In Pakistan, the ineffective innovation management approaches and deprived diffusion of innovation strategies are hurdles to realizing the importance of social media and its usage for health care education [24,25]. The deprived diffusion of innovation is a significant factor in the inability to attain the desired output. Even for digitalized hospital tools other than social media, the country needs more innovative and user-friendly equipment in the hospital sector [25]. The notion of consistent health care challenges and inadequate health resources in Pakistan is also evident from the recent Joint External Evaluation report [24].

For this reason, it is imperative to investigate the impact of social media's effective use on health awareness and health care education in Pakistan using IDT. This may result in highlighting and understanding the effectiveness of social media tools in reducing the disease burden in the country.

Figure 3 explains the theoretical framework of the current study.

XSL•FO
RenderX

Figure 3. Conceptual framework of the study.

Hence, the current study hypotheses are:

1. Hypothesis 1 (H1): social media usefulness positively and significantly impacts health awareness in Pakistan.
2. Hypothesis 2 (H2): health awareness has a significant positive impact on health care education in Pakistan.

Methods

Instrument Development

A quantitative technique was applied to test the study hypothesis and validate the proposed model using the structural equation modeling (SEM) technique [35]. SEM is deemed the most suitable due to its ability to simultaneously test complex relationships among multiple variables and validate the proposed conceptual model. Data analysis was carried out using AMOS 26.0 software (IBM Corp) [36]. Since the study aims to identify social media's impact on health awareness leading to health care education and uses the IDT as a theoretical foundation, scales from previous literature have been adopted. The main advantage of adopting these scales is that they have already been validated in the health industry's acceptance behavior of new technological tools. For instance, the measurement scale for Innovative Technology (social media) usefulness was adopted from a previous study [37], and measurement scales for health awareness have been adopted from another study [38]. Aligning with the psychometric literature, 4-item scales for each construct based on their higher loadings have been adopted [37]. The modified 8-item scale for measuring health care education was adopted based on the questionnaire of Ho et al [39]. For the measurement of each item, a 7-point Likert scale ranging from 1 (strongly disagree) to 7 (strongly agree) was used [38].

Data Collection

A questionnaire was designed based on the variables of the present study, utilizing the aforementioned scales, which are provided in Multimedia Appendix 1. A personally administered questionnaire was used for data collection [32]. For data collection, the current research to eliminate targeted health care professionals and paramedic staff of 2 private hospitals in Lahore, Pakistan. The questionnaire was distributed to more than 450 health care professionals and paramedic staff using convenience sampling and requested their valuable feedback. However, only 389 useful responses were received.

Ethical Considerations

As a matter of ethical concerns, prior permission from the hospital management was obtained, and the purpose of the study was explained to all respondents through "informed consent." It was assured that respondents' privacy would be ensured through confidentiality. Ethical approval was not required for this study as it did not involve identifiable personal data, or interventions falling under the scope of institutional or national ethics review requirements. In accordance with the Declaration of Helsinki (World Medical Association, 2013) research ethics policy, studies that do not involve sensitive data are exempt from formal ethics board approval.

Results

Primary Data Screening

Initial screening was carried out among 389 useful responses to eliminate unusual responses, mainly incomplete questionnaires and respondents who marked similar scores on all items. Furthermore, questionnaires with more than 4 missing values were also excluded. The remaining missing values were replaced with the series mean/average for the rest of the responses. Therefore, the final useful sample was reduced to 340.

Table 1 provides the demographics of the study respondents. Among 340 respondents, 58% (197/340) were male, and the rest were female (143/340, 42%). A total of 91% (309/340) of the respondents were between 25 and 35 years of age, which may lead to the fact that most health care professionals and paramedic staff in private hospitals in Lahore are young. However, we may be unable to neglect the 6% of the population under 25 years old and more eager to start their career in the health care sector. The remaining 3% were more than 35 years of age and had extensive health industry work experience.

[c]MBBS: Bachelor of Medicine, Bachelor of Surgery.

[d]BDS: Bachelor of Dental Surgery.

Data Analysis

An exploratory factor analysis was initially performed on the 16 measurement items to confirm the underlying relationships [36]. For sample adequacy, the KMO value (0.850) was greater than the recommended value (0.60), and the significance value of *P*0.001 confirmed the Bartlett test of sphericity, as shown in Table S1 in Multimedia Appendix 2. All those factors were retained for data analysis, with factor loading greater than 0.50 and Eigenvalue greater than 1.0. Hence, this technique provided 3 factors that explained 72.2% of the variance after varimax rotation. Furthermore, scale reliability coefficients were greater than the acceptable value (0.70) [40], and Shapiro-Wilk tests were conducted to check the data normality [40], as shown in Table S2 in Multimedia Appendix 2 . The results of both tests were significant, meaning there was no normality issue in the data.

For further data analysis, a two-stage structural equation modeling (SEM) technique was used [36-38]. This approach allows researchers to evaluate the measurement and structural models separately using two dissimilar subsamples. For this reason, a sample of 340 participants was divided into two parts: a sample of 170 individuals was used for the measurement model, and a similar sample size was used for the structural model assessment to attain impartial results.

Reliability and Validity Measures

According to Hair et al [35], finding the reliability of each item and construct in the research study is essential. Therefore, squared multiple correlation (SMC) was used to find the reliability of each reliability item of each measurement item. SMC represents “the amount of variance explained by an individual indicator/construct of its respective factor and measured by the square of its (indicator’s) standardized factor loading” [40].

Hair [35] indicated that the cutoff value of SMC is 0.30. Hence, it is evident from Table 2 that all the SMC values are greater than 0.30. For measuring the reliability of each variable, the

XSL•FO
RenderX

Cronbach alpha value was used. As suggested in the literature, the cutoff value of Cronbach alpha is 0.70 [36,37]; it is evident from Table 2 that all variables' Cronbach alpha values are more than 0.70. Furthermore, Hair et al [35] also highlighted that for measuring the convergent validity, there are three common approaches: (1) standardized factor loading (0.5 or greater), (2) average variance explained (0.5 or higher), and (3) composite reliability (0.7 or above).

Table . Measurement of reliability and validity.

Constructs and item	Values, mean (SD)	Standardized factor loading	Squared multiple correlation	Composite reliability	Cronbach alpha	Average variance explained
Social media usefulness (SMU)						
SMU1	5.19 (1.65)	0.781	0.607	0.788	0.774	0.589
SMU2	5.33 (1.71)	0.780	0.687			
SMU3	5.01 (1.12)	0.777	0.671			
SMU4	5.05 (1.32)	0.787	0.646			
Health awareness (HA)						
HA1	5.45 (1.56)	0.859	0.677	0.769	0.773	0.592
HA2	5.98 (1.45)	0.874	0.681			
HA3	5.39 (1.43)	0.881	0.675			
HA4	5.51 (1.39)	0.867	0.654			
Health care education (HED)						
HED1	5.23 (1.77)	0.719	0.651	0.783	0.789	0.678
HED2	5.22 (1.74)	0.775	0.629			
HED3	5.60 (1.64)	0.721	0.622			
HED4	5.41 (1.49)	0.739	0.637			
HED5	5.22 (1.15)	0.787	0.663			
HED6	5.11 (1.23)	0.772	0.654			
HED7	5.09 (1.43)	0.759	0.691			
HED8	5.32 (1.59)	0.768	0.609			

Hence, each standardized factor loading was statistically significant (P<.001), and values ranged from 0.719 to 0.881, thus validating adequate convergent validity as shown in Table 2. In addition, the average value explained (AVE) values and construct reliability were also more than their cut-off level of 0.5 and 0.7, respectively, and were statistically significant. Therefore, these measures confirm sufficient convergent validity.

A comparison of shared variance between factors with the average variance explained by individual factors was ensured for measuring the discriminant validity. The diagonal value should be greater than the non-diagonal value to confirm adequate discriminant validity [40]. Hence, results given in Table S3 in Multimedia Appendix 2indicates the correlation matrix of constructs, where non-diagonal elements are correlated among constructs and diagonal elements are the square root of average variance explained (AVE) by that construct and clearly explain that all three constructs differ.

Measurement Model

Using statistical software AMOS 26.0, the measurement model's confirmatory factor analysis (CFA) was performed [40,41]. This provided a passable model fit for the primary measurement model (CMIN=1220.23; CMIN/DF=1.98; GFI=0.72; AGFI=0.80; NFI=0.81; CFI=0.826; RMR=0.089; RMSEA=0.082); however, the number of indicators per item was large; for instance, the number of indicators for health care education were 8. Consequently, 2 items were deleted for further refinement to obtain an adequate model fit through the CFA of the measurement model. This refinement was conducted by deleting items one by one, based on their standardized residual; that is, that item was first deleted, which had a larger error variance than their measurement items. Each item was carefully reviewed before deleting it to ensure that, from a theoretical viewpoint, its error variance also seemed rational. The refinement and assessment process for every construct was first evident by Churchill [41]. Churchill defined this process as; "Though this application may be satisfactory during the early stages of research on a construct, the use of factor analysis in a confirmatory fashion would seem better at later stages." Furthermore, Gerbing and Anderson's [42] study also provided support to Churchill's argument and stated that; "to demonstrate that an explicit evaluation of Unidimensionality is accomplished with a confirmatory factor analysis of the individual measures as specified by a multiple-indicator measurement model. Coefficient alpha is important in assessing reliability but does not assess dimensionality. Although item-total correlations and exploratory factor analysis can provide useful preliminary

XSL•FO
RenderX

analyses, particularly in the absence of a sufficiently detailed theory, they do not directly assess unidimensionality. The reason is that a confirmatory factor analysis assesses the internal consistency and external consistency criteria of unidimensionality implied by the multiple-indicator measurement model.

Hence, this refinement process provided an adequate model fit (CMIN=357.62; the ratio of χ^2 to degree of freedom value (1.80) is remarkably less than its recommended value (5.0). CMIN/DF=1.80; GFI=0.90; AGFI=0.89; NFI=0:915; CFI=0:93; RMR=0:075; RMSEA=0:055) as shown in Table 3.

Table . Structural equation modeling fit indices for the confirmatory factor analysis model.

Fit indices	Cut-off criteria	Results obtained
Absolute fit indices		
Chi-square (*df*)	N/A[a]	357.62 (170)
χ^2/df (CMIN/DF)	<5.00	1.800
Root Mean Square Error of Approximation	<0.06	0.055
Goodness of Fit Index	>0.85	0.900
Adjusted Goodness of Fit Index	>0.85	0.890
Incremental fit indices		
Buntler-Bonett Normed Fit Index	>0.90	0.915
Comparative Fit Index	>0.93	0.930
Tucker Lewis Index	>0.90	0.941
Incremental Fit Index	>0.90	0.932
Parsimonious fit indices		
Parsimony Goodness-Fit Index	>0.50	0.798
Parsimony Normed Fit Index	>0.50	0.848

[a]N/A: not applicable.

Structural Model

The research hypotheses were tested through structural model estimation [40]. Therefore, a second subsample (n=170) was used and provided the adequate structural model fit (CMIN=488.6; CMIN/DF=1.85; GFI=0.861; AGFI=0.893; NFI=0.987; CFI=0.945; RMR=0:079; RMSEA=0.053) as shown in Table 4.

Table . Hypothesized structural model fit indices.

Fit index	Cut-off criteria	Results obtained
Absolute fit indices		
Chi-square (*df*)	N/A[a]	488.6 (170)
χ^2/df (CMIN/DF)	<5.00	1.850
Root Mean Square Error of Approximation	<0.06	0.053
Goodness of Fit Index	>0.85	0.861
Adjusted Goodness of Fit Index	>0.85	0.893
Incremental fit indices		
Buntler-Bonett Normed Fit Index	>0.90	0.987
Comparative Fit Index	>0.93	0.945
Tucker Lewis Index	>0.90	0.976
Incremental Fit Index	>0.90	0.943
Parsimonious fit indices		
Parsimony Goodness-Fit Index	>0.50	0.680
Parsimony Normed Fit Index	>0.50	0.609

XSL•FO
RenderX

Moreover, the significance of the hypothesis is shown in Table 5. Testing of H1 revealed that social media usefulness has a significant effect on health awareness (H1: β=.669, *P*<.001), supporting the IDT proposed by Rogers. Testing of H2 also supplied similar significant outcomes to the current research model (H2: β=.557, *P*<.001), confirming the findins of prior work.

Table . Hypothesis testing results.

S.no.	Impact of	Impact on	Hypothesis	Path coefficient	*P* value	Outcome
1	SMU[a]	HA[b]	H1[c]	0.669[d]	.001	Significant impact
2	HA	HED[e]	H2[f]	0.557[d]	.001	Significant impact

[a]SMU: social media usefulness.

[b]HA: health awareness.

[c]H1: hypothesis 1.

[d]*P*<.001.

[e]HED: health care education.

[f]H2: hypothesis 2.

Discussion

Principal Findings

This study examined the impact of social media on health awareness and its role in health care education, using IDT as the theoretical framework in Pakistan. A conceptual model was developed to assess the mediating effect of health awareness on the relationship between social media usage and health care education. The hypothesis testing results demonstrated significant relationships, with social media positively influencing health awareness (H_1: path coefficient=0.669, *P*<.001) and health awareness positively impacting health care education (H_2: path coefficient=0.557, *P*<.001). These findings highlight the potential of social media as an effective tool for promoting health care education when strategically leveraged by health care stakeholders.

The study also revealed that younger and more educated health staff are more inclined to use social media, while older groups, though recognizing its usefulness, engage less actively. This demographic insight underlines the need for tailored engagement strategies to maximize participation. Limited research in developing countries, including Pakistan, has tested the application of IDT to health care professionals' adoption of social media for health care education. The standardized direct effects from hypothesis testing affirm the significant relationship between social media usefulness, health awareness, and health care education in the Pakistani context.

Given that developing countries are often classified as late adopters of technology, according to IDT, the findings emphasize the importance of region-specific social media content on platforms, such as Facebook, WhatsApp, or locally developed alternatives, for health care interventions. IDT further suggests that simplifying innovations can facilitate broader adoption, making it easier for health care professionals and the general population to engage with digital health initiatives. These insights highlight the need for cost-effective, user-centric solutions to enhance healthcare outcomes in Pakistan.

The government of Pakistan can also play a significant role in spreading health awareness. They can use social media to run campaigns on maternal health, child nutrition, and disease prevention. The health care professionals in private hospitals also indicated that live sessions and webinars on platforms like Facebook Live and Instagram Live to educate the patients and hospital staff on various health issues and answer their real-time questions have been very useful.

Using social media for health care education in Pakistan could be a game-changer, surpassing the expectations of spreading awareness regarding health needs in a particular community. This potential is not just theoretical; it has been proven in developed countries, such as the US, Jordan, the United Kingdom, and Europe, where social media was used during the COVID-19 pandemic to combat the pandemic and other notable diseases [15]. Moreover, social media platforms have been used to promote telemedicine services, enabling health care professionals to connect with patients remotely for consultations, follow-ups, and monitoring of chronic conditions [16,30].

Overall, this study validates the use of social media to improve public health care education through public awareness. Therefore, the study concludes that health care professionals should use social media tools to inform the wider public and address healthcare issues in Pakistan.

Conclusion

The findings of this study underscore the significant role that social media plays in enhancing health care awareness and education among various populations in developing countries like Pakistan. With their wide reach and interactive features, social media platforms have proven to be effective tools for disseminating health-related information and engaging individuals in meaningful health conversations. Social media breaks down geographical barriers, allowing health information to reach a global audience instantly. This broadens the scope of health care awareness campaigns and makes information accessible to a diverse demographic, including those in remote or underserved areas. The interactive nature of social media facilitates active engagement between health care providers and the public. This interaction fosters a sense of community, encourages the sharing of personal health experiences, and allows for immediate feedback and clarification of health information. Also, social media platforms enable the

XSL•FO
RenderX

dissemination of personalized health information tailored to specific audiences' needs. Moreover, the real-time nature of these platforms ensures that information is up to date, which is crucial during health emergencies or outbreaks.

Health care education through social media can help understand how to prevent common diseases such as malaria, tuberculosis, hepatitis, and polio through vaccination, sanitation, and hygiene in Pakistan. Awareness campaigns can encourage healthier lifestyles, reducing the incidence of chronic diseases such as diabetes, hypertension, and heart disease. Educating women about prenatal and postnatal care, safe delivery practices, and child nutrition can significantly lower maternal and infant mortality rates. Awareness through social media about proper nutrition, immunization, and hygiene practices helps improve children's health and development in the rural outskirts of Pakistan. Also, awareness about communicable diseases and their transmission can help in preventing outbreaks of diseases like HIV/AIDS, tuberculosis, and waterborne illnesses.

Governmental policies provide a framework for regulating the content shared on social media, ensuring that the information disseminated is accurate, reliable, and in line with public health guidelines. Information shared by government-endorsed social media accounts is more likely to be trusted by the public. Official policies lend credibility and legitimacy to health messages, increasing the likelihood of public acceptance and compliance. All active organizations (govt and private) working in the health industry of Pakistan seek prior permission or ethical clearance to initiate any new work. Without government support, the organizations lack the confidence to spread and advertise any health-related content due to fear that they may be subject to local resistance.

Despite its benefits, the use of social media in health care awareness also presents challenges, such as the spread of misinformation and the need for privacy and data protection. Health care organizations must implement strategies to verify information and ensure the credibility of the content shared. Hence, the study suggests that Pakistan's health care organizations should continue leveraging social media to enhance health communication strategies and education. Ongoing research is also needed to explore new ways to maximize social media's benefits while mitigating its risks.

In conclusion, social media is a powerful tool for health care awareness, offering unprecedented opportunities to reach and engage with a wide audience. By harnessing its potential in developing economies, health care organizations can improve public health literacy, promote healthy behaviors, and ultimately contribute to better health outcomes. Collaborative efforts between health care professionals, social media platforms, and policymakers will be crucial in leveraging social media's full potential for public health advancement.

Future Research

Future research should move beyond compliance with existing social media policies to explore strategies and variables that demonstrate tangible improvements in the health care sector. This could include investigating how social media can influence enhanced patient outcomes through better communication and engagement, broaden health awareness campaigns by targeting diverse and underserved populations, and improve access to health care services through innovative digital solutions. Additionally, longitudinal studies examining the long-term impact of social media interventions on public health indicators would provide valuable insights. Identifying and analyzing these variables will contribute to a more comprehensive understanding of social media's transformative potential in health care beyond mere policy adherence.

Acknowledgments

The authors would like to thank Mr Nabil Ahmed, Director at Integral Global Consulting LLC, Tucker, GA, US for providing the necessary resources and facilities that enabled the successful execution of this research. The authors also want to extend their special thanks to all the respondents and hospital management in Lahore, Pakistan, for their feedback and the collaborative environment that fostered productive discussions and the exchange of ideas.

Abstract

Background: Telemedicine represents an essential tool with the potential to reduce health costs, thus avoiding patient displacement and improving patient care outcomes, positioning it as a significant social technology.

Objective: This study aims to analyze the implementation of a telehealth cabin at BP Hospital (A Beneficência Portuguesa de São Paulo), focusing on the evaluation of the experiences of both patients and health care professionals, as well as the acceptability of this tool.

Methods: A mixed methods study was conducted with 229 participants, divided into 2 phases. The first phase involved 40 apparently healthy individuals to assess the usability, experience, and satisfaction of this group for the later safe application in the group with clinical complaints. The second phase included 189 participants, with complaints to assess the usability, experience, and satisfaction of patients and doctors. In both phases, participants completed screening questionnaires (to assess the eligibility criteria), a socioeconomic demographic questionnaire before using the cabin, and a questionnaire including the System Usability Scale and the Net Promoter Score (NPS) after using the cabin.

Results: The data analysis of the first phase showed high acceptance of the telehealth cabin, which supported the progression to the second phase. In the second phase, a high usability score was observed among participants with clinical complaints (mean System Usability Scale score of 85.97, SD 15.50) and a high favorability rating (NPS score of 9.4). Health care professionals also reported favorable results, with a usability score of 67.8 and an NPS of 8.0.

Conclusions: The results of this study reinforce the potential for scaling up this practice based on usability outcomes, and highlight its relevance for the development of public policies aimed at expanding access to quality health care in Brazil. This approach improves the interaction of patients with the health care system, while providing professionals with an extended view of clinical conditions through integrated devices, particularly in areas with limited access to medical care.

KEYWORDS

telemedicine cabin; telehealth; teleservice; e-health; connected offices

Introduction

Health is a fundamental right of the population and must be guaranteed to everyone. It is even included in the Universal Declaration of Human Rights of 1948, in Article 25, which defines that everyone has the right to a standard of living that ensures health, well-being, and health care [1]. Although access to health is often presented as a goal in the health policy, there are several challenges to ensure that right into the Brazilian reality, such as inequalities related to the access and use of health services, discontinuities in the geographical distribution of services, especially of medium and high complexity, in addition to the articulation between health systems of several care levels [2,3].

Among the various proposals developed to improve health care at the national level, the use of technological and telecommunication resources for the exchange of information across different levels of health care, between health professionals, and between doctors and patients, has gained prominence.

XSL•FO
RenderX

According to the Ministry of Health, telehealth uses information and communication technologies to promote the expansion and improvement of medical services. Telemedicine is included in telehealth, related only to remote care through technology. According to the World Health Organization, telemedicine is defined as the "delivery of health services where distance to health professionals is a critical factor, through the use of information and communication technologies to the exchange of valid information for the diagnosis, treatment, and prevention of disease and injuries, research and assessment, and to the continuing education of the providers of healthcare and patients."

Telehealth has been used in Brazil since the 1990s, emerging in a decentralized and fragmented way in the health sites [4]. Telemedicine has the potential to reduce health costs, avoid patient displacement, and even improve patient care outcomes [5-7]. Although many studies are being published, especially as a consequence of the COVID-19 pandemic, the implementation of telemedicine can still be challenging, mainly due to technological barriers and poor computer knowledge, and even due to resisting change and the patient's education level [8]. Despite the increasing interest in telehealth, a significant part of the research focuses on the technological aspects rather than on the tool's adoption and acceptance.

One of the limitations of telemedicine is the lack of possibility to monitor the patient throughout medical care, and some telemedicine platform initiatives have been developed for this purpose. However, today, they provide more complete solutions through a digital health ecosystem, which offers medical instruments to be used by the patient, such as a temperature sensor, stethoscope, dermatoscope, oximeter, otoscope, sphygmomanometer, scale, and height sensor. These new functionalities aim to create resources that can improve even more access and affect the quality of life by bringing doctors and patients closer together.

This research aimed to assess the human aspects of the experience and usability when using telehealth cabins with built-in medical devices, thus expanding the diagnostic and interventional capacity of health professionals in clinical, diagnostic, and interventional capacity practice in its remote format.

To this end, the socioeconomic and demographic profile of the population, the experience and usability of the population in the cabin, the doctor's experience in providing care through telehealth cabins, and compliance in handling the equipment available in the self-examination cabin were evaluated.

Methods

Recruitment

This is a mixed methods study using (1) the System Usability Scale (SUS), (2) the Net Promoter Score (NPS), and (3) a thematic analysis based on participant' perceptions. The aim was to assess the usability and favorability of health care provided in a connected cabin for symptomatic and asymptomatic employees of the BP Hospital (Beneficência Portuguesa de São Paulo).

Ethical Considerations

Ethics approval (CAAE: 58070622.9.0000.5483) for this study was provided by the institutional review board of the BP Hospital (Beneficência Portuguesa de São Paulo) on January 31, 2023. All eligible patients signed an informed consent form for this research protocol.

The data was collected on the RedCap platform, which has access control to ensure the security of the data collected in the research. In addition, all data was anonymized to ensure the privacy of the participants.

Sample Size

The Binomial test was used to calculate the sample size for both parts of the study. For the sampling of asymptomatic individuals (phase 1), an 80% test power was stipulated, a 70% acceptance rate of the cabin under the null hypothesis, and a 90% expected in the sampling rate were specified, resulting in 41 asymptomatic patients.

For the sampling of symptomatic individuals (phase 2), we opted for a conservative scenario. Thus, we set a power of 90%, an acceptance rate of 80% under a null hypothesis, and a 90% expected proportion in the sampling, resulting in 169 patients. Anticipating the possibility of a 12% sample loss, the researchers decided to increase the sampling to 190 symptomatic patients.

Inclusion and Exclusion Criteria

Phase 1: Asymptomatic Patients

The study's first phase involved 40 apparently healthy individuals with no clinical complaints or decompensated chronic diseases (exclusion criteria for the first phase) to assess the safety and usability of the cabin.

During this phase, all hospital staff received an email with information about the study, inviting asymptomatic individuals to participate. Interested individuals could schedule an appointment by phone to use the cabin.

Phase 2: Symptomatic Patients

The second phase included 189 individuals who could be with clinical complaints but did not meet the exclusion criteria, which were: inability to understand and answer the screening questionnaire; patients with signs and clinical symptoms indicating the need for urgent medical care, such as cardiac arrest, shock of any origin, reduced level of consciousness, focal neurological signs, epileptic seizure, chest pain, deep wound, and heavy bleeding.

During this phase, individuals who sought medical care at the institution's employee health center and who met the inclusion criteria were invited to participate. Those who agreed to participate were enrolled in the study.

Telemedicine Cabin

The telemedicine cabin Diagnostica, manufactured in Argentina, was used. It is made of plastic and fiberglass and measures 250×150×230cm dimensions. It has a forced air ventilation and filtering system, environmental lighting with intensity and color control, and an audio and video system for videoconferences (Figure 1).

XSL•FO
RenderX

Figure 1. Telemedicine cabin at the location of the research project.

The participant used his cell phone or the device available in the cabin to receive care and to interact with the person through the app developed for Android and IOS. The patient was accommodated in the cabin and selected the self-examination devices according to their needs.

The following devices were available in the cabin: an otoscope, a digital dermatoscope, and a high-definition camera, all manufactured by Firefly Global in 2021; a stethoscope Riester manufactured in 2021; and an oxyhemoglobin saturation monitor (oximeter), an electrocardiography, a heart rate and temperature monitor, and a sphygmomanometer, models PM6100, all manufactured by Berry, 2021. The patient was instructed to use the app on his cell phone, and the light signals in the cabin were added to a video display to operate the devices for the self-examination.

The cabin recorded the measurements taken by the available devices. The patient had the option, at their discretion, to join the medical consultation at any time during the use of the cabin, even if he did not use the devices. During the synchronous service, the doctor could request that the patient use any of the medical devices to obtain additional clinical information.

Doctors were recruited through direct invitations sent to professionals associated with the hospital. Selection criteria included previous experience with similar technologies and availability to participate in all stages of the study.

Data between the patient and the doctor was transmitted via the Doc24 telehealth platform, implanted in the data processing centers, and connected to the internal service network.

XSL•FO
RenderX

Study Procedure

Before starting the service, a nursing technician applied the informed consent form. After the participant's agreement, a screening questionnaire focusing on the inclusion and exclusion criteria and a questionnaire to collect demographic and socioeconomic data before using the cabin were administered. Individuals who met the exclusion criteria or had acute alterations requiring face-to-face assessment were sent to the Employee Health Center for immediate medical care.

The cabin was equipped with a Wi-Fi network and the patient should download an app to access the cabin and the interface (application) which was customized for the project.

During the appointment, the patient, seated in the cabin, can choose between selecting devices for self-examination or opting for a consultation with a doctor. At the patient's discretion, they have the option to join the medical consultation at any time during the use of the cabin, even without having used the devices.

If the participant chooses to attend a medical consultation during the service, the doctor may ask the patient to use some of the equipment to collect clinical information, or to reuse some of the equipment due to observing poor quality results initially measured by the patient.

Equipment-assisted measurements were available for medical assessment, if required, or later, in the outpatient treatment.

At the end of the service, the research participant was invited to answer the usability questionnaires translated and validated including the SUS, which is a method to measure the usability of several products and services through 10 questions answered on a scale of 1 to 5, where 1 is total disagreement and 5 is total agreement [9], and the NPS, which aims to analyze the patient's experience and satisfaction [10].

After assigning the NPS score, participants were asked to explain their ratings. Inductive thematic analysis was used to identify a rating [11]. Two authors carefully read each response individually and grouped the responses. Any disagreement was discussed with the first author, and then the response was labeled into 6 categories: "service," "usability," "difficulty of use," "innovation," "technology resistance," and "unspecific." The final step was to group the responses into potential themes.

In order to check the usability of health professionals, the participating doctors also completed the same questionnaires at the end of the daily sessions.

Statistical Analysis

Study data were collected and managed by an electronic data capture tool, REDCap (Research Electronic Data Capture), and hosted on the BP server [12,13]. REDCap is a secure software web-based platform designed to support data collection for research studies, providing (1) an intuitive interface for the validated data collection, (2) audit trails to track data manipulation and export procedures, (3) automated export procedures for further data downloads to standard statistical packages, and (4) procedures for data integration and interoperability with external sources. Once collected, data were described considering the mean and SD for the numerical variables and the absolute and relative frequencies to the categorical variables. SUS scores were interpreted using the Sauro and Lewis Curved Grading Scale [14].

Patients were classified into 2 groups according to the SUS scale score "Acceptable usability" (SUS ≥68) and "Usability issues" (SUS <68), and the percentage of patients was compared with 70% (for the Symptomatic sample), and 80% (for the Symptomatic sample) by the Binomial test. The cut-off point of 68 was selected because, despite variability in acceptability, this is the threshold at which the technology is considered to have acceptable usability.

The chi-square test or Fisher exact test was used to compare the groups' qualitative characteristics, and the Mann-Whitney Test was used for the numeric characteristics. The significance level of 0.05 was used throughout the study, and the analyses were performed using SPSS software (version 25; IBM corporation). Graphs were generated using R (version 4.3.2; R studio Team) software and the *ggplot2* package.

Results

Overview

The study was divided into 2 phases: the first occurred from March 6, 2023, to March 16, 2023, and 40 asymptomatic patients were included. The second occurred from March 17, 2023, to June 1, 2023, and 189 symptomatic patients were included.

Assessment of Asymptomatic Patients

The demographic distribution of the asymptomatic patients is shown in Table 1. Most were female, White, married, university-educated, and of higher socioeconomic status.

Concerning the use of the cabin, most of the patients requested support to use the cabin at some point during use. Only 3 patients described the reasons for requesting assistance as difficulties in using the equipment. The appointment had a duration between 10 and 52 minutes.

Upon assessing the satisfaction (Figure 2), we observed that the SUS had a mean value corresponding to Grading A+ (Table 2). When defining the cut-off point for SUS, we identified that only 5 (12.5%) patients had a score of <68 points, whereas 35 (87.5%) had a score of ≥68 points. Thus, the acceptability of 87.5% was statistically different from 70% (P=.009) and had a 95% CI 75.5%-100%, justifying the acceptability of the asymptomatic sample and allowing the study to proceed with the sampling of symptomatic patients.

Table . Distribution of patients by Curved Grading Scale grades of asymptomatic and symptomatic groups.

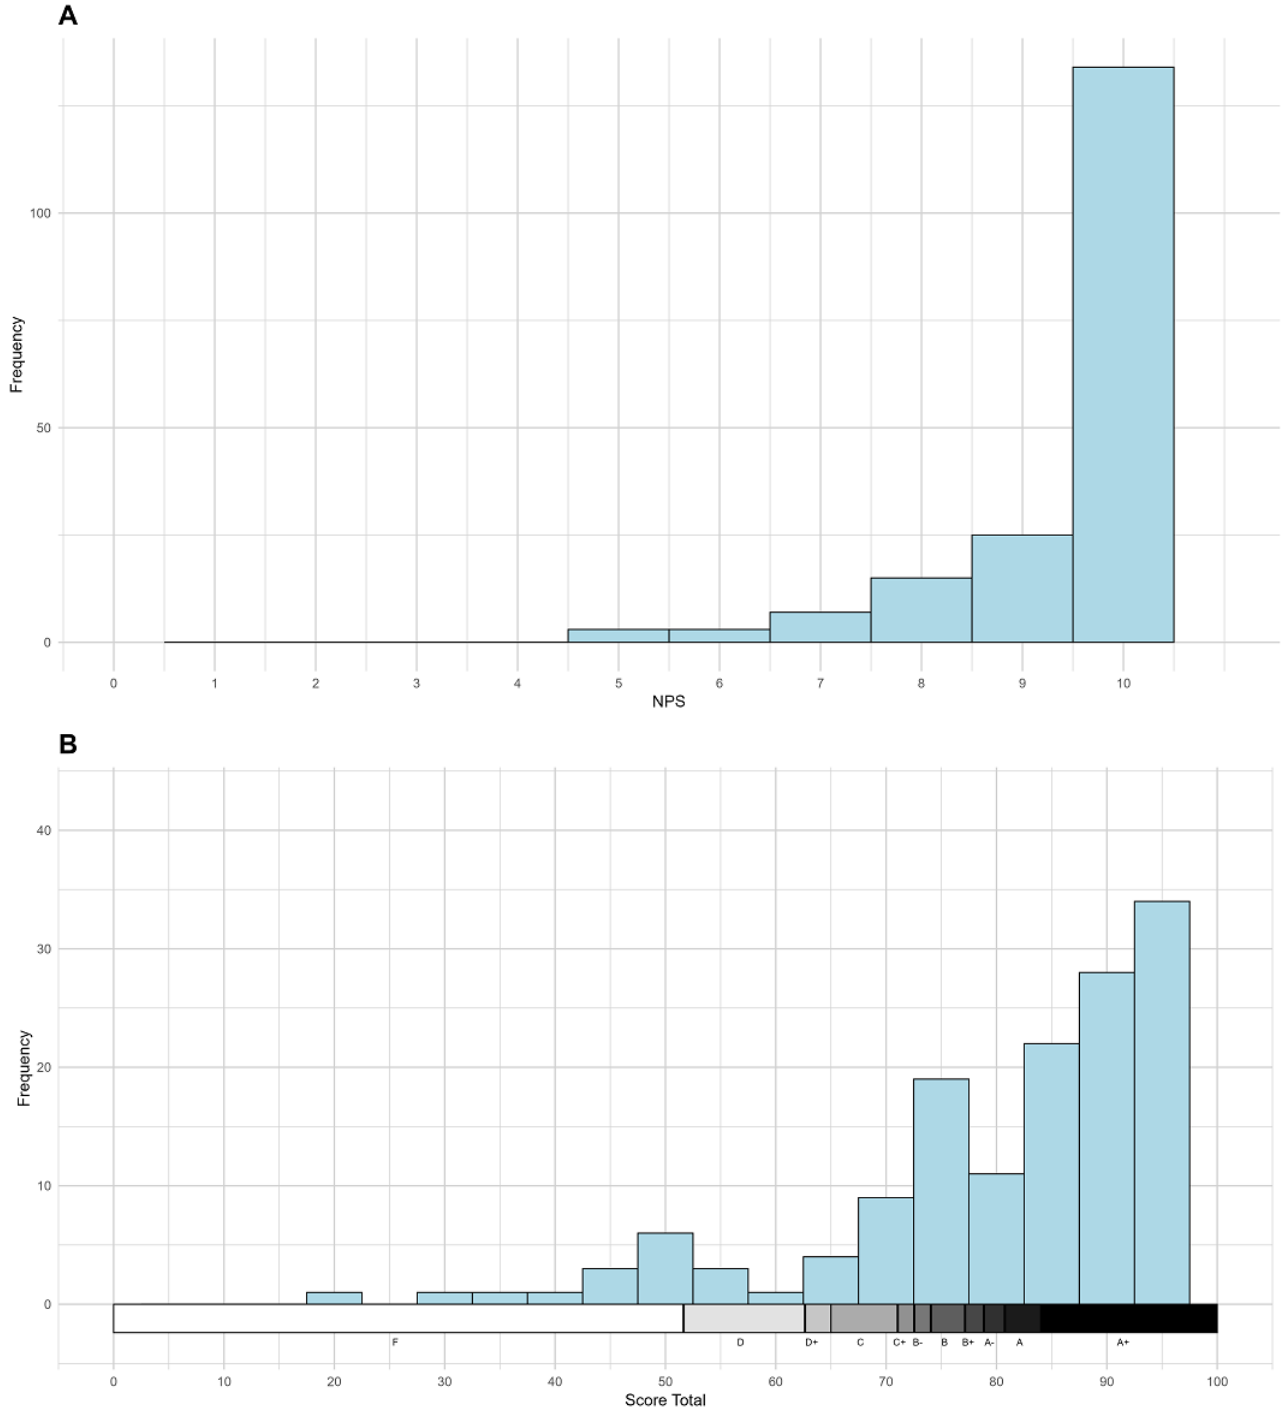
SUS score range	Grading	Asymptomatic (n=40), n (%)	Symptomatic (n=189), n (%)
84.1 - 100	A+	26 (65)	128 (68.1)
80.8 - 84.0	A	3 (7.5)	8 (4.3)
78.9 - 80.7	A−	1 (2.5)	3 (1.6)
77.2 - 78.8	B+	1 (2.5)	11 (5.9)
74.1 - 77.1	B	2 (5)	8 (4.3)
72.6 - 74.0	B−	0 (0)	0 (0)
71.1 - 72.5	C+	1 (2.5)	2 (1.1)
65.0 - 71.0	C	3 (7.5)	11 (5.9)
62.7 - 64.9	C−	0 (0)	0 (0)
51.7 - 62.6	D	2 (5)	6 (3.2)
0.0 - 51.6	F	1 (2.5)	11 (5.9)

Assessment of Symptomatic Patients

The demographic distribution of the symptomatic patients is shown in Table 2. Most were female, white, single, had a college degree, had a household income up to 3 minimum wages, did not perform care functions, and had a mean age was 35.1 years.

Only 5 (2.7%) patients requested support to use the cabin outside the previously established times. The 3 reasons described for requesting support were inconsistencies in performing the cabin and difficulties in using the instruments (otoscope and oximeter) available in the cabin.

The most of participants requested medical orientation and performed the measurement under medical orientation. The duration of the appointment ranged from 2 to 58 minutes. Regarding satisfaction (Figure 3), the variable SUS mean corresponds to Grading A+ (Table 2). When assessing the participants' score in relation to the cut-off point of the SUS scale, we found that only 21 (11.1%) patients had scored <68 points, while 167 (88.8%) had scored ≥68 points. Thus, 88.8% acceptability was statistically different from 80% (P=.001) and had a 95% CI 84.3%-100%.



The 21 patients with a score of 68 or less on the SUS were considered in the group "Usability issues" at the cabin. Eleven (52.4%) were female, 13 (61.9%) self-declared White, 11 (52.4%) had a college degree, 13 (61.9%) were single, 5 (45.5%) were married, 7 (63.6%) earned up to 3 minimum wages, 8 (72.7%) did not carry out welfare activities, and had a mean age of 32.64 years (SD 8.43).

Regarding the use of the cabin by these participants, none of them required assistance from the nursing technician, 8 (38.1%) participants requested medical instruction to perform the tests, 7 (33.3%) participants requested medical orientation and made the tests under medical orientation, while 6 (28.6%) participants did not request medical orientation.

The mean appointment duration was 20.38 (SD 10.29) minutes, ranging from 6 to 40 minutes. When comparing the characteristics of patients with SUS ≥68 related to SUS <68, all of them were not statistically significant (attaining a value equal to or higher than P=.05) (Table 3), meaning that we did not identify characteristics that could have influenced the difference in the SUS score.

[a]There was 1 missing value for the variable "SUS" and 1 missing value for the variable "Has the patient requested support to use the cabin outside the previously set times?".

[b]Chi-square test.

[c]Fisher exact test.

[d]NPS: Net Promoter Score.

Regarding the reasons for their ratings, only 3 participants chose not to answer this question. After careful reading of each response by 2 researchers, the answers were grouped according to the following categories:

- Service: assessment of the interaction between the cabin's professionals and the patient, considering the attention to the needs, clarification of doubts, and resolution of problems. Examples: (1) "Doctor's attention and understanding of my problem"; (2) "The speed and attention of the professionals who cared for me"; and (3) "Spectacular service. All my questions were answered. I thought it was excellent."
- Usability: an assessment of the ease of use of both the interface and the equipment. Examples: (1) "The experience was excellent; I enjoyed doing the tests myself and talking to the doctor about them"; (2) "Super practical, efficient, easy to use the equipment to diagnose, and talk to the doctor afterwards. Loved it!"; and (3) "I found it practical, accessible, and easy to use."
- Difficulty of use: difficulty in using equipment and tools to locate and understand the functions. Examples: (1) "Difficulty in accurately showing images and pain sites to the professional and the client's lack of affinity with the equipment can make it difficult to reach a diagnosis"; (2) "Some people may have difficulty with technology"; and (3) "Conflicting instructions between the cell phone and the screen at the self-diagnosis."
- Innovation: considerations about new products and technologies that can be aggregated to a business or project to bring about improvements. Examples: (1) "Great technology"; (2) "Very advanced technology"; and (3) "For being an innovative, versatile, and practical project."
- Technology Resistance: resistance to technological change. Example: "In no way does it replace the personal contact with the doctor, as there is no way of knowing for sure what you are feeling."
- Nonspecific: answers that were not intended or that did not belong to a predetermined group or situation, in this case, to classes of sentences mentioned above. Examples: (1) "Ok"; (2) "I loved it"; and (3) "Top."

The distributions of the classifications are shown in Table 4.

Most opinions are classified as related to "Usability." When comparing the classes of sentences of those who scored SUS equal or less than 68 (usability issues) with the remaining (acceptable usability), we found statistical differences in the class "Difficult Usability." In the group "Usability issues," 5 (27.8%) scored in this class, while 8 (4.8%) scored in the group "Acceptable usability."

Medical Assessment

At the end of the day's work, the doctor performing the appointments was oriented to answer the NPS and SUS, evaluating his or her day's work. The assessment was performed by 2 doctors, reducing the variability of the influence of the medical service on usability; 89% of the services were performed by one of the doctors, and 11% were performed by the other. The distribution of the NPS and SUS is shown in Table 5.

The main difficulties were related to technical difficulties, such as software updates and network connection problems, besides difficulties in adjusting the cabin's technology (problems with the sensors for measuring the weight and height; problems with the image or screen in the cabin).

Figures 4 and 5 show the evolution of the allocation of medical grades over time.

Table . Distribution of the Net Promoter Score (NPS) and System Usability Scale (SUS) values answered by the doctor at the end of each day of service.

	Patient's number (N)	Mean (SD)	95% CI	Min[a]	1oQ[b]	Medium	3oQ[c]	Max[d]
NPS	41	8.0 (1.4)	7.6-8.4	5.0	7.0	8.0	9.0	10.0
SUS	41	67.8 (13.6)	63.5-72.1	45.0	57.5	65.0	72.5	95.0

Discussion

Principal Findings

The assessment of the implementation of the telehealth cabin in this study aimed to observe the level of favorability and usability of users (doctors and patients) to the cabin and the self-examination devices available, added to their experience of remote service through the technologies available.

The analysis of the results showed that the participants of the first phase of the research (asymptomatic patients) had a different socioeconomic profile than those of the second phase (symptomatic patients), with higher education and monthly income, probably due to the new technology, which attracted leaders and directors of the institution to the research. Although this group was only used to assess the acceptability of both the cabin and the self-examination devices in order to continue the study with symptomatic patients, the outcomes of the favorability and usability were similar between the groups.

Therefore, despite the disparity in access to technology among populations of different economic levels, such a result suggests that the telehealth cabin may have broad applicability for several publics due to the increasing availability and use of mobile devices among the whole population, thus promoting health the equity and reducing social inequalities.

A study with similar equipment performed with French students also concluded that the personal relationship with the technology did not influence the intended use of the telemedicine cabin [15].

XSL•FO
RenderX

A significant portion of the participants did not work in the hospital care sector and therefore did not routinely use the self-examination devices, suggesting that lack of familiarity with the use of the self-examination devices may not impact the use of the cabin. However, this study was performed with professionals working in a hospital, which may bring a certain level of familiarity with those devices, even for those not directly working in the care sector.

Still, we observed that more than half of the patients requested an interview with the doctor, either before or after self-examination, indicating the relevant role of the doctor in such a kind of service.

High favorability and usability were observed for both patient groups (symptomatic and asymptomatic). No statistically significant differences were found when comparing the socioeconomic and cultural profile of those patients with the group of symptomatic who considered the cabin to have acceptable usability, which shows that the usability and favorability of the cabin are unrelated to socioeconomic and cultural factors. However, concerning comments from this group show that some aspects were considered positive even in this group. Furthermore, only one patient described a comment that could be classified in the category "Resistance to Technology," suggesting that most of the population tested is interested in learning and adopting technologies that improve their routines and experiences.

The findings of this study support the work by Scott Kruse et al [8], asserting that the principal barriers to telemedicine are technology specific. They can be overcome by continuous improvement of these technologies, adequate training of technology users, and personal interaction between the patient and the care provider [8].

Concerning the favorability and usability of doctors who performed the cabin services cabin, we found that the answer was also positive, but with a slightly lower level of usability than that of the patients. This fact seems to agree with other studies that assert that some health professionals may be reluctant. However, this resistance may be related to the difficulty of the technology. Therefore, both the favorability and usability can improve with the advancement of technology and the due training of doctors in web-based physical tests [16,17]. This phenomenon highlights the importance of training programs as a strategy to improve user experience and expedite the adoption of this technology.

A limitation of this study is the participation of only individuals without respiratory symptoms (a consequence of the COVID pandemic) or without symptoms that could indicate a medical emergency. Another limiting factor is the poor accessibility of the cabin for people with disabilities. Furthermore, because the total sampling included people employed at the hospital, and so, in the productive age group and predominantly female [18], along with workers in the day shift, this study may have introduced a bias in the perception of favorability and usability of the participants (for instance, older men are less prone to participate in several telehealth activities [19]).

Finally, we emphasize that the results obtained from health professionals should also be interpreted with caution due to the limited number of professionals who provided care for the study.

It should also be noted that no studies using this type of technology were identified in South America to compare the results obtained. In addition, the fact that this study was conducted after the pandemic may have influenced the results given the impact of the COVID-19 pandemic on people's lives, which may have affected perceptions.

Based on the favorable assessment of the technology by the participants in this study (patients and doctors) new studies that extend its use to different populations, without any link to the hospital and from different sectors of activity, different work shifts, sex, and different age groups, may bring new inputs to the application of such technology, expanding the service types and favoring the inclusion of the service in remote locations and for diverse populations.

Conclusions

The authors conclude that the telehealth cabin had good usability and favorability by patients, regardless of the socioeconomic and cultural profile of the population. Doctors who performed the cabin services attested to the cabin's good usability cabin but with a usability index slightly lower than patients. Most patients used the devices for self-examination, with little need for technical assistance. However, a SUS score greater than 68 does not necessarily mean that there are no usability issues to be addressed.

The outcomes of this research allow us to assess as feasible the expansion of this kind of practice from the point of view of usability and that this study can contribute as a subsidy to the construction of public policies to expand the access of the Brazilian population to qualified medical care, promoting the engagement of patients in their health, providing health professionals with an extended view of the clinical conditions through embedded devices even in areas with a shortage of this type of assistance.

Acknowledgments

All authors would like to thank the Votorantim Institute for subsidizing the possibility of this project and for partnering with DOC24 and Diagnóstica, which brought a new way of experiencing the health of the future through innovative equipment.

Abstract

Background: Transgender and nonbinary (TGNB) individuals are increasingly intentionally becoming pregnant to raise children, and hospital websites should reflect these trends. For prospective TGNB parents, a hospital website is the only way they can assess their safety from discrimination while receiving perinatal care. Cisnormativity enforced by communication gaps between medical institutions and TGNB patients can and has caused delays in receiving urgent care during their pregnancy.

Objective: The aim of this study was to evaluate the current prevalence of gender-inclusive terminology among labor and delivery services in the New York tristate area.

Methods: The labor and delivery web pages of 189 hospitals from New York, New Jersey, and Connecticut were examined for gender-inclusive language. “Fully inclusive” websites explicitly acknowledged lesbian, gay, bisexual, transgender, queer, intersex, and asexual plus other gender- and sexual-oriented (LGBTQIA+) parents, “inclusive” websites did not use gendered terminology for parents, and “noninclusive” websites used gendered terms at least once in the text reviewed. The hospitals’ web pages were further stratified by Healthcare Equality Index scores and population classifications defined by the 2013 National Center for Health Statistics Urban-Rural classification given to the county that each hospital was located in.

Results: Of the 300 hospital websites reviewed, only 189 websites met the criteria for inclusion. Overall, only 6.3% (n=12) of labor and delivery web pages were “inclusive” or “fully inclusive.” No geographic areas (*P*=.61) or Healthcare Equality Index scores (*P*=.81) were associated with inclusive or fully inclusive language.

Conclusions: Hospitals need to use inclusive language to help TGNB people identify hospitals where their existence and needs are acknowledged and thus feel more comfortable in their transition to parenthood.

KEYWORDS

OBGYN; transgender; nonbinary; pregnancy; maternity; transmasculine; observational study; gestational; perinatal care; communication; labor; USA; United States; New York City; sexual orientation; inclusion; parents; obstetrician gynecologist; delivery

Introduction

Within the last 2 decades, as transgender and nonbinary (TGNB) people have gained greater legal and social recognition, those in the TGNB community who want to become pregnant have become increasingly more common, as have the number of families with same-sex, transgender, or nonbinary parents [1]. Despite this trend, the field of medicine has mostly maintained the heteronormative model of a “mother” and “father” as opposed to a more fluid, freeform reality that accompanies the rise of lesbian, gay, bisexual, transgender, queer, intersex, and asexual plus other gender- and sexual-oriented (LGBTQIA+) couples who raise children.

As pregnant TGNB people attend numerous prenatal visits, they make repeated contact with heterosexist health care systems without the ability to hide their transgender status. Pharr [2] explains that heterosexism is not an active form of discrimination but rather “a belief that the world is and must be heterosexual.” According to the heterosexist worldview, every couple contains—or should contain—only 2 gender-conforming people of the opposite sex [3].

Heterosexism works with homophobia to make health care inaccessible for LGBTQIA+ populations. Current literature has

XSL•FO
RenderX

found that these parents and couples are often invalidated and marginalized throughout the health care process through obstacles like registration forms, comments from ancillary staff, and physicians who are unprepared to deal with LGBTQIA+ couples [4-6]. These experiences can take a deep mental and emotional toll—doubly so during the sensitive transition to parenthood [7].

Beyond these mental health impacts, the invisibility of TGNB parents can negatively affect pregnancy outcomes. LGBTQIA+ patients were less likely to trust providers and divulge important medical information when they received heteronormative medical treatment [8,9]. Patients may also experience delays receiving urgent pregnancy care due to the systematic heterosexism built into the health care system.

For example, Parker et al [6] discuss the experiences of a transmasculine patient who was delayed in seeing the doctor because the receptionist argued that he was not the intended person. These patterns are not limited to individual heterosexist health care workers but also integrated into hospital software. Berger et al [10] describe another scenario where a transmasculine patient's care was delayed, this time because the hospital's electronic medical record required that he reregister as female to document the pregnancy, regardless of his actual gender identity. A delay in care to circumvent cisnormative systems can be dangerous for all pregnant TGNB people. Ultimately, discrimination has often necessitated that prospective TGNB parents discern a "safe" hospital before seeking care.

Historically, LGBTQIA+ people have relied on word of mouth from their personal social circles to find safer health care [11]. However, younger LGBTQIA+ people, especially ones without LGBTQIA+ support networks, also rely on the internet to search for health information and providers that are inclusive of LGBTQIA+ people [12,13]. This vetting of hospitals, along with the increase of patient choice and consumerism for perinatal care in general, has prompted hospitals to advertise their unique benefits, such as low cesarean rates, "baby-friendly" designations, and private rooms [14-19]. Hospitals have tailored their advertisements for other demographics around them, but there is a dearth of literature showing how hospitals advertise their services for LGBTQIA+ populations, who rely on publicly available information to find inclusive care and preserve their health and safety [20].

Purdie-Vaughns et al [21] point to purposeful word choice as one safety cue that, when recognized, signals protection from identity-based discrimination. Hospitals might therefore attract pregnant LGBTQIA+ parents by crafting more inclusive obstetrical web pages. These pages could signal inclusivity by explicitly referencing LGBTQIA+ care or by avoiding gender-exclusive language like "mother and baby," "mom," or presumptive she/her pronouns for parents. Through the words chosen on these public-facing web pages, hospitals thus enable parents to choose to give birth in places where their existence is actively supported during the physically dangerous and psychologically difficult transition to parenthood.

The states surrounding New York City—New York, New Jersey, and Connecticut—boast an exceptionally high population density of LGBTQIA+ individuals, who make up between 3% to 5% of the total adult population [22]. This geographical region is viewed as more inclusive towards LGBTQIA+ people than average, so hospitals may have more incentive to provide inclusive care [23,24]. This study aims to evaluate the current prevalence of LGBTQIA+ inclusion and gender-inclusive terminology among labor and delivery (L&D) service web pages in the New York tristate area.

Methods

Study Design

The targeted words used to assess gender-inclusiveness for this study were largely adapted from the Jennings et al [25] study of gender-inclusive language on National Health Service websites.

The official public-facing obstetric web pages of nonfederal, short-term, acute-care hospitals from Connecticut, New Jersey, and New York were analyzed (n=300). Hospitals without L&D services or web content describing these services were excluded (n=189). Websites were reviewed from late November 2022 to January 2023.

Hospitals were categorized by state, 2013 National Center for Health Statistics Rural-Urban classification, and Healthcare Equality Index (HEI) score. The National Center for Health Statistics Rural-Urban classification is a tool used to identify urban and rural areas of the United States. It was used to analyze any association between urbanization and hospital-based inclusiveness of LGBTQIA+ people. The HEI score is the national LGBTQIA+ benchmarking criterion that assesses health care facilities' policies and practices regarding equity and inclusion of LGBTQIA+ patients, visitors, and employees. It was also used to identify if there was any association between a hospital's publicly perceived LGBTQIA+ inclusivity and word choice on the web pages.

For each hospital, at least 1 web page was examined alongside up to 2 additional pages as supplementation for language analysis. The gendered language used was recorded and analyzed by a single reviewer. The complete L&D-related text was analyzed and the types of gendered language used were recorded. (Explicit discussion of related services, such as chestfeeding, within the same site was excluded.) Any non–gender-inclusive descriptors for the name of the building or third-party services were also excluded from analysis, as these are often not controlled by hospital administration.

Language Analysis

Each web page was reviewed independently by the chief reviewer to minimize any discrepancies. Each hospital's L&D web page was rated as "fully inclusive," "inclusive," or "noninclusive." "Fully inclusive" websites explicitly acknowledged LGBTQIA+ or TGNB parents. "Inclusive" websites did not use gendered terminology or pronouns for prospective parents. "Noninclusive" websites used the terms "woman" or "women"; "mom" or "mother"; other terms for women; "father" or "dad"; or she/her pronouns at least once in the text reviewed.

XSL•FO
RenderX

Statistical Analysis

Categories were analyzed using χ^2 tests presented as frequencies with percentages. *P* values <.05 were considered statistically significant, and all tests were 2-sided.

Ethical Considerations

Ethics and insitutional review board approval were not required since the study did not include human or animal subjects and all data were collected from publicly available websites.

Results

Of the 300 hospital websites reviewed, 111 hospital websites did not have a L&D web page or did not have content describing their L&D services (Multimedia Appendix 1). Of the remaining 189 websites analyzed, 12 (6.3%) of them used fully inclusive or inclusive language (Table 1). Only 1 hospital (0.5%) was considered fully inclusive because it acknowledged "same-sex" couples in its L&D content. The most common noninclusive terms used were "mom" or "mother" (n=166, 87.8%) and "woman" or "women" (n=94, 49.7%). No geographic areas (*P*=.61) or HEI scores (*P*=.81) were associated with inclusive or fully inclusive language (Tables 2-4).

Table . Labor and delivery web pages that used each type of language (N=189).

	Fully inclusive, n (%)	Inclusive, n (%)	Noninclusive, n (%)	Total, n (%)
Websites	1 (0.5)	11 (5.8)	177 (93.7)	189 (100)
Language used				
woman or women	1 (1.1)	0 (0)	93 (49.2)	94 (49.7)
mother or mom	0 (0)	0 (0)	166 (87.8)	166 (87.8)
she/her (parent)	0 (0)	0 (0)	42 (22.2)	42 (22.2)
she/her (staff)	0 (0)	0 (0)	9 (4.8)	9 (4.8)
synonyms for women (ladies, etc)	0 (0)	0 (0)	1 (0.5)	1 (0.5)
father or dad	0 (0)	0 (0)	33 (17.5)	33 (17.5)

Table . Summary of HEI[a] scores and gender-inclusive language used on L&D[b] web pages .

	Fully inclusive (n=1), n (%)	Inclusive (n=11), n (%)	Noninclusive (n=177), n (%)	Total (N=189), n (%)

Discussion

Principal Findings

These results demonstrate that there is a large barrier for TGNB parents to search for and identify potentially inclusive pregnancy care. Out of the 12 inclusive and fully inclusive L&D web pages, 92% were inclusive not because they included gender-additive language or LGBTQIA+ topics but rather because they omitted the pregnant person's gender altogether by addressing the reader in the second person. The websites may have been inclusive not by intention but by coincidence. In stark contrast, there are multiple private reproductive endocrinology and infertility clinics that specifically target LGBTQIA+ couples using specific gender-inclusive language on their websites [26]. TGNB parents who are accustomed to a purposefully inclusive experience during their fertility journey and early pregnancy may be caught off guard by the sudden invisibility of their identities as they progress further through their pregnancy.

Interestingly, none of the hospitals that are acknowledged for their excellence in LGBTQIA+ care in other specialties discussed serving prospective TGNB parents for L&D care on their websites. This likely reflects a wider societal trend of "repronormativity," by which society at large does not recognize reproductive sex between TGNB parents as possible or legitimate [27].

The accessibility of websites and web-based platforms is important for TGNB people to find services and connect to similar parents. Our above findings suggest less than 10% of hospitals use gender-inclusive language when representing their services. Thus, TGNB parents who are not connected to a wider LGBTQIA+ community may struggle to find inclusive prenatal care and delivery services due to the lack of representation.

Limitations

The use of multiple surrogate end points may limit this study. The analyzed web pages, while used as a proxy for the culture in L&D departments, may not fully represent institutional attitudes and practices once parents start using their providers. This is exacerbated by delays between institutional attitude changes and hospital website updates. HEI scores were ineffective in predicting the LGBTQIA+ inclusivity of hospitals' web pages because HEI scores are determined purely through institutional measures like nondiscrimination policies; they do not directly address subtler, underlying heterosexism that hopeful TGNB parents try to avoid in their health care. Finally, the methodology used in this study makes it impossible to establish a causal link between gendered terminology and the quality of LGBTQIA+ inclusive care.

Additionally, it is important to note that individual TGNB people may feel varying levels of dysphoria around maternal terms; some TGNB parents may not consider the words "mom" or "mother" to be exclusively for women. However, using gender-inclusive language and terminology is an important step towards providing a more welcoming and inclusive environment for TGNB parents, regardless of those individuals' personal dysphoria triggers.

Conclusions

Using gender-inclusive language and terminology is the first step towards providing a more welcoming and inclusive environment for pregnant TGNB parents. Hospitals that want to be recognized as more inclusive towards LGBTQIA+ people can integrate gender-additive language into their L&D web pages (eg, "mothers and birthing parents") rather than omit mentions of gender entirely [28]. US hospitals should consider expanding this language to meet the needs of a growing group of people who are having children. Future research should be done including LGBTQIA+ patient advocate groups on the use of inclusive language within health care providers' obstetrical and gynecology departments, specifically in L&D units and on how this language impacts TGNB parents' health outcomes and rapport with physicians.

Conflicts of Interest

None declared.

Abstract

Background: Telemedicine has been utilized in the care of patients with COVID-19, allowing real-time remote monitoring of vital signs. This technology reduces the risk of transmission while providing high-quality care to both self-quarantined patients with mild symptoms and critically ill patients in hospitals.

Objective: This study aims to investigate the application of telemedicine technology in the care of patients with COVID-19, specifically focusing on usability, effectiveness, and patient outcomes in both home isolation and hospital ward settings.

Methods: The study was conducted between January 2022 and December 2022. More than 800 cases were monitored using the QOCA remote home care system, a telemedicine platform that enables remote monitoring of physiological data—including heart rate, blood pressure, temperature, and oxygen levels—through Internet of Things devices and a 4G-connected tablet. Of these, 27 patients participated in thie study: the QOCA remote home care system was deployed 36 times in the isolation ward and 21 times to those in home isolation. The QOCA remote care system monitored isolated cases through remote care packages and a 4G tablet. Case managers and physicians provided telemedicine appointments and medications. Innovative methods were developed to enhance usage, including online health education, remote care equipment instructions via QR core links, and video consultations for patients without smartphones.

Results: A clinical nurse satisfaction survey revealed that most respondents found the content of the remote care package comprehensive and the interface easy to learn. They expressed a desire to continue using the system. The majority also agreed that using the remote care system and package would reduce their workload and that patients and caregivers could easily learn to use the package. While some respondents expressed concerns about network and Bluetooth connectivity, the majority (24/27, 89%) agreed to include the remote device as part of their routine equipment, with an average score of 84.8 points.

Conclusions: The integration of telemedicine technology improves the quality of care while reducing the workload and exposure of health care workers to viruses.

Introduction

COVID-19, a global pandemic, has posed significant challenges to health care systems worldwide [1,2]. While Taiwan has achieved success in epidemic prevention, the reopening of borders raises concerns about potential gaps in prevention measures and strains on health care resources. Addressing these

XSL•FO
RenderX

challenges, this study identifies critical needs in the context of COVID-19 care.

The need for home quarantine and home medical care is vital. National Taiwan University Hospital Yunlin Branch has pioneered a telecommunication-based remote consultation model [3], providing video consultations for individuals under home quarantine. This initiative has not only met their basic health care needs but also minimized the risk of infection by reducing hospital visits. However, with the majority of cases being mild or asymptomatic, and a higher proportion of symptomatic cases among middle-aged and older individuals [4], it is crucial to develop a comprehensive telemedicine model for continuous medical care during home quarantine or isolation and for patients with mild COVID-19 undergoing home treatment [5-7].

During the COVID-19 pandemic, home monitoring of patients has gained popularity. There are two main research designs: (1) assessing patients before hospital admission to reduce virus exposure and identify deterioration and (2) postdischarge monitoring to provide continued care [8]. Monitoring methods include online platforms, paper-based operations with telephone interviews, or wearable devices [9-11]. Paper-based operations with telephone interviews are more inclusive due to limited digital literacy among the target population [12,13]. Most studies focus on vital signs rather than psychological issues. Wearing a pulse oximeter is important for monitoring, but it may cause anxiety and has limitations for certain patients [14-16]. Home monitoring during COVID-19 has benefits and can reduce health care costs [17]. Improving accessibility and convenience is key for future adoption.

Due to the pandemic, health care providers are unable to provide patients with the usual standard of care during hospitalization, leading to various challenges and impacts. Health care workers face psychological stress and staffing shortages, while patients experience isolation and mental health issues. Family members are unable to visit their loved ones in critical condition [18,19]. Technology can offer some assistance in addressing these issues, such as self-monitoring of blood oxygen levels and the integration of vital sign monitoring [20]. Collaboration between technology companies and health care providers is crucial, especially as the pandemic becomes normalized in the community. The development of information-assisted solutions is urgent in order to improve health care delivery [21].

There is a need for low-contact health care for hospitalized, isolated patients. To mitigate the risk of infection among patients with confirmed COVID-19 infection or those at high risk of being infected in dedicated isolation wards, the integration of smart ward solutions and telemedicine is proposed. Real-time remote physiological monitoring can minimize exposure risks and reduce the workload of health care staff, optimize management processes, and preserve valuable isolation rooms and personal protective equipment. Furthermore, obtaining real-time patient information enables early intervention and improves work efficiency, thereby enhancing the safety of patients with confirmed COVID-19 infection.

The study was conducted as a collaboration between National Taiwan University Hospital Yunlin Branch and Quanta Computer, utilizing their expertise in big data analysis and telecommunication telemedicine technology. The project focuses on the COVID-19 response hospitals, with the National Taiwan University Hospital Yunlin Branch serving as the testing ground. Specifically, it aims to provide assistance to patients with confirmed COVID-19 infection or those at high risk of being infected in the dedicated isolation ward, using advanced telemedicine equipment for clinical care. By implementing real-time remote physiological monitoring, the project aims to reduce the exposure risk and workload of health care personnel, simplify management processes, and optimize the utilization of valuable isolation rooms and personal protective equipment. Furthermore, by promptly assessing patient conditions and intervening as needed, the project seeks to enhance work efficiency and ensure the safety of patients with confirmed COVID-19 infection.

Methods

Ethical Considerations

The Institutional Review Board (IRB) of National Taiwan University Hospital approved this study (202009106RIPA). Questionnaires were collected after obtaining informed consent.

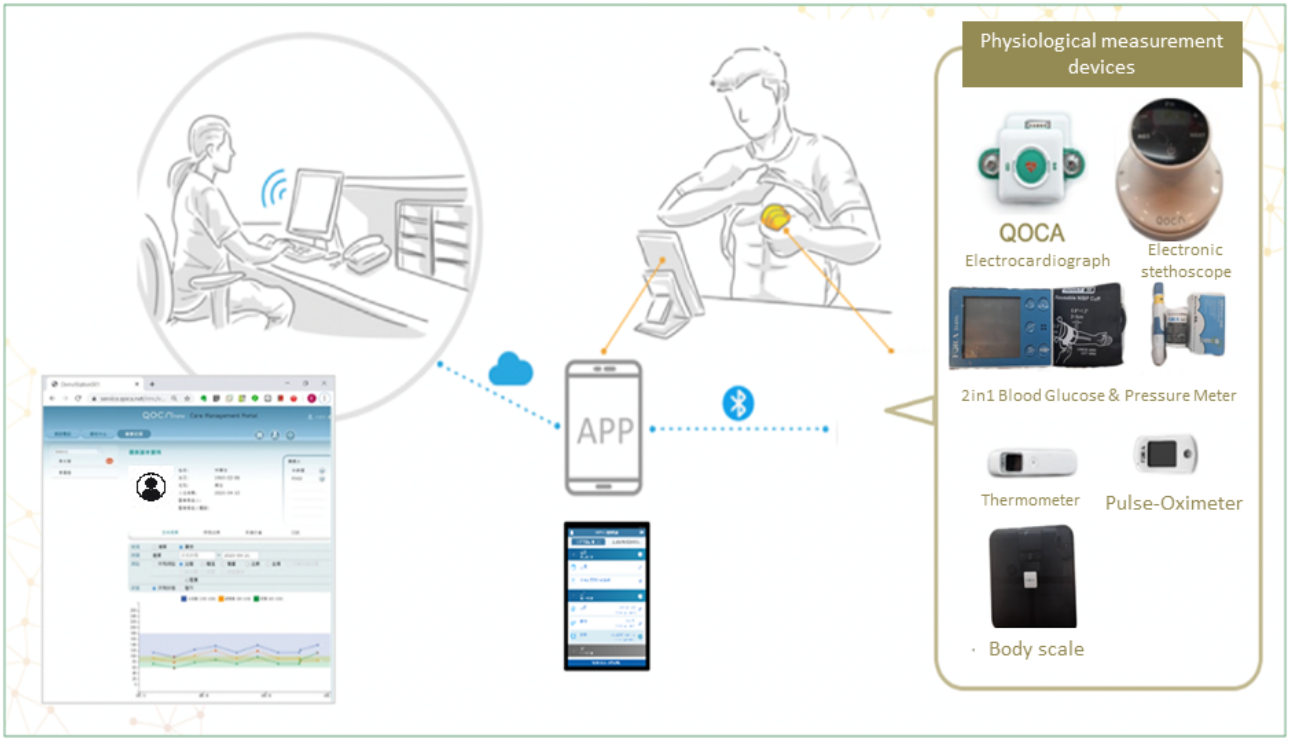
All participant data were anonymized or deidentified to ensure privacy. Participants voluntarily provided informed consent, and no personal identifiers were included in the analysis or dissemination. Additionally, anonymous surveys were used to ensure there were no risks of information leakage.

Participants in the study were not compensated monetarily or otherwise. Their involvement was voluntary, and all necessary support for participation, such as the provision of remote care packages and telemedicine tools, was offered free of charge. This ensured equitable participation without financial coercion.

Study Design, Data Sources, and Population

The study was conducted at the National Taiwan University Hospital Yunlin Branch. The inclusion criteria comprised individuals diagnosed with COVID-19, while exclusion criteria included moderate to severe COVID-19 cases, patients unwilling to participate in telemedicine monitoring, and individuals deemed unsuitable for telemedicine evaluation by physicians. Participants were required to be 20 years of age or older and provide informed consent approved by the IRB. The study enrollment period spanned from January to December 2022.

Home Quarantine and Home Medical Care



This study included individuals who have tested positive for COVID-19 and were classified as mild cases or have been determined by the Center for Disease Control, Taiwan, to not require immediate hospitalization due to severe conditions. These individuals can undergo self-isolation monitoring and were either required to quarantine or be monitored at home or quarantine hotels.

The QOCA home system, developed by Quanta Computer, is the core of the remote health care platform. It utilizes a 4G-connected tablet computer for patients, offering features like remote video communication, physiological signal measurement transmission, and remote physical examination (Figure 1). Home monitoring occurs at the patient's residence

XSL•FO
RenderX

or quarantine hotel, providing audiovisual communication and simple consciousness assessment. Vital signs, such as heart rate, blood pressure, temperature, and oxygen level, are measured and transmitted using Internet of Things (IoT) devices. A remote physical examination system, including electronic stethoscope devices, captures and uploads important findings like lung and heart sounds. An interactive care app records visual aspects and clinical conditions, which can be uploaded for health care providers. An online questionnaire system tracks COVID-19 symptoms, comorbidity control, and psychological well-being. Medication assessment and personalized care planning are provided. The hospital-side system manages home isolation quarantine and home-based COVID-19 care. Case managers track patient conditions through a dashboard, maintain daily health logs, and determine if hospital treatment is needed. Information and communication technology–based remote health care ensures continuous medical care and psychological support for individuals in home quarantine or isolation and home-based patients with COVID-19. Remote care packages enable self-isolated individuals to monitor and report symptoms and vital signs, with data transmitted back to the hospital. Dedicated care managers communicate with patients, report to physicians, and provide necessary support in case of discomfort or abnormalities.

Figure 1. The QOCA home system by Quanta Computer is central to the remote health care platform. Utilizing a 4G tablet, it enables remote communication, physiological data transmission, and virtual exams. Monitoring occurs at homes or quarantine locations, allowing audiovisual contact and basic assessment. IoT devices measure and send vital signs, while an electronic stethoscope captures and uploads lung and heart sounds. An interactive app records visual and clinical data for health care providers. An online questionnaire tracks COVID-19 symptoms, comorbidity control, and psychological well-being and includes medication assessment and personalized care planning. IoT: Internet of Things.

Smart Hospital Ward

Patients with COVID-19 admitted to negative pressure isolation wards or intensive care units at National Taiwan University Hospital Yunlin Branch were monitored using the QOCA home system developed by Quanta Computer. Tablet computers, IoT physiological monitoring devices, and video cameras were installed in patient rooms for remote monitoring. Patient physiological data, including heart rate, respiration, body temperature, blood pressure, and blood oxygen levels, were automatically recorded and uploaded to the cloud. The care team accessed these data without entering the rooms. The smart ward included an electronic stethoscope device for recording heart and lung sounds. A central monitoring module and a patient dynamic dashboard were established at the nursing station, providing alerts for abnormal conditions. Patient laboratory reports and images were integrated, enabling health care providers to interact with patients through the video system. The study aimed to utilize information and communication technology, including 4G-connected tablets and IoT monitoring platforms, to facilitate remote health care for patients with COVID-19 in isolation units. This system enabled continuous medical care, psychological support, and remote consultations with physicians; nursing care; psychological counseling; and rehabilitation therapy. It allowed for monitoring of vital signs and COVID-19 symptoms, promoting patient well-being without direct contact.

Satisfaction Survey for the QOCA Smart Ward Remote Care System: Clinical Nursing Staff and General Population

This questionnaire aimed to understand the relevant settings of the remote care system and its clinical application in dedicated wards for COVID-19. The information gathered will be used for future improvements and optimization. This survey was anonymous, and there were no concerns about personal

XSL•FO
RenderX

information leakage. The questionnaire included aspects of communication quality, user-friendliness, overall satisfaction, and suggestions. Each option consisted of strongly agree, agree, neutral, disagree, and strongly disagree (Multimedia Appendix 1).

Results

Overview

Before officially enrolling patients in the monitoring care package, thorough explanations and assistance were provided to each individual in the isolation ward to ensure their understanding and obtain their consent to participate in the research study. Following this, every isolated patient was equipped with a set of remote care packages. This became standard practice in the ward, significantly reducing the frequency of health care personnel entering patient rooms to don and remove isolation garments. Patients were empowered to self-measure their vital signs whenever they felt unwell, providing immediate access to physiological data that could alert health care professionals to any discomfort or changes in their condition. This approach not only alleviated patients' psychological anxiety about their disease progression but also allowed health care staff to spend less time in isolation garments while maintaining a real-time understanding of the patients' current status, ultimately improving the quality of clinical care.

Enhancing Hardware Infrastructure for Remote Care System in Isolation Ward

To enhance the hardware aspect of the remote care system implemented in the isolation ward, the original 7-bed negative pressure ward was expanded to accommodate the installation of 32 sets of care packages, with one set allocated to each bed. Additionally, the nursing treatment cart and the nursing station computer were equipped with the QOCA remote care system platform and individual nursing staff accounts. This setup empowered the nursing personnel to monitor the patients' vital sign data in real time, which were automatically uploaded by the system after patient measurements. Continuous monitoring of vital signs was made possible throughout the patients' entire hospitalization and isolation period. Moreover, the QOCA system facilitated real-time video communication when necessary, enabling consultations with psychiatric physicians to address any illness-related anxieties that the patients may have. By extending the focus of care beyond the patients' physiological needs, the hospitalization and treatment process also addressed their psychological well-being.

Remote Home Care Package for Individual Who Are COVID-19 Positive Under Self-Isolation

For individuals who have tested positive for COVID-19 and can self-isolate at home without requiring hospitalization, a comprehensive remote home care package was provided. This package enabled individuals to independently monitor their health, even without monitoring devices at home. It included daily self-observation of symptoms and measurement of vital signs, with the numerical data automatically transmitted to the hospital through a tablet computer connected to 4G.

To ensure prompt attention to any discomfort or adverse conditions, a dedicated care manager was assigned to each patient. The care manager promptly reported any concerns to the responsible physician and maintained regular contact to inquire about the patient's condition throughout the home isolation period. If individuals experience symptoms, they could also schedule telemedicine appointments to closely monitor changes in their condition.

In cases where symptom management was necessary, the responsible physician could prescribe appropriate medications to help alleviate symptoms. This comprehensive remote home care package aimed to provide effective care and support to individuals with COVID-19, ensuring their well-being while minimizing the risk of further transmission.

Advancing Care Through QOCA Telecare System for COVID-19 Monitoring and Isolation

The number of cases monitored using the QOCA remote home care system exceeded 800. Among them, 29 individuals voluntarily participated in this research study and provided their consent by signing the IRB consent form. The QOCA remote home care system was deployed 36 times in the isolation ward and 21 times to those in home isolation, as indicated in Table 1. In the ward, patients primarily monitor themselves or receive assistance from family members for monitoring, while a small number of individuals without family support or hired caregivers receive help from nursing staff for measurements.

The participants in this study represented a diverse range of age groups, with the majority being aged 41-60 years (13/29, 45%), followed by the 61-80 years age group (9/29, 31%), and the fewest participants in the 21-40 years (3/29, 10%) and 80+ years age groups (4/29, 14%). The sample was predominantly male, with 27 (93%) male participants and only 2 (7%) female participants. Regarding the need for assistance, 11 (38%) participants required help during the study, while 18 (62%) managed independently. The participants' education levels varied, with most having elementary or junior high education (20/29, 69%), while a smaller number had completed high school or higher education (9/29, 31%). In terms of technology usage, 21 (72%) participants used digital devices daily, while 8 (28%) reported no prior experience. Health engagement levels were mixed, with the majority (20/29, 69%) not actively seeking information about their conditions, while some participants regularly consumed health-related content. Additionally, 17 (59%) participants had prior experience with health monitoring devices, further illustrating the range of familiarity with telecare technology among the group.

In contrast to traditional inpatient monitoring methods, the ward implemented a specialized remote home care system designed specifically for the isolation care required during the COVID-19 pandemic. This system enables patients to independently measure their vital signs and automatically transmit the data to the nursing staff. To ensure effective utilization of the remote home care system by patients and their accompanying family members, innovative care methods have been developed, including the following:

XSL•FO
RenderX

1. Online health education materials: With the widespread use of smartphones due to technological advancements, disease-specific health education materials are provided through QR codes during hospitalization. This allows patients to access relevant information whenever needed.
2. Guidelines for operating remote care devices: Some individuals may be unfamiliar with monitoring devices. Even after receiving instructions from health care professionals, patients may require repeated practice. To facilitate practice sessions without overwhelming the nursing staff, instructional videos demonstrating device operation can be accessed through QR codes. Patients can practice as many times as necessary to ensure accurate measurements.
3. Tablet-based video consultations for remote care: Patients without smartphones can still access important information through tablet-based video consultations offered by the remote care system.

