected, with a response rate of 63.6%.

There were no significant differences in baseline characteristics between the intervention and control groups ([Table 1](#)). In the intervention group, there were 691 male and 615 female students; the corresponding numbers in the control group were 459 and 412, respectively. The proportion of households earning less than ¥5000 (US \$702.97) was relatively small in both groups (9.8% and 8.9%). Finally, the proportions of students whose parents had college education and above was 72.7% in both groups.

Table 1. Sociodemographic characteristics of third-grade students from 11 pilot schools in Longgang District of Shenzhen, China.

Characteristics	Intervention group, n/n (%)	Control group, n/n (%)
Sex		
Male	691/1306 (52.9)	459/871 (52.7)
Female	615/1306 (47.1)	412/871 (47.3)
Monthly household income (¥^a)		
<5000	140/1430 (9.8)	95/1066 (8.9)
5000~10,000	359/1430 (25.1)	267/1066 (25.0)
10,000~20,000	403/1430 (28.2)	311/1066 (29.2)
≥20,000	528/1430 (36.9)	393/1066 (36.9)
Parent's educational level		
Junior high or below	116/1430 (8.1)	82/1066 (7.7)
High school or technical secondary school	275/1430 (19.2)	209/1066 (19.6)
College and above	1039/1430 (72.7)	775/1066 (72.7)

^a¥1=US \$0.1445.

Correct Answer Rates of Questions Related to Infectious Diseases

At baseline, the correct answer rates for questions related to influenza symptoms, influenza preventive measures, and norovirus diarrhea symptoms were different between the intervention and control groups. Specifically, the correct answer rate was higher in the control group (Table 2). In terms of the correct answer rates for questions regarding influenza transmission, chicken pox symptoms, mumps transmission, and

COVID-19 symptoms, there were no significant differences between the 2 groups (Table 2). After the intervention, the differences between the 2 groups in the correct answer rates for questions regarding influenza symptoms, influenza preventive measures, and norovirus diarrhea symptoms were no longer observed (Table 2). By contrast, the differences in the correct answer rates for questions regarding chicken pox symptoms, mumps transmission, and COVID-19 symptoms between the 2 groups at the end point were significant, such that intervention group outperformed the control group (Table 2).

Table 2. The correct answer rates for questions related to infectious diseases in the intervention and control groups.

Questions	Total, %	Intervention group, %	Control group, %	P value
Baseline				
Influenza symptoms	67.57	65.39	70.84	.008
Influenza transmission	81.86	81.47	82.43	.57
Influenza preventive measures	84.66	83.08	87.03	.01
Norovirus diarrhea symptoms	56.41	54.21	59.70	.01
Chicken pox symptoms	28.34	28.79	27.67	.57
Mumps transmission	6.89	7.27	6.31	.39
COVID-19 symptoms	29.54	28.33	31.34	.13
End point				
Influenza symptoms	86.09	86.77	84.89	.26
Influenza transmission	78.30	78.69	77.63	.60
Influenza preventive measures	92.91	93.09	92.59	.69
Norovirus diarrhea symptoms	72.93	73.80	71.41	.26
Chicken pox symptoms	43.18	47.01	36.44	<.001
Mumps transmission	10.15	13.23	4.74	<.001
COVID-19 symptoms	49.14	52.40	43.41	<.001

Regarding the pre-post changes in the correct answer rates after the intervention, the differences between the 2 groups were significant for all items (Table 3). Specifically, the correct answer rates for questions regarding influenza symptoms, influenza preventive measures, norovirus diarrhea symptoms, chicken pox symptoms, and COVID-19 symptoms increased in both groups (for all, $P < .001$). However, the correct answer

rates of the intervention group increased more than those of the control group. In the intervention group, the correct answer rate for questions regarding mumps transmission increased in the intervention group but decreased slightly in the control group. Compared with that before the intervention, the correct answer rate for questions regarding influenza transmission decreased slightly after the intervention (Table 3).

Table 3. Pre-post changes in the correct answer rates after the intervention in the intervention and control groups.

Questions	Total, %	Intervention group, %	Control group, %	P value
Influenza symptoms	18.52	21.38	14.05	<.001
Influenza transmission	-3.56	-2.78	-4.80	.02
Influenza preventive measures	8.25	10.01	5.56	<.001
Norovirus diarrhea symptoms	16.52	19.59	11.71	<.001
Chicken pox symptoms	14.84	18.22	8.77	<.001
Mumps transmission	3.26	5.96	-1.57	<.001
COVID-19 symptoms	19.60	24.07	12.07	<.001

Crude and IRT Scores for Questions Related to Infectious Diseases

Before the intervention, there was a significant difference in the mean scores for questions regarding infectious disease knowledge between the 2 groups. The mean IRT score of the intervention group (-0.0375 , SD 0.7784) was significantly lower

($P=.01$) than that of the control group (0.0477 , SD 0.7481). After the intervention, the mean IRT score of the intervention group (0.0543 , SD 0.7569) surpassed that of the control group (-0.1115 , SD 0.7307). Notably, the postintervention mean score of the intervention group increased from that at baseline, whereas the control group displayed an opposite trend (Table 4). The situation is similar for the crude score (Table 4).

Table 4. The crude and item response theory (IRT) score of questions related to infectious diseases in the intervention and control groups.

	Crude score, mean (SD)			IRT-based score, mean (SD)		
	Intervention group	Control group	<i>P</i> value	Intervention group	Control group	<i>P</i> value
Baseline	3.49 (1.628)	3.65 (1.552)	.02	-0.0375 (0.7784)	0.0477 (0.7481)	.01
End point	4.45 (1.469)	4.11 (1.420)	<.001	0.0543 (0.7569)	-0.1115 (0.7307)	<.001

COVID-19 Vaccination Rates

The COVID-19 vaccination rates of the intervention and the control groups at baseline were 94.8% and 93.2%, respectively;

by the end of the program, they increased slightly to 97.6% and 96.6%, respectively. The differences, however, were not significant (Table 5).

Table 5. The COVID-19 vaccination rates of third-grade students before and after the intervention.

	Intervention group, n/n (%)	Control group, n/n (%)	<i>P</i> value
Baseline	1238/1306 (94.8)	812/871 (93.2)	.13
End point	1158/1187 (97.6)	652/675 (96.6)	.23

Willingness to Get Vaccinated and the Reasons for Not Being Vaccinated

Among the study participants who have not been vaccinated against COVID-19, the differences between students' and parents' willingness to receive the vaccine in the 2 groups were not significant (Table S10 in Multimedia Appendix 1). After stratifying by parents' sex, the differences between the 2 groups were still not significant (Table S11 in Multimedia Appendix 1). For students who had not been vaccinated against COVID-19 after the intervention, the students and their parents were worried about side effects among many other reasons (Table S12 in Multimedia Appendix 1).

approach proposed in this study represents a viable approach to improve student health literacy during pandemics and should be considered in future programs of healthy behavior promotion among school students. The fact that the program was effective among third-grade students does not restrict the potential of this approach since senior students are likely to capture the contents of the program better than third-grade students. Second, the results from the second session of this study partially indicate that web-based teaching may also be an effective tool to promote student engagement in health education, which has been highlighted in previous studies but not confirmed [7].

Discussion

Principal Results

Using a quasi-randomized controlled design, this study assessed the effectiveness of a video-assisted health education program sequenced by peer education on infectious disease health literacy among school students. The results suggest that the proposed multicomponent model of health education improved the knowledge of infectious diseases among students, and are consistent with those of previous randomized controlled trials in health education among primary school students [12,21,22]. Moreover, this study not only showcases an innovative approach to raise awareness of disease prevention by incorporating technology and behavioral elements, but also represents a preliminary effort to test the effectiveness of an infectious disease health education program using IRT-based scores.

The possible long-term effects of the first session from our findings should not be ignored. The postintervention survey was carried out immediately after the second education session (including chicken pox, mumps, and COVID-19) and 4 months after the first education session (including influenza and norovirus diarrhea). Despite the time elapsed, the correct answer rates of questions related to infectious diseases that were of focus in the first session were still higher in the intervention group than in the control group. Therefore, third-grade primary school students may endure the impact of health education for at least 4 months. Given the low likelihood of frequently setting up health education sessions in schools, the slow waning of the program's effects is a desirable feature. However, the cross-over effect from the second session could not be ruled out. For example, the learning of COVID-19 may strengthen the students' previous understanding of influenza and increase the effect of intervention in influenza. In addition, the second session may sensitize the students in the intervention group. They may review the knowledge of the first session to prepare for the postintervention quiz, which may also enhance the effect of the first session.

Our results encapsulate important implications for the practice of health education and healthy behavior promotion. First, the inexpensive and convenient innovative health education

It is noteworthy that there was some difference in response rates between the interventional and control groups. The difference in response rates might be attributable to an absence of treatment blinding. In fact, the intervention in this study could not be blinded due to its physical nature, in which case, the intervention group students might be motivated by the education sessions to meet the expectation of the educators to respond to the surveys.

In addition, there was no significant difference in the correct answer rate for questions related to flu transmission routes before or after the intervention, but the pre-post changes in the correct answer rates was different between the 2 groups, and the intervention group performed better than the control group. Owing to countrywide vaccination campaigns, the COVID-19 vaccination rates between the intervention and control groups were not significantly different. The results of the 2 questionnaire surveys showed that the vaccination rates of the 2 groups increased, which was related to the local epidemic and the country's policy encouragement for vaccination.

Limitations

Several limitations of the study should be noted when interpreting the results. First, we did not collect data on the incidence of related infectious diseases before and after the intervention. A previous study reported that in areas with a high incidence of infectious disease, the health education package had no overall effect in preventing infections. However, the intervention was effective in preventing infections in areas where the baseline prevalence was relatively low [21]. Further studies are needed to explore the impact of our composite intervention on preventing infections. Second, this study was limited in its ability to evaluate component-specific versus composite effects of the educational video, the didactic lessons, the cooperative learning exercises, and peer engagement. The 2-arm trial design could not parse out the influence of each element. Future work should incorporate multiple comparison arms to better isolate the impacts of intervention components. Third, we regret that we did not measure changes in attitudes and behaviors after the intervention, as the health education package is hypothesized to influence these aspects. This is a gap that exists in our study, which future research could explore. Fourth, we used a self-rating questionnaire to collect data. Although self-reporting is a common and accepted method, we could not completely rule out the possibility of measurement error. However, the reliability and validity of self-reporting among children aged >8 years have been shown to be good in health-related questionnaires [23,24]. Fifth, the contamination in this study may underestimate the effect of our intervention. We adopted a clustered quasi-randomized controlled trial design to mitigate within-class person-to-person contamination, although interclass contamination caused by students and teachers could not be eliminated. However, the contamination, if any, happened more likely to the first session rather than the second session since students were physically isolated during the latter. Sixth, as we did not receive the questionnaire from the students lost to follow-up, the primary analysis was not

intent-to-treat. Seventh, the second session of health education originally scheduled to enter the campus was changed to web-based classes owing to the serious local epidemic. Therefore, the students were required to fill in the web-based questionnaire at home, which affected the independence of the participants in answering questions; hence, the correct answer rates of the 2 groups were generally higher than those at baseline. Besides, the recovery of the questionnaire was decreased probably due to the lack of the teachers' supervision outside the schools. However, the missing rates were balanced between the 2 groups, thereby reducing the chances of influencing our conclusions. Moreover, the effect of the health education provided herein may be underestimated because this missing group of students and parents might have lower health literacy, in which case, the intervention would have incremental value.

Comparison With Prior Work

Despite these limitations, the primary strengths of our study are that it is the first quasi-randomized controlled trial to evaluate the effect of a video-assisted health education program sequenced by peer education on the health literacy of COVID-19 and other infectious diseases among school children, and it is also the first to report IRT scores for questions related to the infectious diseases. Additionally, while our study is quasi-randomized, the allocation process likely achieved reasonable randomization, effectively balancing confounding factors across study arms as evidenced by the systematic allocation of students to intervention or control groups based on their odd or even class numbers, as outlined in Table 1. Importantly, the allocation of students to odd or even classes was not based on systematically different characteristics, as the Ministry of Education of the People's Republic of China does not permit students to be segregated into different classes based on specific attributes. Therefore, the grouping of students based on class number parity can be considered to approximate the effects of randomization. Moreover, the sample size in this study allowed minimal chances of underpowered analyses. Previous studies might have engaged nonrandomized designs such that mixed results were reported [12,21,22,25-30]. Although most studies demonstrated that the health intervention is effective in improving health knowledge and health literacy, a quasi-randomized controlled trial in China found that the intervention's effect was not significant among primary school students [25]. Moreover, a number of studies adopted self-control, or observational designs, based on which solid conclusions are difficult to derive [3-5,26-30].

Conclusions

Our study confirmed that the combination of video-assisted and peer education in a health education program had significant effects on school children. In addition, the effect of the first health education session may endure after 4 months. As such, the proposed program was effective in improving health literacy related to infectious diseases among school children and should be considered for en masse health promotion campaigns during pandemics.

Acknowledgments

This study was carried out by the Longgang District Bureau of Health as an administrative task. This sponsor was involved in developing the intervention and study design, and was kept informed during data collection and data analysis. The corresponding authors had full access to all of the data in the study and had the final responsibility for the decision to submit the paper for publication. We also appreciate Jing Chen and Wanjing Zhang from the Longgang District Health Inspection Institute for their contribution and support to the early development of the intervention package.

Data Availability

The data presented in this study are not publicly available because of ethical requirements but are accessible upon reasonable request to the corresponding author.

Authors' Contributions

All authors conceptualized and designed the study and provided administrative, technical, and material support; they also supervised the study. XZ and YJW acquired the data. XZ analyzed and interpreted the data and drafted the manuscript. YJ critically revised the manuscript for important intellectual content. XZ carried out the statistical analyses. NH is a co-correspondent (email: 207baby@163.com).

Abstract

Background: Implementation of remote monitoring solutions and digital alerting tools in health care has historically been challenging, despite the impetus provided by the COVID-19 pandemic. To date, a health systems-based approach to systematically describe barriers and facilitators across multiple domains has not been undertaken.

Objective: We aimed to undertake a comprehensive mixed methods analysis of barriers and facilitators for successful implementation of remote monitoring and digital alerting tools in complex health organizations.

Methods: A mixed methods approach using a modified Technology Acceptance Model questionnaire and semistructured interviews mapped to the validated fit among humans, organizations, and technology (HOT-fit) framework was undertaken. Likert frequency responses and deductive thematic analyses were performed.

Results: A total of 11 participants responded to the questionnaire and 18 participants to the interviews. Key barriers and facilitators could be mapped onto 6 dimensions, which incorporated aspects of digitization: system use (human), user satisfaction (human), environment (organization), structure (organization), information and service quality (technology), and system quality (technology).

Conclusions: The recommendations proposed can enhance the potential for future remote sensing solutions to be more successfully integrated in health care practice, resulting in more successful use of “virtual wards.”

Trial Registration: ClinicalTrials.gov NCT05321004; <https://www.clinicaltrials.gov/study/NCT05321004>

Introduction

Since the onset of the COVID-19 pandemic, adoption and implementation of novel health care pathways have accelerated

globally. A key change has been transitioning beyond the traditional face-to-face model of health care delivery with the incorporation of novel remote monitoring solutions [1,2]. They offer a significant advantage in moderating viral exposure risk

to health care staff, reducing community spread, and delivering quality health care remotely for exposed or infected individuals [3,4].

The integration of telemedicine and remote monitoring into medical practice is expected to expand by appropriately permitting selected individuals to continue living at home rather than admitting them into secondary care; this very premise is the foundation of “virtual wards” [5]. With the recent improvements made to wearable technology, they can support health provider assessment and clinical decision-making through collected biometric data both in secondary care and in the community [6-10].

However, successful implementation of digital technologies across complex hospital systems is seldom a smooth process [11-13]. The absence of standardized procedures for implementation and evaluation alongside the deficiency of published implementation strategies adds to these difficulties. One study in the National Health Service (NHS) that implemented wearable sensors and alerting systems in secondary care reported no improvements in clinical outcomes among patients [14,15]. The aim was to use wearable sensors to provide continuous remote monitoring to patients admitted to acute (nonintensive) wards and alert health care staff upon recognition of deterioration. Interestingly, although the digital solution was able to pick up clinical deterioration in vital signs and alert health care staff, responding to the alert was met with significant delay. This was in spite of health care staff in the NHS reporting favorable perceptions of digital solutions with potential improvements to patient safety and reduced staff burden [16]. Therefore, there is a need to further explore implementation issues.

Patients have reported high levels of acceptance, comfort, and safety and deemed such digital tools favorable [17-19]. The main concerns, from a patient perspective, surround potential overreliance on numbers with diminishing contact from clinical staff [17,20,21]. Health care staff perceptions, however, have been more mixed, with concerns regarding changing and increasing workloads, uncertainty surrounding the clinical meaningfulness of captured data, and alert fatigue [19-21]. Although mixed methods exploration of these 2 key stakeholder groups has been well documented, understanding how to integrate remote monitoring digital tools in the NHS requires further examination of cultural and management issues in the health care organization, an area where evidence is missing.

In the United Kingdom, large health informatics programs and widespread digital transformations are delivered by NHS Digital, a nondepartmental public body [22,23]. To support digitization, NHS England has formed a framework consisting of 3 ambitions: digital readiness, maturity, and data-enabled services [24]. In line with this, NHS England has supported the development and use of virtual wards, further indicating the “digital push” [5]. For policy makers, understanding the barriers and facilitators as perceived by key organizational members is crucial for the effective provision and smooth deployment of digitally enabled care. A proposed framework evaluates these aspects, incorporating the concept of fit among humans, organizations, and technology (HOT-fit) [25]. This framework

offers a structured basis to examine factors that focus on alignment and compatibility across these 3 domains, thereby enhancing the effectiveness of digital health care initiatives.

Therefore, the aim of this study was to evaluate key stakeholder perspectives on an organizational level of implementing remote monitoring solutions in the NHS, identifying factors that could affect successful execution and adoption using the HOT-fit framework. In doing so, we propose a road map for implementing wearable solutions in secondary care.

Methods

Study Design

A mixed methods approach was implemented that consisted of semistructured interviews and questionnaires [26]. This was developed in accordance with recommendations from the Standards for Reporting Qualitative Research (SRQR) guidelines where appropriate [27]. The semistructured interviews were conducted with high-level stakeholders from industry and academia, as well as with health care providers who played an instrumental role in and had prior experience of implementing digital solutions. Additionally, a validated questionnaire was used to ascertain the perceived technological acceptance of new remote monitoring systems.

To ensure appropriate recruitment among all key stakeholder groups, a key informant strategy was followed for purposive recruitment [28,29]. Individuals were identified through their notable work with implementation of remote monitoring solutions in health care, including authors of impactful research in the literature, major digital technology companies, technicians involved with digital tool infrastructure development, and experts recommended by peers. This represented a variety of groups, including academics, clinicians, allied health care professionals, and employees of Google Health, who had experience with implementing digital solutions with the NHS.

Ethical Considerations

All recruited participants provided written informed consent. Ethical approval for this study was obtained by Imperial College London’s Science Engineering Technology Research Ethics Committee (20IC6331), and it was conducted in accordance with the Good Clinical Practice guidelines and the Declaration of Helsinki. Storage and handling of personal data complied with the General Data Protection Regulation. Interviews were recorded, anonymized, and transcribed.

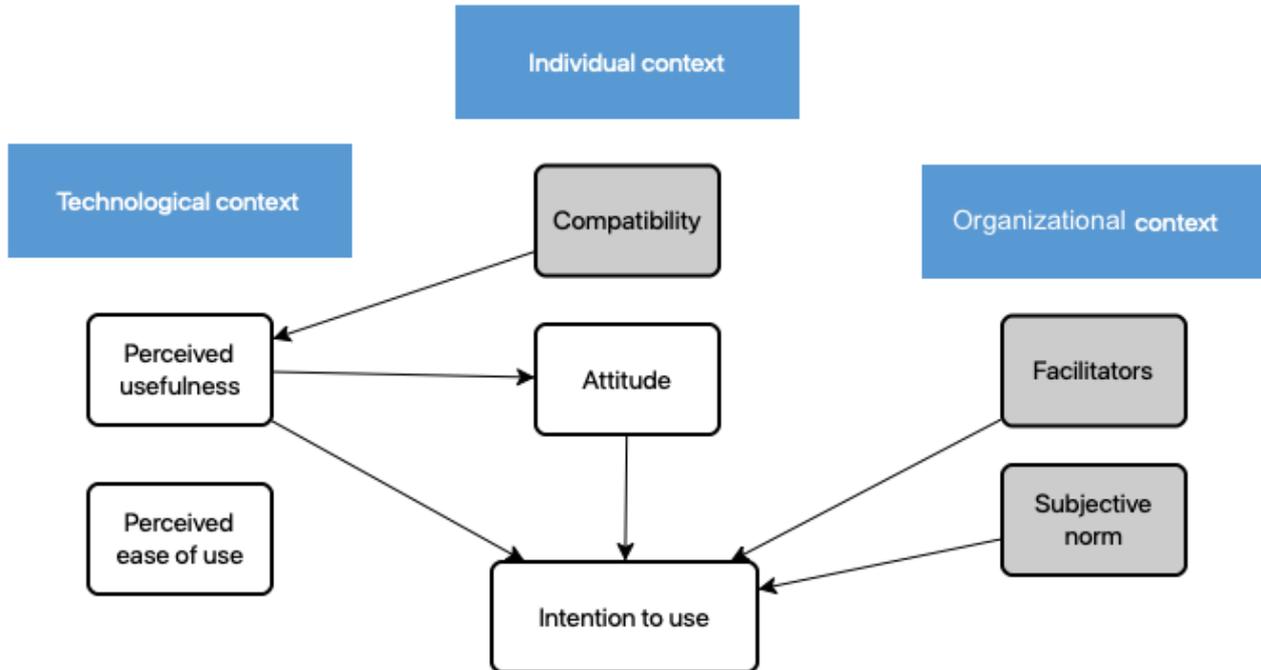

Questionnaires

An adapted version of the Technology Acceptance Model (TAM) questionnaire was used; this validated questionnaire has shown acceptably high Cronbach α values [30]. This ensures the reliability of our findings, contributing to the robustness of the study’s methodology and its implications in understanding technology acceptance dynamics. The proposed theoretical framework (information technology acceptance) is shown in Figure 1. It has been adapted from Chau and Hu [31], comprising individual context, technological context, and organizational context. Further adaptations from Gagnon et al [30], with the inclusion of theories of interpersonal behavior

and reasoned action building on the TAM, proposed by Davis [32], have been included [30-34]. As such, individual context consists of compatibility (factors that affect acceptance of a new technology) and attitude (perception of the individual to adopting a technology); technological context consists of

perceived usefulness and perceived ease of use of technologies. Lastly, organizational context consists of facilitators and subjective norms; the latter can be described as social (an individual's perception of a behavior) or descriptive (behavior of others).

Figure 1. Theoretical framework for the modified Technology Acceptance Model questionnaire [30].

Semistructured Interviews

All participants were invited to take part in semistructured interviews conducted by the lead researchers. A structured topic guide was created following a literature review that drew heavily from a model proposed by Simblett et al [35] and by the HOT-fit framework [25].

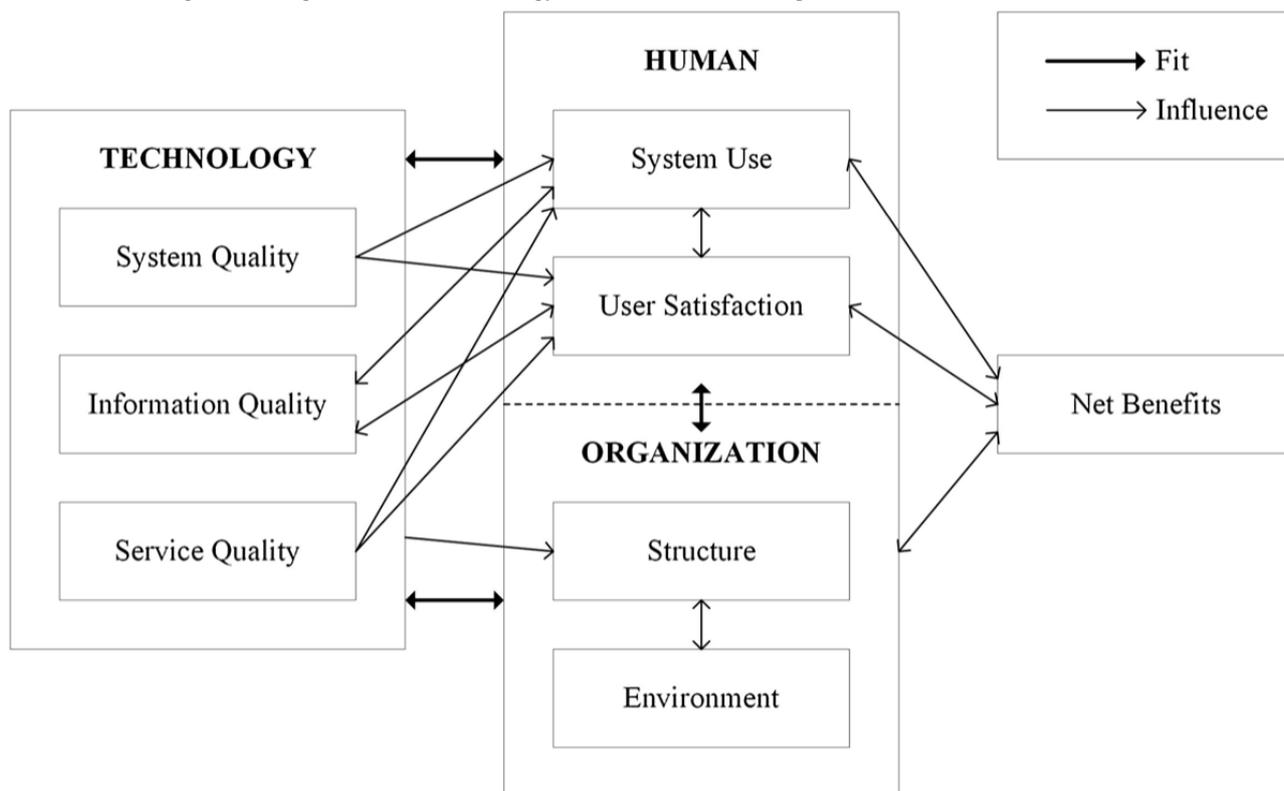

Data collection was an iterative process; emerging recurring concepts were incorporated into the interview guide for further exploration with remaining participants. Interviews were

recorded, anonymized, and transcribed verbatim before being entered into NVivo (version 12; QSR International) for analysis.

HOT-Fit Framework

This validated framework identifies dimensions that can be mapped onto and used as reference models for evaluating the performance, effectiveness, and impact of health systems [25,36]. A fit between human, organizational, and technological factors is required to ensure successful implementation and has been highlighted in Figure 2.

Figure 2. The fit among humans, organizations, and technology (HOT-fit) framework, adapted from Yusof et al [25].

Data Analysis

Frequency distributions were generated for the 7-point Likert scale responses to the modified TAM questionnaire using R studio (R Foundation for Statistical Computing) with the *Likert* package (Bryer and Speerschneider).

Transcribed interviews were analyzed using a broadly deductive approach [37], with the topic guide adapted as previously described [35]. This formed the basis for the initial predefined coding framework and was undertaken by 2 independent researchers to determine barriers and facilitators [37]. An

iterative process of coding and data indexing occurred, ensuring key aspects were not missed from the predefined coding framework. Subsequent emerging themes were summarized and mapped to the evaluation measures corresponding to each dimension of the HOT-fit framework [25]. The results were discussed until consensus was reached.

Results

Overviews of the included participants and the reported evaluation measures are shown in [Tables 1 and 2](#), respectively.

Table 1. Demographics of included participants.

Group	Role 1	Role 2	Role 3	Role 4	Role 5	Role 6	Role 7

TAM Questionnaire

A total of 11 participants (response rate 11/22, 50%) responded to the questionnaire; the responses are represented as a Likert plot (Figure 3). Overall, the technology surrounding remote monitoring and virtual wards was perceived well by the questioned stakeholders, who considered that it facilitated the

care of patients and that these pathways, initially introduced during the pandemic, were likely to change long-term provision of health care. However, some concerns were noted regarding whether the existing infrastructure could support the technology’s use and whether it would improve efficiency. Of note, there was uncertainty regarding whether most patients would welcome virtual wards or remote monitoring.

Figure 3. Likert plot displaying responses to the modified Technology Acceptance Model questionnaire. The percentages on the left and right sides of the plot represent the totals for negative and positive responses, while the percentages in the center represent neutral responses.