The ward continues to fully utilize the remote home care system for clinical monitoring, and the number of users continues to grow. Health care professionals not only provide personalized care to patients but also make adjustments to the care process based on the implementation of the remote home care system. This approach reduces the risk of viral exposure and eases the workload for health care staff, streamlines management procedures, and ultimately enhances the quality of care provided.

Clinical Nursing Staff Satisfaction Survey

This survey aimed to assess the satisfaction and experiences of the clinical nursing staff in using the telecare system in the dedicated COVID-19 isolation wards. The questionnaire was divided into 3 main categories: *communication quality*, *user-friendliness*, and *overall experience*. The objective was to identify and analyze the challenges and difficulties faced by users in relation to equipment, signals, and interface operations.

A total of 27 questionnaires were collected exclusively from nursing staff working in the dedicated COVID-19 wards, specifically Ward 7A and Ward 7B. Regarding the transmission signals of the equipment, 44% (n=12) of the respondents believed that the internet connection of the telecare system was stable, while 37% (n=10) found the Bluetooth connection between the tablet and the devices in the package to be stable. When using the telecare system for video calls, 56% (n=15) stated that the image quality was clear, and 56% (n=15) stated that the sound quality was clear (Table 2).

In terms of usability, following training on the telecare system's interface, 89% (n=24) of the respondents found it easy to learn, and an equal percentage (n=24, 89%) expressed their willingness to continue using the telecare system to assist in clinical care. Furthermore, 67% (n=18) believed that patients or caregivers could quickly grasp the usage of the telecare package. Moreover, 81% (n=22) of the respondents indicated that the telecare package contained all the necessary components and fulfilled the requirements for clinical monitoring. Additionally, 89% (n=24) agreed that the use of the telecare system and package could help alleviate the burden of clinical care (Table 3).

Overall, 89% (n=24) of the respondents agreed to incorporate the telecare device as a regular piece of equipment in isolation wards, with an average satisfaction score of 84.8. The majority (24/27, 89%) of the responses highlighted the short monitoring time of the device and the instability of signal transmission. They expressed a desire for improved stability in wireless internet and Bluetooth signals, as it would lead to a smoother user experience (Table 4).

Discussion

Principal Findings

The enhancement of the hardware infrastructure for the remote care system in the isolation ward has significantly improved the quality of care and patient outcomes [22,23]. By expanding to accommodate more care packages, each patient receives continuous monitoring and support. The integration of the QOCA remote care system into nursing carts and computers allows real-time access to vital sign data, enabling prompt interventions and ensuring patient well-being. The system also facilitates video consultations with psychiatric physicians, addressing patients' anxieties and holistic needs. This approach benefits both patients and nursing staff, who can efficiently monitor multiple patients, respond promptly to changes, and access patient data remotely, thus saving time and reducing errors.

The implementation of a remote home care package for individuals who are COVID-19 positive in self-isolation offers effective care and support while reducing transmission risk [24]. Patients can independently monitor their health by observing symptoms and measuring vital signs, actively participating in their care. A tablet connected to 4G enables real-time transmission of data to health care providers, facilitating informed decisions. Dedicated care managers provide personalized support, regularly checking in on patients and promptly reporting concerns. Telemedicine appointments allow close monitoring, adjustment of treatment plans, and direct access to medical professionals, thus reducing anxiety. Remote prescription of medications ensures symptom management without visiting a health care facility. However, challenges include subjective self-reporting and disparities in internet access and technological skills [23,25]. Education and efforts to address disparities are essential for equitable care.

XSL•FO
RenderX

The implementation of the QOCA remote home care system for COVID-19 monitoring and isolation has been successful in advancing care and improving patient outcomes. With over 800 cases monitored, the system allows patients to independently measure vital signs and transmit data to nursing staff, reducing the need for frequent in-person monitoring. Innovative methods, such as online health education materials and instructional videos, ensure optimal utilization of the system. Tablet-based video consultations cater to patients without smartphones. By fully utilizing the remote home care system, the ward provides personalized care, streamlines management procedures, reduces viral exposure, and eases the workload for staff, ultimately enhancing care quality [26]. Ongoing monitoring and evaluation are crucial for system refinement, and its success in COVID-19 care opens doors for its application in other health care settings, showcasing the transformative potential of technological advancements in patient care.

During the COVID-19 pandemic, nursing professionals have made substantial achievements in delivering adequate patient care by utilizing telehealth [8,12,24]. The results of the clinical nursing staff satisfaction survey regarding the telecare system in COVID-19 isolation wards provide valuable insights into their experiences and challenges [27]. The majority of respondents found the telecare package to be usable and to have met the requirements for clinical monitoring. After training, the respondents stated that the interface was easy to learn, and they expressed their willingness to continue using the system. A substantial percentage believed that patients and caregivers could quickly grasp its usage, and that the use of the telecare system helped alleviate the burden of clinical care [12]. Regarding transmission signals, opinions were mixed. While a portion of respondents found the internet connection stable, others highlighted issues with Bluetooth connectivity. In terms of video calls, a majority found the image and sound quality to be clear. Overall, the survey indicates high satisfaction with the telecare system, with a majority of respondents expressing their support for incorporating it as a regular equipment in isolation wards. The average satisfaction score was positive [13]. However, feedback emphasized the need for improvements in signal stability, particularly in wireless internet and Bluetooth connections [24]. The short monitoring time of the device was also a concern.

The difficulties and obstacles in telemedicine for COVID-19 care include insufficient hardware environment and the short monitoring time of equipment [28]. The negative pressure isolation environment in the ward, with multiple walls and controlled doors, leads to weak signals. Installing signal amplifiers, as suggested by the hospital's IT department, can improve signal stability. The monitoring time of the equipment is too short, but through discussions with engineers and the manufacturer, it is believed that adjusting the monitoring time according to individual patient needs can align it with clinical requirements, enabling more accurate monitoring of values. Addressing these challenges will enhance the effectiveness and reliability of telemedicine in COVID-19 care.

One potential limitation of this study is the relatively small sample size, which may affect the generalizability of the findings. With only 36 deployments in the isolation ward and 21 deployments in home isolation, the results may not fully represent the broader population of patients with COVID-19 or other health care contexts. Additionally, the voluntary nature of participation could introduce selection bias, as those who agreed to participate may differ from those who declined in terms of health status or access to technology. Another limitation is that the study was conducted within a single hospital, potentially limiting the applicability of the results to other settings with different resources or patient demographics. Lastly, the short-term focus of the study may not capture the long-term effectiveness or sustainability of telemedicine interventions, warranting further research in this area.

Conclusion

The implementation of the QOCA telemedicine system demonstrated significant benefits in managing patients with COVID-19 who have mild symptoms, both in isolation wards and home quarantine settings. By enabling continuous remote monitoring of vital signs and offering real-time communication between patients and health care providers, the system not only improved the quality of care but also reduced the workload and exposure risk for medical staff.

However, the study had some limitations, including a relatively small sample size and the potential for selection bias, which may affect the generalizability of the findings. Additionally, the short-term nature of the study may not fully capture the long-term impacts of telemedicine in patient care.

Despite these limitations, our findings suggest that telemedicine systems like QOCA can play a crucial role in pandemic response and future health care delivery. Further research with larger, more diverse populations and extended follow-up periods is recommended to fully explore the potential of telemedicine in improving patient outcomes and health care efficiency.

Acknowledgments

We sincerely thank Quanta Computer for their invaluable support in establishing the following health care systems: the Smart Ward Cloud Care System, QOCA Home, Intelligent Remote Health Care System, and Remote Home Care Package. This study was supported by the National Science and Technology Council, Taiwan, for the research (MOST 109－2823－8－002－013-CV).

Abstract

Background: Telehealth is an increasingly important component of health care services. Telehealth services may present an opportunity to increase the equity, accessibility, and effectiveness of health care. As such, it is critical that telehealth design focuses on reducing the barriers to access and usability that may impair some telehealth users.

Objective: Our goal was to identify different demographic characteristics, behaviors, or opinions that may predict groups who are likely to face a barrier to using telehealth services.

Methods: We used data from the National Health Interview Survey and multiple logit regression models focused on different aspects of telehealth to examine three different avenues of telehealth service: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider through email using the internet in order to consider the ways in which different telehealth services may face different barriers.

Results: Our results suggest that middle-aged (36-55 years old) and older adult (56-85 years old) respondents were significantly less likely to look up health information using the internet or schedule an appointment using the internet versus younger individuals (18-35 years old). Specifically, our analysis found that middle-aged adults were found to have a higher odds ratio than older adults (0.83 vs 0.65) for looking up health information using the internet. We also found that there were differences in age groups for using technology to perform health care–related tasks. In terms of searching for health information using the internet and scheduling appointments using the internet, we found differences between men and women, with women being significantly more likely than men to look up health information using the internet, schedule an appointment using the internet, and communicate with a care provider through email using the internet. Across all the investigated variables, we found that the rates of using the internet for looking up health information, scheduling an appointment, and communicating with a care provider over email increased substantially across the study period. The impact of costs was inconsistent across the different models in our analysis. We also found that there is a strong correlation between respondents' collaboration in their personal health and the likelihood that they would use telehealth services to meet these needs.

Conclusions: This analysis provides an exploratory look at the data to highlight barriers that may impact a user's ability to access telehealth services in the context of other potential predictor variables to account for the real-world variability that these may present. Future work should examine the complex relationships of those variables and understand how these interactions are correlated with the respondents' use of telehealth.

Introduction

Background

With the advancement of digital technologies, the use of technology in health care has grown [1,2]. While there have been several attempts to better understand the use of digital technologies in health care, much of the work has been done in silos and is sometimes limited in scope [2,3]. Generally, telehealth refers to health care communication through technology, often used in conjunction with telemedicine and eHealth [3-5]. Mobile health is an additional term that describes telehealth services in the context of mobile devices [6]. Telehealth is increasingly being used in growing populations, offering distinct advantages and potential barriers for different patient populations and their care.

Benefits Associated With Telehealth

The increased adoption of telehealth services has allowed for its impacts to be examined on actual patients receiving telehealth care [7]. It has been shown that when telehealth is implemented with current best practices, it may help to balance the health care supply and demand disparity [8], improve patient access to care [8,9], and reduce the cost of care [8,9]. Due to increasing demand with changes in population sizes and demographics, as well as decreasing supply as care providers retire or change careers [8], telehealth services and telehealth programs have helped bridge this gap [10,11]. Telehealth also has been shown to improve patients' ability to access care, thus enabling patients to receive efficient and cost-effective care [8,10] by reducing the impacts of geographical barriers [12] and cost barriers to care [13]. Telehealth may also improve the cost-effectiveness of care, with [14] finding that the "all-cause" cost of providing care to older patients (older than 65 years) decreased from US $937.25 to US $491.52 with the inclusion of telehealth services. Telehealth can also offer support for individuals seeking mental health care where mental health specialties are distant or when there may be patient privacy issues in obtaining mental health care [15].

Barriers to the Use of Telehealth Services

There are several potential barriers that have been identified related to the use and effective implementation of telehealth services [7]. A notable barrier to telehealth services is patients' health literacy [16-18]. Individuals with lower levels of health literacy have shown lower comfort levels with using telehealth technologies [17,19]. Older people are using as well as providing telehealth services [20]. Yet, it has been suggested that older patients (older than 60 years) might have greater difficulty using telehealth services [21]. Additionally, technological infrastructure issues (low-quality, limited internet access) may reduce the ability of individuals to access telehealth services [22]. Individuals' access to electronic devices (ie, smartphones, computers, and tablets) may also be a barrier to engaging in telehealth services [22]. In addition to the access issues, the time and costs required to engage in the services (both for the patients as well as clinicians) may be a barrier to rolling out large programs or integrating them into the workflow processes for clinical staff [23].

Changes in Health Care Populations Over Time

There are several factors that have been shown to impact the use of web-based resources for health care and other telehealth services [24]. A 2018 study suggests that demographic factors, such as living in rural areas, age, and insurance types, impact telehealth implementation and use in health care facilities [24]. There have also been racial and ethnic discrepancies reported in the literature, with Black and Hispanic patients preferring emergency departments to telemedicine compared to White patients [25]. Age is also an important factor as the use of telehealth differs among different age groups [14,25]. In addition, health insurance access, and having internet access also influence the use of telehealth [14].

It is important to consider how user needs with telehealth change over time [26]. Changing population demographics, such as age, have major impacts on the use and function of health care [27]. Other additional factors, such as socioeconomic factors and changes in the prevalence of different health conditions, also impact the function of the health care system [27]. Over time, population demographics, access, and technology can change significantly, leading to incorrect conclusions or missed critical trends due to observing only one moment. It is important to consider all these elements when examining which predictors may indicate barriers to telehealth access. The objective of this research is to examine how individuals used the internet to support their health care over 7 years (2012-2018) using the National Health Interview Survey (NHIS) data. Specifically, we examined how different demographic variables and respondents' perspectives influenced how individuals looked up health information using the internet, scheduled appointments using the internet, and emailed to communicate with a care provider using the internet.

Methods

Ethical Considerations

An ethics board review was not required for this analysis as this study used publicly available data.

Overview

Each year the Centers for Disease Control and Prevention (CDC), a government agency assigned to monitor the general public's behavior and health status conducts the NHIS, which is an annual cross-sectional survey designed to gather data on a variety of health-related topics throughout the United States with oversampling of certain demographic groups in a way that is nationally representative [28]. The survey weighting variable is poststratified based on the US Census data to represent national population characteristics [28]. These survey weights are identified for all combinations of persons within the variable WTFA_SA in the NHIS data. Due to the complex survey sampling strategy, the survey person weights must be used in analyzing the data to avoid substantial bias in the results [28].

For this analysis, the NHIS sample adult files for each year from 2012 to 2018 were used. For the files from 2012 to 2014, the American Standard Code for Information Interchange data file was combined using the stringr, stringi, foreign, and RCurl packages in R (R Foundation for Statistical Computing) to run

XSL•FO
RenderX

the associated Statistical Analysis System statements to produce a .csv version of the sample adult file. For the years 2015-2018, a csv file was provided for the sample adult survey data. We created a single file by combining responses for each year using the R functions rbindlist from the data.table package to match each survey year on the corresponding variable columns. Only identical questions related to our research objectives were included in the combined data set.

All responses recorded as the option "not ascertained" were recoded as NA for all variables. All the variables were recoded by assigning binary values or group responses to facilitate the data analysis. The variables used as outcome variables were recoded to become binary variables: health information seeking using the internet (HIT1A), scheduling health care appointments using the internet (HIT3A), and communication with health care providers through email using the internet (HIT4A). Demographic variables were also recoded, including the respondent's race (RACERPI2), Hispanic ethnicity (HISPANI_I), sex (SEX), region (REGION), marital status (R_MARITL), internet use (AWEBUSE) and the frequency of using the internet (AWEBOFNO and AWEBOFTP), email use (AWEBEML) and the frequency of using email (AWEBMTP), whether a respondent would go to a clinic or doctor's office (AUSUALPL and APLKIND), and where a respondent goes to seek preventative care (AHCPLKND). Additionally, whether a respondent skipped medication doses to save money (ARX12_1), whether a respondent took less medication to save money (ARX12_2), if a respondent had delayed filling a prescription (ARX12_3), preferred low-cost medication (ARX12_4), reported buying prescription drugs from another country to save money (ARX12_5), used alternative therapies to save money (ARX12_6), affordability of prescribed medication (AHCAFYR1), affordability of mental health care or counseling (AHCAFYR2), affordability of dental care (AHCAFYR3), affordability of eyeglasses (AHCAFYR4), and worries about paying medical bills (AWORPAY).

All responses where the data were coded as "not ascertained" or "missing" were recoded as "NAs" for all of the variables and were dropped from the analysis. Whether or not a survey respondent had looked up health information using the internet in the last 12 months was recoded to a binary response of 1 to indicate if the respondent had looked up health information on the internet or 0 if they did not indicate looking up health information on the internet (all other responses). Similarly, all binary variables were recoded in the same manner. A survey respondent's race was identified within the data by the RACERPI2 variable from the NHIS data. The variable was recoded to indicate if the survey respondent reported their race as being White, Black or African American, American Indian or Alaska Native, Asian, or multiple races. A survey respondent's Hispanic ethnicity was recoded to indicate if the survey respondent reported being Hispanic, multiple Hispanic, Puerto Rican, Mexican, Mexican-American, Cuban or Cuban American, Dominican (Republic), Central or South American, other Latin American (type not specified), other Spanish, Hispanic or Latino or Spanish (nonspecific type), Hispanic or Latino or Spanish (type refused), or were not Hispanic (a response of 12, not Hispanic or Spanish origin). A survey respondent's region was identified within the data using the variable REGION from the NHIS data. The variable was recoded to indicate if the survey respondent reported residing in the Northeastern, Midwestern, Southern, or Western United States. A survey respondent's marital status was recoded to indicate if the survey respondent reported living with a spouse or partner or not living with a spouse or partner (all other responses). A survey respondent's internet use was identified in the data using the AWEBUSE variable from the NHIS data. The variable was recoded to indicate if the survey respondent reported using the internet, or not. Additionally, a survey respondent's internet use frequency was identified in the data using the AWEBOFNO and AWEBOFTP variables. The variables were recoded to indicate frequently using the internet (responses of once per day or more frequently) or not using the internet frequently (all other response combinations). The variable APLKIND was recoded to indicate if a respondent goes to a clinic or doctor's office (a response of clinic or health center, or doctor's office or health maintenance organization) or somewhere other than a clinic or doctor's office (all other responses). These variables were combined to indicate if a respondent goes to a clinic or doctor's office when sick, goes somewhere other than a clinic or a doctor's office when sick, or does not indicate going anywhere when sick. Where a respondent goes to seek preventative care was identified using the variable AHCPLKND in the NHIS data. The variable was recoded to indicate if a respondent goes to a clinic or doctor's office for preventative care (a response of clinic or health center, or doctor's office or health maintenance organization) or does not go to a clinic or doctor's office for preventative care (all other responses).

We used logit regression models to examine the relationship between our predictor variables and each of our 3 separate questions about the survey participants' use of telehealth: looking up health information using the internet, scheduling an appointment with a health care provider using the internet, and communicating with a provider over email using the internet. In the field of machine learning and statistics, a wide range of computer models can be used for predicting clinical outcomes such as logit regression, decision trees, artificial neural networks, and Bayesian networks. We have selected Logit regression because it is a well-known statistical fitting model that is frequently used for modeling medical problems where it is needed to identify the relation between a binary response variable and a set of independent predictor variables [29]. The models were built using the svyglm function within the survey package in R version 4.2.1 (R Foundation for Statistical Computing) in R Studio 2023.03.0+386 (Posit PBC). The svyglm function includes the ability to account for a weighting variable in the data to facilitate population estimates. The stepAIC function within the MASS package was used to identify the best-fit model for this data.

Results

Overview

Young adults (18-35 years old) made up between 32.1% (n=10,140, unweighted) and 31.26% (n=6902, unweighted) of

XSL•FO
RenderX

weighted survey respondents in 2012 and 2017, respectively, as shown in Table 1, while older adults (56-85 years old) accounted for 32.37% (n=12,662, unweighted) in 2012 and 35.63% (n=11,483, unweighted) in 2018. Women made up between 51.72% (n=13,867, unweighted) and 51.87% (n=19,252, unweighted) of the weighted survey respondents over the years.

Table 1. Demographic information broken down by year; given as count of response and percentage of weighted totals[a].

Parameter	2012	2013	2014	2015	2016	2017	2018
Age, n (%)							
Younger adult	10,140 (32.10)	10,183 (31.92)	10,431 (31.85)	9230 (31.73)	8662 (31.68)	6902 (31.26)	6177 (31.34)

[a]The table shows the unweighted sample size for each variable and the related percentage once the weights are applied to the data.

[b]AIAN: American Indian or Alaska Native.

The percentage of frequent internet users increased from 58.77% (n=18,016, unweighted) in 2012 to 73.15% (n=17,153, unweighted) in 2018. The percentage of email users increased from 64.46% (n=20,038, unweighted) in 2012 to 74.37% (n=17,635, unweighted) in 2018. The number of individuals who reported living with their spouse or partner ranged from 48.07% (n=14,160, unweighted) of weighted survey respondents in 2016 to 48.89% (n=11,031, unweighted) in 2018.

As shown in Figure 1A, older adult respondents tend to look up health information less than the middle-aged or younger adult groups over the years, while the percentage of the respondents looking up health information using the internet grew at similar rates for all groups. As shown in Figure 1B, men tend to look up health information using the internet less than women across all years of the study. Older adult respondents tended to report scheduling an appointment using less than younger adults or middle-aged respondents (Figure 2A). Across the years included in this study, the proportion of younger and middle-aged respondents tended to grow at similar rates. As shown in Figure 2B, men tended to report scheduling an appointment using the internet less often than women. As shown in Figure 3A, a higher percentage of middle-aged adults tended to report communicating with their care provider through email than older adults; a higher percentage of older adults tended to report it than younger adults. As shown in Figure 3B, men tended to report communicating with their care provider through email less often than women.

Figure 1. Percentage of respondents that looked up health information using the internet (A) for each age group and (B) by sex.

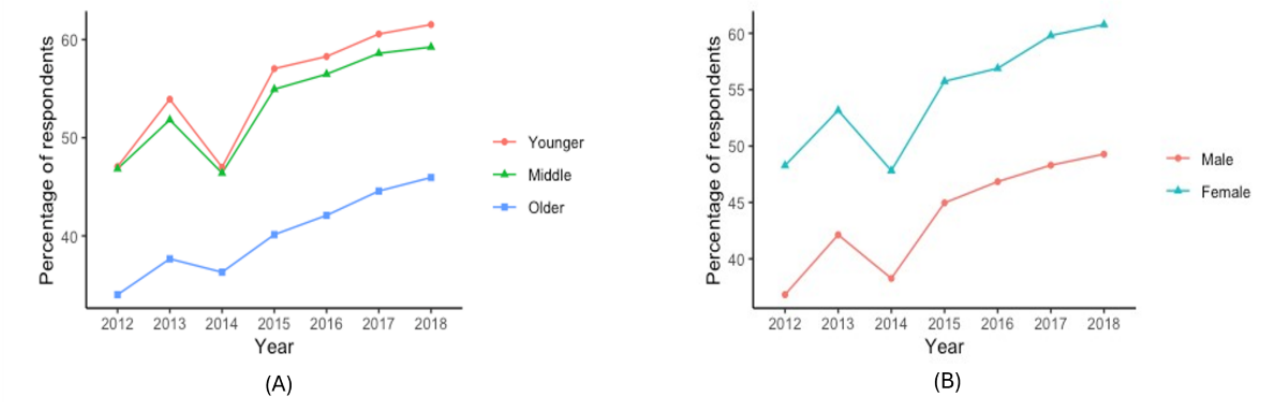

Figure 2. Percentage of respondents that scheduled an appointment using the internet (A) for each age group and (B) by sex.

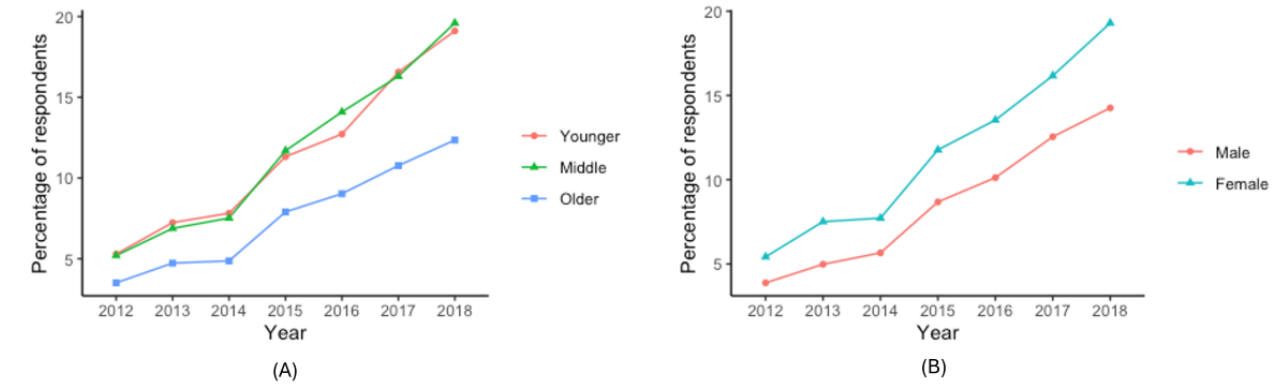

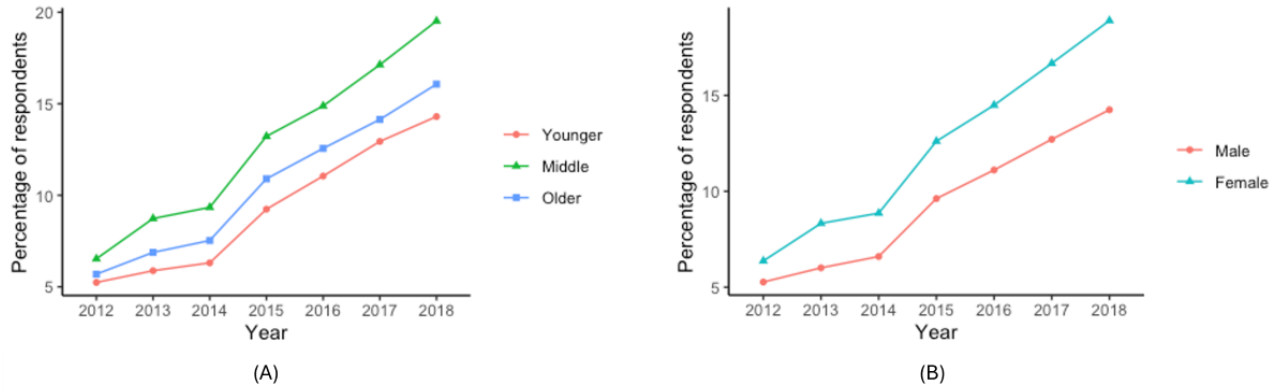

Figure 3. Percentage of respondents that emailed their care provider using the internet (A) for each age group and (B) by sex.

The number of respondents who accessed health information by using the internet increased from 42.76% (n=13,621, unweighted) in 2012 to 55.22% (n=13,677, unweighted) in 2018 (Table 2). In 2018, the percentage of respondents who scheduled an appointment using the internet rose from 4.68% (n=1463, unweighted) in 2012 to 16.86% (n=3962, unweighted). The number of respondents emailing their provider using the internet increased from 5.84% (n=1800, unweighted) in 2012 to 16.65% (n=4176, unweighted) in 2018. The number of respondents seeking medical care who visited a clinic or doctor's office increased from 79.95% (n=27,085, unweighted) in 2012 to 82.03% (n=21,092, unweighted) in 2018. The number of respondents seeking preventive care who visited a clinic or doctor's office increased from 35.96% (n=2706, unweighted) in 2012 to 45.16% (n=2133, unweighted) in 2018. The number of respondents concerned about paying medical bills decreased from 50.24% (n=17,267, unweighted) in 2012 to 43.54% (n=10,637, unweighted) in 2018. The use of alternative therapies to save money increased from 4.07% (n=1454, unweighted) in 2012 to 5.14% (n=1294, unweighted) in 2018.

[a]The table shows the unweighted sample size for each variable and the related percentage once the weights are applied to the data.

Looking Up Health Information Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent accessed health information using the internet (Table 3). With each successive year, respondents were more likely to look up health information using the internet (odds ratio [OR] 1.12, 95% CI 1.10-1.15). Middle-aged adults (OR 0.83, 95% CI 0.75-0.93) and older adults (OR 0.65, 95% CI 0.57-0.73) were less likely in comparison to younger adults to look up health information using the internet. Women were more likely to look up health information using the internet in comparison to men (OR 1.69, 95% CI 1.54-1.85). Black or African American respondents were less likely to look up health information in comparison to White respondents (OR 0.77, 95% CI 0.67-0.89). The survey respondents in the South region were less likely to look up health information using the internet compared to those in the

XSL•FO
RenderX

North region (OR 0.73, 95% CI 0.63-0.85). A frequent internet user was more likely to look up health information (OR 3.40, 95% CI 3.00-3.85). Similarly, respondents who used email regularly were more likely to look up health information using the internet than those who reported not using email frequently (OR 3.88, 95% CI 3.41-4.42). Respondents who reported asking their clinicians for lower-cost medications in order to save money were more likely across all years to look up health information (OR 1.55, 95% CI 1.38-1.75). Respondents using alternative therapies in order to save money were almost twice as likely to look up health information using the internet (OR 1.92, 95% CI 1.57-2.36). Respondents who reported going to a clinic or doctor's office when they were sick were more likely to look up health information using the internet than those who did not report going there (OR 1.21, 95% CI 1.08-1.36). Respondents who reported going to a clinic or doctor's office as part of preventative care were also more likely to look up health information using the internet than those who did not seek out preventative care at a clinic or doctor's office (OR 1.18, 95% CI 1.07-1.31).

Scheduling an Appointment Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent scheduled an appointment using the internet (Table 4). With each successive year, respondents were more likely to schedule an appointment using the internet (OR 1.30, 95% CI 1.26-1.34). Older adults were less likely in comparison to younger adults to schedule an appointment using the internet (OR 0.63, 95% CI 0.51-0.78). Women were more likely than men to schedule an appointment using the internet (OR 1.61, 95% CI 1.40-1.85). Respondents who use the internet frequently were more likely to schedule an appointment than those not using the internet frequently (OR 2.75, 95% CI 2.02-3.74). Survey respondents using email were more likely than respondents not using email to schedule an appointment using the internet (OR 3.92, 95% CI 2.78-5.53). Respondents who used alternative therapies in order to save money were more likely to schedule an appointment using the internet than those who did not report using alternative therapies to save money (OR 1.70, 95% CI 1.34-2.16). Respondents who were worried about paying medical bills in the last 12 months were less likely than those who did not report being worried about paying medical bills to schedule an appointment using the internet (OR 0.77, 95% CI 0.66-0.89). Respondents going to a clinic or doctor's office for preventative care were more likely to schedule an appointment using the internet than those who did not report going to a clinic or doctor's office for preventative care (OR 1.55, 95% CI 1.33-1.82).

Communicating With a Care Provider Through Email Using the Internet

We constructed a model to examine the relationship between the predictor variables and whether or not the survey respondent communicated with a care provider through email using the internet (Table 5). With each successive year, respondents were more likely to communicate with a care provider through email using the internet (OR 1.24, 95% CI 1.20-1.28). Women were more likely than men to communicate with a care provider through email using the internet (OR 1.48, 95% CI 1.28-1.71). Respondents who use the internet frequently were more likely to communicate with a care provider through email than those not using the internet frequently (OR 2.08, 95% CI 1.56-2.76). Survey respondents using email were more likely than respondents not using email to communicate with a care provider through email (OR 5.56, 95% CI 3.84-8.05). Respondents who could not afford mental care in the last 12 months were more likely to communicate with a care provider through email using the internet than those who could afford mental care in the last 12 months (OR 1.92, 95% CI 1.39-2.66). Respondents who reported going to a clinic or doctor's office when they were sick were more likely to communicate with a care provider through email using the internet than those who did not report going there when sick (OR 1.32, 95% CI 1.12-1.55). Respondents who reported going to a clinic or doctor's office as part of preventative care were also more likely to communicate with a care provider through email using the internet than those who did not seek out preventative care at a clinic or doctor's office (OR 1.57, 95% CI 1.34-1.85).

Discussion

Principal Findings

This study used NHIS data, which is weighted to represent national characteristics, to examine the use of technology for performing some health care–related tasks over time: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet. Across all our models, we found that middle-aged and older adult respondents were significantly less likely to use technology to look up health information using the internet or schedule an appointment using the internet versus younger individuals. It has been shown that some older adults may need additional special usability requirements due to their inexperience in the use of technology [21], yet this population is a growing user of technology [30]. This also reaffirmed the results found in the existing literature [26]. Across all of the variables we investigated, we found that the rates of looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet increased substantially across the study period. This demonstrates that there is an increasing use and need for these

XSL•FO
RenderX

services to support larger populations of users including devices and abilities to engage with technology.

Specifically, our analysis found that middle-aged adults were found to have a higher OR than older adults (0.83 vs 0.65) for looking up health information using the internet. We also found that there were differences in age groups for using technology to perform health care–related tasks. In terms of searching health information and scheduling appointments using the internet, we found differences between men and women, with women being significantly more likely than men to look up health information using the internet, schedule an appointment using the internet, and communicate with a care provider through email using the internet. There are conflicting results in the literature related to sex differences in the use of the internet and technology associated with health-related tasks. Newhouse et al [31] found that men were more likely to use email communication for health care than women; however, Baumann et al [32] found that women were more likely to use the internet and technology for health-related tasks such as scientific literature review, communicating with their physician or medical team, and interpreting the diagnostic test results and medications used in treatment. These sex differences may be related to the social construction and perceptions of technology [33]. Future research needs to explore why these trends are occurring and what factors are associated with the differences between men and women especially since there are conflicting results in the literature about use but also about the factors associated with the differences in use.

The impact of costs was inconsistent across the different models in our analysis. With respect to looking up health information using the internet, there was a significant association with using lower-cost medications and alternative therapies to save money. For individuals scheduling a health care appointment using the internet, respondents who indicated using alternative therapies to save money were more likely to schedule appointments using the internet, and surprisingly those who indicated being worried about paying for medical bills were less likely to schedule appointments using the internet. Individuals using email to communicate with a care provider had two different cost-related variables that were significant. Respondents who reported not being able to afford mental care were more likely to email, while those who indicated not being able to afford dental care were less likely to email. In some ways, the included cost-related variables did not seem to indicate a consistent response around cost. This reinforces the notion that determining the extent to which the cost of care is a barrier is challenging and unclear [34]. By examining the results across several cost-of-care–related variables and different elements of health care, it appears that there may be other barriers whose interaction with cost impacts the effect of cost as a barrier. As suggested by Clarke et al [34], and supported by our results, telehealth research should continue to investigate the ways in which different types of costs are intertwined with the use of telehealth; especially as it relates to different avenues of care.

Going to a clinic or doctor's office for preventative care was associated with a greater likelihood of looking up health information using the internet, schedule a health care appointment using the internet, and communicate with a care provider through email using the internet. Going to a clinic or doctor's office when sick was associated with using technology to look up health information and communicating with a care provider through email. This suggests that there is a strong correlation between respondents' collaboration in their personal health and the likelihood that they would use telehealth services to meet these needs. In fact, Sawesi et al [35] found that information technology platforms can enhance patient engagement and improve health outcomes. It is crucial that telehealth research investigate ways in which telehealth can be used to either support individuals in developing an engagement in their own health or identify ways to encourage users to develop an engagement in their own health.

Limitations and Future Work

There are several factors that limit the generalizability of our analyses. One notable limitation of this research is that it relies on self-reported survey data and may not fully capture specific perspectives and opinions about the "why" for some of the activities reported in the NHIS. Yet, the NHIS data collected and maintained by the US CDC is widely used [36-38] and the data, the data design, and the imputation for national representation are widely documented [39,40]. Future research should expand on these results to try to identify if these trends continue or what factors may be driving the differences identified over time.

This research uses responses from specific questions from 2012 to 2018, as those were the only consecutive years where these questions were consistent. As a result, being able to project current and future use of technology for telehealth is limited. Additionally, the COVID-19 pandemic had a major impact on health care as it presented a unique situation that resulted in overcoming many of the traditional barriers to telehealth adoption [41]. COVID-19 also emphasized the use cases of a variety of different technological tools that can be used in telehealth such as chatbots [42]. As our data was limited to data collected before the COVID-19 pandemic, it is important that future work examine the impact that the pandemic has had on the use of telehealth services and if these effects have been sustained in the following years. Future research should also investigate the ways in which the pandemic might have impacted or altered the trends and barriers examined in this research. For example, it may be interesting to evaluate if the exposure and use of these tools during the pandemic have had lasting impacts on the use of the internet tools. To do this, we need similar data from 2020-2023 or later from the NHIS on the use of telehealth services to be able to apply time series modeling techniques to evaluate specific trends in how using telehealth services have changed over time. Interestingly, some initial work has suggested that there is a decline in the use of telemedicine between 2021 and 2022 in the United States, [43] and future work should evaluate if that trend continues or if the trend prior to the COVID-19 pandemic continues.

In order to develop a fundamental understanding of the important barriers, this research did not examine the complex relationships between demographic and response variables. Future research should focus on understanding how these interactions (eg, older women vs middle-aged women vs

XSL•FO
RenderX

younger women) might be correlated with the respondents' use of telehealth. Our models also did not investigate telehealth use for specific socioeconomic levels. Instead, it includes questions regarding a respondent's ability to afford different health care services, which is different from financial security or socioeconomic conditions [44].

Conclusions

As telehealth is increasingly becoming an important component of health care services, it is important to focus on different aspects of telehealth to determine the demographic characteristics, behaviors, or opinions that may predict or influence groups that are likely to face a barrier to using telehealth services. This study used NHIS data to examine the use of technology for performing some health care–related tasks over time: looking up health information using the internet, scheduling an appointment using the internet, and communicating with a care provider over email using the internet. From this analysis, we have found some potential barriers that may impact a user's ability to access telehealth services, as well as differences in the use of these tools for different groups. Understanding those who are using the internet for health care–related activities and the barriers that they may face is important for the design and implementation of these systems to be as effective as possible. Systems and technology designers, as well as health care providers, should be aware of these differences and the impacts they may have on engaging individuals in their health care.

Abstract

Background: Cardiac pain has been widely considered to be the primary indicator of coronary artery disease. The presentation of cardiac pain and associated symptoms vary in women, making it challenging to interpret as cardiac, possibly cardiac, or noncardiac. Women prefer to consult with family and friends instead of seeking immediate medical care.

Objective: This study aimed to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (System Usability Scale; SUS) of a progressive web application for women with cardiac pain.

Methods: Following ethics approval, a purposive sample of women aged >18 years with cardiac pain or associated symptoms lasting >3 months and able to speak and read English was recruited to participate in 2 iterative usability testing cycles. The first cycle assessed the performance of and satisfaction with *at heart* using a web application, and the second cycle assessed the performance of and satisfaction with *at heart* across various Android and iOS devices. In total, 2 investigators recorded user comments and documented problems. At the end of the testing session, the participants completed the SUS and 4 semistructured interview questions.

Results: In total, 10 eligible women participated in usability testing from March 31, 2020, to April 17, 2020 (cycle 1), and from November 17, 2020, to November 30, 2020 (cycle 2). Women across usability testing cycles had a mean age of 55.6 (SD 7.3) years, and most (9/10, 90%) were well educated. In total, 50% (5/10) were employed full or part time, and 60% (6/10) earned >CAD $70,000 (US $48,881.80) annually. Participants across 2 testing cycles reported the overall usability of the *at heart*

XSL•FO
RenderX

progressive web application as highly acceptable (mean SUS score 81.75, SD 10.41). In total, 90% (9/10) of participants rated the user-friendliness of *at heart* as good or excellent. All participants (10/10, 100%) thought *at heart* was easy to use and efficient. Only 2 testing errors were noted as high priority; these were low contrast or small font and clarification that the chatbot was not a real person. User satisfaction was assessed using themes that emerged from the debrief and 4 semistructured interview questions; *at heart* was engaging, comprehensive, understandable, credible, relevant, affirming, personalized, and innovative.

Conclusions: This study provides initial support for the *at heart* progressive web application for women living with cardiac pain and symptoms. Ongoing evaluations in phases 3 and 4 should aim to examine the feasibility and acceptability of and the extent of engagement with the *at heart* core feature set: Heart Check, Wellness Check, and the library. In addition to assessing effectiveness in the phase-4 effectiveness-implementation hybrid trial (type I), describing and better understanding the context for implementation (eg, race and ethnicity and geography) will be necessary.

Introduction

Background

Cardiovascular diseases constitute the leading cause of mortality worldwide, exerting a substantial economic burden on the health care system [1-4]. As the most prevalent form of cardiovascular disease, coronary artery disease (CAD) is estimated to be associated with 8.93 million deaths annually worldwide across all ages [1]. CAD is a complex condition that varies in clinical presentation across sexes, with both obstructive (macrovascular) and nonobstructive (microvascular) CAD being associated with cardiac pain and other symptoms [5]. Although cardiac pain has been widely considered to be the primary indicator of CAD [6], cardiac pain and associated symptoms reported by women with CAD differ markedly from those reported by men [7,8]. The presentation of cardiac pain and associated symptoms may vary in frequency, pattern, and distribution in women [8], making it challenging to interpret as cardiac specific [9]. Similarly, women that undergo a percutaneous coronary intervention or cardiac surgery report higher prevalence of persistent pain of moderate to severe intensity after treatment as compared to men [10-12]. This cardiac pain is often described by women as sharp and burning and may present with varying extent of dyspnea, fatigue, anxiety, and discomfort that may radiate to the jaws, shoulders, back, and arms [6,8,13]. The manifestations of cardiac pain and associated symptoms contribute to substantial morbidity and impairments in health-related quality of life (HRQoL) in women [14,15].

The complex presentation of CAD in women poses a challenge for timely recognition and management of symptoms. Recent data have shown that women often delay seeking medical care when experiencing acute cardiac pain or associated symptoms, with time between symptom onset and emergency department arrival being 85 to 320 minutes [16]. Women report experiencing difficulties in interpreting, understanding, and attributing their cardiac pain or symptoms to CAD, preferring to consult with family and friends instead of seeking immediate medical care [17]. Moreover, women often hesitate to seek medical care for cardiac pain or associated symptoms as a result of their gendered roles as caregivers [17,18]. Women describe having gendered roles that they are unable to delegate, such as providing care for dependent family members [17,18]. The cumulative effect of symptom underrecognition and hesitancy in women leads to delayed care-seeking behaviors and an increased risk of major adverse cardiac events or mortality as compared to men [6]. As such, it is imperative to promote proper recognition, assessment, and management of symptoms in women to improve health outcomes and HRQoL.

Self-management programs are designed to engage users as active participants in the management of their conditions; they are key predictors of successful behavior change [19,20]. These interventions generally use educational strategies designed to assist users in achieving optimal knowledge, understanding beliefs, and skills, as well as providing meaningful social supports [21]. Digital health–based self-management programs have been developed and effectively used to help women manage weight [22-25], increase physical activity [26], monitor for perinatal depression, and assist with postpartum smoking cessation [27]. Many women describe digital health interventions as being novel and supportive [22] and effective in motivating healthy behaviors, reducing symptoms [28], and improving HRQoL [23]. However, there is a lack of evidence-informed digital health self-management programs specifically for women with CAD living with cardiac pain and associated symptoms [7], demonstrating a clear need for a digital self-management program.

At heart (formerly HEARTPA♀N) [29], a self-management progressive web application, was developed for women with CAD using a sequential phased approach recommended by the Medical Research Council (MRC) [30-32]. In phase 1, an integrated mixed methods systematic review was conducted to evaluate the current evidence related to the self-management of cardiac pain and associated symptoms (eg, dyspnea and fatigue) in women [7,29]. The results of the review suggested that self-management interventions could reduce cardiac pain and associated symptoms if they targeted a greater proportion of women (standardized mean difference [SMD]=−0.01; SE 0.003; *P*=.02), goal setting (SMD=−0.26, 95% CI −0.49 to −0.03), and collaboration or support from a health care provider (SMD=−0.57, 95% CI −1.00 to −0.14) [33]. The review also identified a lack of self-management interventions targeted specifically for cardiac pain and associated symptoms in women

XSL•FO
RenderX

[33]. In phase 2A, the content and core feature set, chatbot, and symptom triage algorithms were co-designed with health care professionals and women with CAD [29]. In phase 2B, the usability of *at heart* was evaluated to ensure that the platform was intuitive and acceptable for women with cardiac pain, and it is the focus of this paper. In phase 3, a process and preliminary efficacy evaluation using a 2-group parallel pilot randomized controlled trial (RCT) will be undertaken, and then a phase-4 effectiveness-implementation hybrid trial is planned (Figure 1).

Figure 1. Phases of the *at heart* progressive web application development.

Objectives

The objectives of this study were to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (interviews and System Usability Scale [SUS]) of a progressive web application for women with cardiac pain.

Methods

Participant Selection

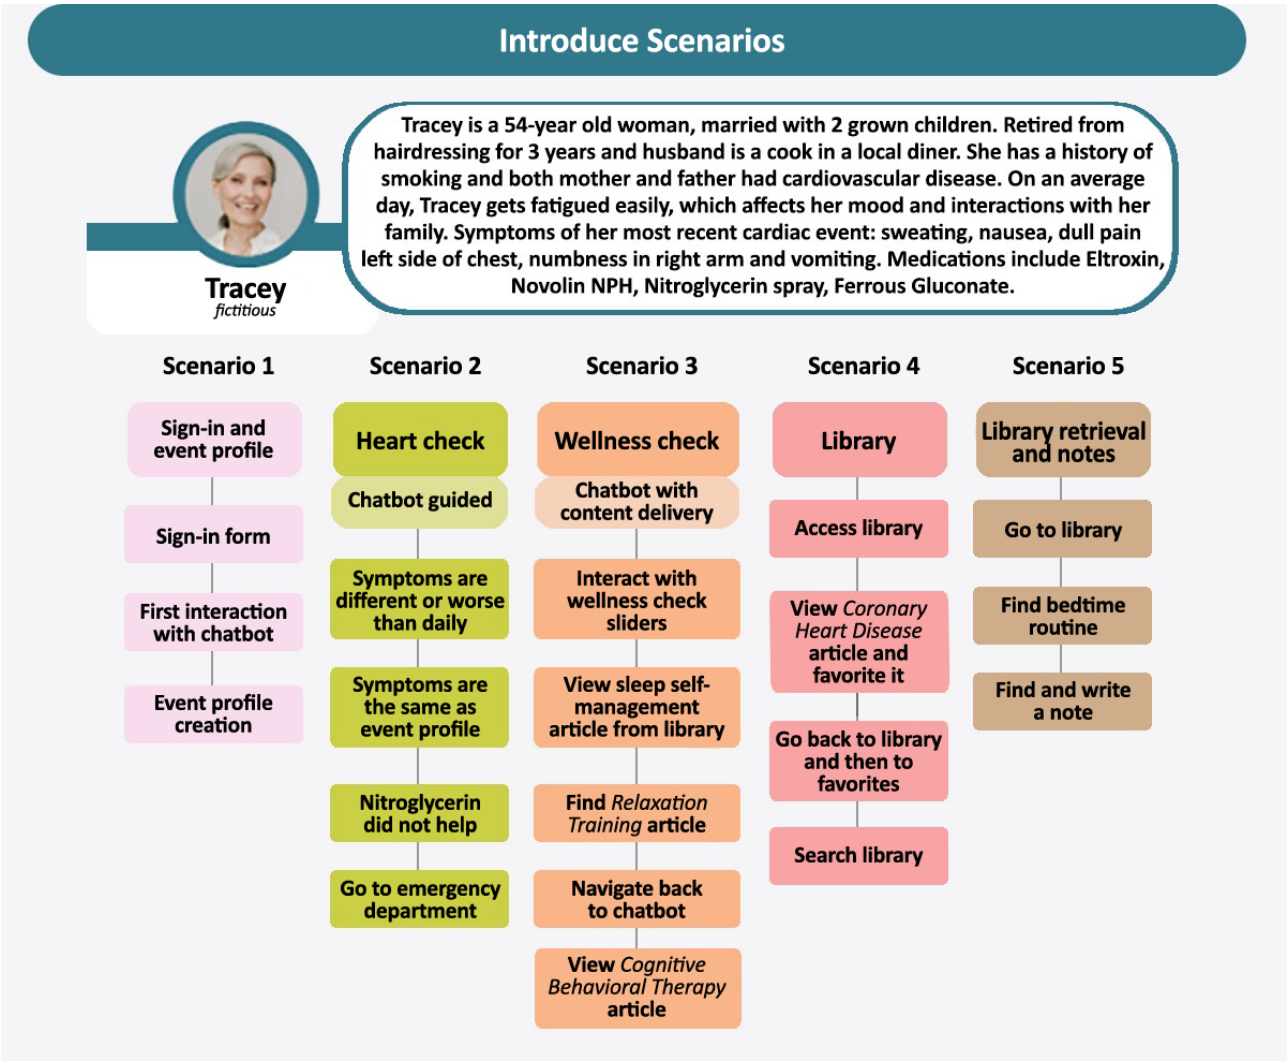
Following ethics approval, a purposive sample of women was recruited from (1) an ambulatory care hospital focused on women's health, (2) an adult tertiary care transitional pain clinic; (3) the Alberta Provincial Project for Outcome Assessment in Coronary Heart Disease registry; (4) the CorHealth Ontario Cardiac Registry; (5) established strategies through the Canadian Pain Coalition; (6) the Ontario Women's Health Network's listserve, which reaches >1900 women and community organizations in Ontario, Canada; and (7) social media. The Ontario Women's Health Network regularly brought women who lived in rural and remote areas together, including women who were disabled, women of color, women with a low income, and Indigenous and older women. Women were eligible to participate in the usability testing if they (1) were aged >18 years, (2) had been diagnosed with obstructive or nonobstructive CAD pain or pain after a percutaneous coronary intervention or cardiac surgery lasting >3 months, (3) were able to speak and read English, and (4) had not previously used or tested the *at heart* progressive web application. Women were excluded from the study if they had (1) severe cognitive impairment, assessed using the Six-Item Screener administered via telephone; or (2) a major comorbid medical or psychiatric condition that would preclude their ability to participate in the usability testing. The Six-Item Screener is a brief instrument for identifying individuals with cognitive impairment, and its diagnostic properties are similar to those of the Mini-Mental State Examination [38,39].

Usability testing is an important phase in the development of digital health interventions [34,35]. End users test a prototype in iterative cycles; they provide feedback about what works, what does not work, and where gaps might exist in the information and functionality [34,35]. These factors contribute to the frequency of use, understanding, and acceptability and enhance the likelihood that users will use the end product [35,36]. Testing the usability of the intervention also serves to assess the suitability of the platform interface and content [37].

Ethical Considerations

The phase-2B usability testing was approved by the Health Sciences Research Ethics Board (REB; 36415) at the University of Toronto on November 26, 2018, and the Health Sciences and Affiliated Teaching Hospitals REB (6026830) at Queen's University on June 20, 2019. An amendment was granted by the Health Sciences REB (36415) at the University of Toronto on March 26, 2020, to use secure video- or web conferencing (Zoom; Zoom Video Communications) for the usability testing sessions due to COVID-19 pandemic restrictions, which prohibited in-person participant contact. Informed consent and a demographic and clinical information form (Multimedia Appendix 1) were obtained from participants before each iterative cycle. Participants were identified using a study ID, and data were stored on a secure OneDrive folder (Microsoft Corp) accessible only to the principal investigator and research officer. All participants were compensated with a user-identified CAD $25 (US $17.52) gift card.

Study Design and Procedures



The usability of the *at heart* progressive web application focused on a think-aloud scenario-based approach to assess user performance (ie, ease of use, efficiency, and errors) and user satisfaction with *at heart's* content and functionality assessed qualitatively through the short scenario debrief questions and the interviews and quantitatively using the SUS [40]. This multi-method approach to usability testing is supported by a recent scoping review [41]. A sample of 10 eligible women was recruited to participate in the iterative usability testing cycles (n=5, 50% of the women participated in each of 2 testing cycles). This sample size was based on the experience of others [42-44], as well as recommendations that usability testing by 3 to 5 users can find approximately 85% of interface usability problems [45,46]. The first cycle tested user performance and satisfaction on a desktop computer, and the second cycle assessed user performance and satisfaction across various Android and iOS devices (ie, smartphones and tablets). Participants were provided with a brief explanation of the study and the *at heart* progressive web application before undergoing a 60- to 90-minute one-on-one observation period conducted and recorded through

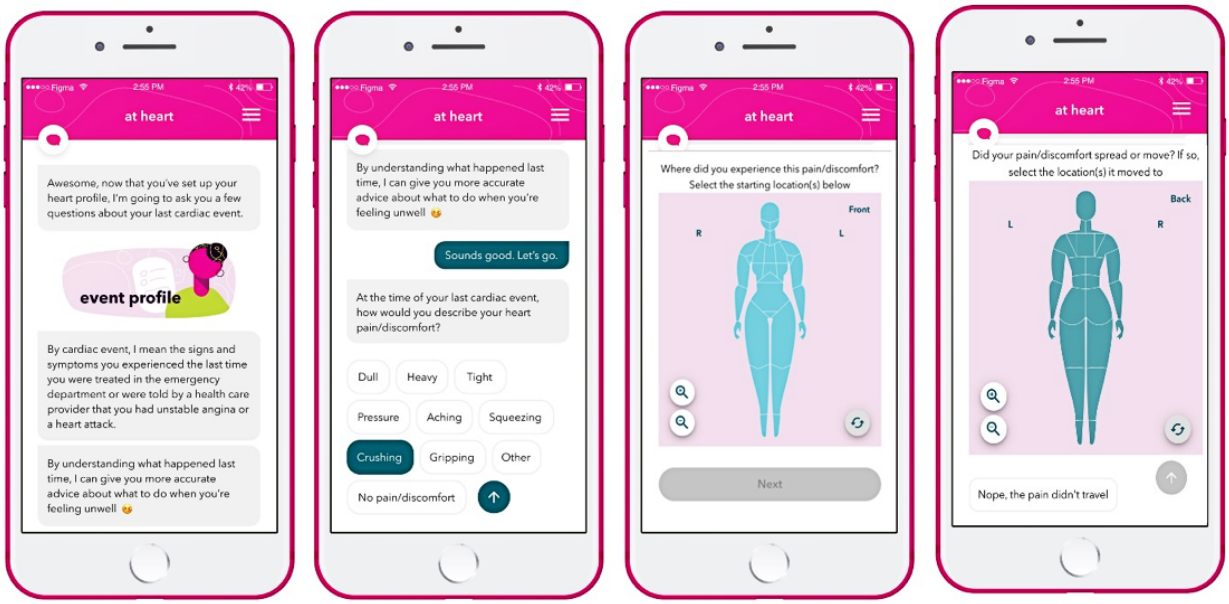
XSL•FO
RenderX

the Zoom videoconferencing platform. Participants were introduced to a case of a woman aged 54 years with symptoms that were "possibly cardiac" [47] and asked to sign in, complete an event profile (scenario 1), and then progress through a set of standardized scenarios that incorporated each core feature of *at heart*: Heart Check, Wellness Check, and the library (scenarios 2-5; Figure 2).

The "think-aloud" approach was used to capture users' thought process and problem-solving as they progressed through *at heart's* core features in a systematic manner. After each scenario, the participants answered two short debrief questions: (1) "What did you like about the content and functionality of this specific scenario?" (2) "What did you dislike about the content and functionality of this specific scenario?"

Figure 2. Usability testing workflow.

In total, 2 investigators also recorded user comments and documented any problems encountered during each scenario using the usability testing error and efficiency documentation form (Multimedia Appendix 2). Three error types were captured on this form: (1) navigation errors (ie, failure to locate a function or follow the recommended screen flow), (2) presentation errors (ie, selection errors due to labeling ambiguities), and (3) control use errors (ie, improper entry field errors). Four semistructured interview questions were posed following the think-aloud scenarios to assess the overall satisfaction with *at heart's* content and functionality: (1) "What was your overall impression of the *at heart* progressive web application?" (2) "What did you like or dislike about the *at heart* progressive web application?" 3) "Is there anything that could be improved or changed?" (4) "Is there anything missing from the *at heart* progressive web application?" Participants then completed the SUS on the web using REDCap (Research Electronic Data Capture; Vanderbilt University), a secure web application. The SUS is a widely used scale that quantifies the usability of digital health applications. It consists of 10 questions with Likert scales that range from *strongly agree* to *strongly disagree*, and it has been validated across a range of interfaces, including web pages and web applications [40,48,49]. Scores range from 0 to 100, with an accepted benchmark mean SUS score of 68 (SD 12.5) [40]. One 7-point adjective-anchored Likert scale was added to the bottom of the SUS so that participants could rate the overall user-friendliness of *at heart* as *worst imaginable*, *awful*, *poor*, *ok*, *good*, *excellent*, or *best imaginable*. This adjective rating scale helps inform the absolute usability of a product [50-52], such as the *at heart* progressive web application. Numerical equivalents of 1 (*worst imaginable*) to 7 (*best imaginable*) were assigned to the adjectives for scoring. After the first cycle,



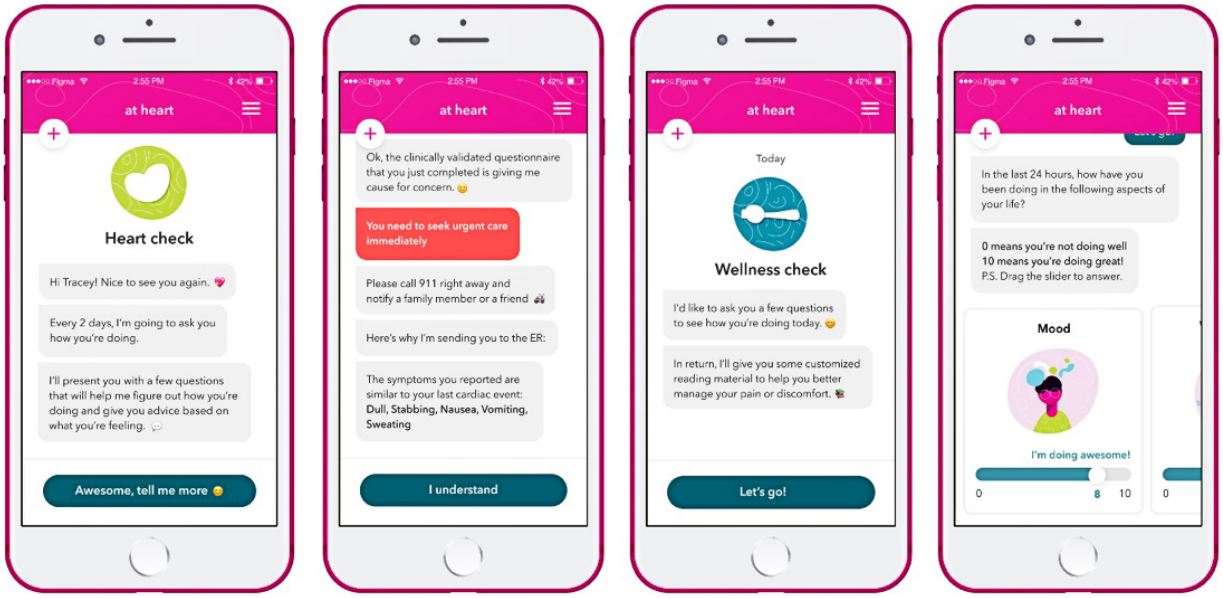
XSL•FO
RenderX

revisions were made to the prototype, and the revised prototype was tested in a second usability testing cycle.

At Heart Progressive Web Application

At heart is a novel progressive web application that consists of 3 core features: Heart Check, Wellness Check, and a library. Users are guided through the core feature set by a rule-based chatbot that manages content and conversations. An Event Profile is created on the initial log-in to the progressive web application (Figure 3). The Event Profile contains individualized or personalized data that include the quality and location of cardiac pain or associated symptoms experienced at the time of the participant's last heart event (ie, treated in the emergency department). Female front and back full-body maps were specifically developed for *at heart* using the chest pain or associated symptom locations most commonly described in the literature [6,8,13,47,53].

Figure 3. Screenshots of the *at heart* feature Event Profile prototype.



Chatbot Holly asks women the same series of cardiac pain and symptom assessment questions in the Heart Check, which is programmed into the *at heart* progressive web application to occur every 3 days (Figure 2). The Heart Check can occur more frequently simply by asking chatbot Holly for a Heart Check. Rule-based symptom triage algorithms compare each Heart Check to the individually stored Event Profile to make recommendations on an appropriate level of care. Level of care recommendations are based on the similarity and timing of current cardiac pain or discomfort to that stored Event Profile, noting similarities between the current and previous descriptions of the quality (ie, heavy, tight, or pressure), location, radiation, and associated symptoms. Recommendations are assigned to one of three categories: (1) *red* or high risk (ie, similar or high-risk symptoms that have occurred within 24 hours), (2) *yellow* or moderate risk (ie, similar or high-risk symptoms that have occurred beyond 24 hours but within 7 days), and (3) *green* or low risk (ie, no similar or high-risk symptoms). Women who are categorized as *red* are encouraged to notify a family member of their current symptoms and call 911 (ie, to seek appropriate and urgent assessment of their symptoms). Women who are categorized as *yellow* are encouraged to see their primary care provider within 48 hours, and women who are categorized as *green* are permitted access to the *at heart* progressive web application. High-risk symptoms are defined as ≥3 new typical symptom features (ie, dull, heavy, or tight chest pain) [53] or any new associated symptoms, including shortness of breath; palpitations; a racing heart rate; or feeling lightheaded, faint, or dizzy [47].

Women complete the Wellness Check, informed using features of the Brief Pain Inventory–Interference Subscale [54], to indicate the degree to which cardiac pain or associated symptoms interfere with 7 domains of life, which include general activities, paid and unpaid work, walking, mood, relations with others, sleep, and overall enjoyment of life (Figure 4). Wellness Checks are programmed to occur every 7 days at a minimum, and if the score in any domain is below a threshold, the chatbot uses rule-based algorithms to deliver educational content from the library.

The library contains scientific papers, each with a lay summary, covering educational content about CAD in women, with self-management advice to promote good health and well-being [29]. The library also contains videos and podcasts from women with lived experiences of CAD. *At heart* was evaluated by Health Canada and deemed not to be a medical device as defined in the Guidance Document: Software as a Medical Device (SaMD): Classification Examples [55]. *At heart* provides self-management support to women who have CAD and, through a chatbot, guides women to the most appropriate form of assessment (ie, primary care and emergent care) based on their medical symptoms.

Data Analysis

Quantitative descriptive data from the demographic and clinical information form and the SUS were analyzed using SPSS Statistics (version 29; IBM Corp). Debrief feedback from each of the 5 scenarios with data from the usability testing error and efficiency documentation form was reviewed after each of the 2 iterative usability testing cycles. Conventional content analysis as outlined by Sandelowski [56] was used to analyze qualitative data obtained from the interview questions. In total, 2 researchers independently assigned codes to label key actions, thoughts, and ideas. Related codes were grouped into categories, and any disagreements were discussed between the 2 researchers. A list of prototype issues was generated and prioritized based on risk to patients and ease of improvement [57]. Modifications were communicated to the website design and development team. Prototype changes made after the first cycle were evaluated in the second cycle, and prototype changes following the second cycle were completed before the phase-3 RCT.

Results

Participant Characteristics

A total of 10 women meeting the eligibility criteria were invited to participate in the usability testing from March 31, 2020, to April 17, 2020 (cycle 1), and from November 17, 2020, to November 30, 2020 (cycle 2). Women across the usability testing cycles had a mean age of 55.6 (SD 7.3) years, and most had a diploma (5/10, 50%), an undergraduate degree (2/10, 20%), or a graduate degree (2/10, 20%). Most of the women were employed full (3/10, 30%) or part time (2/10, 20%) and earned >CAD $70,000 (US $48,881.80) annually (6/10, 60%); 50% (5/10) lived with a disability, 50% (5/10) were the primary household earners, and 80% (8/10) were the primary persons responsible for housework in the home. The women reported cardiac pain or associated symptoms for 1 to 2 years (3/10, 30%), 2 to 5 years (3/10, 30%), or >5 years (3/10, 30%). The most common comorbid conditions included depression (4/10, 40%) and anxiety (4/10, 40%), and 40% (4/10) of the women had had a previous myocardial infarction. Participant demographics by usability testing cycle are reported in Table 1.

All women (10/10, 100%) had a computer at home and were comfortable (3/10, 30%) or very comfortable (7/10, 70%) using a computer, comfortable (1/10, 10%) or very comfortable (9/10, 90%) using the internet, and comfortable (3/10, 30%) or very comfortable (7/10, 70%) using smartphone or tablet apps. Participants' comfort levels and use of the computer, the internet, and smartphone or tablet apps are reported in Table 2. All women selected their own devices for usability testing. Women in the first cycle used only the Google Chrome browser (5/5, 100%), and women in the second cycle used an iPad mini version 9.3.5 (1/5, 20%), Samsung Galaxy S10e (1/5, 20%), iPhone 8 (2/5, 40%), and iPhone 11 (1/5, 20%).

Comfortable using smartphone or tablet apps, n (%)		
Comfortable	1 (20)	2 (40)
Very comfortable	4 (80)	3 (60)

User Performance

User performance was assessed through ease of use, efficiency, and observation of testing errors (ie, navigation, presentation, and control use errors) through each scenario and cycle of usability testing. Testing errors included those related to navigation (difficulties moving through or locating content), presentation (selection errors due to labeling), or control use (improper entry field errors) across the 5 scenarios in 2 usability testing cycles (Figure 2). In scenario 1 of cycle 1 (sign-in, chatbot, and Event Profile), participants reported a low contrast between the text and the background and small font at sign-in. Participants also wanted clarification that the chatbot was not a real person. These were flagged as high priority, and subsequent revisions included larger font and chatbot and user text boxes identified using different colors, and a page was added to the *at heart* progressive web application to describe the chatbot, including its development and function. Specific text included the following: “let me tell you a little more about myself. I’m an educated chatbot, thoughtfully designed by a group of women’s heart health experts. I’ll be here to help you understand more about your heart pain/discomfort through regular check-ins, and I’ll send you tips and tricks for managing that pain. If you want to learn more about my makers, the same ones who named me Holly, go to the menu above...” A summary of suggestions and subsequent changes made to the progressive web application during usability testing cycle 1 is shown in Table 3.

The scenarios were repeated in the second cycle to assess user performance and user satisfaction across various Android and iOS devices (ie, smartphones and tablets). In scenario 1 of cycle 2 (sign-in, chatbot, and Event Profile), participants requested clarification on the terminology used in some of the questions at sign-in, so descriptors and more answers were added to these questions. Participants also had difficulty choosing specific areas on the body map, so the body maps were subsequently amended. In scenario 2 of cycle 2 (chatbot-guided workflow for the Heart Check), participants appeared confused with the order and speed of the questions delivered by the chatbot. The chat time stamp was subsequently increased for desktop, Android, and iOS devices. This allowed women ample time to read and respond appropriately to the Heart Check questions, especially those with longer messages and prompts. Finally, the Heart Check button was reported to be too small and gray, so the size and contrast were adjusted. The chatbot-guided workflow for the Wellness Check (scenario 3, cycle 2) required minor adjustments to ensure that the chatbot selected appropriate resources from the Wellness Library based on wellness scores of ≤4. One participant suggested that “anaphylaxis” be added to the Share My Data section and related articles be added to the library. As a result, lay summaries were generated, and scientific papers were added to the library for Kounis syndrome (n=3) and mast cell activation syndrome (n=2). Kounis syndrome is a complex multisystem arterial condition caused by mast cell activation and T-lymphocyte and macrophage interactions [58]. The resulting allergic, hypersensitivity, and anaphylactic reactions cause coronary symptoms (ie, cardiac pain), and this is referred to as Kounis syndrome [59]. A summary of suggestions and subsequent changes made to the progressive web application during usability testing cycle 2 is also shown in Table 3.

XSL•FO
RenderX

Table 3. Summary of suggestions and subsequent changes during usability testing.

Suggestions	Changes
Cycle 1 (n=5)	
Scenario 1—sign-in, chatbot, and Event Profile	
There was a low contrast between the text and the background and small font at sign-in.	Larger font and chatbot and user text boxes identified using different colors were implemented.
Clarification that the chatbot is not a real person was requested.	A page was added to the *at heart* progressive web application to describe the chatbot, including its development and function.
Participants selected only 1 descriptor on the body map and reported lack of clarity that more than one descriptor could be selected.	Directions for completing the body map were enhanced.
Scenario 2—Heart Check	
None	None
Scenario 3—Wellness Check	
None	None
Scenario 4—library	
Participants had difficulty locating the Favorites section of the library.	The Favorites section was moved to the top of the screen and identified with a larger icon that represented a heart.
Scenario 5—library retrieval and notes	
None	None
Other	
None	None
Cycle 2 (n=5)	
Scenario 1—sign-in, chatbot, and Event Profile	
Participants requested clarification on the terminology used in some of the questions at sign-in.	Descriptors and more answers were added to the questions for clarity.
Participants had difficulty choosing specific areas on the body map to describe their symptoms.	The body maps were subsequently amended to include axillae and body map descriptors.
Scenario 2—Heart Check	
Participants appeared confused with the order and speed of the questions delivered by the chatbot.	The chat speed was reduced for desktop, Android, and iOS devices.
The Heart Check button was reported to be too small and gray.	The size and contrast of the “Heart Check” button were adjusted.
Scenario 3—Wellness Check	
The chatbot says the following: “based on what you’ve told me, here are some topics...” However, the chatbot presented all topics even for wellness scores that were excellent (ie, the readings from the library did not appear tailored to the needs of each participant).	Minor adjustments were made to the rules to ensure that the chatbot selected appropriate resources from the wellness library based on wellness scores of ≤4.
Scenario 4—library	
None	None
Scenario 5—library retrieval and notes	
None	None
Other	
Add anaphylaxis to the Share My Data section.	This was added.
Add anaphylaxis articles to the library as they related to women and heart disease.	Lay summaries were generated and scientific papers were added to the library for Kounis syndrome (n=3) and mast cell activation syndrome (n=2).
Participants requested to have a more robust Share My Data section, with opportunity to record medications and other comorbid conditions.	The introduction and the content of the Share My Data section were enhanced.

User Satisfaction

Overview

User satisfaction was assessed using the SUS and the 4 semistructured interview questions. Overall, 10 participants across 2 cycles of testing reported the overall usability of the *at heart* progressive web application as highly acceptable (mean SUS score 81.75, SD 10.41). There was no difference in SUS scores between cycle 1 (mean SUS score 81.5, SD 8.59) and cycle 2 (mean SUS score 82.0, SD 13.04; t_8=−0.72, 95% CI −16.6 to 15.6). A total of 90% (9/10) of the participants rated the user-friendliness of *at heart* as good or excellent. All participants (10/10, 100%) thought that *at heart* was easy to use (SUS question 3; ie, most women could learn to use *at heart* very quickly):

> *I think everything was pretty straightforward. It was overall really, really good.* [Cycle 2; participant 3]

None of the participants indicated that they would need the support of a technical person to be able to use *at heart* (SUS question 4), and 80% (8/10) of the participants found the various functions in *at heart* well integrated (SUS question 5) with minimal inconsistencies (SUS question 6):

> *Well...I was a bit worried it might be confusing, but it's not confusing at all. It's very intuitive, it, you've built it so it's similar to a lot of other apps out there, right? So, clicking here, you know, submitting the button. So, it seems to be pretty normal as far, it looks, the same look and feel as other apps that are out there which are good. It seems to be easy. I'm not a tech person, so I wanted to make sure that—I was nervous that I wasn't going to be able to manage it because I, I'm not great with technology, but it was easy. So, yeah. I mean, I think it's a great tool.* [Cycle 2; participant 5]

A total of 8 themes emerged from the interview data (ie, engaging, comprehensive, understandable, credible, relevant, affirming, personalized, and innovative) and can be found in Multimedia Appendix 3.

Engaging

Participants commented on the layout, visual appeal, language, and name and logo of the progressive web application. They found the content easy to read and maneuver. Important content was highlighted, and participants reported this to be helpful. Article summaries were presented in larger font and used lay language. At the outset of this study, the progressive web application was named HEARTPA♀N [29]. Participants recommended a name change to one that was less focused on pain as many women describe their cardiac pain as discomfort and have other associated symptoms (eg, dyspnea and fatigue). They felt that the name *at heart* was more personally welcoming and less focused on pain. The heart logo was simple yet distinctive and recognizable.

Comprehensive

Participants indicated that the progressive web application provided necessary information for helping them make decisions about their cardiac symptoms. They liked that it was specific to women and that they could search through the library to improve their knowledge about wellness and women's heart health. Participants also commented that the chatbot assisted them in making decisions:

> *...the bot kind of identifies for me what the big blind spots are that I am perhaps not noticing.*

Understandable

Participants indicated that *at heart* was intuitive, the content made sense, and it flowed well. The tone and the language were suitable and clear. Participants commented on the appropriateness of the associated symptom descriptors included in the Event Profile and Heart Check.

Credible

Participants liked that *at heart* was developed as a living progressive web application. They particularly liked the breadth and depth of scientific articles and lay summaries included in the *at heart* library. Participants valued having an evidence-informed digital health self-management program specifically designed for women with CAD living with cardiac pain and associated symptoms.

Relevant

Participants commented on the relevance and accessibility of content in the *at heart* library. The chatbot asked relevant questions and was able to use rule-based algorithms to provide advice to women about timely assessment in the emergency department. They particularly noted the relevance of having their Event Profile and Heart Check information stored so that they could refer to it when visiting their health care providers. The content was applicable to their everyday lives.

Affirming

Participants looked for affirmation from *at heart's* chatbot when they were having cardiac symptoms. They indicated that they would have otherwise consulted with family members or Facebook group members for guidance. Affirmation of symptoms was important to women, and they appreciated the high-alert messages to seek urgent care immediately.

Personalized

Participants liked the chatbot. They found it to be personal, immediately interactive, accessible, calming, and friendly. They commented that the chatbot may help make them feel less alone if they went to the emergency room because it checked in with them to see how they were doing. The chatbot provided comfort at times when participants felt scared. Participants also valued the videos and podcasts as they also helped them feel that they were not alone in their experience with heart disease.

Innovative

Participants felt that *at heart* provided an opportunity for further research focused on women's heart health. They were willing to share anonymized data on socioeconomics, risk factors, gynecological or obstetrics history, lifestyle, medications, and other conditions (eg, arthritis or depression) to improve outcomes for women at risk of or with heart disease. Participants also valued the ability to journal and take notes in the

XSL•FO
RenderX

progressive web application. They valued the opportunities that *at heart* could provide to women who live in more isolated areas or those who live alone. The *at heart* progressive web application was described as all-encompassing, covering necessary content to improve knowledge and decision-making, with a chatbot to ask questions and deliver information in a comforting manner.

Discussion

Principal Findings

There is growing support for the importance of usability testing for mobile health and eHealth innovations [60-62]. Usability testing incorporates an iterative process of testing and refining to meet end-user needs [63]. The objectives of this study were to assess the user performance (ie, ease of use, efficiency, and errors) and user satisfaction (SUS) of a progressive web application for women with cardiac pain. User performance was assessed through ease of use, efficiency, and observation of testing errors (ie, navigation, presentation, and control use errors) through 5 brief scenarios and 2 cycles of usability testing.

The overall usability of the *at heart* progressive web application was rated highly by 10 participants who completed the usability testing cycles; the progressive web application was easy to use and efficient. However, 2 high-priority testing errors were identified during the usability testing cycles. The first involved small font at sign-in and low contrast between the text and background, and these were corrected by enlarging the font and making alterations to the text and background colors. The second was to clarify that the chatbot was not a real person. A significant amount of time was committed to addressing potential language challenges during the development of the chatbot, and there were no technical, design, or language challenges identified during the usability testing cycles. In fact, the design and language or conversation of the chatbot appeared to mimic human-to-human interaction so closely that participants requested confirmation that the chatbot was actually nonhuman.

The *at heart* chatbot is a simple rule-based conversational agent designed to mimic human-to-human interaction at sign-in and creation of an Event Profile and during completion of the Heart Check and Wellness Check. Our previous systematic review and meta-analysis indicated that self-management programs were more effective in reducing cardiac pain and associated symptoms (eg, dyspnea and fatigue) in women if they included collaboration and support from health care providers [33]. Chatbots are conversational agents able to promote health and provide education and support [64]. Their use in health care is still in a developmental stage; they could improve access to care and health care provider–patient communication, but more evidence is needed. Technical, design (ie, lack of empathy), and language challenges [65] can impede the integration of chatbot technologies into health care [64]. Adopting user-centered and theory-based designs, optimizing user experiences, and addressing patient concerns can improve chatbot uptake and use [64]. Our chatbot relies on scripted computational algorithms, with specific rules for its text-based conversations [66]. More advanced human-machine conversation is now based on natural language processing and large language models that use artificial intelligence methods to learn, understand, and produce structured language content [66,67]. Health care delivery is rapidly changing and is driven by social, scientific, and technological change; our future chatbot may need to emulate person-to-person conversation through dialogue and body movements, with appropriate expressions of empathy and compassion [68]. We are really at a cusp in health care; growth in chatbot use will be driven by a desire for health and wellness and 24-hour access to care, with a growing number of platforms from which to build an intelligent and emotive chatbot in the future [69].

At heart is the first of its kind; no smartphone- or web-based self-management program has been co-designed and systematically developed with women who have lived experience (phase 2A) and then tested with women who have cardiac pain (phase 2B). We used the individual and family self-management theory [70,71], mobile device functionality, and the pervasive information architecture of mobile health interventions [72] and followed the MRC's guidance for developing complex interventions [30-32]. *At heart* was designed as a progressive web application aimed at delivering nativelike user experiences regardless of the browser or the mobile device [73]. This study identified that the comprehensiveness and credibility of the information was important to women. The information helped them understand more about CAD and wellness and provided them with guidance in decision-making. At inception, women clearly articulated the need for a web application that was accessible across Android and iOS operating systems, including computers, smartphones, and tablets. In phase 1, women identified the need to access the library anytime and anywhere (eg, while waiting for dental appointments). As women were involved at the outset in co-design, no other significant user performance or satisfaction–related issues were identified. Female front and back full-body maps were specifically developed for *at heart* using the chest pain or associated symptom locations most commonly described in the literature [6,8,13,47,53]. These required only minor refinements during usability testing (ie, more precise identification of the axillae). Importantly, participants also viewed *at heart* as a way to contribute to the future of women's heart health. Women feel "stopped at the gate," and they want to take charge and advocate for better awareness, education, diagnosis, and management [74].

Limitations and Strengths

First, usability testing was conducted on a predominantly affluent sample of participants, which limits the generalizability of our results. A total of 60% (6/10) of the participants who took part in usability testing earned >CAD $70,000 (US $48,881.80) annually. They were also well educated, and most (8/10, 80%) were White. Canada is known for its diversity in race and ethnicities— over 450 ethnic or cultural origins were reported in the 2021 census [75]. A total of 1 out of 5 people in Canada is born elsewhere; the 3 largest visible ethnic groups are South Asian, Chinese, and Black individuals, representing 60% of the Canadian racial and ethnic populations [76]. Although this was a limitation in the sample for the usability testing, this is not a limitation specific to the *at heart* progressive web application. In fact, the *at heart* library contains heart

XSL•FO
RenderX

disease and heart wellness scientific papers and lay summaries related to South Asian and Indigenous people. These include risk and traditional practices such as drumming and healing and talking circles. However, it will be necessary to include a more diverse sample of women that encompasses those in less populous areas where age-standardized cardiovascular-related deaths in women are highest [77]. It will also be important to target recruitment of women from South Asian and Afro-Caribbean races and ethnicities, those with disabilities, those of a lower socioeconomic status, and those across age and gender identities who also experience greater risk of cardiovascular disease [77-79].

In addition, heterogeneous use of platforms and devices may also be a limitation to the usability testing. Progressive web applications are designed to work across platforms, eliminating the cost, fragmentation, and need to develop the same application several times for multiple platforms. They are designed to behave like mobile apps, working seamlessly across Android and iOS devices. However, past research indicates that progressive web applications may not be as smooth as mobile apps on Android devices [80]. Our sample size was limited, and only 10% (1/10) of the participants used an Android device for testing. Further research is needed to evaluate the usability of the *at heart* progressive web application across various platforms and devices. The phase-3 pilot RCT will determine the feasibility of implementing the *at heart* intervention, including the *feasibility* of randomization, recruitment, and retention; *acceptability* and barriers to implementing the intervention; and the extent of engagement with the intervention. The phase-4 effectiveness-implementation hybrid trial (type I) will investigate the effectiveness and implementation of *at heart* among women living in Canada using the practical, robust implementation and sustainability model [81]. The MRC [30-32] discusses 4 phases of complex intervention research (eg, development, feasibility, evaluation, and implementation) and the importance of refinements with each phase transition depending on the context [70,71] in which the intervention is evaluated and implemented. The practical, robust implementation and sustainability model [81] aligns contextual needs with intervention design using an inequity, systems thinking, and cocreation engagement approach. Context will be addressed by considering the individual perspectives on the intervention, external environment, characteristics of those receiving the intervention, and supports and resources needed to deliver the intervention [81]. Recruiting representative populations can be improved through strengthened community partnerships in governance and decision-making [82-84], and this will be a focus in subsequent phases of this research.

Second, remote usability testing methods were used during the COVID-19 pandemic. Testing a technology's usability remotely has inherent advantages as well as limitations. While participants can prefer remote testing to in-person testing, it can take longer for participants to complete tasks during remote testing, more errors can be made compared to in-person testing sessions, and context and indirect cues can be missed during remote testing sessions [85]. However, the approach taken to usability testing in this study was iterative, comprehensive, and aligned with methods used by others recently reported in a scoping review [41]. Of 133 articles included in this scoping review, 105 used questionnaires, 45 used a think-aloud approach, and 37 used interviews in their usability testing methods [41]. Moreover, many studies used a combination of 2 (n=46) or 3 (n=30) methods of testing, and the SUS was the most reported and validated questionnaire used to assess satisfaction and usability [41]. Finally, the *at heart* chatbot is rule based and designed for specific functions within the progressive web application. It is not led by artificial intelligence technologies (ie, natural language processing or large language models) and, therefore, may have inherent limitations that were not identified during the 2 cycles of usability testing (ie, personality, flexibility, dialogue structure, and conversation complexity or flow) [65].

Conclusions

This study does provide initial support for the *at heart* progressive web application for women with cardiac pain. Participants rated the performance of and satisfaction with this progressive web application as high. Ongoing evaluations in phases 3 and 4 should aim to examine the feasibility and acceptability and the extent of engagement with the *at heart* core feature set: Heart Check, Wellness Check, and the library. In addition to assessing effectiveness in an effectiveness-implementation hybrid trial (type I), describing and better understanding the context for implementation (eg, race and ethnicity and geography) will be necessary.

Acknowledgments

The authors thank the women who were participants in this study. They also thank the women with lived experience who collaborated in the co-design of *at heart* and the Heart and Stroke Foundation of Canada for their partnership. Phases 2 and 3 of the *at heart* program of research are supported by the Canadian Institutes of Health Research (389044) Project Grant: Fall 2017 competition.

Abstract

Background: Globally, mental health (MH) problems increasingly affect young people, contributing significantly to disability and disease. In low- and middle-income countries, such as Colombia, barriers to accessing care exacerbate the treatment gap. In addition, the lack of widespread digital interventions further deepens the digital health divide between the Global North and Global South, limiting equitable access to innovative MH solutions.

Objective: This study aims to co-design and develop an MH platform using participatory design methodologies and conduct a 15-month naturalistic observational trial to assess its feasibility among Colombian youth.

Methods: This study used a mixed methods approach within a structured research and development cycle. To ensure a user-centered design, we began with a series of co-design workshops, where stakeholders collaboratively identified key user needs. Following this, usability testing was conducted in 2 stages, alpha and beta, using the System Usability Scale (SUS) to assess functionality and user experience. To capture real-world interactions, a naturalistic observational trial ran from July 2022 to October 2023, collecting data on user engagement and system performance. This study integrated quantitative and qualitative analyses.

Results: A total of 146 individuals participated in the co-design process, with 110 (75.3%) contributing to the development of platform components and 36 (24.7%) participating in usability testing. The co-designed platform integrated several key features, including social media and advertising, an MH screening tool, registration, targeted psychoeducational resources, automated tailored recommendations, and a “track-as-you-go” feature for continuous MH monitoring. Additional elements included user-friendly follow-up graphs, telecounseling integration, customizable well-being nudges, an emergency button, and gamification components to enhance engagement. During usability testing, the beta prototype received a median SUS score of 85.0 (IQR 80-92.5), indicating high usability. In the subsequent observational trial, which ran from July 2022 to October 2023, a total of

XSL•FO
RenderX

435 users interacted with the platform—314 (72.2%) as registered users and 121 (27.8%) anonymously. Emotional distress was prevalent, with 63.7% (200/314) of the registered users and 61.2% (74/121) of the anonymous users reporting distress, as measured by the 6-item Kessler Psychological Distress Scale. Despite 102 users requesting telecounseling, only 26.5% (27/102) completed a session. While usability scores remained high, engagement challenges emerged, with only 18.8% (59/314) of the users continuing platform use beyond the first day.

Conclusions: This study explored the development and user experience of a youth MH platform in Colombia, demonstrating that a cocreation approach is both feasible and effective. By actively involving users throughout the design process, the platform achieved high usability and incorporated features that resonated with its target audience. However, sustaining long-term engagement remains a challenge, as does addressing privacy concerns, particularly for younger users. These findings highlight the importance of continuous user-centered refinement to enhance both accessibility and retention in digital MH interventions.

Introduction

Background

Globally, 1 in 7 young people aged 10 to 19 years are estimated to experience a mental illness [1]. Depression, anxiety, and behavioral disorders are considered some of the main contributors to the burden of disability and disease in young populations [2,3]. Likewise, suicide has been found to be one of the main causes of death in this population [1,4]. Unsurprisingly, the economic and human costs of mental ill-health represent a public health concern where urgent actions are required to improve health outcomes, reduce years of life lost due to preventable mortality and disability, and save millions in health care spending [4]. The impacts of mental ill-health are particularly challenging for low- and middle-income countries, which are home to 90% of the world's youth [5].

Evidence suggests that there can be up to a decade-long delay between the first symptoms of a mental health (MH) disorder and initial contact with services, especially among young people [6]; consequently, the use of digital health tools (DHTs) has gained attention as a potential solution, as young people often seek information online about their MH before discussing it with family members or engaging with MH services [7]. Young people have a preference to find a middle ground between formal and informal sources of information, which opens the opportunity to engage them with MH services or with sources of care [8]. Notwithstanding the value of DHTs, challenges to their adoption exist. First, the internet and digital technologies might not be equally accessible across and within countries [9,10]. Second, even in countries where DHTs are readily available, retention of users and usability are still their main challenges, as it is reported that their use decreases throughout the trials, and most evaluations are limited to short periods [11-13]. To promote the adoption of DHTs [14], participatory design approaches [15,16] offer a promising solution by centering users' needs. This user-driven methodology not only enhances usability but also fosters long-term engagement, ensuring that the technology remains relevant and effectively integrated into everyday practice [17].

Colombia is an upper–middle-income country [18] that faces many societal and economic challenges, further exacerbated by the COVID-19 pandemic [18]. The latest MH survey indicates that 26.5% of adolescents and 26.2% of adults aged 18 to 44 years are likely to experience >2 MH problems [19]. Despite this high prevalence, service use remains low, with only 12.4% of the individuals in urban areas with MH disorders having accessed any health services, according to the World Health Organization [20]. The substantial treatment gap in MH care underscores the critical need for enhanced access to services, particularly given the high prevalence of multiple MH issues among adolescents and young adults. This gap is intrinsically linked to the help-seeking process, as barriers, such as stigma, lack of awareness, and limited availability of resources, prevent individuals from seeking and receiving necessary support [21].

This Study

To the best of our knowledge, there are no comprehensive DHTs available in Bogotá, the capital city, or elsewhere in Colombia that assist young people with their MH. Using participatory design methodologies with end users, this research study explored the ideal design of an MH platform for young people in Colombia, with a focus on essential functionalities and visual appearance to effectively address their MH needs and preferences. We aimed to describe the co-design process and outcomes, outline the development process, and conduct preliminary testing of the minimum viable product (MVP) of this youth MH platform.

Methods

Overview

In line with the World Health Organization framework for developing digital interventions [22], through a well-tested research and development (R&D) cycle [15,23,24], a youth MH platform was co-designed, developed, and tested.

Recruitment involved convenience and snowball sampling, using peer groups and advisory representatives. Participants represented end users of the platform (young people, people with lived experience, their supportive others [eg, carers, family,

XSL•FO
RenderX

friends, and educators], and health professionals [eg, MH professionals and allied health professionals]).

Ethical Considerations

The study was approved by the human research ethics committee of Pontificia Universidad Javeriana and Hospital Universitario San Ignacio (protocol number FM-CIE-0103-21). Using REDCap (Research Electronic Data Capture; Vanderbilt University), informed consent was obtained from adult participants and legal representatives of minors, who also provided their informed assent, as per national regulations. Data were deidentified and safely stored in institutional cloud servers (OneDrive), only accessible to the principal investigator and research officers. Participants in the study received a grocery store voucher in recognition for their time and expertise. For codesign workshops, nonmedical staff and community participants (including young people, people with lived experience, and their supportive others) received a COP $50,000 voucher, while health professionals who participated outside of regular working hours received a COP $100,000 voucher. For user testing sessions, the same groups received COP $40,000 and COP $60,000 Colombian, respectively. These differences in voucher amounts reflected the varying levels of time and effort required for each activity (COP $1000=US $0.26, on average, during project activities).

Co-Design

Co-design workshops (CDWs) aimed to determine the needs and wants of end users as well as understand the functionalities and interface ideas they had for an MH platform. The information collected in these workshops was used to shape the actual development of the platform. What was developed and what it could look like was first determined in a knowledge translation session held after the workshops. The meeting included a multidisciplinary team composed of researchers, psychologists, psychiatrists, legal team members, engineers, and young people and representatives of people with lived experience. Mock-ups were then iteratively refined across each workshop. Furthermore, in between these meetings, several sessions with the reference group were held to always have the end users engaged in the decision-making process.

The CDWs were run using the Google Meet platform [25] in a 2-hour period with around 6 to 8 participants. Information collection was undertaken via surveys, word clouds, Cartesian planes, sketching pads, and scribble sheets [25].

Qualitative data were analyzed using NVivo (Lumivero) and a thematic analysis framework with deductive and inductive coding. An iterative approach guided each phase, and consensus methods were applied at the end of each phase (eg, counts and frequencies). Coding frequencies (CFs) were calculated for all subcategories within the main themes. Interrater reliability was measured using NVivo's coding comparison feature, with 2 researchers independently coding CDW transcriptions until achieving at least a fair agreement based on Cohen κ statistic [26]. Once reliability was reached, the remaining material was individually coded.

Development

Guided by young people's wants and needs and considerations from the multidisciplinary team, several software prototypes were developed as responsive web applications for mobile and desktop devices. Considerations included the assessment of technical feasibility, resource availability, complexity, prioritization, and compliance requirements, among others.

Usability testing was divided into 2 stages. The alpha prototype testing involved 90-minute, one-on-one sessions using a think-aloud protocol, with task difficulty measured by the Single Ease Question scale [27]. Following this, feedback on corrections and reasonable adjustments was provided to the engineering team for the beta prototype. As this version offered a more refined MVP, beta testing followed the same procedures as the alpha sessions but included a more detailed usability evaluation using the System Usability Scale [28].

For data analysis of user testing, sets of notes were generated for each session according to the interviewer's guide. Each section of all sets of notes was read for the first time to identify common themes or recommendations made by participants. Once themes were identified, sections were examined a second time to calculate frequencies (ie, to identify how many participants gave the same recommendation or expressed a similar opinion). Careful attention was given to negative or divergent opinions, for which the number of occurrences was also calculated. This process was carried out for each section of the notes until all sections were completed. Notes from alpha tests were examined first, followed by notes from beta tests. Microsoft Excel was used for frequency calculation.

Testing

To test the MVP, a naturalistic trial was run from July 2022 to October 2023, collecting data on use in real-world settings, including feature use, survey responses, and sociodemographic information.

The quantitative analysis used descriptive statistics to summarize the data. For skewed distributions, the median was used as the preferred measure of central tendency. Variability was assessed through SDs and IQRs, while frequencies and percentages were used to summarize categorical variables. The relationships between categorical variables were analyzed using the chi-square test with a 95% CI. The analysis was conducted using SPSS (version 23; IBM Corp) and Microsoft Excel.

Results

Overview

A total of 146 participants were part of the co-design (n=110, 75.3%) and development (n=36, 24.7%) of the platform's MVP. Most participants were female (n=103, 70.5%), with a median age of 18 (IQR 16-29) years. Middle (tiers 3 and 4) and low (tiers 1 and 2) socioeconomic tiers were the most represented in the sample, with 130 (89%) individuals. Vulnerable populations, such as survivors of armed conflict (n=6, 4.1%), ethnic minority individuals (n=5, 3.4%), and people with disabilities (n=1, 0.7%), were also part of the study.

XSL•FO
RenderX

Co-Design

Overview

A total of 19 CDWs were run, 125 source documents were collected, and 1309 annotations were coded. The deductive coding included 3 themes based on the framework by Ospina-Pinillos et al [15,23]: functionality (actions that can be performed within the platform; annotations: n=504, 38.5%, including all subcategories), user interface (annotations: n=420, 32.09%), and privacy and data management (annotations: n=86, 6.57%). In total, 2 themes emerged, namely technology use for health (annotations: n=111, 8.48%) and youth MH problems (annotations: n=188, 14.36%). Interrater reliability demonstrated a moderate agreement (Cohen κ=0.490).

Results on the use of technology for health and youth MH problems, presented subsequently, highlighted the potential of a technological platform for young people and provided key insights for the development stage. Specific wants and needs regarding functionality, user interface, privacy, and data management are also described subsequently.

Technology Use for Health

Most participants said they used the internet for information seeking (eg, symptoms, tips for managing health concerns, information about healthy lifestyles, and reviews about health professionals), teleconsultation (both from the health care provider and patient perspectives), education, and low intensity treatments (yoga, meditation, and breathing exercises). Information was obtained both from formal sources (eg, e-books) and informal sources, including peer-generated information, influencers, and social media. Acknowledging the amount of misinformation on the internet, participants mentioned developing diverse techniques to triangulate the veracity of the information.

Youth MH Problems

During workshops, each participant contributed to word clouds of youth MH problems, which were used to identify 123 concerns and guide platform development. The most frequently mentioned difficulties, shown in Table 1, involved social relations (n=39, 31.7% mentions), followed by MH disorders (n=28, 22.8% mentions) and problems with self-esteem and self-concept (n=23, 18.7% mentions).

XSL•FO
RenderX

Table 1. Most frequently mentioned youth mental health problems in Bogotá, as reported by co-design workshop participants (N=123).

Category	Mentions, n (%)
Problems with social relationships	39 (31.7)
Family problems	10 (8.1)
Peer problems	8 (6.5)
Bullying (including cyberbullying)	3 (2.4)
Couple problems	2 (1.6)
Others	16 (13)
MH[a] disorders	28 (22.8)
Substance use	9 (7.3)
Depression	9 (7.3)
Anxiety	6 (4.9)
Eating disorders	2 (1.6)
Attention deficit	2 (1.6)
Problems with self-esteem and self-concept	23 (18.7)
Self-esteem	10 (8.1)
Self-concept	7 (5.7)
Life project	6 (4.9)
Emotional difficulties	16 (13)
Emotion regulation	4 (3.3)
Loneliness	4 (3.3)
Stress	3 (2.4)
Resilience	1 (0.8)
Recklessness	1 (0.8)
Hope	1 (0.8)
Boredom	1 (0.8)
Sadness	1 (0.8)
Sexual health	5 (4.1)
Economic difficulties	5 (4.1)
Self-harm and suicide	3 (2.4)
Academic difficulties	3 (2.4)
Pandemic	1 (0.8)

[a]MH: mental health.

Functionality

This theme included 12 subcategories, for which we calculated the CF.

Reliable Information

Participants wanted to receive reliable, targeted, customizable, and periodically updated information (annotations: 52/504, CF=10.3%) delivered in multimedia format. They suggested adapting the platform to users' needs by including an initial test to personalize content and featuring an animated character to guide users and deliver information.

In terms of topics, participants believed the platform should provide general information about MH (eg, warning signs); specific recommendations for healthy lifestyles (eg, nutrition); instructions or tutorials for mental hygiene activities (eg, breathing exercises); and infographics, worksheets, and information on leisure activities (eg, hiking groups). Where relevant, the platform should also redirect users to other, more specialized resources (eg, fitness apps). Information about helplines, spirituality, alcohol and drugs, as well as sexual health was also mentioned. For informative pieces on high-risk topics, such as sexual abuse or suicidal ideation, allied health and MH professionals stated that clear information should be provided about the formal service routes available in Colombia.

XSL•FO
RenderX

Registration

Participants highlighted the value of choosing to explore the platform anonymously or creating an account (annotations: 36/504, CF=7.1%). They proposed to have different user profiles (eg, young people, health professionals, and caretakers), which would receive targeted content.

They proposed the inclusion of different user profiles (eg, young people, health professionals, and caretakers), acknowledging that a young person's MH care benefits from a collaborative support system involving both school and family. By incorporating multiple profiles, the platform would facilitate better interaction and coordination among these key stakeholders, ensuring more comprehensive support for young people:

> *I would create the account so that, let's say, you would have more options, right? Because if you say, "Well, I'm a woman, a teenager, a girl," it would give you more tailored options, right?* [Adolescent from a CDW]

Virtual Care

Participants emphasized the importance of being heard, suggesting the platform should offer options for discussing MH with professionals via videoconference, call, or chat while also highlighting the need for both crisis support and follow-up care (annotations: 33/504, CF=6.5%).

Participants expressed a desire for counseling, guidance, and practical advice tailored to their concerns, with some suggesting virtual care should include professional-led activities such as meditation or life project discussions:

> *I liked the idea of the calls because something similar was done in another project. Two young psychology students would call us monthly or weekly, depending on our schedule, to check in on how we were doing. They even had a project to help us create a life plan, guiding us on what we wanted and providing orientation.* [Adolescent from a CDW]

Others preferred simpler interventions, such as having professionals available to answer specific questions. A blended approach, combining virtual care with face-to-face interactions for initial meetings or home visits, was recommended by some to build rapport and foster empathy.

Screening Tests and Continuous Monitoring of MH Areas

Participants prioritized the ability to evaluate their well-being through tests (annotations: 153/504, CF=30.4%) with immediate results to track progress and express their feelings:

> *It works well because it might help the person express how they're feeling at that moment. Maybe they don't have someone to talk to and share those feelings, like saying, "I haven't been sleeping well" or "I'm feeling sad" or "This happened to me yesterday." It's a way to express yourself while also getting help to feel better and reflect, asking yourself, "What can I do to sleep better?" I'd say it's a good thing.* [Adolescent from CDW]

They wanted diverse response formats (eg, text, video, and audio), customizable survey reminders, and coverage of various topics, such as loneliness, physical health, and emotions. MH professionals suggested tracking coping strategies and integrating the platform into therapy. They emphasized that test results should include actionable feedback or resource links to support improvement or maintain progress.

Gamification

Participants emphasized the value of gamification (annotation: 42/504, CF=8.3%) to engage and motivate young people, suggesting elements, such as video games, avatars, digital medals, and incentives, such as vouchers, or proposing combinations, such as avatars, integrated into games or tied to rewards.

Social Media and Advertising

Participants suggested integrating the platform with social media (annotations: 68/504, CF=13.5%) through visually appealing and relatable advertisements on platforms, such as Facebook, Instagram, TikTok, and Twitter (subsequently rebranded X), focusing on common concerns, such as sleep and mood. They proposed using hashtags for awareness campaigns, adding a share button for easy promotion, and collaborating with influencers or YouTubers to donate content to engage young people and normalize MH concerns.

Well-Being Nudges

Participants acknowledged the diversity of MH concerns and coping strategies among young people. Suggestions included a calendar to track results, a virtual trainer to encourage engagement in activities, and notifications with motivational messages and activity reminders (annotations: 36/504, CF=7.1%).

Emergencies

Participants expressed a desire to either talk to someone immediately or receive guidance from the platform, but they also wanted the option to act independently or support a friend in need. In emergency situations, they emphasized the importance of quickly accessing help (annotations: 3/504, CF=0.6%). In addition, they suggested the ability to notify the platform if another user appeared to require urgent care.

Community Participation

Participants suggested adding blogs and forums (annotations: 60/504, CF=11.9%) moderated by health professionals for safety. They wanted to discuss MH and shared interests, such as soccer or movies, emphasizing that interaction with others could foster support, bonding, and mood improvement.

Chatbot

Participants suggested including artificial intelligence (annotations: 6/504, CF=1.2%) in the platform to provide care during after-hours or weekends, offering general advice, or linking users to specialized resources. They noted that chatbots could also benefit introverted users who may find it difficult to share their concerns.

XSL•FO
RenderX

Interoperability With Local Services

Participants recommended integrating the platform with local services (annotations: 12/504, CF=2.4%) either by referring users to specialized city services or incorporating it into existing programs offered by private and public organizations.

Research and Public Health Surveillance

Participants, particularly MH and allied health professionals, highlighted the research and public health value of an MH platform (annotations: 3/504, CF=0.6%). They suggested using data from continuous monitoring for epidemiological purposes to improve care for young people and integrating it into health surveillance systems.

User Interface

User interface refers to the visual presentation of content and functionalities. Participants stated that the platform should be visually appealing, engaging, and responsive, using inclusive language. Lay terms were preferred over clinical jargon. Customization and interactivity were essential characteristics to be considered across all platform functionalities.

The most important aspect for end users was an eye-catching, aesthetically pleasing appearance. Participants consistently mentioned using images, cartoons, and icons but emphasized that the platform should not appear childish.

Privacy and Data Management

Regarding data management, participants preferred clear, concise information about how their data would be used, favoring simple language over lengthy, jargon-filled documents while still adhering to privacy standards. Concerns were raised about obtaining consent for children aged <14 years, who could not legally provide consent in Colombia. While some younger participants were open to involving their legal guardians, most preferred to engage independently without parental authorization. In addition, most parents expressed a desire to access their children's data:

> *If she were to use the platform, I would want to know absolutely everything—the good, the risky, the threatening, the happy—everything.* [Parent from a CDW]

They acknowledged that children may be hesitant to share their concerns if parents had access to the data, and although most would allow them to use the platform, for some, it could be a sign of poor or declining MH. Some parents indicated they would like to use the platform too, which showcased the multiple ways in which they wished to be involved:

> *Each child is a different world, everyone has their own way of thinking, and not everything in life is complete. I believe that both children and us as parents have our flaws or gaps. When looking at the platform, I think it would be great to use it to explore those gaps or the things we sometimes don't understand about them or wish we could know.* [Parent from a CDW]

Development

Functionality

Reliable Information

To expand access to Spanish-language psychoeducation resources, we integrated our platform with Mental Punto de Apoyo [29], the largest repository of MH materials in the region. This integration allows users to explore a wide range of resources, including videos, pamphlets, and podcasts on MH topics, along with practical techniques to enhance well-being (eg, meditation).

On our platform, these resources are presented with their title and images. When users click on an image, they are redirected to the Mental Punto de Apoyo website for full access. The repository is regularly updated, ensuring users have access to the latest information.

In addition, registered users benefit from tailored recommendations based on periodic survey results and can track a chronological record of all suggested resources, strengthening the connection between both platforms and enhancing the user experience.

Registration

We developed a registration feature that allows users to either create an account or continue anonymously. Anonymous users can access general MH resources but must provide basic demographic details and accept the terms of use. However, registered users gain access to additional features on their home page, including an SOS button, a customizable well-being plan, and avatar selection.

During development, parents and caregivers expressed interest in having their own profiles to better support their children. However, this feature was not included in the MVP.

Virtual Care

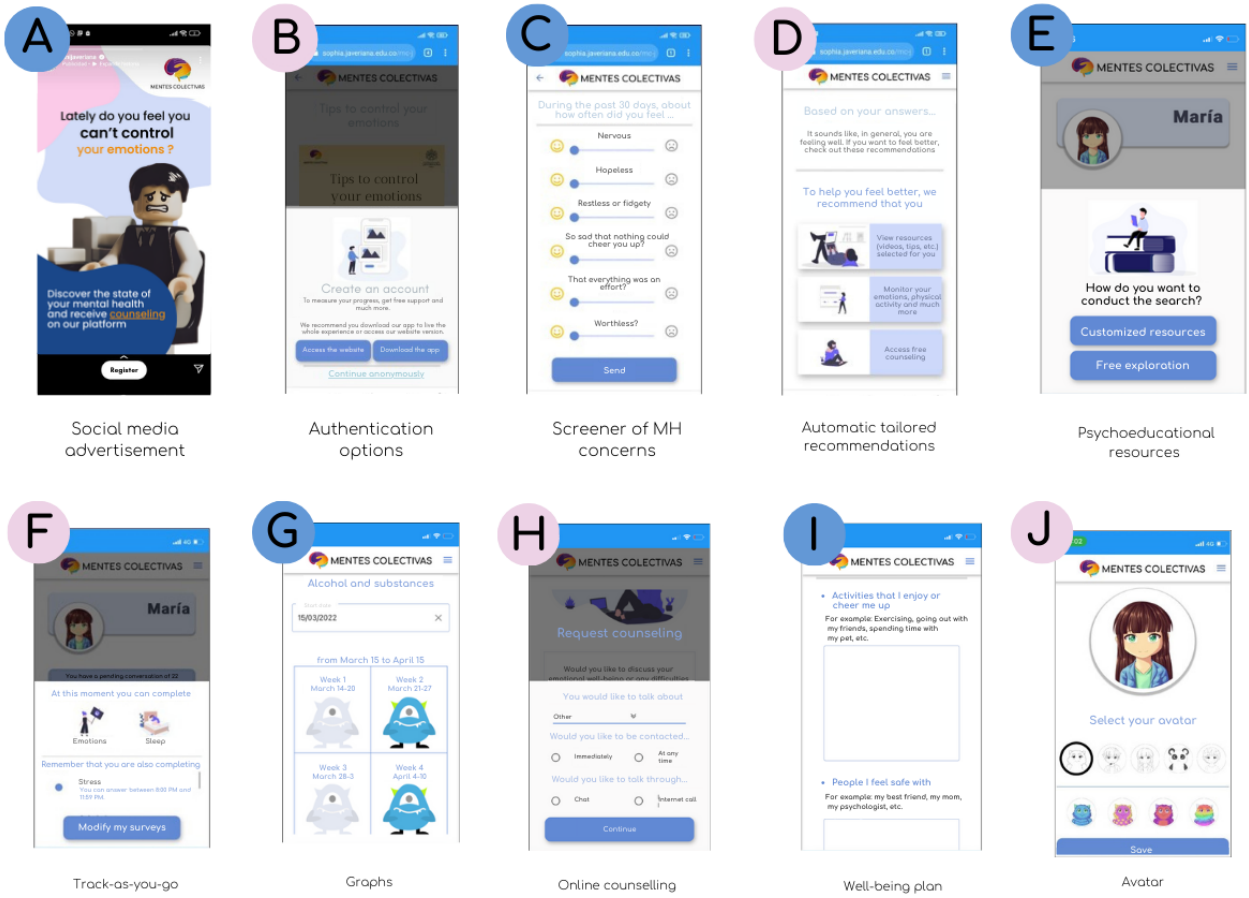
To provide access to virtual care, we integrated the platform with Mentes Colectivas, a free web-based program providing counseling and support for individuals aged ≥14 years. The program, accessible on a website [30], offers a safe space where users can seek guidance on emotional well-being, sexuality, and family planning. Users can connect with a team of students, professionals, and volunteers through their preferred digital contact method—telephone call, web-based chat, or web-based call. Appointments can be scheduled within 72 hours, with up to 5 follow-up sessions available as needed. For emotional well-being counseling, support is provided directly through the platform, including follow-up sessions. Users requiring urgent assistance outside of service hours are redirected to emergency services. For sexuality and family planning counseling, users are seamlessly transferred to a designated website using their platform credentials, with unlimited follow-up sessions available if needed [31].

Screening Tests and Continuous Monitoring of MH Areas

An MH screening and continuous monitoring feature ("track-as-you-go" functionality) was developed based on key concerns identified by CDW participants (Table 1). First-time users, whether anonymous or registered, complete an initial

XSL•FO
RenderX

screener using the survey by Kessler et al [32] to assess concerns and distress levels, receiving tailored feedback and psychoeducation through automated algorithms. Registered users can access the continuous monitoring function, selecting from 13 areas (stress, loneliness, well-being, emotions, physical activity, sleep, subjective health status, self-esteem, relationships, eating, alcohol and substance use, bullying, and sexual and reproductive health) to track their progress. Surveys can be scheduled daily, weekly, or biweekly, with a maximum of 2 available at a time to encourage mindful participation. Registered users also gain access to visual progress charts, including line graphs, gauges, and calendars, with options to filter results by date, view them alongside resource histories, and export them as PDFs.



Gamification

During knowledge translation sessions, we recognized the importance of gamification in enhancing user engagement. However, due to the complexity of developing video games and incentive systems, we focused on implementing avatars as the first step. Users can choose from a set of predefined avatars and update them at any time, allowing a degree of personalization. While this feature laid the foundation for a more interactive experience, future iterations may explore additional gamification elements to further enhance user motivation and engagement.

Social Media and Advertising

Recognizing the importance of outreach, we developed a social media campaign featuring advertisements with cartoons to promote the platform and attract users (Figure 1). While awareness campaigns and influencer collaborations could further enhance visibility, they were not included at this stage. This initial approach allowed us to gauge user engagement and refine strategies for future promotional efforts.

Figure 1. User journey of the platform. Platform screenshots were translated from Spanish to English for clarity. The app version of the platform is currently under development. MH: mental health.

From Well-Being Nudges to Well-Being Plan

To encourage young people to engage in MH-promoting activities, we aimed to incorporate well-being nudges throughout the platform. Some of these nudges were successfully integrated into the monitoring graphs, providing gentle prompts to encourage reflection and engagement. However, expanding nudges across the entire platform proved challenging.

As an alternative, we developed the well-being plan, a structured tool inspired by safety plans. It helps users identify uplifting activities, supportive people, and emotional warning signs. Users can personalize their plan with open-text responses and are encouraged to practice beneficial activities when facing challenges. The platform also provides examples of warning signs, such as weight loss or insomnia, ensuring accessibility at all times.

Given development constraints, we prioritized the Wellbeing Plan as the core feature for the MVP, with the potential for further integration of nudges and additional tools in future iterations.

XSL•FO
RenderX

Emergencies

To respond to this need, we designed the telecounseling feature to allow participants to speak with someone immediately from Monday to Friday, 7 AM to 7 PM. During off-hours, the button provided continuous access to emergency local services information (eg, gender-based violence and suicide-related Colombian helplines), ensuring support was always available. Given that the platform is web based, automatic dialing could not be integrated.

Deferred Functionalities

The remaining functionalities were not developed for this MVP due to resource constraints and implementation complexities. Community participation was deprioritized to ensure platform sustainability and focus on essential features such as virtual care, as moderation and content creation required dedicated budgets and personnel. Artificial intelligence functionalities were also not included due to technical challenges and safety concerns, as current large language models in Spanish required significant refinements to ensure reliability and user safety. Interoperability with local services was set aside due to the complexity of institutional agreements, data management, and privacy concerns. Finally, while research and public health surveillance were recognized as valuable, they fell outside the MVP's scope, as they required advanced data management, administrative agreements, and rigorous validation for public health use. Future developments may reassess the feasibility of these features to enhance user experience and support services.

User Journey

The user journey (Figure 1) begins by attracting potential users through targeted advertisements on social media. When users click on an advertisement, they are redirected to the platform's landing page, where they find general information about the platform, MH, and well-being. From there, they can choose to log in and create an account for full access or continue anonymously with limited functionality. If they opt to register, they are guided through a straightforward sign-up process where they provide informed consent, accept the platform's terms and conditions, and acknowledge the habeas data regulations for data protection.

After completing registration, users take a screening test designed to assess their MH concerns. Once they finish the test, they immediately receive feedback on their results and are invited to explore targeted and specialized resources based on their responses. They can also start monitoring their MH through the track-as-you-go feature, which allows them to select areas of interest and continuously track them over time. On the basis of their tracking results, further specialized algorithms provide tailored recommendations and psychoeducational resources. Users can also request a web-based counseling session if needed.

Registered users can access additional features on their home page, including the SOS button, a customizable well-being plan, and avatar selection. As users continue engaging with the platform, they receive increasingly personalized information, whether by tracking additional areas or adjusting their preferences over time. This ensures that the platform evolves with their needs, offering continuous and adaptive support for their mental well-being.

Usability Results

A total of 36 individuals participated in usability sessions for the alpha prototype (n=16, 44%) and the beta prototype (n=20, 56%).

Task Completion Results

In alpha tests, the median task completion time was 43 (IQR 23.5-66.5) seconds, with a median score of 1.00 (IQR 1-1) on the Single Ease Question scale, showing minimal difficulty in performing tasks. The beta tests showed similar results, with a median completion time of 28 (IQR 16-48) seconds and a score of 1.00 (IQR 1-2; Table 2). The track-as-you-go surveys generally showed favorable results with short completion times, except for the physical activity test, which had the longest time and highest difficulty. Accessing resources, returning to profiles, and requesting telecounseling increased completion time without impacting the experience (Table 3).

The beta prototype had a System Usability Scale median score of 85.0 (IQR 80-92.5), indicating acceptable usability. Nearly all participants (18/20, 90%) found the monitoring surveys easy to use. Most (14/20, 70%) found the avatar functionality visually appealing, though some (7/20, 35%) suggested more customization options. The SOS feature was considered useful by all (14/20, 70%), with participants suggesting it should be made more visible.

Improvements between the alpha and beta builds mostly included corrections to the back end of the platform to solve bugs and reduce malfunctioning. Front-end improvements were limited to changes in the wording of instructions, feedback from test results, headings, or descriptions.

XSL•FO
RenderX

Table 2. Completion times and Single Ease Question (SEQ) scores for tasks conducted in alpha and beta user testing sessions. The number of participants who performed the task or responded to the SEQ is presented for each task, as time restrictions or platform malfunctioning impeded all participants from completing all activities[a].

Task	Alpha test		Beta test	
	Completion time (s), median (IQR)	SEQ score, median (IQR)	Completion time (s), median (IQR)	SEQ score, median (IQR)
Creating an account	67.50 (47-89.75)[b]	1.00 (1-1)[b]	61.50 (53.25-91.75)[c]	1.00 (1-1)[c]
Filling the screener of concerns	43.00 (34.25-50.75)[b]	1.00 (2-1)[d]	34.00 (30.5-44.5)[c]	2.00 (3-1)[c]
Accessing MH[e] resources	21.00 (15.25-70)[b]	1.00 (1-1.25)[f]	59.50 (35-83)[c]	1.00 (1-1)[c]
Going to my profile	5.00 (2.75-13)[f]	1.00 (1-1)[g]	6.00 (5-13)[h]	1.50 (1-3)[i]
Requesting a web-based counseling session	44.00 (39-72.5)[j]	1.00 (1-1.5)[j]	76.00 (64-101)[h]	1.00 (1-1)[i]

[a]Median values were used, considering the small samples, to provide a more accurate representation of central tendency.

Reliable Information

Participants (13/16, 81%) from alpha user testing sessions found the topics of the tips useful and relevant. Furthermore, they (12/16, 75%) liked the images and tips design and described them as striking and pleasant. In total, 12% (2/16) of the participants believed the tips were generic or random, and 6% (1/16) of them found the design boring. In the beta sessions, participants (16/20, 80%) expressed their satisfaction with the tips and their content. However, most of them (16/20, 80%) suggested design changes, including color and image updates, and adding more information to the tips by providing links to additional resources. Tips were not accepted by 15% (3/20) of the participants who did not find them useful and suggested changes to the text and more detailed explanations.

Registration

Most (14/16, 88%) of the participants from the alpha testing sessions found the account creation process easy. Only 1 participant was confused by the registration process. In terms of registration options, 31% (5/16) of the participants favored the web version, 31% (5/16) preferred the app version, 12% (2/16) opted for the anonymous route, while the rest (4/16, 25%) did not express any preferences. Most participants (14/16, 88%) understood the sociodemographic questions, and more than half (11/16, 69%) found the images and questions design aesthetically pleasing. The others suggested making changes, especially regarding the gender question and the text description of the platform. Moreover, 19% (3/16) of the participants thought that the survey should collect information about their motive for consultation. The platform's description was changed based on feedback; however, the motive for consultation was not included due to the platform's focus on promotion and prevention, and no changes were made to the gender questions due to limitations in illustration availability.

In the beta sessions, 9 (45%) of the 20 participants preferred logging in to the platform through the web, and 6 (30%) of the 20 participants chose to access the platform anonymously. All participants (20/20, 100%) found the survey easy and clear and

XSL•FO
RenderX

considered the gender question to be acceptable, inclusive, and noninvasive. They made some recommendations related to including more questions or additional answer options.

Virtual Care

In alpha user testing sessions, all participants (13/13, 100%) were able to easily access the feature. They valued its shortness and simplicity but suggested adding more MH topics in the request form. A participant stated that requesting a session involved too many steps. Due to parameterization issues, no topics were added to the request form. In beta user testing sessions, almost all interviewees (18/19, 95%) liked the web-based counseling functionality for its usefulness and flexibility.

Screening Tests and Continuous Monitoring of MH Areas

In alpha user testing, 62% (10/16) of the participants found the screener test easy but suggested adding instructions and more intermediate options. Most (11/16, 69%) participants understood the recommended functionalities, though 25% (4/16) of the participants had trouble with the monitoring feature. Most (12/16, 75%) participants had no issues completing surveys or sharing information but suggested improving the design, adding options to the emotions survey, and making the survey list more prominent. For the beta build, instructions were revised, but intermediate options were excluded to preserve consistency with the original scales. The appearance of the feature on the main profile was also revised, changing the wording of the title to increase clarity.

In beta sessions, nearly all participants (18/20, 90%) liked the screener of concerns, finding it easy, useful, and interactive. They suggested changes to the visibility of the scale, such as making the slider larger, making the answer options visible, or adding instructions (13/20, 65%). More than half of the interviewees (12/20, 60%) understood the 3 recommendations given after the test, with the monitoring feature recommendation being the least understood (7/20, 35%). Nearly all of the participants (18/20, 90%) found most surveys easy to use, and the feedback was positive overall. The most difficult survey was physical activity (6/20, 30%), where participants had trouble making estimates in minutes. They suggested changing the survey to ask about hours; however, due to parameterization restrictions, it was not possible to accommodate this request. Participants also recommended including more targeted resources and additional answer options for the emotions, bullying, and self-esteem surveys, among others. To comply with these recommendations, changes would have to be made to algorithms, which require investments in time and resources. Thus, this recommendation will be considered for further developments. Graphs were also tested in beta sessions, where the calendar type with icons was the most accepted. Participants suggested changes to the icons for most of the graphs, especially the well-being graph (12/20, 60%), followed by the loneliness graph (10/20, 50%).

Gamification

To prioritize other functionalities, the avatar selection feature was only tested in beta sessions. Most of the participants (14/18, 78%) found it visually appealing. Some of them (7/18, 39%) suggested more options, such as color customization and adding more avatar types. In total, 1 participant did not like the anime style.

Integration With Social Media and Advertising

Alpha user testing participants (9/16, 56%) suggested changes in the image and colors to make the advertising more striking and more related to the MH topic. Among the options, the most liked one used cartoons (12/20, 60%) instead of pictures. This advertisement was used in beta sessions where slightly more than half of the participants (13/20, 65%) found it appealing.

Well-Being Nudges

The well-being plan was tested in beta sessions. Participants liked the tool and found it useful and easy to manage. They suggested adding examples of signs of distress or default options to choose from.

Emergencies

The SOS feature was only tested in beta sessions, where all participants (14/14, 100%) found it useful. They valued the variety of helplines and contact options and suggested making it more visible in the main profile.

Testing

Although the platform was designed for young people, feedback from CDWs indicated interest from support individuals, such as parents, caregivers, or health professionals, who expressed a desire to explore the platform before their children or patients used it. In response, we decided to collect demographic information from all users, specifying their role or profile. During the naturalistic trial, no age restrictions were imposed, allowing us to analyze data from all users, including adults, as part of the platform evaluation.

A total of 452 individuals entered the platform. Due to technical difficulties (and hence incomplete information), 17 (3.8%) records were excluded from the analysis. There were 3 registration peaks: the first in November 2022, the second in March 2023, and the third in June 2023. The platform reached 26 of the country's 32 departments; most of the users were from Bogotá (139/314, 44.3%), Cundinamarca (25/314, 8%), Boyacá (23/314, 7.3%), and Antioquia (15/314, 4.8%). During the observed period, 435 individuals used the platform, with 314 (72.2%) users registering and 121 (27.8%) using it anonymously. Most anonymous users were female (89/121, 73.6%) as well as identified to be a young person (31/121, 25.6%). Importantly, more than half (74/121, 61.2%) of the users presented some degree of emotional distress according to the 6-item Kessler Psychological Distress scale (mild distress: 29/121, 24%; moderate distress: 33/121, 27.3%; and severe distress: 12/121, 9.9%) [32].

In relation to those who registered, the median age was 34 (IQR 23-46) years, and most of them (232/314, 73.9%) were female. About the role in the platform, 21% (66/314) of those who registered were young individuals, 26.8% (84/314) were carers, 22% (69/314) were educators, and 20.7% (65/314) were health professionals. Most users (200/314, 63.7%) presented some degree of emotional distress (mild distress: 68/314, 21.7%;

XSL•FO
RenderX

moderate distress: 70/314, 22.3%; and severe distress: 62/314, 19.7%).

To evaluate the relationship between the level of distress and the selected role, a chi-square test of independence was executed. In the registered group, the relationship was statistically significant (χ^2_9=37.9; *P*<.001), and observed frequencies revealed that young individuals had more severe, moderate, and mild levels of distress, while health professionals appeared more frequently with low levels of distress. In addition, an effect size was calculated using Cramér V, which was found to be 0.20. While this effect size is statistically significant, it is small in magnitude. In the group of anonymous users, the relationship was statistically significant (χ^2_9=17.0; *P*=.048), and the Cramér V test showed a weak effect (0.22). The observed frequencies showed that young people had more severe levels of distress, carers and young people had more moderate levels of distress, carers and educators had more mild levels of distress, and health professionals had lower levels of distress more frequently.

Regarding user engagement, 81.2% (255/314) of the individuals used the platform for just 1 day, 8.9% (28/314) used it for 15 days, 2.5% (8/314) used it for 1 month, and 7.3% (23/314) used it for over a month up to 1 year. Among the functionalities, the screening test (314/314, 100%) was the most used as it was mandatory, followed by track-as-you-go (118/314, 37.6%), telecounseling request (102/314, 32.5%), well-being plan (32/314, 10.2%), SOS button (15/314, 4.8%), and finally avatar (14/314, 4.5%). A chi-square test of independence was executed between the level of distress and the platform's use. The relationship was statistically significant (χ^2_{12}=24.5; *P*=.02), and the effect size was calculated using Cramér V, which was found to be 0.16, which meant a weak effect size. The observed frequencies indicated that people who only used the platform on the day of registration were more likely to report no discomfort in the emotional distress screening. In addition, severe discomfort was the most common outcome for people who used the platform during their first month of registration. People who used the platform for 2 months or between 3 and 6 months most often experienced moderate discomfort. By contrast, those who used the platform for >6 months had higher scores in severe and mild discomfort.

Among the individuals who used the tracking component, the most frequently used survey was the emotion tracker (32/118, 27.1%), followed by sleep (25/118, 21.2%), stress (21/118, 17.8%), and physical activity (10/118, 8.5%). The rest of the surveys (loneliness feeling: 6/118, 5.1%; well-being levels: 6/118, 5.1%; self-esteem evaluation: 5/118, 4.2%; risk of eating disorders: 4/118, 3.4%; health perception: 3/118, 2.5%; sexual health: 3/118, 2.5%; relationships: 2/118, 1.7%; and bullying: 1/118, 0.8%) represented less than 5% use. In addition, only a small number of participants opted to continuously monitor any of these areas, with 47% (15/32) tracking their emotions, 44% (11/25) tracking sleep, 24% (5/21) tracking stress, and 20% (2/10) tracking physical activity beyond the initial use.

Concerning the baseline (first time) responses, neutral emotion was the most reported with 41% (13/32), followed by sadness 22% (7/32), fear 19% (6/32), anger 12% (4/32), and joy 6% (2/32). In terms of sleep quality, 96% (24/25) of the users who answered the sleep survey reported sleep problems. With respect to the perceived stress, 71% (15/21) of the participants experienced high levels of stress, 24% (5/21) had some degree of stress, and 5% (1/21) had low stress. In relation to physical activity, participants reported spending a median of 10 (IQR 0-37.5) minutes doing moderate activity per day, with just 10% (2/10) of the users doing it for >60 minutes daily. Median sitting time was 210 (IQR 47.5-345) minutes.

Of the 102 participants who requested telecounseling, only 27 (26.5%) had a complete counseling session. Regarding the reasons for consulting, the most frequent problem was anxiety, reported by 67% (18/27) of the participants, followed by sadness at 11% (3/27), and everyday problems at 11% (3/27). In terms of the form of communication, the platform offered 5 types: immediate chat, chat later, immediate internet call, internet call later, and video call and traditional phone call. Chat later and immediate call options were the main forms chosen by users, with 48% (13/27) and 33% (9/27), respectively. Moreover, the immediate chat option and internet call me later option were less popular among participants, with only 19% (5/27) and 15% (4/27). Finally, video call (1/27, 4%) was the least used option. During the counseling session, only 4% (1/27) of the individuals reported self-harm and suicide plans, which required referral to emergency services.

Discussion

Principal Findings

This study aimed to co-design, develop, and test an MH platform tailored for youth in Bogotá, Colombia. Using a rigorous R&D cycle, we actively engaged a diverse sample, ensuring representation across different ages, socioeconomic backgrounds, and marginalized or hard-to-reach populations. Findings revealed a strong interest in a youth-focused MH platform that prioritized a visually appealing and user-friendly interface, clear privacy protections, and a range of essential features. These included registration, access to reliable information, virtual care options, MH screening and continuous monitoring, gamification, social media integration, personalized well-being plans, emergency support, connections to local services, chatbot interaction, and support for research and public health surveillance. Through knowledge translation sessions, we refined these insights into a platform with 11 key features, including social media integration, registration, MH screening tools, psychoeducational resources, automated recommendations, real-time MH tracking across 13 areas, follow-up graphs, telecounseling integration, customizable well-being nudges, an emergency button, and gamification components. Usability testing confirmed high functionality and acceptance, and a naturalistic trial further evaluated real-world engagement and use patterns. This extensive participatory approach not only ensured that the platform was contextually relevant and user driven but also demonstrated its acceptability, usability, and potential impact in supporting youth MH.

A notable aspect of our research is the extensive engagement of end users throughout the co-design process, with a sample size of 146 participants. Existing literature indicates that most

XSL•FO
RenderX

studies using participatory methodologies in the development of MH DHTs are conducted in high-income countries and often involve relatively small sample sizes (<50 participants). In Latin America, a unique instance of co-design was conducted in Colombia, featuring culturally adapted approaches [24]. Despite the inclusive methodology, men and other genders represented <30% of the sample. This level of participation aligns with research showing that men tend to seek less MH support [33] and engage less in research [34]. This disparity highlights a research gap in understanding the engagement of men and gender-diverse individuals in MH initiatives, which may also impact their adoption and use of DHTs [16]. Future work is needed to address this gap and ensure these technologies are truly inclusive and accessible to all [16,35].

Moreover, the ample sample size of this study allowed for the inclusion of individuals who may act as gatekeepers in young people's MH help-seeking journeys, offering valuable insights into how their involvement can support youth. In addition, the study captured a broad spectrum of perspectives, including diverse and sometimes conflicting opinions, not only regarding design preferences but also in the roles and expectations of caregivers versus young people. These conflicting perspectives highlight a fundamental tension in designing DHTs, that is, balancing the autonomy and preferences of young users with the concerns and involvement of caregivers. However, this diversity of opinions enriches the research process by prompting critical discussions and leading to more adaptable, inclusive, and responsive solutions. Future work should further explore these tensions and develop strategies to ensure that DHTs effectively support both young users and their caregivers while respecting youth autonomy and privacy [36].

This paper provides a comprehensive description of the participatory processes, thereby enriching the literature, as many studies do not provide comprehensive details, thus limiting the reader's understanding of the methodologies used and the extent of user involvement [37]. Our study sought to provide detailed information on the participation of end users at every stage of the development process, including design, feedback provision, knowledge translation, decision-making, and testing. These results highlight the need for end users to be at the center of the design and implementation process rather than just being mere consultants [22,23]. In the same line, the process involved young people and people with lived experience in a meaningful way, avoiding tokenism and promoting genuine participation [38].

In terms of use, engagement is a significant challenge in the eHealth field, with research consistently showing high attrition and low engagement rates [11]. For example, studies indicate that retention rates for mental well-being apps are as low as 3.9% after 15 days and 3.3% after 30 days [39]. In our study, we observed a particularly striking trend on the first day of use, with only 18.8% (59/314) of the users continuing to engage with the platform after the first day. Understanding and improving the first-day experience is crucial for enhancing overall retention and ensuring users continue to benefit from the platform. In our study, participants with higher levels of distress demonstrated a tendency to use the platform for extended periods, aligning with existing evidence [40]. This suggests that the platform may be particularly well-suited for individuals already engaged in the MH care process. Engagement remains a key area for future R&D to address the substantial drop-off after initial use. While our user engagement rates were better (longer periods of engagement) than those reported in previous research, possibly due to our thorough co-design process tailored to users' needs and preferences, achieving long-term engagement requires sustained efforts and innovative strategies to keep users motivated and invested over time. Some alternatives were highlighted by our participants, which referred to integration with local services (in person or virtual), which are already available in Colombia and are known to communities. This synergistic approach could provide more customized follow-ups for service users while expanding the platform's reach to communities outside of social media, creating a blended approach to engagement. However, integration represents a challenge as it requires coordinated responses as well as administrative and data protection agreements.

Our study aimed to contribute to reducing the significant delay in seeking help for MH problems, which averages >10 years [6] from the first symptom to professional contact. By implementing our platform, we provide a potential tool to facilitate earlier access to support, addressing the urgent need for more accessible and timely MH interventions. Internet-based interventions have shown promise in this regard, offering a cost-effective alternative to traditional care [16]. A meta-analysis indicated that these interventions are marginally more effective than usual care in terms of quality-adjusted life years gained, have similar prices, and have a net benefit of US $255 (95% CI US $91-US $419; P=.002) [41]. Furthermore, research has shown that targeted prevention efforts are generally more cost-effective than universal approaches in the youth population [42]. Specifically, interventions that are deployed in community settings (eg, schools or workplaces) and coupled with specific interventions (eg, psychotherapy) have proven highly cost-effective for preventing MH disorders in children and adolescents [42].

Our findings support the need for rethinking services and care pathways, as two-thirds of the users (both anonymous and registered) showed some level of emotional distress. Young users exhibited higher distress levels, with a notable relationship between distress levels and user roles (χ^2_9=37.9; P<.001) as demonstrated in the Results section. These insights emphasize the potential of our platform to identify individuals in need of immediate support. By integrating such technologies with traditional MH services, we can enhance early detection and intervention, ultimately improving MH outcomes. Our findings advocate for the continued innovation, development, and implementation of DHT to detect early signs of distress and integrate these tools with conventional care systems to better support young people and those at risk early in the course of illness.

Limitations

In academia, it is difficult to compete with commercial DHTs that offer highly intuitive and engaging user experiences, even though their content often lacks solid evidence-based support [43,44]. A significant limitation of our study is the absence of

XSL•FO
RenderX

collaboration with industry partners, which could provide valuable resources and expertise in user-centered design and technology development at commercial standards. Partnerships that leverage industry expertise could result in more usable and high-fidelity technologies [44] while also facilitating improved data collection methods, such as the use of phone sensors or wearable devices, to enhance data accuracy and enable more timely notifications, advancing to precision medicine [45]. Furthermore, partnerships with industry could help address the critical challenges of innovation, sustainability, and scalability. Moving forward, it is essential to combine rigorous evidence-based methods with the engaging design features typical of commercial products, along with the advantages provided by industry collaboration, to develop effective, sustainable, and scalable digital health interventions.

Implementation in the Colombian Context

Although participants reported good acceptability of the platform, there are several barriers to its implementation in the Colombian context. A key issue is the discrepancy between young people's needs and legal requirements. Colombian regulations mandate parental consent for access to most health services [46]. While some young people were willing to involve their guardians, most preferred using the platform independently. Parents, while desiring access to their children's information, recognized this might deter openness. To address this, an anonymous browsing option was created, requiring registration only for specialized functions, such as receiving targeted information or telecounseling.

The co-design process was conducted in Bogotá, which, though diverse, may not represent all populations. Further adaptations are needed to tailor the platform to the MH needs of different Colombian communities, including minority groups.

Conclusions

In conclusion, this study successfully co-designed and tested an MH platform tailored for youth in Bogotá, Colombia, to promote help-seeking behaviors for MH issues. Engaging a diverse sample of 146 participants from various backgrounds, the platform addressed the preferences of users across different ages and socioeconomic statuses, demonstrating high acceptability and usability. Unlike many studies with smaller sample sizes, our inclusive methodology underscored the importance of involving end users throughout the development process. However, engagement remains a challenge, with only 18.8% (59/314) of the users continuing to engage with the platform after the first day. Future work must enhance the initial user experience and consider differences in age, sex, region, and socioeconomic background to improve long-term engagement.

Despite the promising results, a significant limitation was the lack of collaboration with industry partners, which could provide valuable resources and expertise in user-centered design and technology development. Partnerships could improve data collection methods, address challenges of sustainability and scalability, and integrate rigorous evidence-based methods with engaging design features. While the platform was well received, implementing it in the Colombian context presents challenges, such as legal requirements for parental consent, which can deter young people from seeking help. Further research and adaptations are needed to tailor the platform to the unique characteristics and MH needs of diverse Colombian communities, ensuring it effectively supports early detection and intervention.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

LO-P, JAO, and CG-R contributed to conceptualization. LOP contributed to supervision. MNS-N, DLS-R, MIR-F, and AM contributed to data collection. MNS-N, DLS-R, AM, MIR-F, and ACB-T contributed to data curation. LO-P, MNS-N, DLS-R, MIR-F, AM, and ACB-T contributed to formal analysis. LO-P contributed to the methodology. DLS-R and MIR-F contributed to validation. LO-P, DLS-R, AM, MNS-N, ACB-T, and LCG-S contributed to writing the original draft. JAO, IBH, CG-R, MIR-F, MNS-N, AP-Q, JAP-M, AN-M, and LCG-S contributed to reviewing and editing the manuscript. AP-Q and JAP-M led the platform development. JAO and LOP contributed to funding acquisition, and CG-R to resources. All authors read and agreed to the published version of the manuscript.

Conflicts of Interest

JAO is the head of systems modeling and simulation and codirector of the Mental Wealth Initiative at the University of Sydney's Brain and Mind Centre (BMC). She is also the managing director of Computer Simulation and Advanced Research Technologies (CSART) and acts as an advisor to the Brain Capital Alliance. IBH is the codirector, health and policy at the BMC, University of Sydney. The BMC operates early-intervention youth services at Camperdown under contract to Headspace. He is the chief scientific advisor to, and a 3.2% equity shareholder in, Innowell Pty Ltd, which aims to transform mental health services through the use of innovative technologies. All other authors declare no conflicts of interest.

Abstract

Background: Anxiety and depression symptoms have been rising among college students, with many increasingly meeting the criteria for 1 or more mental health problems. Due to a rise in internet access and lockdown restrictions associated with the COVID-19 pandemic, online mediums, such as teletherapy, repositories for mental health information, discussion forums, self-help programs, and online screening tools, have become more popular and used by college students to support their mental health. However, there is limited information about individual-level factors that lead college students to use these online tools to support their mental health.

Objective: This mixed methods study aimed to examine the associations between demographics, symptom severity, mental health literacy, stigma, attitudes, and self-efficacy and the use of online tools to seek psychological information and services among racially and ethnically diverse college students. This study also aimed to qualitatively characterize types of online tools used, reasons for using tools or lack thereof, and perceived helpfulness of tools.

Methods: Undergraduate students (N=123) completed validated measures and provided open-ended descriptions of the types of online tools they used to seek psychological information and services and their reasons for using those tools. Logistic regression analyses were used to test associations of online tool use to seek mental health information and hypothesized predictors. Descriptive statistics were conducted to examine online tool types, reasons for using online tools, and helpfulness explanations.

Results: In total, 49.6% (61/123) of the participants used online tools (eg, search engines) to seek mental health information, while 30.1% (37/123) used online tools (eg, medical websites) to seek mental health services. Mental health literacy (P=.002; odds ratio 1.14, 95% CI 1.05-1.24) was associated with greater use of online tools to seek mental health information. None of the hypothesized variables predicted online tool use to seek mental health services. In total, 82% (50/61) of participants who sought information found online tools somewhat helpful, while 49% (18/37) of participants who sought services found online tools very helpful. Of the students who did not use online tools to seek information, 19% (12/62) reported it was because they did not know which online tools to use and 31% (19/62) stated they would be encouraged to use online tools if it was recommended by professionals, therapists, family, or friends. Of the students who did not use online tools to seek services, 33% (28/86) reported it was because they did not think mental health help was necessary.

Conclusions: These findings highlight the use of online tools to provide mental health information and connect to professional services, suggesting that online tools are widely used to access mental health support.

Introduction

Mental Health Prevalence and Service Use

Due to an increase in the prevalence of mental disorders among college students over the past decade, exploring and addressing mental health concerns has become highly necessary. In 2024, approximately 70% of college students reported mild to severe depression or anxiety, which is a substantial increase in depression and anxiety symptoms since 2013 [1,2]. College students have reported that mental health problems affected their academic success, with depression symptoms predicting their grade point average and likelihood of dropping out, further highlighting the need to increase access to and use of effective mental health treatments among this population [3,4]. While past-treatment use for mental health problems has increased among college students, young people (aged 18-25 years) have the lowest rates of mental care use among the adult population [1,2,5]. Furthermore, racial or ethnic minority (eg, Black, multiracial, and Arab American) college students have lower rates of mental health care use, including psychological and pharmacological treatment, compared to non-Hispanic White college students, resulting in a need to examine novel tools that can increase mental health service use rates and potentially offset barriers to care for racial or ethnic minority college students [2].

Digital Help-Seeking Behaviors

One way to increase mental health service use rates is to improve help-seeking behaviors, which refers to the act of seeking out and using formal sources (eg, clinical psychologist), semiformal sources (eg, teachers and clergy), informal sources (eg, friends and family), and self-help (eg, unguided website use) sources to address mental health problems [6]. Due to a rise in internet access and lockdown restrictions associated with the COVID-19 pandemic worldwide, online mediums such as virtual counseling and therapy services, repositories for mental health information and resources, discussion forums, self-help programs, and online screening tools have become more popular among college students to support their mental health [7,8]. Global initiatives (eg, World Mental Health International College Student initiative) have prioritized focusing on research that leverages digital mental health interventions to support young peoples' mental health, further demonstrating the potential of digital technologies and online resources to increase service use among college students and potentially address inequities in care access [9,10]. Despite the increased use and research prioritization of online resources to support college students' mental health, there is limited information about individual-level factors that lead college students to use online tools for mental health support. In addition, there is little research examining why college students might opt out of using online tools for mental health support.

Predictors of Digital Tool Use

Past Therapy and Symptom Severity

Research shows that young adults who had previously used formal counseling services started to use those services digitally during the COVID-19 pandemic to support their mental health as they transitioned to online spaces [8]. Positive past experiences with mental health services were associated with greater engagement in digital mental health interventions [11]. Furthermore, a systematic review found that globally, students who had received a mental health diagnosis in the past and wanted to monitor their mental status were more likely to use online mediums compared to those without a diagnosis [7]. Even among students without a mental health diagnosis, being curious about their symptoms or having severe symptoms increased students' likelihood of using online tools, such as educational materials, self-help interventions, screening tools, and online therapies delivered by professionals, for their mental health [7,12,13].

Stigma and Attitudes

Worldwide, stigma is a well-documented barrier to traditional mental health help seeking, often deterring individuals from pursuing care due to concerns about disclosure and social judgment [14]. However, the anonymity, immediacy, and confidentiality of online platforms may reduce concerns about disclosure and social stigma, possibly making them a more accessible option for help seeking [14]. Unlike traditional help seeking, research suggests that stigma does not significantly impact the use of online self-help resources [15]. Similarly, negative attitudes toward mental health or external influences from others do not appear to deter online help-seeking intentions among young people [16,17]. Nevertheless, more research is needed to understand why these factors may not have a strong influence on online help-seeking behaviors.

Mental Health Literacy and Self-Efficacy

Despite the accessibility and anonymity of online tools, barriers such as low mental health literacy continue to limit their use among college students [7,14]. Students with limited mental health literacy may lack the knowledge needed to recognize their symptoms and identify available services. Without this essential knowledge, students may struggle to initiate the online search process, including identifying relevant keywords or finding evidence-based mental health resources and tools online. Another barrier to using online tools may be due to students' self-efficacy [18]. While studies worldwide have explored self-efficacy as a predictor of traditional help-seeking behaviors within this population, research examining the role of self-efficacy in online tool use remains limited [19]. Further investigation is needed to better understand this relationship.

Race or Ethnicity, Gender, Age, and Non–US Born Status

It is possible that there are disparities in the use of online tools based on college students' demographics. One study found that racial and ethnic minority students expressed more interest in teletherapy and online self-help guided mental health support when they were free compared to non-Hispanic White students, but their interest declined when a cost was involved [16]. However, another study found that racial and ethnic minority students were just as likely as their non-Hispanic White counterparts to enroll in and initiate teletherapy [20]. There are also mixed results on the association between gender and use of online tools for mental health, with some studies reporting

XSL•FO
RenderX

no gender differences and others reporting that women are more likely to use online tools than men [7,20,21]. In terms of age, younger adults are more likely to use smartphone apps for their mental health or well-being compared to older adults [22]. Finally, while non–US born immigrants are more reluctant to partake in traditional mental health help-seeking behaviors due to stigma and language barriers, research exploring the relationship between non–US born status and digital help-seeking behavior is limited [23]. For immigrants and refugees, digital tools may still impose barriers to help seeking due to limited language services and the cultural appropriateness of content [24]. These mixed and limited findings highlight the need to explore disparities in the use of digital mental health tools among students from diverse racial and ethnic, gender, and non–US backgrounds.

Objectives of the Study

The relationship between individual-level factors such as symptom severity, stigma, mental health literacy, and online tool use among university students still needs to be further explored to better understand how digital tools can be leveraged to promote mental health equity among college students [21,24]. Consequently, we first examined the association between race and ethnicity, non–US born status, gender, symptom severity, mental health literacy, stigma, self-efficacy, and attitudes toward mental health treatment and the use of online tools for mental health. Then, we identified themes related to factors influencing online tool use and perceptions of the helpfulness of online tools by exploring the types of online tools used, reasons for using or not using online tools, helpfulness of online tools, and motivators for using online tools in the future.

Hypotheses of the Study

This study had four primary hypotheses: (1) we hypothesized that racial and ethnic minority and non–US born students would be more likely to use online tools to seek help due to digital tools addressing stigma-related barriers hindering traditional help seeking among these students [14,25,26]; (2) we also hypothesized that younger students and women would be more likely to use online tools due to existing research showcasing that they are more likely to use online mental health tools, such as smartphone apps, discussion forums, and internet searches [21,22]; (3) we hypothesized that more severe symptoms of depression, anxiety, and trauma would each be independently associated with a greater likelihood of using online tools to seek help as well because symptom severity predicts students' use of different online mental health resources [7,12]; (4) finally, we hypothesized that lower mental health stigma, higher mental health literacy, greater self-efficacy, and more positive attitudes toward help seeking would each be independently associated with a greater likelihood of using online tools for mental health support, as these factors predict traditional help-seeking behaviors [14,18,19,25].

Methods

Study Design and Sample

This study is a cross-sectional mixed methods analysis derived from a larger study examining the use of direct-to-consumer strategies to increase initial engagement in mental health services. Participants (N=123) were recruited through the University of California, Los Angeles (UCLA) Psychology Subject Pool, a university system that allows researchers to recruit participants for research studies, from May 2021 to December 2021. Data collection occurred during the COVID-19 pandemic, during which there were lockdown restrictions in the United States, such as school and nonessential business closures, large gathering bans, and stay-at-home orders [27]. The study was designed to be completed entirely online. The UCLA Psychology Subject Pool system was used to post study advertisements with the inclusion criteria and allow participants to sign up for the study on a secure online platform. The inclusion criteria included undergraduate students at UCLA who were interested in seeking mental health services, were aged at least 18 years, and had corrected to normal vision. The participants represent UCLA's student body, which is racially and ethnically diverse, with approximately 75% of the undergraduate population reporting a racial or ethnic minority identity [28]. In addition, around 15% of the student population at UCLA has indicated the need to use mental health services in the past [29].

Ethics Approval

All study procedures were approved by the UCLA Institutional Review Board (IRB#20-002082). After signing up for the study on the UCLA Psychology Subject Pool system, participants met with an undergraduate-level research assistant through Health Insurance Portability and Accountability Act–compliant Zoom (Zoom Communications, Inc) video call to discuss consent procedures. Only after consenting to participate in the study were participants allowed to complete a series of surveys. Students received 1 course credit for their participation in completing the surveys. Collected data were deidentified and securely stored. Only authorized personnel had access to the data.

Measures

Demographic Form

Participants completed a 14-item self-reported demographic form. Demographic variables included age, gender, assigned sex at birth, race, ethnicity, place of birth, total household income during childhood, and past experiences with medication and the use of therapy or counseling for mental health treatment. Race or ethnicity were categorized as racial and ethnic minorities and White for our sample. Middle Eastern was categorized as a racial or ethnic minority, alongside Asian, Latinx, Black or African American, and multiracial. This categorization aligns with research findings indicating that the designation of "White" does not correspond to Middle Easterners' lived experiences or others' perceptions of them [30]. One participant did not report their race or ethnicity, resulting in 1 missing value for the race or ethnicity demographic variable.

Patient Health Questionnaire-9

The Patient Health Questionnaire-9 comprises 9 questions designed to detect the 9 diagnostic criteria for major depressive disorder according to the *Diagnostic and Statistical Manual of Mental Disorders, 4th Edition* [31]. Responses to these questions

XSL•FO
RenderX

were measured on a 4-point scale from 0 to 3, where 0 indicated "never" and 3 represented "nearly every day." To comply with the institutional review board requirements, item 9, which assesses suicidality, was removed. The total score was calculated by combining reported values from all 8 questions. In this sample, reliability was fairly high (α=.88) [32]. There were no missing data for this variable.

General Anxiety Disorder-7

The General Anxiety Disorder-7 questionnaire consists of 7 questions used to measure each 1 of the 7 core symptoms of generalized anxiety disorder [33]. Responses to these questions were measured using a 4-point scale from 0 to 3, where 0 indicated "never" and 3 represented "nearly every day." The total score was calculated by combining reported values from all 7 questions. In this sample, reliability was fairly high (α=.90) [32]. There were no missing data for this variable.

PTSD Checklist for DSM-5

The PTSD Checklist for the DSM-5 comprises 20 questions, each designed to measure 1 of the 20 corresponding posttraumatic stress disorder (PTSD) symptom criteria outlined in the DSM-5 [34]. Responses for these questions were measured using a 4-point scale from 0 to 3, with 0 indicating "not at all" and 4 referring to "extremely" in terms of how bothered the individual feels by the given PTSD symptom over the past month. The total score was calculated, combining reported values from all 20 questions. In this sample, reliability was deemed fairly high (α=.95) [32]. There were no missing data for this variable.

Mental Health Literacy Scale

The mental health literacy scale consists of 31 questions used to measure the mental health literacy of individuals [35]. The first 15 items were measured using a 4-point scale from 0 to 3, with 0 indicating "very unlikely" or "very unhelpful" and 3 referring to "very likely" or "very helpful." The rest of the questions were scored on a 5-point scale from 0 to 4, with 0 indicating "strongly disagree" and 4 indicating "strongly agree." The total score was calculated by combining reported values from all 31 questions. Our sample indicated fairly high reliability (α=.82) [32]. This scale was incorporated into the original study at a later stage, resulting in missing data for 29% (36/123) of the participants who did not receive this measure.

Internalized Stigma of Mental Illness Scale-10

The Internalized Stigma of Mental Illness-10 scale comprises 10 questions designed to measure the extent of internalized stigma among individuals with psychiatric disorders; responses are rated on a 4-point Likert scale, ranging from 1 (strongly disagree) to 4 (strongly agree) [36]. The total score was calculated by combining reported values for the 10 questions. Our sample had high reliability (α=.74) [32]. There were no missing data for this variable.

Attitudes Toward Mental Health Treatment Scale

The Attitudes Toward Mental Health Treatment Scale consists of 20 questions and is used to assess internalized stigma and attitudes and behaviors related to seeking mental health treatment [37]. Responses to these questions were measured using a 4-point Likert scale, where participants ranked their level of agreement with statements about mental health treatment, with 1 indicating "strongly disagree" and 4 representing "strongly agree". The total score was calculated by combining reported values from all 20 questions. Our sample also indicated fairly high reliability (α=.78) [32]. There were no missing data for this variable.

Self-Efficacy in Seeking Mental Health Care Scale

The Self-Efficacy in Seeking Mental Health Care Scale consists of 9 questions used to measure self-efficacy for mental health care by assessing 2 subscales: confidence in knowledge and confidence in coping [38]. Responses to these questions were measured using a Likert response scale ranging from 1 to 10, where 1 represents no confidence and 10 indicates complete confidence in the individual's ability to conduct a given behavior. For this study, only the total score was calculated by combining reported values from all 9 questions. Finally, our sample had fairly high reliability (α=.89) [32]. There were no missing data for this variable.

Online Tool Use

Questions from the California Health Interview Survey were used to assess online tool use [39]. Participants were asked 2 dichotomous (ie, yes or no) questions: "Have you used an online tool (eg, mobile apps, texting services, webpages, or forums) to learn about problems with your mental health, emotions, nerves, or your use of alcohol/drugs?" and "Have you used online tools (eg, mobile apps, texting services, or webpages) to find, be referred to, contact, or connect with a mental health professional/service?" In addition, participants were asked to rate the helpfulness of the online tools, with response options being very helpful, somewhat helpful, or not at all helpful. There were no missing data for these variables.

To obtain more detailed information about online tool use, participants who responded "yes" were asked to provide open-ended descriptions of the type of online tools used, reasons for their use, and why they were helpful. Those who responded "no" were asked to share open-ended descriptions of reasons for not using online tools and the motivators that would encourage them to use such tools for learning about mental health problems or connecting with mental health services. Open-ended responses varied in length, with some participants providing brief 3- to 4-word answers, while others offered more detailed responses consisting of a few sentences.

Statistical Analyses

Mixed Methods Design

A Qual+QUAN mixed methods design was used to analyze the data [40]. This design incorporated simultaneous collection and analysis of both quantitative and qualitative data for confirmation and hypothesis testing. Quantitative data analysis was the primary method, examining a priori constructs that could impact online tool use. The qualitative data expanded upon the quantitative findings, such that it provided a deeper understanding of the relationship between a priori constructs and online tool use. Specifically, the qualitative analysis aimed to identify themes related to factors influencing online tool use

XSL•FO
RenderX

and perceptions of their helpfulness by exploring the types of online tools participants used and the reasons behind their use.

Quantitative Analysis

To analyze sample characteristics, descriptive analysis was conducted using jamovi (version 2.3; the jamovi project [41]). In addition, associations between student-level factors and the use of online tools for mental health were examined using multiple logistic regressions. These regressions assessed the relationship between demographics, symptom severity, mental health literacy, stigma, attitudes toward mental health treatment, self-efficacy, and engagement with online tools for seeking mental health information and professional services. Finally, due to previous research showcasing past therapy use as one of the few consistent predictors of online tool use for mental health, we controlled for past therapy use for the regression analyses [7,8,11].

Qualitative Analysis

Qualitative data underwent an inductive ("bottom-up") approach, creating codes based directly on the participants' open-ended text responses without applying a preexisting theoretical framework or a priori codes [42]. The first author familiarized themselves with the data, taking notes and highlighting important points. Using 20% of the data, initial codes were generated based on emerging concepts, such as reasons for using or not using online tools. These codes were categorized based on how responses were related (eg, "gave me helpful techniques to calm myself down" and "it taught me how to breathe in stressful situations" were combined into the code "coping mechanisms") and refined iteratively by the first and second authors in weekly coding meetings throughout March 2023. Definitions were developed for each code and category, which were then grouped into themes to create a final codebook. The final codebook consisted of a label, definitions, and exemplar statements derived from the data. The first author then coded the open-ended responses based on the final codebook. Coding decisions were reviewed during consensus meetings held with the second author, which is an approach commonly used to address coding biases and ensure coding reliability [43]. Open-ended responses that were not consistent with the codebook definitions were also discussed during consensus meetings. When responses were too vague (eg, "online resource" and "I don't know"), it was decided to categorize those statements as "vague" rather than forcing them into previously established categories in the final codebook. After coding all the responses, the codes and categories were interpreted at the theme level. Thematic analysis allowed us to identify overarching patterns within the data to better understand factors influencing online tool use and perceptions of the helpfulness of online tools.

Results

Sample Characteristics

A total of 123 participants completed the survey and were aged on average 21 (SD 3.39) years. The majority self-identified as women (104/123, 84.6%) and belonged to racial or ethnic minority groups (98/123, 79.7%). Racial or ethnic minority participants were primarily Asian (47/123, 38.2%) followed by Middle Eastern (19/123, 15.4%), Latinx (16/123, 13%), multiracial (11/123, 9%), and Black or African American (5/123, 4.1%). Furthermore, a substantial proportion of participants were born outside the United States (32/123, 26%) and spoke non-English languages at home (55/123, 44.7%). Finally, more than half (65/123, 52.8%) of the participants had received therapy or counseling for a mental health condition in the past, but a majority (90/123, 73.2%) had not taken medication for a mental health condition in the past. Refer to Table 1 for more demographic information.

Using the symptom checklist cutoffs for the Patient Health Questionnaire-9, General Anxiety Disorder-7, and PTSD Checklist for the DSM-5, participants on average reported mild depression (mean 8.16, SD 5.74) and mild anxiety (mean 7.06, SD 5.60) and did not meet criteria for a probable PTSD diagnosis (mean 20.6, SD 18.0). The mean mental health literacy score was 117 (SD 9.14), indicating high mental health literacy. The mean score for internalized mental illness stigma was 13.2 (SD 7.33), suggesting low stigma. The mean score for attitudes toward mental health treatment was 57.4 (SD 6.48), indicating more positive attitudes toward mental health. The mean score for self-efficacy in seeking mental health care was 64.2 (SD 15.1), suggesting high self-efficacy.

[a]Missing value for 1 participant (n=122).

[b]Breakdown of ethnicities for the category racial and ethnic minority (n=98).

Quantitative Results

In total, 49.6% (61/123) of the participants used online tools to seek mental health information, while 30.1% (37/123) used online tools to find, be referred to, contact, or connect with a mental health professional or service.