Semistructured Interviews

A total of 22 participants were approached, of whom 18 (response rate: 82%) participated in the semistructured interviews (Table 1). An overview of the factors, by dimension, that respondents felt were responsible for contributing to implementation is summarized in Table 2.

System Use

Expectations and Beliefs

The prospect of introducing novel remote monitoring technologies was felt to facilitate implementation through improved efficiency, particularly since the implementation of electronic health records has improved data availability and clarity:

...with the implementation [and] introduction of electronic health records where the data that's available is so granular. And in addition to new technologies that are coming. I think that you can do a lot more, remotely or virtually, and it does make things a lot more efficient... [Participant 15]

Moreover, respondents also commented that for successful implementation, a selective process should be in place for patients who would benefit the most from novel technologies, rather than using the technology in cases that would not be meaningful:

From a patient perspective, we don't want to one size fits all approach. We need to be clear about how we personalize this and how it's relevant and meaningful. [Participant 17]

Training, Knowledge, and Expertise

Problems with troubleshooting and available training were reported to reduce successful implementation due to a lack of support:

We've had problems when trying to use the remote monitoring, it came up with an error and then I have to try and sort that out, you know? It's just things like that that make extra work. [Participant 16]

I know that the nurses have struggled a huge amount with remote monitoring, and I expected that...because there's a lot of upskilling. [Participant 18]

However, engaging early with health care workers and obtaining their involvement was shown to improve implementation of remote monitoring solutions:

[We received] better engagement by tying the implementation with the new starters in the role and the changeover of junior doctors, because it was a new product to offer to new junior doctors. [Participant 3]

Motivation

It was felt that motivation to engage with technologies would be impacted through the excessive availability of data acting as a deterrent:

We need to be mindful about the data burdens, not just for patients but for staff because this kind of

remote technology follows you around. You basically could work 24/7 365 of the year. [Participant 17]

In addition, following the pandemic, many health care workers were fatigued and unmotivated to engage in change, acting as a barrier to successful remote technology implementation:

Post-COVID the workforce has been decimated, been exhausted and is fatigued. It's not the only problem though, because you know as well as I do that the NHS has run this model of where it's good will. We've never had infrastructure that we needed to do stuff and we still get a huge amount done. So it's not the only driver at the moment. It's more noticeable because of where people's heads are at and obviously where their physical levels and mental levels of exhaustion are... [Participant 17]

However, respondents also noted that finding a few motivated individuals to champion change at a local level can help implementation:

I asked them to self-nominate three of them who were interested in helping [implement]. So they led and supported the [technology]... [Participant 18]

User Satisfaction

Respondents reported that previous experience with digital tools tied into user satisfaction. Feedback to end users demonstrating meaningful impact was deemed important for engagement and successful implementation:

Where staff or patients, for example, have been involved in projects before that they haven't had any feedback from, haven't seen any meaningful outcome from...they're like, well, why would I want to get engaged with this? That's a lot of energy and effort from me and I won't see any benefit. [Participant 17]

...develop relationships, so between, if you like, supplier and developer and clinical staff so you've got these rapid cycles of feedback and learning. [Participant 1]

Environment

Respondents reported that previous hindrance of effective implementation was because of an overburdened system unable to give the appropriate attention to integrating a digital solution in the NHS:

NHS is overburdened and so that level of diligence...wasn't there until it had to be, until things became mission critical...that comes down to a bandwidth problem... [Participant 10]

Similarly, underresourcing was noted to be a barrier, particularly during the early stages, where issues would arise:

More resource[s] to get [things] kick started [are usually needed]...because we had to go through all the teething problems ourselves which created extra work for us. [Participant 16]

We've got very limited resources, that they're very thinly spread across all of the IT projects that require integration and interoperability...just the sheer volume

of work that the Trust has heaped on us over the last three or four years is the bigger constraining factor. [Participant 4]

Lastly, organizational culture supporting digitization was a commonly reported theme, with some institutions more readily accepting of innovation than others:

Organisational culture can be both the barrier and facilitator. We know that there are some organisations that are much more ready and able to adopt innovation. I think from an organisational perspective, competing priorities are a huge issue...If your IT is majorly engaged in doing something else, for example an EHR implementation, its ability to support remote monitoring and other technologies is really poor. [Participant 17]

Structure

Respondents also commented on the need for a clear process and said that developing a strategic partnership and framework would facilitate implementation and should be planned before rollout:

Strategic framework is crucial on things.... What does a strategic partnership look like? What is the direction that we want to jointly head in? What do we want to achieve together, and what are the different components to get there... [Participant 1]

Making [the product vision and roadmap] clear as early on and getting that input right at the beginning of any kind of feature development. So that there is expectation alignment on what is being developed whether the minimal viable product meets the use cases that it needs to, and that there's a partnership in prioritizing these features and when they're delivered. As opposed to just showing a feature set a few weeks before it gets deployed.... I think that initial understanding of the vision...and getting that clinical engagement as early on helps to set the path going forward. [Participant 12]

Information and Service Quality

Respondents noted the need for digital tools to be interoperable and usable, as poorly designed digital tools would be a barrier, hindering an overly strained NHS system:

The challenges are IT and interoperability...you don't want 20 bits of data...from 20 apps that don't work, so that's the usability and the accessibility and the staffing of these models because traditionally they basically get added onto someone's day job. But that day person's already overwhelmed. [Participant 17]

System Quality

Respondents highlighted that for a digital tool to be successfully implemented, it needed to provide added value, with perceived usefulness and ease of use being crucial.

[What] was the added value in [this digital app]? All it did was render some of the information that we

already had in a limited manner, back in the mobile device. [Participant 8]

Usability, the accessibility, and the staffing of these models [are really poor] because traditionally they basically get added onto someone's day job.... The data element [is also] really poor, so you get a lot of enthusiasts doing a lot of projects. But if you then say where's your evidence that makes any difference to anything meaningful that matters to patients and staff, they can't produce that. I think the digital health tech industry has been really slow at that. [Participant 17]

Furthermore, it was believed that the best way to implement a digital tool (eg, remote monitoring solutions) was through rapid quality improvement cycles following the plan-do-study-act (PDSA) technique, focusing on targeting user experience issues:

...believe the technology suffered from very poor clinical and user engagement. So I know [technological companies] will tell us they've had loads of user engagement, but actually most patients wouldn't say that, they'd say well, why is it like this? No, why is nobody been engaged in the design for this? [Participant 17]

...trying to give clinical input into feasibility, usability, implementation in terms of the design of how we were going to implement stuff, so...[a] genuine PDSA type approach to implementation, and I was quite involved in some of the thinking about spread and how do you get this utilized across different parts of the Trust... [Participant 1]

Discussion

Principal Findings

This study explored barriers and facilitators for implementing digital tools, in particular remote monitoring solutions, in the NHS, alongside the acceptance of such technology using the modified TAM questionnaire. Using the HOT-fit framework, human, organization, and technological factors were categorized, allowing for a multiple-angled approach to a multifaceted problem. Therefore, key barriers and facilitators could be mapped onto 6 dimensions, which incorporated aspects of digitization: system use (human), user satisfaction (human), environment (organization), structure (organization), information and service quality (technology), and system quality (technology).

With regards to system use, the importance of improving workflow efficiency, having appropriate troubleshooting support available for staff, finding local champions to help integration within the clinical workforce, and positively engaging with health care staff were highlighted as facilitators. To support this, young staff have been deemed the most likely to engage with and benefit from a new workflow [36,38-40]. This, in part, may be explained by more adept digital literacy skills and technical proficiencies associated with junior members [41]. In the literature, concise and tailored education surrounding implementation has been promoted as an important facilitator [42].

Key barriers relating to system use and environment included poor training and the burden of data, particularly with continuous remote monitoring of vital signs. These data may not always be clinically meaningful or because of poor resourcing may not be acknowledged appropriately, generating additional work for existing staff, who are already overburdened [14,43]. Previously, this unincentivized workflow change led to poor response times to alerts generated through alerting systems in an acute surgical ward [14]. In this study, 36% (4/11) of respondents to the modified TAM questionnaire were unsure whether allied health care professionals would welcome virtual wards (Figure 3). One study highlighted that these workers, in particular nurses and clinicians, were the most important gatekeepers for remote monitoring solutions [44]. Therefore, engaging these groups, fostering positive relationships, and delivering regular feedback would enhance user satisfaction, allow user interface and engagement issues to be proactively tackled, and subsequently enable successful implementation.

Concerning system quality, perceived usefulness and ease of use were deemed as important facilitators for successful implementation. In the literature, intuitive and user-friendly systems have been confirmed to have easier acceptance [36,39]. The modified TAM questionnaire similarly confirmed this in our cohort, particularly through questions concerning acquiring new skills and impact, emphasizing that remote monitoring technology could be readily accepted.

Limitations

This study included key stakeholders belonging to a broad selection of groups (academics, industry, and health care) in order to create a broad understanding of factors that influence implementation of remote monitoring solutions in the NHS. Given that previous studies have focused on end user testing, this study sought to provide a top-down view to give a better understanding of considerations that could influence widespread implementation [16,18]. However, in doing so, our interpretations have some limitations. First, the broad, heterogeneous sample of key stakeholders included may identify issues that are generalizable, but the nonprobabilistic sampling may have resulted in a selection bias. Moreover, the included sample size was limited. Despite this, the use of semistructured interviews yielded pertinent considerations for pragmatic implementation in hospital settings. In addition, differences between various hospitals and departments, which may have different attitudes toward digital technologies, were not explored in this study. A final limitation relates to the HOT-fit framework; although it is considered useful, the mapping of factors is a subjective undertaking and mapping to one specific measure was, at times, difficult.

Acknowledgments

Infrastructure support for this research was provided by the National Institute for Health and Care Research (NIHR) Imperial Biomedical Research Centre and the NIHR Imperial Patient Safety Translational Research Centre.

Data Availability

The data sets used and/or analyzed during the study are available from the corresponding author on reasonable request.

Further Research and Recommendations

Although our cohort showed that there was overall acceptance of remote monitoring technology (Figure 3), there remains a deficiency with respect to successful implementation. This was noted most recently in one study where the median time to acknowledge an alert from health care staff was 111 (range 1-2146) minutes, despite early recognition of deterioration from remote sensing [14]. Therefore, further research should incorporate human factors and behavior evaluation when implementing remote monitoring solutions with the NHS; moreover, implementation frameworks such as HOT-fit should be used to ensure multiple angles have been carefully considered.

To facilitate the effective integration of remote monitoring solutions in clinical workflows, a comprehensive strategic framework is paramount. This framework should prioritize the early involvement of end users, fostering relationships that enable rapid feedback on implementation strategies, user interfaces, and user experience issues. Such engagement allows for iterative enhancements through PDSA cycles, promoting continuous improvement [45].

Industries aiming to develop remote monitoring technologies must collaborate closely with key stakeholders, ensuring the creation of products that provide significant value and feature user-friendly interfaces. This approach emphasizes the importance of a bottom-up strategy in technology implementation, valuing the autonomy and insights of end users, who play a crucial role in the successful adoption of these solutions. Crucial to this process is the establishment of robust infrastructural support prior to the deployment of remote monitoring systems. Adequate resourcing and the involvement of technical support staff are essential to facilitate seamless integration with existing information technology frameworks, thereby enhancing the prioritization and effectiveness of digital health initiatives. By adhering to these guidelines, health care organizations can enhance the integration of remote monitoring into clinical practice, leading to improved operational efficiency, patient care, and overall health care service delivery.

Conclusion

Implementation of remote monitoring solutions in the NHS remains a complex challenge. The results of this study have highlighted key stakeholder perceptions that could influence successful integration. Through the proposed recommendations, there is potential for future remote sensing solutions to be more successfully integrated into our health care practices, resulting in novel pathways expanding beyond virtual wards.

Authors' Contributions

FMI drafted the manuscript. Significant amendments were made by RA, MJ, MW, SK, HA, and AD. All authors approved the final manuscript.

Conflicts of Interest

AD is chair of the Health Security initiative and HA is chief scientific officer at Flagship Pioneering UK Ltd. Flagship Pioneering had no role in the development, conduct, or analysis of the study.

Abstract

Background: As social media platforms gain popularity, their usage is increasingly associated with cyberbullying and body shaming, causing devastating effects.

Objective: This study aims to investigate the impact of social media on Generation Z users' body image satisfaction. More specifically, it examines the impact of TikTok on body image satisfaction among TikTok users aged between 17 years and 26 years in Indonesia.

Methods: The methodology used mixed-method approaches. Quantitative data were obtained from 507 responses to a questionnaire and analyzed using covariance-based structural equation modeling. Qualitative data were obtained from the interviews of 32 respondents and analyzed through content analysis.

Results: This study reveals that upward appearance comparison is influenced by video-based activity and appearance motivation. Conversely, thin-ideal internalization is influenced by appearance motivation and social media literacy. Upward appearance comparisons and thin-ideal internalization comparisons detrimentally impact users' body image satisfaction.

Conclusions: The results of this study are expected to provide valuable insights for social media providers, regulators, and educators in their endeavors to establish a positive and healthy social media environment for users.

Introduction

Background

In 2022, the estimated number of social media users was 4.80 billion, with an expected increase to 7 billion by the decade's end [1]. Concomitantly, the use of social media appears to be increasingly linked to cyberbullying, especially in the context of body shaming—the act of criticizing and stigmatizing

someone's physical appearance [2]. Noteworthy cases involving public figures such as Kylie Jenner and Adele [3,4] underscore the fact that nobody is exempt from such incidents.

Individual perceptions of one's body can range from positive to negative [5], with positive perceptions indicating body satisfaction (BS) and negative perceptions indicating body dissatisfaction. Body image, including BS or dissatisfaction [6], plays a pivotal role in various aspects of psychological development, interpersonal relationships, and overall quality

of life [6,7]. A survey of 5623 adolescents and adults in England by the UK Mental Health Foundation [8] shows that 1 in 5 individuals felt ashamed of their body image, resulting in feelings of anxiety, depression, and even suicidal thoughts. Disturbances in body image perception, such as body dissatisfaction, are pertinent factors in clinical issues, including obesity and eating disorders [6]. Generally, body image perception is an indicator of quality of life [7]. Consequently, understanding the relationship between social media use and body image is essential for addressing these significant issues.