Predictors of Online Tool Use to Seek Mental Health Information

The multiple logistic regression model was not statistically significant for online information seeking (N=86, χ^2_{12}=19.2; *P*=.08). Age, gender, race and ethnicity, non–US born status, past therapy use, symptom severity, stigma, self-efficacy, and attitudes toward mental health treatment did not predict online information seeking. However, mental health literacy was associated with an increase in the likelihood of online information seeking, such that odds of online tool use to seek mental health information increased by 14% for every additional increase in mental health literacy (odds ratio 1.14, 95% CI 1.05-1.24).

Predictors of Online Tool Use to Seek Mental Health Services

The multiple logistic regression model was not statistically significant for seeking mental health services online (N=86, χ^2_{12}=20.4; *P*=.06). None of the hypothesized predictors were associated with online help-seeking behaviors (Table 2).

XSL•FO
RenderX

Qualitative Results

Types of Online Tools Used

Qualitative results indicated that participants used search engines, medical websites (eg, BetterHelp and Psychology Today), informational websites, apps (eg, MindDoc, LiveHealth, and Calm), and university-affiliated tools to seek mental health information and connect to services. Refer to Table 3 for a summary of qualitative responses.

XSL•FO
RenderX

Table 3. Summary of qualitative responses on types of online tools used for seeking mental health information and connecting with professional services (N=123).

Tool type codes	Definition	Seek mental health information[a] (n =61), n (%)	Connect with professional services[b] (n =37), n (%)
Search engines	Tools that carry out web searches to identify websites that correspond to given keywords	20 (48)	3 (8)
Medical websites	Websites with information related to mental health diagnosis, symptoms, or professional services	12 (20)	11 (30)
Informational websites	Websites that provide general background information and research on mental health disorders and coping mechanisms or exercises	6 (10)	2 (5)
Apps	Downloadable apps that can be used for mental health information, services, or resources	5 (8)	4 (11)
Discussion forums	Internet forums or message boards where an individual can post about issues or reply to other individual's posts that they may find relatable	4 (7)	—[c]
Social media	Apps that can be used to share content	1 (2)	—
University-affiliated tools	Tools created by universities to provide mental health services or information to students	1 (2)	9 (24)
Call, video, and SMS text messaging	Platforms that can be used to connect with family, friends, or professionals through voice, video, or messages	—	4 (11)
Insurance	Tools created by insurance companies to be used for insurance-covered services and information	—	3 (8)
Vague statements	Statements that are too vague to code under a given category	3 (5)	1 (3)

[a]Codes endorsed for seeking mental health information online.

[b]Codes endorsed for connecting with professional mental health services online.

[c]Not applicable.

Reasons for Using Online Tools

Qualitative findings yielded 3 themes related to the reasons why participants used online tools. Participants used online tools because they (1) sought psychoeducation; (2) recognized a mental health need; and (3) perceived online tools as beneficial due to increased accessibility, usability, and availability of support.

A primary reason participants used online tools was to increase their knowledge and to access psychoeducation about mental health. Online tools, such as discussion forums and social media, were frequently used for seeking mental health information, including gaining a better understanding of their own mental illness (eg, understanding PTSD and anxiety symptoms) and due to having a general interest in mental health topics. For example, participants stated that they wanted to "better understand PTSD and ways to cope with anxiety" and to learn more about their "symptoms at the time and to see if they can explain any other bodily functions (ie, pain or aches, inconsistent menstruation cycles, and headaches)." Participants also used online tools to learn about coping skills that they could use to manage their mental health concerns. Participants reported wanting to learn about a variety of coping skills, such as exercise, sleep, nutrition (eg, "vitamin intake"), and "emotion regulation and meditation skills."

Another reason participants used online tools to seek mental health information and connect with a mental health service was due to perceived need concerns, such as recognizing a mental health need and noticing that their symptoms were becoming more severe. For example, a participant reported, "I had been having anxiety that led to a panic attack and decided I needed to seek help in managing my anxiety," while another mentioned that "I was having depersonalization panic attacks and did not understand what was happening to me." Participants also used online tools, such as voice, video, and messaging tools, along with tools created by insurance companies, to connect with mental health services. Participants reported actively seeking help, expressing their intent to "find a therapist" and choosing online platforms because they "knew this is where" they "could find a mental health professional." Participants stated that these online tools were often "recommended by someone trusted," such as friends or family, who were aware of the participants' mental health needs.

Participants also used online tools to find mental health information and connect with services because they found them beneficial. Many participants cited accessibility as a key factor, noting that they often could not find other traditional support and resources in a timely manner and instead turned to online tools because "it was fast, easy, and free." Other participants highlighted usability as a key factor, describing online tools as convenient and intuitive, with a participant stating, "It's convenient and I don't need to ask someone else" and another expressing, "It's quick and easy, and I can look for any information and get different input." In addition, some participants used online tools to connect with others who shared similar mental health experiences, seeking a sense of community and emotional support "to feel less alone." Refer to Table 4 for summary of themes and codes related to reasons for using online tools.

XSL•FO
RenderX

Table 4. Summary of qualitative themes and codes related to reasons for using online tools and perceived helpfulness (N=123).

Theme and code	Definition	Seek mental health information[a] (n =61), n (%)	Connect with professional services[b] (n =37), n (%)
Reasons for using online tools			
Sought psychoeducation			
Knowledge about personal symptoms	Wanting to learn more about mental health disorders and their symptoms	19 (31)	—[c]
Generalized interest	Had a generalized interest in learning more about mental health	10 (16)	—
Coping skills	Searching for techniques, strategies, or exercises to help cope with mental health issues or boost self-efficacy	9 (15)	—
Perceived benefits: accessibility, usability, and availability of support			
Accessibility	Increased access to mental health services, information, or resources and usability	8 (13)	9 (24)
Lack of availability	Other resources being unavailable	1 (2)	1 (3)
Connecting with community	Wanting to connect with others with similar mental health issues, wanting to not feel alone, or searching for a sense of community	4 (7)	—
Perceived need			
Symptom severity	Feeling a heightened personal struggle with mental health, elevated symptoms, or using tools as a last resort	6 (10)	6 (16)
Testimonial	Receiving a recommendation to use an online tool from another individual	1 (2)	2 (5)
Help-seeking behaviors	Vague statements wanting to generally seek help from professionals or services	1 (2)	17 (46)
Vague statements	Statements were too vague to code under a given category	2 (3)	2 (5)
Helpfulness of online tools			
Provided valuable psychoeducation			
General information	Provided broad information about mental health	18 (31)	3 (9)
Knowledge from personal experience	Provided information about mental health disorders and their symptoms, so the individual was able to better understand	16 (27)	—
Coping mechanisms	Provided techniques, strategies, or exercises to help cope with mental health issues	11 (19)	—
Normalizing mental health	Normalized mental health disorders, symptoms, and treatments and boosted the individual's confidence in their ability to improve mental health	3 (5)	—
Confirmed previous knowledge	Provided information that confirmed what they already knew about mental health issues	1 (2)	—
Help-seeking behaviors	Provided resources to seek help through a professional or service	1 (2)	15 (44)
Attainable and convenient support			
Accessibility	Provided resources or services in an easily accessible manner	1 (2)	8 (24)
Specialty filter	Provided a tool to filter through website content to cater it to individuals' needs	—	2 (6)
Delayed care	Eventually provided connection to care but had some challenges and barriers	—	3 (9)
Connections with community	Provided a connection to others with similar mental health issues or made the individual feel less alone	5 (9)	—
Vague statements	Statements that are too vague to code under a given category	3 (5)	3 (9)

Helpfulness of Online Tools

Most participants reported that the online tools they used to seek mental health information were somewhat (50/61, 82%) and very (9/61, 15%) helpful. Online tools used to connect to services were also reported to be somewhat (16/37, 43%) and very (18/37, 49%) helpful.

Qualitative findings yielded 2 themes related to the reasons why participants found online tools helpful. Online tools were perceived as helpful because they (1) provided valuable psychoeducation and (2) made obtaining support more attainable and convenient.

Students found online tools to be helpful because they provided information about symptoms of mental health disorders (eg, anxiety, depression, and panic attacks), coping mechanisms (eg, techniques to calm down), general mental health facts (eg, "Provided me with more information than I originally had"), and ways to seek help (eg, resources on using university counseling and psychological services). For example, a participant reported that online tools "allowed me to have more understanding of myself before seeking treatment" and "they helped me realize that these feelings were symptoms of anxiety and depression." Given that psychoeducation was the primary reason for both using online tools and finding them helpful, this indicates that most participants who used online tools were able to find the information they were initially searching for. Some participants expressed that online tools were also helpful because the psychoeducation normalized mental health (eg, "They helped normalize my behavior and gave me the confidence to make progress with my CBT") and confirmed previous knowledge they had about mental health (eg, "Didn't tell me new information, just confirmed what I already had expected").

Participants expressed that online tools were helpful because they made obtaining support more attainable and convenient, with a participant mentioning, "It was a lot easier to schedule a time," and other participants stating, "it gave me support when I needed it." Participants also expressed that online tools were easy to use, with a participant explaining, "The site was extraordinarily simple to use." Certain features, such as specialty filters, made support more attainable, with a participant stating, "I was able to specify my search via provider specialty and modality." However, a couple of participants experienced delays in accessing care, as a participant mentioned, "It took so long to go through the list, but I eventually found someone." In addition, online tools made it easier to connect to others who were dealing with similar feelings or symptoms, resulting in participants feeling less alone. For example, a participant shared, "It is nice to know that others feel the same way that you do and that you can feel more normal because of it." On the basis of these responses, participants who had aimed to connect to community and mental health services using the online tools found that they were able to effectively do so. Refer Table 4 for themes and codes related to online tool helpfulness.

Reasons for Not Using Online Tools

In total, 50.4% (62/123) of the participants reported that they did not use online tools to seek mental health information, and 69.9% (86/123) of the participants reported that they did not use online tools to connect with professional mental health services.

Qualitative findings yielded 3 themes related to why students did not use online tools. Participants did not use online tools due to (1) a lack of awareness about existing online tools, (2) negative attitudes toward online tools, and (3) a lack of perceived need.

Many participants refrained from using online tools to seek mental health information or connect with services because they did not know they existed. Participants reported a lack of awareness about suitable platforms, with some explaining they "have not seen them" or "didn't know of any" online tools for mental health information or connecting to services.

For participants who were aware of online tools, they expressed not using online tools because they did not "trust them" and because they believed that online tools were "not personalized or accurate." Along with finding online tools unreliable or unhelpful, some participants disclosed a preference for traditional help, such as already having a "personal therapist" or receiving in-person referrals from trusted individuals (eg, primary care providers, family, and friends).

Another commonly reported reason for not using online tools to find mental health information or connect to services was due to a lack of perceived need, as participants reported that mental health help was unnecessary or that they were not dealing with severe symptoms. For example, participants stated, "I don't believe that I have needed to connect with a professional/service" and "I don't think it has reached a point for me where I need to seek professional help." Others expressed avoidance and self-reliance tendencies, explaining that they did not "put much thought into learning about mental health" or "how to feel better," and that "I tend to deal with any problems I have by myself." Refer to Table 5 for a summary of themes and codes explaining why online tools were not used.

XSL•FO
RenderX

Table 5. Summary of themes and codes explaining why online tools were not used to seek mental health information and connect with professional services, as well as factors motivating increased use (N=123).

Theme and code	Definition	Seek mental health information (n =62), n (%)	Connect with professional services (n = 86), n (%)
Reasons for the lack of use			
Lack of awareness			
Lack of awareness	Reasoning related to not knowing tools existed or which tools to use	12 (19)	10 (12)
Attitudes toward online tools			
Unreliable	Reasoning related to not finding tools to be reliable or trustworthy	8 (13)	2 (2)
Inaccessible and unhelpful	Reasoning related to ease of tool use or believing the tools would not be helpful	5 (8)	4 (5)
Traditional help preference	Reasoning related to preferring to talk to a professional or trusting a professional more	10 (16)	19 (23)
Lack of perceived need			
Mental health help is unnecessary	Reasoning related to broadly believing mental health help or services to be unneeded, so no online tool was used	11 (18)	28 (34)
Low symptom severity	Reasoning related to not experiencing mental illness or any problems with mental health	10 (16)	10 (12)
Avoidance	Reasoning related to not wanting to resurface negative feelings or deal with problems	2 (3)	—[a]
Self-reliance	Reasoning related to dealing with mental issues by themselves or on their own	1 (2)	1 (1)
Vague statements	Statements that are too vague to code under a given category	3 (5)	9 (11)
Motivating factors			
Reliability			
Recommendation	Suggestions related to referral from friends, family, or professionals; support and encouragement; and positive reviews and testimonials	19 (31)	19 (22)
Trustworthiness	Suggestions related to reliability and confidentiality	4 (7)	4 (5)
Accessibility, availability, and usability of support			
Specific features	Suggestions related to specific website and app features, technological services, personalization, and usability	10 (16)	7 (8)
Accessibility	Suggestions related to finances, time, and other aspects of increased accessibility	6 (10)	10 (12)
Awareness	Suggestions related to advertising or promoting awareness	4 (7)	8 (9)
Perceived need			
Symptom severity	Suggestions related to an increase in negative symptoms or behaviors or an increase in negative impact on everyday life	6 (10)	13 (15)
Help seeking	Suggestions related to broadly wanting to seek help	2 (3)	3 (4)
Personal preferences			
No motivators	Includes reasoning related to individuals currently in therapy or services	4 (7)	8 (9)
Vague statements	Statements that are too vague to be coded under a given category	6 (10)	14 (16)

Motivators for Using Online Tools in the Future

Of participants who reported not using online tools, a majority expressed motivation to use online tools to seek mental health information (58/62, 94%) or connect with services (78/86, 91%).

Among those who did not use online tools, 3 key factors emerged as potential motivators for future use. Participants expressed they would be motivated to use online tools for their mental health in the future if (1) they perceived a mental health need, (2) they trusted that the tools were reliable, and (3) the tools were accessible and easy to use.

Participants expressed that they would be motivated to use online tools if they found their symptoms to be severe or if their symptoms started to impact their functioning. For example, students stated that they would use online tools "If stress/depressed state impacted my other responsibilities and friends/family" and "if my anxiety keeps getting worse after the school year ends."

Participants expressed that recommendations from trusted individuals, such as "a professional," "family or friends," or a "therapist," would motivate them to use online tools, as recommendations would indicate that the online tool was reliable and trustworthy. One participant stated they would use an online tool "if I heard a good review from people I know," while another added, "if a professional gave me some to use." Other participants noted encouragement from others would also increase the likelihood of using online tools to seek help, such as "knowing that it's encouraged to reach out for help may make me feel more inclined to reach out if I found myself in the position."

Regarding accessibility, participants reported that they would be open to using online tools if they were "free" or "not expensive" and if the online tools used "easy to understand language" and provided "easily accessible information." Many participants also emphasized that raising awareness of the online tools would improve their accessibility, stating "awareness of their existence and that they have proven to be effective" and "more advertisement" as key motivators. Finally, students suggested that specific features improving the usability of the online tool, such as "video chats, scheduled appointments, surveys," or "a comprehensive search filter on the app so you can find the best therapist for your needs" would make them more willing to use the online tool in the future. They also emphasized that the online tool should have "no association to emails, names, or locations" to improve usability. Refer to Table 5 for additional motivating factors that would encourage the use of online tools for mental health.

Discussion

Principal Findings and Comparison to Previous Work

Due to the high prevalence of mental health problems, low use of mental health services among university students, and the rise of the internet, there has been an increase in online tools available for mental health, including online tools to reach and connect youth to mental health services [2,5]. However, the availability of digital tools for mental health has not translated to widespread use [44]. Our study found that about half of the participants (61/123, 49.6%) used online tools to seek mental health information, and only a third (37/123, 30.1%) used online tools to connect with mental health professionals or services. Regarding the types of online tools used, our findings are consistent with previous reports stating that a high proportion of young people use search engines to locate mental health resources, with smaller percentages using platforms such as discussion forums and mental health apps [8]. Our study also found much lower rates of using these online tools to actively seek professional mental health help, in comparison to mental health information [8].

We found that students who had higher mental health literacy were more likely to use online tools to seek information but not professional help. This might suggest that students with more knowledge on mental illness, such as the ability to recognize and label their symptoms or attribute them to mental health rather than other causes, may be better equipped to seek help online. For example, students with higher mental health literacy may know what specific key terms to use to search for relevant information. In addition, those knowledgeable about coping skills (eg, relaxation skills for anxiety) may be more likely to use online tools to find more information on how to practice these skills. Although higher mental health literacy is associated with increased intentions to seek help, it might not translate to actual service use [45]. Considering the cross-sectional nature of our study, it is also possible that greater use of online tools may improve the mental health literacy of students by increasing exposure to online information. The lack of association between mental health literacy and the use of online tools to connect with professional services may be due to individuals interpreting online psychoeducational resources and coping strategies as sufficient, leading them to conclude that their symptoms did not require professional care [44,46]. This may also reflect students' perception of digital mental health tools as either a more accessible alternative to traditional services or as a complement to conventional care [7].

Our study found that mental health symptoms, including depression, anxiety, and trauma symptoms, did not predict online tool use. Past research has found mixed findings on this association, with 1 study finding anxiety symptoms to predict app use, while depression did not [12]. It is possible that we did not find this association because participants were asked about overall online tool use and not specific online tools, such as apps. Moreover, students may be using different types of online tools available (eg, websites, apps, and smart devices) depending on different symptom-related concerns. For example, some individuals may prefer using websites rather than an app for information seeking and psychoeducation on symptoms, while others may prefer self-help apps that provide tips to regulate symptoms and promote relaxation [12]. Although mental health symptoms were not statistically significant predictors of online tool use, given that some associations trended toward significance (depression: P=.05, PTSD: P=.07), it may be possible that the study was too underpowered to detect a statistically significant relationship between mental health symptoms and online tool use.

Furthermore, our sample reported mild depression and anxiety on average, with very few PTSD symptoms. On the basis of the

XSL•FO
RenderX

qualitative findings, a common reason for not using online tools was a lack of perceived need. Therefore, it is possible that the absence of an association between mental health symptoms and online tool reflects students' belief that their symptoms did not warrant significant attention. Other evidence indicates that young people with more severe symptoms, especially those with higher depression severity, may avoid traditional care, preferring to use anonymous electronic sources (ie, internet forums, support groups, and chat rooms) and digital tools to better understand and cope with their symptoms on their own [47]. Considering students who have more severe symptoms of depression may not seek care compared to those with more moderate symptoms due to coping with specific depression symptomology (ie, lack of motivation, low energy, increased fatigue, and reduced problem-solving abilities), such self-reliance may further reduce their perceived need for professional mental health services [48,49]. Future research should examine what factors may play a role in students' perceived need of mental health care.

Participants in our study reported that online tools to seek information were accessible, easily providing fast information and answers to questions quickly, which is consistent with past research [21,50,51]. While previous research had mixed results about existing disparities in online tool use based on race or ethnicity, non–US born status, and gender, our study found no differences in online tool use based on these factors [7,16,23]. However, it is important to note that our sample was highly educated, had lower stigma, and had more positive views and knowledge about mental health than the general population. These factors likely facilitated the use of online tools for mental health among our participants. Although we did not find associations between stigma, attitudes toward mental health treatment, or self-efficacy and online tool use among our sample, this may be a result of the privacy provided by the digital nature of these tools. While support from family and friends may be incorporated in digital tools to promote the management and treatment of mental health disorders, for those dealing with more social or family-based stigma, the anonymity and privacy of online tools may provide more autonomy to decide who they would like to involve in this process, if any [7,52,53]. For those who do not feel comfortable using online tools, it may be due to harboring certain attitudes and beliefs about digital tools, such as finding them untrustworthy or unreliable, that resulted in their unwillingness to use them. As for self-efficacy, digital self-efficacy, such as students' confidence in navigating digital spaces, may have a greater impact on their willingness to use online tools rather than their confidence in seeking mental health support itself [18]. Therefore, stigma that exists around the confidentiality of online data, negative attitudes toward the use of digital platforms, and students' confidence in their ability to navigate them effectively may play a role in online help seeking. This highlights the importance of research examining the different types of attitudes and beliefs that exist about digital mental health tools, specifically.

Recommendations to Improve the Implementation of Online Tools

Due to possible differences in barriers faced by students across a variety of school settings, we recommend that researchers consider the needs and priorities of their target population to increase the relevance and fit of the digital tools. It is important to recognize that students from other educational settings, aside from 4-year institutions, may experience barriers to using online tools for mental health. For example, research has found that community college students face many barriers to using digital tools (eg, mental health apps), including financial challenges, privacy concerns, self-reliance, skepticism about the seriousness of symptoms, and concerns about others' perceptions of them [51]. This suggests that accessibility and stigma barriers may exert a more pronounced impact on community college students than on their university counterparts [51]. Thus, it is important to consider the target population and setting when implementing digital tools. To develop digital tools that are acceptable to college students from a variety of educational backgrounds, we recommend that formative research be conducted with the population of interest, such as identifying primary mental health concerns and including user content and interface suggestions (ie, crisis text line, telehealth, websites for connecting to services, SMS text messaging with counselors, personalization, anonymity, privacy, security, and peer engagement) that may promote service use before the implementation and dissemination of a digital tool [8,54,55].

Our qualitative results demonstrated that many students are unaware of how digital tools could be used to connect with care. There is a need to improve the digital tool's user interface because many online tools do not have the ability to connect users directly to a coach or therapist [44,56]. Given that students view the ability to connect to care as important, we recommend that online tools help users assess symptoms and include a direct connection to professional services, as it may increase use of mental health services among college students with unmet mental health needs [12]. For example, rather than having students navigate help seeking on large search engines, which may be a dissatisfying process, digital tools that could triage help should be promoted and researched, as highlighted by our participants' requests for features that personalize the help-seeking process. Young people have reported higher satisfaction when online tools such as Link, a navigation website that connects youth to treatment based on reported mental health symptom type and severity, were tailored specifically to their needs (ie, immediate return of personalized options for help seeking, stories from individuals dealing with similar symptoms, and self-care tips) [57]. Digital interventions, such as the Screening and Treatment for Anxiety and Depression program that screens college students for mental health symptoms and reliably connects students to evidence-based care (eg, self-guided wellness program, sessions with peer coaches, or individual therapy) based on the severity of depressive symptoms, might act as a gateway to connect students to care [49]. This type of online tool could circumvent barriers such as misjudging perceived need and self-reliance, facilitating a more efficient pathway for students to access the necessary mental health support [49].

Qualitative findings also indicated that students used online tools for psychoeducation and general information about mental health and found them helpful. Although there are websites that provide general psychoeducation, such online tools may lack

XSL•FO
RenderX

detailed information about evidence-based treatments and guidance on connecting with professionals [8,12,58]. Without adequate psychoeducation on available treatments and how to access them, students may struggle to take the next step in pursuing professional services, ultimately leaving their mental health needs unmet. College students have reported that online platforms, such as clinic websites, should provide more comprehensive information, including clear explanations on how to get started with services, detailed descriptions of services available for specific mental health disorders, and mental health professionals' background information, which in turn can increase a students' willingness to seek mental health care [59]. Thus, we recommend that digital tools provide explicit psychoeducation on how to receive evidence-based treatments, as that may increase students' likelihood of using online tools to connect to mental health services. Another recommendation for content creators who design mental health websites is to include resources for crisis lines, which was suggested by participants who did not use online tools to connect to care as a possible motivating factor for future use. Crisis lines have been shown to connect people with immediate help and promote engagement with long-term mental health services (ie, referrals to mental health professionals) [60,61].

Recommendations to Increase the Dissemination of Online Tools

Our qualitative results demonstrated that a major reason why college students did not use online tools to support their mental health was because they were unaware of what digital tools were available. Indeed, previous studies have found that many participants are unaware of formal online resources (ie, charities and health services) available to support them [8]. Considering we found mental health literacy to predict online tool use, video interventions and digital media campaigns targeting young people with low mental health literacy should also include information on available online tools for mental health support. These interventions can enhance mental health literacy, reduce stigma, and promote help seeking by increasing awareness of various online tools for accessing care [62].

Referrals from friends, family, or health care professionals could help raise awareness about available online tools. As support from loved ones often encourages help seeking, recommendations from these sources signal to participants that the tools are more reliable and trustworthy [7,44,55]. Although numerous digital tools have become more readily available, proper evaluation and validation of these tools and their implementation is limited, resulting in students needing to deduce whether a tool is trustworthy or not [63]. While young people may be motivated to search the internet for mental health help, their ability to deduce the quality and reliability of the mental health information may prove to be more challenging with limited mental health literacy, further hindering their willingness to use online tools. It is recommended that mental health professionals receive training on available digital tools so they can confidently recommend them to patients, who may then share these tools with friends and family [43,63,64]. Therefore, referrals and recommendations by trusted individuals can spread awareness of credible digital tools, and in turn, reach underserved populations who may have negative perceptions of the internet and digital mediums or find the digital tools unreliable due to privacy concerns [13,14,45,55,65].

Limitations and Future Directions

As data for this study were collected in 2021, findings should be interpreted within the unique context of the COVID-19 pandemic. Although our study found that a third of participants (37/123, 30.1%) used online tools to connect with mental health professionals or services, which was consistent with online help-seeking rates before the COVID-19 pandemic [21], general use of online tools to seek mental health information likely increased during the pandemic [8,25,27]. At that time, lockdowns and social distancing measures significantly limited in-person mental health services, which may have influenced students' decisions to seek information and support through online tools. These conditions may have contributed to both increased exposure to and reliance on online mental health resources. Consequently, patterns of online help seeking captured in this study may reflect a period of heightened necessity rather than sustained preference. Future research is needed to examine how students' attitudes and behaviors toward online mental health tools have evolved after the pandemic, when the use of digital resources is increasingly optional rather than mandated.

We used standardized procedures to code the qualitative responses; however, some open-ended responses were too vague to be coded (eg, "it was something" was provided as a response to "Why was this online tool helpful?"). In addition, our small sample size limited our ability to quantitatively examine patterns in types of online tools used, perceived helpfulness, and motivating factors across different demographic groups. To better tailor these tools to populations considered marginalized, we believe that future research should aim to identify if there are differences in these outcomes based on demographic characteristics. Related to our sample size, post hoc power analyses suggest the study may have been underpowered to detect small to moderate associations between various key predictors and outcomes. For example, analyses examining the relationship between mental health symptoms (depression, anxiety, and trauma symptoms) and online tool use were underpowered (eg, depression: power=0.69, anxiety: power=0.10, and trauma: power=0.63), potentially limiting our ability to detect significant effects. Our study sample also had a positively skewed distribution of mental health symptoms, with most participants reporting mild symptoms, as well as a negatively skewed distribution for self-efficacy and attitudes, where most participants expressed high self-efficacy and more positive attitudes toward mental health. Future research with larger, more diverse samples and greater variability in responses is needed to clarify whether these null findings reflect a true absence of association or limitations in statistical power. Due to the cross-sectional design of our study, the directionality of associations between our key predictor variables and online tool use also could not be established. Future longitudinal or experimental research is needed to clarify causal pathways and better understand the temporal sequencing of these relationships.

Furthermore, this study did not measure the following factors that are associated with the use of online tools for mental health:

XSL•FO
RenderX

access to reliable technology, digital literacy (ie, ability to locate, evaluate, and communicate information using digital mediums), internet self-efficacy (ie, confidence in one's ability to master new technology), attitudes toward digital mental health (ie, positive and negative views relating to trustworthiness, credibility, and efficacy), and preferences for in-person help seeking [11,12,15,65,66]. Future research should examine how these factors play a role in the use of online tools for mental health purposes, as highlighted by our qualitative responses. In addition, participants in our sample were recruited from students enrolled in psychology courses and may be more knowledgeable about mental health and have less stigma than students with other majors [67,68]. These findings are limited to the study sample, which included university students attending a 4-year institution, and may not be applicable to students from other educational backgrounds.

Conclusions

There is a need to bridge the gap between effective online tools for mental health and users. Research exploring digital mental health tool design, acceptability, and feasibility can promote access to psychological information and professional services among college students [10]. Our study shows that university students find online tools to be an acceptable and feasible method to seek mental health information; however, more research is needed on how to optimize online tools to help students connect to mental health care. To optimize the utility of online tools, it is crucial to conduct research that will yield rich user insight to identify and implement user-suggested components, such as psychoeducation about disorders, treatments, and services; personalized content; interactive features; and connections to professional care [9,69-71].

Abstract

Background: Trust in artificial intelligence (AI) remains a critical barrier to the adoption of AI in mental health care. This study explores the formation of trust in an AI mental health model and its human-computer interface among clinicians at a web-based mental health clinic in the Region of Southern Denmark with national coverage.

Objective: This study aims to explore clinicians' perspectives on how trust is built in the context of an AI-supported mental health screening model and to identify the factors that influence this process.

Methods: This was a qualitative case study using semistructured interviews with clinicians involved in the pilot of a mental health AI model. Thematic analysis was used to identify key factors contributing to trust formation.

Results: Clinicians' initial attitudes toward AI were shaped by prior positive experiences with AI and their perception of AI's potential to reduce cognitive load in routine screening. Trust development followed a sequential pattern resembling a "trust journey": (1) sense-making, (2) risk appraisal, and (3) conditional decision to rely. Trust formation was supported by the explainability of the model, particularly through (1) visualization of confidence and uncertainty through violin plots, aligning with the clinicians' expectations of decision ambiguity; (2) feature attribution for and against predictions, which mirrored clinical reasoning; and (3) use of pseudo-sumscores in the AI model, which increased interpretability by presenting explanations in familiar clinical formats. Trust was contextually bounded to low-risk clinical scenarios, such as preinterview patient screening, and contingent on safety protocols (eg, suicide risk flagging). The use of both structured and unstructured patient data was seen as key to expanding trust into more complex clinical contexts. Participants also expressed a need for ongoing evaluation data to reinforce and maintain trust.

Conclusions: Clinicians' trust in AI tools is contextually and sequentially constructed, influenced by both model performance and alignment with clinical reasoning. Interpretability features were essential in establishing intrinsic trust, particularly when presented in ways that resonate with clinical norms. For broader acceptance and responsible deployment, trust must be supported by rigorous evaluation data and the inclusion of clinically relevant data types in model design.

Introduction

Background

Effective and accessible mental health treatment is crucial in addressing the growing global burden of mental health disorders. Untreated mental health disorders not only impact individual well-being but also result in substantial economic and societal strain through lost productivity, increased health care costs, and reduced quality of life. With the economic burden estimated to be US $5 trillion in 2019 [1], the need for timely and appropriate intervention has never been more urgent.

XSL•FO
RenderX

Like many aspects of society, the treatment of mental health disorders stands to be transformed by artificial intelligence (AI). By recognizing complex patterns and analyzing vast amounts of data, AI has the potential to enhance early detection, personalize treatment, and deliver digital therapy at scale [2,3].

AI adoption depends on factors related to trust, such as system reliability, robust performance, and perceived competence, which is especially important in medical [4] and psychological decision making. In mental health, lack of trust is seen as a key barrier to adoption of AI-based decision support systems [5,6]. Explainability is an important factor in fostering trust in AI systems. When users understand why an AI makes certain decisions (explainability) and can clearly comprehend the reasoning behind those explanations (interpretability), they are more likely to adopt AI.

Trust has also been identified as one of the most critical elements of AI adoption in clinical settings. In a scoping review, Hassan, Kushniruk, and Boryck [7] highlight that a lack of trust remains a major barrier to implementation in health care. Transparency, system reliability, and alignment with clinical reasoning are identified as key facilitators. This reinforces the idea that explainability needs to be considered from the perspective of those expected to use the model in practice. Other stakeholders, such as regulators, also play a role in ensuring that digital mental health tools are safe, effective, and trusted through robust regulation and evaluation, which builds public trust [8].

When an AI model predicts a classification with near 100% probability, this implies that the model is near 100% confident that its prediction is correct. As such, the prediction probability is known as the confidence of the prediction [9]. Uncertainty occurs when an AI model is unsure about its confidence prediction, ie, predictive uncertainty [10]. This may occur due to aleatoric uncertainty (uncertainty in the data), or epistemic uncertainty (uncertainty in the model or a shift in the statistical distribution of the data) [11]. The quantification of predictive uncertainty depends on the type of model being evaluated. In neural network models, a single prediction vector is typically output for each data point. The uncertainty is quantified as the deviation of the true-class probability from 100% confidence, measured as the negative log likelihood, or the deviation of all probabilities in the prediction vector, from the true-class probability, measured as the static calibration error or the Brier score. When predictive uncertainty distributions are available, as in Bayesian, Ensemble, or Monte Carlo dropout models, uncertainty manifests itself as the shape of the probability distribution associated with the prediction, with a narrow, peaked distribution indicating certainty, and a wide, flat distribution indicating uncertainty.

Although confidence and uncertainty estimation are considered essential for safe clinical deployment of AI [12], most machine learning methods in the recent medical literature are said to neglect the important issue of model uncertainty [10]. This is an issue, as it is well known that machine learning models can be confidently wrong [13]. In the absence of an uncertainty estimate, such confidently wrong model predictions may undermine end user trust in the model.

Accordingly, there is a need to understand how trust in AI manifests in the interaction between clinical users and an AI system that predicts both treatment probability and uncertainty, in the context of mental health decision support. This includes understanding how such trust affects decisions to use the system, and in which contexts. This qualitative study explores aspects of trust in clinicians' use of an AI model as a part of a decision support system for treatment prediction.

Clinician Trust in AI and the Role of Explainability

Although trust is a prerequisite for adoption, it must be appropriate. The review by Asan et al [14] emphasizes reliability, transparency, and alignment with clinical reasoning as central determinants of clinicians' trust in AI and argues that trust should be appropriate rather than maximized, in order to avoid unwarranted trust. In mental health specifically, the sensitivity of decisions and the potential for harm heighten the need for trustworthy behavior under distribution shift and within workflow constraints.

Explainability is often proposed as the main lever for calibrating trust; however, its effects are context-dependent. The systematic review by Rosenbacke et al [15] reports mixed effects of explainable artificial intelligence (XAI) on clinicians' trust. Explanations can increase trust when they are clear, concise, and clinically relevant, but they can also have no effect or reduce trust when they are confusing, cognitively heavy, or poorly matched to the task.

Evidence from applied settings shows similar patterns. The empirical study by Wysocki et al [16] examines explainability, utility, and trust in clinical decision making and describes a mixed role for explanations. Benefits include help with sense-making in ambiguous cases and support for less experienced staff, while drawbacks include added interaction effort and the risk of confirmation bias or over-reliance if limitations are not clear. These findings underline the relevance of the design and presentation of explanations in context.

Accordingly, explanation content should be clinically aligned and should be paired with uncertainty communication, such as calibrated confidence or abstention, in order to discourage unwarranted trust [14,15]. Altogether, trust improves when explanations are concise, fit the clinical task, acknowledge limitations, and respect clinicians' expertise; conversely, trust erodes when explanations are opaque, verbose, or misaligned with workflow [14-16].

Explainable AI and Trust

XAI refers to the ability of AI systems to provide explanations of their predictions in a way that is understandable and clear [17]. XAI techniques help bridge the gap between AI algorithms and user comprehension. In their transparency and interpretability for understandability framework, Joyce et al [18] describe how XAI relates to the application of AI in mental health. They argue that trust is built when clinicians and patients feel confident that an AI system's reasoning is transparent and is seen to align with clinical understanding—a concept similar to face validity. Jacovi et al [19] suggest that users tend to trust an AI if its decision-making process aligns with their

XSL•FO
RenderX

expectations of rational behavior. Transparency and interpretability are central to the evaluation of such a rationale.

However, the terms surrounding the explainability, interpretability, and transparency of AI models and their operation lack consensus definitions [20,21]. Explainability refers to the ability to understand why a model has made a specific prediction. Interpretability may be thought of as empowering explainability: providing the ability to understand how a prediction was made. Being able to convey the meaning of an AI model's operation to a human in understandable terms operationalizes the "how" and is therefore an important aspect of interpretability [21]. Interactivity with the AI model and visualization of its operations also play a role in interpretability [22]. Li et al [23] point out that the user interface is a key factor influencing user experience, acting as the main medium through which an AI system communicates its internal reasoning and decision-making process. The way explanations are presented, therefore, plays an important role in how users form trust in the AI.

Transparency, which is related to interpretability, emphasizes a shared, user-centered understanding of the meaning of model features and their operation [19,21]. Transparency implies that the whole model can be understood [20], or in a less strict sense, that the model features and parameters are understandable [17]. In clinical models, transparency implies that the meaning of features has a direct clinical interpretation [18].

Lacking a consensus and in consideration of the various aspects of explainability, involving trust, understanding, confidence, etc, Barredo Arrieta et al [21] suggest that explainability depends on who is required to understand the model, suggesting the following definition: "Given an audience, an explainable Artificial Intelligence is one that produces details or reasons to make its functioning clear or easy to understand." In a clinical sense, this may be thought of as AI coformulation.

Understandability is used as a proxy for explainability in the transparency and interpretability for understandability framework of XAI [18]. In this framework, transparency and interpretability are the constituent components of understandability (and therefore, explainability). Consistent with the description of those terms above, interpretability is seen as being determined by the model architecture, structure, and how the prediction is presented (similar to the concept of algorithmic transparency); transparency is determined by the features and data used by the model. Taking logistic regression as an example, interpretability comes from the linear model structure and probabilistic presentation of model predictions inherent in logistic regression. The data and features of such a model can be designed so that the meaning of features has a direct clinical interpretation, fulfilling the requirement for transparency.

Jacovi et al [19] frame trust as an explicit contract between the AI and users in a context in which there is a risk to the user if the AI breaks the contract. The contract lays out what the model is being trusted to provide: transparency, predictability, and fairness (for example). Predictability in this context means that model performance is known to the user and accepted. This may involve an overall performance metric, but it may also involve contextual conditionality, implying that the user knows in which context to trust the model performance and in which contexts the model should not be trusted (eg, on certain data subgroups or out-of-domain data). The mechanisms by which an AI model gains a user's trust can be understood through a differentiation into intrinsic and extrinsic factors. Intrinsic trust is based on the AI's reasoning process aligning with human expectations (eg, interpretable models, logical decision-making). Therefore, intrinsic trust depends on the user, for example, a clinician, being capable of interpreting the meaning of the features of a transparent clinical model. Extrinsic trust is based on external behavior or evaluations of the model, such as observing consistent past performance or validation of performance reliability. Extrinsic trust is therefore a trust in the model's evaluation quality. In this way, trust is seen as having both human and quantitative factors, upon which the user judges whether to trust the model or not.

Trust in AI systems often involves a degree of control relinquishment, yet this trust is highly contextual. As Lipton [20] points out, interpretability is not a one-size-fits-all goal, and trust arises not just from transparency but from the alignment of model behavior with user expectations in specific settings. In many cases, users are willing to trust AI when its judgments match their own, whether or not those judgments are objectively correct. That is, both humans and AI may classify a case as a "mistake" or "non-mistake" depending on the category and context, reinforcing or undermining trust.

This context-sensitive nature of trust highlights the importance of aligning AI outputs with human reasoning, not just through outcomes but through explanations. AI models typically associate data features with predictions based on correlations, whereas humans tend to understand scientific models through cause-and-effect relationships. To bridge this conceptual gap, Holzinger et al [24] introduced the concept of causability, defined as the extent to which AI explanations support users in forming causal understanding from inherently correlational outputs.

In the context of AI recommender systems, Shin [25] found that users' trust increased when they were able to comprehend explanations in causal terms. Rather than offering purely statistical associations ("feature X correlates with outcome Y"), causability emphasizes understanding why such correlations arise. As such, it is considered a prerequisite for effective explainability. A comparable shift can be observed in high-stakes fields such as suicide prevention, where decision-making must be both evidence-informed and explainable to clinicians. In suicide research, for example, there has been a call to move from risk factors to predictive algorithms [26], and clinical guidelines now advocate a shift away from categorical risk classification toward individualized, formulation-based approaches [27,28].

According to Shin [25], trust in AI systems develops through a dual process: a heuristic route, where users form quick judgments based on prior knowledge or biases, and a systematic route, where trust emerges from deeper evaluation, particularly when explanations are clear, meaningful, and causally informative.

XSL•FO
RenderX

Since explainability depends on humans seeking the explanation, the views of users in the clinical context are central. The purpose of this qualitative study is to explore what affects the trust as perceived by clinical users of an AI model aimed at a mental health decision support system. Using thematic analysis, this study explores how users understand the operation of the model, how they interpret its outputs, and what influences their trust. By focusing on user perspectives, it aims to develop a context-sensitive understanding of explainability that is grounded in clinical reasoning and practice.

Methods

Study Design and Procedure

The clinical setting for this study was the Internet Psychiatry Clinic, an internet-based cognitive behavioral therapy (iCBT) service operated by the Centre for Digital Psychiatry within the Mental Health Services of the Region of Southern Denmark [29]. This publicly funded, free-of-charge service is integrated into routine mental health care in Denmark. Individuals self-refer and are screened in 2 stages: an initial request form is followed by a clinical assessment conducted by trained psychologists. The screening referred to in this study is the first part of the clinical assessment, with the second part being a clinical interview. Eligibility criteria include being aged 18 years or older and meeting diagnostic criteria for one of the following conditions: mild to moderate depressive disorder, single phobia, social phobia, or panic disorder with or without agoraphobia [30]. The center delivers its iCBT treatment with a nationwide coverage of approximately 4.8 million adults. The AI model and human-computer interface (HCI) used in the moderated cognitive walkthrough is the Probabilistic Integrated Scoring Model (PrISM) originally reported by Kelly et al [31] (further described below), that predicts the probabilities of the 4 available treatment options—depression, panic disorder, social phobia, and specific phobia; based on patient questionnaires in step 1 of the clinical assessment.

In this study, following informed consent, semistructured interviews were conducted with the clinical psychologist participants, guided by the frameworks of perceived trust in AI discussed earlier. The interviews took place in the clinic in Odense, Denmark, over a period of 2 days. Interviews were conducted one-on-one with one participant and one researcher present in the room.

A trust framework-driven interview guide (Multimedia Appendix 1) was used to ensure that key dimensions of trust were systematically explored across all participants, while also allowing space for participants to raise personal or contextual factors that may have influenced their perception of AI [32]. Questions focused on concepts such as explainability, interpretability, confidence, uncertainty, and perceived trust. The flexible nature of the semistructured format made it possible to follow up on unexpected or participant-driven topics that emerged during the discussion.

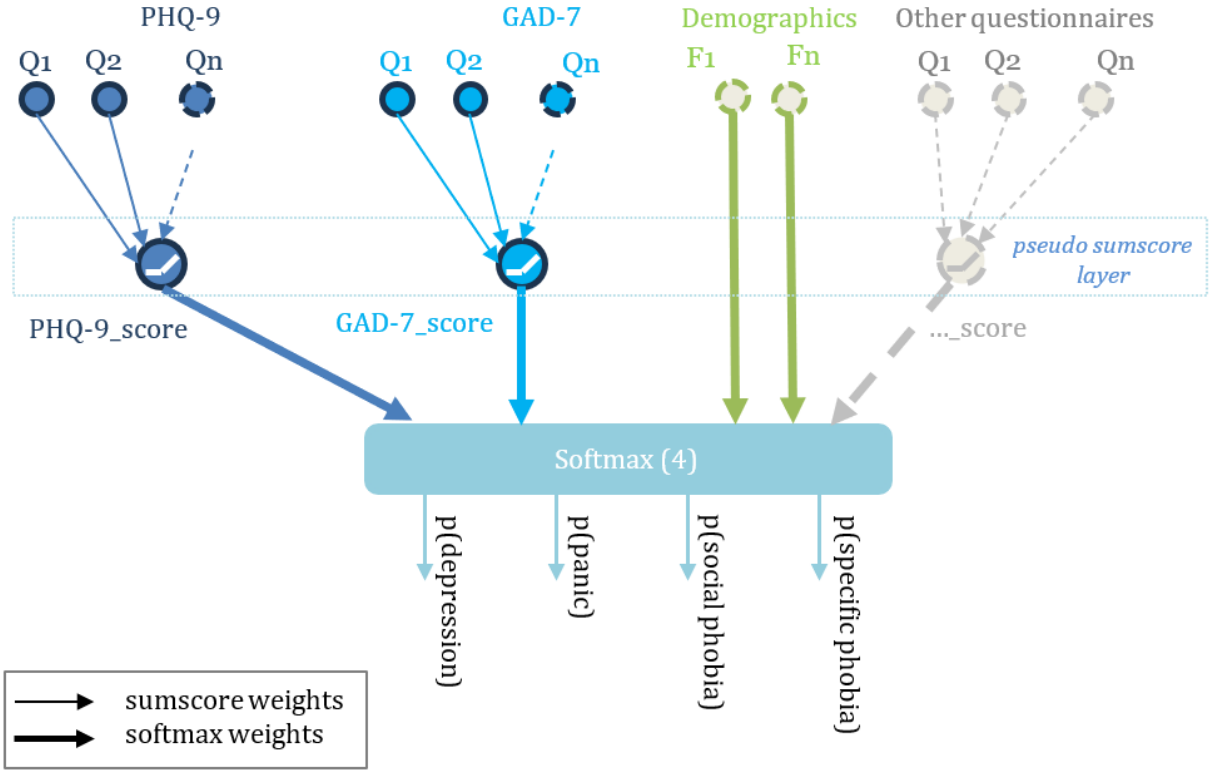
To support the interviews, a moderated cognitive walkthrough was carried out. During this process, participants interacted with the AI system while responding to questions. The interaction involved navigating synthetic patient records, using the AI to generate treatment predictions, and reviewing both the prediction and its explanation through the user interface. This method allowed for the observation of trust-related responses during actual system use, aiming to minimize the influence of the interview structure on participant behavior, and helped to identify usability issues that may influence trust [33]. The cognitive walkthrough is particularly useful in assessing the user experience and understanding how people cognitively process the interface [34]. In this study, it also served to situate participants' reflections in a realistic decision-support context, linking system outputs to users' thought processes in real time.

Individual interviews provided insight into the cognitive, emotional, and experiential factors shaping trust in AI [32], while the cognitive walkthrough allowed for an examination of how perceptions evolved during live interaction with the system so that the interview structure affected behavior as little as possible [34]. Together, these methods enable a deeper exploration of the factors influencing trust, providing both subjective self-reports and objective behavioral data.

This qualitative study used reflexive thematic analysis (RTA) [35,36] as an individual case study [37] to explore participants' experiences of using an AI-enabled decision support tool in a Danish web-based mental health service. The aim was to investigate how clinicians perceived trust and explainability in the AI model during real-time interaction. Data were generated using think-aloud protocols embedded within the semistructured interviews, allowing participants to verbalize their thoughts and responses as they navigated the AI interface. This approach made it possible to capture both spontaneous reactions and more reflective evaluations of the model's performance and trustworthiness.

Individual interviews were selected to provide participants with a private and uninterrupted setting to share their views. This was considered particularly important given the sensitivity of topics such as trust and clinical judgment, where participants might feel more comfortable expressing concerns or critiques in a one-on-one context [32]. The interviews were audio recorded consensually, for transcription purposes. The semistructured interview format allowed for flexibility in exploring participants' responses while ensuring a consistent set of topics related to perceived trust and explainability in AI [38].

The RTA was conducted by 2 researchers independently, with complementary lenses. Reflexively, one of these (AK) brought an AI trust perspective to the analysis. The other (TTHSM) brought a clinical perspective. Our aim was interpretive, focusing on meaning-making rather than reliability metrics. Consistent with RTA, we did not seek intercoder agreement, did not hold intercoder dialogue aimed at consensus, and did not conduct member-checking. The analysis followed Braun and Clarke's [35] six-phase process: (1) familiarization with the data, (2) initial coding, (3) generating initial themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report. The analysis was conducted as an iterative, reflexive, and nonlinear process, in line with Braun and Clarke's [36] guidance for RTA [39]. This involved the formulation of



XSL•FO
RenderX

semantic codes of surface meaning, but also where an underlying meaning emerged, latent codes were formulated, involving a more subjective interpretation.

AI Model

The PrISM AI model [31] (Figure 1), used in the moderated cognitive walkthrough, is a 2-level feed-forward neural network that emulates the traditional "sum-score" logic of mental-health screening instruments while retaining full differentiability and probabilistic predictions. Item-level responses from 6 validated questionnaires—Patient Health Questionnaire-9 (PHQ-9) [40], the Generalized Anxiety Disorder Questionnaire-7 [41], the Social Interaction Anxiety Scale (SIAS) [42], the Panic Disorder Severity Scale [43], and the Fear Questionnaire [44], and selected MANSA items—together with 8 sociodemographic variables constitute the input vector. In the pseudosum layer, each questionnaire's items are combined by nonnegative, L1-regularized weights and passed through a rectified-linear activation, yielding learned questionnaire scores that remain directly interpretable to clinicians. These scores, augmented by the raw demographic features via a skip connection, are then supplied to a softmax output layer that performs multiclass logistic regression across 4 treatment categories (depression, panic disorder, social phobia, and specific phobia).

Figure 1. Structure of the Probabilistic Integrated Scoring Model (PrISM). GAD-7: Generalized Anxiety Disorder Questionnaire-7; PHQ-9: Patient Health Questionnaire-9.

Uncertainty was quantified at inference time through Monte Carlo dropout: a 5% dropout mask is retained during every forward pass, and the network is sampled 100 times, producing an empirical posterior distribution over class probabilities. This procedure approximates a fully Bayesian logistic model while incurring negligible computational overhead and enables case-level reporting of both confidence and epistemic uncertainty.

The user interface to the PrISM model, presented to the participants, is shown in Figure 2. The top panel shows violin plots of the posterior distribution over class probabilities for the treatment prediction for a specific patient example, indicating a prediction of depression. The explanation of the prediction is shown in the middle panel. This shows graphs of ranked feature importance; the features that explain the class prediction selected (left) and the features that counter that prediction (right). The "explain prediction" dropdown above the panel allows the user to select which of the 4 class predictions (depression, panic disorder, social phobia, and specific phobia) to explain. The bottom plot shows individual questionnaire answers that relate to a selected questionnaire.

XSL•FO
RenderX

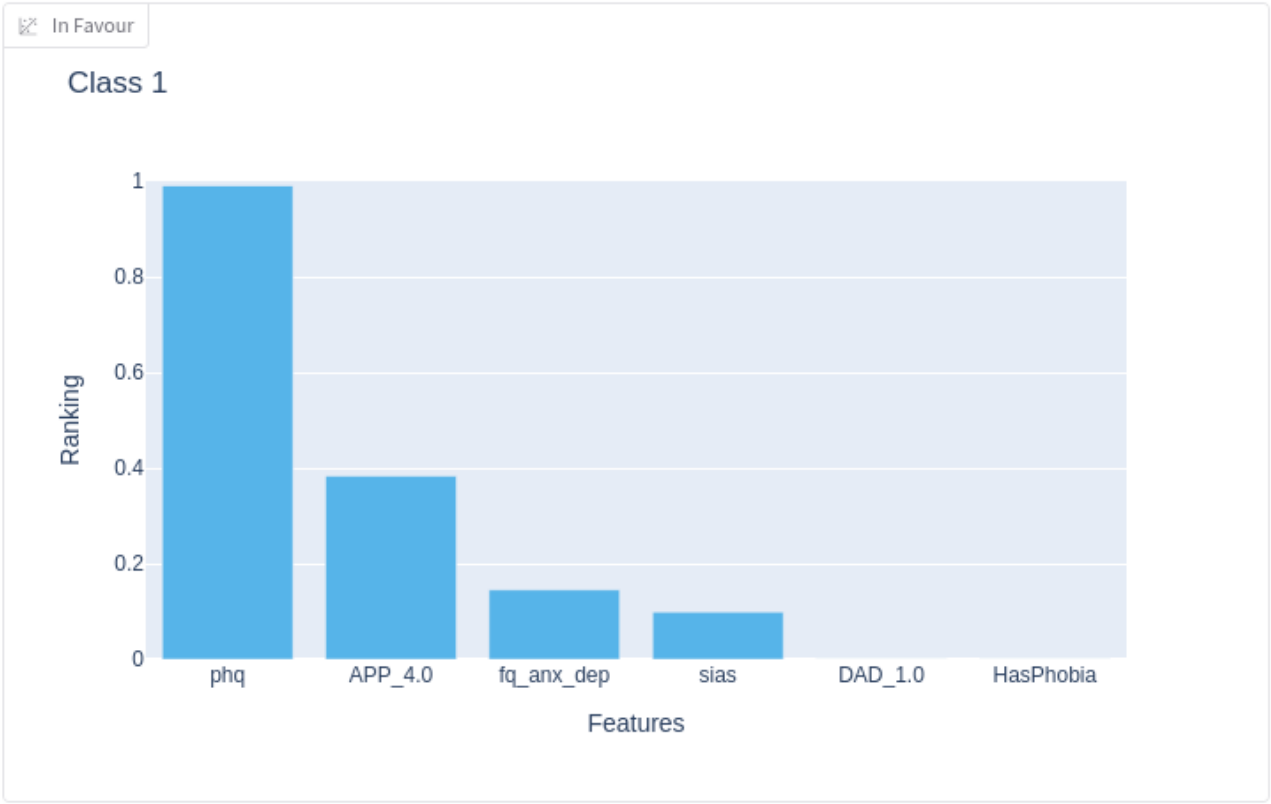


Figure 2. Illustration of the artificial intelligence human-computer interface. The top plot shows the prediction of the 4 classes (y-axis), with the probability distribution of the predictions on the x-axis, illustrated as violin plots. The middle plots show the features that explain the class prediction selected (left) and the features that counter that prediction (right). The bottom plot shows individual questionnaire answers that relate to a selected questionnaire.

The detail of the prediction explanation for a specific patient is shown in further detail in Figure 3. The chart indicates that the PHQ-9 score (phq), the demographic feature “doesn’t know what treatment to apply for” (APP_4.0), and the fear questionnaire anxiety-depression subscale (fq_anx_dep) have the most influence on the prediction of the depression class (class 1) in this specific patient example. When interacting with the AI HCI, hover-overs provided text explaining the meaning of the features and score totals where relevant, for improved usability.

XSL•FO
RenderX

Figure 3. Details of the features that explain the class prediction selected (left middle panel of the artificial intelligence human-computer interface).

The reference implementation (TensorFlow 2.19, Python 3.11) was trained on retrospectively collected data from 1068 adults referred to the Danish national internet-psychiatry service. Records were stratified by diagnosis and partitioned 75%/25% into development and held-out test sets. Optimization used the Adam algorithm (batch=32, learning rate=0.001) for 2000 epochs, with L1-regularization (λ=0.001) promoting sparsity and retaining only clinically salient inputs.

On the unseen test cohort, the model achieved a balanced accuracy of 0.79 and per-class AUC ranging from 0.91 to 0.98. This architecture, therefore, provides two properties considered essential for the safe deployment of machine-learning systems in frontline mental health care: (1) transparent, score-level explanations that align with routine clinical reasoning and (2) probability distributions that facilitate the identification of low-confidence or uncertain cases.

Data

A dataset comprising patient questionnaire answers and demographics was used to train the PrISM AI model used in the cognitive walkthrough semistructured interviews. The data were gathered between November 14, 2019, and December 31, 2022, from patients of the “Internetpsykiatrien” web-based treatment services delivered by the Centre for Digital Psychiatry, Denmark. The center delivers routine care and internet-delivered cognitive behavioral therapy with nationwide coverage [29]. The data consisted of answers to the PHQ-9, the Generalized Anxiety Disorder Questionnaire-7, the SIAS, the Panic Disorder Severity Scale, and the Fear Questionnaire. Additional features included demographic information and a brief medical history, such as previously diagnosed conditions. The ground truth of the dataset was the choice of treatment selected by the psychologists in the clinic for each patient. Further details can be found in [31].

Ethical Considerations

Data for the AI model were extracted from Internetpsykiatrien after approval from the Regional Council in Southern Denmark. Since this was a secondary data analysis, separate informed consent was not required. The Regional Committees on Health Research Ethics for Southern Denmark were informed about the study and were provided with the case number S-20232000 - 65. In accordance with Danish national ethical guidelines, no additional ethics approval was needed.

Ethical review and approval were not required for the study on human participants in accordance with the local legislation. The patients/participants provided their written informed consent to participate in this study. The study was reported to the Danish Data Protection Agency. Data were anonymized before being provided to the researchers. No compensation was provided.

Participants

The participants were clinical psychologists working in the Region of Southern Denmark. The group comprised 5 participants (N=5; 2 female and 3 male), with a mean age of 35.8 years. All participants were members of the screening team at an iCBT clinic within the service. Their role involves screening patients for interview prior to possible treatment, as well as conducting clinical interviews as part of the treatment assessment process.

Participants were recruited based on their clinical role in the service, with a range of experience levels represented, from junior to senior staff. The study included 55% (5/9) of the entire

XSL•FO
RenderX

screening team, meaning that the majority of clinicians responsible for initial patient triage were included. This provides a strong representation of the perspectives within the clinical setting and enhances the validity of the findings. To preserve anonymity within this small team, specific age and experience ranges are not disclosed.

In a review of sample size requirements for usability studies, Lewis [45] concluded that 5 participants are typically sufficient to reveal around 80% of usability issues. This implies a sample size of 5 is considered appropriate for a qualitative study focused on human-AI interaction. Thematic saturation appeared to be reached, and the inclusion of most of the staff involved in the relevant clinical task provides additional justification for the adequacy of the sample.

Structured Interview Guide

A structured interview guide was developed to explore participants' experiences with the AI model and interface. The interview's semistructured format guided the participants through a process of (1) enquiring about attitudes to AI in mental health care and in their role; (2) a cognitive walkthrough of using the AI system with various patient scenarios; and (3) an in-depth discussion on trust and explainability (Table 1). The guide consisted of open-ended questions designed to elicit detailed responses about usability and trust. Once introduced to the system (Table 1), the Cognitive Walkthrough and Interface Interaction section allowed for an open use of the AI system with the synthetic patient profiles, allowing an observation of natural behavior with the system, in order to minimize the influence of the interview structure on participant behavior. Since the interviews were limited to 1 hour, further follow-up questions were answered in written form. These included the topics: (1) usability and workflow integration, and (2) feedback and improvement.

XSL•FO
RenderX

Table . Description of the structured interview.

Topic and subtopic	Explanation/example question
Opening and background	
Reconfirm the informed consent	—[a]
Participant demographics	If not collected ahead of time
Initial attitudes toward AI[b] in health care	When you hear "AI" in the context of patient care, what comes to mind?
Perceived usefulness of AI in health care	Based on your experience, do you think AI could be useful in patient care or treatment decision-making?
Introduction to the AI system	A brief explanation of the system's function as a treatment recommendation system for mental health and set expectations for the cognitive walk-through.
Introduction to AI definitions	
Overview of the AI model	
Instructions for cognitive walkthrough	
Cognitive walkthrough and interface interaction	
First impressions	Take a look at the interface. What are your initial impressions?
Clinical assessment	Looking at the patient record, what would your assessment of the treatment recommendation be for this patient?
Locating and understanding the recommendation	Please use the AI tool to make a prediction for the patient.
Interpreting confidence and uncertainty	Do you feel you understand whether the model is "very sure" or "not very sure" about its recommendation?
Accessing and reviewing the explanation	Can you find or access the explanation for why the AI made this recommendation?
Explanation depth and satisfaction	Does the system provide enough detail about how it arrived at its decision?
Trust and ease of use	So far, do you feel comfortable trusting the system's recommendations? Why or why not?
In-depth discussion on trust and explainability	
Reliability and past evidence	Would it help your trust if you saw data on how often the AI's predictions were correct in previous cases of this type?
Transparency	How important is it for you to see exactly how the AI weighs different questionnaire scores?
Interpretability	Would it help to understand how this model generally works, beyond just one case?
Interactivity	Do you feel the interface is interactive enough for you to explore the patient record and model explanations?
Fairness	Do you have concerns about the AI being biased or missing certain patient subtleties?
Closing	
Summarize final thoughts and close	What would be your key takeaway from this experience with the AI system?

[a]Not applicable.

[b]AI: artificial intelligence.

To clarify the definitions of the terms used in the interviews, the definitions in Table 2 were provided to participants. Although confidence and uncertainty are somewhat ambiguous, we took confidence to be aligned with aleatoric uncertainty and uncertainty to be aligned with epistemic uncertainty.

XSL•FO
RenderX

Table . Definitions of terms provided to participants.

Term	Description
Explainable (AI[a])	Relates to understanding "why" AI models make their decisions.
Interpretable (AI)	Understanding "how" an AI model makes its prediction.
Transparent (AI)	How the prediction is made is clear from the model and features.
Confidence	The "probability" of the prediction.
Uncertainty	How "wide" the probability distribution is.

[a]AI: artificial intelligence.

Patient Profiles

Four patient profiles were developed to support the moderated cognitive walkthrough and provide a basis for exploration during the interviews. These profiles were designed to represent a diversity of treatment predictions and comorbidities that are typical of treatment decisions routinely seen in the clinic (Table 3). The patient profiles were accompanied by corresponding data suitable for presentation to the AI model. The data involves the answers to patient questionnaires and demographic data for the various patient scenarios [31]. The data was presented to the participants via a patient record view in the AI interface. The written description, provided in Table 3 for context, was not presented until the postinterview debrief.

XSL•FO
RenderX

Table . Patient profile scenarios.

Scenarios	Patient profile	Clinical rationale
Scenario 1	• Jane presents with persistent low mood, a significant decrease in energy levels, and an overwhelming sense of hopelessness. She reports difficulty concentrating at work and has recently been reprimanded for missing deadlines, which has exacerbated feelings of inadequacy. She also experiences intense anxiety in social and professional settings, including meetings and casual social gatherings, which has led her to withdraw from colleagues and friends. Jane's symptoms began approximately 8 months ago, following a critical performance review at work. Her lack of energy and motivation caused her low work performance, she believes. Initially, she noticed an increased reluctance to speak up in meetings due to fear of judgment. Over time, this fear extended to informal social settings, making her avoid after-work social events and even casual conversations. Concurrently, she began experiencing a pervasive sense of sadness, feeling "empty" most days, with episodes of crying without a clear trigger. • She reports difficulty sleeping, often lying awake ruminating over interactions where she feels she may have been perceived as inadequate. She has lost interest in hobbies she once enjoyed, such as painting and attending book club meetings, citing both a lack of motivation and a fear of being judged by others. Previous episodes: Jane recalls experiencing a similar period of low mood and social avoidance during her late teens but did not seek treatment. Family history: A history of depression in her father. No significant medical conditions or history of substance abuse.	• Ambivalent case where either depression or social anxiety could be primary. • Would tend to treat depression as a priority.

XSL•FO
RenderX

Scenarios	Patient profile	Clinical rationale
Scenario 2	• Susan M, a 34-year-old administrative assistant, presents with a 6-month history of persistent low mood, chronic worry, and reduced functioning. She describes feeling "stuck" and unable to engage fully in her personal and professional life. Her symptoms began following a period of prolonged work-related stress, which has since resolved, but her distress has persisted and gradually intensified. • Susan reports a constant sense of unease that permeates most of her day, particularly in the mornings. She wakes up feeling restless and on edge, with racing thoughts about her responsibilities and potential shortcomings. These worries often spiral into feelings of inadequacy, leaving her preoccupied with the fear of disappointing others. Despite recognizing that many of her concerns are unlikely to materialize, she struggles to control or dismiss them. She also reports difficulty concentrating, which she attributes to her mental preoccupation and lack of energy. There is some anxiety and depression history in her family, with her brother having had severe depression at some point and her mother being an anxious and overbearing person.	• Primary depression with features of generalized anxiety.
Scenario 3		• Panic disorder.

XSL•FO
RenderX

Scenarios	Patient profile	Clinical rationale
	• John D is a 42-year-old accountant who is currently unemployed. He describes experiencing sudden episodes of intense fear, accompanied by physical symptoms such as chest tightness, shortness of breath, sweating, and dizziness. He reports catastrophic thoughts about having a heart attack. These episodes, which John recognizes as panic attacks, occur unpredictably, often when he is driving or in crowded spaces like grocery stores. The fear of these episodes has led him to limit his outings and rely increasingly on his wife to run errands, though he continues to apply for jobs where he can work from home. John admits that he has started avoiding situations where he feels escape might be difficult, such as long car rides, crowded events, or unfamiliar environments. While he can still attend essential outings, such as dropping his kids off at school, he often feels on edge and hypervigilant for signs of an impending attack. These restrictions have caused strain in his family life, as he worries about burdening his wife and missing family outings. To cope with his anxiety, John has started drinking small amounts of alcohol in the evenings, which he finds calms his nerves and helps him unwind. He is careful not to exceed the recommended daily intake, consuming 1 to 2 drinks a night, and denies any history of problematic drinking. However, he acknowledges that he relies on this habit to manage his discomfort and worries about its long-term implications. John has experienced a general sense of fatigue and low mood. While he denies feeling hopeless or experiencing anhedonia, he describes difficulty finding joy in his usual hobbies, such as woodworking and jogging, because he feels “too keyed up” or “too drained” to engage. His sleep is often restless, disrupted by worry about his health and family, though he sleeps sufficiently most nights. He also reports a pervasive sense of guilt, believing that his anxiety is a weakness and that he is failing to be a strong role model for his children. When John went to the gymnasium, he received a diagnosis of anxiety, but he doesn’t remember much about that, and he did not receive treatment other than antianxiety medication.	
Scenario 4		• Single phobia

XSL•FO
RenderX

Scenarios	Patient profile	Clinical rationale
	• Mark, a 37-year-old software developer, presents with a persistent fear of bridges and heights that has mildly impacted his daily life for the past several years. His fear began in his late twenties after a stressful experience driving across a high suspension bridge during a storm, which left him feeling uneasy and lightheaded. While he did not experience a full-blown panic attack, the incident caused him to develop a wariness of high bridges. Over time, this fear generalized to other situations involving heights, such as tall balconies or observation decks. Mark avoids bridges when convenient but does not let his fear entirely dictate his life. He reports experiencing mild physical symptoms, such as increased heart rate and sweating, but these subside once he is off the bridge. Mark also feels discomfort in high places where there is an open or exposed view, such as glass elevators or balconies with low railings. He avoids these situations when possible but can manage if necessary, often relying on grounding techniques like focusing on a fixed point or staying close to a wall. Mark is seeking therapy now because he wants to feel more confident in situations involving heights, particularly as his daughter has expressed interest in visiting landmarks like bridges and observation towers. He is motivated to address his fear so that he can fully participate in family activities without hesitation or discomfort.	

Results

Thematic Analysis

Consistent with Braun and Clarke's [36] reflexive approach, we aimed for reflexive interpretive richness, rather than intercoder reliability, with each coder's distinct point of view contributing to a wider perspective interpreting the data. Therefore, 2 analysts with complementary skills (AK and TTHSM) undertook the RTA, each bringing a distinct epistemic lens.

Coder A, with a nonclinical background in AI trust and HCI, designs and evaluates decision-support tools, holding a pragmatic stance that emphasizes usability, explainability, and uncertainty communication. They adopted a predominantly inductive, bottom-up stance. First, descriptive codes were generated and clustered into provisional subthemes. Since a "trust journey" emerged in the subthemes, a top-down, deductive pass interrogated the data through trust frameworks to articulate the journey in terms of established models. Any latent emerging themes were also preserved.

Coder B, who practices in psychology, prioritizes patient safety, workflow fit, and risk management. They worked with a context-led, primarily semantic focus, ensuring that emergent themes remained grounded in front-line priorities such as areas of clinical hesitancy and reassurance, and how AI intersects with their duty of care.

Braun and Clarke [36] identify this analytic-storytelling mode within reflexive TA when the aim is to surface latent, practice-based logics that a purely code-centric read might miss.

The RTA generated 4 sequential themes. Together they outline a notional "trust journey" that begins with a first encounter and culminates in an informed decision to adopt the tool in real-world screening.

1. "Why engage with AI?": participants articulate the anticipated utility that motivates engagement.
2. "Making sense of the model": they attempt to follow and investigate the system's reasoning, building intrinsic trust and causability.
3. "Should I rely on it?": they appraised the AI by interpreting probabilistic outputs and explanations in the light of their clinical judgment of the patient record and current work practices.
4. "Deciding to use the model in practice": they elaborated on when, where, and under what safeguards they would rely on the AI in clinical screening.

In Figure 4, the themes are illustrated as a process of cognitive steps in the process of establishing trust:

1. Anticipated utility: "Why engage with AI?"

XSL•FO
RenderX

2. Sense making: “Making sense of the model.”
3. Appraisal: “Should I rely on it?”
4. Deciding to rely: “Deciding to use the model in practice”

Figure 4. Stages of artificial intelligence–mediated trust.

In the themes that follow, quotations are referenced by participant ID (P1-P5); square brackets denote clarifications.

Theme 1: “Why Engage With AI?”—Anticipated Utility

Although none of the clinicians had deployed AI tools in routine practice, four of the five were already experimenting with generative AI in their personal lives. This prior exposure produced a sense of guarded optimism about AI: as one participant put it, in relation to generative AI:

> *I don’t necessarily trust the idea it provides; I trust my own interpretation of the idea.* [P5]

The perceived value of an AI-enabled screening tool is centered around three expectations:

1. Improved efficiency and reduced bureaucracy: Highlighting that AI could examine “Multiple variables at a quick pace—perhaps faster than an experienced clinician could do” (P1); and that screening “Needs to go fast” (P4).
2. Greater consistency and mitigation of human bias: “I think a model like this could maybe also fight...prejudice or bias to some degree” (P2); “I would hope it would be more sure than a person” (P3).
3. Reallocation of clinician time to higher-value tasks: “If it frees me to do more clinical work, that’s very nice” (P2); “Less time looking at numbers” (P5).

Overall, participants framed AI as a complementary aid rather than a replacement for clinical judgment. They were willing to engage with the technology because they believed it could accelerate mundane evaluation tasks, apply rules impartially, and create time for deeper patient engagement. This motivational backdrop set the tone for the subsequent trust-building process described in the following themes.

Theme 2: “Making Sense of the Model”—Sense-Making Through Intrinsic Trust and Causability

Theme 2 reflects the initial stage of trust-formation where participants inspected violin plots, feature-level importance, and question-level explanations to decide whether the AI’s logic aligned with their mental model of clinical reasoning. Since explanations are only effective if they are understandable to the user [25], this theme captures how participants build intrinsic trust in the AI by attempting to follow and investigate the system’s reasoning.

This theme comprises four subthemes that relate to sense-making and trust-building: (1) orientation and navigation, capturing how participants initially find their way around the interface and data; (2) explainability-by-design, capturing aspects of the model or UI design that improve understanding, currently or in the future; (3) AI-driven insight, capturing clinical or data insights revealed by the model that the user had not initially noticed; (4) UI improvement/usability, capturing improvements that may make the interface easier to use.

During “Orientation and Navigation,” participants navigated the interface easily, spending time on the patient record tab to make their own assessment of the treatment required (as directed in the structured interview). The questionnaire total scores on this tab (eg, PHQ-9, SIAS) were familiar and therefore aided sense-making, often in the form of a patient story:

> *And then there’s a graph...And it tells me that there’s...both social phobia and Depression score. There’s symptoms of generalised anxiety and...could be...multiple diagnosis, but it could also be...an image of someone who's depressed and...feels very self-conscious about...dealing with depression. They might be very worried about the future...* [P2]

However, in the “Explainability-by-Design” subtheme, the y-axis scaling of the bar chart of the questionnaire total scores caused some confusion:

> *The bar graph on the scores page may mislead people because that scale has a larger range, it looks like, statistically, it may be much higher, but the range for the depression scale is much smaller.* [P1]

Other common understandability improvements involved the provision of hover-overs giving more information on the violin plots*:*

> *I wish there was some hover over’s here [points at the violin plots].* [P1]

The graphical explainability, which was enabled by the model transparency, was seen as a major bonus of the AI:

> *the graphics impressed me the most, but I think it’s very nice that you can go down and see how the model works* [P2]

While using the AI model for prediction and subsequently exploring the explanations of the predictions in the interface, some novel insights were revealed, as captured by the “AI-Driven Insight” subtheme. For example, participants found scenario 4 (Table 3) challenging to assess because the questionnaire total scores, which they typically relied on, were uniformly low in this case. The recommended scenario treatment was Specific Phobia, which was explained mainly by the

XSL•FO
RenderX

demographic question “Has Phobia.” When the AI prediction explanation revealed this, many participants expressed surprise:

> *So, they answered yes. Oh, didn’t see that* [P3]

> *So looking at this...What I'm thinking is I should probably have checked the fear questionnaire for specific phobias, OK, because that's nice.* [P2]

> *So, I will try to explain...to see what it says.[gets explanation from UI] They have actually said that they have a phobia...I think again, it makes sense, if it is...some kind of phobia.* [P4]

In one case, the prediction in the form of the violin plots, rather than the model explanation, revealed the insight:

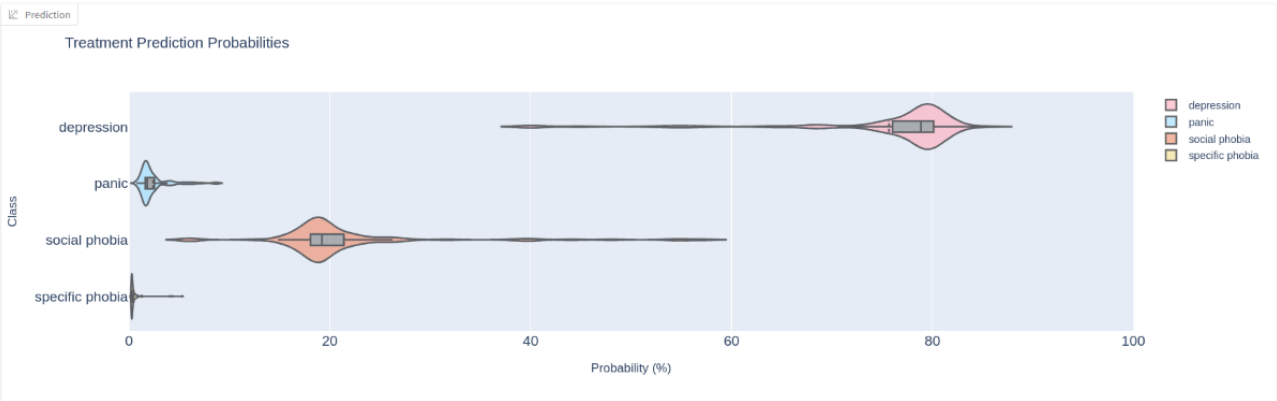
> *So this one, this definitely helped me this graph [violin plot]...More so than the other ones, because well, because I didn't see the fear...the specific phobia.* [P1]

As well as highlighting unseen aspects of the patient record, the violin plots also revealed insights about uncertainty, which is typified by this comment from participant 1:

> *The probability level wouldn't really matter. It’s just the uncertainty. If they are overlapping too much...definitely it would need to be reviewed by the team.* [P1]

In the subtheme of “UI Improvement/Usability”, participant 2 saw the Violin plots as the main aspect of sense-making:

> *As a Screener I would probably...just look at the photo [violin plots] and then I would...If it wasn’t as clear cut as this. I would click around. But you know it needs to just needs to be easy to work with.* [P2]



Theme 3: “Should I Rely on It”—Risk and Uncertainty Appraisal

Since AI adoption depends on user trust [25], theme 3 captured the bridge between making sense of the AI model and deciding to rely on it.

The guided interviews started by defining confidence and uncertainty to set the foundation for the concepts to be discussed. However, the terminology was hard to remember, and the terms were often confused with each other. Nevertheless, participants demonstrated understanding of the concepts from the violin plots, often articulated using their own terms. For example, when referring to confidence, participant 1 says, “Maybe even 70, I think would be sufficient for probability if we don’t have a lot of uncertainty either.” (P1); when referring to uncertainty, participant 3 correctly identifies it as relating to the dispersion of the violin plot, articulating it as being “unsure” “And then social phobia is somewhere between 20% and 40%, but it seems a lot more unsure about what this is actually about” (P3). This shows us that the terminology may be confusing, but the concepts were clear. For example, participants intuitively interpret the violin plots (Figure 5) to reveal the confidence (probability) and uncertainty (dispersion). Participant 4 articulates this well:

> *I think I would do it a little bit primitively, just look at where is this big round shape and where is it on the probability percent and yeah, that’s probably how I would do it...And then...about how certain it is? Yeah. OK, so I don’t know if this is very wide or not because I think that this fat bit is quite concentrated...But I think that to me, intuitively I would look at the round bit.* [P4]

Figure 5. Treatment prediction violin plot for hypothetical patient 1: treatment-depression.

All participants saw the absence of free-text input as a significant limitation of the AI model. In their normal workflow, free text provides significant information:

> *looking at what did the person actually write? I think that that’s actually where we get the most information.* [P2]

Participant 1 stressed that the free text provides important clarifying information over and above the questionnaire scores:

> *This...number three here [patient example 3] I think would need to be reviewed because there could be information in the free text that would either clarify this or make us think there’s...it’s too complicated or something else is going on that’s not picked up by our screening measures or the AI prediction.* [P1]

Although free text was seen as complementary to certain questionnaire items—for example, the Fear questionnaire specific phobia question where the free text describes the specific phobia (P1)—the lack of free-text input was also seen as a limitation to adoption:

> *I wouldn’t be comfortable not having the patient’s own words...because it can mean something else.* [P4]

XSL•FO
RenderX

> *Sometimes it can be a very clear-cut depression on the scores alone, but then we read the text, and this is a clear rejection because what they're applying for is not correct. So, I think if the AI sort of interpret the qualitative text as well and that be even better...I'd be even more in favour of it* [P5]

Theme 4: "Deciding to Use the Model"—Extrinsic Trust/Reliance

Theme 4 captures how participants moved from appraising risk to deciding to use the model in practice. In this decision phase, participants looked for external confirmation in the form of agreement with their own judgment, evidence of validation, and consistent performance, before deciding if the AI model could be relied upon, and in what circumstances. Therefore, this theme captured how the AI model fits in the process of patient screening, and the limits of perceived competence of the AI and the data it is trained on.

As patient scenarios were examined, participants demonstrated skill in the use of the AI system: making predictions, drilling down into explanations, then jumping back to the record for demographics. Participant 4 illustrates this fluidity as they gain practice assessing patient scenarios, as though they are conversing with the AI as they think-aloud:

> *We start with just panic and say 'why did you choose this' and they say that the PDSS score is a significant, which makes sense I think, and also generalised anxiety.* [P4]

The AI aligning with clinical judgment was an important factor in deciding to trust the AI. Participant 1 provided commentary commensurate with having adopted a trusting attitude whilst staying alert to clinical incongruence:

> *I haven't seen anything to suggest that I would not trust it. Everything fits with my own clinical judgment from what I've seen.* [P1]

Participant 2 highlighted the role of data in trust, implying that an AI system should come to the same conclusions as a person, given the same data:

> *[I would trust the AI] To the same degree that I would trust the system we have now because it's, you know, it's the same data.* [P2]

Participant 2 decided to adopt the AI prediction as their own fairly early in the process, when they were somewhat undecided (scenario 1), showing early willingness to put faith in the system. However, in general, trust was seen to be conditional on confidence, certainty, and context. The model could be trusted in screening clear cases to go to an interview, especially for certain cases, but not for making a diagnosis. Participants expressed this as follows:

> *If it only comes to screening, then I would probably trust it, especially if it's certain. And then if it's not certain, I would maybe spend a little longer to look at it* [P4]

> *For the clear yeses that we don't have to use our time for that, but they can just go straight to our screening interviews.* [P3]

> *I think the model thinks the same way as a Screener does. But it doesn't think like a clinician does. So as a screening tool, something that might work automatically, I can see how something like this could probably be implemented like soon. As clinical tool, I wouldn't...with what I see now, trust it to the degree that it could make a diagnosis.* [P2]

Contextually, participants wanted reassurance that the AI would take into account patient risk factors before they would recommend the AI as a screening tool.

> *We cannot have someone with a high suicidal risk. So, but if I knew this prediction took that into account, then that would be OK.* [P3]

And then only to allow a patient to proceed to the interview, never to exclude a patient:

> *I think that's long as it confirms and does not reject, I think ethically I'm less hesitant...I think as soon as we start rejecting people or limiting people's access to treatment based on automatic AI responses. That would be problematic.* [P5]

Screeners routinely assess the severity of presentation (eg, severe depression), and so any decision to put patients through to interview should take account of severity, as well as prediction confidence and uncertainty: "It doesn't say the degree of the illness or treatment or disorder." (P3). In addition, some patients (eg, suicidal or severe cases) should be rejected at the interview stage, and an AI putting patients through to an unnecessary interview could be unethical. This re-emphasizes the need to include free text in the prediction, so any prediction is as complete as possible:

> *It's a waste of patient time if they specifically write about something that in their application that I, after an hour's interview with them, says we can't help you because of this. But they already informed me about it, so they wouldn't have to sit there and open up, and get a rejection if I had just...read that before.* [P4]

The issue of causability was evident when participants questioned the reasons why certain demographics were associated with prediction explanations. Even though the participants all expressed trust in the AI generally, there was a sense that trust was suspended or withheld when explanations were associative but did not lend themselves easily to a causal explanation:

> *Yeah, and I understand that it can't necessarily explain why the data says it, but the more it can explain why, at least guess why the data says, the better. And that would definitely increase my confidence as well...So, it's not random, but it doesn't tell the story why the item is important.* [P5]

Increased use of the AI tended to build trust further:

> *Yeah, but I think I trust it more because I agree with it, or it agrees with me. Yeah, I think because I first looked at it and made my mind up from very limited data, actually...But who knows if I'm wrong and this is wrong as well. But I think I definitely trust it more*

XSL•FO
RenderX

> *than now that I've interacted a bit more with it, yeah.* [P4]

Once participants had decided to trust the AI, not agreeing with the AI's prediction, after some experience with it, evoked a suspension but not a revocation of trust:

> *With the specific phobias, there was the factors against, so I might not agree, but that doesn't make me trust the model less.* [P2]

The violin plots were seen as effective in communicating predictions, but the AI outputting notifications of when to trust/when not to trust, based on the model's own uncertainty, was thought to be required for deployment.

There was a view that the AI could be more trustworthy than humans because of its systematic reasoning:

> *It concerns me when individual clinicians look at an elevation on that score and interpret it, giving it too much weight, but I don't have a fear that the algorithm is doing that.* [P1]

However, since the participants were not given data on the verifiable validity of the model as part of the guided interview process, and although trust was evident intrinsically, future use was conditional on the validity being evidenced extrinsically:

> *I don't know how reliable or valid the model is. I think it would be an improvement of the current system.* [P2]
>
> *Perhaps we will have the data to support this in the future when the appropriate studies have been completed.* [P1]

Discussion

Thematic Analysis

The cautiously positive initial attitudes toward AI set a positive tone and likely eased movement toward reliance. If the baseline attitude had been skeptical, it is possible that the same interface features might have been interpreted more critically. Concerns about algorithmic bias were muted because the model was trained on the same data the screeners themselves used, and it was viewed as representative of the patient population and therefore acceptable.

As participants worked through the interface, a 4-stage "trust journey" (Figure 4) became apparent, providing a useful support to the literature on AI trust that conceptualizes trust as a staged, context-sensitive process [19,25]. First, participants oriented themselves to the user interface layout and information; next, they made sense of the model's operation; then they appraised risk and uncertainty. Finally, they decided whether to rely on the output, under what safeguards, and in which contexts. Progress along this trust journey was shaped by 2 elements: how specific visualizations supported sense-making and risk appraisal, and how duty-of-care requirements set boundaries for reliance. It is notable that this journey appeared to emerge in the context of using the AI in a free manner to explore various patient scenarios, rather than being enforced by the interview structure.

Understanding confidence and uncertainty in the predictions was central to trust building, with the violin plots communicating both concepts intuitively. Even though the terminology surrounding these concepts was sometimes confused, the understanding was clearly demonstrated and articulated. In use, violin plots were the main aspect that participants referred to and said they would refer to in the future, given the limited time given to screening. In moving back and forth between record, prediction, and explanation, clinicians repeatedly tested the AI's reasoning against their own judgment and, in doing so, built intrinsic trust.

The dataset available from the clinic did not include the patients' free-text inputs. From the clinical safety perspective emphasized by Coder B, trust depended on narrative completeness and safeguarding. The absence of free text limited the assessment of suicidality, comorbidity, and context, which in turn constrained willingness to rely on the tool. Integrating patient free text and providing risk-related cues in summary form would extend the contexts in which reliance is acceptable. Relatedly, questions of causability surfaced when demographic variables appeared in explanation panels: correlations were accepted as "in the data," but clinicians still sought a story that linked those variables to clinical reasoning. Adopting a pedagogical/causability approach, adding ceteris paribus ("what-if") sensitivity plots to the interface (eg, partial dependence and individual conditional expectation), could be beneficial. These displays let clinicians vary a single input while holding others constant and observe the corresponding change in the model score, supporting understanding.

Once clinicians felt that the system "thought like a screener," occasional disagreement with a prediction did not revoke trust outright; rather, it triggered a momentary suspension while they compared the model's output and explanations with their own assessment. An implication is that early alignment between user judgment and model output may accelerate reliance, but it may also seed confirmation bias. A more skeptical starting stance may have led to alignment being scrutinized more stringently.

Willingness to rely on the AI remained conditional. It was strong when the model expressed high confidence with straightforward cases but tempered in the presence of uncertainty or missing contextual information. Participants indicated that the AI may expedite low-risk referrals, but they resisted allowing it to exclude patients or establish diagnoses without human oversight.

Intrinsic trust accrued through interaction with visualizations and explanations; extrinsic trust depended on evidence of validity and calibration. The reliability analysis presented earlier addresses this requirement and should sit alongside uncertainty displays and clear guardrails as deployment criteria.

The clinical perspective (coder B) clarifies 3 conditions for acceptable use: practice-legible explanations, inclusion of narrative data for risk detection, and strict boundaries where stakes or uncertainty are high.

First, explainability must map to everyday reasoning. Violin plots conveyed the prediction confidence effectively, but transparency had to translate into explanations that clinicians

XSL•FO
RenderX

could understand in relation to their practice. The graphical explanations (Figure 3) were also effective in this regard.

Second, trust was built on the belief that the AI model and the clinician relied on the same data and had the same "understanding" of it. Repeatedly, participants returned to the absence of free-text in the patient data, believing that short-form questionnaires alone were insufficient for capturing detail, suicidality, or the subtleties of comorbidity. This concern underlined a priority for clinical safeguarding so that the AI builds trust, rather than eroding it by ignoring critical information.

Third, automation boundaries should reflect accountability. The model should be used to confirm low-risk referrals and escalate ambiguity, not to exclude patients or assign diagnoses without human oversight.

Taken together, the clinical perspective aligns with the main themes that depict a pragmatic balancing of promised efficiency against the need for interpretability, contextual trust, and ethically defensible deployment. Only when these conditions are met can the AI become dependable in the screening process. In settings where clinicians are skeptical about AI, explanations may need to be deeper and more informative, uncertainty cues may need to be more explicit, and evidence of external validation may need to be available up front, to avoid premature dismissal or resistance.

Overall, the findings portray trust as contextual and conditional. Clinicians recognize the efficiency and consistency that AI can bring to mental health screening, but require interpretability, narrative completeness, and contextual safeguards before embracing the tool fully. Trust, in this setting, is a negotiated, context-sensitive stance that evolves as users see the model's reasoning align, or fail to align, with their own.

Principal Findings

This qualitative study offers several insights into how clinicians in a web-based mental health clinic in Southern Denmark, with national coverage, formed trust in an AI-mental health model and HCI.

The participants' initial attitude to AI in mental health was framed by their positive interactions in the past with AI (eg, generative AI), and their view of the possibilities for AI to improve productivity or reduce the burden of low-expertise tasks.

Framed by the anticipated utility of AI, trust developed across a further 3 sequential themes that outlined a notional "trust journey": sense-making, risk appraisal, and a conditional decision to rely. This reflects the literature on AI trust: moving between (1) building intrinsic trust by understanding the model contextually in relation to potential use cases and user experience; (2) deciding the model can fulfill the trust contract; (3) extrinsic trust based on the functional performance. This "trust journey" provides a useful support to the literature on AI trust that conceptualizes trust as a staged, context-sensitive process.

The explainability of the AI was of particular importance in trust building. This involved several elements. First, displaying prediction confidence and uncertainty in violin plots effectively conveyed the ambiguity inherent in differential clinical decision-making. This was found to be of critical importance in building intrinsic trust, underscoring the role of interpretability in building trust in relation to the expert users' expectations. Second, the presentation of key features influencing the predicted class—including those supporting and opposing the outcome—allowed users to see that the model reasoned in a manner similar to a clinical screener. This underscores the role of interpretability in allowing an understanding to form, that the model "thought" like a clinical screener. Third, the PriSM model's feature structure, incorporating pseudo-sumscores, improved interpretability by presenting explanations in familiar terms.

Trust was contextually confined to low-risk areas of clinical practice, such as screening patients prior to interview, and with a guarantee that safety protocols would be incorporated (eg, suicidality indicator checks). Incorporating free-text patient data, which clinicians typically rely on in screening, in addition to tabular data, would increase the contextual area of trust because the model would then have exactly the same data available as the screener.

Limitations

This study offers a focused and detailed, but necessarily bounded view of clinician trust in an AI model and HCI for mental health treatment prediction. Several constraints should be acknowledged.

The participant pool was deliberately small and clinic-specific: 5 screeners from a single web-based mental health clinic in Southern Denmark, providing national coverage. While this concentration allowed for deep, reflexive engagement with the clinic context—and included the majority of its screeners—it also limits transferability, as attitudes, workflows, and organizational norms may differ in other clinical settings or professional cultures.

The encounters took place with a high-fidelity prototype, not a fully deployed system. Although the interface replicated key functions, it operated on prepared case scenarios under interview conditions. Real-world contingencies—time scarcity, partial records, competing clinical duties—were only indirectly represented. The trust trajectory observed here may evolve when the tool is embedded in day-to-day use.

The think-aloud, semistructured protocol channeled attention toward predefined topics. While this ensured coverage, it may have shaped the sequence of concerns, potentially different from those that would surface in naturalistic use. In particular, this may have influenced the notion of a trust journey that surfaced in the analysis. However, it is believed that the protocol reflected a natural workflow wherein clinicians examine the patient record and assess the treatment required. The inclusion of the AI in this workflow seemed to flow naturally during the interviews, and this gives confidence that the semistructured protocol did not overly influence the results.

The available dataset and prototype excluded free-text input, a feature that clinicians regarded as important for detecting suicidality, subtle comorbidity, and patient voice. As a result,

XSL•FO
RenderX

participants evaluated a system that they acknowledged as limited; their conditional trust therefore reflects both the strengths of transparent visualizations and explainability and the recognized absence of narrative data.

No quantitative performance metrics, such as accuracy, calibration, or validation results, were provided during the sessions. Participants formed judgments on the basis of interactive experience alone. The trust documented here thus stands without the extrinsic evidence being available to the participants.

Finally, the thematic account is explicitly reflexive. This approach, building on the expertise of 2 complementary perspectives, prioritizes interpretive richness but also means that alternative analytic lenses might organize the material differently. Because the 2 analysts conducted separate reflexive analyses, some interpretive tensions may remain; we view these as theoretically informative.

Future Work

Future work should address the concerns of participants in evaluating the AI model's conditional domain of trust. In the contractual view of trust [19], an AI model should "know what it doesn't know" and communicate this distinction to the user. The importance of known model uncertainty can be appreciated when the data distribution shifts from the statistical distributions of the training data. During these data distribution shifts, the model's predictions should be more uncertain. Thus, evaluating confidence-based metrics (eg, negative log likelihood, Brier score, static calibration error) in this scenario is an important next step in answering whether the model's uncertainty estimates are responsive to a shift even when its class predictions are unaffected, which is a desirable property in high-stakes or safety-critical applications where knowing when not to trust a prediction is as important as the prediction itself.

Once trust has been built, participants expressed a desire that less interaction with the AI would be required, so it could fulfill the participants' hopes for AI to save time. To fulfill this, we require a method of expressing confidence and uncertainty that does not rely upon inspecting violin plots. To this end, approaches such as conformal prediction should be explored as a principled method to express these factors, which are important for the context of trust. In conformal prediction, conformal sets contain the predicted class labels with a mathematical guarantee such that sets that contain more than one label, for example,{depression, panic}, can be interpreted as being uncertain [46]. Accordingly, the size of the prediction set can drive a traffic-light trust indicator: singleton (green), multilabel (amber), and abstention/empty (red).

The integration of free text in the dataset and as a model feature will be another important next step. Architecting a hybrid model that associates the text with the existing model's tabular and demographic data would bring closure to the issue of detecting suicidality, subtle comorbidity, and patient voice in the patient record. In addition, the severity of conditions expressed in text may be taken into account. We plan to address this limitation by seeking to add the free-text data to the dataset and building a hybrid model, bridging the text and tabular data into a common feature space for model processing.

Conclusions

This study supports the literature on AI trust by providing insights into how clinicians form trust in AI tools within the context of web-based mental health care. Trust was not given unconditionally but developed over time through a process of understanding, risk evaluation, and conditional reliance. This journey mirrors the AI trust literature in which AI users approach AI through trust heuristics [25] based on the alignment between the perceived explanations and their mental models [24]; ie, causability. Graphical explanations, especially violin-plot probability distributions, were readily interpreted and became the primary vehicle for intrinsic trust.

The explainability of the AI system played a critical role in this trust journey, particularly when interpretability features matched clinicians' cognitive models and expectations. Trust was seen as contextual [20]; strongest in low-risk, well-defined contexts, and was contingent on safeguards and transparency.

As such, trust was constrained by three factors with varying emphasis: (1) narrative data completeness (the absence of free-text limited perceived safety), (2) causability (clinicians would like an explanatory story, not correlations alone, but were willing to trust the data); (3) external evidence (formal validation metrics were still expected before full explicit trust would be realized). However, once the contextual risk was appraised, using the AI in the areas of trust was evident, leading to explicit trust building in the screening domain.

For AI systems to gain broader acceptance in mental health practice, they must not only be accurate but also interpretable, context-aware, and subject to ongoing evaluation. Expanding the types of patient data the AI can process—especially free-text notes—could extend the boundaries of trust and enhance clinical adoption.

Abstract

Background: The growing prevalence of allergic diseases alongside a shortage of trained allergists creates significant challenges in delivering timely care, especially for underserved populations. Telemedicine presents a promising solution, offering remote care through digital tools. While telemedicine has been widely adopted in other fields, its use in allergy care remains underexplored.

Objective: This study aimed to assess the potential of telemedicine in managing allergic diseases by examining patient preferences and experiences.

Methods: A survey of 27 questions was distributed to adult patients (>18 y) with allergic diseases attending the outpatient allergy clinic at the Division of Allergy, University Hospital Basel, Basel, Switzerland, between May and August 2024. The survey covered demographic information, prior use of telemedicine, and preferences for teleconsultation modalities. It also assessed patients' willingness to share various types of clinical data, including images and written reports, and explored which allergic diseases were considered appropriate for telemedicine.

Results: A total of 102 patients participated in the survey, with a mean age of 44.4 years (SD 16.7 y). For further analysis, the patients were stratified into four age groups: 18 - 34 years (36/102), 35 - 49 years (26/102), 50 - 64 years (31/102), and ≥65 years (9/102). Among them, 44% (41/94; *P*=.22) had previously used telemedicine services, with 34% (32/94; *P*=.04) specifically using it for allergic diseases. When asked about consultation formats, 49% (49/100) of patients preferred in-person visits, while 41% (41/100) favored a hybrid model combining telemedicine and in-person care. Regarding telemedicine tools, 57% (51/89) preferred telephone consultations with a doctor. Patients would use telemedicine preferentially for mild compared to severe allergic diseases as well as for chronic compared to acute conditions. The spectrum of diseases for which patients would use telemedicine comprised a wide range of allergic conditions, with allergic rhinoconjunctivitis (16%; 14/85), Hymenoptera venom allergy (13%; 11/85), and food allergy/intolerance (13%; 11/85) cited most frequently. Only 7% (6/85) of patients indicated they would not use telemedicine for any allergic disease.

Conclusions: This study emphasizes the growing adoption and importance of telemedicine in allergy care, with a significant proportion of patients already having experience using it for managing allergic diseases. Patients' inclination toward multiple communication formats underscores the growing need for individualized management of allergic diseases.

teleallergy; telemedicine; healthcare access; allergy management; teledermatology; synchronous communication; asynchronous communication; digital health; allergy diagnosis; teleconsultation; healthcare technology; patient-centered care

Introduction

Challenges in Allergy Care

The increasing prevalence of allergic diseases, combined with a persistent shortage of trained allergists, presents significant challenges in delivering timely and accessible allergy care. This issue is especially pronounced in underserved rural areas and among vulnerable populations, such as older adults and those with mobility impairments [1,2].

Allergic diseases encompass a wide spectrum of conditions, from common diseases such as allergic rhinitis, eczema, and food allergy, to rare and frequently severe disorders such as

XSL•FO
RenderX

mastocytosis and hereditary angioedema. Despite their varying severity, these diseases share the need for specialized expertise and ongoing, long-term management [1,2].

Potential of Telemedicine

Telemedicine, particularly during the COVID-19 pandemic, has emerged as a promising and cost-effective solution to address these challenges, utilizing digital technologies to connect patients with health care providers. It offers two primary modes of communication: synchronous, where patients and providers interact in real-time (such as video consultations) and asynchronous, which allows communication at different times. A widely used asynchronous method is store-and-forward technology, where clinical data, such as images or medical records, are uploaded in a digital patient folder for later review. This approach has been particularly effective in teledermatology, where visual assessments are crucial [3-5].

In addition to communication tools, various digital applications and technologies are available to support health care management, such as e-diaries ("digital companion") that track symptoms and therapy adherence, as well as electronic prescriptions and appointment scheduling systems that streamline health care processes [6].

While telemedicine is well-established in many medical specialties, there is limited data on its application for patients with allergies. In this study, we employed a patient-centered questionnaire to evaluate the current use of telemedicine in allergy care, to identify patients' preferred communication tools and the specific allergic conditions for which they would be open to using telemedicine.

Objective

This study aimed to assess telemedicine's role in allergy care by evaluating patient preferences, usage patterns, and conditions considered suitable for remote management.

Methods

Study Design and Participants

To evaluate patient experiences and preferences with telemedicine, we conducted a survey of 27 questions targeting adult patients (over 18 y) with various allergic diseases prior to their consultations at our outpatient allergy clinic. Exclusion criteria included language barriers, cognitive impairment, and lack of informed consent.

Inclusion and Exclusion Criteria

The questionnaire, developed in German, French, Italian, and English, collected demographic data, educational background, travel time to the nearest allergist, prior use of telemedicine services, the extent of health insurance coverage for telemedicine, and patients' preferences regarding teleconsultation modalities. It also explored which digital communication tools and clinical data types (eg, images or medical reports) patients were open to sharing. Furthermore, the survey assessed which allergic diseases (categorized as mild or severe and acute or chronic based on patients' subjective evaluation of their symptoms) patients considered appropriate for telemedicine. Questions were formatted as binary responses, multiple-choice items, visual analog scales (0 - 10), and open-ended text fields to capture comprehensive insights.

Statistical Analysis

To analyze the data collected through the questionnaire across different demographic categories, the 102 patients were categorized into four age groups: 18 - 34 years, 35 - 49 years, 50 - 64 years, and over 65 years. For continuous variables such as age, the mean and standard deviation were calculated, while categorical variables are presented as absolute frequencies (n) and percentages (%). Group differences in telemedicine usage and preferences were evaluated using χ^2 tests, with Bonferroni correction applied to adjust the family-wise error rate in multiple pairwise comparisons. Statistical significance was defined as a two-sided P value <.05. All analyses were conducted using R software (version 4.2.0; R Foundation for Statistical Computing).

Ethical Considerations

The study was reviewed by the Ethics Committee of Northwest and Central Switzerland (EKNZ). According to their assessment (Ref: Req-2024 - 00650), the project does not fall under the Swiss Human Research Act, as only anonymized data were processed, and therefore no formal approval was required.

Results

Demographics

Between May 29, 2024, and August 8, 2024, a total of 102 patients completed the questionnaire (mean age 44.4, SD 16.7 y). Age distribution was as follows: 35% participants (36/102) were 18 - 34 years old, 25% (26/102) were 35 - 49 years, 30% (31/102) were 50 - 64 years, and 9% (9/102) were ≥65 years. 61% were women (62/102). Most of the respondents lived in suburban areas with populations between 10,000 and 1,00,000 (37/101; 36%) or in rural areas with fewer than 10,000 inhabitants (36/101; 35%). Approximately, 57% participants (58/101) reported a travel time of 10 to 29 minutes to reach an allergist, and 49% (50/102) held a university or college degree (Table S1 in Multimedia Appendix 1).

Experience With Telemedicine

44% of the respondents (41/94; P=.22) reported previous use of telemedicine services. Prior telemedicine use was significantly associated with age group (P<.001), as was prior use of tele-allergy services (P<.001). The highest rate of telemedicine use was observed in the 35 - 49 age group (16/26; 62%), significantly higher than in the 50 - 64 group (P<.001) and the ≥65 group (P=.04) (Figure 1A). 39% patients (37/94; P=.04) had used telemedicine specifically for allergy-related care (Figure 1B). Prior tele-allergy use was significantly associated with age group (P<.001), and was most frequent in the 50 - 64 age group (14/30; 47%), significantly more than in the 18 - 34 group and the ≥65 group (both P<.001).

Figure 1. Patients' experience and preferences in telemedicine. (A) Patients (%) with previous experience in telemedicine. (B) Patients (%) with previous experience in telemedicine consultations for allergic conditions. (C) Patients (%) with insurance coverage for telemedicine. (D) Patients (%) by preferred consultation method. Levels of statistical significance are indicated as follows: * P< .05; ** P< .01; *** P< .001.

XSL•FO
RenderX

Awareness of Insurance Coverage

Uncertainty regarding insurance coverage for telemedicine was high, with 71% (73/102) unsure about reimbursement. This proportion was significantly greater than among those who responded with "yes" or "no" (P<.001). Awareness differed by age group (P<.001), with only 12% (3/26) of the 35 - 49 age group reporting uncertainty compared to all other age groups (P<.001) (Figure 1C).

Preferences for Consultation Formats

49% respondents (49/100) preferred exclusively in-person consultations (P=.04), whereas 41% (41/100) favored a hybrid model (P=.07) compared to telemedicine. Age-related differences in preference were significant (P<.001), with the ≥65 group being significantly less inclined to use telemedicine than all younger groups (P<.001) (Figure 1D).

Preferred Telemedicine Communication Tools and Consultation Formats

A significantly greater number of patients (70/92; 76%; P<.001) expressed interest in sharing photos and images with health care providers, whereas 61% patients (56/92; P=.01) preferred sharing brief written reports (<5 pages) (Table S2 in Multimedia Appendix 1).

A statistically significant association was observed between age and the preference for sharing photos or brief written reports (P<.001). All younger age groups showed a significantly higher preference for these communication methods (P<.001) compared to participants aged ≥ 65 years (data not shown).

The most favored telemedicine communication formats included phone calls with doctors (51/89; 57%; P=.02). Asynchronous modes such as email/chat with trained staff (27/89; 30%; P=.002) or physicians (24/89; 27%; P=.0014), video consultations with trained staff (33/89; 37%, P=.03), and digital patient information like instruction videos (27/89; 30%; P=.002) and symptom diaries (24/89; 27%; P=.0014) were significantly less preferred. Of these, preferences for phone calls with doctors differed significantly by age (P<.001). Only 4% (2/89) of participants aged ≥65 endorsed phone calls this consultation format, compared to those aged 18 - 34 (P<.001) (data not shown).

Allergic Conditions in Telemedicine

Telemedicine was considered especially helpful for managing mild allergic conditions (70/100; 70%; P=.007) and chronic conditions (48/100; 48%; P=.84), while considerably fewer participants supported its use for severe (11/100; 11%; P<.001) or acute conditions (27/100; 27%; P<.001).

Participants aged ≥65 were significantly less likely to consider telemedicine appropriate for mild allergic conditions compared to all younger age groups (Figure 2A).

For severe allergies, individuals aged 35 - 49 reported a significantly higher willingness to use telemedicine compared to all other age groups (all P<.001) (Figure 2B).

For acute conditions, adults aged ≥65 again reported a significantly lower willingness to use telemedicine compared to all other age groups (all P<.001) (Figure 2C).

Regarding chronic diseases, patients aged between 18 - 34 years, reported a significantly higher willingness to use telemedicine compared to individuals aged 50 - 64 and ≥65 (both P<.001) (Figure 2D).

XSL•FO
RenderX

Figure 2. Patients' willingness to use telemedicine based on the type of allergic disease. (A) Patients (%) willing to use telemedicine for mild allergic diseases. (B) Patients (%) willing to use telemedicine for severe allergic diseases. (C) Patients (%) willing to use telemedicine for acute allergic diseases. (D) Patients (%) willing to use telemedicine for chronic allergic diseases. Levels of statistical significance are indicated as follows: *P< .05; **P< .01; ***P< .001.

XSL•FO
RenderX

The spectrum of allergic diseases for which patients would use telemedicine encompassed allergic rhinoconjunctivitis (16.47%; 14/85), Hymenoptera venom allergy (12.94%; 11/85), and food allergy/intolerances (12.94%; 11/85) as most frequent diseases, followed by various less frequent allergic conditions (Multimedia Appendix 2).

Only a minority of patients (7.06%; 6/85) indicated they would not use telemedicine for any allergic disease (data not shown).

Discussion

Principal Findings

Our study demonstrates the increasing role of telemedicine in allergy care. We found high adoption rates of telemedicine, especially among younger patients, and a preference for hybrid models that combine telemedicine with in-person consultations. Telemedicine in allergy care is seen by patients as especially useful for managing mild conditions.

Demographics

Demographic data on age and gender in allergy patient surveys are limited, but our findings align with previous telemedicine studies, showing a mean age of 44.4 years and a higher participation rate among women [3]. The proportion of urban residents in our cohort was slightly lower compared to data from the Swiss Federal Statistical Office [7], likely due to the lower density of allergists in rural areas, requiring travel to urban centers for consultations [8].

Experience With Telemedicine

A high percentage of respondents reported using telemedicine services (Figure 1), consistent with findings from other medical fields [3,9]. This increased adoption of telemedicine in our cohort may partly be explained by the higher educational attainment often associated with higher usage rates [9]. Patients aged 35 - 49 years were the most frequent users of telemedicine (Figure 1), aligning with previous research. Interestingly, those aged 65 and older used telemedicine services more than those aged 50 - 65 years, suggesting an unmet need for digital health services among older, potentially less mobile patients—a trend also observed in other studies [10]. However, given the small sample of patients aged 65 and older (9 patients), this finding should be interpreted cautiously.

Although we could not determine the specific share of allergy services within telemedicine offerings, allergy services were not typically emphasized in studies assessing usage rates across specialties [11]. The high utilization rates in our study may also be influenced by selection bias, as participants were surveyed in the waiting area of the outpatient allergy clinic.

Awareness of Insurance Coverage

Despite 29 of the 37 Swiss health insurance providers offering telemedicine policies and basic insurance (OKP) covering telemedicine services when proven effective, 71% (73/102) of patients in our cohort were unaware of their coverage [12]. This suggests an unmet need for allergy services, as many patients may be paying out-of-pocket for telemedicine. On the other hand, younger patients, who often opt for insurance plans with higher deductibles, may find telemedicine more cost-effective than in-person visits. This trend is likely influenced by the Swiss health care system, which allows for flexible deductible options.

Older patients tend to prefer in-person consultations, likely due to concerns about remote care quality, limited familiarity with technology, and reliance on face-to-face interactions for building trust [13,14]. In contrast, 41% (41/100) of all patients preferred a hybrid model that combines telemedicine with in-person visits, while only 8% (8/100) favored telemedicine exclusively. This suggests that digital services are seen as complementary to, rather than a replacement for, traditional in-person care, enhancing access and alleviating pressure on health care systems [4,9]. Younger patients (18 - 34 y) preferred telephone consultations, particularly when integrated with video or in-person visits for comprehensive assessment. In contrast, patients over 50 years favored video consultations by a doctor (44%), likely due to their preference for face-to-face interactions [5,15].

Digital health tools, including online appointment scheduling and e-prescriptions, were widely embraced by patients aged 18 - 49, indicating higher comfort with technology in these age groups. However, adoption was lower among patients over 65, likely due to barriers such as unfamiliarity with digital platforms and concerns about data security [15-17].

The field of allergy care lacks substantial evidence on the most useful communication types for telemedicine consultations [5]. In our study, most patients expressed interest in uploading photos, a preference similar to findings from dermatology, where visual information is crucial for remote consultations [4]. Over half of the patients in our study preferred sharing detailed written reports, reflecting the complex and heterogeneous nature of allergic diseases, which may require more individualized data exchanges.

Allergic Conditions in Telemedicine

Patients in our survey expressed a preference for telemedicine in managing mild and chronic allergic diseases (Figure 2), aligning with broader trends in telemedicine across specialties [18]. While a small proportion of patients expressed concerns about using telemedicine for severe allergic diseases, some studies suggest that telemedicine can positively impact outcomes for diseases like anaphylaxis by providing specific management instructions [19]. However, telemedicine should not be considered a substitute for emergency care. It can play an important role in managing allergies, but cannot replace emergency responses or in-person care. Given that many allergic diseases are chronic and benefit from ongoing monitoring, telemedicine represents an effective approach for long-term management, a view that was supported by most participants in our study.

Limitations

While our study offers valuable preliminary insights into telemedicine use in allergy care, several limitations should be considered when interpreting the findings.

First, the sample size of 102 participants, though sufficient for initial exploration, limits the statistical power, particularly for

XSL•FO
RenderX

subgroup analyses by diagnosis and age groups. The small number of respondents aged 65 and older further restricts conclusions for this demographic, which is particularly relevant given their lower engagement with telemedicine.

Second, recruitment was conducted at a single center and participation was voluntary, which may have introduced self-selection bias. Individuals with a greater interest or familiarity with digital health tools may have been more likely to participate, potentially skewing the findings and limiting generalizability to broader patient populations.

Third, the study population included both new and follow-up patients. While this reflects real-world clinical diversity, differences in experience and expectations between these groups may have influenced their responses, particularly regarding telemedicine preferences and awareness of insurance coverage. To address these limitations, future studies should include larger and more diverse samples across multiple sites.

Conclusion

In conclusion, our study highlights the growing role of telemedicine in allergy care. High adoption rates, especially among younger patients, suggest that telemedicine can complement in-person care. Future retrospective research is needed to refine teleconsultation strategies, enhancing diagnostic accuracy, therapeutic effectiveness, and patient satisfaction, thereby maximizing patients' benefits from telemedicine in allergy care.

Acknowledgments

We sincerely thank all patients in this study for their time and effort in completing the questionnaire, which provided invaluable insights.

Conflicts of Interest

All authors declare that economic interests had no influence on the preparation of this manuscript. Abstract

Background: Artificial intelligence (AI)–driven mobile health (mHealth) apps are emerging as a promising tool for health management, yet little is known about users' psychological perceptions and attitudes toward these technologies. Understanding these aspects is crucial for both the appropriate design and the effective use of these technologies, ensuring the psychological and physical well-being of potential end users.

Objective: This study aimed to investigate the attitudes and perceptions of young adults toward a possible use of AI-driven mHealth apps, focusing on the perceived benefits and potential concerns related to their future adoption.

Methods: A qualitative focus group methodology was used. Fifteen participants (12 men, 3 women; mean age 27 years, range: 25 - 34 years) were recruited. Data were analyzed using thematic analysis to identify key themes influencing engagement with these technologies.

Results: Four main themes emerged: "Usability," which emphasized the importance of user-friendly, personalized experiences; "Innovation and Reliability," where participants expressed both enthusiasm and skepticism towards AI's potential; "Affectivity and Interaction with AI," highlighting mixed opinions on the emotional impact of AI interactions; and "Perceived Risks," which focused on concerns regarding data privacy and the need for human supervision. These factors contributed to ambivalent attitudes toward AI-driven mHealth apps, with some participants being open to adoption, while others remained cautious.

Conclusions: To foster greater engagement with AI-driven mHealth apps, developers should prioritize usability, trust, emotional support, and privacy issues, considering users' psychological needs and expectations. The findings offer valuable insights for designing more user-oriented mHealth solutions. Further research should explore how perceptions evolve with direct experience and long-term use.

AI-driven mHealth apps; user attitudes; thematic analysis; perceived risks; usability; innovation and reliability; emotional interaction; privacy concerns; mobile health; artificial intelligence

Introduction

In recent years, the rapid advancement of artificial intelligence (AI) has had a profound impact on various sectors of society, shaping industries, decision-making processes, and everyday experiences [1-3]. One of the most significant developments has been the rise of generative AI models, such as ChatGPT, Midjourney, and Gemini, which have gained widespread attention for their ability to generate human-like text, images, and other creative outputs. This rapid proliferation of AI-driven tools has sparked discussions about their integration into multiple aspects of daily life, from education and entertainment to professional services and health care [4].

Among these domains, health care has emerged as a particularly critical area for AI innovation, with growing interest in leveraging AI technologies to improve medical diagnostics, treatment recommendations, and patient support systems [5-7]. A specific and increasingly relevant subset of AI applications within health care is mobile health (mHealth) [8]—digital platforms designed to support health-related services and patient engagement via smartphones and other mobile devices. mHealth apps have gained popularity due to their accessibility and convenience, enabling users to track their health metrics, receive medical advice, and engage with health care providers remotely [9].

The integration of AI into mHealth apps is gaining momentum as developers seek to enhance functionalities through AI-powered tools, such as chatbots for patient interaction, symptom checkers, and personalized health recommendations [10,11]. In this context, AI-driven mHealth apps—defined as mHealth platforms that integrate AI-based tools to process health data, provide interactive support, and deliver tailored

XSL•FO
RenderX

recommendations [8]— are emerging as a new frontier in digital health care. However, given the current state of development, only a small number of users have had a direct experience with these beta versions that incorporate AI-driven features. This limited exposure reflects the early stages of these apps and the challenges in widespread implementation. Despite this momentum, the introduction of AI in such a sensitive domain as personal health management raises several concerns and uncertainties [12,13]. Unlike traditional health care solutions, AI-driven mHealth apps rely on machine learning algorithms, raising concerns about privacy, security, transparency, and potential biases. While these technologies offer promising advancements, current discussions in the literature and public discourse reveal a landscape marked by both enthusiasm for innovation and apprehension regarding ethical, technical, and social implications [14,15].

One of the key gaps in the literature concerns the public perception toward the integration of AI within mHealth apps. While previous studies have explored the technical feasibility and the general acceptance of AI in health care settings, including hospitals and clinical diagnostics, there is limited research focusing specifically on mHealth apps incorporating AI-powered tools—such as interactive chatbots handling personal data and health-related information—and the way everyday users perceive their benefits and risks [16-18]. Given that these apps are designed to operate in highly personal and private contexts—potentially serving as a first point of contact for health-related inquiries—it is crucial to explore what expectations, concerns, and attitudes individuals hold toward them, even in the absence of direct experience or exposure to these tools, and what factors influence their acceptance or skepticism [19]. Unlike AI adoption in traditional medical environments, where health care professionals act as intermediaries, mHealth AI tools are envisioned to function autonomously, making user trust and acceptance even more critical key factors to investigate [20].

Existing research on AI acceptance has examined factors like trust, perceived usefulness, and data privacy concerns [12,14,21], but studies specifically addressing these aspects within mHealth apps remain limited. Given the relatively early stage of AI implementation in mHealth, understanding public attitudes is crucial for shaping ethical, effective, and user-centered AI applications in health care. Issues related to data privacy, trust in AI-generated recommendations [12], potential biases in AI algorithms [19], and the perceived reliability of AI-driven health tools remain underexplored in relation to users' willingness to adopt such innovations [6].

Given the novelty of AI integration in mHealth, this study specifically examines young adults (25‐35 years old) as a strategically relevant demographic. This cohort represents both the primary users of digital health technologies [22-24] and digital natives who are more likely to engage with emerging AI interfaces compared with older aged groups [25,26]. Focusing on this population helps minimize age-related technology adoption biases that might confound perceptions in older groups, while providing insights from individuals most likely to shape early adoption patterns.

Against this backdrop, this study aims to explore the key factors shaping individuals' attitudes toward the integration of AI tools within mHealth. Specifically, it investigates perceived risks, doubts, and concerns, as well as potential benefits and innovations that users associate with AI-powered health technologies.

The remainder of this article is structured as follows: the next section outlines the materials and methods used in this study, detailing the research design, data collection process, and analytical framework. This is followed by a comprehensive presentation of the results, highlighting key findings related to public perception, concerns, and expectations. The discussion section then interprets these findings in the context of existing literature, drawing comparisons with previous studies and identifying potential implications for developers, health care professionals, and policymakers. Finally, the conclusion summarizes the primary insights derived from this research and outlines possible directions for future studies in this rapidly evolving field.

Methods

Study Design

The study used a qualitative research approach based on focus group discussions. Two focus groups were conducted in January 2025 to explore participants' perspectives, experiences, and opinions on the topic. Focus groups were chosen as they foster discussion, allowing for the emergence of insights that might not surface in individual interviews [27]. This format enables participants to engage with one another, facilitating a more comprehensive understanding of shared and divergent viewpoints [28,29].

Ethical Considerations

The study design, procedures, and informed consent form were evaluated and approved by the local commission for minimal-risk studies of the Psychology Department of the University of Milan-Bicocca (protocol number RM-2024‐854). Participants did not receive any compensation for their involvement.

Study Participants

The study involved 15 participants (12 males and 3 females) aged 25 to 34 years old. The first focus group included 7 participants (6 males and 1 female) aged 25 to 28 years old, while the second group consisted of 8 participants (6 males and 2 females) aged 25 to 34 years old. Participants were selected through a snowball sampling method via messaging apps (eg, WhatsApp [Meta]) to ensure diversity while maintaining relevance to the research topic. Each session lasted approximately 120 minutes.

Eligibility criteria required participants to: (1) be young adults or digital natives (18-35 years old), (2) have varying levels of familiarity with mobile health (mHealth) apps and AI, assessed through a preliminary question during recruitment, and (3) be over the legal age. The participants were evenly distributed between the 2 groups based on their levels of familiarity with and usage of mHealth apps and AI, in order to create as

XSL•FO
RenderX

homogeneous groups as possible and encourage a more productive discussion.

While recruitment efforts sought a balanced sample, the final composition resulted in a gender imbalance (12 men vs 3 women), primarily due to participant availability and recruitment challenges. This limitation is further addressed in the discussion section, where its potential impact on the findings is considered, along with other constraints of this study.

Procedure

Each focus group followed a structured discussion guide to ensure consistency while allowing for open-ended exploration of key themes. The sessions were moderated by a researcher and lasted approximately 120 minutes. The focus groups were conducted remotely via WebEx, ensuring accessibility for all participants.

At the beginning of each session, participants were welcomed and thanked for their participation. The moderator briefly introduced himself and provided an overview of the study's objectives. A general definition of mHealth apps was presented, outlining their main types and uses. The concept of a focus group was explained, including its purpose and ground rules, such as mutual respect, open expression of opinions, and the absence of right or wrong answers. Participants were reassured that their insights were valuable and encouraged to share their perspectives freely.

To create a comfortable and engaging atmosphere, the discussion began with an icebreaker activity, where participants introduced themselves by sharing their names, age, and professional background. This step aimed to foster interaction and establish a collaborative dynamic. The discussion proceeded with a series of structured interactive exercises. First, a free association exercise (mHealth apps), in which participants were asked to list 3 words that came to mind when thinking about mHealth apps. Their responses were visualized in a word cloud using Mentimeter. Each participant then explained their choices, and an open discussion followed to explore shared and contrasting views. Second, anchored association exercise (mHealth apps and AI); the previous exercise was repeated, this time focusing on AI-driven mHealth apps. Participants provided 3 words, which were compiled into another word cloud. The discussion centered on emerging themes and differences in perception between traditional and AI-enhanced mHealth apps. Third, a role-playing scenario (using an AI-integrated mHealth app), where participants were asked to imagine using an AI-integrated mHealth app and to identify one advantage and one disadvantage of such technology. Their responses were collected, and a group discussion was conducted to explore the potential benefits and challenges of AI in health care apps. Fourth, preferred communication style for AI chatbots; participants described their ideal AI chatbot communication style by selecting three descriptive words, which were visualized in a word cloud. They then explained their choices, leading to a broader discussion on expectations and preferences regarding AI-driven health communication. Fifth, ranking exercise (AI chatbot communication features), in which participants were asked to rank the words from the previous exercise in order of importance, reflecting their priorities for chatbot interaction. The final group ranking was analyzed collectively, and participants shared their reflections on the results. The focus groups concluded with a summary of key discussion points, followed by a debriefing on the study's objectives and the intended use of the collected data. Participants were invited to ask any final questions or provide additional comments before the session ended.

Data Analysis

The 2 focus group sessions were audio-recorded and subsequently transcribed. The transcripts were analyzed qualitatively using inductive thematic analysis, following the 6-phase approach outlined by Braun and Clarke [29]: (1) familiarizing with the data, (2) generating of initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes and, (6) producing the report. This analytical approach is inherently recursive rather than strictly linear, allowing for flexibility in revisiting and refining earlier phases as new insights emerge. Thematic analysis was chosen as it enables an in-depth exploration of participants' perspectives, capturing both shared viewpoints and individual divergences, thereby facilitating a nuanced understanding of the topic under investigation.

To ensure a rigorous and unbiased analytical process, 2 researchers independently reviewed the transcripts multiple times, noting initial impressions and generating preliminary codes. This parallel approach was intended to minimize researcher bias and provide a broader interpretative perspective. The degree of agreement between the 2 researchers was calculated directly, resulting in an agreement rate of approximately 82.76%, indicating a very high level of consistency. After calculating the agreement, the researchers presented their identified codes, explaining the rationale behind their choices and highlighting areas of consensus and divergence. Through discussion, they worked toward a shared interpretation, reconciling differences where necessary. This collaborative process enabled the researchers to refine the thematic structure, identifying the main themes for the thematic analysis.

Once the themes were clearly defined and named, representative verbatim excerpts were selected and organized in a table, alongside their corresponding codes and main themes. Data were analyzed in their original language to preserve participants' intended meanings, while coding and theme development were conducted in English. The selected transcript examples were translated into English for reporting purposes.

Results

Overview of the Findings

The participants were divided into the 2 groups considering their levels of familiarity with and usage of mHealth apps and AI. Specifically, 8 out of 15 (mean 53.3%, SD 12.9%) reported frequent use or a positive attitude toward mHealth apps, while 7 out of 15 (mean 46.7%, SD 12.9%) used them less often or not at all. Similarly, all participants had used AI at least once, with 9 out of 15 (mean 60.0%, SD 12.6%) being frequent users,

XSL•FO
RenderX

while the remaining 6 (mean 40.0%, SD 12.6%) used AI sporadically or were opposed to it.

Four themes were identified in relation to the research question: "Usability," "Innovation and Reliability," "Affectivity and Interaction with AI," and "Perceived risks." The "Usability" theme included 3 subthemes: personalization, accessibility and cost, and AI communication style. The "Innovation and Reliability" theme encompassed subthemes related to reliability and understanding, perceived innovation and trust in technology, and use as a monitoring tool. The "Affectivity and Interaction with AI" theme explored the emotional and interactive dynamics with AI, with subthemes of psychological impact and human-AI interaction. Finally, the "Perceived Risks" theme addressed concerns about data privacy and management, the need for human supervision, and uncertainties surrounding the use of AI in mHealth apps, with subthemes including privacy and data security, human oversight and control, and uncertainty and knowledge gaps (refer to Table 1 for a brief description of the themes and subthemes).

Table . Summary of the themes and subthemes that emerged from the thematic analysis.

Themes and subthemes	Description
Usability	This theme addresses how participants perceive the features of mHealth[a] apps with AI[b], focusing on aspects like personalization, accessibility, and AI communication style.
Personalization	The extent to which AI adapts to individual needs, progress, and personal data, offering tailored support and interactions.
Accessibility and cost	Reflections on how easy it is to access and use these apps, along with considerations of their affordability.
AI communication style	Preferences regarding the tone, manner, and ideal interaction style of the AI when addressing users.
Innovation and Reliability	This theme explores the level of trust participants have in mHealth apps with AI, their perception of innovation, and how these technologies are used.
Reliability and understanding	How reliable participants perceive AI to be in providing accurate and useful responses.
Perceived innovation and trust in technology	How participants perceive AI as either a necessary advancement or a technology to be approached with skepticism.
Use as monitoring tool	Reflections on the role of mHealth apps with AI primarily as tools for tracking personal health data.
Affectivity and Interaction with AI	This theme examines the emotional dynamics, uncertainties, and interactions between users and AI in mHealth apps.
Psychological impact	Emotions evoked by interacting with an AI chatbot in a health context, including motivation, anxiety, trust, and skepticism.
Human-AI interaction	Reflections on the comparison between AI chatbots and human operators, highlighting the advantages of personalization and constant availability, but also the need for human interaction for trust and understanding.
Perceived Risks	This theme addresses concerns related to data privacy, the need for human oversight, and uncertainties regarding the use of AI in mHealth apps.
Privacy and data security	Concerns about who manages the collected data, the level of access AI has to personal information, and the differences between traditional health apps and those with AI.
Human supervision and control	The need for human oversight to ensure safety, particularly in managing sensitive health data and situations.
Uncertainty and knowledge gaps	Difficulties in understanding how AI-powered apps work, concerns about the technology, and broader issues such as environmental impact.

[a]mHealth: mobile health.

[b]AI: artificial intelligence

Usability

Overview

Participants emphasized the practical advantages of AI-driven mHealth apps, particularly their precision, ease of use, and ability to deliver personalized, real-time support that enhances user experience. In addition, affordability was identified as an important factor that might influence the adoption of such technologies. However, opinions diverged regarding the preferred communication style, with some imagining a preference for a formal and direct approach, while others anticipated a more friendly and engaging interaction.

XSL•FO
RenderX

> *Like, just thinking about AI doing an initial screening for acceptance—it could speed things up. Or you ask it something, and it gives you an answer in 30 seconds instead of having to book an appointment six months later. But that's only if it's really accurate. I don't know, maybe for very basic things. I'm not sure where the line is between what you can actually ask a chatbot in an app and what really needs a doctor in a proper visit.* [Female #1]

> *So, it turns out to be more precise and easier to use compared to a regular app—more targeted and more user-friendly. I think this would make people more likely to use it.* [Male #8]

> *Artificial intelligence offers more engaging suggestions compared to a regular application that lacks this feature.* [Male #10]

Subtheme 1: Personalization

A major perceived advantage of AI-driven mHealth apps was thought to be their ability to provide a highly personalized experience. Participants highlighted the value of dynamic personalization, imagining apps that refine recommendations based on progress and align with individual needs and goals to enhance engagement. This dynamic personalization was considered a key differentiator from traditional mHealth apps.

> *Personalization is the key because, imagining this app, I see a section where I can specify my interests, what I enjoy doing, and my goals. […] In my view, the main advantage of artificial intelligence in this context is a better match between user interests and objectives […] For example, I imagine an app that suggests hiking trails—places I wasn't aware of but that, thanks to artificial intelligence, it can recommend based on my activity level and the preferences I've set.* [Male #7]

> *The ability to customize a tool definitely adds value—it can do the work for us, access more data, process it, and provide what I'd consider a better answer.* [Female #2]

Subtheme 2: Accessibility and Cost

Participants valued the immediacy of AI-powered responses, considering them a key advantage for health and fitness management. However, some raised concerns that the speed of response might compromise the depth and accuracy of the provided insights. Given these potential limitations, participants agreed that these services should ideally be financially accessible, ensuring that they could remain a cost-effective alternative to professional consultations.

> *The cost is a concern—it shouldn't be more expensive than consulting a nutritionist, that's for sure.* [Male #9]

> *The ability to receive immediate information is always a strong point.* [Male #2]

> *Speed is crucial—the fact that I don't have to wait for a human response would be a fundamental advantage.* [Male #7]

Subtheme 3: AI Communication Style

There was no consensus on the preferred communication style for AI-powered chatbots, which are considered a key tool for the envisioned AI-driven mHealth apps in this study. Some participants favored a pragmatic, direct approach—emphasizing clarity and efficiency in responses—could be more effective. Others preferred a friendlier, more conversational tone, which might be preferable, especially when discussing sensitive health-related topics, where the ideal tone might depend on context. While a professional, detached tone could enhance credibility in medical discussions, a warmer and more engaging approach could be better suited for fitness or lifestyle guidance.

> *It should be pragmatic—it needs to provide concise and direct answers to the issues I bring up.* [Male #10]

> *(it should be) Formal and straightforward, because I'm not looking for casual chat or small talk. If I use an app or chatbot, I don't need friendliness—I just want something fast, efficient, and simple, without being overly technical.* [Female #1]

> *I don't think I'd want a friendly interaction. In fact, that kind of interaction bothers me.* [Male #12]

> *I'd like the chatbot to address me in a friendly manner, but not as if it were a doctor or an ultimate expert trying to teach me how to live.* [Male #4]

> *Whatever role this bot is designed to take on, I believe each role requires a different communication style. If it is meant to provide medical advice, it should, like human doctors, maintain a professional and detached approach to preserve its credibility.* [Male #1]

Innovation and Reliability

Overview

Participants expressed mixed opinions regarding the reliability of AI-driven mHealth apps, particularly in terms of the accuracy of the information these apps might provide. While some recognized their potential, others emphasized the need to verify AI-generated insights before relying on them. Trust in AI technologies varied among participants, with some seeing it as an intriguing and potentially valuable tool for health management, while others remained skeptical about their consistency and applicability across different health-related contexts.

> *I don't mind if the app has a deeper understanding of me—this doesn't scare me; on the contrary, it intrigues me. In a way, it even adds a bit of creativity to using the app.* [Male #11]

> *How reliable is the information provided by artificial intelligence? It might be useful in certain areas, but I'm not sure it's equally reliable across all applications.* [Male #3]

Subtheme 1: Reliability and Understanding

A recurring concern among participants was the degree of trust they might place in AI-generated responses. While some recognized advancements in AI technology, they remained

XSL•FO
RenderX

cautious about the possibility of errors or misleading recommendations. Several participants highlighted that the reliability of these apps could depend on the sophistication of the AI model used, acknowledging the significant progress made in 2025. Despite these improvements, many participants indicated that they would still prefer consulting a human expert, particularly when dealing with complex or highly personalized health concerns—a topic that will be further explored in relation to theme 4: perceived risks, subtheme 2: human supervision and control.

> *A chatbot can make serious mistakes. Trusting a bot instead of a human is risky—of course, humans can also make errors, but a person can look you in the eye and read between the lines, whereas a bot operates in a more uncontrolled manner.* [Female #2]
>
> *The risk is that it might promote certain behaviors that are not suitable for everyone.* [Male #12]
>
> *The chatbot's level is important. If we're talking about something as advanced as ChatGPT or Gemini, I think we've reached a very high standard by 2025.* [Male #9]

Subtheme 2: Perceived Innovation and Trust in Technology

Participants expressed divergent views on the role of AI in health care, oscillating between enthusiasm for its potential and skepticism about its long-term impact. Some perceived AI as a temporary trend, doubting that its applications would revolutionize health management in a meaningful way. Others, however, regarded AI as an evolving tool with growing significance, predicting that it would become increasingly integrated into daily life and professional settings.

> *I wrote down "innovation" and "trend" … But to be honest, I have some doubts about calling it "innovation"—I see it as more of a trend, in my opinion.* [Male #5]
>
> *I don't agree with calling it a trend. Even though AI is experiencing a huge boom right now, it's being used everywhere, and I don't think it's just a passing fad. I believe AI is here to stay, to improve further, and, in a way, to increasingly permeate our lives.* [Male #4]

Subtheme 3: Use as Monitoring Tool

One of the most frequently mentioned applications of AI-driven mHealth apps was their role in health monitoring, with participants seeing AI tools as a way to enhance traditional mHealth apps they were already familiar with. These apps were envisioned as valuable for tracking health parameters like medical health, sleep patterns, nutrition, and physical activity, offering the ability to record, manage, analyze, and visualize personal data, especially when combined with AI-driven personalization and real-time feedback.

> *What I like most about these apps [traditional mHeatlh apps] is their ability to track progress. It's not so much about receiving notifications to remind me to move […] I would appreciate If they provided me an overview of how things have been going over time—whether there have been improvements or declines.* [Male #11]
>
> *I used an mHealth app for running, mainly for tracking my progress. […] If the app included also an AI chatbot that guides my training and suggests specific workouts it would be even easier.* [Male #5]
>
> *The fact that an app can monitor my physical condition, diet, and habits is really convenient. I can see changes over time and adjust my habits immediately.* [Male #4]

Affectivity and Interaction With AI

Overview

The focus groups highlighted various concerns and reflections regarding the psychological implications of interacting with AI-driven mHealth apps, especially if chatbot-based consultations were to replace human specialists. Participants expressed mixed feelings about this potential shift, recognizing both potential benefits and drawbacks.

> *Anxiety and motivation go hand in hand. I haven't used these apps [mHealth traditional apps] much, but when I did, they always started with motivation but ended up making me anxious.* [Male #2]
>
> *If it's about something sport-related—like asking the chatbot how many kilometers I should run to train for something—that's fine. But if it's a deeper health-related conversation about symptoms or medical issues, it would feel strange to discuss it with a chatbot. I would find it a bit distant.* [Female #1]

Subtheme 1: Psychological Impact

From an emotional perspective, participants described a range of potential psychological effects associated with these apps. Some raised concerns about increased stress levels, particularly due to frequent health-related notifications, which could inadvertently heighten anxiety rather than alleviate it. Participants also raised concerns about how AI-generated recommendations might affect motivation and emotional well-being, suggesting that the absence of human interaction could reduce accountability or increase stress in some users. Conversely, several participants viewed AI-driven support as an opportunity for greater personal empowerment. In this regard, they suggested that receiving recommendations from an app—without the perceived pressure of a direct human interaction—might foster a sense of autonomy and reduce stress.

> *I already don't sleep much. If I had an app telling me "It's 8 PM, time to go to bed," I'd get even more anxious, and, in the end, I'd probably stay up until 3 AM.* [Female #3]
>
> *My fear is that if this AI provides recommendations, support, and guidance, I might lose autonomy—especially regarding diet and exercise. Since the chatbot is always available, it's different from dealing with a professional.* [Male #11]

XSL•FO
RenderX

> *Thinking of something that is a pro and con at the same time... For example, besides sports, another thing mentioned earlier is the area of diets, meal plans, etc. Maybe you don't feel the anxiety of saying, "Oh no, I didn't stick to this," if you just report it to an app. Indicating that you didn't meet a certain goal doesn't come with the fear of judgment or reactions. [...] But the downside is that you might lack some motivation, because you think, "Who cares if I write on my phone that I binged on sweets?"—compared to having to admit it to a real person, like a professional you're seeing.* [Female #1]

Subtheme 2: Human AI Interaction

The nature of the interaction between humans and AI was another key theme that emerged. Some participants reported that chatbot-based consultations could potentially lack warmth, emotional support, and the relational aspects that characterize human interactions, particularly in health care settings. This perceived absence of a human element was viewed as a limitation, potentially reducing the effectiveness of AI-driven consultations. However, others saw the use of AI as an advantage, as it might provide a neutral and judgment-free environment for discussing personal or sensitive health concerns. In this sense, rather than creating a sense of detachment, AI-driven apps could offer a new and alternative way of engaging with health-related issues.

> *The real loss would be the human element—the fact that we would be handing over this work to something that isn't human.* [Male #5]

> *If I imagine consulting a human—a doctor or a nutritionist—they can provide reassurance and emotional support. I'm not sure a chatbot could offer the same kind of relational interaction.* [Male #11]

> *There are now online platforms offering certified psychotherapy sessions. On one hand, these services involve professionals, but on the other, the screen can be both a barrier and a tool that helps people open up.* [Female #2]

Perceived Risks

Overview

The adoption of AI-driven mHealth apps could bring various uncertainties that would need to be addressed before these technologies can become widely implemented with minimal risks to users. Among the most prominent concerns raised during the focus group discussions were issues related to data privacy, the potential need for human oversight, and broader knowledge gaps regarding AI's role in health care.

> *The risk is that the app might promote behaviors that are not suitable for all individuals or body types and fail to acknowledge differences.* [Male #12]

> *The issue of privacy is significant. How much data do I have to provide to get a personalized AI-powered service? That's something I worry about.* [Female #2]

Subtheme 1: Privacy and Data Security

A significant portion of participants voiced concerns regarding the collection and management of sensitive personal data, particularly health-related information. They questioned the extent of the data being requested, the entities responsible for processing it, and the specific purposes for which it might be used. Some participants advocated for state or governmental oversight of data management, believing that public regulation would provide greater protection than private organizations. However, a shared expectation across the discussions was the need for transparency in data handling. Participants emphasized that sensitive health data should not be exploited for commercial purposes, such as market profiling.

> *Speaking of privacy, I remember an incident—last year, I think—in the United States. In some states where abortion had been made illegal, women using period-tracking apps found out that their sensitive data had been sold. That's definitely worrying.* [Female #3]

> *In my opinion, the data shouldn't be, let's say, managed by private companies, but by the national healthcare system. So, basically, the management should be as state-run as possible.* [Female #2]

> *Privacy is a big concern. You hear people talking about it—what happens to our data when we use these apps?.* [Female #1]

Subtheme 2: Human Supervision and Control

Many participants agreed that AI-driven mHealth apps should be envisioned not as standalone tools but rather as supplementary aids under the guidance of health care professionals. These apps were viewed as potentially useful in assisting specialists but not as substitutes for expert judgment. The presence of a medical professional was regarded as crucial to ensure the accuracy of recommendations, assist users in interpreting AI-generated advice, and safeguard sensitive data.

> *Losing the human element is dangerous, especially in healthcare. I would feel more comfortable talking to a doctor who can guide me through my health journey.* [Male #5]

> *As long as there is human oversight, AI in these apps is fine.* [Female #3]

Subtheme 3: Uncertainty and Knowledge Gaps

The discussions also highlighted various uncertainties and knowledge gaps surrounding AI technology and its integration into health care applications. Participants expressed uncertainty about how well AI could handle the complexity of health-related issues, particularly when distinguishing between everyday concerns and more serious conditions. They also raised unexpected but resonant concerns about the long-term implications of widespread AI adoption, such as its environmental footprint.

> *For very basic issues, AI might work. But where is the boundary between what a chatbot can handle and what requires a real doctor's visit?* [Female #1]

XSL•FO
RenderX

> *I think the risk of errors decreases over time, but another concern that hasn't been mentioned is the environmental impact. AI consumes a huge amount of energy, and if we start using it for everything, including these apps, we might face sustainability issues.* [Male #7]

Discussion

This section presents the principal findings regarding individuals' attitudes toward AI-driven mHealth apps, followed by a discussion contextualizing these results within existing literature. Both consistencies with previous work and novel insights from the study are highlighted, followed by an examination of the limitations and suggestions for future research directions.

Key Findings

This study explored how potential users perceive and anticipate AI-powered mHealth applications, identifying key factors that could influence usability, reliability, emotional interaction, and perceived risks. The findings suggest that participants associated personalization, accessibility, and data monitoring with significant advantages, whereas primary concerns centered around privacy, data security, and the reliability of AI-generated information. In addition, aspects such as communication style and the role of human interaction elicited mixed opinions, highlighting an ambivalent attitude toward adopting these technologies. These attitudes seemed closely linked to past experiences, with factors like monitoring and cost being evaluated through familiarity with traditional mHealth apps, while aspects like speed and automation were framed within broader AI-related expectations.

Participants appreciated the potential accuracy and adaptability of AI-driven mHealth apps, recognizing their ability to enhance user experience through tailored recommendations and real-time updates. However, preferences regarding AI's communication style varied: while some users favored a clear and professional tone, others found a more friendly and engaging approach to be more effective. To accommodate this diversity, app developers could consider integrating customizable tone settings or adaptive algorithms that adjust communication style based on user preferences or behavior [30,31]. Furthermore, despite acknowledging the accessibility and cost-effectiveness of these technologies, some participants expressed concerns about the quality and depth of AI-provided responses compared to professional consultations. This highlights communication style as a key design consideration and suggests that tone flexibility may improve user comfort and engagement.

Reliability emerged as another critical issue. While some participants viewed technological advancements as a positive factor, many emphasized the need to verify AI-generated information before fully relying on it. This concern reflects broader uncertainties about AI's role in health management, balancing its potential as a supportive tool with skepticism about its ability to replace human judgment, particularly in complex or sensitive situations.

Given the novelty of AI-driven mHealth apps and the limited direct experience with these tools, participants' attitudes were largely shaped by past interactions with traditional mHealth apps for certain factors (eg, monitoring and cost) and by their broader knowledge or experiences with AI for others (eg, speed and automation). This suggests that their perceptions stem from an attempt to integrate these 2 reference points. Future research could further investigate how these general attitudes develop, whether certain factors weigh more heavily in shaping acceptance or rejection, and what individual differences contribute to the ambivalence observed in responses to these emerging technologies.

Relation to Existing Literature

While very few studies have directly examined users' perceptions of the risks and benefits of AI-driven mHealth apps [8,32], existing research has explored related aspects by focusing either on AI in health care more broadly or on the characteristics and user expectations of traditional mHealth apps. Some findings from these studies are consistent with those of this study, whereas others reveal key differences that emerge when AI is integrated into mHealth solutions.

Usability emerges as a key factor influencing attitudes toward AI-driven mHealth apps, with personalization playing a particularly strong role in fostering positive perceptions. Participants anticipated AI's ability to offer tailored recommendations, real-time feedback, and enhanced accessibility—features that, when combined with the affordability of mHealth solutions (eg, diet planning or personalized fitness programs), were imagined to make AI integration particularly appealing. These findings align with existing literature on user engagement in mHealth, which emphasizes customization as a critical driver of adoption [9,27,28]. However, this study also reveals a degree of ambivalence: while many users envisioned AI as efficient and convenient, others expressed uncertainty about its communication style and interaction patterns. This variability in perception suggests that attitudes are shaped not by direct experience with these technologies but by an attempt to extrapolate from existing knowledge of AI and mHealth.

The theme of innovation and reliability elicited mixed reactions, with attitudes varying significantly based on users' previous knowledge of AI and mHealth apps rather than the actual use. Some participants imagined AI as a natural progression in digital health care, viewing it as a promising tool for health management—an attitude that may reflect a form of pro-innovation bias [33], where technological advancements are perceived as inherently beneficial. Conversely, others remain skeptical, particularly regarding the accuracy and reliability of AI-generated recommendations. This skepticism appeared more connected to general concerns about AI technology rather than direct experience with AI-driven mHealth apps [12,21], suggesting that participants' attitudes reflected pre-existing beliefs about AI's trustworthiness rather than firsthand interactions [10,34,35].

Reliability concerns also intersected with how users perceive mHealth apps as a monitoring tool. While some individuals expected AI-driven mHealth apps to enhance traditional tracking

XSL•FO
RenderX

features through advanced data analysis and personalization, others remained cautious about their role in delivering medical advice. The qualitative data suggests that trust in AI-driven recommendations depended more on participants' general exposure to AI-based tools rather than direct usage of AI-driven mHealth apps. Participants familiar with AI-powered technologies appeared more open to their guidance, whereas those with limited knowledge expressed greater hesitation—a dynamic consistent with patterns observed in AI adoption literature [19,21,36]. These findings reinforce the notion that trust in technology is not only shaped by technical performance but also by users' broader conceptualizations, expectations, and personal experiences of AI in different contexts.

The psychological and emotional impact of AI-driven mHealth apps presents a particularly nuanced dynamic, as the same features were imagined to elicit contrasting reactions among different users. One central factor in this divergence was human-AI interaction, particularly in hypothetical scenarios where AI replaced direct human engagement. Some users expected AI-based coaching to reduce social pressure, finding it less intimidating than interactions with human professionals. For them, AI was envisioned as a judgment-free space for self-improvement, enhancing feelings of control and autonomy—a benefit highlighted in studies examining patient-clinician dynamics [37]. However, others express discomfort with the absence of human empathy, speculating that AI may fail to provide the emotional support and nuanced understanding required in sensitive health-related contexts, as noted in research on AI's limitations in therapeutic settings [38].

This tension is closely connected to the broader discussion on human supervision and control. Participants who are skeptical of AI's role in health care emphasize the need for human oversight, particularly in situations where AI-generated advice could have serious implications. This perspective aligns with frameworks proposing hybrid human-AI systems [39], and is supported by findings showing concerns about fully automated health solutions in the absence of clear human intervention mechanisms [40]. These observations collectively reinforce the perspective that AI-driven medical solutions were imagined as more readily accepted as assistive tools rather than autonomous decision-makers [6,12].

Privacy concerns and data governance emerged as dominant themes, revealing participants' surface-level awareness of legal risks surrounding sensitive health data management. While users expressed concrete anxieties about data access controls [18], storage security protocols, and risk-benefit tradeoffs of AI convenience versus potential breaches, their understanding of specific regulatory frameworks remained limited. This highlights the need for clearer communication around data governance. Developers could help bridge these knowledge gaps through evidence-based user education strategies, such as (1) interactive onboarding tutorials with just-in-time explanations, (2) "privacy nutrition labels" for transparent policy summaries, and (3) participatory consent processes that visualize data flows—all proven to enhance comprehension and trust in health AI contexts [41,42]. Critically, these approaches move beyond static disclosures to dynamic, user-centered designs that align with real-world decision-making needs [42]. These findings mirror broader literature identifying privacy paradoxes in digital health adoption [14], where expressed concerns often outweigh practical protective behaviors. Notably, these apprehensions coexisted with broader skepticism about AI's reliability in health care contexts, leading some users to stress the perceived necessity of human supervision, framing it as both a quality control mechanism and an ethical safeguard. This concern permeated multiple discussion topics in the findings, suggesting it represents a core barrier to trust in AI-driven health care tools.

This landscape of uncertainty spanned multiple dimensions—both technical and conceptual. Participants questioned not only how AI-driven systems function algorithmically but also how they comply with existing regulations, what monitoring systems are in place, and who holds accountability for decision-making. Notably, these knowledge gaps extended beyond core functionality to include unexpected concerns, such as the potential environmental impact of AI infrastructure. Although mentioned only once in focus groups, this issue quickly resonated with other participants, suggesting that ecological considerations (eg, energy consumption of AI models [43]) may subconsciously influence perceptions of mHealth solutions, even among users without direct technical knowledge. Such broad uncertainty, encompassing both technical and nontechnical factors, frequently characterizes public reception of emerging health technologies [18], particularly when transparency about decision-making processes appears insufficient. These concerns frequently translated into demands for clearer accountability frameworks [44] and verifiable regulatory compliance [45], as fundamental requirements for trust-building.

The analysis reveals that attitudes toward AI-driven mHealth apps stem from multiple interconnected factors. These include: (1) theoretical expectations about technical app characteristics (eg, usability and personalization features), (2) individual tendencies to trust or distrust technology, and (3) broader ethical-legal concerns. Crucially, these factors do not operate in isolation but interact dynamically, creating unique perceptual configurations for different users. This complex interplay ultimately determined the spectrum of observed responses—from enthusiastic anticipation to cautious skepticism or outright rejection.

Limitations

While this study provides valuable exploratory insights, several limitations should be acknowledged. First, the gender imbalance within the sample (12 men vs 3 women) may have influenced the findings. Although existing evidence refers separately to mHealth apps and to AI apps in health care, studies suggest that gender can affect attitudes toward these technologies, and similar dynamics may also apply to AI-driven mHealth apps. For example, women tend to report higher health literacy and greater concerns about privacy, while men may place more emphasis on response efficacy and perceive these technologies as easier to use [46,47]. This imbalance may have shaped the salience of certain themes—such as emotional interaction, communication style, and privacy concerns—highlighting the importance of considering gendered perspectives when interpreting qualitative findings [48]. Future research should therefore aim to achieve

XSL•FO
RenderX

more balanced gender representation and could more rigorously explore gendered dimensions by incorporating stratified sampling strategies, gender-sensitive interview protocols, or comparative analysis frameworks designed to detect gender-specific themes [49].

Regarding the age distribution, the study focused on young adults (mean age: 27 years; range: 25 - 34 years), a demographic that represents a particularly relevant target group for AI-mHealth given their high engagement with digital health tools and greater trust in AI technologies [22-24]. However, this choice necessarily limits the generalizability of findings to other age groups, whose needs, digital literacy, and expectations may differ [50,51]. Future research could explore these age-related differences through targeted sampling and quantitative approaches. Finally, as an exploratory qualitative study, the methodological approach is inherently limited by potential group dynamics, such as dominant voices or social desirability [52]. Future research could benefit from robust mixed methods designs to address some of the limitations mentioned earlier.

Conclusions and Future Directions

This study offers valuable insights into users' attitudes toward the potential integration of AI in mHealth apps, focusing on key advantages such as personalization, accessibility, cost-effectiveness, and their potential as monitoring tools that leverage AI for tailored recommendations. The immediacy and affordability of such apps were seen as notable benefits, suggesting that they could make health management more accessible compared with traditional professional consultations. However, concerns about data management, transparency, and users' understanding of these technologies emerged as significant barriers. Given the novelty of AI-driven mHealth apps, many participants formed opinions based on general perceptions of AI or traditional mHealth apps rather than direct experience, highlighting a broader uncertainty about their functionality and reliability.

Ambivalent attitudes were particularly evident regarding the perceived reliability of AI-generated recommendations, the need for human supervision, and the psychological impact of AI interactions. These factors elicited mixed reactions, with responses largely influenced by previous knowledge, pre-existing opinions about AI, and attitudes toward digital health tools. In addition, certain themes, although not central to the main discussion, warrant further exploration. For instance, a pro-innovation bias was observed in some users, indicating a tendency to view technological advancements as inherently beneficial. Furthermore, concerns about the environmental impact of AI systems—though mentioned only briefly—resonated with a broader segment of participants, highlighting a potential influence on consumer attitudes.

Developers could focus on highlighting the positive aspects that emerged in this study, such as the increased personalization options offered by AI-driven mHealth apps, their cost-effectiveness, and their strong monitoring capabilities for health data. At the same time, they should address potential risks or concerns, such as enhancing the clarity and transparency of data management practices, particularly around privacy, and ensuring systems of periodic human supervision. Furthermore, developers could provide greater customization for those ambivalent factors by allowing users to select the type of interaction with the AI, adapting the intensity of interactions to suit personal preferences—for example, adjusting the tone to be more formal or informal, scientific or motivational, and so on.

Future research should address the limitations of this study and explore these underlying factors in greater depth. Using quantitative or mixed-methods approaches could provide deeper insight into the psychological and behavioral drivers that influence attitudes toward the integration of AI in mHealth apps. This would ultimately guide the development of more user-centered and ethically responsible strategies for these technologies, ensuring a vision that not only protects and supports end users in the most comprehensive way possible, but also addresses the delicate nature of health-related matters. Furthermore, as AI-driven mHealth apps become more widely available, longitudinal studies tracking user perceptions before and after direct experience with such technologies could offer valuable insights into the evolution of attitudes toward these technologies over time [27,28]. Given the novelty of these technologies, such contributions can make a real difference, both in the academic landscape and in practical terms, by helping design safer, more effective, and widely accepted AI-driven mHealth apps that truly meet the needs of end users.

Acknowledgments

This research was funded by the Italian Ministry of University and Research under the scheme Research Projects of National Interest (PRIN 20227BY88A).

Abstract

Background: Immune-mediated inflammatory diseases, such as rheumatoid arthritis and spondyloarthritis, pose challenges due to recurrent flares and gaps in patient monitoring. Traditional health care models often fail to capture disease progression effectively.

Objective: This study aimed to describes the structured cocreation of the IMIDoc platform, an interdisciplinary initiative aimed at improving patient monitoring, education, and health care provider decision-making.

Methods: IMIDoc was cocreated through an interdisciplinary team involving clinical experts, biomedical engineers, and technical developers, using user-centered design principles. The development process included the identification of unmet clinical needs, user-centered app design, implementation of medication management features, patient data recording capabilities, and educational content. A 3-month feasibility and functionality testing was performed to evaluate the usability and technical performance of the apption.

Results: During the feasibility testing, 111 entries were logged for the patient mobile app, comprising 76 errors identified and corrected, 16 improvements addressing functionality, usability, and performance, and 10 evolutionary suggestions. The professional interface received 45 entries, identifying 40 errors and 5 evolutionary suggestions. Ten iterative updates significantly enhanced the user interface intuitiveness and medication reminder functionality, aligning the solution closely with clinical workflows and user needs.

Conclusions: The IMIDoc platform, developed by a multidisciplinary cocreation methodology, shows potential to improve the management of immune-mediated inflammatory diseases ithrough enhanced communication and monitoring. A multicenter clinical study with 360 patients across 5 Spanish hospitals will further evaluate its impact.

KEYWORDS

immune-mediated inflammatory diseases; cocreation; health care provider; digital health solution; inflammatory; inflammatory disease; monitoring; care model; patient care; development; app; user centered; patient monitoring; decision-making; user needs

Introduction

Immune - mediated inflammatory diseases such as rheumatoid arthritis (RA) or spondyloarthritis(SpA) are chronic diseases characterized by joint or spinal inflammation with sporadic flares, leading to significant functional impairment in affected individuals [1,2]. Managing these diseases often involves complex therapeutic regimens, necessitating close monitoring and effective communication between patients and health care providers to promptly identify changes in disease progression or treatment-related concerns. Traditional care models, which rely heavily on scheduled clinical consultations, may fail to provide a comprehensive and continuous view of disease activity, resulting in gaps in patient care [3].

Advancements in digital health technologies present promising opportunities to enhance the management of immune - mediated inflammatory diseases. Telemonitoring, in particular, offers the potential to bridge the gaps between face-to-face consultations by enabling real-time disease activity tracking and facilitating timely interventions during periods of disease instability [4]. Smartphone data collection offers enhanced research and clinical care capabilities, notably with electronic patient-reported Outcomes (ePROs) [5]. Such integration aims to optimize the quality of patient care and facilitate effective communication between health care professionals and their patients.

In this context, our research group designed the mixed care model (MAM, from the Spanish Modelo Atencion Mixta), which incorporates the use of information and communication technologies, and also designed a previous pilot study called Digireuma, with the goal of developing a digital health tool for monitoring ePROs in patients with RA and SpA[6]. The Digireuma study demonstrated that while remote monitoring via digital tools could reduce the need for physical consultations, challenges such as declining patient adherence, with around half of the patients dropping out during the follow-up of 6 months, and usability issues (primarily related to the login process), remained persistent. A targeted survey administered at the study's conclusion, gathering insights from both patients and professionals, highlighted these challenges and helped identify critical areas for improvement.