While previous studies have explored the influence of appearance, family, peer, and media pressures on body dissatisfaction among teenage girls (eg, work by Roberts et al [9]), there has been a notable absence of specific attention to the impact of social media activities or aspects on body dissatisfaction. Conversely, Rodgers et al [10] found a connection between social media use, upward appearance comparison (UAC), and body dissatisfaction, with the latter being mediated by the internalization of an idealized appearance. Upward social comparison typically involves evaluating oneself with the aim of self-improvement by assessing the perceived advantages of the objects being compared and learning ways to enhance one's own attributes. Meanwhile, downward comparison is the process of comparing oneself with someone judged to be worse than oneself. Upward social comparison is often deemed unfavorable since the assessed object holds a higher "value" than oneself, while downward comparison is considered favorable as the object holds a lower "value" than oneself [11]. Therefore, this research will primarily focus on the dynamics of upward comparisons.

Furthermore, prior research has predominantly focused on platforms such as Snapchat, Facebook, and Instagram [9,12,13]. Studies related to TikTok delve into areas such as body dissatisfaction [14,15], BS in dancer challenges [16], body neutrality [17], and systematic literature reviews on body image [18]. TikTok has a substantial user base primarily consisting of Generation Z (Gen Z) individuals, aged between 11 years and 26 years, with approximately 37 million users worldwide. Indonesia stands as the second largest TikTok user in the world to date [19,20]. Finally, TikTok is one of the social media that focuses on user-generated videos that display the appearance of the human body, such as content in the category's selfie videos, self-portrait videos, dance, fashion, beauty and skin care, fitness or sports, and entertainment [21]. TikTok also strives to create an environment to support user's body positivity [21].

Conceptual Model

Jarman et al [12] applied the tripartite influence model (TIM) to investigate the relationship between social media intensity, frequency of use, BS, and well-being mediated by internalization and comparison in Australia. However, their study did not explicitly consider content related to appearance. This study uses the TIM, a sociocultural theory that explores the influence of family, friends, and media on body image dissatisfaction and eating disorders. To narrow the focus to social media use, we chose to emphasize 1 sociocultural aspect—social media. TIM suggests that the stimulus aspect has a notable impact on

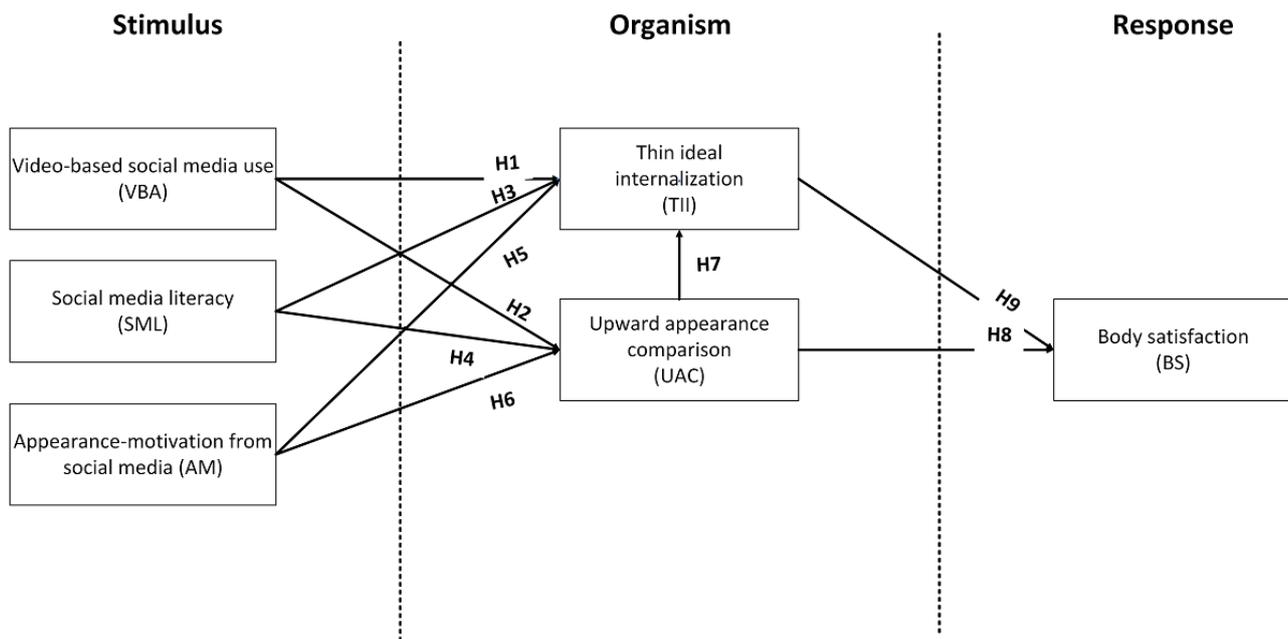

physical appearance [14]; yet, it does not thoroughly address how social media specifically affects body image. To address this gap, our focus lies on social media use involving videos prominently featuring physical appearance. Moreover, we use stimulus-organism-response (SOR) theory to categorize factors into stimulus, organism, and response. The SOR framework states that environmental conditions can present signs that can trigger (stimulus) the inner state of an individual (organism) so that the individual will produce a response (response) in either positive or negative form [22]. The development of SOR theory can help in understanding the reasons behind a person's behavior with the assumption that most human behavior reflects the stimuli we feel, so this theory is very relevant when it is related to problems related to human behavior under certain conditions. The combination of SOR and TIM offers a more comprehensive context for understanding the influence of social media use on human BS, using the explanatory power of SOR theory to delve into the reasons behind human behavior (response) in specific situations.

By focusing specifically on TikTok, we aim to identify the factors within this social media platform that influence BS among Gen Z individuals. Through this investigation, our goal is to shed light on the factors that contribute to body shaming incidents, increase user awareness of the effects of social media on body image perception, and empower individuals to take control of their usage. These insights can also serve as valuable guidance for social media developers, aiding them in creating platforms that foster a positive digital environment. Moreover, stakeholders can use these findings to inform and shape regulatory efforts, contributing to the establishment of a safer digital space.

According to TIM, pressure related to appearance is a consequence of sociocultural factors [9]. Therefore, the use of social media, especially on platforms such as TikTok, offers a means to assess these sociocultural influences. TikTok, being a platform centered around appearance, typically entails activities oriented toward videos (referred to as video-based social media use [VBA]), such as viewing, uploading, and interacting with images of oneself and others [23]. Examining specific activities to measure social media use can facilitate a deeper understanding of how social media affects body image [12].

Mink and Szymanski [14] suggested that variables of social media literacy (SML) could moderate the impact of TikTok usage on body dissatisfaction. Similarly, Tort-Nasarre et al [24] highlighted the importance of this variable in research concerning the impact of social media use on BS, noting that a high level of SML can assist individuals in developing positive body perceptions in conjunction with social media use. Furthermore, Roberts et al [9] indicated that internalization encompasses various aspects, such as thin-ideal internalization (TII), muscular internalization, and social media internalization. For our purposes, we narrow our focus to TII and social media internalization, as these variables are more inclusive of both genders than the more gender-specific muscular internalization. Thus, we propose Figure 1 as our conceptual model.

Figure 1. Proposed conceptual model. AM: appearance-motivation from social media; BS: body satisfaction; H: hypothesis; SML: social media literacy; TII: thin-ideal internalization; UAC: upward appearance comparison; VBA: video-based social media use.

Research Hypothesis

The activities examined in this study pertain to video-related actions because TikTok is a social networking site centered around video-based appearances [14]. According to Mink and Szymanski [14], these activities allow users to engage with the physical representation of other people's lives, including their appearance, through features such as share and comments. TII is an individual's cognitive level to believe and inspire that the ideal social definition of attractiveness, namely a thin appearance, is an actual attractiveness [25]. Jarman et al [12] stated that the use of social media, including the activities carried out on it, is one of the reasons for the internalization of an ideal thin appearance. Jarman et al [12] found that the more frequent use of social media led to a higher likelihood of internalizing an ideal thin appearance. In addition, Duan et al [26] found that people who are involved in activities on social media are more likely to internalize their ideal appearance; in this case, they internalize their appearance to make themselves look thin. Such internalization is made possible because videos posted on social media, such as selfies, can be seamlessly modified and edited using filters, artificial intelligence, and image processing tools and uploaded selectively by people to meet social body standards [27,28]. Considering various activities on social media, such as viewing posts or comments portraying ideal physical appearances on platforms such as TikTok, users are likely to internalize the notion of an ideal thin appearance. Therefore, we assume the following hypothesis:

H1: VBA influences TII.

Users engaging in VBA activities have several goals, such as admiring individuals whose physical appearance aligns with societal standards, maintaining relationships, and receiving visual feedback [29]. However, many studies have found that user participation in activities on social media, such as scrolling through posts adhering to ideal standards [30], uploading content

with positive comments [31], and content receiving numerous likes [32], can negatively impact individual perceptions of body image. As outlined by Mink and Szymanski [14], activities within VBA platforms allow users to be involved with the physical representation of others' lives, including their appearance, through features such as likes, shares, and comments. UAC is an individual behavior where one assesses their appearance against individuals deemed to possess a superior appearance, such as celebrities or social media influencers [33]. According to Wang et al [34], social media users who engage in appearance comparisons often do so with individuals considered superior, especially those portraying an idealized life on social media. This comparison prompts individuals to seek improvement, often leading to the editing of selfies to compensate for perceived weaknesses [27]. Women, in particular, may seek quantitative proof of popularity through metrics such as likes, comments, and followers [28]. After reviewing several previous studies, we posit that UACs, including those with celebrities or influencers, are also influenced by VBA usage activities. When TikTok users encounter videos showcasing an ideal physical appearance uploaded by influencers or celebrities, accompanied by positive reactions from other users, they are likely to initiate comparisons of their own physical appearance with these influencers or celebrities. Therefore, we propose the following hypothesis:

H2: VBA influences UAC.

SML is the application of critical analysis regarding the motivations behind postings on social media and the nature of images that are constructed, generally unrealistically, when viewing images that focus on appearance on social media [35]. According to Tamplin et al [36], a high level of media literacy is characterized by the ability to think critically about media. Tamplin et al [36] explained that the ability to critique idealized performance images, considering their realism and commercial intent, helps offset the impact of viewing these images on

individuals. The level of media literacy is also marked by the ability to judge whether or not an image in the media is intended to reduce the credibility and persuasive influence of the media [37]. Individuals with high levels of media literacy tend to avoid comparing themselves with ideal thin appearances in media that are considered unrealistic [37]. McLean et al [37] also found that media literacy produces a protective effect, in which research respondents who have a low level of critical thinking are easily negatively affected when viewing images that display someone who has an ideally thin appearance, and research respondents who have high critical thinking are not easily negatively affected. Therefore, we propose the following hypothesis:

H3: SML influences TII.

McLean et al [37] explained that individuals with high media literacy tend to prefer to compare themselves with ideal thin appearances in the media, which are considered unrealistic. A high level of media literacy, such as thinking that postings of someone whose physical appearance looks ideal in the media are unrealistic or manipulated, can protect users from upward comparisons, such as those with celebrities or influencers [37]. McLean et al [37] also stated that high critical thinking is a protective factor from a high upward comparison. Mink and Szymanski [14] also found that SML exacerbated the direct relationship between TikTok use and UACs. When users have low SML skills, they may not be able to determine the authenticity of the TikTok videos they see. They may need to realize that the videos have been edited or changed [14]. Therefore, we assume the following hypothesis:

H4: SML influences UAC.

Appearance motivation (AM) from social media is a feeling that arises when individuals want to look attractive and try to improve themselves because they are motivated by messages conveyed by the media [10]. The media plays an important role in spreading the message that an ideal appearance is a good thing, such as popularity, and success can be achieved if someone has an attractive appearance [38]. Attractive appearance in the media has standards, such as that women must be young, thin, and sexy [38]. When the message reaches the audience, they will become motivated and try to change their appearance to make it look more ideal [38]. In addition, Kvardova et al [39] explained that the effects of media use tend to affect the internalization of an ideal thin appearance. In line with Wilson et al [40], internalizing an ideal thin appearance can be interpreted as an indicator of a motivational approach to thin bodies. According to Graff [41], social media displays content that is somewhat unrealistic and causes users to compare their appearance, thus motivating them to engage in diet and exercise. Therefore, we propose the following hypothesis:

H5: AM from social media influences TII.

Motivation for appearance from social media is a feeling that arises when individuals want to look attractive and try to improve themselves because they are motivated by messages conveyed by the media [10]. The motivation to improve by making comparisons based on the desire to improve aspects of oneself has been associated with increased exercise activity and

BS [15]. When individuals are motivated to improve their physical appearance, they tend to make upward social comparisons [42], such as following attractiveness standards by changing their physical appearance to become ideally thin [43]. In addition, when individuals are urged to improve themselves, they will compare themselves with others who are better off, such as idealized models in the media [10]. Then, we suggest the following hypothesis:

H6: AM from social media influences UAC.

UAC indicates that individuals evaluate their appearance against other individuals who are considered to have a superior appearance than themselves, such as celebrities or social media influencers [44,45]. TII or internalization of an ideal thin appearance is an individual's cognitive level to believe and inspire that the ideal social definition of attractiveness, namely a thin appearance, is an actual attractiveness [25]. Rodgers et al [10] found that social media use may be associated with body dissatisfaction through comparisons of upward appearance and internalization of thin appearance. According to Seekis et al [45], a comparison of upward appearances with celebrities or health influencers leads to the drive to be thin and dissatisfied, respectively. In addition, according to Hsu et al [46], internalization measures of ideal thin appearance include statements that assess the degree of comparison with an ideal thin body, such as "I wish I looked like a swimsuit model" and "I often read magazines such as Cosmopolitan, Vogue, and Glamor and comparing my looks to models." Therefore, we assume the following hypothesis:

H7: UAC influences TII.

Social media impacts the development of body dissatisfaction through 2 channels: the comparison of appearances on social media and the internalization of ideal appearance [12]. According to Wang et al [34], social media users who compare themselves may engage in upward comparisons, considering the appearance and ideal life posted on social media, which is likely to have a detrimental effect on BS and well-being. According to the TIM, exposure to the media can increase the likelihood that individuals will adopt an ideal appearance as their standard and contribute to a greater tendency to compare their physical appearance with someone's unrealistic uploads in the media [12]. Individuals who compare themselves with social media's ideal physical appearance standards will likely feel that they do not conform to them, reducing their BS [12]. Mink and Szymanski [14] showed that the more often individuals use TikTok, the more they engage in appearance comparisons and the more body dissatisfaction they experience. Today, individuals have access to people worldwide, meaning that comparisons can occur at an unprecedented level and scale [47]. Thus, we assume the following hypothesis:

H8: UAC influences BS.