Based on previous results, the medical team decided to develop a digital health solution specifically tailored to the needs of both health care professionals and patients. Feedback indicated a demand for reliable educational resources, leading to the development of tailored modules incorporating interactive texts, infographics, and videos created in collaboration with health care professionals. To enhance adherence, the app integrates personalized medication management tools with automated reminders and scheduled messages for patients demonstrating positive clinical evolution, thereby reinforcing a sense of continuous clinical follow - up. In addition, bidirectional communication between patients and providers facilitates real - time feedback, ensuring that the solution effectively bridges the gaps observed in previous digital health interventions for RA and SpA.

In the current manuscript, we delineate the collaborative effort among a clinical team, a group of biomedical engineering experts, and a dedicated team of developers, in cocreating an application tailored to the unique needs of patients with immune - mediated inflammatory diseases. Drawing upon interdisciplinary expertise, their efforts culminated in the IMIDoc app, an innovative digital health solution, which has also led to invaluable insights and lessons for future collaborative health-tech initiatives.

Methods

Development of IMIDoc

In the development of our digital health app, we adopted a structured cocreation process encompassing 2 distinct phases. The initial "planning phase" involved the clinical team meticulously reviewing their previous experiences and identifying prevalent unmet needs in disease management. Concurrently, the clinical team engaged in a comprehensive assessment of potential funding strategies. Then, preliminary discussions with the engineers to outline the envisioned features and functionalities were initiated. This process culminated in the articulation of a clear statement of purpose. The subsequent "development phase" involved the technical and development teams, who adhered to Agile methodologies, fostering a dynamic collaboration between clinicians and engineers [7]. Central to this phase was a rigorous evaluation of pivotal factors influencing technology selection, the formulation of user profiles, as well as the definition and development of the functionalities to be incorporated into the digital solution. In addition, paramount attention was devoted to assessing the correct functioning of the digital solution by end users through pilot testing.

Planning Phase

Overview With the Developers and Statement of Purpose

Upon successfully securing a sustainable funding source, we initiated consultations with several development teams, leveraging our collaboration with the biomedical engineering team from the Universidad Politécnica de Madrid. Following a public tender process, the project was awarded to Kairos DS [8]. During several collaborative sessions with Kairos DS, we meticulously crafted a statement of purpose for our digital health solution, including a description of its main functionalities and features.

XSL•FO
RenderX

Funding

To secure funding for a new medical app, efforts were diversified across private funding contests, collaboration with pharmaceutical companies [9,10], and exploration of public grants focused on health care innovation [11], tapping into multiple sources to maximize potential financial support.

Analysis of Previous Experience

An analysis of the previous remote monitoring experience, the Digireuma study [6], was conducted. For this, semistructured telephone interviews were conducted by an external expert with a randomly selected subset of patients, in order to gain a comprehensive understanding of user experiences, capturing both the strengths and potential areas for improvement of the application and implementation methodology. Clinicians who participated in the previous project completed a questionnaire to evaluate the usability of the medical interface, the usefulness of the solution and its utility in medical practice. Further information on these questionnaires can be found in Text S1 inMultimedia Appendix 1.

Development Phase

Throughout the development phase, interdisciplinary work was shared among the clinicians, the technical software and biomedical engineering team. This also involved intensive dialogue among engineers and end-users, including both patients and clinicians.

Due to the nature of the project, Scrum was adopted by the development team and the product development stakeholders [12]. This framework is based on small, iterative cycles or sprints with each iteration adding value to the product, so that corrective measures can be taken without compromising the entire project [13].

An initial kick-off meeting between clinicians and the technical team aimed at establishing shared objectives and product expectations was held. The development schedule included 15 sprints, with each sprint ending with a review.

Definition of User Profiles and Functionalities

We used a user-centered design approach [14], for which by definition must consider the needs and experiences of end users via a continuous series of evaluations [15,16]. Initial user profiles were established based on interviews with clinicians and patients [6], categorizing users into health care providers and patients. For health care providers, functionalities such as patient data monitoring, alert resolution, and telematic contact were developed. For patients, features included ePROs registration, medication management, reminders, and access to educational content covering disease information, management strategies, and relevant hospital information.

Technical Requirements

As a starting point for designing the architecture of the system, the MAM protocol and the agents that comprise the proposed clinical intervention were considered, combining face-to-face and telematic follow-up protocols [12]. The profiles, needs and functionalities previously defined were then considered. With all of this in mind, the system and components to be developed were then defined: a mobile app for patients, an application for health professionals, and services for communication, data processing and storage.

Throughout the design and development process, it was necessary to evaluate possible technologies and their deployment (Text S2 in Multimedia Appendix 1). The system architecture was designed using cloud-based technologies, specifically Amazon Web Services (AWS), to optimize resource usage and ensure data security [17-19]. To ensure cost-effectiveness, scalability, and ease of maintenance, we selected hybrid and cross-platform technologies [20], allowing IMIDoc to be deployed on both Android and iOS platforms efficiently.

In addition, to carry out the clinical evaluation study, a series of requirements had to be met and specific documentation had to be submitted to the Information Systems Security Office of the Madrid Health Service.

Preclinical Testing Phase of IMIDoc

During the first sprints of the project execution and once the main components and specifications of the user applications were identified, those activities associated with the interface design were carried out—that is, generating wireframes, sketches, and mock-ups. This process is key in user centered-design (UCD) and allowed us to preliminarily evaluate the structure of the applications, the composition of the scenarios and the interactions before the development phase [17].

An initial phase of testing was conducted by a multidisciplinary team of clinicians, engineers and patients, generating discussions in 3 online meetings. A subsequent digital solution testing phase with active users was planned for 4 weeks. Both patients and health care professionals were actively involved. A comprehensive guide detailing functionality, data input methods, and troubleshooting steps was provided to all participants before the testing period. The guide aimed to standardize the usage of the application for all users, thereby minimizing variation and enhancing the validity of the pilot results. During the 4-week period, feedback was collected through forms and informal interviews, focusing on usability, feature relevance, and overall experience.

Ethical Considerations

The protocol of the study was approved by the local ethics committee, CEIm Hospital La Paz (PI-4519) and has been registered as a clinical trial (ClinicalTrials.gov Identifier: NCT06273306).

Results

Planning Phase

Scope and Main Objective of IMIDoc

In a dedicated meeting with the multidisciplinary development team, the scope of the digital solution was outlined by conducting a scoping analysis to delineate its potential capabilities and limitations. The name IMIDoc was selected for the digital health solution proposed in this project. The primary purpose of IMIDoc was defined as addressing an unmet need in the care of patients with RA and SpA, which is the providing

XSL•FO
RenderX

of continuous monitoring. Conventional clinical practices often allow for discrete, scheduled medical consultations, leaving gaps in patient care when immediate attention is most needed. The IMIDoc app was designed to bridge this gap, ensuring timely medical oversight of patients.

Primary Source of Financing

This project was financially supported by a grant from the Fondo de Investigaciones Sanitarias (FIS) of the Instituto de Salud Carlos III (PI22/00777). The grant specifically facilitated the technical development of our digital solution and will allow us to carry out the clinical-technical evaluation in a clinical study.

Analysis of Previous Experience and Unmet Needs

In the platform ideation phase, relevant aspects and features that the digital solution should incorporate were identified. During this phase we considered the opinion of 41 patients and 4 clinicians about their experience with the previous digital solution (Table S1 in Multimedia Appendix 1). Regarding the patients, usability ranged from 85.3% - 97.5%; most found the digital solution easy to use, and well adapted. Over 90% (38/41) of participants found the application was well adapted to its objective, with an adequate level of detail. Most patients reported considered that it allowed them to record their current health situation and would recommend it. The areas patients most frequently cited as needing improvement were the application's design and the amount and detail of informational content related to the disease. On the other hand, clinicians rated the overall usability and design (0 - 10, from worse to best) of the application with a mean (SD) of 8.50 (1.22), the app utility with 8.50 (1.16), and the feasibility with 7.56 (2.41). They primarily expressed concerns regarding the feasibility of the implementation in clinical practice, particularly in terms of time and logistics, followed by the performance of the solution.

Development Phase

The iterative development process was carried out over 15 sprints from January to August 2023, each punctuated by a bi-weekly update meeting and culminating in a final review meeting (Supplementary Figure 1 in Multimedia Appendix 1). The initial meetings laid the groundwork by focusing on service architecture and basic functionalities like login and user registration. Subsequent meetings were geared toward enhancing the user interface, developing workflows in the digital solution, and integrating questionnaire designs. In these bi-weekly review meetings, the development team assessed progress and recalibrated, when necessary, thereby allowing them to respond to changing requirements and deliver a high-quality product efficiently. During each sprint, different tasks were assumed by the development team with the aim of achieving the sprint goal, which was previously set in an online meeting by the clinical team. The middle phase emphasized refining communication features, resource and medication development, and incident management. Data visualization tools like historical graphs and evolution screens were also integrated. The concluding meetings targeted system debugging, specifically in messaging and error management, before a comprehensive final review was conducted.

The collaborative and interdisciplinary process made it possible not only to define the instruments to be implemented for the collection of data of interest, but also to design and develop the applications for the users; that was , mobile apps for patients with RA or SpA, and a Web application for clinicians.

Set of Variables and Instruments

In accordance with the objectives of the clinical study, in which the implementation of the MAM model in clinical practice through IMIDoc will be evaluated, Textbox 1 specifies the clinical and ePROS variables that the solution was designed to capture and that comprise the monitoring and follow-up of patients with RA and SpA.

In addition to the capture of clinical variables, instruments have been implemented to evaluate the usability of the applications, satisfaction, and user experience: System Usability Scale (SUS) and the Net-Promoter Score (NPS) indicator [18,19]. These were evaluated at 10 weeks and 34 weeks, respectively.

XSL•FO
RenderX

Textbox 1. Clinical variables and electronic patient-reported outcomes collected by the IMIDoc app.

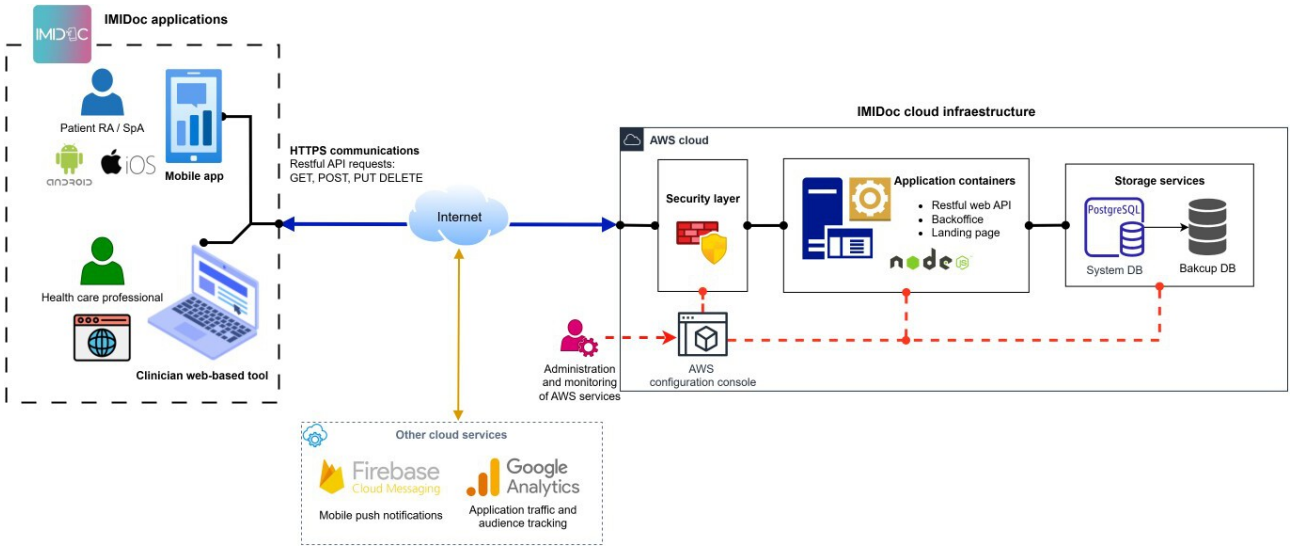
1) General characteristics

- Sociodemographics and treatment information including age, sex, toxic habits, date of diagnosis, date of initiation of treatment, medication, etc.
- Electronic patient-reported outcomes (ePROs)
  - a) Patient Global Health (PGH)
  - b) Visual Analogue Scale (VAS)
  - c) Tender Joint Count (TJC) and Swollen Joint Count (SJC)
- Events or incidents
  - a) Flare
  - b) Infection
  - c) Medication problem
  - d) Other reasons
- Adherence

a) Compliance Questionnaire on Rheumatology, CQR

2) Rheumatoid arthritis (ePROs)

- Disease Activity Score 28 (DAS28)
- Health Assessment Questionnaire (HAQ)



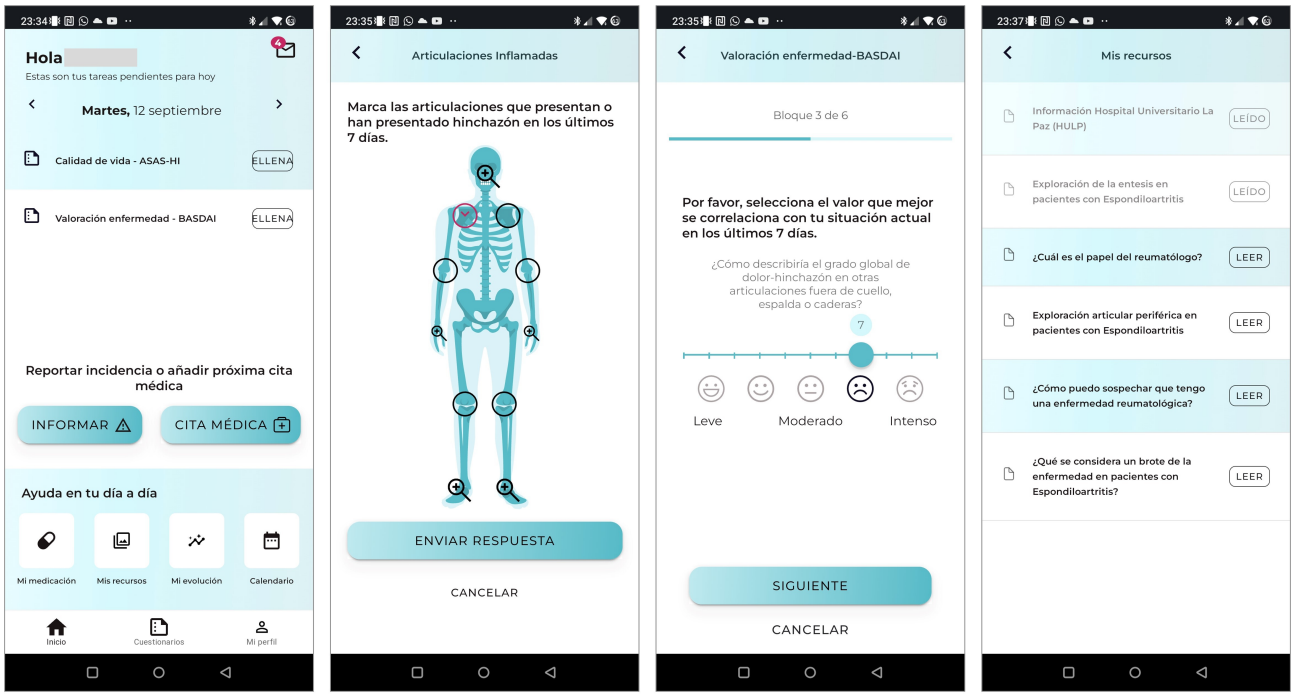
3) Spondyloarthritis (ePROs)

- Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)
- Axial Spondyloarthritis Disease Activity Score (ASDAS)
- Assessment of SpondyloArthritis International Society Health Index
- Painful enthesis count

System Architecture

The analysis and design phase of the project made it possible to identify the user profiles and the functionalities and characteristics of the applications included in the IMIDoc digital health solution. Figure 1 shows a schematic of the main agents, components, and services of the system architecture using the MAM applied to RA and SpA. The figure shows the users (patients and health care professionals) accessing their respective applications and communicating with the service infrastructure deployed in the cloud.

Figure 1. Diagram of the architecture of the IMIDoc solution. RA: rheumatoid arthritis; SpA: Spondyloarthritis; AWS: amazon web services; DB: database; API: Application Programming Interface.



XSL•FO
RenderX

IMIDoc Applications

The first steps in the development of the IMIDoc applications (the mobile app for patients and the web interface for professionals) were focused on addressing the interface design. For this purpose, we used the Figma platform, which is a cloud prototyping platform that facilitates collaborative work.

The IMIDoc mobile app (Figure 2) was designed to incorporate functionalities for recording disease activity, as well as some other domains potentially affected by RA or SpA.

Figure 2. Screenshots of the Spanish version of IMIDoc app designed for patients with rheumatoid arthritis (RA) and spondyloarthritis. (a) Home screen displaying pending tasks, including daily questionnaires, and options to report incidents, access medication details, educational resources, disease progression, and a calendar. (b) Interface for marking swollen joints by patient's perception. (c) Example of a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score questionnaire item for disease assessment. (d) List of informational and educational resources available within the app.

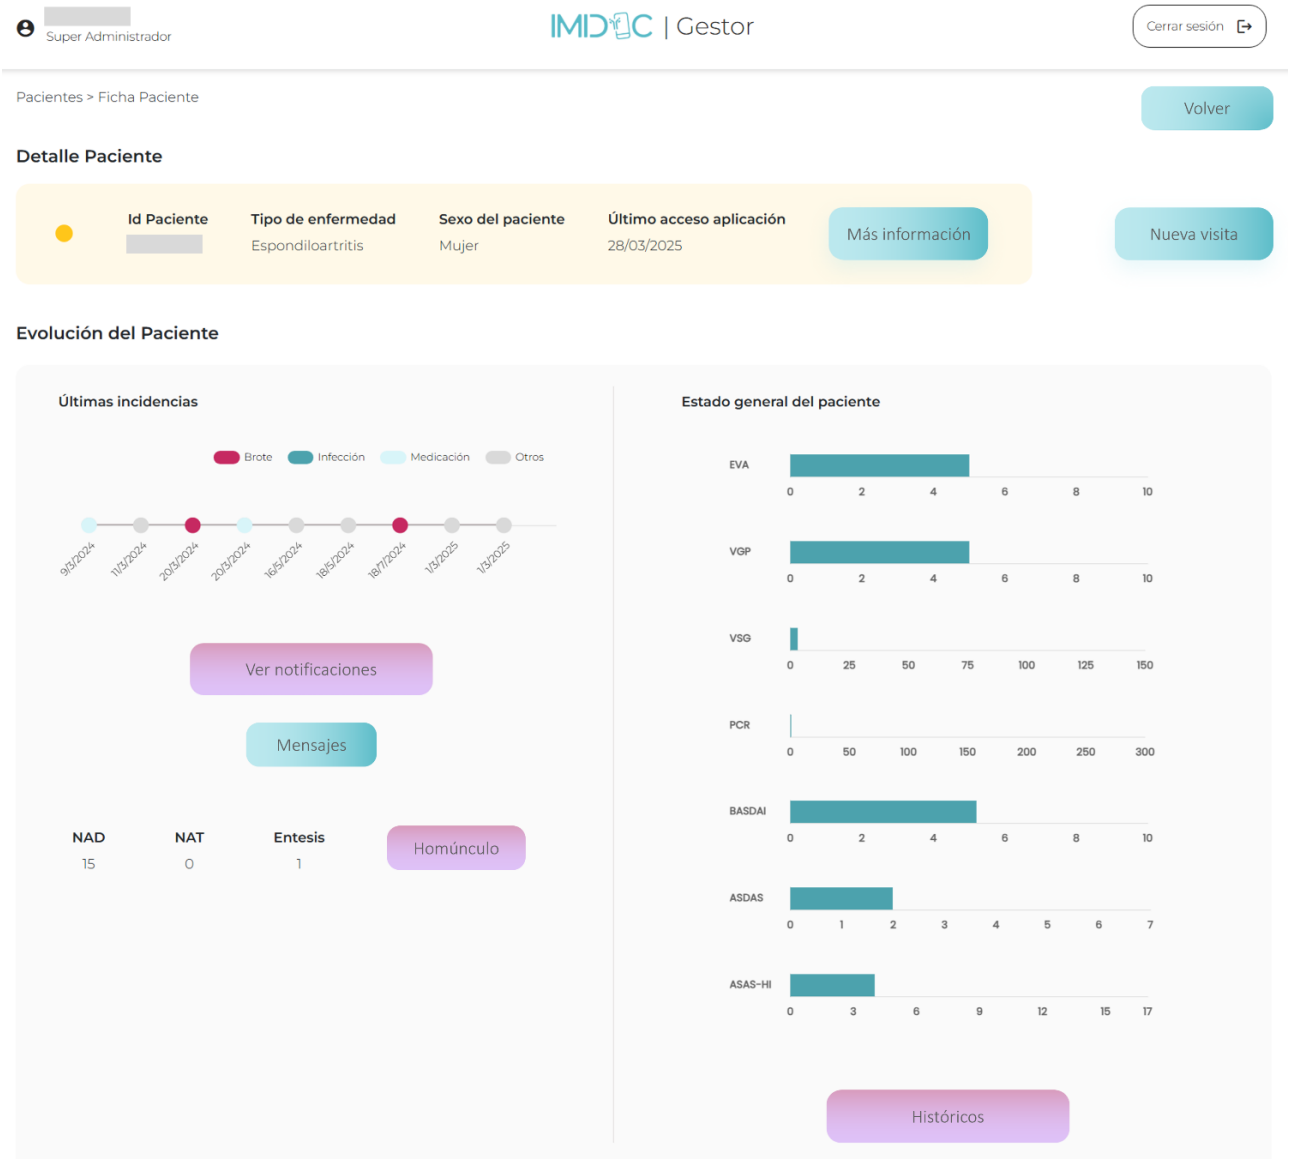
(a) (b) (c) (d)

In addition, the IMIDoc app included scenarios for medication management. To achieve this, the professional team carefully consulted the latest clinical practice guidelines for RA and SpA. This comprehensive review of current guidelines informed the creation of tools for monitoring disease activity and managing medication within the app.

A section with educational and informative content to help patients understand their disease and treatment options was also included; specifically, 26 educational articles were generated by clinicians with multimedia components, images and 12 educational videos. Specialists in various fields, including immunology and obstetrics, were engaged to contribute to the development of educational resources. The material produced included illustrated resources designed to improve patient understanding of their condition and the treatment options available. In addition, a diverse range of formats was used to adapt to different preferences. This included the creation of infographics, interactive texts, and videos. Each format was carefully selected to best suit the content being presented, with the aim of enhancing user engagement and understanding.

Another feature of the app involves task and medical appointment reminders in a personalized questionnaire that is complemented by push notifications.

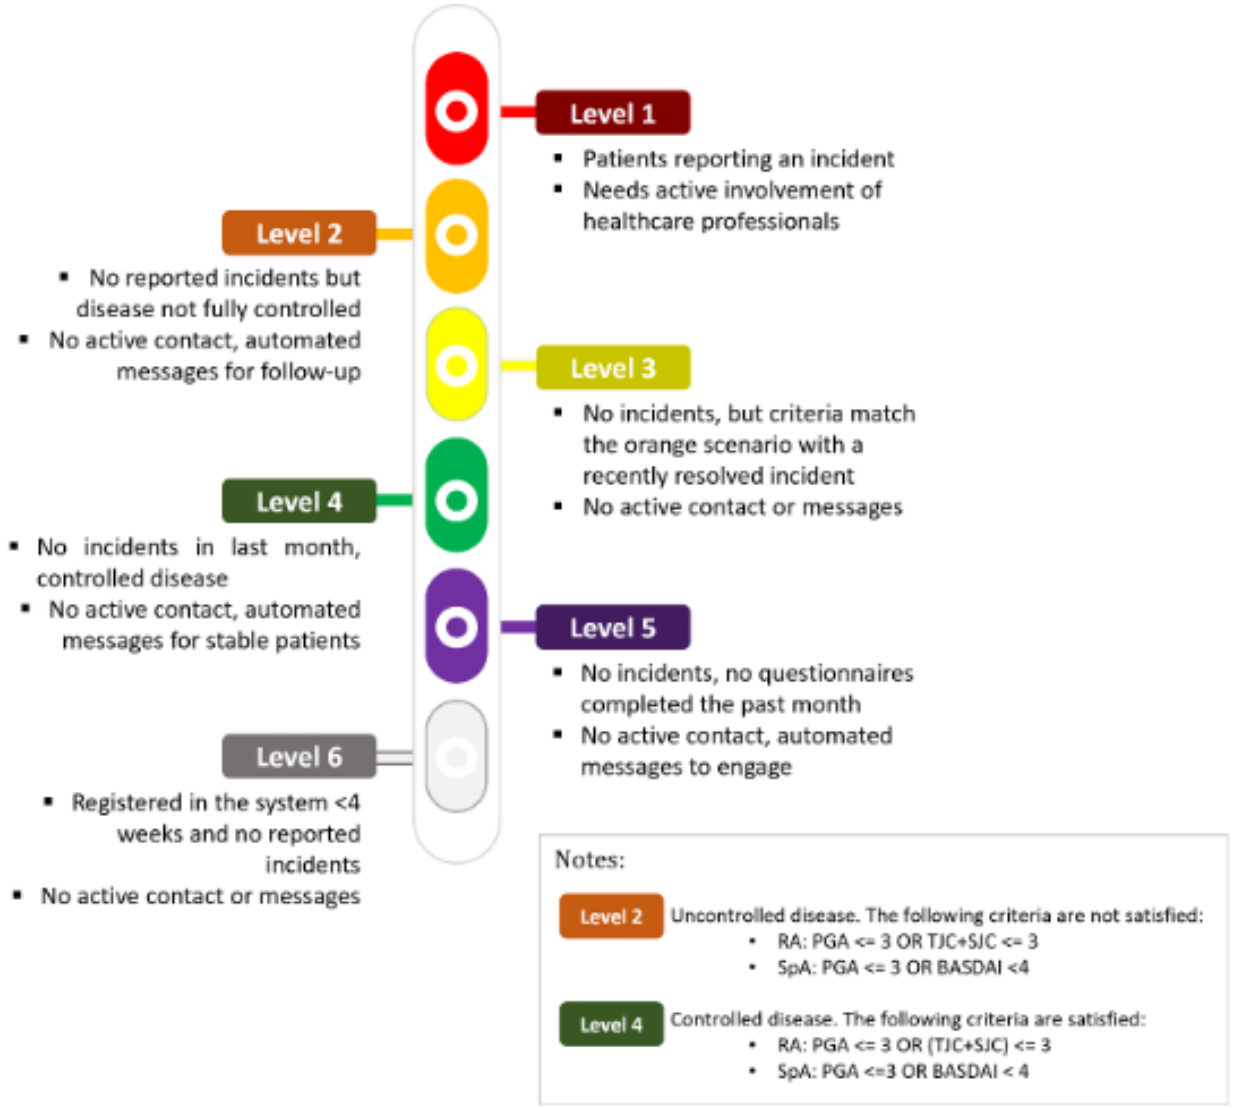
The IMIDoc clinician web platform is a web-based application for health care professionals, primarily clinical rheumatologists [21]. The IMIDoc clinician web platform includes scenarios for monitoring ePROs in a prespecified time frame and generates events or alerts. These features will enable clinicians to respond in near real-time to significant changes in disease activity. Figure 3 shows an image of the screen displaying the data recorded by a patient.



The top section displays basic patient information, including patient code, sex, and last application access. Below, the left panel shows recent incidents (flares, infections, medication issues, or others), the number of swollen joints (NAT, Spanish acronym for “Número de Articulaciones Tumefactas”), the number of tender joints (NAD, Spanish acronym for “Número de Articulaciones Dolorosas”), enthesitis, and access to a homunculus visualization, along with options to view patient messages. The right panel below features bar graphs tracking patient progress, including pain scale (EVA, Spanish acronym for “Escala Visual Analógica”), patient global assessment (VGP, Spanish acronym for “Valoración Global del Paciente”), erythrocyte sedimentation rate (VSG, Spanish acronym for “Velocidad de Sedimentación Globular”), C-reactive protein level (PCR, Spanish acronym for “Proteína C Reactiva”), Bath Ankylosing Spondylitis Disease Activity Index score (BASDAI), and Axial Spondyloarthritis Disease Activity Score (ASDAS).

Through IMIDoc, clinicians could quickly identify the health status of patients and their level of adherence based on the

XSL•FO
RenderX



automatic processing of data. The IMIDoc classification algorithm assigns 6 different levels to patients as shown in Figure 4.

Figure 3. Screenshot of the Spanish version of IMIDoc web-based tool for monitoring patients with rheumatoid arthritis and spondyloarthritis.

XSL•FO
RenderX

Figure 4. Classification of the health status and clinical adherence of patients with rheumatoid arthritis and spondyloarthritis. PGA: patient global assessment, TJC: tender joint count, SJC: swollen joint count, BASDAI: bath ankylosing spondylitis disease activity index.

IMIDoc Backend

As mentioned above, there are several platforms available from technology providers such as Amazon Web Services (Amazon), Azure (Microsoft), Google Cloud (Google) and IBM Cloud Computing (IBM), among others. For the implementation of IMIDoc, we selected Amazon Web Services (AWS) to deploy the backend components. In addition, AWS offered a number of features of interest for our implementation [15,16]. We used AWS Fargate which is a serverless computing engine for containers, in which a Node.js-based application has been deployed that features a RESTful API to respond to requests using GET, POST, PUT, DELETE methods via HTTPS. For the storage of ePROs data and clinical actions, a relational database PostgreSQL with Amazon RDS was implemented and deployed in the European region (Spain). An important aspect to consider was security, for which the Security Hub service was enabled. This integrates functionalities to detect and manage security events, in addition to other components such as a Firewall and distributed denial of serviceprotection. Moreover, AWS complies with various certifications, accreditations, European laws and regulations such as ENS (high category), DESC CSP, CISPE and the General Data Protection Regulation (GDPR). It should be noted that these characteristics, in terms of security and data processing, are requirements mandated by the Information Systems Security Office for the approved use of the application in health care. Finally, AWS allows us to use a continuous integration and delivery service and, in this way, allows us to maintain and prepare system updates for subsequent release in production.

The system has modules that run automatically, monitoring the data, establishing the patient's health status, and generating notifications that are sent to the patients' app through the Google Firebase service. Table 1 specifies the types of notifications included in IMIDoc.

Google Analytics was used to track and process dimensions and metrics related to the use of both applications: country, device, operating system, app version and user interactions with the app (number of sessions, duration of sessions, screen views, and interaction times). Google Analytics service and mechanisms were integrated to record the usage metrics of both applications.

XSL•FO

Table . IMIDoc mobile app notifications.

Dimension	Trigger	Title	Body
Messages	Response from a health care professional to an incident.	IMIDoc[a] notification	"You have a new message".
Medication	Time of medication intake	IMIDoc medication	"You have medication pending confirmation".
Resources	New reading resource available	IMIDoc multimedia content	"You have new educational resources available".
Questionnaire(s)	New questionnaire(s) to fill out	IMIDoc questionnaires	"You have new questionnaire(s) to fill in".
Medical appointment	One day before the medical appointment	IMIDoc medical appointment	"Remember that you have a doctor's appointment tomorrow, please check that you have provided all the necessary information".
Adherence support	One week without logging into the app	IMIDoc misses you	"We have noticed that you have not been using the application for a while, we encourage you to give us another chance".

[a]IMIDoc: Immune-mediated inflammatory diseases

Preclinical Testing Phase of IMIDoc

The involvement of the multidisciplinary team in the initial testing phase led to several modifications to the digital solution, primarily to the mobile solution. These mainly focused on the user interface, the wording used within the application, and its distribution mechanisms, aiming to ensure that the application was intuitive for both patients and health care professionals.

During the subsequent 12-week digital solution testing phase with 10 active users (7 professionals and 3 patients), several functional issues and areas for potential improvement were identified. Detailed functionality reports for the mobile app recorded 111 entries—76 errors, 16 improvements, and 10 evolutionary suggestions—while the professional tool generated 45 entries, with 40 errors and 5 evolutionary suggestions. Based on this feedback, users' reported difficulties with navigation and data entry prompted a redesign of the interface to reduce logging steps and incorporate clearer prompts. In addition, the need for customizable alerts led to refinements in medication and appointment reminders and improvements in the messaging system to enable prompt clinician responses. These iterative enhancements, delivered over 10 update cycles, set the stage for a multicenter clinical study involving 360 patients from 5 Spanish hospitals.

Discussion

This study underscores the efficacy of using a structured cocreative approach to crafting the IMIDoc digital health application tailored for rheumatology practice. Over the years, the rheumatology community has voiced the demand for refined apps and tools to yield meaningful clinical outcomes [20,22]. Despite advancements in mobile health technology (mHealth) and treatment in rheumatology, there persists a notable gap in continuous patient monitoring [23,24]. Recognizing this unmet need in rheumatology care, particularly during intervals between scheduled consultations, informed the conceptualization of the digital health solution presented here.

Our initial needs assessment drew from past experiences, incorporating feedback from clinicians and patients to identify key features and functionalities of IMIDoc [6]. This information informed requirements and specifications, supporting a participatory design approach complemented by UCD principles to enhance usability, acceptability, and user experience [17]. Embracing such techniques is crucial for crafting more effective health interventions as it incorporates diverse perspectives [25]. A recent systematic review underscores the increasing adoption of cocreated technology solutions in health care [26]. This aligned with our own approach in developing IMIDoc, in which the representation of both patients and clinicians ensured that real needs were met. The involvement of all relevant stakeholders, including biomedical engineers and technicians, throughout design and development fostered communication, transparency, and a design that aligned with users' priorities.

Furthermore, the application of agile methodologies during the development phase, with iterative cycles, proved invaluable. This approach facilitated continuous adjustments and input, minimizing risks and adapting to emerging changes, and proved particularly valuable in a rheumatology clinical setting [27]. While previous literature has acknowledged the benefits of Agile methodologies [28], our study empirically substantiates its efficacy in this specific context. The pilot testing phase provided valuable insights and led to necessary adjustments, highlighting the dynamic and responsive nature of a development cycle based on agile methodologies. As an example, participants frequently reported difficulties in navigating the app and entering data. In response, the interface was redesigned to minimize the number of steps needed to log information and incorporate clearer prompts to guide users. Additional feedback highlighted the need for customizable alerts, leading us to refine medication and appointment reminders, and to improve the messaging system so clinicians could rapidly respond to patient messages.

Challenges in managing the project scope and addressing various complexities led to a shift toward a more strategic and modular

XSL•FO
RenderX

approach, prioritizing essential features and refining functionalities based on end-user needs. To ensure a rigorous assessment of usability and patient satisfaction, instruments such as the SUS and NPS have been implemented and will be applied in the upcoming multicenter clinical study involving 360 patients from 5 Spanish hospitals.

To ensure the long-term sustainability and continuous improvement of IMIDoc, the project team is actively pursuing additional funding avenues beyond the initial grant. This includes applying for public research grants, seeking private partnerships with health care technology companies, and exploring collaborations with pharmaceutical firms interested in supporting digital health initiatives. In addition, we are developing a strategic plan that outlines regular updates and maintenance schedules for the IMIDoc platform to keep pace with technological advancements and evolving clinical needs. By diversifying our funding sources and establishing a robust maintenance framework, we aim to maintain the app's functionality, incorporate user feedback, and expand its features to better serve patients and health care providers in the future.

Previous literature has provided insights into patient perspectives on digital health interventions and has revealed diverse opinions among patients. Moreover, it has highlighted both advantages and concerns regarding telemedicine in rheumatology. A mixed-methods approach study that explored the acceptability and safety of telemedicine in rheumatology during the COVID-19 pandemic highlighted the need for careful patient selection and further consultation with clinicians to improve telemedicine's acceptability and safety [29]. A prospective study including patients referred to a Veterans Affairs rheumatology clinic found that telerheumatology was well-received by patients, and accurately identified all inflammatory rheumatic conditions at the telerheumatology visits. This suggests that remote monitoring may be suitable for screening and prioritizing patients for in-person rheumatology clinics [30]. Recent research has demonstrated the potential for digital tools to yield positive outcomes in health care. Two randomized trials have been conducted in RA. Pers et al [31] compared a smartphone application connected to a physician's interface for monitoring RA with conventional monitoring. The connected monitoring group had significantly fewer physical visits while maintaining tight control of disease activity and improving quality of life [31]. Salaffi et al [32] investigated the effectiveness of a telemonitoring strategy in early RA, showing higher rates of remission by CDAI within a 1 year compared with the conventional group (38.1% vs 25%) [32].

Our approach has certain limitations. At present, the focus is restricted to RA and SpA, which may limit the generalizability of IMIDoc to other rheumatologic disorders. The small number of participants in the pilot, without extensive demographic characterization, constrains broad interpretations of feasibility and usability. Continued funding is crucial for further feature enhancements and to maintain robust data protection measures, ensuring compliance with evolving regulations. Future large-scale evaluations are planned to validate the efficacy of IMIDoc, broaden its applicability to wider patient populations, and strengthen its long-term sustainability.

While patient opinions on telemedicine may vary, these studies have shown the potential for digital tools to improve clinical outcomes, such as achieving disease remission and reducing clinical visits. Therefore, it is essential to embrace these technological advancements by implementing digital health solutions in real-world rheumatology practice. To this end, it is essential to carefully select patients, and work closely with clinicians to ensure that digital health interventions are effectively integrated into clinical practice, ultimately enhancing the care and well-being of rheumatology patients.

Conclusions

The development of IMIDoc underscores the significance of a cocreative design approach in health care, on that can lead to a product that not only excels in functionally, but that is also contextually relevant to rheumatology practice. Addressing unmet needs such as the integration of ePRO collection, tailored alerts, and a robust messaging system into a single platform, IMIDoc provides a digital health platform for comprehensive disease activity tracking, medication management, patient education, and empowerment in self-health management. This innovation is pivotal to navigating the complexities of managing patients with immune‐mediated inflammatory diseases, offering personalized and effective management strategies while reducing the gap between clinic visits. This work strives to be a breakthrough in rheumatology care, and the proposed multicenter study aims to further validate and support these findings.

Acknowledgments

The authors would like to thank all of the health professionals, researchers, and technicians who collaborated in the development of IMIDoc and the patients who participated in the technical validation tests; specifically, We acknowledge IMIDOC Research group and the members: Leticia Lojo-Oliveira, Verónica García, Claudia María Gómez, Carlos Cañado, Jaime Arroyo, Helena Borrell, Mariana Díaz for their dedicated involvement and support throughout the research process and thanks to Laura Miguel Berenguel, Ricardo Cuesta Martín de la Cámara, Ana Martínez Feito, Gabriela Torres, and Mariela Uyaguari for their invaluable contribution to the development of educational materials. The authors would like to acknowledge the PI22/00777 "Hacia la Telemonitorización en Enfermedades Inflamatorias Inmunomediadas: Implementación de un Modelo Asistencial Mixto (MAM) en una Unidad de Terapias Complejas" Project, financed by the Fondo de Investigaciones Sanitarias (FIS) of the Instituto de Salud Carlos III (ISCIII) and cofinanced with EU Structural Funds. We extend our gratitude to the Rheumatology Society of the COmmunity of Madrid (SORCOM), the Catalan Society of Rheumatology (SCR), and the patient associations that contributed to our survey, including CEADE and ConArtritis. Furthermore, we wish to express our appreciation to the dedicated individuals

XSL•FO
RenderX

who participated in the pilot phase of this study, sharing invaluable insights into their experiences with RA and spondyloarthritis. The authors thank the Spanish Foundation of Rheumatology for providing editorial assistance during the preparation of the manuscript.

Abstract

Background: Digital health interventions (DHIs) have the potential to enhance dermatological care by improving quality, patient empowerment, and efficiency. However, adoption remains limited, particularly in Germany.

Objective: This study explores German dermatologists' attitudes toward DHIs, clustering them by acceptance levels and analyzing differences in sociodemographics and current and future DHI use.

Methods: We conducted a cross-sectional survey, randomly inviting 1000 dermatologists in Germany to participate. The questionnaire consisted of Likert scale items rating the acceptability of DHIs from 1 to 5. Items on the current and future use of DHIs were also included. Exploratory factor analysis was used to identify factors and reduce data as input for a 2-step clustering algorithm.

Results: The survey with 170 dermatologists (mean age 50.8, SD 10.3 y; 74/167, 55.7% female) identified four factors through the exploratory factor analysis: (1) "Positive Expectancies and Acceptability of DHIs," (2) "Dermatologists' Digital Competencies," (3) "Negative Expectancies and Barriers," and (4) "Dermatologists' Perspectives on Patients' Acceptability and Competencies." The analysis identified three distinct clusters: (1) Indecisives (n=69)—moderate intentions to use DHIs and moderate negative expectations toward them; (2) Adopters (n=60)—high intentions to use DHIs and high digital competencies; and (3) Rejectors (n=26)—low intentions to use DHIs and low digital competencies. Adopters were significantly younger, more often based in urban centers, and exhibited the highest adoption rates of DHIs compared to the other clusters. Across all clusters, inadequate reimbursement and perceived structural barriers were cited as significant challenges to DHI adoption. Still, only one-third of the Adopters used DHIs including teledermatology or artificial intelligence.

Conclusions: Dermatologists in Germany exhibited varied levels of acceptance and readiness for DHIs, with demographic and structural factors influencing adoption. Addressing barriers such as reimbursement and investing in digital literacy could promote wider use, potentially reducing health inequalities by improving access to digital health care.

(JMIR Hum Factors 2025;12:e59757) doi:10.2196/59757

KEYWORDS

dermatology; cross-sectional survey; cluster analysis; acceptability; eHealth; Germany; attitude; dermatologist; digital health intervention; teledermatology

Introduction

Dermatology is marked by the presence of prevalent chronic conditions, including acne, psoriasis, atopic dermatitis, and skin cancer [1,2]. In Germany, approximately 27% of adults have at least one dermatological condition requiring specialized care each year, resulting in long waiting times for patients [3,4]. Additionally, limited capacity also impacts comprehensive patient consultations, and the demographic shift could exacerbate these challenges [5-7].

Digital health interventions (DHIs) are proposed as one mitigating solution to sustain health care by enhancing the quality of care, efficiency, and empowering patients [8,9]. In this study, DHIs are defined as health services that use information and communication technologies for patients, consumers, or health care professionals [9,10]. In dermatology, numerous promising DHIs have already been developed [11], including artificial intelligence (AI) [12], teledermatology, diagnoses or monitoring tools [13-16], and patient-targeted apps for medication adherence [17]. The 2020 consensus guideline for teledermatology recommends its use for certain indications but also stresses the necessity for stronger evidence to evaluate benefits and risks [18]. Currently, no guidance exists for other apps.

XSL•FO
RenderX

Digitalization of health care in Germany lags behind that of other European nations [19]. Teledermatology, for example, is less frequently adopted in Germany [20]. The complexity of the situation is grounded in the intricacies of the German health care system, encompassing aspects such as missing interoperability, missing incentives for physicians, and high standards of data protection [21,22].

Apart from the system perspective, the reluctance of medical professionals to embrace digital health may be another potential barrier for the implementation [21,22], but can also function as a facilitator. Their acceptability can compensate for low patient demand or financial resource limitations and can additionally improve patient adherence to these interventions [23-26]. Dermatologists' overall acceptability of DHIs appears to be lower than that of patients with a dermatological condition [27]. Nevertheless, it is noteworthy that dermatologists differ in their perspectives and adoption of DHIs, shaped by various factors including younger age, practicing in urban settings, positive prior experiences with DHIs, or the social influence of colleagues [28-30].

The objective of this study was to explore the acceptability and current and future use of DHIs among dermatologists. Additional objectives included identifying and describing clusters of dermatologists based on their acceptability and examining differences between these clusters and sociodemographic variables, as well as the current and future use of DHIs.

Decision makers or developers of DHIs can use these results to tailor strategies for a successful implementation.

Methods

The consensus-based Checklist for Reporting of Survey Studies and the Checklist for Reporting Results of Internet E-Surveys were applied [31,32]. The full checklist is displayed in Checklist 1.

Study Design and Questionnaire

An anonymous cross-sectional survey among German dermatologists was conducted in June 2022. The questionnaire was based on existing questionnaires from the literature, and in particular, on preconducted focus groups among dermatologists, patients, and nurses (not yet published). The focus groups dealt with the acceptability, barriers, and facilitators of DHIs in dermatology using the Unified Theory of Acceptance and Use of Technology [33,34]. The questionnaire development resulted in 27 items related to the acceptability of DHIs in general (eg, "I could imagine using more digital applications for the care of my patients"). Five items on the potential future use of specific DHIs (eg, "medication reminder application") and four items on the benefits and costs of the nationwide eHealth Strategy (eg, "The eHealth Strategy has strengthened patient care") were added to the survey. All items were answered on a 5-point Likert scale (5=strongly agree; 1=strongly disagree). The survey also included 10 items about dermatologists' current use (>1 per wk) of available DHIs (eg, live-interactive teledermatology or electronic doctor letters) with a simple "check all that apply" option.

In addition, sociodemographic information covering age, sex, type of employment (eg, working in an outpatient clinic or medical practice), and postcode of the clinic or practice were collected. The postcode was used to assign additional regional data to participants (eg, urban or rural areas). The questionnaire was tested with 5 dermatologists of the Institute for Health Services Research in Dermatology and Nursing (German: Institut für Versorgungsforschung in der Dermatologie und bei Pflegeberufen). The final questionnaire is provided in Multimedia Appendix 1.

The offline version of this survey was designed to fit two DIN-A4 pages, while the web-based version was adapted to six screens or pages.

Study Population, Recruitment, and Data Entry

In order to conduct an exploratory factor analysis (EFA; statistical analysis), we aimed for a minimum sample size of 150 dermatologists [35]. To reach the required sample size, the questionnaire was randomly distributed to 1000 members of the German Dermatological Academy (German: Deutsche Dermatologische Akademie [DDA] with ~3500 active dermatologists) in June 2022. The DDA comprises members of the Federal Association of German Dermatologists (German: Berufsverband der Deutschen Dermatologen), representing dermatologists from medical practices, and of the German Dermatological Society (German: Deutsche Dermatologische Gesellschaft), representing dermatologists from both outpatient clinics and medical practices. Dermatologists were asked to participate via email (Unipark), receiving one reminder or offline via mail on paper. The web-based survey was an open survey (no password protection). Additionally, participants could review their responses before submission. The survey was voluntary, and no incentives were offered. The survey was terminated after 8 weeks. The paper-based data were digitized, double-checked, corrected, and combined with the data of the web-based version. To prevent multiple entries by a single dermatologist in the web-based survey, participation was tracked using Unipark's cookie system. To identify and eliminate further duplicate entries from the web-based and offline survey, demographic information and postcodes were cross-referenced and thoroughly checked. No duplicate entries were identified.

Ethical Considerations

The study was submitted to the local ethics committee and was waived due to its noninvasive and anonymous nature. The study was reviewed and approved by the Lokale Psychologische Ethikkommission am Zentrum für Psychosoziale Medizin (LPEK), under the reference LPEK-0407. The study was conducted in accordance with Good Scientific Practice and the Declaration of Helsinki [36,37]. Due to the anonymous nature of the study, informed consent was not collected. Participants received no compensation for their participation and had the option to opt out of the survey at any time.

Statistical Analysis

After conducting a descriptive analysis of all sociodemographic and geographic parameters, an EFA including all 27 items related to acceptability was performed for two reasons: (1) for data reduction by identifying underlying factors, also commonly

XSL•FO
RenderX

used and recommended prior to running a cluster analysis; and (2) to use the underlying factors to closer describe and explore dermatologists' acceptability toward DHIs [38,39].

Adequacy of the EFA for factor analysis was assumed with a Kaiser-Meyer-Olkin criterion (KMO) ≥0.8 and Bartlett's test of sphericity <0.05. All factors with an eigenvalue ≥1.0 were considered. Criteria for retaining an item were a substantial factor loading (>|0.4|) on one factor and no strong cross-loading onto other factors. Cross-loading was defined as loadings (>|0.3|) on another factor and a difference of at least 0.2 between the loading on the main factor and the strongest loading on any other factor [40]. Internal consistencies of the factors were measured by Cronbach α, where values >0.7 are acceptable, >0.8 are good, and >0.9 are considered excellent.

To identify distinct clusters of dermatologists that differ in their acceptability, a combination of hierarchical and K-means cluster analysis was applied. The mean scores (using Likert scale ratings: 1–5) of the factors were used as input variables for the 2 approaches. The hierarchical cluster approach was used to identify the optimal number of clusters. Subsequently, a K-means cluster analysis was conducted with this optimal number. To test on differences between the identified clusters based on mean scores, a one-way ANOVA was performed. In order to create a profile of the identified clusters, first, each item of the EFA (acceptability items) was binary coded (1=strongly agree or agree; 0=neither, disagree, strongly disagree). Then, a descriptive analysis was conducted, analyzing each item for each cluster. Next, chi-square tests were applied for categorical variables to identify differences in sociodemographic parameters, as well as current and potential future use of DHIs between clusters. In case more than 20% of cells had a count below five, Fisher's exact tests were used. For continuous variables, one-way ANOVAs were used. A significance level of .05 was applied. Missing rates were reported for all variables. No imputation methods or weighting methods were applied.

Results

Participant Characteristics

In the survey, 170 dermatologists participated, resulting in a response rate of 17% (170/1000 invited dermatologists). In 131 (77.1%) cases, participation took place online. The online participation rate was 75.7%, calculated as the ratio of unique visitors who agreed to participate (131) to the total number of unique visitors who viewed the first survey page (173). Participants had a mean age of 50.8 (SD 10.3) years, 55.7% (74/167) were female, and for 84.2% (117/139) of participants, the practice or clinic was located in an urban county or city (Table 1). Missing data on all items were below 5% (9/170), except for regional variation (31/170, 18.2%) and outpatient clinic or medical practice (17/170, 10%).

Factors of Acceptability

The KMO criterion (0.92) and Bartlett's test of sphericity ($\chi^2_{210}=2264$; $P<.001$) revealed that the data were appropriate to conduct an EFA. Four factors with an eigenvalue >1 were identified (Table S1 in Multimedia Appendix 2). Cronbach ɑ values (0.93, 0.90, 0.73, and 0.80) indicated at least an acceptable internal consistency for all factors. The explained total variance of the EFA was 67.6%. A total of 6 items were excluded with a factor loading below 0.4. We named the factors as follows:

- Factor 1: "Positive Expectancies and Acceptability of DHIs" comprised of 10 items.
- Factor 2: "Dermatologists' Digital Competencies" comprised of 5 items.
- Factor 3: "Negative Expectancies and Barriers of DHIs" comprised of 4 items.
- Factor 4: "Dermatologists' Perspectives on Patients' Acceptability and Competencies" comprised of 2 items.

The four mean scores of the factors ranged between 2.9 (SD 0.8) for Factor 4 and 3.5 (SD 0.8) for Factor 2 (Table 2). Ranging from 1 to 5, higher scores indicate a higher agreement with the items of a factor, except for Factor 3, where it is the other way around.

Clusters of Dermatologists According to Acceptability Levels

After exploring 2-, 3-, and 4-cluster solutions, the hierarchical cluster analysis recommended the 3-cluster solution as it provides the best fit based on the K-means evaluation. The performed ANOVA and subsequent post hoc tests revealed that all differences between the four mean scores of the three clusters were significant.

Cluster 1 (n=26, 16.7%) exhibited the lowest willingness (Factor 2: mean 1.9, SD 0.7) and digital competencies (Factor 2: mean 1.9, SD 0.7). Correspondingly, this cluster demonstrated the highest negative expectancies of DHIs (Factor 3: mean 3.8, SD 0.3) and low expectations regarding patients' adequate competencies and willingness to use DHIs (Factor 4: mean 2.2, SD 0.7).

Cluster 2 (n=69, 44.5%) showed moderate positive expectancies toward DHIs (Factor 1: mean 3.2, SD 0.6), along with moderate digital competencies (Factor 2: mean 3.4, SD 0.6) and also moderate negative expectancies (Factor 3: mean 3.5, SD 0.4). Cluster 2's expectations of patients' intention to use DHIs and of patients' digital competencies were low (Factor 4: mean 2.7, SD 0.6).

Cluster 3 (n=60, 38.7%) had higher intentions (Factor 1: mean 4.1, SD 0.3), greater competencies (Factor 2: mean 4.3, SD 0.4), and lower, though still moderate, negative expectancies (Factor 3: mean 3.0, SD 0.5) compared to Clusters 1 and 2. The cluster's opinion about patients' intention and competencies was higher, though still moderate (Factor 4: mean 3.5, SD 0.6).

Based on these differences, we will henceforth refer to Cluster 1 as Rejectors, Cluster 2 as Indecisives, and Cluster 3 as Adopters in the subsequent sections.

Differences in Sociodemographic Information Between Clusters

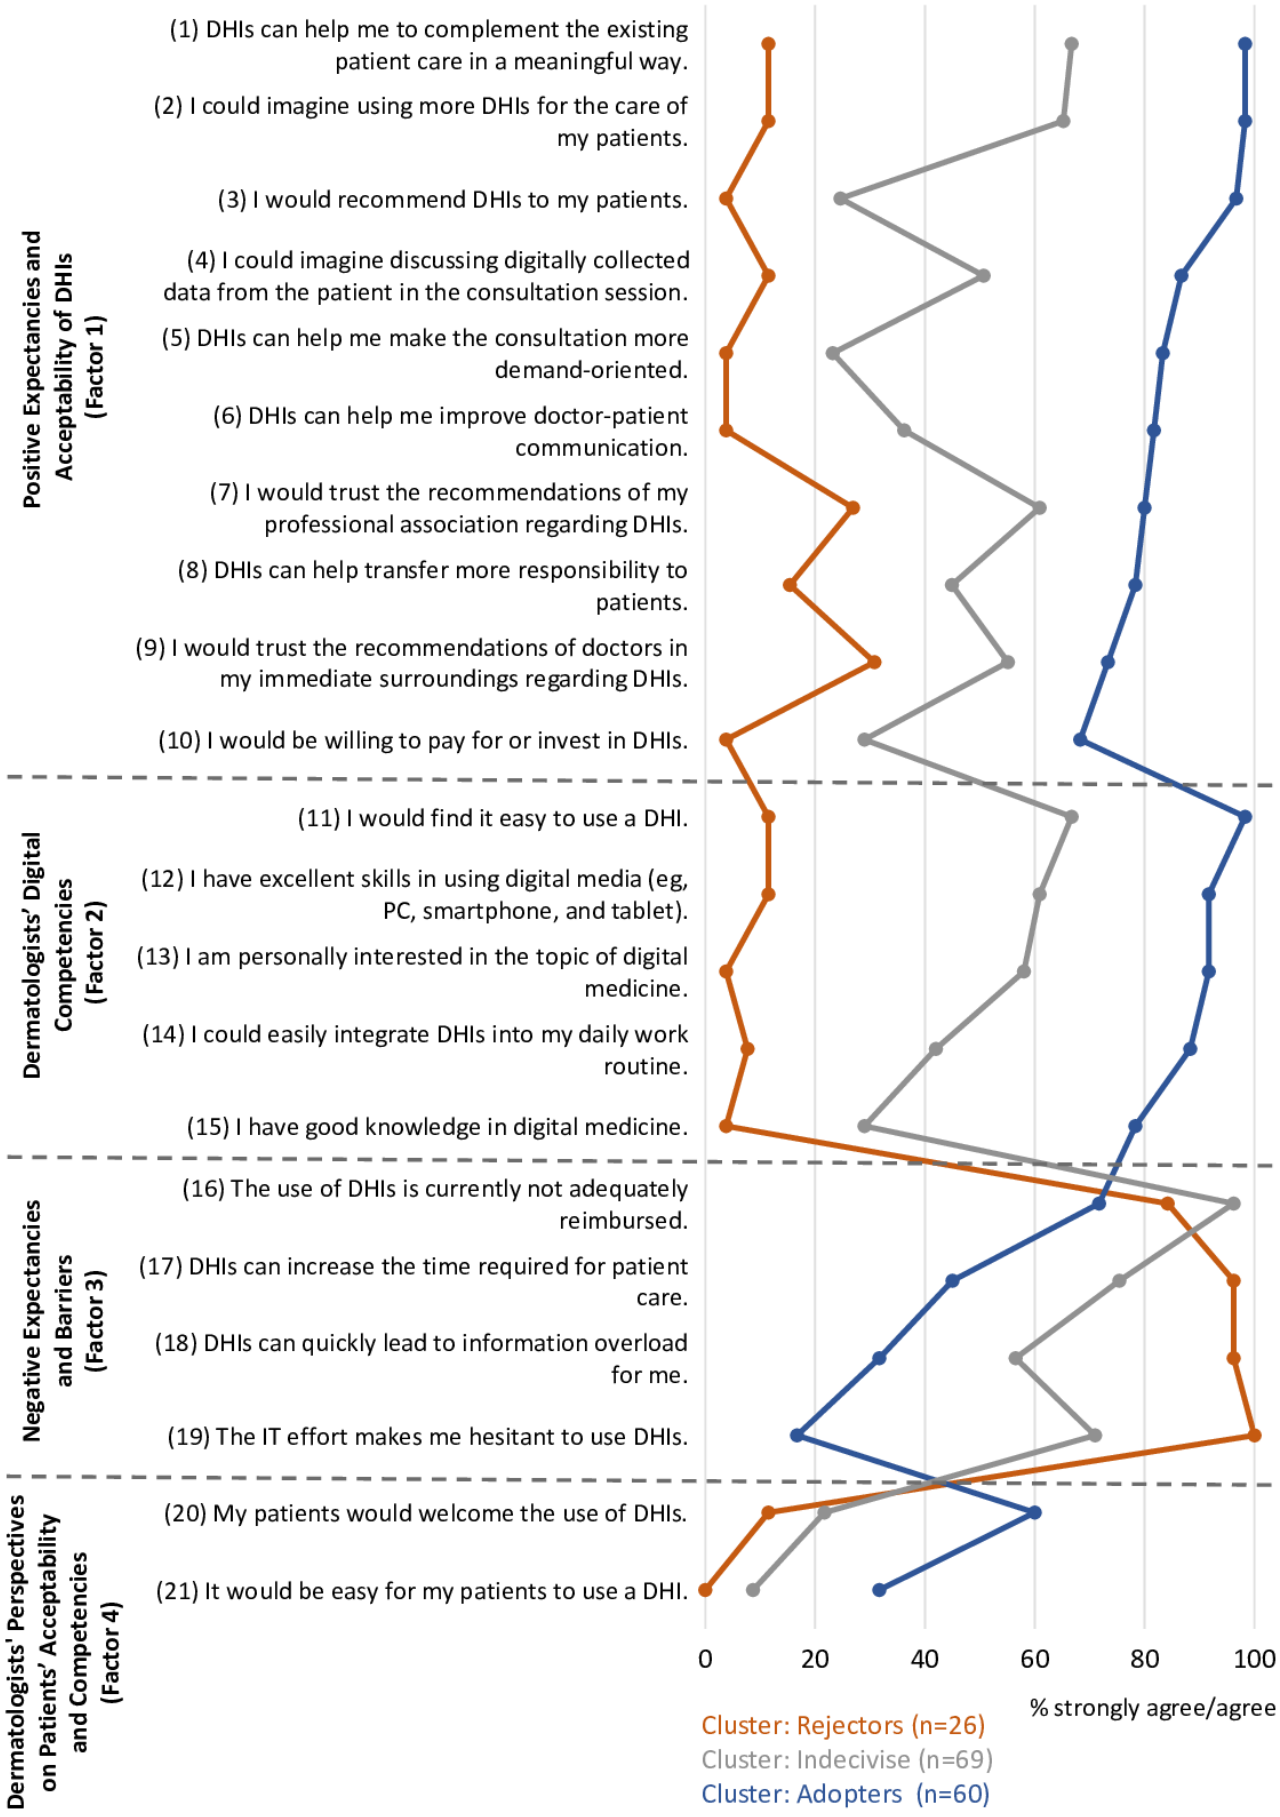
The Adopters (mean age 46.9, SD 11.7 y) were significantly younger compared to both the Indecisives (mean age 51.4, SD 7.9 y; *P*=.03) and Rejectors (mean age 58.8, SD 6.7 y; *P*<.001). No significant differences in sex were observed among the clusters (*P*=.33). Notably, an association between regional variation (urban or rural) and the three clusters was identified (*P*=.01): the Rejectors had the highest proportion of participants from rural counties (7/18, 38.9%), while the Adopters had the highest percentage of participants from urban counties or cities (51/56, 91.1%). In addition, Indecisives (54/67, 80.6%) and Rejectors (26/26, 100%) performed their services primarily in medical practices, whereas Adopters (32/60, 53.3%) performed theirs in outpatient clinics (*P*<.001).

Acceptability Profiles of the Clusters

The analysis of individual items revealed distinct profiles of the three clusters on their attitude toward DHIs. The following paragraphs describe selected items for each factor and cluster. A comprehensive overview of all item ratings is presented in Figure 1.

Nearly all Adopters expressed openness to using (Item 2: 59/60, 98.3%) and recommending DHIs (Item 3: 58/60, 96.7%) in the future (Figure 1; Factor 1). However, a lower proportion was willing to pay for DHIs (Item 10: 41/60, 68.3%). They rated themselves highly in digital media skills (Item 12: 55/60, 91.7%) and expressed confidence in the easy integration of DHIs into daily routines (Item 14: 53/60, 88.3%; Factor 2). About 45% (27/60; Item 17) feared an increase in the time required for patient care due to DHIs, but only a minority saw the effort for IT as a burden (Item 19: 10/60, 16.7%; Factor 3). A majority agreed that patients would accept DHIs (Item 20: 36/60, 60.1%), while a minority agreed that patients would find using DHIs easy (Item 21: 19/60, 31.7%; Factor 4).

XSL•FO
RenderX



About two-thirds of Indecisives were willing to use DHIs in the future (Item 2: 45/69, 65.2%), but a minority would recommend (Item 3: 17/69, 24.6%) or invest in DHIs (Item 10: 20/69, 29%; Factor 1). Although the majority would find it easy to use a DHI (Item 11: 46/69, 66.7%), few considered themselves knowledgeable in digital medicine (Item 15: 20/69, 29%; Factor 2). The majority perceived IT effort as a burden (Item 19: 49/69, 71%), expressed concerns about DHIs increasing consultation time (Item 17: 52/69, 75.4%), and causing information overload (Item 18: 39/69, 56.5%; Factor 3). Only 21.7% (15/69) believed patients would welcome DHIs (Item 20), and 8.7% (6/69; Item 21) thought patients would find them easy to use (Factor 4).

Rejectors scored low in Factor 1, with the highest agreement rates in trust toward recommendations of other physicians (Item 9: 8/26, 30.8%) and professional associations (Item 7: 7/26, 26.9%; Figure 1; Factor 1). Only 11.5% (3/26; Item 12) agreed to have high competencies in digital medicine (Factor 2). Almost all Rejectors worried about increased time requirements for patients (Item 17: 25/26, 96.2%) and information overload (Item 18: 25/26, 96.2%). They perceived high IT effort as a barrier to DHIs (Item 19: 26/26, 100%; Factor 3). Only 11.5% (3/26; Item 20) believed patients would welcome DHIs, and none (Item 21: 0%) thought patients would find them easy to use (Factor 4).

Overall, ratings on items in Factors 1, 2, and 3 were distinctly different among the three clusters, with the exception that the majority within all clusters agreed that DHIs are inadequately reimbursed (Figure 1; Factor 3). For Factor 4, Indecisives and Rejectors showed similar low agreement rates on a per-item level (Figure 1).

Assessment of the Nationwide eHealth Strategy

In the assessment of the nationwide eHealth Strategy, most dermatologists across all clusters did not perceive the strategy as successful (Figure 2). A majority within each cluster concluded that the eHealth Strategy did not enhance patient care (Indecisives: 52/69, 75%; Adopters: 35/60, 58.3%; and Rejectors: 26/26, 100%).

However, significant variations could still be observed among the three clusters. All Rejectors disagreed on the strategy being effective in fostering connections between patients and providers (26/26, 100%). The Indecisives shared similar doubts (50/69, 72.4%). This behaved similarly with regard to the strategy being cost-effective (49/69, 71% disagreement for Indecisives; 26/26, 100% for Rejectors) and providing added value to dermatologists (48/69, 69.1% disagreement for Indecisives; 25/26, 96.2% for Rejectors). In contrast, the “Adopters” were more divided in their assessment: one-third of the cluster agreed with the statements, another third disagreed, and the remaining third was inconclusive. For example, 37.1% (22/59) agreed, 32.3% (19/59) disagreed, and 30.6% (18/59) were inconclusive on the statement regarding whether the strategy has connected patients and physicians.

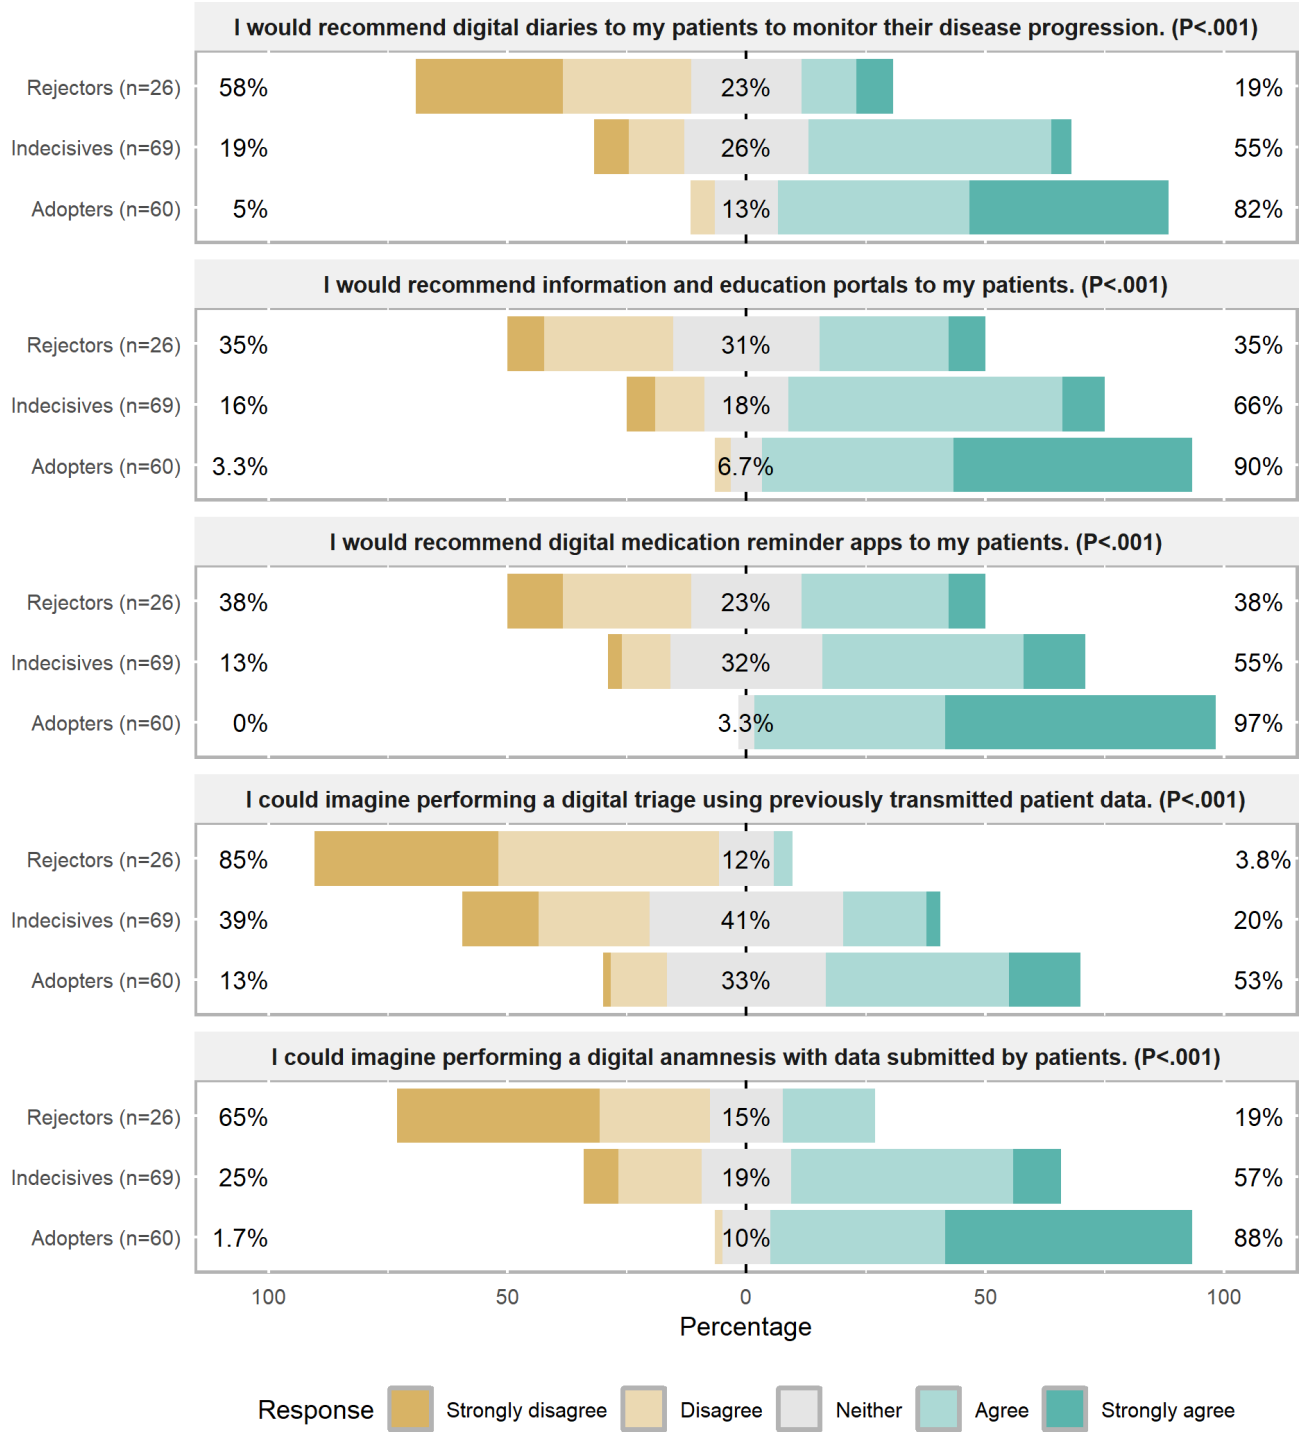
Current Use of DHIs Within Identified Clusters

The use of common DHIs varied significantly between the three clusters, except for AI tools for diagnostic purposes (range: Rejectors 12%-Adopters 28.3%; *P*=.15), electronic patient data (range: Rejectors 0%-Adopters 16.7%; *P*=.05), and telemedical supported monitoring (range: Rejectors 0%-Adopters 5%; *P*=.09; Figure 3). The Adopters demonstrated the highest and the Rejectors the lowest utilization rates across all presented DHIs. A total of 95% (57/60) of the Adopters reported to communicate via email or instant messaging with colleagues, and 86.7% (52/60) used email to communicate with patients. In contrast, only 44% (11/25) and 50% (13/26) of the Rejectors engaged in these communication methods. Apart from email communication, less than half of the Adopters and one-third of the Indecisives used other DHIs. For example, "Appointment Reminders" were used by 50% (30/60) of the Adopters and 26.1% (18/69) of the Indecisives. The Rejectors did not use many of the DHIs at all, such as store-and-forward (0%) and live-interactive teledermatology (0%). Additionally, their utilization of AI for diagnostic purposes was very low (3/25, 12%).

Figure 3. Use of digital technology in the last 12 months by clusters. *P* values indicate the outcome of a chi-square test or Fischer exact tests. AI: artificial intelligence; S&F: store-and-forward.



XSL•FO
RenderX

Future Intention to Use DHIs Within Identified Clusters

When considering the potential use of DHIs for their patients in the future, significant differences were identified among the three clusters (Figure 4). Between 80% (48/60; patient diaries) and 97% (58/60; medication reminder) of Adopters were willing to use 4 out of 5 described interventions. In contrast, only 55% (38/69: medication reminders) to 66% (45/68; education portals) of Indecisives can imagine using or recommend specific DHIs more often than currently. Rejectors had low potential use rates ranging from 19% (5/26; for digital anamnesis) to 35% (9/26; for education portals). While a slight majority of Adopters (32/60, 53%) could envision using digital triage, 33% (20/60) were undecided. However, 20% (14/69) of the Indecisives could imagine using digital triage, while 41% (28/69) were undecided. In contrast, 85% (22/26) of the Rejectors disagreed on using digital triage in the future.

Figure 4. Potential future use of digital health interventions by clusters. *P* values indicate the outcome of a chi-square test.

Discussion

Principal Findings

This study aimed to explore dermatologists' acceptability of DHIs, as well as their current and potential future use. Further, clusters were identified according to their level of acceptability, and differences were examined between the clusters and sociodemographics, as well as DHI current and future use. The current use barely exceeded 30% for interventions like teledermatology, AI for diagnostic purposes, and electronic patient data, even among willing dermatologists.

Overall, acceptability was moderate but varied significantly among the identified clusters. We recognized a cluster of dermatologists with high acceptability (Adopters), another similar-sized cluster with moderate acceptability (Indecisives), and a third minority with low acceptability (Rejectors). Indecisives and Rejectors perceived negative expectancies following the introduction of DHIs (eg, workload increase) and mostly questioned patients' willingness and competence to use them. Adopters were younger, and more commonly practicing in urban settings and outpatient clinics compared to Rejectors. Satisfaction with the nationwide eHealth strategy was generally low, although perspectives among Adopters were more divided. Current and future use of DHIs depended on the type of DHI and cluster, with Adopters showing higher rates.

Significant inequalities in DHI adoption between clusters indicate the presence of a second-order digital divide (disparities in digital competencies and acceptability toward DHIs) [41,42]. The more common adoption of DHIs among younger and urban dermatologists has already been identified [30]. This difference can contribute to existing health inequities by impacting access to health care and potentially even health outcomes [43]. It is crucial to closely monitor the impact of further DHI adoption in dermatology and address any potential health disparities.

In general, inadequate knowledge, as perceived in the survey, is a recognized barrier to the adoption of DHIs [22,44]. Integrating education on digital medicine into medical curricula and continuing medical education programs is, therefore, a potential approach to increase use and mitigate the digital divide [45]. As the health care system undergoes digital transformation, investing in digital health education is crucial [46].

The survey identified structural barriers to the widespread adoption of DHIs, including inadequate reimbursement and incentives, workload concerns, and IT infrastructure challenges. In addition, the inadequate nationwide eHealth infrastructure [47], as also noted by dermatologists in our survey, hinders the seamless integration of DHIs, for example, in teledermatology due to problems with electronic prescriptions and lack of access to patient records [21,48]. These factors may help explain why the adoption rate of innovative technologies, including teledermatology, remained below 30% even among willing adopters. To address these challenges, developers and decision makers must prioritize aligning the eHealth infrastructure with practitioners' needs, as seen in other European countries [19]. Incentivizing physicians, alongside involving them in the development process more frequently to reduce concerns, can be a focus to increase DHI uptake [21].

The limited availability of DHIs may also contribute to the relatively low adoption rates, even among those categorized as Adopters. In Germany, for instance, store-and-forward teledermatology platforms primarily focus on diagnosis [15,16,49], with limited emphasis on triage or referrals [14] and follow-up of patients with chronic conditions [13]. This limitation restricts the broader use of the technology for different patient groups. Additionally, patient electronic health records remain incompletely implemented [19], and there is a shortage of patient apps capable of either generating (eg, heart rate) or supporting patients in generating (eg, patient-reported outcomes) health data. Conversely, the swift uptake of AI apps, even among those categorized as Rejectors, underscores the benefits of this technology for dermatologists [50]. Our research suggests that most Adopters and the majority of Indecisives express a desire to use and recommend specific DHIs more frequently, highlighting the need for increased availability of evidence-based DHIs.

The perspective that patients would not welcome or find DHIs easy to use aligns with evidence that over 70% of the German population lacks adequate digital health competencies [51]. Patients also demonstrate low to moderate acceptability toward DHIs [34,52-54]. Other research contradicts those findings, suggesting that patients with dermatological conditions even have a higher acceptability toward DHIs in comparison to dermatologists [27]. Nevertheless, physicians and nurses can provide vital guidance, given their significant influence on patients [23,25,26]. Notably, Adopters recognized this role, expressing a willingness to recommend DHIs despite acknowledging patients' overall lack of digital competencies. This proactive stance should be complemented by health insurers, who also have a responsibility to promote DHIs and enhance digital literacy to ensure their appropriate utilization [55]. Such efforts are aligned with insurers' interests in supporting cost-effective health care services [55, 56].

One key distinction we found is that Adopters are more commonly affiliated with a hospital-connected outpatient clinic, while the majority of the other clusters involve self-employed dermatologists in medical practices. This may explain the differences in opinions on costs, reimbursements, or investments. Physicians in outpatient clinics may be less concerned with IT costs and IT investments than physicians in private practices, as they do not have to organize or pay themselves [57].

Similar to other studies on acceptability toward digitalization, it is important to consider the Intention-Behavior gap when interpreting the survey results. Here, intending to adopt DHIs in the future may not guarantee increased actual adoption in the future [58]. Additionally, while an association has been observed between a group exhibiting high acceptability (Adopters) and their current adoption of DHIs, the cross-sectional nature of the study means that the direction of this association remains ambiguous and cannot be extrapolated into the future.

XSL•FO
RenderX

Limitations

The survey has further limitations. Only 170 dermatologists participated out of over 6000 practicing dermatologists, of which 3500 were organized in the DDA and 1000 were invited [59]. Additionally, while dermatologists were randomly invited, our survey exhibited an overrepresentation of dermatologists in the medium age group (50–59 years), with younger dermatologists (40–49 years) and older dermatologists (60+) being underrepresented [59]. This observation is particularly significant considering the age differences identified between the clusters, where younger participants are more commonly affiliated with the Adopters cluster and older participants with the Rejectors cluster. The survey is also prone to voluntary participation, which might have attracted dermatologists with more extreme views on health care digitalization. Hence, the sizes of the clusters and other findings may not be fully generalizable to the real world. We also did not account for the potential integration of certain DHIs, such as the use of AI to preanalyze images submitted through store-and-forward teledermatology. Future research should therefore explore the impact of AI on perceptions and attitudes toward DHIs [54].

A factor analysis was conducted, as recommended, to reduce data dimensionality before performing the cluster analysis [39]. EFA was chosen instead of confirmatory factor analysis, as no theoretical assumptions about item interactions were made. The approach limits the comparability with other research on acceptability [33,34]. In addition, it is often recommended to conduct a confirmatory factor analysis following an EFA [60]. However, our sample size was not large enough to split the dataset to allow for a subsequent analysis. Despite this limitation, EFA calculations were deemed appropriate based on the KMO criterion and Bartlett's test of sphericity, resulting in factors with acceptable internal consistency [40]. To validate the findings of our research, the results could be further explored by conducting qualitative interviews with dermatologists and using a mixed methods approach [61].

Conclusions

The survey results indicate that dermatologists' overall acceptability toward DHIs is moderate. However, a sizable cluster expresses a high willingness to incorporate these interventions and recommend them to patients. Two other distinct clusters exist: one indecisive about health care digitalization and another rejecting DHIs.

The observed variation in actual adoption rates among clusters suggests a nuanced relationship between willingness and the implementation of DHIs. Dermatologists who express willingness are more inclined to adopt DHIs more frequently. However, despite this willingness, overall use rates remain moderate. This may be attributed, in part, to several structural barriers, including inadequate reimbursement, insufficient IT infrastructure, limitations of the nationwide eHealth infrastructure, and the limited availability of DHIs.

A notable perception among dermatologists, especially those with low acceptability, is the perceived low patient willingness and competency regarding digital health. This points to efforts needed to enhance digital literacy among patients. It is imperative for all stakeholders in the health care system, including health insurers, to invest in initiatives to improve patient education and empowerment in digital health.

Additionally, prioritizing education for health care providers on digital health and involving them early in the development of DHIs could mitigate potential disparities in digital health.

Addressing all the mentioned barriers could improve the acceptability and use of DHIs among dermatologists, particularly among those who are indecisive, thereby enhancing the integration of DHIs to support patient care.

Abstract

Background: A substantial number of newborns face postdelivery respiratory issues annually. Current ventilation devices in immediate newborn care lack integrated sensors and supporting mechanisms for medical professionals. This is a potential field of improvement, as safe ventilation relies on accurate pressure administration in current t-piece resuscitators. As the needed support during the process is currently limited, it highlights the demand for innovations in neonatal ventilation technology to improve efficacy and reduce potential errors.

Objective: The objective of the study was to facilitate collaboration between medical and engineering experts to evaluate the critical factors for the successful implementation of an innovative ventilation technology in clinical immediate newborn care. Incorporating the views of medical professionals into the survey is expected to offer valuable insights to engineers for subsequent technological refinement.

Methods: An international multicenter online survey was conducted among 51 neonatal health care professionals in the DACH region (Germany, Austria, and Switzerland) in order to (1) assess the specific functionalities required in a neonatal ventilation assistant in immediate newborn care from a medical technology viewpoint, (2) characterize the acceptance of such a device as support tool using the extended technology acceptance model, and (3) identify further steps toward integration of such technologies.

Results: According to the results, a visual representation of the current mask leakage and tidal volume is an essential feature. Integrating alarms in visual rather than audible form when limit values are exceeded is preferable. In contrast, medical professionals ranked an external control using a foot pedal as the least necessary feature. Based on the findings, acceptance constructs of the neonatal ventilation technology were moderately scored. Perceived usefulness (β=.76, P<.001) was the main predictor of the behavioral intention to use such a supportive instrument.

Conclusions: There is an evident willingness to integrate sophisticated support techniques into a neonatal ventilation device for immediate newborn care.

infant; neonatology; medical device; respiration disorders; pulmonary ventilation; medical engineering; technology acceptance model; technology acceptability; resuscitation; critical care

Introduction

The probability of survival of newborns depends on the extent to which they can adapt to the new environment and living conditions after delivery. Nevertheless, 3% of premature or newborn infants required respiratory support in the form of mask ventilation in the first few minutes of life [1], with approximately 1% of infants requiring postnatal resuscitation [2]. The lungs and associated tissue need to develop in the first few minutes of life before they are fully functional [3]. This period is highly critical, as excessive positive pressure ventilation can lead to damage to the lung tissue [3].

XSL•FO
RenderX

This issue is further compounded by the stress [4] experienced by medical personnel during a resuscitation scenario or ventilation procedure, which disrupts their typical level of physical performance and further exacerbates the situation. This can lead to inaccurate assessment of color [5] and heart rate [6]. One study [7] showed that despite a constant level of peak inspiratory pressure (PIP), maximum pressure on the lungs during inhalation, there was a range in the tidal volume administered, with the rationale that chest movement may not be accurately detected [8]. In such instances, the utilization of medical devices becomes paramount, as they have the potential to alleviate the psychological burden on health care providers.

The choice of ventilator used by medical personnel makes a difference in the actual quality of neonatal ventilation [9,10]. One study [11] has determined that the currently used technology (t-piece) may result in excessive ventilation pressures for newborns. Encounter emerging criticism regarding the inaccurate administration of ventilation pressures through t-piece devices [12], it is fundamental to design upgraded products in medical care to enhance safety in newborn life support.

This study aimed to assess essential device features for neonatal ventilation during immediate newborn care, as existing research addresses this aspect only in a limited way. The goal is not to replace the clinician but to enhance support through predefined functions that minimize potential errors and improve patient outcomes. The primary objective was to identify neonatologists' acceptance and need for technology that aids neonatal ventilation in the delivery room. The study sought to establish a collaborative interface between engineers and neonatologists, thereby aligning their perspectives and guiding the development of technology in this domain. A central objective was to address potential misunderstandings between medicine and technology proactively.

Methods

Recruitment

This survey was conducted online using the platform LimeSurvey (LimeSurvey Cloud Version 6.3.0, LimeSurvey GmbH). The first page of the survey stated the objective; the inclusion criteria, which were limited to individuals with (1) completed medical degrees and (2) a valid license to practice in neonatology; and the imperative need for their participation. The second page was dedicated to the information leaflet and the electronic consent form. Sociodemographic data and experiences with neonatal ventilation (ie, inquired about how participants would assess their personal experience in neonatal ventilation, the frequency of their exposure to this practice, and their familiarity with specific ventilation equipment used in the delivery room) were then asked, followed by the evaluation of particular requirements and assessment of the acceptance of a possible prototype of a medical device in the area of newborn ventilation in immediate newborn care.

Individual responder contacts were not available, therefore, cluster sampling was used to target the responders by their neonatology departments. The survey link was sent to a total of 351 neonatology departments in the DACH region (Germany, Austria, Switzerland), which provided contact information to the Department of Neonatology of the University Hospital Salzburg. Neonatology departments were asked to distribute the link to the survey to their medical experts using a prepared email. Departments were contacted 3 times to improve the response rate. Respondents were given the option to answer the questionnaire in either German or English. Data collection took place in September and October 2023.

Measurement

The survey consisted of two parts: (1) evaluation of specific requirements, suggested by a consensus of experts in neonatology of the University Hospital Salzburg, for a medical device in the area of newborn ventilation in immediate newborn care; and (2) evaluation of the acceptance of a possible prototype of this technology based on the extended technology acceptance model (TAM) [13].

To assess the acceptance of the ventilation device for premature and newborn patients, we used the TAM constructs [13], extended with the constructs of trust and risk [14], and the construct of social influence [15], which were adapted for this specific technology. In this adaptation, we substituted "information technology" [16] with "Neonatal Ventilation Device in Immediate Newborn Care." Data were gathered through an adapted TAM questionnaire containing 29 items distributed across 6 dimensions—perceived usefulness (6 items) [17], perceived ease of use (6 items) [18], behavioral intention to use (4 items) [16], social influence (5 items) [17], trust (3 items) [14], and perceived risk (5 items) [16]. The German version was translated based on existing versions [19] and adapted for the technology studies.

A pretesting phase preceding the study was conducted to ensure the comprehensibility of the included questionnaire items. Participants rated questions on a scale of 1 to 7, where "1" represented "not understandable" and "7" denoted "completely understandable." All items were above a cutoff of 4 at the end of the iterative phase, with an average rating of 5.4/7 (SD 1.3), indicating a good understanding of the individual items when applied to the response scale. Respondents (n=19), both academic and medical professionals, carried out this assessment.

The survey used a 7-point Likert scale for evaluation, where "1" indicated "strongly disagree" and "7" represented "strongly agree." The original survey version is attached in the Multimedia Appendix 1. In our sample, TAM dimensions showed high internal consistency (Cronbach α ranged from 0.73 to 0.94) [20]. Overall, the survey was structured according to that suggested by Burns et al [21] in their work with clinicians, with a cluster sampling design, a mixture of free-text and structured questions (mainly based on validated questionnaires), as well as a pretesting phase to ensure comprehensibility of the survey.

Statistical Analysis

The statistical analysis was undertaken using Excel (Microsoft Excel 2016, Microsoft Corp) and SPSS (IBM SPSS Statistics 29.0.0, IBM Corp). Means, medians, and SDs were used to present continuous measurements, and results from categorical measurements are shown as numbers and proportions. Multivariate ANOVAs were performed to examine differences

XSL•FO
RenderX

in the perceptions of the technology requirements as a function of the participants' characteristics (gender, age, and experience). Furthermore, 2 authors (ASK and DS) were involved in the analysis of the qualitative data by deductive analysis using the software MAXGDA (MAXGDA 24, VERBI – Software. Consult. Sozialforschung. GmbH).

Ethical Considerations

The study was conducted in accordance with local ethical guidelines as stipulated by the seventh revision of the Declaration of Helsinki. Ethical clearance was obtained from the Ethics Committee Salzburg (415-EALL/4/207/6 - 2024). Informed consent was obtained from all participants at the start of the study, and their data were analyzed anonymously. No forms of financial compensation were provided to the participants in this study.

Results

Sample Characteristics

A total count of 131 clicks was captured, 82 were identified as eligible attempts to respond by providing consent to participate, resulting in 51 valid responses. The survey was undertaken in German only. Physicians of pediatrics and adolescent medicine specializing in neonatology contributed to all responses. No anesthesiologists engaged in the field of neonatology participated, despite meeting the inclusion criteria. Participants reported their personal experience with neonatal ventilation with a mean of 6.0/7 (SD 1.2, median 6.0, IQR 5.00-7.00) and indicated the frequency of exposure with a mean of 5.8/7 (SD 1.4, median 6.0, IQR 5.00-7.00). Refer to Table 1 for detailed participant characteristics.

[a]CR: completed residency in pediatrics and adolescent medicine.

The ventilator from Paykel Healthcare, which operates under the name Perivent in German-speaking countries, but is also called Neopuff, was named the most frequently used device (n=44). The participants had the opportunity to select multiple devices simultaneously, depending on which ones they were currently using and with which they had previous experience. Furthermore, 2 of the devices mentioned were originally not designed by the manufacturers for ventilation of newborns in the delivery room, but for continuous ventilation in an intensive care setting. One of the devices cited is not intended for use in the immediate newborn care setting by the manufacturer, as it is specifically designed as a monitoring system for the neonatal ventilation process. Further details on the devices used for

XSL•FO

ventilation in the delivery room setting are illustrated in Table 2.

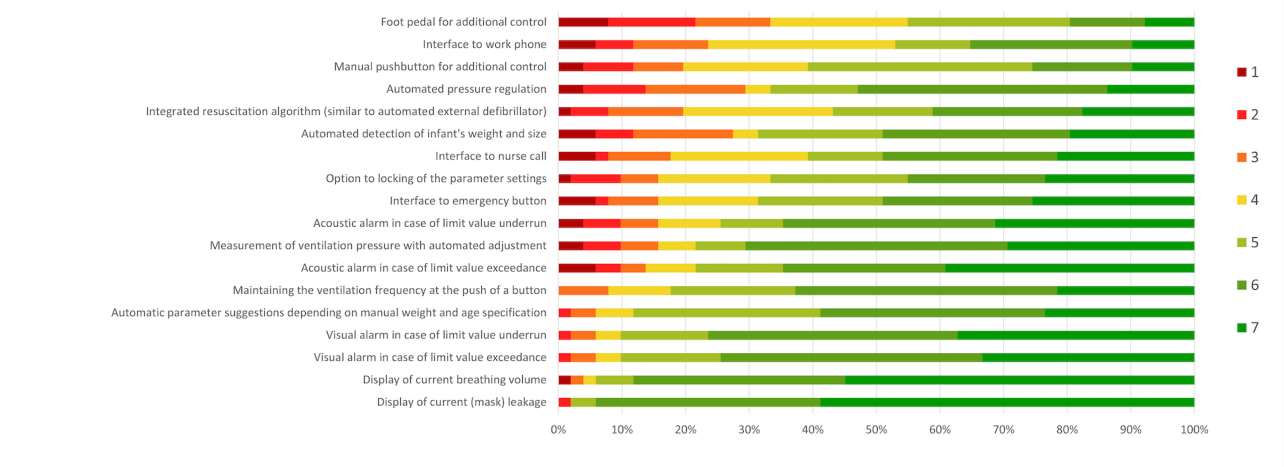
[a]Monitoring device for ventilation in immediate newborn care.

[b]Not designed for neonatal ventilation in immediate newborn care.



Device Functionalities

The participants rated the listed device features in terms of their future needs for implementation. Figure 1 illustrates the percentages of each rating score in a bar chart for each requirement. In addition to these predefined ratings, the participants were asked to what extent automation of workflows of neonatal ventilation at the push of a button might make sense: “1” represented a manual system, where the whole responsibility lies with the individual, whereas “7” indicated a fully automated system where the person is solely responsible for monitoring the device. The results show an average score of 4.2/7 (SD 1.7, median 4.0, IQR 3.00-5.00).

In addition to the predefined device requirements that participants were asked to rate, respondents were also provided with the opportunity to express their opinion on various requirements through a free-text field (n=18). Accordingly, a neonatal ventilation device used in the delivery room should include a “display of fraction of inspired oxygen” (n=3), along with the output of the “measurement of End-tidal carbon dioxide” (n=2) and the display of a “pressure-volume curve” (n=1). Another potential integration into such technology would be the capability for “humidification” (n=2) and “warming” (n=1) of breathing gases. Furthermore, features such as “time measurement” (n=1), “tidal volume per body weight” (n=1), and “alarms in the event of technical defects” (n=1) should be incorporated into this device. Another suggested feature could be an “automated start procedure with first ventilation” (n=1). A “memory function” (n=1) of the entire process would be beneficial for postintervention analyses. Finally, some participants expressed the preference “not to rely exclusively on the device with integrated technology” (n=2), emphasized the importance of considering “users’ experience” (n=1), and suggested that, in case of uncertainty, preset parameters can be “manually overwritten” (n=4).

XSL•FO
RenderX

Figure 1. Assessment of requirements for a ventilation device in immediate newborn care (n=51; no significant gender [$F_{18,32}$=1.40; P=.20], age [$F_{72,128}$=0.95; P=.60], or experience [$F_{72,128}$=1.01; P=.47] differences were shown based on multivariate ANOVAs).

Technology Acceptability

The participants expressed moderate levels of acceptance for the ventilation device in immediate newborn care based on the extended TAM (mean perceived usefulness 5.2, SD 1.1; mean perceived ease of use 4.8, SD 0.7; mean social influence 4.6, SD 1.1; mean trust 4.3, SD 1.2; mean risk 3.0, SD 0.9; mean behavioral intention 5.1, SD 1.2). Perceived usefulness, perceived ease of use, social influence, trust, and behavioral intention were all rated positively, while risk was rated as negligible.

Difficulties in Usage

Overview

In addition to the possible functions of such a device in the delivery room, participants were free to comment on any difficulties that might arise when using it. The ratings were divided into difficulties with first use (n=47), repeated use (n=25), and routine use (n=31).

First Use

Possible difficulties when using this type of technology for the first time can be divided into 6 categories based on the responses. Potential problems could lead to “incorrect operation” (n=10) during the process due to “personal uncertainties” (n=13) with the new technology. In addition, the “complexity of the system would require training” (n=9). There is also a risk of “relying on device support” (n=3) without additional follow-up checks of essential parameters. In addition, there is still the possibility of “technical malfunctions” (n=1) when using the system for the first time. In the “other” category (n=6), the following comments were made: on the one hand, that “curiosity to try something new” (n=1) arises personally when using the device for the first time, which allows “sensible setting of parameters” (n=1) and is “easy to use” (n=2). On the other hand, participants could imagine that the “individual assessment of the newborn” (n=1) plays a role in first-time use and that “focusing on the technology could lead to a reduction in observation of the child” (n=1).

Repeated Use

With repeated use of a new type of neonatal ventilation technology in the delivery room setting, the participants mentioned the difficulty that “clinical knowledge could be lost” (n=7) if a particular “reliance on the device” (n=3) was established. What would exist would be an “incorrect use” (n=2) with an “increased training effort” (n=4) in order to achieve a specific “safety in use” (n=4). However, after repeated use, the participants could already imagine having “fewer problems with increasing routine” (n=3). The “robustness of the device” (n=1) should, therefore, not be underestimated, as should “overly liberal use” (n=1) during this process.

Routine Use

In the course of routine use of such an assistance tool, the participants stated, among other things, the difficulty that users could “lose their clinical judgment” (n=11) due to increasing “familiarization with the technology” (n=5). However, “easy handling” (n=3) with little to “no” (n=5) issues in handling should arise in the course of routine. This technology could provide more “time for decisions relevant to care” (n=1), but there would still be the option of “no significant improvements” (n=1) in the overall process, for example, by “ignoring alarms” (n=2) because personal “expectations” (n=1) are different. In addition, “additional costs” (n=2) could be incurred for materials or upgrading an existing device.

Life-Threatening Malfunctions

In addition to the information on possible issues and difficulties in using such a respiratory assistant, the participants could also give their thoughts on life-threatening malfunctions (n=39). Comments were primarily related to “malfunctions in the area of ventilation pressure” (n=15), with incorrect outputs, both too high and too low, in the area of PIP and positive end-expiratory pressure (PEEP), as well as possible difficulties adjusting to the patient’s conditions. A “total failure” (n=9) of the entire system for no foreseeable reason and without a workaround (eg, switching to manual mode) was the second most common unacceptable malfunction. “Personal confusion” (n=8) when using such a tool can also lead to life-threatening situations, which must be considered during development. Incorrect

XSL•FO
RenderX

"measurements of the system" (n=5), starting with incorrect detection of the child's weight and the associated miscalculation of ventilation pressures, must be prevented at all costs. In addition, a "too long activation time" (n=1) before ventilation can take place, and "complicated handling" (n=1) can pose a life-threatening risk.

Additional Comments

In the final part of the questionnaire, there was also the option to provide general comments on medical technology in neonatal ventilation that the participants wished to contribute in the course of the survey. A total of 29 comments were received, with one response stating that "no" further issues were brought forward. In this section, the participants were concerned that "manual mode" (n=8) could be used to override any automated default settings or, if in doubt, switch them off. Such a system should be "easy to use" (n=6) in order to support both newcomers to the profession and neonatologists with many years of experience in their work. In addition, users should receive good and regular "training" (n=4) on the assistance tool in order to ensure that the familiarization phase and the assessment of therapy needs are of high quality. In the area of technical functionalities, functions such as "warming and humidification" (n=3) of the respiratory gas, "coupling with vital parameters" (n=1) and a "display of the ventilation strokes applied" (n=1) as well as a "sufficient battery" (n=1) and "alarm management" (n=1) should be considered. Depending on the different hospitals and clinics, there is also a difference as to which "group of people would use such technology" (n=1). The option to switch to a "mobile and portable version" (n=1) would avoid possible structural difficulties.

Discussion

Principal Results

This paper describes the results of a questionnaire survey in the field of ventilation technology for neonates in immediate newborn care. The responses highlighted the need for support mechanisms during the neonatal ventilation process, as participants rated the desired level of automation of such a technology as 4.1 out of 7, representing a medium to high degree of automation. The guidelines for neonatal care [22] further indicate that while situations requiring neonatal resuscitation are rare, the routine expertise to provide optimal quality is often lacking. Our findings should therefore serve as a starting point to support neonatologists in their practice in the best possible way, in terms of making high efforts in development in pressure administration, intuitive device design for easy handling, and display of critical vital parameters.

The current state-of-the-art neonatal ventilation in the delivery room uses a tube system containing a t-piece with a mask or tube plugged in. This system connects to an air-powered ventilator, where a specific oxygen saturation is set. A valve on the t-piece allows control of PEEP to manage lung pressure at the end of expiration. However, it lacks integrated monitoring of parameters such as tidal volume, ventilation pressure, in particular the PIP, and the determination of pressure loss due to mask leakage.

Our results are consistent and confirm a previous study [23] examining the influence of human factors during this process and improving the situation with assistive tools, such as integrating a display of current (mask) leakage, rated as the leading requirement. Free-text comments from individuals in our research support this trend. On the other hand, it is essential to highlight that one particular study [24] demonstrated that individuals with greater expertise in this domain exhibit an elevated mental workload and encounter higher cognitive demands throughout the process compared with inexperienced individuals using an assistive tool. In order to enhance personal performance during neonatal ventilation or resuscitation, the equipment to be used should be kept to a minimum in order to avoid fixation errors [25].

A topic addressed in the free-text comments pertained to the potential for "manual overwriting" of the device and the "incorrect usage during initial operation." According to the established standards, specifically the norm titled "Medical Devices -- Part 1: Application of Usability Engineering to Medical Devices" (IEC 62366-1:2015), such concerns should be anticipated during the manufacturing process and are fundamental prerequisites for any medical device. The operation of a medical device is intended to be seamless for the user and should minimize the awareness of the underlying technical interactions. It is recommended to carry out so-called usability tests to obtain such device properties. These tests are based on a specific scheme which, in addition to other considerations, should bring to light the problems mentioned earlier and provide opportunities to improve them [26].

It is important to note that this study focused on neonatologists, as they are the specialists in the ventilation of newborns. However, it is also worth considering that other medical staff, such as midwives, nurses, and anesthesiologists, could use the designed device. It is equally essential to acknowledge that some of the aforementioned devices for neonatal ventilation are not intended for immediate newborn care but rather for continuous ventilation in an intensive care setting or monitoring purposes only. This reinforces the importance of this work in providing an in-depth understanding of the needs of physicians for the development of assistive technologies specifically dedicated to neonatal ventilation in immediate newborn care.

Limitations

This work has some limitations, one of which is that the link to the survey was solely shared with neonatology facilities in German-speaking countries (DACH region). Therefore, only German-speaking neonatologists participated in the survey. No physicians with a background in anesthesia specialized in neonatology took part in this study. It could be speculated that they do not feel enough concerned by the survey. Second, to ensure a clear understanding of the questionnaire study, a pretesting phase was carried out on a small scale to assess the comprehensibility of the questions within the target group. Although considerable efforts were made to obtain a sufficient number of replies by broadly diffusing the survey, it ultimately resulted in a limited number of valid responses. It may be that not every center contacted and disseminated the survey due to

XSL•FO
RenderX

the high volume of inquiries that doctors receive. It is advisable to consider this potential limitation when interpreting the results.

Third, there was a huge difference in group sizes of the sample in relation to the educational level, where the group of fully qualified physicians of pediatrics and adolescent medicine with completed specialization in neonatology were overrepresented. Fourth, the method of free text response used to examine complementary user requirements could have been better examined through qualitative interviews. Based on these findings, future research could include qualitative interviews for a first prototype.

Comparison With Previous Work

Simulation training using a respiratory function monitor is already being conducted to further assist health care professionals by providing real-time information on the ventilation process [27]. However, certain studies [28-30] indicate a tendency for individuals to shift their focus from the infant to the monitor. This underlines the importance of a broad analysis of technologies in the delivery room. Our findings are in line with the idea that additional information, such as the display of current mask leakage and tidal volume, during the neonatal ventilation process may be beneficial, as well as with the experience of resuscitators using a respiratory function monitor [23]. However, additional information should not distract from the child nor overwhelm the caregiver. Considerations for individual functions should prioritize visual alarm functions over auditory ones to minimize potential distractions as well as to regain focus on the child.

Conclusions

The integration of supportive mechanisms into neonatal ventilation within the context of immediate newborn care is essential for the assistance of medical personnel. The acceptance of neonatologists of a device with additional functionalities and integrated sensors indicates a promising outlook. The objectives are clearly defined—to enhance the safety, efficacy, and quality of neonatal ventilation by minimizing human error and optimizing the overall care provided. The priorities encompass the improvement of device functionality, the assurance of user-friendliness, and the reduction of ventilatory complications. The analysis of technology acceptance reveals significant potential for future incorporation into existing systems.

The participation of physicians in the development process is of utmost importance. Their clinical expertise guarantees that the technology is aligned with real-world needs, remains intuitive, and integrates seamlessly into established protocols. Engaging with clinicians from the initial stages establishes a connection between medical and technological necessities, thereby ensuring that the technology improves patient care and aids clinicians in the delivery room.

Acknowledgments

ASK conceptualized the study, coordinated the data collection, conducted the statistical analysis, and prepared the first draft. MH supported within the methodology for the study design as well as the statistics. MW distributed the link to the survey within all the neonatology centers and supervised at all stages. DS checked the coding of the qualitative analysis. All authors critically reviewed the manuscript for improvement.

Abstract

Background: The health care sector's digital transformation has accelerated, yet adverse drug events continue to rise, posing significant clinical and economic challenges. Clinical decision support systems (CDSSs), particularly those related to medication, are crucial for improving patient care, identifying drug-related problems, and reducing adverse drug events. Hospital pharmacists play a key role in using CDSSs for patient management and safety. Human factors and ergonomics (HFE) methods are essential for designing effective, human-centered CDSSs. HFE involves 3 phases—exploration, design, and evaluation—with exploration being critical yet often overlooked in the literature. For medication-related CDSSs, understanding hospital pharmacists' tasks and challenges is vital for creating user-centered solutions.

Objective: This study aimed to explore the actual practices and identify the needs of hospital pharmacists analyzing electronic prescriptions. This study focused on the preliminary stage of the user-centered design of a pharmacist-centered CDSS.

Methods: The study involved observing 16 pharmacists across 5 hospitals in mainland France (a university hospital, 2 large general hospitals, a smaller general hospital, and a specialized clinic). Pharmacists were selected regardless of expertise. The observation method—systematic in situ observation with shadowing posture—involved following pharmacists as they analyzed prescriptions. Researchers recorded activities, tools used, verbalizations, behaviors, and interruptions, using an observation grid. Data analysis focused on modeling pharmacists' cognitive work, categorizing activities by action type, specificity, and information source. Sequential time data analysis and distance matrices were used to generate hierarchical clustering and identify similarity groups among the pharmacists' analyses. Each group was described using its typical sequences of analysis and related covariates.

Results: In total, 16 pharmacists analyzed and validated electronic prescriptions for 140 patients, averaging 5.48 minutes per patient. They spend 91% of their time searching for information rather than transmitting it. Most information comes from the list of prescriptions, but it is the time spent in electronic medical records (EMRs) that dominates at the heart of the analysis. Pharmaceutical interventions are most frequently transmitted in the last third of the sequence. The pharmaceutical analyses were grouped into 4 clusters: (cluster A, 22%) interventionist clinical analysis with extensive crossing of various sources of information and almost systematic pharmaceutical interventions; (cluster B, 52%) most common clinical analysis focusing on EMRs and biology results; (cluster C, 13%) logistical analysis, focusing on the pharmacy workflow and the medication circuit; and (cluster D, 13%) quick, trivial analyses based exclusively on the list of prescriptions.

Conclusions: The pharmaceutical analysis process is complex and multifaceted. Pharmacists are detectives, accessing a wealth of information to discriminate drug-related problems and respond accordingly. They also carry out different types of analysis, which lead to different needs and require different solutions from CDSSs. This exploratory study is an essential prerequisite for meeting the challenge of designing tools to support pharmaceutical analysis and pharmacists.

Introduction

Background

The digital transformation of the health care sector has accelerated over the past decade [1]. This digitization has reduced some risks associated with the use of health care products, such as handwriting-induced confusion [2]. However, adverse drug events continue to represent a significant clinical and economic burden for populations [3]. This paradox is due to the very diverse origins of adverse drug events and to the fact that the computerization of health care organizations corrects some drug-related problems but introduces many others, such as lack of ergonomics and alert fatigue [4,5]. Nowadays, health care providers must make more complex decisions [6], with an exponential increase in clinical and pharmaceutical information. Knowing that certain patient data are available, knowing how to access the data, having the time to search for information, and keeping up to date with the latest treatment recommendations are all challenges faced by professionals in their daily practices [7,8]. Out of this chaos came the interest in clinical decision support systems (CDSSs) to help clinicians make informed decisions and to derive full benefit from hospital information systems [9]. In particular, medication-related CDSSs have the greatest potential to benefit patient care and reduce drug-induced iatrogeny [10-12].

Hospital pharmacists are key users of CDSSs. The pharmacy department is responsible for the entire hospital's health care product circuit, and the pharmacist's activity is essential to patient safety and the reduction of health care expenditure [13]. Several studies have demonstrated the value of pharmacist-oriented CDSSs for patient management [10-12]. Of course, in health care, the patient's well-being is the main concern. Nevertheless, it is also necessary to consider the well-being of health care providers because they are responsible for the majority of medication-related errors [14]. This is why human factors and ergonomics (HFE) methods are fundamental in promoting the human-centered design of systems that support individuals and teams. As defined by Holden et al [15], "HFE is a scientific and practical human-centered discipline that studies and improves human performance in sociotechnical systems." It is also a standard of practice [16], with applications in many fields: aviation, surface transportation, military, and energy. In this respect, HFE methods are equally applicable to pharmacy challenges and medication-related CDSSs [15,17,18].

Using HFE to design digital products involves three phases [19]. (1) *Exploration* (or *analysis*) aimed at examining users in their natural environment, determining their tasks, activities, goals, constraints, and needs. Here, the real user problems are identified. (2) *Design* takes advantage of exploration data to provide solutions to identified problems. This ranges from simple wireframes to more complete prototypes. (3) *Evaluation* helps to assess ideas and the proposed design in order to optimize and correct it. It involves testing and scoring the user experience, ergonomics, and messages in both form and content. The first stage is fundamental to the success of the other two. However, HFE studies in the pharmacy sector tend to focus on the design or evaluation phase [20,21]. The same is true of studies on CDSSs [22-24]. Exploring the practices of hospital pharmacists would appear to be a crucial step, particularly for the development of medication-related CDSSs. Software editors need to study the complexity of the task of analyzing and validating electronic prescriptions in order to design products in accordance with the principles of human-centered design [16].

Prior Work

HFE methodologies are now well established in the health care sector, with a growing number of publications [25]. They all deal with exploration, design, and evaluation, but some phases of human-centered design are better represented than others. Evaluations are clearly the most represented [20,21,23], often involving products already designed or at the end of development, on which usability studies are carried out [26,27]. Unfortunately, these studies give little indication of the earlier stages, unless they also deal with design or co-design [19,22].

In fact, it is rare to find publications that focus solely on the analysis phase, especially in relation to health care providers and pharmacists. Studies focus on the patient [19,28,29] or on the patient's involvement in the health care system [30]. There are also studies on physicians [31-33], but these tend to focus on the usability of already implemented digital systems [34,35]. Finally, a few studies focus on the importance of the physician-pharmacist relationship for patient safety [12,36]. These studies use questionnaires, interviews, and focus groups, which are HFE methods that have the disadvantage of transcribing user subjectivity rather than actual behavior [37]. More objective methods, such as systematic observations, are better suited to identifying problems and needs for pharmacy research and clinical practice [15].

Several studies use observations as part of their methodology [38-46]. However, they tend to complement other methods in order to diversify data sources and reduce the risk of systematic bias based exclusively on reported behaviors and experiences [38]. Observations are treated here from a qualitative point of view, rather than as quantifying the activity of professionals. Moreover, as with all exploratory publications, the study participants are patients [38,39], physicians [40,41], nurses [42], and health care professionals as a whole [43-45], not just hospital pharmacists. Finally, they are not always user-centered [42], but rather focused on products [45,46] and their usability [39].

Ultimately, some studies have examined pharmacists' practices using quantitative field observations [47-51]. They do not necessarily focus on HFE methods but rather on the study of professional practice to improve the quality and safety of care [52]. One focuses on community pharmacists and the other 3 on hospital pharmacists. However, they do not deal specifically with the pharmaceutical analysis of prescriptions, but with the work pattern as a whole, and the impact of the medication

XSL•FO
RenderX

management system on this work pattern. In the context of developing a CDSS, the information provided by these studies is interesting but does not provide the exploratory data needed to design a prescription analysis support module. Moreover, it is difficult to retrieve exploratory data from the design and evaluation phases, as they only give access to the tip of the iceberg of product design: that is, "What was done?" and not "Why was it done?" To the best of our knowledge, there are no HFE or professional practice publications on prescription analysis by hospital pharmacists. There are only recommendations from professional associations, with useful elements for analyzing and improving practice [53,54].

Goal of This Study

This exploratory study focuses on the first stage of user-centered design: the phase of in-depth understanding of the user, his or her activity, and the context in which this activity takes place [15]. The aim is to explore hospital pharmacists' practices when analyzing and validating electronic prescriptions. It also aims to find their specific needs for the design of user-centered CDSSs.

We make several exploratory hypotheses: (1) there are different types of pharmaceutical analysis, (2) pharmacy logistics play a significant role in analysis, and (3) some information is difficult to access for pharmaceutical analysis.

Methods

Ethical Considerations

Ethics approval was not sought, as no identifiable health data were collected, and the pharmacists who were observed signed a free and informed consent form after they were informed of their personal data rights, in line with the General Data Protection Regulation (EU 2016/679). The observed pharmacists were not compensated for their participation in this study.

Recruitment

We visited 5 hospitals in mainland France for a total of 16 pharmacists observed: a university hospital with more than 2000 beds (3 pharmacists), 2 general hospitals with between 1000 and 2000 beds (4 pharmacists), 1 hospital with fewer than 1000 beds (5 pharmacists), and a specialized clinic with fewer than 200 beds (4 pharmacists).

Pharmacists are selected regardless of their expertise or status. This includes pharmacy residents, as they perform much of the validation of hospitalized patients. The only exclusion point is that the pharmacist's usual task is not to analyze and validate prescriptions (the activity must be performed at least once a week).

The number of participants observed depends on the discrepancy between pharmacists' practices: the greater the discrepancy, the more observations are needed to describe the different pharmaceutical analysis groups.

Observations

Protocol

Our exploration approach is based on systematic observations in an in situ context [37]. This method enables us to characterize the current state, analyze the environment, and identify the needs of hospital pharmacists. It will also describe how hospital pharmacists access, process, and return information over time in order to analyze and validate patients' electronic prescriptions.

Each observation consists of following a pharmacist analyzing and validating electronic prescriptions for about an hour. Pharmacists are informed of the objectives of the study before participating. They also receive some instructions, but the full methodological details are not given until the end of the observation to avoid influencing their behavior. Participants are instructed to act as they normally would. They are allowed to verbalize as much as they wish. They can move from one patient to another and can return to a patient who has already been validated. Task interruptions are natural in the professional practice of pharmacists [55], so the participant can interrupt his or her activity at any time.

At the start of each observation, the researcher notes generic information about the environment (date, time, site, and location) and the pharmacist being observed (area of expertise and status). At the end, he or she enters the time and comments, debriefing the participant. In 1 hour of observation, the pharmacist will analyze and validate several electronic prescriptions corresponding to different patients. For each patient, the researcher uses an observation grid to structure data collection.

Grid and Posture

An observation grid is completed for each patient (Multimedia Appendix 1). It is organized in the form of a successive list of activities, with each activity necessarily associated with the time required to perform it. Depending on the situation, other information may also be entered: (1) tools used, (2) verbalizations relevant to understanding the activity, (3) behaviors and reactions, and (4) the occurrence of a task interruption and its origin. The researcher records all the pharmacist's activities, taking care to provide sufficient detail for understanding, but without going too far, at the risk of losing the thread of the process.

The observation method requires the researcher to adopt a posture clearly defined by the study protocol. This is the shadowing technique [56,57]. It consists of following the user's activities as closely as possible, without intervening directly in the observed situation. However, the researcher may ask the participant questions in order to better understand the reasons for certain behaviors. Here, the researchers are hospital pharmacists familiar with user experience methods. This choice enhances the discernment of very specific professional activities and limits the questions asked of the participant.

Data Analysis

Observation Processing

In order to model pharmacists' cognitive work from raw observation data, each activity is assigned (1) a type of *action*

XSL•FO
RenderX

(search or transmit), (2) a level of *specificity* (generic or specific), and (3) a *source* of information (list of prescriptions, electronic medical records [EMRs], biology results, pharmaceutical interventions, pharmacy logistics, drug information, other information, or alert from prescriptions). Analysis times are represented in relative terms (percentage of total time) rather than absolute values to facilitate the comparison of activity sequences with wide time disparities.

The processing of temporal successions of activities is inspired by the processing of sociological data where populations change state as a function of time (eg, professional status: student → employee → unemployed → employee → retired). In particular, we drew on the work on exploratory analysis in a social context by Mariette et al [58]. To this end, we use the R package *TraMine*R [59] and multidomain case studies (in our case, activities are combinations of 3 domains) [60]. These methods are used to split up activities and generate comprehensible representations.

Clustering

Another advantage of these sequential data analysis methods is their ability to generate distance matrices between pharmaceutical analysis sequences [59,60]. This is followed by hierarchical clustering using the R package *cluster* [61] to distribute observations into different similarity groups. Finally, we describe the clusters by matching the graphs of typical sequences for each group (*TraMineR* package), with the description of covariates provided by the R package *FactoMineR* [62] and its class-based modality description function (contingency table, *V* test, and chi-square test).

Results

Observations and Sequences of Activities

Overview of Observations

The 16 pharmacists analyzed and validated the electronic prescriptions of 140 patients. The distribution of the time data for the 140 observations (mean 5.5; range 0.5-15; median 5, IQR 3.5-7.5 min) was nonnormal (Multimedia Appendix 2).

Pharmacists take an average of 5 minutes and 29 seconds to analyze one patient. The fastest analyses take 30 seconds, and the longest 15 minutes. The time spent on task interruptions is deducted from the total analysis time.

The observations show 17 different types of activity, formed by combining the 3 domains of *action*, *specificity*, and *source* (combinations are available in Multimedia Appendix 3). The representations of the activities (Table 1) separate the action, finesse, and source domains to better compare proportions.

The *action* domain is mostly represented by the search category, accounting for 90.7% of the total analysis time (Table 1). Pharmacists thus spend almost 91% of their time looking for information, and 9% transmitting it. In terms of *specificity*, information is more often generic (66%) than specific (34%). As for the *source* of information, the list of prescriptions is the most common (37.5%), along with the EMRs (28.2%); next in order of frequency are biology results (13.1%), pharmaceutical interventions (7.7%), pharmacy logistics (4.7%), drug information (4%), other information (3%), and alert from prescriptions (1.8%).

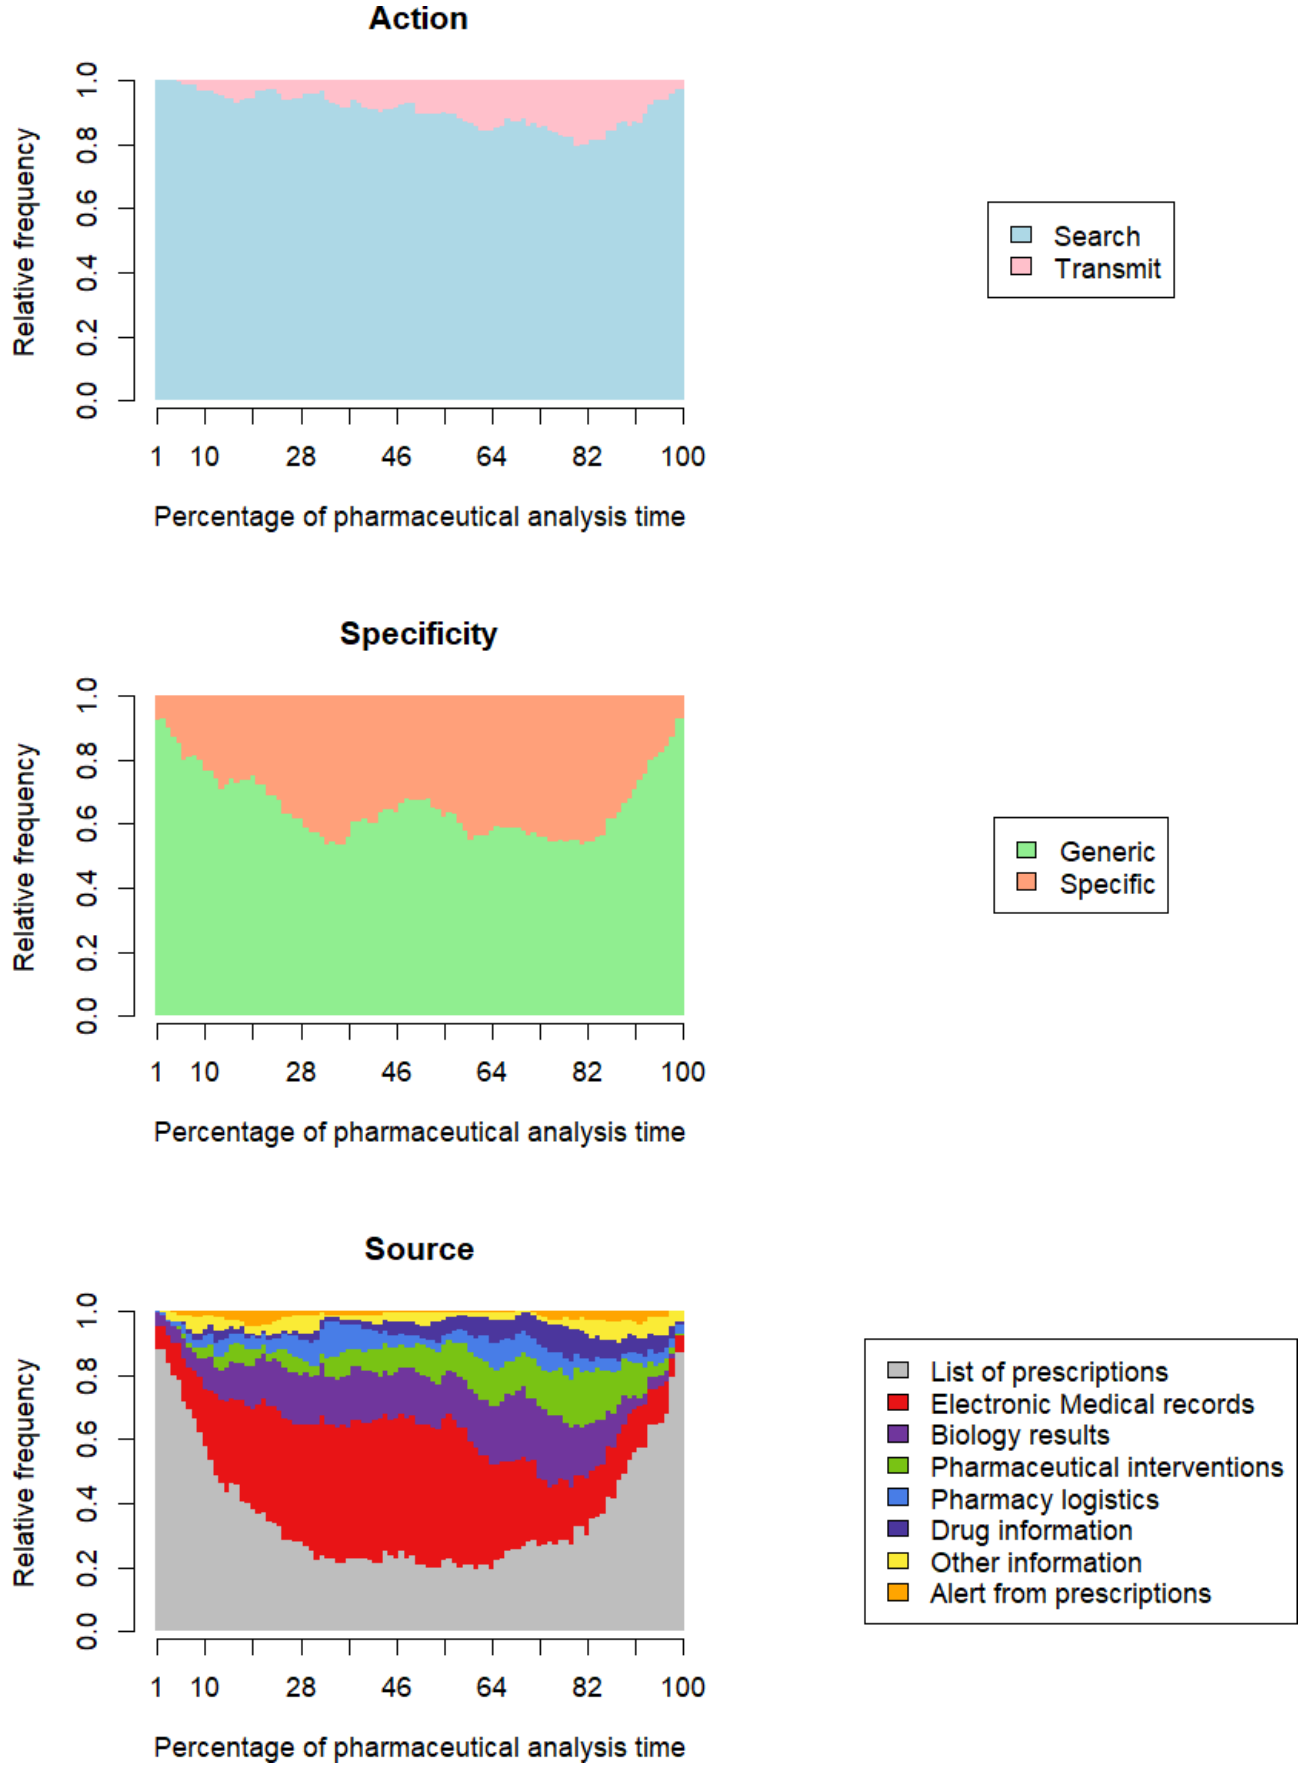
Table . Time distribution of categories in each area (action, specificity, and source). Results are expressed as a percentage of total analysis time.

Area and categories	Time distribution, %
Action	
Search	90.7
Transmit	9.3
Specificity	
Generic	66.0
Specific	34.0
Source	
List of prescriptions	37.5
Electronic medical records	28.2
Biology results	13.1
Pharmaceutical interventions	7.7
Pharmacy logistics	4.7
Drug information	4.0
Other information	3.0
Alert from prescriptions	1.8

Time Sequences

Time trends in activity categories are shown in the graphs of relative activity frequencies (Figure 1). They are based on graphs of the individual activity sequences of the 140 patients (Multimedia Appendix 4).

XSL•FO
RenderX



For the *action* domain, information search predominates over information transmission throughout the analysis. The transmit category rises slowly from the start of the analysis, peaking at the end, with a frequency of 20% (82% analysis time), before falling back to zero.

For the *specificity* domain, the beginning of the analysis mainly concerns generic information, with a gradual increase in the proportion of specific information as the analysis progresses. After 30% of the analysis time, the share of specific information stabilizes at around 40% of the total information consulted or transmitted. At the end of the analysis, pharmacists return to a large majority of generic information.

For the *source* domain, the list of prescriptions is consulted frequently throughout the analysis (basal frequency 20%), with 2 peaks at the beginning and end. Between 28% and 64% of the analysis time, the EMR is in the majority, representing around 40% of all activities performed during this period. The proportion of "biology results" remains fairly constant, as do "pharmacy logistics," "other information," and "alerts from prescriptions." Pharmaceutical interventions and drug information are poorly represented at the outset but increase to reach a peak of around 82% of analysis time. Details of the relative frequencies of the *source* domain for each observation are available in Multimedia Appendix 5.

XSL•FO
RenderX

Figure 1. Graphs showing the relative frequency of each type of activity in relation to the percentage of time spent analyzing the prescription.

XSL•FO
RenderX

Types of Pharmaceutical Analysis

The distance matrix between analysis sequences is generated by assigning greater weight to the source domain than to the action and specificity domains (ratio of 2:1). The reason behind this ratio is that the source domain is more objective than the specificity domain (less bias) and more discriminating than the action domain (improving the strength of the classification structure). The agglomeration coefficient of the hierarchical clustering is 0.88 (see dendrogram in Multimedia Appendix 6).

In order to facilitate interpretation and maximize class coherence, the clustering is divided into 4 groups (A, B, C, and D).

The characterization of pharmaceutical analysis typologies is done using graphs of the reference sequences for each sequence cluster (Figure 2). The results in this figure can be read using the tables describing the clusters according to covariates (Tables 2 and 3).

Figure 2. Reference activity sequences for each cluster and domain. Dist.: statistical distance (used to assess the dissimilarity or difference between two statistical objects).

[a]N/A: not applicable.

Cluster A comprises 31 (22.1%) sequences of the 140 patients analyzed. The typical group A sequence includes a wide variety of information *sources*, with many alternating between them. The level of *specificity* is balanced between generic and specific information. The *action* of transmitting occurs mainly at the end of the analysis, in correlation with the "pharmaceutical interventions" *source*. Cluster A analyses took significantly longer for pharmacists. They are mostly carried out by assistant pharmacists, and their validations are mostly made with reservations (pharmaceutical interventions).

Cluster B involves the most patients, with 73 (52.1%) sequences of the 140 patients analyzed. The typical cluster B sequence is characterized by the *action* of searching for information (no transmission), and the *specificity* of the information is more generic than specific. The diversity of information *sources* is lower than in cluster A: pharmacists alternate between the list of prescriptions and the EMRs, with a few passages in biology results and drug information. Cluster B sequences contain almost all the sequences produced by junior pharmacists and give rise to unreserved validations (no pharmaceutical interventions). Cluster B patients are more likely to be hospitalized in medical departments than in surgical ones.

Cluster C contains 18 (12.9%) sequences of the 140 patients analyzed. The typical cluster C sequence devotes most of its analysis time to the *action* of transmitting. Most of the information is specific, with generic information used mainly at the beginning and end of the analysis. Activity *sources* are few when compared to cluster A, and alternate between list of prescriptions, pharmacy logistics, and pharmaceutical interventions. The sequences in cluster C relate more to the analysis practices of senior hospital practitioners who validate surgical services. Validation is generally carried out with reservations (pharmaceutical interventions).

Cluster D also comprises 18 (12.9%) sequences of the 140 patients analyzed. The typical cluster D sequence is the simplest of the 4 groups. It consists solely of search *actions*, with generic *specificity* and the list of prescriptions as its *source*. Cluster D analyses take significantly less time for pharmacists and result in unreserved validation (no pharmaceutical interventions). This type of analysis is more common among pharmacists working in open spaces.

Discussion

An Investigative Posture

The goal of this study is to understand how pharmacists analyze prescriptions, and in particular, whether analysis profiles exist. The 16 pharmacists who participated in the observations took an average of 5 minutes and 29 seconds to analyze and validate a patient. Although this value is close to the median (5 minutes), it should be noted that the total range of validation times is rather wide (between 30 seconds and 15 minutes) and that the distribution of values does not follow a normal distribution (Multimedia Appendix 2). We can therefore expect major disparities in analysis typologies, but we will come back to this point later.

From an overall point of view, the pharmacists' posture is overwhelmingly focused on seeking information from

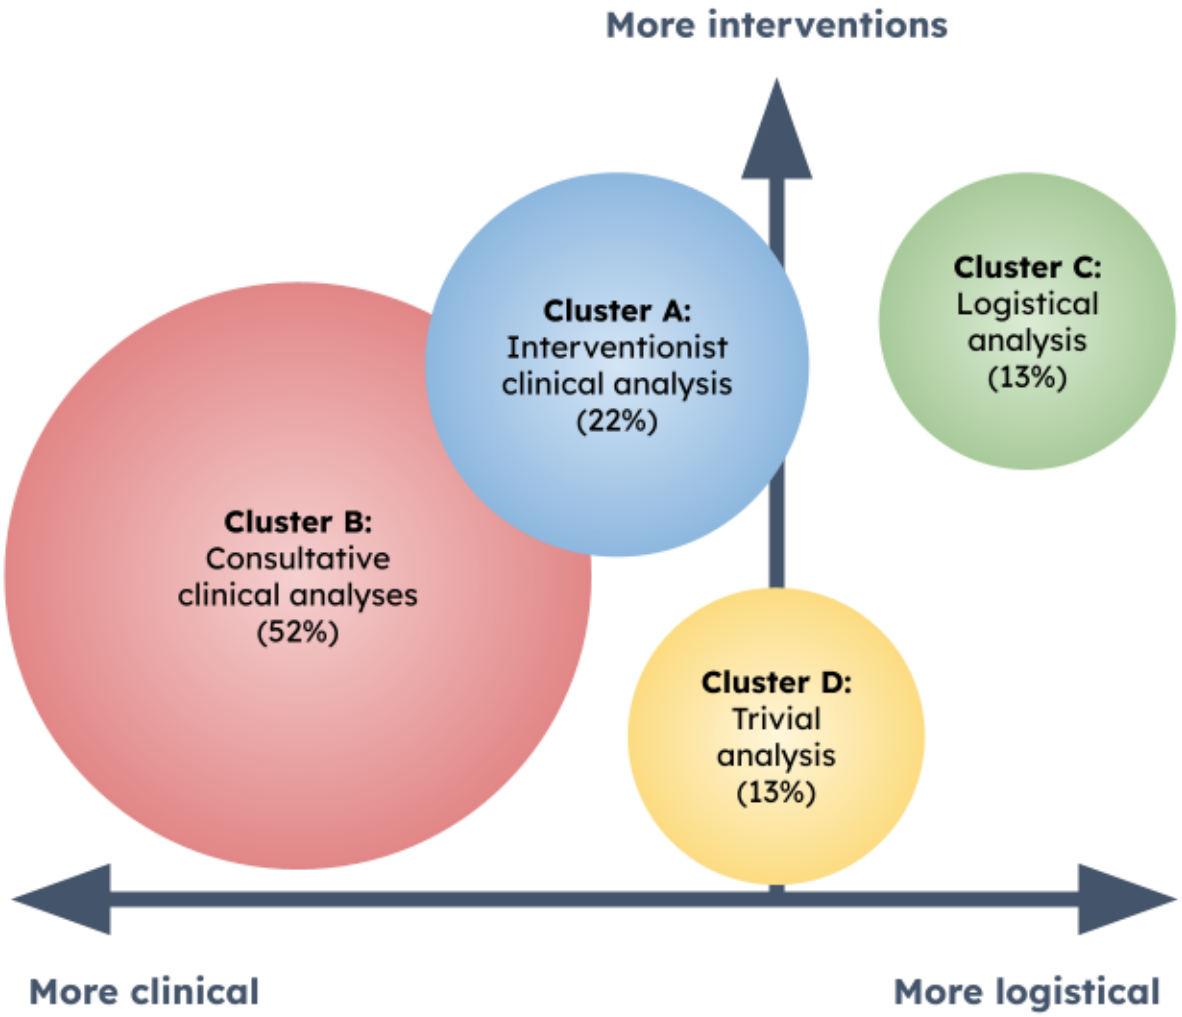
XSL•FO
RenderX

prescriptions (Table 1). Whether they are identifying a drug-related problem, or justifying the absence of a problem, the professionals are constantly questioning the list of prescriptions (Figure 1). A new question leads to a new search, which in turn may lead to further questions. The pharmacists keep in mind (or physically note) the questions that come to mind when reading the list of prescriptions and then access the appropriate source of information. At the end of the analysis, as they return to the prescriptions for final validation, they make a final review in order to "not miss anything important." Overall, pharmacists are naturally at ease when interacting with the drug list, and it is during these periods that participants exchange the most with the researchers.

In terms of specificity, the results are less clear-cut than for the "action" domain. Specificity depends more on the nature of the information researched or transmitted by pharmacists. Information is more often generic in the list of prescriptions and EMR sources, and predominantly specific in the biology results, pharmaceutical interventions, and pharmacy logistics (Figure 2). The need for specific data tends to come at a more advanced stage in the pharmacist's cognitive process. In general, a specific activity follows generic research of information and is more likely to take place in a structured data source such as biology results. In the case of generic activities, we find structured information sources (prescription lists) and unstructured sources (EMRs). So, it is not the structure of the information that counts here but rather the fact of having a global view of a situation. Generic searches are therefore a way for pharmacists to retrieve as much information as possible about the drug and clinical context, and then focus on more specific activities.

Importance of Clinical Contextualization

Searching for information in a patient's medical record is by far the most cognitively demanding activity for professionals. As soon as participants immerse themselves in the clinical data, their verbalizations diminish, and their posture shifts toward reading and concentration. While the total time allocated to clinical contextualization is the second highest of all analyses (Table 1), it dominates between 20% and 70% of analysis time (Figure 1). Moreover, this activity is expressed as the most time-consuming by the participants and is probably the most critical point of the analysis. Pharmacists find themselves highly dependent on information provided by other medical professionals. The search for clinical data is made all the more difficult by the wide disparities in information architecture from one department to another and from one facility to another. Typically, pharmacists find less relevant information on treatments in surgical departments than in medical specialty departments. As for establishments, the way in which they search for clinical data depends on the software that is used for "electronic medical records" and its affinity with pharmacy practice. Finally, if we compare clinical record activities with biology activities, it is clear that the biology laboratory provides much more structured information, enabling pharmacists to target specific data and waste less time searching for it (Table 1). In short, the lack of structure in clinical data requires hospital pharmacists to make a more intense cognitive effort at the core of their analysis. This validates the hypothesis that access to relevant information is often difficult.



The use of other information sources is more sporadic but no less interesting. The search for drug information is correlated with the transmission of pharmaceutical interventions. Pharmacists have a strong need to verify and justify their transmission actions: Acting as drug experts who inspect prescribers' actions, they do not want to leave any room for uncertainty. In addition, they have a preventive posture toward their medical colleagues, and many participants double their written intervention with a call to ensure that it is properly transmitted. Curiously, iatrogenic alerts prompted by EMRs are rarely consulted, even though they are presented by vendors as aids to analysis and decision-making. When questioned on this subject, all the pharmacists answered that "these alerts are not appropriate," as they are "too general" and "irrelevant to the context." Finally, it is the activities related to pharmacy logistics that are the most difficult to describe from raw observations. A review by typology would be necessary to better understand the place of pharmacy logistics, as well as the disparities between the other analyses.

Several Types of Analysis

The classification of analysis sequences into 4 clusters highlights very different analysis typologies (Figure 2). This confirms the first hypothesis of the study. Groups A and B are referred to as "clinical," as they comprise sequences containing more information from the clinical and biological file than the other clusters. In total, these "clinical" sequences account for almost 75% of the analyses carried out. The remaining 25% is divided equally between clusters C and D. Although cluster D provides fewer elements for understanding professional processes (very rapid analysis, based only on prescriptions), it nonetheless illustrates situations that do not require in-depth expertise and the intervention of a pharmacist. Cluster D is ultimately a group of "trivial" analyses for drug experts. On the other hand, cluster C involves sequences that call on the logistical skills of hospital pharmacists, including their ability to intervene finely in the medication circuit. In the following, cluster C is referred to as the "logistical" group. The terms "clinical," "logistical," and "trivial" are introduced to qualify clusters more effectively and to give them a distinctive color. Analysis groups cannot be reduced to their names, as a clinical typology may include a logistical component, and vice versa. The following diagram provides a visual representation of the 4 analysis clusters (Figure 3).

XSL•FO
RenderX

Figure 3. Representation of the 4 pharmaceutical analysis clusters, according to their clinical or logistical trend, and their composition in pharmaceutical interventions. The size of the circles is proportional to the number of analyses concerned.

The 2 "clinical" clusters differ mainly in the overall dynamics of their analysis sequences. Cluster A is richer in sources of information, the data sought are more specific, and the sequence of activities is long and complex. Furthermore, these sequences regularly identify drug-related problems and generally lead to validations with reservations (pharmaceutical interventions at the end of the analysis). The value of pharmaceutical analysis of cluster A prescriptions is therefore indisputable, particularly in the fight against iatrogenesis.

Cluster A can be described as "clinical and interventionist," as opposed to cluster B, which is more "clinical and consultative." Cluster B's analysis sequences focus primarily on consulting the patient's medical file, with the addition of a few biological elements or information on treatments. It is hard to say whether consultative sequences require more cognitive effort from pharmacists than interventionist sequences. In any case, cluster B analyses concern more than 7 out of 10 "clinical" sequences and generally result in full validation (74% of cases). The impact of the clinical advisory analysis is consequently more limited. Finally, it should be noted that cluster B is devoid of logistical aspects, unlike cluster A. This is certainly because cluster A comprises a majority of associate practitioners, who are often more involved in logistics than juniors. In addition, type A analyses are generally more complex, both clinically and logistically, with an important alternation in the specificity and source of information.

The "logistics" cluster includes sequences produced exclusively by hospital practitioners (senior pharmacists). It reflects the increasing specialization of these professionals in the analysis and validation of prescriptions. In fact, their intention is to focus on the medication circuit rather than on iatrogenicity. Their interactions are therefore less with prescribers than with nurses, pharmacy assistants, and automated dispensing systems (dispensing robots and secure cabinets). The clinical aspect, while not completely omitted, tends to be secondary in this type of sequence. As expected, pharmacy logistics therefore play an integral role in prescription analysis.

Finally, "trivial" analyses are not linked to a particular category of pharmacist or hospital. Rather, they appear in relation to clinical situations that do not require the intervention of a pharmacist. This might be a straightforward surgical protocol, a prescription with a limited number of drugs, or standardized palliative care management. In all these situations, pharmacists

XSL•FO
RenderX

quickly realize that there are no drug-related problems. However, before opening the prescription list, pharmacists have no way of knowing whether these are "trivial" prescriptions. Given that it represents 13% of analyzed prescriptions, this raises the question of the place of this kind of analysis in the pharmacists' workflow.

Identifying Pharmacists' Needs

The diversity of pharmaceutical analysis typologies adds a further challenge to the design of pharmacist-centered decision support systems. Between "clinical," "logistical," and "trivial" validation intentions, the needs seem very different, and perhaps these intentions should be treated separately.

For "clinical" analysis, contextualization is a key concern. Pharmaceutical professionals need rapid access to relevant information, that is, without having to search through all the documents and unstructured data. Further, in the case of interventionist analyses, additional elements need to be included to facilitate the drafting and justification of pharmaceutical interventions.

For "logistics" validations, the need lies in the integration of stock management software and the import of highly specialized information (stock-outs, equivalences, and traceability). Since the act of validating a prescription means that it has been approved by the pharmacist, whatever the type of analysis performed, it is important that "logistical" analyses include some support for "clinical" analysis. This is to ensure that iatrogenic risk is minimized.

For "trivial" validations, the need for a decision-support system is more for prioritization. In fact, the time pharmacists devote to analysis is precious and should be used in priority for other types of validation.

Limitations

One of the first limitations of observation methods is their representativity [52]. In fact, this method requires a great deal of resources to collect field data and then to process and analyze the activities. This limits the number of observations made and calls into question the generalizability of the results. This is why the study of pharmaceutical analysis typologies is based on the analysis sequences of each patient (140 in all) rather than on each pharmacist (16 in all), and why the link between the analysis clusters and the pharmacists observed is not discussed. This also has to do with intraindividual variability: in the study, there was no indication of whether pharmacists changed their testing intention according to the time of day, the day of the week, or the month of the year. It is simply a 1-hour observation of their pharmacy practice at a given point in time.

Although our study includes 5 different hospitals, it would be necessary to generalize the results to other French hospitals and regions. Based on our data, it is not possible to assess the extent of variability attributable to different hospital workflows or pharmacist profiles. Indeed, it would be valuable to analyze the impact of hospital regions, facilities with varying workflows, or pharmacists with differing levels of experience on hospital pharmacy practices.

The aim of the study was to create a general model of pharmaceutical analysis and to form analysis groups. Unfortunately, by generalizing, it is not possible to detail every action performed by professionals. Moreover, in the health care environment, actions are rarely complete and linear [52], making it impractical to group very precise tasks into 140 different sequences. It is also for this reason that task interruption data were not exploited, as there were too many hazards and their use was not relevant to the study's objective.

Comparison With Prior Work

Few publications deal with the analysis of hospital pharmacists' practices and needs with regard to the pharmaceutical analysis of prescriptions. And most of these are usability tests rather than exploratory studies. Nevertheless, 4 studies have similar methodologies and subjects of observation [47-50]. They all use a pay-for computerized data collection tool, the validated Work Observation Method By Activity Timing (WOMBAT, Macquarie University) software [52]. This tool is very useful for observing complex situations, enabling the collection of multiple dimensions of work (who, what, when, why, and how). However, our situation is specific to a given practice, that is, analyzing prescriptions. In the publications cited above, the perception of tasks is more global, more general, and more exhaustive of the daily work of pharmacists. By combining the *action*, *specificity*, and *source* domains, we are able to better characterize tasks relating specifically to pharmaceutical analysis. On the other hand, we lose information on social interactions and other tasks such as dispensing and medication reconciliation. This difference in objectives explains why it is difficult to compare the times obtained in our study with those of other publications: the tasks studied are not homogeneous.

Three of the studies use observations to make comparisons. These are either before-and-after comparisons of the computerization of the prescription management system [50], sometimes adding a comparison between different countries [48], or comparing the activities of pharmacists with those of pharmacy technicians [47]. None of these studies attempt to group together or identify specific typologies of professional practice; the methodologies are based solely on descriptive statistics. Further, the observations are carried out in just 1 or 2 hospitals, with observed pharmacists working in the same ecosystem. This makes it more difficult to eliminate the bias associated with environmental conditions and to distinguish the needs associated with each type of pharmaceutical practice [49]. These studies are therefore not really to be considered as first steps in user-centered design.

Finally, there are some very interesting points of agreement between prior research and our results. Hospital pharmacists spend the majority of their time reviewing prescriptions, affirming the importance of the analysis activity in professional practice. We can also see from the publication by Lo et al [50] that the task of reading the patient's medical record ranks second in frequency, just after reviewing the prescription list, regardless of the presence or absence of an electronic medication management system. Prior works thus confirm the importance of clinical contextualization in making medicines safer. Even if it is difficult to compare our study to prior work, the problems

XSL•FO
RenderX

observed seem to be common. We have every reason to believe that pharmaceutical analysis is an activity whose workings do not differ fundamentally from one organization to another, and whose same needs persist over time. It should also be noted that we do not know if these needs are well addressed by CDSSs. It would be interesting to make this assessment in a future study, comparing it with the needs identified in our exploratory study.

Conclusions

This exploratory study focuses on pharmaceutical analysis and validation practices for intrahospital prescriptions. We can confirm that the process of analyzing is multifaceted and complex. It depends on the clinical or biological situation, the treatments involved, and the profile of the validating pharmacist. Given that all patients must benefit from the same quality of care, software product teams need to ensure that user needs coincide with the regulatory and ethical constraints of the health care sector. They must also take into account the diversity of pharmaceutical analyses and their specific needs. User-centered design solutions can emerge from this type of exploratory study, leaving designers free to define the right challenges to address and draw innovative ideas from them.

Beyond the interest of this study for the development of useful, usable, and acceptable digital solutions, the work presented here proposes a singular methodology for evaluating the activity of hospital pharmacists. We hope that this methodological contribution will provide a better understanding of the complexity of this medicotechnical profession and make it easier to measure professional practice evolutions, especially after the introduction of a pharmacist-oriented CDSS.

Acknowledgments

PharmIA SAS financed the study and paid the publication fee.

Authors' Contributions

JB wrote the article. N Chaniaud, EC, and N Cirnat helped with proofreading and corrections. JB and N Cirnat conducted the observations. JB carried out the data processing and analysis. JB and MA established the interest of the research topic. JB and N Chaniaud designed the study, and JS participated in the choice of statistical treatments.

Conflicts of Interest

JB, N Cirnat, MA, and EC work for PharmIA SAS, which funded the study. JS and N Chaniaud have no conflicts of interest to declare.

Abstract

Background: Women with limited English proficiency continue experiencing an unequal cancer burden. Non-White immigrant women present with more advanced breast and cervical cancer than non-Hispanic Whites, attributed to significant cultural barriers as well as low health literacy in attempting to navigate the United States health care system for cancer screening. Community-based Health litEracy-focused intervention for breast and cervical Cancer Control (CHECC-uP) was an in-person, community health worker-led intervention, addressing both cultural and health literacy barriers through health literacy education and follow-up counseling with navigation assistance. The in-person program was tested in a large cluster-randomized trial and yielded high efficacy in promoting mammogram and Papanicolaou test screening in Korean-speaking women. With over 90% of Americans now having online access, the in-person program was adapted to web-based delivery.

Objective: This study aimed to evaluate the feasibility, acceptability, and preliminary efficacy of the web version of the intervention—e-CHECC-uP.

Methods: A randomized pilot trial was conducted. A total of 40 women were enrolled and randomized (20 per arm). The study intervention consisted of web-based health literacy education followed by phone counseling with navigation assistance. Study assessments were done at baseline, 3 months, and 6 months. The study's primary outcomes were cancer screening behaviors verified by medical record review. Upon completion of final study assessments, intervention participants were invited to join postintervention interviews.

Results: In total, 34 women (intervention: n=15; control: n=19) completed the assessment at 6 months, yielding a retention rate of 85%. The intervention participants were highly satisfied with e-CHECC-uP with a median rating of 8 on a 10-point scale. Between-group differences in screening rates were 34.6%, 47.9%, and 37.5%, respectively, for completion of the mammogram, Papanicolaou test, and both at 6 months.

Conclusions: We achieved a high retention rate and high participant satisfaction. Although the study was not powered for significance testing, the e-CHECC-uP intervention resulted in large group differences across all cancer screening outcomes in the pilot sample. Online technology can help address multiple logistical barriers associated with in-person intervention delivery. Our findings suggest that web-based delivery of CHECC-uP may be used to promote cancer screening among immigrant women with limited English proficiency, as a promising avenue to ultimately reduce health disparities in underserved communities.

Introduction

Despite significant progress in the early detection of breast and cervical cancer in the United States, certain racial and ethnic minoritized groups—particularly those with limited English proficiency (LEP)—continue to experience an unequal cancer burden, which is strongly associated with underusage of cancer screening. Non-White immigrant women present with more advanced disease than do non-Hispanic Whites [1,2], which is attributed to significant cultural barriers [1-3] as well as low health literacy [2-6] in attempting to navigate the health care system in the United States. Korean Americans are the fifth largest Asian population in the United States [7] and represent one of the most vulnerable groups for late cancer diagnosis due to significant language barriers and limited health literacy [6,8].

Community health worker (CHW)–led interventions have grown rapidly in health care as possible solutions to alleviating health inequalities. CHW-led interventions have demonstrated to be efficacious and are a commonly used approach in promoting health outcomes among vulnerable populations at risk for health disparities [9-11]. A systematic review revealed that CHW-led interventions promoting cancer screening resulted in 6% - 33% between-group differences for mammography and 7% - 29% for Papanicolaou screening [11]. Likewise, a randomized clinical trial involving Asian immigrant women showed that a CHW-led health literacy-focused intervention was highly efficacious in promoting breast and cervical cancer screening with a group difference of 46% for mammography and 45% for Papanicolaou screening [12].

eHealth—"the use of information and communication technologies for health" [13]—is an effective health communication and educational approach for preventive and self-care practices [14,15]. Today, it is estimated that over 90% of Americans have online access [16]. According to a recent community survey [17], 66% of Korean immigrant women have access to the Internet and use the internet as the main method to obtain health information; 98% of them have access to a mobile phone. In light of high digital accessibility, the potential of eHealth as an effective health communication and education tool has been demonstrated [15]. Although CHW-led interventions have shown efficacy in promoting cancer screening among underserved populations, there remains a critical gap in scalable, accessible delivery models—particularly digital formats—that can extend the reach and impact of these interventions for immigrant women with LEP. This study directly addresses this gap by adapting a previously successful CHW-led, health literacy-focused cancer screening intervention (CHECC-uP: Community-based Health litEracy-focused intervention for breast and cervical Cancer Control [12]) into a web-based format (e-CHECC-uP), leveraging the high rate of digital access among Korean American immigrant women. The purpose of this study was to evaluate the acceptability and feasibility of e-CHECC-uP. The study also aimed to address preliminary efficacy of the e-CHECC-uP intervention in addressing cancer screening and psychosocial outcomes.

Methods

Design and Sample

A pilot randomized trial was conducted to test the feasibility, acceptability, and preliminary efficacy of e-CHECC-uP in 40 Korean American women. Eligibility criteria included: (1) women self-identifying as Korean living in the Baltimore-Washington Metropolitan area, (2) aged 21 to 65 years, and (3) overdue for mammogram (>2 y since last mammogram for women 40 y and older) [18] or Papanicolaou smear screening (>3 y since last Papanicolaou test for women 21 y and older) [19]. Study participants were recruited from Korean churches in the Baltimore-Washington Metropolitan area. Using computer-generated random numbers, enrolled study participants who completed the baseline study survey were randomized into either the intervention or the control arms (n=20 each). This study was conducted in line with CONSORT (Consolidated Standards of Reporting Trials) guidelines (Checklist 1).

E-CHECC-uP Intervention

The study intervention consisted of web-based health literacy education and monthly phone counseling with navigation assistance over 6 months. The prototype intervention CHECC-uP consisted of health literacy education and follow-up phone counseling, both delivered by trained CHWs, and was successfully tested in Korean immigrant women from ethnic churches [12]. The health literacy education, which was delivered in-person, was designed to help Korean American women to better understand essential medical terminology used in mammogram and Papanicolaou test screening with relevant medical instructions, while increasing familiarity with the navigational processes to get these screenings done. In order to scale up, we transformed the print materials used for in-person health literacy education into a web-based platform. Details of the online module development will be described elsewhere. Briefly, we worked with a community advisory board to develop the web-based platform of the health literacy education component of CHECC-uP. The community advisory board consisted of 7 Korean American women aged 40 - 65 years residing in California or Maryland. Over 2 months, the advisory board members assessed module contents for its organization, relevance, and comprehension. Also, they reviewed both audio and visual quality of the modules and consistency and overall design of them. The final version consisted of 9 educational modules with an estimated completion time of approximately 30 to 60 minutes.

Procedures

After the online modules were finalized, a trained bilingual research team worked with 5 ethnic churches to identify potential study participants. Upon verbal verification of study eligibility, potential participants were given detailed information about the study and an informed consent form. As the participants signed the form and completed the baseline questionnaire, each participant was assigned to one of 2 groups. For the intervention group, trained study staff handed the participants a tablet along with a log-in instruction sheet with individualized ID and password. Once successfully logged in,

XSL•FO
RenderX

the participants were guided to touch the "Start" button on the screen when they were ready to begin and stated that the narrator would walk them through the modules. The staff stood by to answer any questions while the intervention participants completed the modules. Upon module completion, intervention participants received a hard copy version of the educational contents covered in the modules, along with detailed instructions to enable them to log in and view the modules at their convenience. Within 2 - 3 weeks after completing the modules, intervention women received monthly phone counseling for about 6 months. The purpose of phone counseling was for CHWs to address participant questions or concerns about mammogram and Papanicolaou test screening as well as monitor participant progress toward screening completion, while providing necessary navigation assistance. For both the intervention and control groups, a bilingual research assistant provided an informational brochure in Korean about breast and cervical cancer and mammogram and Papanicolaou smear screening.

Trained bilingual staff who were masked to the group assignment collected data at baseline, 3 months, and 6 months. During the follow-up phase of the study, our team developed Qualtrics surveys for participants who were not available to come to our scheduled in-person data collection visit at each community site. In addition, at 6 months, intervention participants were asked to join postintervention in-person or phone interviews to share their experiences with e-CHECC-uP. The main goal of these interviews was to better understand intervention participants' experiences so that the study team could identify areas for improvement and enhance future implementations. Example questions included: "Please share what you gained from participating in the e-CHECC-uP program. What was the most valuable part or lesson of the program? What made it more valuable than others?" or "What did you like least about the program? What changes would you suggest to help improve the e-CHECC-uP program?" All interviews were recorded and transcribed verbatim.

Measurement

A study questionnaire was developed to collect sociodemographic and medical characteristics of participants. Primary outcomes were age-appropriate mammogram and Papanicolaou test screening uptake [18,19], which were verified by medical record review. Secondary outcomes included health literacy, social support, cancer screening-related self-efficacy, and quality of life. The questionnaire was translated into Korean and available to participants. All study instruments were used at baseline, 3 months, and 6 months except for social support and quality of life, which were administered at baseline and 6 months. In addition, the 6-month survey included items addressing satisfaction with the e-CHECC-uP intervention (intervention group only).