TII or internalization of an ideal thin appearance is an individual's cognitive level to believe and inspire that the ideal social definition of attractiveness, namely a thin appearance, is an actual attractiveness [36]. Individuals often post carefully edited and curated content about their physical appearance, which presents unrealistic content to make them appear

attractive [25]. Rodgers et al [10] stated that individuals involved in internalizing an ideal appearance have a lower level of performance satisfaction. Individuals use media content as a source of information about how to improve their physical appearance and compare their physical appearance with media models to set standards that must be met [10]. Jarman et al [12] also found that internalizing an ideal thin appearance is inversely related to BS. Exposure to images on social media internalizing an ideal thin appearance causes dissatisfaction with the body and face of the individual [32]. Thus, we propose the following hypothesis:

H9: TII influences BS.

Methods

Study Design

This study used a mixed methods approach using questionnaires (quantitative approach) and interviews (qualitative approach). A readability test was carried out on the questionnaire to verify the appropriateness of the questions within the research context. This assessment encompassed an examination of the diction

and grammar used in the questionnaire to ensure clarity. The primary aim was to ascertain that all questions and instruments in the questionnaire could be easily and clearly understood by the respondents. The readability test was carried out for 6 days with a total of 13 respondents. This evaluation took place through both digital and offline channels. We conducted a pilot study of 33 respondents where the Cronbach α (CA) value for each construct was more than 0.7 [48].

The questionnaire link was distributed through various social media, such as Instagram, Twitter, Line, and WhatsApp, from February 28 to March 29, 2023, with a total duration of 30 days. Respondents involved in this study are TikTok users who are Gen Z (aged between 17 years and 26 years). Most of the respondents are in Greater Jakarta and are bachelor students. Most users' frequent activities on TikTok are liking videos and they often view content related to physical appearance as well as seeing body shaming comments on TikTok. This study obtained 507 respondents, and Table 1 summarizes the demographics of the respondents. After obtaining quantitative data, we collected qualitative data by conducting interviews with 32 TikTok users in the age range of 17-26 years.

Table 1. Demographics of respondents who filled out the questionnaire.

Demographics	Respondents, n (%)
Gender	
Men	134 (26)
Women	373 (74)
Age (years)	
17-19	76 (14.99)
20-22	339 (66.86)
22-26	92 (18.15)
Domicile	
Greater Jakarta	312 (61.54)
Java Island outside Greater Jakarta	125 (24.65)
Outside Java Island	70 (13.81)
Education	
High school students	93 (18.34)
Diploma students	45 (8.88)
Bachelor students	355 (70.02)
Master students	14 (2.76)
Reasons to use TikTok	
Entertainment	421 (47.09)
Increase creativity	129 (14.43)
Know the latest information	301 (33.67)
Add friendship	29 (3.24)
Others	14 (1.57)
Most frequent activities on TikTok	
Upload a video	128 (18.47)
Comment on a video	132 (19.05)
Like a video	433 (62.48)
Frequency of viewing content related to physical appearance on TikTok	
Never	15 (2.96)
Rarely, occasionally when using TikTok	244 (48.13)
Often, every time TikTok is used	248 (48.92)
Frequency of seeing body shaming comments on TikTok	
Never	51 (10.06)
Rarely, occasionally when using TikTok	220 (43.39)
Often, every time TikTok is used	236 (46.55)

Quantitative data for this study were processed using the covariance-based structural equation method (CB-SEM) using the AMOS 24 (IBM) app, SPSS Statistics (version 27; IBM Corp), Google Sheets, and Excel (Microsoft Corp). CB-SEM aimed to confirm the relationship between variables defined theoretically in a model, attempting to minimize the differences between the covariance matrices implied in the model and the covariance matrices obtained from research samples [48]. The CB-SEM procedure included 3 stages: model specification, measurement model evaluation, and structural model evaluation

[48]. In addition, content analysis was used to process qualitative data.

To analyze in more detail the results of hypothesis testing, interviews were conducted with respondents aged between 17 years and 26 years who had at least actively used the TikTok application. A total of 32 respondents were interviewed from April 19, 2023, to May 13, 2023, digital and offline. All interview results obtained were then processed and analyzed using one of the qualitative data processing methods, namely

content analysis. This stage produces an interpretation of all patterns resulting from the interview process so that it can support the explanation of the hypothesis results in this research.

Research Instruments

The questionnaire was composed of 4 parts. The first part contained instructions for filling out the questionnaire, the respondent's consent, and validation that the respondent is a TikTok application user and is aged 17-26 years. The second part contained questions on the demographics of the respondents. The third section contained general information about the TikTok application, physical appearance content, and body shaming. The fourth section contained 32 measurement items. [Multimedia Appendix 1](#) describes the questionnaire used in this study, and [Multimedia Appendix 2](#) explains the interview questions for each hypothesis.

Ethical Considerations

This study has obtained approval from the research unit of the Faculty of Computer Science, University of Indonesia (letter S-1/UN2.F11.D1.5/PPM.00.00/2024). In accordance with the Decree of the Board of Trustees of the University of Indonesia, based on the research ethics policies applicable to members of the faculty of the University of Indonesia, each research unit or

department implements research supervision guidelines, and oversees and adheres to the responsibilities prescribed therein. In line with university policy, the Research and Community Service Department, Faculty of Computer Science, University of Indonesia, adhere to the guidelines and procedures established by the faculty and provided ethics approval for this study. All respondent data were anonymized and exclusively used for the purposes outlined in this research. All questionnaire respondents provided written informed consent, and all the interview respondents provided verbal informed consent to participate in this study.

Results

All variables in [Table 2](#) surpass the 0.50 threshold of average variance extracted values, indicating the successful representation of the variables by their respective indicators. Additionally, the reliability of the measurements was assessed using CA and construct reliability. All CA and construct reliability values met the recommended minimum threshold of 0.7, signifying strong reliability [48]. Goodness-of-fit index values are outlined in [Table 3](#), while [Table 4](#) provides an overview of the R^2 values.

Table 2. CR^a, CA^b, and AVE^c values.

Variable	CR	CA	AVE
Video-based social media use	0.858	0.896	0.559
Social media literacy	0.788	0.826	0.712
Appearance motivation	0.917	0.888	0.948
Thin-ideal internalization	0.910	0.936	0.857
Upward appearance comparison	0.881	0.913	0.750
Body satisfaction	0.922	0.933	0.834

^aCR: construct reliability.

^bCA: Cronbach α .

Upward appearance comparison	0.451
Thin-ideal internalization	0.452
Body satisfaction	0.099

Next, the hypothesis testing carried out is a 2-tailed test. Hypothesis testing can be done by looking at the significance value or P value. Since the test is carried out in 2 directions, this test uses a significance of 5%, which means that a

hypothesis with a P value of $>.005$ is rejected and vice versa is accepted [48]. Based on Table 5, 2 of the 9 hypotheses were rejected because they had a P value of $>.005$.

Table 5. Hypothesis testing results.

Hypothesis	Estimate	P value	Description
H1: VBA ^a influences TII ^b	-0.082	.19	Rejected
H2: VBA influences UAC ^c	0.469	.002	Accepted
H3: SML ^d influences TII	-0.14	.001	Accepted
H4: SML influences UAC	-0.083	.06	Rejected

^bTII: thin-ideal internalization.

^cUAC: upward appearance comparison.

^dSML: social media literacy.

^eAM: appearance motivation.

^fBS: body satisfaction.

This study concludes that there is no significant relationship between the activity of using VBA and the internalization of an ideal thin appearance. TikTok shares this observation by expressing its commitment to supporting existing content to be more inclusive and a “body-positive environment” [21]. Some of the steps taken by TikTok are increasing restrictions on ads that promote negative body image, reducing advertisements for diet products that exaggerate their promotion, working with creators to promote body positivity, and working with various organizations to help people who experience body image problems [21]. Respondents also felt that an ideal body does not mean thin or slender physical appearance: “In my opinion, a body that is still classified as ideal is if the body is slightly heavier than BMI. If a thin body is not ideal in my opinion” (interviewee 27) and “Body ideal is a body that is not thin and not fat” (interviewee 2). Then, respondents who feel their physical appearance is thin enough or feel their physical appearance is good enough have no desire to be thinner anymore: “Not really wanting to change their appearance to be thinner, but more motivated to change their lifestyle to be healthier” (interviewee 4). This is also encouraged by the growth of TikTok content, which promotes self-love or body positivity toward physical appearance and can improve the mental health and well-being of its users [49]. This movement changes the perspective of its users in viewing their physical appearance positively [49]. They realize that they are not alone when they feel insecure and know that many other users on TikTok are spreading this positive movement [49].

In addition, the relationship between the activity of using VBA influences the UACs. This is in line with Mink and Szymanski [14], who stated that the longer an individual uses TikTok, the more involved they are in comparing appearance and the more they will watch their body. In addition, Jarman et al [12] stated that when individuals are exposed to content on social media, the ideal body for them is the body they see. The impact is that they will compare their appearance with this ideal body perception and tend to produce negative self-evaluations [12]. Furthermore, the results of this hypothesis were strengthened by the results of qualitative interviews, which explained that respondents felt that the longer they opened TikTok, the more they would be increasingly exposed to physical appearance content that displays ideal body standards according to users. At first, they just admired, but over time, the respondents wanted to look as good as the people in the content they saw on TikTok: “If you look at a tall physical appearance, especially men, it will affect self-assessment and comparison with that person” (interviewee 20). In addition, this is exacerbated by the TikTok algorithm, which recommends videos according to the number of viewing likes: “Because I often see physical appearance content, especially for women who like to upload dance content on TikTok, I wonder why people that person is prettier than me. That person has clean skin, and I am also influenced to use skin care so that I look as good as the person I see on TikTok” (interviewee 32). This is also directly supported by TikTok, which explains that their recommendation system works after looking at user preferences through various interactions, such as comments or following certain accounts [49].

This study found that SML influences the internalization of an ideal thin appearance, which aligns with McLean et al [37]. In addition, Tamplin et al [36] explained that the ability to critique idealized performance images, considering their realism and commercial intent, helps offset the impact of viewing these images on individuals. Furthermore, the results of this hypothesis are strengthened by the results of qualitative interviews, which explain that respondents tend to be more aware of content that promotes a thin body as the ideal body, especially in less realistic content, for example, the TikTok trend to show a thin body: “If you have to the point that it is unrealistic, it is very toxic and destructive. If it is more realistic, in my opinion it is quite good, such as the promotion of a healthy lifestyle” (interviewee 19) and “This trend is not good because it sets new standards that lead to body shaming if you don't meet these standards” (interviewee 27). In addition, respondents believe more in content that promotes a slim body is an ideal body if the content creator has credibility, for example, a nutritionist and bodybuilder: “If the content is made by a health professional and can prove it, I agree with the content” (interviewee 26). This is in line with Mink and Szymanski [14], who explained that it is easy for individuals to determine the authenticity of the content they see when they have high SML.

Moreover, this study observed that there is no significant impact of SML on UACs. This is in line with Mink and Szymanski [14], where individuals who have strong SML skills can inadvertently make appearance expectations and appearance evaluations more prominent in women's minds. Hence, women must change their physical appearance by using filters or editing to look as good as people they find attractive. The results of this hypothesis are strengthened by the results of qualitative interviews, which explain that respondents still compare their physical appearance with people they consider better looking in TikTok even though their level of SML is already high, for example, by knowing the use of filters on the videos they watch: “Ever compared because they saw other people use filters too and are curious about how they look on their own faces” (interviewee 7) and “I've compared if it matches my preferences. There was also a thought that I wanted to be like him because it's more in line with preferences and just looks better” (interviewee 29).

Furthermore, this study revealed that AM from social media influences the internalization of an ideal thin appearance, and this result is in line with Trekels and Eggermont [38], where attractive appearance in the media has standards, such as that women must be young, thin, and sexy. When the message reaches individuals, they will become motivated and change their appearance to make it look better [38]. Furthermore, the results of this hypothesis are strengthened by the results of qualitative interviews, which explain that respondents are motivated after watching content that promotes better physical appearance, such as exercise and a healthy lifestyle: “Feel motivated to look more attractive when viewing makeup, skin care, or sports content” (interviewee 5) and “Ever motivated after seeing only gym content but wasn't interested in looking thin like a model” (interviewee 1). After being motivated, the interviewees felt moved to change their physical appearance by doing the same thing to have an equally good physical

appearance. In line with Trekels and Eggermont [38], the media is important in spreading the message that an ideal appearance is a good thing. For example, popularity and success can be achieved if someone has an attractive appearance.

This study affirmed that social media AM influences the UAC, which is in line with Rodgers et al [10,42], where when individuals have the drive to improve themselves, they will compare themselves with other people who are better looking for them, such as idealized models in the media. In addition, when individuals are motivated to improve their physical appearance, they tend to make upward social comparisons [42,43]. Furthermore, the results of these hypotheses were strengthened by the results of qualitative interviews, which explained that 24 out of 32 (75%) respondents felt that if they watched a video that presented an ideal physical appearance in their opinion, the respondents wanted to know whether their physical appearance was as good as the ideal standard derived from the video they watched: "Once motivated to eat healthy food made by people on TikTok, where they have more fit bodies, so they are influenced to make that food" (interviewee 5). In line with Grabe et al [43], when individuals feel motivated to improve their physical appearance, they follow attractiveness standards by changing their physical appearance.

In addition, respondents also felt that content displaying an ideal physical appearance on TikTok received validation, such as praise comments. Hence, respondents felt motivated to change their physical appearance to be more ideal: "Very motivated to look cool and handsome because people also commented that interesting in the content" (interviewee 20) and "Motivated to look more ideal because if you upload a video later the audience will definitely like it and there will be lots of laudatory comments" (interviewee 3). This aligns with Trekels and Eggermont [38], in which media messages that focus on appearance can be strengthened through validation from others, such as comments. Rodgers et al [10] also explained that comments from users on social media on content that focus on physical appearance explicitly describe appearance comparisons and can encourage other users to engage in physical appearance comparisons.

The comparison of upward appearance is found to influence the internalization of an ideal thin appearance. This is in line with the research of Seekis et al [45], where when individuals have the desire to look as good as celebrities and influencers, there is an urge to change their physical appearance to become thinner. Furthermore, the results of the hypothesis are strengthened by the results of qualitative interviews, which explain that respondents try to look as good as people they consider ideal on the TikTok app: "Ever compared with thinner people. Feeling a thin body is interesting and has quite an impact on my thoughts towards an ideal body because it indicates the person has a healthy lifestyle" (interviewee 28). They usually assess to measure how far their score is from the ideal value so that when they feel they have not met these ideal standards, they tend to internalize new ideal standards: "Ever compared and tried to measure whether my body already looks the same as his, because almost every I watch TikTok every day and see interesting people, so it has quite an influence on the perception of an ideal body and beauty standard" (interviewee 3) and "Because I

compare things, I can know what the ideal point is like. If I'm not ideal, I will do certain activities so that I can be as ideal as that" (interviewee 26). This is in line with Hockey et al [50] and Shen et al [51], who stated that the effect of using social media is associated with a high level of comparison and ultimately leads to internalization of the ideal thin appearance of its users.

Next, individuals who compare themselves with ideal physical appearance standards on social media will most likely feel that they do not conform to these standards, thereby lowering their level of BS. This is in line with Weinstock [47], where individuals not only compare themselves with others, but they also compare themselves with other people's optimized versions thanks to video editing apps, which can worsen mental health and lower the individual's level of satisfaction. Conversely, the respondents have no desire to have the same physical appearance as the videos they watch on the TikTok app because their BS tends to be high: "Does not affect self-satisfaction because they are already satisfied with their current physical appearance" (interviewee 25) and "Comparing physical appearance to the one in the video doesn't really affect self-satisfaction because you feel enough with what you are now" (interviewee 18). They already feel sufficient and confident with their current physical appearance: "I don't compare with other people; I don't even care about the scales either. Now, I just look in the mirror and observe whether I have approached the ideal body or not. I feel quite satisfied when, for example, I wear clothes and look good when worn" (interviewee 5). This is also in line with Rodgers et al [10], who stated that high self-confidence or self-esteem tends to result in lower levels of dissatisfaction, especially among women.

This study found that internalizing an ideal thin appearance is inversely related to BS. When individuals are not affected by internalizing the thin appearance of the content they see on social media, they tend to be satisfied with their current physical appearance [12]. Furthermore, the results of this hypothesis are strengthened by the results of qualitative interviews, which explain that 17 out of 32 (53%) respondents internalize the ideal thin body standard with what they see on the TikTok app, so most of their BS levels are also affected because they feel they have not met the ideal body standard. This is in line with Tiggemann et al [32] about exposure to images on social media related to the internalization of an ideal thin appearance, causing dissatisfaction with the body and face of the individual. We found a pattern suggesting that the influence depends on the level of self-acceptance of the respondents. With this internalization, if the current body condition is not per the ideal standard and respondents have low self-acceptance, then they will tend to be affected because they have not accepted the current body condition. Conversely, if respondents already have self-acceptance, they tend to be more accepting of all their body conditions and produce a stable level of BS. This is also in line with Rodgers et al [10], who stated that high self-confidence or self-esteem in individuals tends to result in lower levels of dissatisfaction, especially among women.

Discussion

Principal Findings

The desire to resemble celebrities seen on TikTok (UAC) is shaped by various activities on the platform, including watching videos, perusing comments and likes, and uploading content (video-based activity). TikTok exposes users to diverse physical appearances that are often perceived as more appealing, encompassing facial features, skin type, color, and body shape. Exposure to such diverse physical attributes prompts unconscious self-evaluation, fostering a longing to emulate those deemed more attractive. This desire is further influenced by the heightened motivation to present oneself attractively on social media (AM). Greater motivation heightens the aspiration to mirror the perceived attractiveness of these individuals [38].

Moreover, this study found the development of TII is influenced by AM, SML, and UAC. The drive to present attractively on TikTok (AM) shapes the perception of an ideal body. Regular exposure to videos emphasizing a “thin body as the ideal” (TII) fosters the internalization of this concept. Conversely, users with a higher level of SML can discern realistic content, thus avoiding the internalization of potentially harmful ideals. Although the TikTok algorithm aids in content curation, personal discernment becomes crucial; failure to discern can lead to increased exposure to harmful content. The aspiration to resemble individuals observed on TikTok (UAC) prompts a comparative self-assessment, often yielding unfavorable outcomes, as users perceive those they watch as possessing more attractive physical attributes. This perpetuates an ideal that equates thinness with attractiveness, further reinforcing TII.

Consequently, the intense desire to emulate others on TikTok (UAC) contributes to a diminished self-assessment, fostering a heightened awareness of one’s perceived inadequacies and resulting in body dissatisfaction. Similarly, strong adherence to thin body standards establishes unrealistic benchmarks, potentially leading to dissatisfaction when one’s appearance fails to meet these standards.

Notably, the shift from the original appearance pressure variable to the AM variable revealed its influence on TII and UAC. Findings from the qualitative analysis indicate that users are motivated by positive comments on content, driving a desire to emulate the praised appearance of content creators, aligning with Trekels and Eggermont [38], who highlighted the reinforcement of appearance-focused media messages through social validation. Furthermore, this study indicates that users’ SML levels impact TII but do not significantly affect UAC. Despite users’ adeptness in discerning social media techniques, they still compare themselves with physically attractive

individuals, as seen in their social media feeds. Notably, video-based activity, an original stimulus variable in the TIM, does not significantly impact TII. This contrasts with previous findings [14,26,28], supported by statements from other sources, including research results [50] and statements from social media platforms, such as TikTok [21] and Instagram, signaling a changing trend in the perception of the ideal body, emphasizing self-love and body positivity.

This study establishes the significant impact of organismal variables, namely UAC and TII, on the response variable, BS. Prior research has highlighted the negative impact of comparing oneself with others on social media, leading to decreased BS [9,12,14]. Conversely, individuals exhibiting self-acceptance tend to maintain stable levels of BS [10]. Similarly, previous studies emphasize that internalizing the ideal thin appearance from TikTok content leads to dissatisfaction with one’s physical appearance, while self-acceptance fosters stable BS [10,32].

Practically, these findings offer crucial insights for TikTok, a platform that frequently features content related to physical appearance, aiming to mitigate its potential negative impact on users’ BS. Ong and Sündermann [52] found that a self-guided mHealth app could improve body image concerns and self-compassion in young adult university students. Moreover, a social media-based, fictional 6-episode video series with self-guided web-based activities for improving body image could increase trait BS and mood and decrease internalization of appearance ideals [53]. Therefore, this research encourages the development of a healthier social media environment, fostering users’ mental well-being and comfort.

Limitations

This study has two limitations. First, respondents mostly live in the greater Jakarta area which is the biggest city in Indonesia. Second, the respondents for this study are predominantly undergraduate students who are either currently pursuing or had completed their undergraduate education. Therefore, the background of the area and current activities of these respondents may impact the results of this study which are only based on the perspectives of students and users in the big cities in Indonesia. Future studies could be carried out to involve respondents from urban areas and other users in smaller cities. However, it is important to acknowledge that these limitations align with a survey conducted by the IDN Research Institute [22]. The survey indicated that over 70% of Gen Z individuals in Indonesia are still in junior high school and senior high school, while the percentage of Gen Z individuals currently pursuing education beyond high school is only 10.36% [22]. Future studies are expected to provide comparisons between the results of this study and studies involving other generations and other social media.

Abstract

Background: Digital health interventions (DHIs) could support prevention and management of cardiometabolic disease. However, those who may benefit most often experience barriers to awareness and adoption of these interventions.

Objective: Among South Asian individuals, we evaluated user experience of DHIs for prevention and management of cardiometabolic disease, aiming to understand barriers and facilitators to initial and ongoing use.

Methods: Among South Asian individuals recruited via primary care, community organizations, and snowball methods (n=18), we conducted “think-aloud” interviews using a reflective and reactive approach. Participants included nonusers, as well as those that used a range of DHIs as part of monitoring and improving their health. Participants were asked to think aloud while completing a task they routinely do in a familiar DHI, as well as while setting up and completing a search task in a novel DHI; they were encouraged to behave as if unobserved.

Results: Lack of cultural specificity was highlighted as reducing relevance and usability, particularly relating to dietary change. Preferred features reflected individual health beliefs and behaviors, digital skills, and trust in DHIs. For example, tracking blood glucose was considered by some to be positive, while for others it caused distress and anxiety. Similarly, some users found the novel DHI to be extremely simple to set up and use, and others grew frustrated navigating through initial interfaces. Many participants raised concerns about data privacy and needing to agree to terms and conditions that they did not understand. Participants expressed that with information and support from trusted sources, they would be interested in using DHIs as part of self-management.

Conclusions: DHIs may support South Asians to prevent and manage cardiometabolic disease, but it is important to consider the needs of specific user groups in DHI development, design, and implementation. Despite motivation to make health changes, digital barriers are common. Cultural appropriateness and trusted sources (such as health care providers and community organizations) have roles in increasing awareness and enabling individuals to access and use DHIs.

Introduction

Use of digital health interventions (DHIs) for prevention and management of cardiometabolic diseases (CMD), such as diabetes, heart disease, and hypertension, has increased rapidly in the National Health Service (NHS) [1-3]. Digital health approaches, such as support with diet, activity, self-management, and remote monitoring, have shown some patient benefits, including reduction in cardiometabolic risk factors and outcomes [4,5], glycemic control [6], and reduced hospitalizations [7]. However, increasing use of DHIs may exclude some populations, particularly ethnic minorities at greater risk of health inequalities [8,9].

Although there is evidence related to improving accessibility of DHIs in African-American populations [10,11], there is limited evidence related to DHIs in South Asian populations in the United Kingdom [12,13], who face increased risk of CMD [14] and may be more likely to experience digital inequalities [15,16]. Previous research in South Asian populations in the United Kingdom considered acceptability and design issues related to SMS text messaging services [17]. Among South Asians, lack of awareness and the process of downloading and setting up DHIs have been identified as being specific barriers to ongoing engagement with digital health [18].

Approximately 25% of all apps are estimated to be uninstalled after only one use [19]. A meta-analysis of app use for chronic disease found that in real-world studies lasting between 2 weeks and 1 year, average attrition rate (negligible or ceased use) was 49% [20]. Understanding how participants react and interact with new DHIs and what features encourage them to explore further or stop use could inform recommendations for improvement. As more complex digital approaches (such as remote monitoring and virtual wards) are widely adopted, it is important to understand the needs of different population subgroups, such as South Asians. We aimed to understand the experience of DHI use by South Asian individuals with CMD, as well as how design and implementation can be improved to support uptake and use.

Methods

Ethical Considerations

Ethical approval was by the NHS London - Brent Research Ethics Committee (IRAS 261047). Informed consent was obtained from participants through a written consent form that was explained by the researcher. Participation was voluntary and participants could withdraw at any point of the study. There were no direct risks involved for participants. Data collected were deidentified and stored securely in accordance with the institution's data management policies. Participants were reimbursed £50 (US \$65.62) for their time.

Think Aloud Interviews

A mixed (reactive and reflective) "think aloud" interview approach was used [21-23]. Interviews were conducted by MR and NK, who are both experienced qualitative researchers. Recruitment was via primary care, community organizations, and snowball methods, ensuring representation across South

Asian ethnicity, age, geography, generation, and gender. Participants were English-speaking, had or were at risk of diabetes and/or heart disease (ie, prediabetes was included), and had access to a suitable device (smartphone, tablet, or laptop). Participants were offered WiFi access to facilitate downloading the app, if required.

After written informed consent, interviews lasting 45 - 60 minutes were conducted by MR or NK in person, at a location convenient to participants. Participants were advised that the interview would be audiotaped, would be used for research purposes only, and would not be accessible to anyone outside the research team. It was stressed that the opinions of the participants were important, that there were no right or wrong answers, and that they could withdraw at any time. The interview guide is provided in [Multimedia Appendix 1](#).

All participants were asked to use their device to navigate to the NHS website while explaining what they were doing as a warm-up think aloud activity. Participants who currently used a DHI were asked to navigate through it as usual, narrating what they were doing and why, for example updating and checking their step count.

All participants (including those who did not currently use a DHI) were asked to participate in the next part of the think aloud interview, involving an unfamiliar smartphone app chosen from a list provided by the research team. The 3 options were chosen from commonly used apps in a previous survey, which were in line with interview participant preferences for DHIs that were free, provided by a trusted organization (NHS), and available in iOS and Android online stores [18]. Participants were asked to choose 1 of these 3 apps ahead of the interview and to download it to their device. Support and WiFi were provided to those who needed to download the app during the interview.

Participants were asked to think aloud about the process of setting up these apps and, if they were able and willing to continue, to undertake one action on the app (eg, navigating to a specific page of the selected app). In the second half of the interview, participants were asked to describe and explain their thoughts and preferences on the use of DHIs to the interviewer, with the option of using their devices to demonstrate their views. Discussions focused on exploring use of technology as part of health, as well as barriers and facilitators to use. Participants were provided with a £50 (US \$65.62) retail voucher as compensation for their time.

Recordings were professionally transcribed, and a reflexive thematic approach was taken to analysis [24]. Familiarization and initial coding was completed by MR and DRP, and merged for comparison. Through discussion between MR, DRP, NK, and DS, code definitions were revised, and transcripts further iteratively coded. These discussions drew on the team's experiences in human-computer interactions, think aloud and qualitative methods, health inequalities, and long-term health conditions. Codes were initially grouped by MR, and themes were developed collaboratively through reflective notes and discussion between MR, DRP, DS, and NK.

Results

Participant Characteristics and Current App Use

A total of 18 participants with CMD were recruited, representing a range of gender, age, and ethnicity ([Table 1](#)). Most participants

(n=11, 61%) currently used at least one DHI on their mobile phone, and a further 2 participants (11%) used their desktop, for example to access patient portals. Participants who did not use DHIs beyond receiving SMS text messages as part of appointment or other reminders were also included (n=5, 28%).

Overall, participants described their DHI use as relating to information seeking; supporting exercise and well-being; accessing resources recommended by health care professionals; booking appointments or checking test results; home monitoring

(eg, for atrial fibrillation); and managing diabetes (continuous glucose monitoring [CGM]). Familiar DHIs demonstrated in the first think aloud task included the following: the NHS or NHS Covid app (n=3); wearable step counter (n=3, including

one without an associated app); in-built mobile app used for step tracking (n=3); gym and fitness app (n=1); CGM app (n=1); heart rate monitoring app for atrial fibrillation (n=1); and no DHIs (n=6). Apps chosen in the second think aloud task (novel DHI) included Active 10 [25] (n=11); Weight loss [26] (n=4); and Couch to 5K [27] (n=2). One participant was not able to proceed with app download but participated in the interview.

The key themes identified included facilitators and barriers to use of digital tools for health; terms and conditions, permissions, and data privacy; the changing role of DHIs in addressing health needs over time; and personalization and adaptation to meet needs. Finally, participants offered recommendations for improvement of design and implementation.

Facilitators and Barriers to Making Good Use Of Digital Tools for Health Management

All participants included in the study had a smartphone but had varying levels of engagement with digital health: "...it's not that we are not using [smartphones]. We are still using it but maybe not as freely as others would. If we could motivate ourselves a little bit more, maybe we could all make good use of it." [int 14, female, 53 years old]. Several common barriers to digital uptake were described by participants who had limited or no knowledge of digital health, including lack of digital skills, fear, and previous negative experiences such as scams, viruses, or errors leading to loss of money. Participants also spoke about barriers faced by others, including language, literacy, and digital access. Together these barriers had an impact on the ability of participants to interact with health services:

If they're not answering the phone...they say "...make an appointment online." But what am I supposed to say? I don't know how to, you know, I haven't got the app...So everything is made difficult for us. [int 03, female, 49 years old, DHI nonuser]

Although some described themselves as not confident digitally, they were able to use an app if they had support in setting it up, such as in the place they receive care, or from family members or friends, they would be able to continue with app use independently. However, a few highlighted that while it was easier for family members to do it, then teach them, they were afraid about what would happen when their children left home, particularly as more services became digitized:

There's something that as you're getting older you think, this is digital...I'm like, God what can I do? Especially when the kids leave and everything, me and my husband we're just going to be stuck...You know nobody's reached out to us. So we're just stuck where we are. [int 03, female, 49 years old, limited use]

In the think aloud section related to setting up a novel (to participants) app, participants who considered themselves to be digitally confident found the process to be relatively easy and completed it swiftly. However, 5 of the 18 participants did not finish: 1 was unable to begin the task ("I don't know how to download other apps." [int 10, male, 71 years old, nonuser]) and 2 others did not have the digital skill to proceed. One participant told us: "[I don't know] the simplest sign like swipe

to the left or right or do this" [int 03, female, 49 years old], echoing other participants' reflections on the lack of clarity or instructions about what to do when setting up or using an app for the first time.

Features that promoted engagement with the app included a simple interface, with clear presentation of available functions, and clear signposting and navigation. For example, one participant, who was using an affordable, wearable exercise tracker that did not have an app, praised the simplicity of the design and how it met her specific needs as she could "keep pressing [a button to] look at the time and my steps and that's it" [int 03, female, 49 years old]. The inclusion of pictures and descriptions was praised as something that made it easy for anyone to operate, including those with language barriers. However, gaps were identified, including voice recognition not being good at picking up accented English, a lack of culturally specific information, and apps not always returning relevant results. For example, in relation to an app that was able to calculate calories based on a photo, one participant described its limitations:

You know if it's just standard [Asian sweets] like gulab jamun...if you take a picture of that obviously you've got hundreds...of pictures of it on the internet but if it's some other Asian dessert that's not as common as that, the app might get a bit confused to what you're eating. [int 05, male, 40 years old, DHI nonuser]

Participants who were already using DHIs reported starting using them for a number of reasons, including the following: it was recommended by friends and family, some of whom also installed the app; a need to engage with new digital modes of contact with health care; a recommendation from their health care team as part of routine management; and increased confidence from app use in other areas (such as banking). Some participants described being willing to use DHIs, but they were not aware that they existed, needed more information about their function, or wanted recommendations from trusted sources such as the NHS.

For some, while they might use digital tools in other aspects of their life, limiting their digital use for health self-management was a choice. They expressed a preference to speak to another person directly (on the phone or face-to-face); found no benefit to app use over existing actions to manage their health condition; or considered current service provision to be satisfactory and did not need to use digital to engage with health care providers: "...I can order [my prescriptions] as well through my app but I have not done it so far...usually they already given me [paper copy]..." [int 18, male, 77 years old, DHI user]

Design and implementation features that participants highlighted as specific barriers to initial and continued use of digital for health purposes included the affordability of DHIs, complexity of sign-ins to maintain security, and suitability to manage their health needs. Affordability was raised in particular regarding CGM, which is available through the NHS for all adults with type 1 diabetes and for some adults with type 2 diabetes (eg, if insulin-treated or other clinical need is identified) [28]. The need to set up health apps in a secure fashion, such as

remembering passwords, entering a lot of information, or setting up other security features, caused some people to pause the setup process to seek help or terminate the activity:

But it was quite difficult actually to go through the process [of setting up the NHS app to use the COVID passport]...they ask for the information but then they weren't recognising like the face recognition... [int 01, male, 52 years old, DHI user]

Linked to the reasons for stopping app setup, participants identified reasons that they might choose not to use the app. These include malfunctions (such as the app freezing or not syncing), needing to repeat log-in and administrative tasks, or a lack of integration with other apps—for example, participants might have to use multiple portals for appointment booking, reminders, and viewing test results. In addition, 2 participants described apps as having poor usability for individuals with complex needs (eg, cannot scroll and select all medications for reordering, or the buttons being too small on a smartphone, making entering data “tricky”), although in both these cases they opted to complete these tasks on their desktop computers rather than avoiding digital altogether.

Terms and Conditions, Permissions, and Data Privacy: Participant Concerns About Agreeing to the Unknown

In the think aloud portion of the interview, many participants agreed to the terms and conditions without reading them or after taking only a cursory look, with one participant summarizing attitudes observed across the sample: “Yes, I'm not going to view terms and conditions, but I will agree to them because nobody reads terms and conditions” [int 08, female, 49 years old, DHI user]. A similar approach was taken in regard to permissions associated with the app (location and motion-tracking), with some participants choosing to accept to continue rapidly onto the app.

All participants were encouraged to stop installation at any point they wished, and of the 5 participants who did not complete installation of the app in the think aloud portion, 3 who did so had concerns about permissions and privacy. Difficulty with access to the terms and conditions through an external link; the length of terms and conditions and the technical language used; and not being sure of what they should be looking for were all highlighted as specific worries:

But I'm just wondering what- when it's saying there's a link, why can't I find it, you know. If I put continue, it says I have to tick these two boxes. Because then you think “I might as well tick them”, don't you? [int 13, female, 64 years old, limited DHI user, did not continue with installation after this comment]

Participants did not necessarily understand the purpose and requirement for permissions. Some felt that they needed to agree to enable apps to work, for example in relation to tracking activity. Although generally attitudes toward the NHS and NHS-related DHIs were positive, 1 participant explained that for them, media coverage of issues around “track and trace” (the NHS COVID-19 contact tracing program) had undermined their trust in NHS data handling. Although the participant did not give further details, multiple instances of poor practices in

relation to data handling were reported during the pandemic [29,30]. Unknowns about data sharing and privacy were raised in a number of different ways, around the purpose of sharing and the risk of potential misuse:

I mean my GP knows my medical history and my husband, but I don't know if I want everybody to know it, you know. And how would they actually use it, you know. If I put [health details on the app]...how would they- what would they do with it? Is it necessary to put on there? I don't know. [int 13, female, 64 years old, limited DHI user]

A lack of clear and specific information about permissions led to concerns such as that agreeing to one set of permissions might give access to their data for another purpose: “you don't know what type of apps come to you with the main things but actually, tracking you for other things” [int 06, male, 59 years old, DHI on PC only]. Another participant was worried about whether data from their devices could be linked externally:

[...] say I have [a smartwatch] I'm sending emails and like, [from its ID] you know that it's me, right? So, then I'm sending my medical data and then it'll be known that that's my medical data. So, for somebody down the road, you know, i.e. in the database, it'll be isolated as my data. That is concerning, yes. So, the anonymity isn't there if I'm using that watch because linked to that watch is my, you know, account effectively. [int 09, male, 55 years old, DHI user]

To mitigate these concerns, participants described being selective in the types of DHIs used (such as only for low-risk activities such as step tracking) or, in the case of 2 male participants, used multiple phones. However, they highlighted that there was a balance between concerns about privacy risks and perceived benefits, as 1 participant stated: “But does [data sharing] really matter if you're going to get a health benefit out of it?” [int 09, male, 55 years old, DHI user].

DHIs Play a Changing Role in Addressing Health Needs Over Time

Four main types of DHI benefits were described: accessing and keeping contact with health care providers (eg, appointment booking and reminders via SMS text messages, general practitioner platforms, or the NHS app); benefits related to COVID-19 during the pandemic (eg, information and vaccination passports); helping manage their overall health and well-being (eg, diet, exercise, and other lifestyle changes); and supporting the management of specific health conditions (eg, glucose, heart rate, or blood pressure monitoring). The discussions focused on DHIs for behavior change and specific support with health conditions, as well as the changing relevance of DHIs over time.

In relation to behavior change, participants identified that DHIs had supported their needs through features such as availability of relevant information, setting of manageable goals, tracking progress, motivation through rewards and competition with others, and prompting action through reminders and notifications.

I didn't know this information, it's quite helpful for me. I can walk the 10 minutes brisk walk...It's good. And it's the matter the information that people don't know about these things and that is the information gap. If the people know these little information, these very tiny things, then many people can improve their health. [int 12, male, 55 years old, DHI user, reflecting on the NHS app Active 10]

Yes, it encourages me because I do like to compare with my wife...who has done more. So it's like a bit of a competition as well. So it's- I find that really good, you know. At the end of the day, evening time I'll see what I've done today. And then the next day if I've done less I'll try and do more. [int 01, male, 52 years old, reflecting on their step tracker]

General app features, such as heart rate monitors, were also considered meaningful to those with a family history of heart disease. Specific app features that were described as helpful included a personalized home screen with key information, clear visuals around progress and rewards (“your own personal win”), and reasonable prompts. For example, while demonstrating the in-built health app on their phone, 1 participant said:

...what I do here I go to the option “steps” to see what I have done. So I can see today I have only done 1,127 steps...but I can go for the weekly option there...and it also actually gives me the option to see my monthly data...I do [it] regularly, normally I actually see my weekly data and see what I have done. [int 12, male, 55 years old]

However, most participants did not know where and how to find and select the apps relevant to their needs.

Although many participants described their experiences of digital health in relation to general engagement with the health system or behavior change for overall risk reduction, a few described them as part of a program of management of CMD. There were 2 participants who spoke about the use of CGM in diabetes, 1 for themselves, and another as part of managing their relative's health. Specific benefits highlighted included real-time monitoring, ability to monitor family members remotely as part of a team with their caregivers, alerting to the need to rapidly respond, and improved understanding of how their glucose responded to their diet, which contributed to better long-term management of their diabetes.

I was actually able to keep my blood sugars at a constant because it become almost like, it's like you gamify it you know... Very soon you learn what makes your sugar goes up and what makes it go down. And, it's very sad to say this but the knowledge that I might go blind doesn't make as much as a difference as the fact that I've got that little graph that's telling me you're going to hit nine. [int 08, female, 49 years old, reflecting on experience of self-funded CGM]

It's confidence, it's less cost...You can imagine, you know, the ailments that you get from high sugar and low sugar. It was constant chaos and that's kind of completely- almost completely taken that out. So, you're in control, and you're comfortable and relaxed

about it really... [int 09, male, 55 years old, supporting a family member with diabetes]

Additionally, changes to health over time could impact interactions with specific digital interventions. One participant described how they avoided looking at historical data as it reflected their decreased mobility: “...it's quite upsetting knowing that a couple of years ago I did nine, ten thousand steps and I can't do it now” [int 13, female, 64 years old, limited user]. Another highlighted how they preferred to make practical decisions based on their experience, rather than following technology that gave generic advice or was unable to adapt:

I think some people [become anxious and check] blood pressure like every day, two times a day...as long as I know I'm feeling alright a particular day, I don't think I need to know, you know. My legs swell up a particular day...I just take it easy that day and elevate it as much as I can, you know support it. And I think I like to do it...in a more practical way. I don't always want to be led by technology. [int 13, female, 64 years old, limited user]

Perception of the accuracy of apps played a significant role in whether they considered them beneficial to their needs. In relation to activity trackers, a lack of explanation about how they work and how to set achievable goals meant that one participant discounted the readings as it would count when they moved their arm:

I don't think they're very accurate. So it's like even if I'm sat there just moving my arm around and then I'll try to get something, it just increases my tally of my steps I've done. So I know it's not true. [int 05, male, 40 years old, limited user]

Although some participants recognized the potential benefit of DHIs for others, they felt that they had limited benefit for themselves, for example, if they were already active (and did not need a reminder or tracker) or managed their health in other ways. There were 2 participants who expressed a preference for not taking a phone to track exercise due to concerns about theft or loss, although one used a simple wearable device instead.

Anxiety around health caused by searching for health information (“it was like my addiction”), constant monitoring, competing with others, not meeting goals, or potential inaccuracy of readings led to a few participants choosing to use their existing DHIs less or discontinue them:

...One reason I'm checking is because I want to know how I can make my sugar level go down. Other reason I don't want to check is because when the sugar high, it makes me more anxious... We're relying on all these numbers and digital and all the technology, and sometimes, of course it's all the time is good, but sometimes we think, can we not just lead simple life? And sometimes I'm thinking that if machine is not working properly, then that's giving us wrong reading and making you feel even more nervous. [int 14, female, 53 years old, DHI nonuser]

Finally, the time-consuming nature of entering exercise or diet data, or reacting to notifications, was another reason that people

did not feel DHIs could meet their current needs. A busy working mother, undergoing menopause, described an overload of notifications to her phone, which acted as an interface for her duties to other people: *“too many notifications to do- too many emails, too many phone calls to call back.”* However, while taking care of her health was an additional burden, she expressed an interest in trying: *“But I think maybe this...could be helpful for me at least to remind me to move. Maybe I- I will defer other notification...I need to make my health the priority, not always the other people.”*

User Personalization and Adaptation of DHIs to Meet Their Needs

Participants described several ways in which they tailored their experience of DHIs to meet their needs. The first was in selection, trialing several apps before identifying the right one; for example, 1 participant with diabetes described the process of finding one for dietary management:

I think what has happened is over the past four, five years, I've tried to do different kinds of diet...it helps for an app to give you the information you require. So I tried [calorie counting app]...but I eventually ended up using [another] so yes, it's been a trial and error thing. So yes, one after the other. [int 08, female, 49 years old, DHI on PC only]

Participants also limited ways in which they engaged with apps to those that directly met their needs or were easy to use. As one participant put it: *“I want it in the most simplest form and whatever I think I need that's what I've gone for.”* Participants who used in-built health apps for step tracking were aware of other features but did not consider them relevant at this time.

...I never actually use these things...There are many things to explore but to be honest this is it...I kind of focus on how many steps or how many miles I am doing. [int 12, male, 55 years old]

This also varied temporally, such as choosing not to wear heart rate or activity monitors overnight due to discomfort, or using DHIs only when they felt they were needed. This need included changes in symptoms, or when they felt they needed to reestablish behavior change:

If my symptoms start telling me something I'll check my blood sugar immediately and also if I'm feeling

more thirsty, I'm going frequent to the toilet, I start noticing all these, check it on there whether I need to look and do something else. [int 15, male, 69 years old, DHI user]

Although apps were considered useful for providing information, the actual practice of maintaining behavior change was identified as being challenging, with participants describing returning to previous behaviors after achieving change. Participants demonstrated a variety of “bargaining” strategies in how DHIs were used to manage health behaviors, such as not collecting data when the answer will be “bad” or only checking when they know it will be “good,” or using more than one app to compare data and predictions and using the preferred answer.

If you feel like you're going off track and you're suddenly going through sort of like a binge eating period, you can kind of see that there's like a certain month period where I've not - I've just decided not to document what I'm eating because you don't want to see that I'm having... [a] whole tub of [ice-cream].

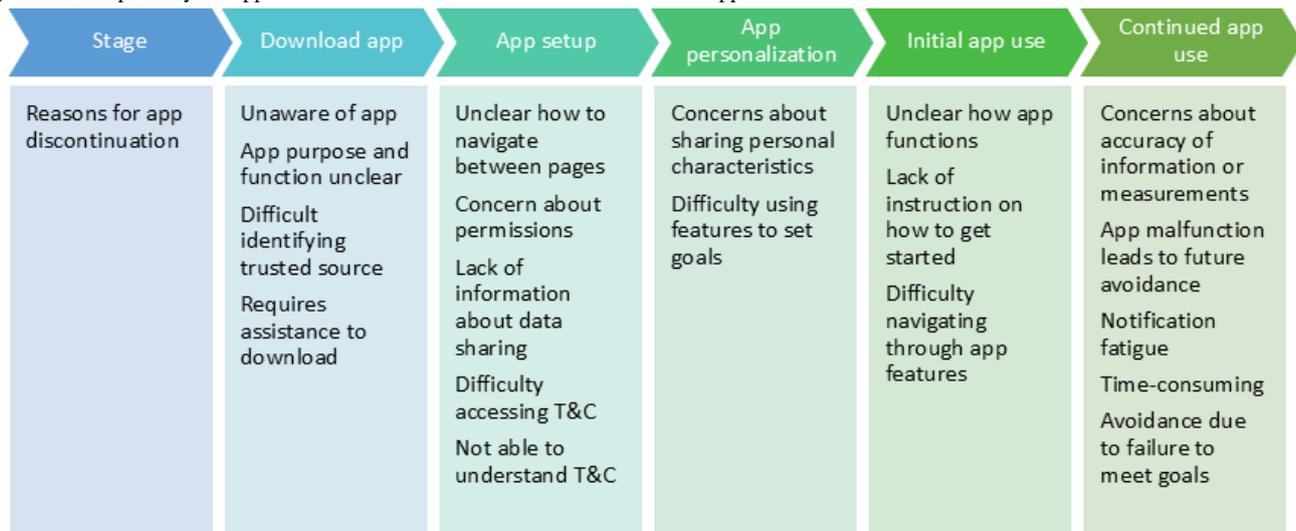

[int 02, female, 42 years old]

For participants who had sufficiently embedded the required behavior change to achieve stable management of their cardiometabolic condition, DHIs were identified as having a natural endpoint or a reduced role:

There's a certain amount of time, two or three months, that you kind of really use the [CGM] app and then after that it peters out because you're comfortable...it's almost the usefulness of the app is for that three months, right, and beyond that it's almost like- almost like an insurance policy... [int 09, male, 55 years old]

Participant Recommendations for Improving Design and Implementation to Support DHI Uptake and Use

Participants made several recommendations aimed at improving their own experience or that of those in their wider community that they thought could benefit from DHIs with some adaptations. [Figure 1](#) summarizes the process of setting up and using a DHI described by participants, reasons for discontinuation, and opportunities to intervene to promote uptake and use of DHIs, using apps as an example.

Figure 1. User pathways to app use for cardiometabolic disease and reasons for app discontinuation. T&C: terms and conditions.

Participants thought that the DHIs discussed had potential benefits for a wide range of people who were interested in making changes to their health. Suggestions for increasing accessibility in app features included: information provided in a range of languages, and with audio or video options; options for font size; visual aids on the page of where to click; and in-app support (such as live-chat options). They mentioned that relevance to the South Asian population could be improved through including a variety of cultural foods in diet-tracking apps, as well as including relevant celebrities, voices, or avatars in apps that included these. When introducing or implementing digital interventions, suggestions included the use of wearables or simple devices to promote exercise; installation and start-up support from health care providers; and providing safe spaces for digital upskilling and practice. Younger participants suggested utilizing social media such as WhatsApp and Facebook to engage people in issues around health as these were popular among the older generation who did have access to phones; however, there is mixed evidence supporting the use of social media for peer-to-peer information sharing [31] or as a channel for delivering diabetes education [32].

Participants also suggested engaging with the current “middle-aged” generation who could be supported to improve their health as they move into their fifties and sixties. In both app setup and ongoing use, participants wanted clear communication about the reasons for inputting personal details (ie, whether this information will be used to personalize the service and how this will be handled by third parties). Although goal setting was seen as beneficial, individuals suggested that they would benefit from instructions and guidance, such as in the form of a “how to” section or videos, as well as explaining exactly how the app works—for example, whether an activity-tracking DHI requires activation or collects information passively. The importance of keeping a range of options available was emphasized, including support for desktop versions of interfaces, and respecting the need to keep nondigital channels open for those with new concerns or for people who might choose to never use digital, including some older people.

In relation to their own use, participants wished for increased personalization and accountability, such as through digital

programs that included coaching. Improved integration, particularly in accessing their health data, test results, appointments, and other NHS functions, was also seen as being beneficial. A participant who had not been offered CGM also identified that they would want something to “do with my diabetes and I could see what my levels were. You know sometimes, because I have to do pricking every day,” suggesting that there is an appetite for CGM among populations who are not aware of it or able to ask for it. Ideal DHIs included joined-up dietary support for those with diabetes, which would suggest and track food intake, and allow for inputting exercise details. Additionally, participants suggested the idea of a “lab on a watch,” which could act as a one-stop shop to monitor health.

The final areas of recommendations related to terms and conditions and data collection. Including a link to terms and conditions that navigated to a web page was confusing for some participants, and it would be helpful if it was integrated within the app. However, for a more meaningful way for a user to engage with the agreement, participants suggested that a lay summary of key messages should be included ahead of the checkboxes. Similarly, an explanation of the purpose of each permission, and how that data would be shared, would reassure people that the app was safe to use.

Discussion

Principal Findings

We present experiences of utilizing DHIs for prevention and management of CMD across a diverse group of UK individuals from a South Asian background, building on previously identified barriers and facilitators of digital acceptability, uptake, and use [18]. We highlighted willingness to use technology as part of prevention and management of CMD, but one single approach did not suit all, including the choice not to use DHIs among individuals who might otherwise use internet-based communication and entertainment, as described in other populations [33,34]. A review of nonuse of telemedicine also highlighted “other preferences” as a key aspect of attitudes

toward telemedicine technologies, describing preferences for conventional solutions or other technical solutions [35].

Across all levels of digital skill, a key concern in downloading and setting up apps focused on data privacy and needing to agree to difficult-to-understand terms and conditions to use DHIs, including those for essential services. Recent studies in other contexts have also put forward ways to improve user engagement with terms and conditions, including not using hyperlinks and ensuring that they are transparently displayed early in user interaction [36]. Others have included terms of use as a factor to consider in a digital health evaluation tool for patients and clinicians [37]. However, many participants would not have been able to utilize this tool as it assumes a level of digital knowledge. There is a pressing need for improved communication and education for meaningful consent. Moreover, some concern about data safety within DHIs appears justified in light of evidence around vulnerabilities in medical devices and commercially available wearables [38-40], highlighting the need to provide assurance to the public.

The types of DHIs used by participants ranged from step counters to those with more complex features such as CGM. Features that were considered by one user to be positive (such as monitoring and tracking measurements) were reported by others to cause distress and anxiety. Regular DHI users found the NHS apps used in the “think aloud” portion of the interview to be extremely simple to set up and use, while participants who described themselves as less confident with technology grew frustrated navigating through the initial information screens. International recommendations on diabetes highlight the importance of designing apps with the level of technology proficiency of different patient populations in mind and increasing accessibility by using languages other than English, as well as increasing accessibility for people with visual impairment [41]. However, even when individuals did not face these barriers, a lack of cultural specificity in provided information reduced relevance and usability, particularly in relation to CMD, where dietary change may form a significant part of patient self-management [18,42].

Participants described dynamic changes in their interaction with and expectations of DHIs, reflecting variation in their health needs and exploration of approaches, in the short- and longer-term, both in relation to lifestyle change and management of specific CMDs. This supports previous findings in other populations such as those with diabetes, where after addressing initial acute needs after diagnosis, individuals may decrease use until a new event prompts interaction [43,44]; a similar pattern is demonstrated in people who may have a long-standing diagnosis but are newly introduced to DHIs. Digital approaches may also be seen as unsupportive or not relevant for newly diagnosed cardiometabolic conditions [18,45], which should be considered in South Asian populations as minority ethnic groups have been associated with an increased prevalence of diabetes distress [46].

Comparison With Prior Work

Our findings in this study reflect in a health setting the framework for temporality of use of a new digital tool by Karapanos and colleagues: anticipation (participant expectations

prior to use); orientation (excitement and frustration in learning and exploration); incorporation (meaningful use of product in daily lives); and identification (form a relationship with a product as it becomes part of their routine and social interactions) [47].

Positive impacts of DHIs for diabetes on individuals have been suggested to include helping them understand and feel in control of their condition; construct positive identities through being experts in their disease; increase their sense of power in clinician interactions; and demonstrate their goodness [44,48]. Although our findings reflect common positive outcomes in some users, we found that without adequate consideration of individual need, DHIs may instead increase anxiety or disempower patients. This may result in users feeling that they are being “led by the technology” rather than the technology supporting their needs, and this raises questions about the suitability and acceptability of automation in health interventions [49].

Studies in older populations in the United States have highlighted that people who are actively engaged in health management are more likely to use wearables and are willing to share health data with providers [50]. DHIs can be beneficial to older individuals when adapted for use and supported by communication with medical professionals [51,52]. Participants suggested a range of ways in which the design and implementation of digital technologies in health could support a diverse population, including promoting localization to different languages and cultures, including audio options; clear design and other accessibility measures; and provision of information and instruction within the app and through health care teams. Similar recommendations have been made for DHIs relating to CMD [53], in South Asian communities in the United Kingdom and India in relation to lifestyle change [42,54], for other health conditions [55-57], and for patient populations with different needs [58]. Embedding these approaches can have benefit beyond any single patient population [59]. However, for participants (of any age) who are digitally confident, more complex and integrated interventions may be suitable. This highlights the importance of having a range of interventions that are targeted to the needs and expectations of populations who may benefit from them (eg, other ethnic or minority groups) [60].

Limitations

There is significant diversity within the South Asian population in the United Kingdom, by migration generation, country of origin, ethnicity, religion, education, occupation, and income, as well as by age and gender; with a relatively small sample size (n=18), this study cannot represent all experiences of digital access. In addition, due to the think aloud method, only participants with mobile phones or other devices able to support apps, and who were able to speak English, were recruited. In 2011 census data, most people of South Asian ethnicity in the United Kingdom were able to speak English, with nonspeakers tending to be older, female, and from Bangladeshi and Pakistani backgrounds [61]. This emphasizes the need for appropriate support to ensure these groups are able to access and benefit from health services for CMD. However, there is a significant difference between age groups; although Bangladeshi women

over the age of 65 years reported the highest rate of not speaking English (44.9%), this was only 2.8% in the 25 - 44 year age group [61]. This suggests that there is a large demographic of English-speaking South Asians in the United Kingdom that could potentially benefit from digital health approaches, given the right support.

There is currently limited evidence on the experiences of digital health among South Asian populations in the United Kingdom, particularly in relation to CMD [12,13]. This study makes an important contribution toward understanding opportunities for culturally relevant DHI design and implementation. In addition, broader findings and recommendations have the potential to benefit other populations that may currently be digitally excluded. Future research should explore implementation approaches to support those new to digital to install and use apps, as well as explore how to improve communication around permissions, privacy, and terms and conditions to ensure patients can meaningfully consent to the use of DHIs.

Conclusion

In our study, we demonstrated that individuals from a South Asian background in the United Kingdom are interested in DHIs as part of prevention and management of CMD, and in addressing short- and long-term needs, including engaging with family members and carers for the benefit of those who may be otherwise digitally excluded. Initial access to technology (by which we mean awareness, downloading, and setting up a device or app) is a significant barrier. This emphasizes the importance of support from appropriate trusted sources, such as health care teams, in initiating DHI use. Suggestions to improve relevance and utility of DHIs for the South Asian population in the United Kingdom focused on inclusion of cultural foods in advice around dietary management of CMD. Participants made a number of recommendations around DHI design and implementation that would improve accessibility across user groups. This highlights that design approaches for DHIs for prevention or management of cardiometabolic disease should take into account the diverse needs of many populations for universal benefit.

Authors' Contributions

The study concept was designed by A Banerjee, MR, and LP. Interviews were carried out by MR and NK. Analysis was conducted by MR and DRP with support from NK and DS. MR wrote the original draft with support from DRP, and review and edits by A Banerjee, NK, and DS. The figure was designed by MR. Additional review was carried out by PG, KK, LP, WH, A Blandford, MS, and FS for the Digital Interventions for South Asians with Cardiometabolic Disease Study consortium.

Conflicts of Interest

KK is the director of the University of Leicester Centre for Ethnic Health Research. AB, WH, and KK are trustees of the South Asian Health Foundation. WH is also a trustee of Diabetes UK.

Multimedia Appendix 1

Interview guide.