Health literacy was measured with the Assessment of Health Literacy in Cancer Screening (AHL-C). The AHL-C includes a total of 52 items addressing five dimensions of health literacy in the context of breast and cervical cancer screening: familiarity, comprehension, reading ability, navigation, and numeracy [20]. Based on previous research [21], we chose 3 subscales addressing familiarity, comprehension, and reading ability. Example items are "Please read out loud the listed words below" and "Please find the correct meaning of each word listed below" [20]. The AHL-C has been validated among Korean women in the United States [20] and in Korea [22], and Black women living with HIV in the United States [23] with α coefficients ranging from 0.70 to 0.96.

We used the 8-item Medical Outcomes Study Social Support Survey (MOS-SS) to measure social support. This shorter version was modified from the original 19-item MOS-SS and includes the emotional and instrumental domains of social support on a 5-point Likert-type scale (1=none of the time to 5=all of the time), with higher scores indicating greater perceived social support [24]. An example item is "How often is someone available to take you to the doctor if you need it?" The shorter version had excellent reliability coefficients ranging from 0.88 to 0.92 [24].

Cancer screening-related self-efficacy was measured by the Korean translated Breast and Cervical Cancer Self-Efficacy scale which measures how confident a woman is in carrying out each of the 4 tasks in relation to mammogram and Papanicolaou tests, respectively. Each scale uses a 4-point Likert type item (1=not at all confident to 4=very confident) with higher scores indicating higher confidence in getting cancer screening [25]. The reliability of the Korean version had an α coefficient of 0.92.

We assessed quality of life using the Korean version of the EQ-5D [26]. The EQ-5D is a widely used validated instrument measuring quality of life [27]. It defines health in 5D: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Each dimension has 3 response levels (no problems, some problems, and extreme problems) [27]. In the validation study, the Korean version of the EQ-5D had good reliability and validity through various methods including test-retest reliability using intra-class correlations and Kappa statistics along with a priori hypothesis testing [26].

Analysis

Final analysis included data from 34 women who completed 6 months assessments and whose cancer screening status was confirmed objectively by medical records. We performed descriptive statistics using means, SD, and frequencies to summarize sample characteristics and study variables and to compare the primary outcomes of the completion of a mammogram, a Papanicolaou test, or both at 6 months. We also used chi-square tests and independent samples *t* tests to compare intervention and control groups at baseline. Statistical significance was determined at P=.05. For secondary outcomes, effect sizes were calculated by dividing the difference in mean changes (from baseline to 3 mo and from baseline to 6 mo) by the pooled SD at baseline [28]. Finally, for postintervention interview data, we used a thematic analysis [29] to identify common themes related to participants' experiences with the e-CHECC-uP program. In total, 2 trained research assistants independently coded the interview data to identify themes, which were then reviewed to determine those that were most common and relevant. Any discrepancies in coding were resolved through team consensus.

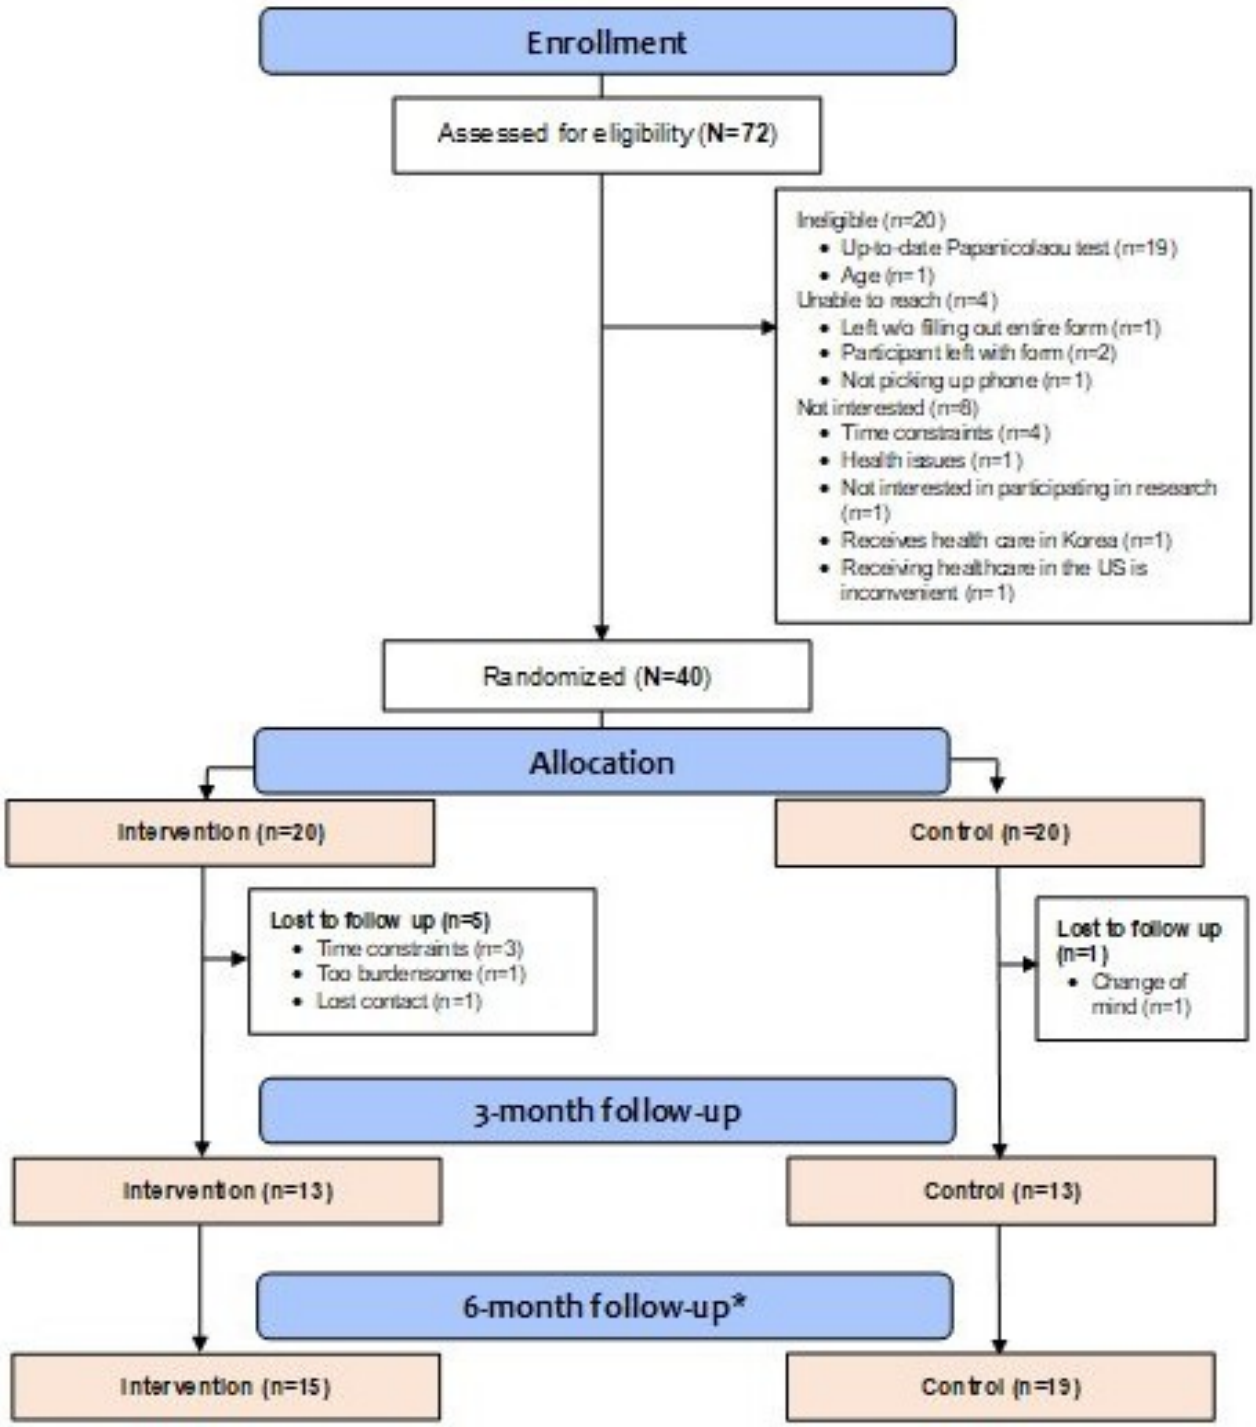
Ethical Considerations

This study was approved by the Johns Hopkins Medicine institutional review board (IRB00180383). Every participant provided written informed consent before their participation, at which time they were informed of the study's aims, procedures, and the benefits and potential risks. The voluntary nature of their participation was underscored, and participants could withdraw from the study at any given time without any negative consequences. Participants were compensated US $20 in cash, each at baseline survey and 3-month follow-up, and US $40 in cash at 6-month follow-up. Those who participated in the postintervention interview were compensated an additional US $30 in cash at the end of the interview.



Results

Sample Characteristics

A total of 52 of the 72 women who were screened for this study were identified as eligible for enrollment. In total, 8 of those eligible declined to participate in our study. In addition, we were unable to reach 4 eligible women after initial contact, yielding a total of 40 women enrolled in the study (77% response rate). A total of 34 participants (intervention: n=15; control: n=19) completed the final study assessment at 6 months (retention rate=85%; refer to Figure 1 for details on recruitment and attrition). Table 1 summarizes participant characteristics at baseline. The final sample was mostly middle-aged (mean 46.3, SD 11.4 years), married (27/34, 79.4%), employed (29/34, 85.3%), and highly educated (years of education: mean 15.6, SD 3.0 years). While more than two-thirds (25/34, 73.5%) reported just okay, difficult, or very difficult to manage with current income, 76.5% (26/34) had limited English proficiency despite living in the United States for an average of 17.3 (SD 10.5) years. The majority of the sample had health insurance (27/34, 79.4%); nevertheless, less than one-third (11/34, 32.4%) indicated that they had a primary care provider at the time of the study. Nearly all (32/34, 94.1%) had access to the internet with 100% (34/34) of the sample reporting mobile phone access. Table 1 also compares the sample characteristics by group. The intervention and control groups were generally compatible at baseline except English proficiency: the intervention group had a significantly higher proportion of women with limited English proficiency (ie, speaking English less than proficient) than the control group (93.3%, 14/15 vs 63.2%, 12/19).

Have mobile phone access, %	100	100	100	—

Outcome Changes

Table 2 compares the study's primary outcomes of cancer screening behaviors between intervention and control groups at 6 months. Of 34 women included in the analysis sample, 26, 22, and 14 were overdue for a mammogram, Papanicolaou test, or both tests, respectively, at the time of study enrollment. There were noticeable differences in screening rates between intervention and control groups for completion of mammogram, Papanicolaou test, and both tests at 6 months (34.6%, 47.9%, and 37.5%, respectively).

Table . Comparison of behavioral outcomes between groups at 6 months (N=34).

Screening test	Intervention group, n/n (%)	Control group, n/n (%)	Difference between groups, %
Mammogram (n=26)	5/12 (41.7)	1/14 (7.1)	34.6
Papanicolaou test (n=22)	5/9 (55.6)	1/13 (7.7)	47.9
Both tests (n=14)	3/6 (50.0)	1/8 (12.5)	37.5

Table 3 presents mean scores of psychosocial outcomes at baseline, 3 months, and 6 months for the intervention and control groups, along with mean change scores and effect sizes. e-CHECC-uP resulted in small to large effect sizes across various psychosocial outcomes measured. Specifically, e-CHECC-uP yielded small effect sizes for reading ability and for both self-efficacy measures related to breast and cervical cancer screening (effect sizes=0.10, 0.06, and 0.06, respectively). One of the dimensions of health literacy—comprehension—resulted in an effect size of 0.27 at 3 months, but the effect was attenuated and in a negative direction at 6 months. Social support was another variable with a medium-size effect of 0.37. Finally, e-CHECC-uP was associated with medium to large effect sizes for a health literacy domain—familiarity—and quality of life with values for each being 0.58 and 0.65 at 6 months.

XSL•FO

Acceptability and Feasibility

e-CHECC-uP was well received by the intervention participants. When asked about how satisfied they were with the e-CHECC-uP overall, 11 of 15 (73.3%) rated 7 or higher on a 10-point scale (range 5 - 10, median 8, mean 7.6, SD 1.8). In total, 13 (86.7%) women were somewhat satisfied or satisfied with the information they learned about mammogram and Papanicolaou test screening, as well as with the way they learned about the screening; 2 women were not satisfied with either. Similarly, 13 (86.7%) women were somewhat satisfied or satisfied with phone counseling, while 2 women were not satisfied. When given an opportunity to comment further, the 2 participants who were not satisfied said the program was either "too tiresome" or "too difficult for a person who is not familiar or comfortable with English."

Using postintervention interview data, we identified a few themes addressing the experiences of intervention participants: Recognizing the importance of cancer screening, improved health literacy and self-confidence, and improved knowledge about screening procedures. In terms of recognizing the importance of cancer screening, one participant noted:

> *Personally, I knew that screening for breast and cervical cancer is important, but I would always skip it because I was too busy. Through this program, I was convinced and learned that I should actively get the screenings.*

Similarly, another intervention participant shared how e-CHECC-uP helped improve health literacy which led to boosting her self-confidence:

> *I am always hesitant to go to the hospital because of the language barrier like the words I am not familiar with, but I gained some confidence through this program.*

Finally, intervention participants talked about how their knowledge about cancer screening procedures improved as a

XSL•FO
RenderX

result of their participation in the intervention program. One woman said:

> *It was great that I learned about the [cancer] screening procedures and processes through the listening components [of the web modules].*

The trial was feasible in terms of recruitment, retention, and intervention delivery. Specifically, we were able to meet the recruitment goal of 40 women with a response rate of 77%, after accounting for 12 women out of 52 eligible women who either declined (n=8) or were unreachable (n=4). We achieved a retention rate of 85% at 6 months, after accounting for 6 women who were lost to follow-up due to time restraints, participation burden, or loss of contact (Figure 1). Finally, all of our intervention components, including online modules and phone follow-up, were delivered as planned.

Discussion

Principal Findings

e-CHECC-uP was highly acceptable and feasible with promising outcome changes. We were able to achieve 85% retention at 6 months with overall high satisfaction ratings in this pilot sample. Given the target population being underserved with limited English proficiency, low health literacy, and limited access to care [6,8], high feasibility and acceptability observed in the pilot sample is encouraging and suggests possible avenues for promising intervention programs to promote breast and cervical cancer screening in Korean immigrant women who often suffer from late diagnoses [1].

Our successful recruitment, retention, and intervention delivery are a result of multiple factors such as authentic care, community partnership, self-directed web-based intervention with human support, and diverse yet standardized modes of communication with study participants [30]. We recruited participants and collected baseline data mainly through face-to-face interactions. As noted by Felsen et al [31], adopting in-person methods may likely have led to successful recruitment as it helps recruiters build rapport with potential study participants. Throughout the study period, we provided various but streamlined approaches for communication. At the earlier stage of the study, phone calls were used as the main method of contact and communication with participants. However, we quickly learned that adding text messaging and email yielded higher rates of response from study participants. Indeed, nearly every woman in the study sample had internet and mobile phone access (Table 1). Additionally, in this sample, 85% participants used texting daily [30], which made it easier to adopt text messaging as one of the main methods of communication. The high rate of internet and mobile phone use among Korean immigrant women with LEP demonstrates strong digital readiness and supports the feasibility of scaling e-CHECC-uP to broader immigrant populations with similar technology access profiles. Taking into account the patterns of technology access and use among the target sample would also facilitate the process of recruitment, retention, and data collection.

e-CHECC-uP pilot resulted in promising group differences across all cancer screening outcomes (range 34.6%-47.9%). While traditional face-to-face CHW interventions designed to promote same cancer screening outcomes have resulted in about 6% - 33% differences [11], the in-person version of this health literacy-focused CHW-led intervention achieved a larger group difference of 46% for mammography and 45% for Papanicolaou test screening [12]. The results indicate that the health literacy-focused approach is effective and perhaps better than the traditional cancer knowledge education. e-CHECC-uP produced comparable preliminary cancer screening outcome changes relative to the original in-person version [12]. This suggests digital CHW-led interventions may serve as scalable alternatives to in-person programs. Additionally, our finding highlights the importance of multilingual digital platforms for delivering health education. Health agencies and payers should invest in scalable, culturally competent eHealth infrastructure to reduce screening disparities. A sufficiently powered, full-scale clinical trial is warranted to rigorously investigate the efficacy of e-CHECC-uP in addressing breast and cancer screening outcomes.

We observed medium to large effect sizes for some of the key psychosocial outcomes including familiarity, social support, and quality of life, whereas self-efficacy showed smaller effects. Additionally, the effect size for comprehension attenuated between the 3- and 6-month follow-up assessments. The reasons for the smaller effect size in self-efficacy and the attenuation in comprehension over time are not entirely clear. One possible explanation may be an artifact of the pilot sample, which included a higher proportion of women with LEP in the intervention arm compared to the control arm (Table 1). The comprehension domain of health literacy required participants to associate each term on the list with a corresponding word or picture, assessing their understanding of the meaning [20]. The reduction in effect size over time may also reflect memory decline related to the learned terms, suggesting a need for reinforcement of health literacy education and an opportunity for scalability through various strategies such as digital refreshers or SMS nudges to sustain health literacy gains during the follow-up period. Existing research documents that people with low health literacy have poorer health outcomes due to its impact on self-efficacy, disease knowledge, or usage of health services [32,33]. For example, diabetic patients with higher health literacy had better understanding of their conditions and self-care behaviors [34,35]. Similarly, other studies support the positive relationship between health literacy and cancer screening, in that people with better health literacy are likely to have a better understanding of cancer screening and improve care-seeking behavior, thereby increasing the use of cancer screening services [36-38]. Postintervention qualitative interviews revealed that e-CHECC-uP helped intervention participants recognize the importance of cancer screening, improved health literacy and self-confidence, and enhanced their knowledge about screening procedures. Future research should investigate the mechanism of e-CHECC-uP for its impact on behavioral outcomes through mediation analyses.

Limitations

Our study has a few limitations to note. First, due to the nature of a pilot study, there is a small sample size and insufficient power. Additionally, the limited number of intervention

XSL•FO
RenderX

participants constrained our ability to systematically integrate qualitative themes with corresponding quantitative findings. A fully powered trial is warranted to test the efficacy of the e-CHECC-uP intervention program and to enable a more robust integration of quantitative outcomes with participants' qualitative feedback. In addition, the study sample was recruited from ethnic churches in the east coast region of the United States; hence, the study findings may not be generalizable to women who live elsewhere or who do not attend church. We also note that intervention participants were provided tablet devices on-site with technological assistance from the study team as a part of the web-based health literacy education. Such aspects of the study may also prevent findings from being generalizable to those who may face barriers related to use of and access to technology and the internet [17].

Conclusions

Online technology allows and engages experiences for learners at relatively low cost, given that facilities and instructors are not required. While prior studies have consistently documented inadequate cancer screening in women with LEP [1,2], few have focused on methods to actually address far-reaching, modifiable barriers such as low health literacy and to improve screening participation. Our use of eHealth to deliver health literacy education may represent a promising strategy for promoting engagement and integrating health literacy skills training aimed at educating and empowering women with LEP to improve their mammogram and Papanicolaou test screening.

Abstract

Background: Chronic pain is among the most common conditions worldwide and requires a multidisciplinary treatment approach. Spinal cord stimulation is a possible treatment option for pain management; however, patients undergoing this intervention require close follow-up, which is not always feasible. eHealth apps offer opportunities for improved patient follow-up, although adherence to these apps tends to decrease over time, with rates dropping to approximately 60%. To improve adherence to remote follow-up, we developed a remote follow-up system consisting of a mobile app for patients, a website for health care professionals, and a remote support center.

Objective: Our objective was to evaluate patient adherence to remote follow-up using a system that includes a mobile app and a remote support center.

Methods: After review of the literature and approval of the design of the follow-up system by a multidisciplinary committee, a team of experts developed a system based on a mobile app, a website for health care professionals, and a remote support center. The system was developed in collaboration with health care professionals and uses validated scales to capture patients' clinical data at each stage of treatment (ie, pretreatment phase, trial phase, and implantation phase). Data were collected prospectively between January 2020 to August 2023, including the number of total surveys sent, surveys completed, SMS text message reminders sent, and reminder calls made.

Results: A total of 64 patients were included (n=40 women, 62.5%) in the study. By the end of the study, 19 (29.7%) patients remained in the pretreatment phase, 8 (12.5%) patients had completed the trial phase, and 37 (57.8%) reached the implantation phase. The mean follow-up period was 15.30 (SD 9.43) months. A total of 1574 surveys were sent, along with 488 SMS text message reminders and 53 reminder calls. The mean adherence rate decreased from 94.53% (SD 20.63%) during the pretreatment phase to 65.68% (SD 23.49%) in the implantation phase, with an overall mean adherence rate of 87.37% (SD 15.37%) for the app. ANOVA showed that adherence was significantly higher in the earlier phases of treatment (P<.001).

Conclusions: Our remote follow-up system, supported by a remote support center improves adherence to follow-up in later phases of treatment, although adherence decreased over time. Further studies are needed to investigate the relationship between adherence to the app and pain management.

Introduction

Chronic pain is one of the most common conditions globally and is associated with reduced quality of life, increased medical expenses, and significant economic costs [1]. Its prevalence ranges between 2% - 40% [1-3], and annual health care costs due to pain amount to US $300 billion in the United States [1] and €12 billion (US $12.3 billion) in Norway [2].

The treatment of chronic pain requires a multidisciplinary approach, with spinal cord stimulation being a potential treatment option. This technique is safe and effective [4] and has also shown benefits in management of other chronic pain conditions, such as complex regional pain syndromes, low back

XSL•FO
RenderX

pain, and other forms of pain. However, ensuring consistent follow-up for these patients is challenging, as they require close monitoring, which is not always feasible.

New technologies have opened up a lot of possibilities to address this challenge. The World Health Organization defines eHealth as the cost-effective and secure use of information and communication technologies to support health and health-related areas, including health services, health monitoring, health literature, health education, and knowledge and research [5].

There are numerous tools designed to facilitate medical care, including mobile apps, websites, and other platforms. While there is limited evidence to support their use, preliminary results are promising. For example, mobile apps used alongside conventional treatments have shown better results in the management of chronic pain than conventional interventions alone [6,7].

eHealth apps also offer an opportunity for closer patient follow-up, although adherence to treatment tends to decline over time, dropping to approximately 60%, as previous studies have shown [8,9]. To address this challenge, we have developed a system that includes a mobile app for patients, a website for health care professionals, and a remote support center.

The aim of this study is to assess patient adherence to follow-up care using a mobile app supported by a remote support center.

Methods

Overview

In 2019, researchers at the Department of Pain Surgery at Hospital Virgen de las Nieves in Granada, Spain, initiated approaches to improve the remote monitoring of patients implanted with epidural spinal cord stimulators for chronic pain management. The aim was to reduce the number of face-to-face consultations or hospital visits while providing additional support to these patients. Therefore, we decided to develop an app complemented by a support center to improve patient monitoring as much as possible. After reviewing the relevant literature, we adapted the tool kit published by Marvel et al [10] to suit our needs, following the four key steps outlined in Table 1. As we already had a multidisciplinary group, we sought the agreement of existing team members and assembled a group of experts. Instead of accelerating the project, we adapted our current workflows and protocols to the new working framework. We also developed the follow-up system after adapting the protocols already in place and enrolled patients only after the system was finalized.

Table . Project phases.

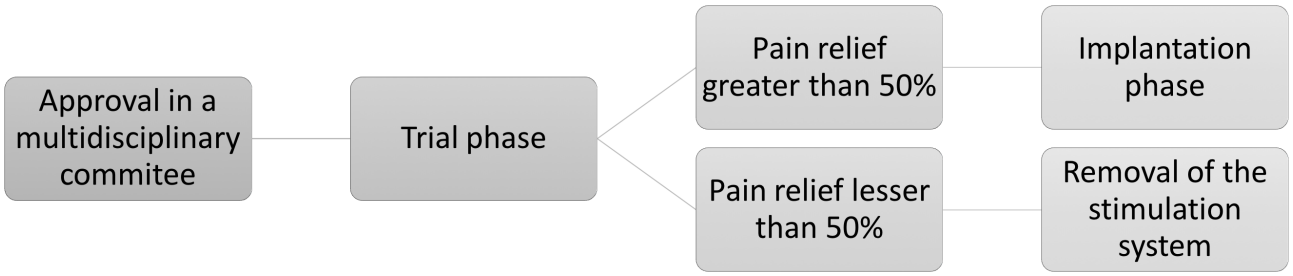
Johns Hopkins tool steps[a]	Project workflow (current study)
Define the problem and the digital tool	Define the problem and the digital tool
Creation of a multidisciplinary group	Creation of an expert team, approval by a multidisciplinary group
Seeking opportunities to accelerate the project	Adaptation of the existing clinical and educational protocol into the framework of the remote follow-up system
Involving professionals	Designing the follow-up system, considering the needs of the involved professionals, and subsequent enrollment of patients
Consulting different partners	Performing quality assessment
Conducting a clinical validation	Conducting a clinical validation

[a]Marvel et al [10].

The concept of a remote follow-up system was presented to a multidisciplinary committee composed of anesthesiologists, neurologists, neurosurgeons, neurophysiologists, and rehabilitation specialists. This committee meets monthly to assess patients with chronic pain who may benefit from interventional therapies such as spinal cord stimulation when conventional treatments have failed. The target population was identified as patients who could benefit from spinal cord stimulation and had not yet started the trial phase, to enable data collection before and after implantation.

The inclusion criteria for patients eligible for spinal cord stimulation system implantation at our center are shown in Textbox 1.

Textbox 1. Inclusion criteria.



- Chronic pain in a specific area of the body (patients experiencing diffuse pain were not accepted)
- Failure of conservative treatments, including rehabilitation and local infiltration
- A favorable psychological evaluation confirming that the patient can wear a spinal cord stimulation system
- No contraindications to surgery or allergies to system components
- No history or current substance use, especially opioids

Once the committee had approved the implantation of a spinal cord stimulator, the procedure was performed in 2 phases, as shown in Figure 1. In the trial phase, one or more electrodes were implanted in the epidural space and connected to an external stimulator. The efficacy of the system was then assessed over a 4-week period using the verbal numerical rating score

XSL•FO
RenderX

(VNRS). The intervention was considered effective if the patient's reported subjective perception of pain relief was at least 50%. If the trial phase was successful, it was followed by the implantation phase, in which a permanent stimulator was implanted in the adipose tissue of the abdomen or lower back. If the 50% threshold was not reached, the system was removed completely.

Figure 1. Algorithm used to evaluate the implantation of the spinal cord stimulation system.

Ethical Considerations

Ethics approval was obtained from the Comité de Investigación Provincial de Granada (study: NC-D-01; ethics committee reference: SICEIA-2020 - 000438), and informed consent for the procedure and follow-up system was obtained from all included patients. To maintain privacy, each patient was assigned a code with a number so that only health care professionals could access the personal data. The platform meets all the standards of Regulation (EU) 2016/679 of the European Parliament and of the Council of April 27, 2016, and has been approved by local and state authorities. This ensures that only health care professionals can access all the data collected and that data security is contractually guaranteed. The study participants have not been compensated in any way.

Design of the Follow-Up System

The remote follow-up system consists of 3 main components: a mobile app for patients, a website for health care professionals, and a remote follow-up center. The mobile app was designed to ensure close monitoring during all phases of treatment, using feedback from all health care professionals involved. The app was developed in collaboration with Clinical Care Connect (Persei) and customized by our team to meet our specific needs. It offers various features including educational content such as brochures and videos, questionnaires with validated scales, pop-up notifications, and a form to contact the remote support center. The validated scales used include Doleur Neuropathique 4 (DN4) to assess neuropathic pain, Oswestry Disability Index/Neck Disability Index (ODI/NDI) to assess back pain, VNRS to assess pain, and 36-item Short Form Survey (SF-36) to assess quality of life. In addition, patient-reported experience measures were used to assess experience and satisfaction with the app. Since pain is a subjective perception, the use of validated scales can help to measure it and compare it between patients.

The website designed by Persei (Vivarium S.L., Spain) can be accessed from anywhere with the necessary authorizations. It also provides alerts using different colors depending on the urgency of the detected problem: red for infection, yellow for insufficient pain relief, and blue for low battery. These alerts are monitored by the remote support center, which contacts the specialist by making a telephone call if necessary, such as, in the event of an infection. For nonemergency issues, such as insufficient pain relief, the support center contacts the patient to analyze the cause, and a priority appointment for treatment is scheduled. This remote support center was set up to increase the efficiency of treatment and improve pain management. The aim was to maximize treatment adherence and ensure the sustainability of the remote follow-up system. Previously, follow-up was carried out 1 month after implantation, 1 year after implantation, and subsequently, as required.

Data Collection and Analysis

We collected data from all patients who were approved for spinal cord stimulation between January 2020 and August 2023 and enrolled in the remote monitoring program. If the committee approved the patient for spinal cord stimulation, informed consent for the remote follow-up system was obtained in addition to consent for implantation. Data were collected automatically and prospectively through surveys completed via the app. The questionnaires were distributed according to the protocol shown in Textbox 2.

XSL•FO
RenderX

Textbox 2. Protocol used to send validated scales.

Validated scales used in the protocol used by the Virgen de las Nieves Hospital

- Pretreatment phase: Doleur Neuropathique 4 (DN4), verbal numerical rating score (VNRS), Oswestry Disability Index/Neck Disability Index (ODI/NDI), 36-item Short Form Survey (SF-36)
- Trial phase: Daily VNRS and patient-reported experience measures (PREMs) at the end of the trial phase
- Implantation phase: DN4, VNRS, ODI, and SF-36 after 1 and every 3 months; the PREMs survey was also distributed after 12 months

The support center sends a notification each time a survey needs to be completed, for a maximum of 3 times. If the questionnaires were not completed, a notification was sent to the hospital so that a specialized caregiver can contact the patient. One of the biggest challenges was ensuring privacy. To achieve this, each patient was coded with a number so that only health care professionals had access to the personal data and that data security was contractually guaranteed.

The data were collected automatically when a survey was answered via the app and stored in a private cloud. This allowed us to minimize potential errors. In addition, the support center guaranteed that the data collected via the app belonged to our hospital's patients and was only accessed and analyzed when a specialist at our center requested it. Demographic information was collected for data analysis. Adherence was measured by calculating the percentage of completed surveys relative to the total number of surveys sent. We analyzed adherence rate during each treatment phase and for the overall study, and compared adherence by demographic variables using ANOVA, adjusting for gender, age, diagnosis, and phase. Age was categorized into 2 groups, with 40 years as the cutoff point, since previous studies have found significant differences in prevalence rates for chronic pain and quality of life [11]. Regarding completeness, we only considered a survey as answered if it was completed. If data were missing, a notification was sent to the patient to complete the survey.

Results

Between January 2020 and August 2023, a total of 64 patients were enrolled in the study, comprising 24 (37.5%) men and 40 (62.5%) women. While identifying the cause of pain, 32 (50%) patients had complex regional pain syndromes, 18 (28%) had failed back syndrome, and 14 (22%) had other diagnoses such as phantom limb syndrome, adhesive arachnoiditis, coccydynia, and axonotmesis. Before the onset of pain, 19 (28%) patients had no fixed occupation, while 10 (18%) were involved in nonphysical and 35 (55%) in physical occupations such as farming or construction (Table 2).

Table . Summary of epidemiological data.

Variables	Patients (N=64), n (%)
Gender	
Men	24 (38)
Women	40 (63)
Age interval	
<40 years	9 (14)
≥40 years	55 (86)

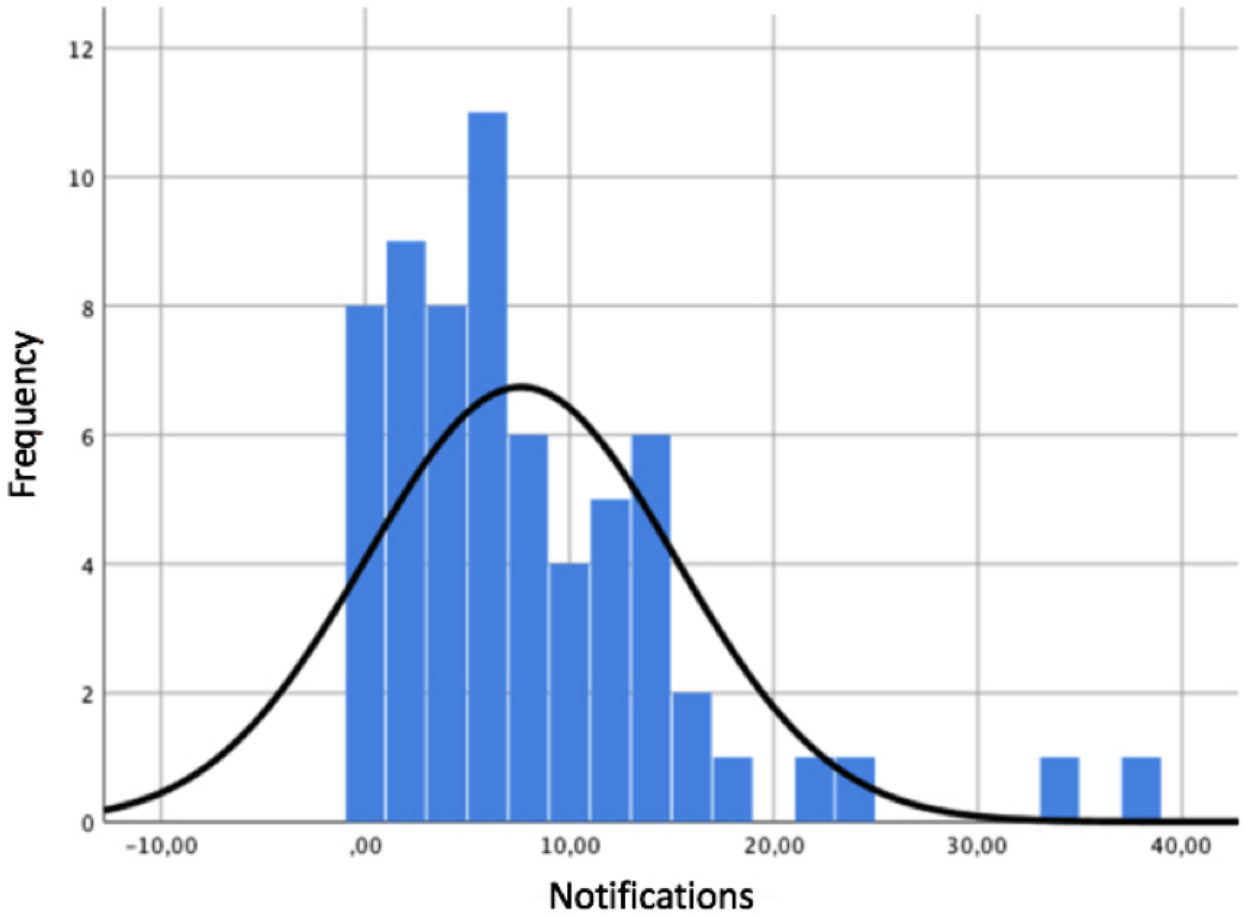
CRPS[a]	32 (50)
FBS[b]	18 (22)
Others	14 (18)
Occupation	
Physical occupation	35 (55)
Nonphysical occupation	19 (18)
No fixed occupation	10 (28)
Phase	
Pretreatment	19 (30)
Trial	8 (13)
Implantation	37 (58)

[a]CRPS: chronic regional pain syndrome.



[b]FBS: failed back syndrome.

XSL•FO
RenderX

At the end of the study, 19 (30%) patients were in the pretreatment group, awaiting the start of the trial phase. A total of 8 (13%) patients reached the trial phase but were not transferred to the implantation phase due to insufficient improvement in pain management. Further, a total of 37 (58%) patients advanced to the implantation phase (Table 2).

A total of 1586 surveys were distributed during the study. SMS text message notifications had to be sent to the patients 488 times, which corresponded to a mean of 7.62 (SD 7.57) SMS text messages per patient. However, 8 (13%) patients did not require SMS text messages notifications, while the remaining (n=56, 88%) patients required at least one notification (Figure 2). It was observed that several patients required more than 30 notifications. In addition, a total of 53 phone calls were made to remind patients to complete the surveys; however, 43 (67%) patients did not require any reminder calls.

Figure 2. Histogram with a normality curve showing the number of patients in groups (frequency) based on the number of required notifications (notifications).

The mean follow-up time was 15.38 (SD 9.43) months. A total of 12 (19%) patients were lost to follow-up, and 3 (4%) patients discontinued using the app (ie, 1 during the pretreatment phase and 2 patients during the implantation phase). For patients who discontinued using the app, any surveys not answered by them were considered failures.

Adherence was analyzed for each phase and overall, as shown in Figure 3, which represents the total number of surveys sent and answered in each phase, as well as the adherence rate in each phase. During the pretreatment phase, 256 surveys were sent, of which 242 were completed, corresponding to a mean adherence rate of 94.53% (SD 20.63%). During the trial phase, 645 surveys were sent, of which 499 were answered, corresponding to a mean adherence rate of 77.36% (SD 37.01%). During the implantation phase, 624 surveys were sent, of which 422 were answered, corresponding to a mean adherence of 65.68% (SD 23.49%). A total of 61 satisfaction surveys were sent (excluding 3 patients who discontinued using the app), of which 55 were answered, corresponding to a mean adherence rate of 92.11% (SD 18.47%). The overall mean adherence rate for using the app was 87.37% (SD 15.37%) across all phases (Table 3).

Figure 3. Surveys and adherence rate.

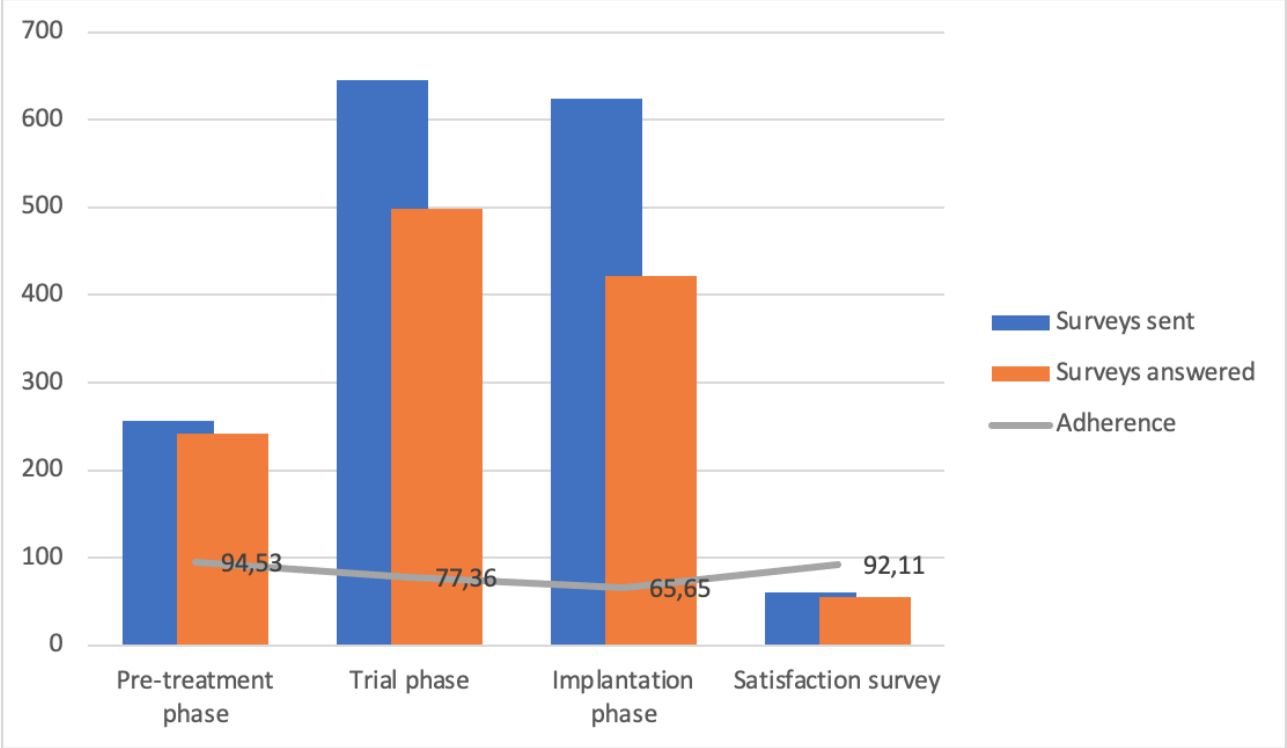

Table . Summary of surveys sent and answered and adherence in each phase.

Phase	Surveys sent, n[a]	Surveys answered, n[a]	Adherence rate[b] (%), mean (SD[c])
Pretreatment phase	256	242	94.53 (20.63)
Trial phase	645	499	77.36 (37.01)
Implantation phase	624	422	65.68 (23.49)
Satisfaction survey	61	55	92.11 (18.47)
Total adherence	1586	1218	87.37 (15.37)

[a]Number of surveys during each phase.

[b]Adherence rate was defined as the total surveys answered x 100/total surveys sent.

[c]The SD represents the variability of adherence rates among individual patients.

ANOVA revealed that adherence rates were significantly higher in the earlier phases of treatment (P<.001). There was also a trend indicating that women were more likely to complete satisfaction surveys (P=.17) and surveys in general (P=.64). However, women also required more SMS text message reminders (P=.70) and phone calls (P=.71). No significant differences in treatment adherence were found when comparing younger patients versus patients older than 40 years or when comparing adherence to treatment based on the cause of pain or type of occupation (Table 4).

Discussion

Comparison With Previous Research

In recent years, there has been increasing interest in the use of pain control apps for various purposes, such as postsurgical follow-up, pain self-management, and chronic pain management [6-10,12-14]. However, many of these tools have not been as effective as expected, often due to inadequate planning and a lack of preliminary studies to anticipate necessary roles [15]. However, some studies have demonstrated that these apps can outperform traditional follow-up methods [6,14]. Our study introduces a remote support center, a feature that we believe is not yet widely adopted internationally. The aim of this study is to determine whether the inclusion of a support center improves adherence compared to other systems.

An analysis of the medical apps across various app stores shows that approximately 86% of these apps were developed without the involvement of medical professionals [16]. Lalloo et al [17] examined 1019 apps developed for postoperative pain management or education and found that only 10 apps met the established criteria. When evaluating apps developed with the involvement of health care professionals, only 5 (0.49%) of them were deemed suitable. Similarly, Bhattarai et al [16] examined 373 apps focused on arthritis pain self-management with only 4 apps meeting the Stanford criteria for pain self-management. Portelli and Eldred [18] evaluated 195 apps for pain management against the guidelines for cognitive behavioral therapy. Of these, only 6 (3%) of these apps met the standards, leading to the conclusion that neither health care professionals nor patients were involved in their development. Despite these limitations, a recent meta-analysis of 4767 patients in 22 randomized trials found that these apps offer a small but significant improvement in long-term pain management [19].

For patients undergoing spinal cord stimulation, close follow-up is required to adjust the type and parameters of stimulation, which usually necessitates face-to-face visits. This increases the time and cost burdens for patients and caregivers, especially for those who live far from specialized centers [20]. Our remote follow-up system was developed to overcome these challenges and ensure optimal patient monitoring. The mobile app in combination with the remote support center reduces the need

XSL•FO
RenderX

for in-person examinations while ensuring a high standard of care. The app's alert system helps to detect problems at an early stage, such as infections or low battery levels so that immediate action can be taken.

In addition, the use of validated scales during an in-person consultation is challenging due to the limited time available. Consequently, this system has allowed a better understanding of the patient's condition. Furthermore, some patients have found that expressing themselves via the app helps them [20] in experiencing privacy and without any time pressure.

Adherence to medical app use is crucial as studies show that 75% of users stop using an app within 48 hours of downloading, and 15% delete it after initial use [21]. A review by Wikström et al [9] found that none of the studies focused on improving adherence or motivating users to continue using medical apps. The easiest way to increase motivation is through notifications, which is why our study focused on the role of the remote support center. We consider this as a key factor in the success of our study. However, numerous motivational elements in medical apps have been analyzed in previous studies, as summarized in Table 5.

[a]Element analyzed in the corresponding study.

Our remote follow-up system was developed based on relevant literature to maximize adherence and achieved an overall mean adherence rate of 87.37% (SD 15.37%). Comparison of this rate with previous studies is difficult, as most of these focused on adherence to a treatment or intervention rather than the use of an app. For example, Gomis-Pastor et al [34] showed that the use of an app significantly improved adherence to treatment and medication regimen, which led to significantly better symptom control, as found in a 2022 review [35]. However, Wikström et al [9] have shown that adherence to app use decreases over time, potentially due to improvement in health status or loss of interest [29], among other factors [26,29,32]. Our study aligns with these findings and shows a decrease in adherence from 94.53% in the pretreatment phase to 77.36% in the testing phase and 65.58% in the implantation phase [36-38].

XSL•FO
RenderX

Limitations

The main limitation of our study is the specificity of the target population, as spinal cord stimulation is a specialized treatment for patients experiencing chronic pain. These patients often display a significant emotional component that can influence the outcomes of the interventions, posing challenges during designing this study and its remote follow-up system. In addition, these systems rely on new technologies that can be challenging for older patients, potentially limiting their ability to fully benefit from them. By using self-reported data, we also acknowledged that omissions or misunderstandings in the surveys may be introduced, which we attempted to minimize using validated scales. Finally, setting up a system similar to this study requires a significant financial investment.

Conclusions

Digital systems are a part of medical care, and it is important that health care professionals are involved in the development of tools to ensure the achievement of desired standards. We have developed a remote monitoring system for patients undergoing spinal cord stimulation, based on scientific evidence and supported by a remote support center that improves treatment adherence. This system also provides us with detailed information about each patient. However, there is a tendency for patients to abandon the app usage over time, which could be related to long-term pain control. Further studies are needed to investigate the relationship between adherence and pain control.

Conflicts of Interest

We have received financial support from Medtronic IHS CareConnect Pain to cover publication costs for this article. However, we declare no conflicts of interest as we implant spinal cord stimulation systems from different brands and treat all equally. In addition, none of the authors work for Medtronic IHS CareConnect Pain or receive economic compensation from Medtronic IHS CareConnect Pain.

Abstract

Background: Aging brings physical and life changes that could benefit from eHealth services. eHealth holistically combines technology, tasks, individuals, and contexts, and all these intertwined elements should be considered in eHealth development. As users' needs change with life situations, including aging and retirement, it is important to identify these needs at different life stages to develop eHealth services for well-being and active, healthy lives.

Objective: This study aimed to (1) understand older adults' everyday lives in terms of well-being and health, (2) investigate older adults' needs for eHealth services, and (3) create design recommendations based on the findings.

Methods: A total of 20 older adults from 2 age groups (55 to 74 years: n=12, 60%; >75 years: n=8, 40%) participated in this qualitative interview study. The data were collected remotely using a cultural probes package that included diary-based tasks, sentence completion tasks, and 4 background questionnaires; we also performed remote, semistructured interviews. The data were gathered between the fall of 2020 and the spring of 2021 in Finland as a part of the Toward a Socially Inclusive Digital Society: Transforming Service Culture (DigiIN) project (2019 to 2025).

Results: In the daily lives of older adults, home-based activities, such as exercising (72/622, 11.6% of mentions), sleeping (51/622, 8.2% of mentions), and dining and cooking (96/622, 15.4% of mentions), promoted well-being and health. When discussing their needs for eHealth services, participants highlighted a preference for a chat function. However, they frequently mentioned barriers and concerns such as the lack of human contact, inefficiency, and difficulties using eHealth systems. Older adults value flexibility; testing possibilities (eg, trial versions); support for digital services; and relevant, empathetically offered content with eHealth services on short-term and long-term bases in their changing life situations.

Conclusions: Many older adults value healthy routines and time spent at home. The diversity of older adults' needs should be considered by making it possible for them to manage their health safely and flexibly on different devices and channels. eHealth services should adapt to older adults' life changes through motivation, personalized content, and appropriate functions. Importantly, older adults should still have the option to not use eHealth services.

Introduction

Background

Aging involves physical and life changes [1-4], where eHealth services have the potential to provide support and benefits [4-7]. The prevalence of many diseases increases with age [8,9], and multimorbidity is common among people aged ≥65 years [10,11]. Conversely, healthy behaviors can extend people's lives [12-14].

eHealth can help people nurture their health and well-being, potentially extending their lives. eHealth can also make treatment more accessible, promote treatment continuity, enhance communication, help shared decision-making, and enable patient self-management [10]. Older adults seem to be generally positive toward eHealth in a health management context [15]. They can benefit from eHealth services, as they often have complex health issues and engage in many self-management tasks supporting their health and well-being [1,5,16].

However, older adults sometimes face challenges with eHealth services [5,16,17], including a lack of skills and interest [3,16,18]. Hirvonen et al [19] reported that some older adults find the content or functionalities of eHealth services irrelevant (eg, [20,21]). Sometimes, older adults might even feel that digital services are not "meant for them" (eg, [20,22]). Thus, older adults might have a risk of exclusion from digital services [16,18,23,24] and society [16,23].

Older adults have not always been involved in technological development, especially in mainstream technology [25-27]. At the same time, the older population is growing [28], and health care costs are rising [29]. Stephanidis et al [30] encourage understanding emerging new technology possibilities and context-based user needs when designing digital solutions for the health and well-being (hereafter, *eHealth services* or *eHealth*) of older adults and a better understanding of the role of technology in older adults' lives [30]. Ideally, the technology should be harmonized with these adults' lives [15].

European older adults regularly engage in work, household chores, exercise, cultural activities, and tourism [31]. On the basis of the literature, many older adults in Europe live in rural areas, where they have easy access to nature and can engage in refreshing activities [31]. On the other hand, older adults with urban lifestyles access a variety of services [31]. For example, in Finland and Sweden, rural areas are in the north and distant from health care services, and eHealth services offer a promising option for taking care of one's health [32]. Physical activities might support older adults' health situation during aging. In 2017, in total 43.2% of Europeans aged 50 to 64 years and 44.5% of those aged 65 to 74 years old spent >3 hours per week engaging in physical activity [31]. On the other hand, older adults' daily routines differ. Older adults are a heterogeneous group of people, and aging is a process, not a static state [33]. Therefore, it is important to obtain qualitative insights into older adults' activities. These could help inform the idea and role of eHealth services and harmonize it with older adults' routines [15,30]. We know that older adults use eHealth services, for example, depending on their digital devices, capabilities, interests, or education [31,34]. Statistically, 100% of Europeans have, at least in theory, access to eHealth services or health information [35].

The best approach to eHealth service development means selecting the optimal approach case by case [36]. In eHealth, technology, tasks, individuals, and contexts are holistically combined, which should all be considered in developments [36-39]. eHealth services should genuinely support people pursuing healthier lifestyles and be accessible to all [10], although older adults may perceive the technology differently from other generations [1,40]. Humanity is needed alongside IT. Therefore, design decisions should also help ensure that as a part of eHealth services development, the human touch of personal care will not be removed [30,41].

Mapping user needs is important because without understanding needs, designing high-quality solutions is challenging [42]. User needs can be defined as the problems that prevent users from reaching their goals or possibilities to support them in reaching these goals [43]. User needs can be personal or more social in nature, and they can be related, for example, to available information or technology functions [44]. Poor understanding of users, user needs, and use contexts increases the risk of failure in eHealth service development [39]. On the other hand, user needs are not a stable phenomenon; they might change with age or the use of technology [45]. However, not much is known about what kind of user needs for eHealth services arise in older adults' lives, which is unfortunate because understanding user needs is a great innovation source [46]. In addition, Hirvonen et al [19] recommend further investigation into older adults' eHealth service use as a part of their daily lives.

Goal of This Study

We aimed to understand older adults' everyday lives in terms of well-being and health and their needs for eHealth services. We investigated 2 life stages: working at an older age and life after retirement, possibly with a chronic disease. We were interested in the health and well-being practices of 2 age groups to understand older adults' needs for eHealth services. Investigating these aspects allows developers and designers to better understand how eHealth services can meet older adults' needs and support their healthy living.

Users' needs change with life situations, including aging [47]. Therefore, if we want to harmonize eHealth services with older adults' everyday use, as is recommended by Cabrita et al [15], and to support technology development for well-being and an active, healthy lifestyle, it is important to identify user needs at different stages of life and daily routines in different life situations. The research questions were as follows:

1. What is everyday life like for older adults?
2. What kind of needs do older adults have for eHealth services?

Prior Work

Qualitative Methods for Investigation of Needs

User needs can be explored in many ways. In the human-computer interaction field [48,49], designers and

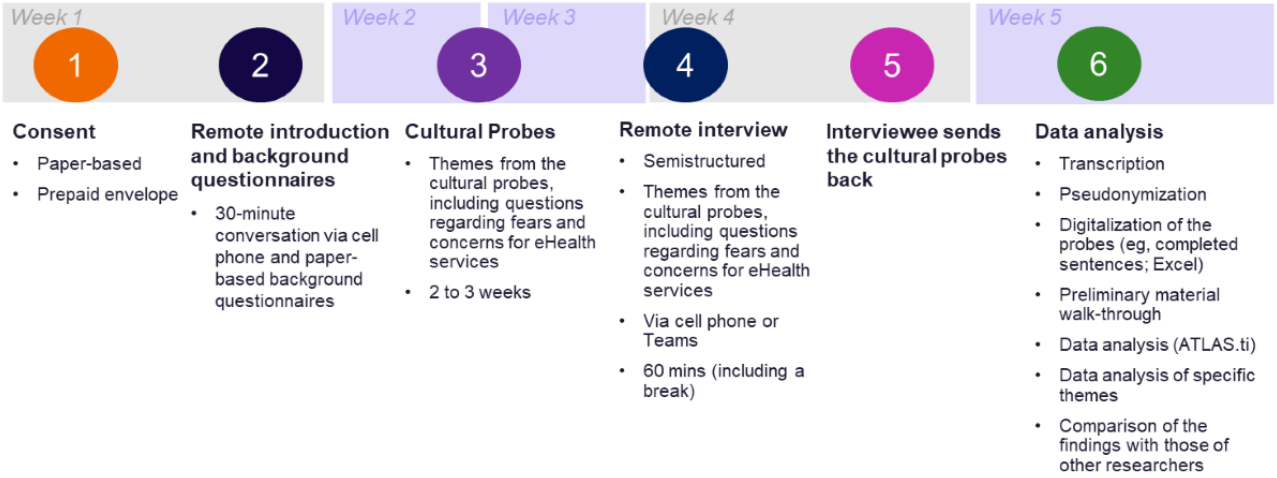
XSL•FO
RenderX

researchers have several methods for investigating user needs. Soraghan et al [50] and Dickinson et al [51] encourage researchers and designers to step into older adults' homes to assess technology use and empathize with respondents' lives, for example, through in-home interviews and observations. Understanding of older adults can be collected through remote, semistructured interviews [52]. Projective techniques, such as cultural probes [53-57] or sentence completion tasks [58], in which the participants provide information about themselves (instead of the researcher asking them direct questions), can be fruitful methods for gaining a deeper understanding of end users when the topic is challenging to verbalize or includes sensitive aspects [42]. For example, the sentence completion technique can be used to gather both an understanding of end users' values and needs as well as inspirational data for design and discussion activation [42,59,60].

Cultural probes are designed to trigger older adults to provide inspirational information about their lives to designers [53]. Following development, they have been widely used for various purposes, including collecting information about caregivers [56], investigating patient experiences with an eHealth service [54], and in other health care contexts [55,57]. Cultural probes are packages or toolkits of various tasks that end users complete and document [53]. While cultural probes show potential as a projective technique for gathering user needs [42], they appear to be underused in identifying older adults' needs for eHealth services.

Older Adults' Needs and Attitudes Toward Technology

Older adults' needs and attitudes toward technology vary. For example, some older adults do not trust computers and find the terminology and content of computers and digital services confusing [17,18,61]. They might even fear computers [61]. Their self-confidence with computers is sometimes fragile, and usability issues can be disastrous for their self-confidence [61]. In addition, older adults as a user group are much more diverse than many traditional user groups; they may have problems such as sensory loss, challenges with language, and attitudes to technology [61].



Many older adults appreciate easy access to eHealth services and their medical records, which should be offered in an easy, understandable, and secure way [5,52]. When medical information has compact and clearly labeled contents in well-organized menus [62], clear interface language, and linear navigation [20], this can assist older adults. Backonja et al [47] recommend eHealth services that adjust functionality and content based on the user's needs. Similarly, Cabrita et al [15] recommend personalization of design and functionality, thus lowering older end users' fears toward technology by allowing it to support its users and even offer empathy and sympathy to them.

Methods

Overview

This empirical qualitative study consisted of cultural probes [53,63], which included 4 background information questionnaires (*background questionnaires*), sentence completion tasks [42,58,59], and a diary-based exercise [64-66], and remote interviews [52]. Data collection included 6 phases, which all played an important role (Figure 1). Data collection started with filling out a consent form. After that, background information was collected, and a short remote interview was conducted. Then, the participant had time to respond to the cultural probe package (ie, sentence completion tasks and diary-based exercise). Participation ended with a long remote interview and the return of the probes package to the researcher. Finally, the data were analyzed.

Figure 1. Research procedure.

Sampling and Recruitment

The research was conducted in Finland between the fall of 2020 and the spring of 2021 (ie, during the COVID-19 pandemic) as part of the DigiIN project (2019 to 2025).

Defining an older adult purely by age is somewhat complex [67]. Generally, they are people in late adulthood. In line with the study by Ware et al [5], this study focused on older age groups associated with a higher risk of chronic disease, with participants from 2 age groups (those aged between 55 and 74

XSL•FO
RenderX

years and employed and those aged >75 years and retired). Group 1 participants (ie, those who were still working) were relevant because aging includes preparing for retirement [68].

The participants were selected through purposive sampling (digital survey) and snowball sampling [69]. Group 1 participants (12/20, 60%) were recruited via a digital survey [70]. Group 2 participants (8/20, 40%) were recruited in 2 ways: via the digital survey and snowball sampling. To ensure a diverse and engaged sample for this long-term study, participants' interest in digital services was assessed in advance. The groups were formed according to the life situation: group 1 participants were still working, and group 2 participants were retired. The age category of group 1 was between 55 and 74 years (later, 55-74 years). The age category of group 2 was between 75 and >90 years (later, >75 years). Participants in group 1 had different professions, such as yoga teacher, director, project manager, or entrepreneur. The participants were from different parts of Finland but did not fully cover the whole country.

After participants expressed potential interest in participating in the study, the researcher explained the study in a telephone call. This call lasted for 15 to 30 minutes, depending on the participant's questions. If the participant was still interested, the researcher mailed or emailed the information letter that described this study in detail and a consent form to the participants for their signature.

Ethical Considerations

The empirical study was conducted as part of the DigiIN project (2019 to 2025). The study protocol was reviewed and approved by the Ethical Review Board of Aalto University (95_03.04_2019_DigiIN). All participants provided their voluntary, informed, and written consent. Patients' ability and willingness to participate in the study were confirmed through a phone conversation before they signed the consent form. During the call, the study process was explained, and it was emphasized that participation was voluntary, with the option to withdraw at any time. This was also mentioned in the written consent form.

Research Procedure

The study comprised six phases (Figure 1):

1. First, the study purpose and research procedure were introduced.
2. Second, the cultural probe packages, including 4 background questionnaires, were delivered. The study procedure and contents of the package were explained again in detail by phone or Teams (version 1.6.00.11166; Microsoft Corporation).
3. Third, the participants filled out the cultural probes for 2 weeks, during which the researcher made 2 short phone calls to the participants, being present for possible questions and collecting specific day-based information about the participants' routines and activities related to health and well-being.
4. At the end of the study, the participants were interviewed remotely.
5. Then, they returned the probes package to the researcher in a prepaid envelope. The data collection took a maximum of 5 weeks. When the researcher received the probes package, the participants were sent a small thank-you gift.
6. Data were analyzed.

Cultural Probes

Overview

In this study, cultural probes made data collection of older adults' everyday lives possible in research environments, where remote data collection was important for safety reasons [52]. It helped in collecting data indirectly, as the participants themselves completed the cultural probes at their own pace as part of their everyday lives [42,52,53]. It also helped the participants prepare for the interview [52].

The cultural probe package, recruitment questionnaire, and recruitment letter were tested with 2 nonparticipating members of the target group. The probes, questionnaires, and letter were revised based on the feedback. The research materials were then tested again with another target group member. Finally, the entire study setup with semistructured interviews was tested with 2 target group members.

Background Questionnaires

Among other tasks, the cultural probe package included 4 questionnaires: a background information questionnaire, the Health Confidence Score (HCS) [71], the eHealth Literacy Scale (eHEALS) [72], and the European Health Literacy Survey Questionnaire (HLS-EU-Q16) translated into Finnish by Eronen et al [73]. The other questionnaires were translated into Finnish by the authors. Questions 3 to 10 in the eHEALS questionnaire were used in this study with the added option of "I don't know" [72].

In addition to demographic questions, the background information questionnaire asked about the participant's internet and device use, the eHealth services they had used, and how useful they found them. The purpose of the HCS, eHEALS, and HLS-EU-Q16 questionnaires was to obtain an overview of the participants' capabilities (or perceived skills) to understand health information and use eHealth services.

Diary-Based and Sentence Completion Tasks

The cultural probe package (1) motivated participants to notice and document their actions related to health and well-being as a part of their everyday lives and (2) worked as a triggering element for remote, semistructured interviews. In this remotely conducted study, cultural probes and their exercises helped make the researcher appear more relatable to the participant. This was especially important given the sensitive and personal topics, such as everyday life around health and well-being, discussed in the study, both from the researcher's perspective, and more importantly, from the participant's perspective [74]. The cultural probe tasks included sentence completion tasks [59] and a diary-based task [64-66]. In the diary-based task, participants were asked to make notes regarding their health routines, decisions, and actions for 5 days. In addition, 13 incomplete sentences were formulated following the best practices explained by Nurkka et al [42] and included in the

XSL•FO
RenderX

pretesting phase. In the sentence completion task, participants were asked to complete sentences (Multimedia Appendices 1 and 2) with 4 themes (Table 1).

Table 1. Themes of the sentence completion tasks.

Theme	Included in group 1	Included in group 2
eHealth services now	Yes	Yes
eHealth services in the future	Yes	Yes
Concerns and fears for eHealth services	No	Yes
Informal caregiver's eHealth services (excluded from the data)	Yes	Yes

The cultural probe packages had differences regarding incomplete sentence themes between the group 1 and group 2 participants. The study started with the younger participant group. As data began to accumulate, additional questions addressing concerns and fears were incorporated into the sentence completion tasks, as shown in Table 1. This could support the participants in preparing for the interview as well [52]. However, the interview covered the theme with both participant groups.

Remote, Semistructured Interviews

The themes of the cultural probes were investigated in more detail in remote, semistructured interviews [52], which took 1.5 hours maximum to complete with group 1 participants and 1 hour maximum with group 2 participants. If an interview took longer, the participants were offered the opportunity to continue the interview the next day. The researcher made phone calls using either the Teams call function or a mobile phone, making it easier for participants to take part. Two researchers conducted the interviews, but only 1 conducted each interview for trust-building purposes. The interviews were audio recorded and documented with field notes.

The interviews comprised different perspectives regarding the participants' everyday lives and activities concerning health and well-being. The interview structure (Multimedia Appendix 3) was created based on the themes of the cultural probes. The participants were asked to describe the contents of their cultural probes. The idea was to empower the participants and let them decide how much or in how much detail they were willing to express their thoughts on their well-being and everyday lives. In the interview design, the interview checklist by Tong et al [75] was followed.

Analysis

Overview

After the data were transcribed and pseudonymized, the background questionnaire was analyzed using descriptive statistics, and the qualitative data were analyzed following the inductive content analysis process [69,76,77]. User needs were formulated based on the content analysis of the interviews and the analysis of the cultural probe data. The cultural probe data included the participants' diary notes of their daily well-being activities and completed sentences. The data were analyzed according to data type. The different analysis phases are explained in the subsequent sections.

Preliminary Material Walk-Through

During the interviews, a researcher (PV) identified the preliminary content-based categories and, after each interview, categorized each participant's direct quotes in Excel (version 2208 Build 16.0.15601.20644; Microsoft Corporation). Due to the richness of the data, an additional preliminary review was necessary. The researcher (PV) manually reviewed the entire dataset through after receiving the cultural probes package, using traditional pen-and-paper data analysis methods [78].

After this preliminary data analysis phase, the analysis needs for the next phases were recognized. The analysis needs were identified, keeping in mind that the purpose was to understand user needs. Similar to the data analysis process proposed by Nielsen et al [79], the preliminary material walk-through process needed both systematic and circular practices.

Content Analysis for Interview Data

Afterward, 2 researchers (PV and KS) read the pseudonymized interview transcripts and coded the data in ATLAS.ti 9 (version 9.1.5.0; Scientific Software Development GmbH; Multimedia Appendix 4) to understand the data as a whole and to support the analysis of the cultural probes data later. The process proposed by Mayring [76] was followed in the analysis. When approximately 30% (11/40) of the transcripts were coded, the researchers (PV and KS) revised and compared their categories and agreed on common ones. Finally, the results were discussed again by 2 researchers (PV and KS), and the findings were reported.

Analysis for Background Information Questionnaire Data

The background information questionnaires were analyzed to understand the participants' characteristics and their internet and IT use habits. These questionnaires provided preliminary information about the sample. The questionnaire analysis was done in collaboration between 2 researchers (PV and SK). The means were calculated for the data from each of the 3 questionnaires (PV), and the results were discussed (PV and SK). Owing to the qualitative nature of the study and the small sample size, detailed quantitative analysis was not performed.

Content Analysis for Cultural Probe Data

The data from the cultural probe package were analyzed in collaboration between 3 researchers. Each sentence's main content was analyzed by a researcher (PV), and the results were discussed with 2 other researchers (KS and SK) to ensure the quality of the analysis. The diary analysis focused on the

XSL•FO
RenderX

participants' descriptions of their well-being activities. Activities were written on sticky notes, 1 per note, with the participant code and time of day. After 2 researchers (PV and KS) created the notes for 1 participant, their consistency was checked: a researcher (KS or PV) read the findings and another one (KS or PV) wrote the findings down. The analysis included 644 grouped sticky notes. The sticky notes were grouped by 2 researchers. The notes were taken during the analysis process.

Results

Overview

The results are discussed in three parts: (1) participant information; (2) description of older adults' everyday lives; and (3) user needs, which were expressed based on the findings from the sentence completion and remote, semistructured interview data.

The data comprised 19 cultural probe packages and 329 pages of transcripts of 20 interviews (in Verdana font, 11-point font size, single spaced). One participant did not return the cultural probe package.

Participants

The study included 20 participants (Table 2). The participants were divided into two groups: group 1, those who were still employed, and group 2, those who were retired. Both groups included active computer users with many different devices, but compared to group 1, group 2 included more participants who did not routinely use the internet and IT. However, the variation in device types was greater in group 2 compared to group 1. The results suggest that perhaps retired people use health and well-being services less frequently in general than those who are working.

Table 2. Participant background information (N=20).

	Group 1 (n=12)	Group 2 (n=8)
Age (y)	55 to 74	>75
Gender, n (%)		
Women	9 (75)	6 (75)
Men	3 (25)	2 (25)
Internet activity, n (%)		
Internet use daily or many times in a day	11 (92)	6 (75)
Internet use on a weekly basis	1 (8)	1 (12)
Do not know to use or do not use the internet	0 (0)	1 (12)
Internet habits, n (%)		
Most popular devices for internet use		
Computer	12 (100)	5 (63)
Cell phone	12 (100)	4 (50)
Tablet	9 (75)	4 (50)
Place of internet use		
At home	12 (100)	7 (88)
Outside home	10 (83)	3 (38)
The most popular reasons to use the internet		
Searching information	12 (100)	7 (88)
Banking	12 (100)	6 (75)
Health and well-being services	12 (100)	4 (50)
eHealth use, n (%)		
Most popular digital public health care services used		
Patient portal: checking health information and receipt renewal	12 (100)	4 (50)
Appointment booking	11 (92)	4 (50)
Chat, email, or SMS text message to health care professionals	8 (67)	—[a]
Visiting a health center's web pages	—	2 (25)

[a]Data not available.

XSL•FO
RenderX

All group 1 participants (12/12, 100%) and half (4/8, 50%) of the group 2 participants checked their health information and renewed their prescriptions via eHealth services. Internet users used it for banking and information searches, and 80% (16/20) of them also used it for health services.

Multimedia Appendix 5 presents the background questionnaire results. The eHEALS results (20/20, 100%) show the participants' familiarity with using digitally offered health information, with differences between the participant groups. The results of the HLS-EU-Q16 (19/20, 95%) on health literacy indicate that the participants seemed to have at least basic health literacy skills. One participant did not send the questionnaire back to the researchers. The HCS results (20/20, 100%) on patients' confidence in taking care of their own health show that the participants had at least a basic understanding of their health situation and how to operate in case of health challenges [63].

Everyday Life of Older Adults

The analysis of the data from the diary-based task and the interviews resulted in 15 themes in the participants' everyday activities. The themes were spending time at home, dining and cooking, routines, hobbies or exercising, sleep, mundane activities, work-related activities, medical treatment, cottage or nature, friends, pets, pampering and rest, communication with a relative, planning and controlling everyday life, and weather.

The most common activity was spending time at home, often watching television (102/622, 16.4%); spending time at home and dining and cooking (96/622, 15.4%) were the most popular regular activities of the participants. The importance of food for well-being was often mentioned in the data. Exercising was also popular (72/622, 11.6%), with walking and jogging being commonly practiced, including Nordic walking and climbing stairs. Walking could also be a social activity with a partner or a dedicated group. Sleep was mentioned in the data 51 out of 622 times (8.2%), as were mundane activities, such as going to the post office or having lunch or a coffee (51/622, 8.2%). The repetitive nature of routines, including spending time at home, the importance of food, and the variety of exercises, is reflected in the following quotes (the quotes are translated from Finnish):

> *From Monday to Friday, I wake up 5.50 am on two mornings, and on other mornings 6.50 am. And that 5.50 am means, that I go swimming. And on other mornings I eat my breakfast normally at home and go to work. I drink my morning coffee at the office.* [Group 1, participant U2]

> *There have been such beautiful days lately. Today it seems it is not so beautiful, or at least the sun is not shining yet. I feel I'm privileged that I'm able to live in my hometown, because this is such a beautiful city. I started with 30 min walking exercises, and now I do my walking exercise two times in week. Each walking exercise takes one and half hours nowadays. I explore those different terrains, and we have here a lot of a lot of stairs and a lot of small hills, which I use to improve my fitness.* [Group 1, participant U12]

> *I start my work at 9 am, then I eat breakfast, and walk with my dogs. I normally work at my computer until 6–8 pm. I eat, and drink coffee during short work breaks. At 4 pm I give food to my dogs. In the evening, I don't meet anybody else than other dog owners. I also meet new employees during my workday.* [Group 1, participant U6]

> *I eat breakfast in the morning, and at the same time, I read news from my iPad. My husband and I have not ordered any paper newspapers.* [Group 2, participant HX4]

> *I might visit quite often to meet my neighbor, but not on an everyday basis. But it is a part of my everyday life. ...And then, I go quite often after 6 pm a short walk, and at the same time, visit at my friend, who has two cats. ...Then I make some dinner and watch TV News. I do not usually follow any TV series, but I might sometimes watch something from TV. I go to sleep at around 12 am.* [Group 2, participant HX5]

> *I don't have so many meetings anymore, but my week starts with English lessons every Monday at 10 am. At 4 pm I go to an hour's outdoor exercise. In the evening, I often go to German language speaking exercise group. Next day, I go to aqua jogging, and after that we take a cup of coffee with the members of that group. Next day I participate in outdoor walking exercise group, with which we normally walk an hour together. And at the end of the week, I often do some housework, a little bit cleaning home or something.* [Group 2, participant U7]

Watching television was emphasized in both groups, and activities related to cleaning and housekeeping were popular. Overall, participants in both groups seemed to like routines. The everyday life activity themes are detailed in Multimedia Appendix 6.

The Needs of Older Adults for eHealth Services

Overview

The older adults' needs for eHealth services were collected based on the main findings from remote, semistructured interviews and sentence completion tasks. The themes discovered from the interviews, the main findings under each theme, and the participants' needs based on those findings are provided in Multimedia Appendix 7. In addition, sentence completion revealed the participants' wishes and needs for eHealth services in the future (Multimedia Appendices 1 and 2). The needs described in the following sections were expressed based on the data.

The Need for a Carefree Mind

Older adults need a carefree mind when taking care of their health and regarding their current health and well-being situation, which can be supported with eHealth services. They need to understand the safety of eHealth service use and be able to manage health-related matters well regardless of the channel (eg, mobile phone, chat, or remote appointment). Users' technical skills vary, and some use technical devices versatilely. Support and training possibilities help with this need. Feedback

XSL•FO
RenderX

on one's current health and well-being situation via eHealth services is appreciated. The safety needs are evident in the following quotes:

> *I avoid using all parts [of the user interface] that have even a little bit of a foreign language to me. Because it might happen there that I don't understand something and make a wrong choice somehow [in the user interface].* [Group 1, participant U2]

> *I think managing my health-related affairs should be safe.* [Group 1, participant U6]

The need to obtain health care service regardless of the service channel is reflected, for example, in the following comments:

> *I would like to be able to use eHealth services in parallel with other service channels in the future.* [Group 1, participant U1]

> *I look for information on the internet every day. I use all possible medical and health services that are available digitally. And the same thing with public services: everything that is possible, I do them in digital channels.* [Group 2, participant H3]

On the basis of the data, people's diversity is emphasized: being able to use the eHealth service can be a big challenge for one person, but for another, it brings benefits and ease. Owing to older adults' varying technology skills and device availability, health self-management was desired in varying ways and different channels, either face-to-face or digitally. In addition, group 1 participants seemed to be experienced or very experienced with technology and felt very comfortable using eHealth services. The clear variations between the participant groups should be considered in all design decisions regarding eHealth service development.

Varying skills and comfort levels with using eHealth services are demonstrated, for example, in the following quotes:

> *For me, using eHealth services is natural and easy.* [Group 1, participant U6]

> *For me, using eHealth services is easy and self-evident.* [Group 2, participant HX4]

> *eHealth services do not help me because I have neither the equipment nor the skills.* [Group 2, participant S8]

> *Learning something new [about digital services] is difficult because of the tricky terminology. I've never studied English at school, and systems use a special system language. ...Then these jungles of safety encryptions and passwords: remembering them is almost the most difficult part of it.* [Group 2, participant S9]

The Need for eHealth Service Adaptation Based on Current Life Situation, Use Contexts, and Everyday Life

Regarding different life situations, the participants needed support via eHealth with their health and well-being in changing situations, such as when retiring, regardless of their current technology skills or devices. eHealth could help them, for example, with mental well-being or keeping physical activity levels high enough. The changing situations are evident in the following quotes:

> *My working years are in the final phase. It's sure that I have a couple of years left until I retire officially. After that, my children are already adults as well. But currently, my life is quite work-oriented, long workdays, and I'm all the time busy.* [Group 1, participant U1]

> *I have done more or less work [in my life]. And now I'm retiring. That's a pretty big change.* [Group 1, participant U4]

> *I'd like to use eHealth services in the future even after I retire.* [Group 1, participant U12]

> *I have a little bit tricky stage of life. My son went to heaven two weeks ago, and I am currently going through grief. Five years ago, my husband died. So, that kind of stage of life I have now.* [Group 2, participant H2]

> *Yes, it was easier when I was healthy. After all, then I could do what I wanted and run if I liked and, in every way. ...That life was completely different then. I can't say, however, that none of these moments in this life have been completely unpleasant. ...When I think about this end of life, yes, I have had a good life the whole time, no matter what era it was. They have all been part of life that was then, and it was good at that moment.* [Group 2, participant S7]

Older adults desired eHealth services that could adapt to their current and evolving life situations, such as retirement or changes in health. These services should be tailored to their lives in terms of both content and functionality, including the user interface, and should be flexible enough to adjust according to the season, regardless of their location. Older adults want to take care of their health and well-being regardless of location (from places other than home or a clinic, such as a summer cottage). Service adaptation to everyday life makes eHealth services relevant.

However, the ease of use of an eHealth service becomes relevant only after it has been ensured that it can be accessed at all. One's health state affects everyday life and the ability and willingness to use eHealth services. For example, when a health situation improves due to following healthy daily routines, the content of the eHealth service should follow this new health situation and its user's new needs for the eHealth service. eHealth services should be adaptable to changes in life and health situations as well as fluctuations in motivation to use eHealth, both in the short and long term. eHealth service's role and value as a part of changing life situations and user needs regarding eHealth service's adaptability are reflected in the following quotes:

> *eHealth services help me very well in my health situation.* [Group 1, participant U12]

> *eHealth services help me plan schedules flexibly.* [Group 1, participant U7]

> *For me, the most important thing with eHealth services is that I don't have to commit to a specific time.* [Group 1, participant U10]

XSL•FO
RenderX

For me, the most important thing in eHealth services is the right information at the right time. [Group 2, participant S9]

For me, the most important thing with eHealth services is that I get information immediately without waiting. [Group 2, participant HX4]

Using them [eHealth services] saves time. [Group 1, participant U8]

The Need for a Holistic Perspective

Older adults need content that supports their health and well-being holistically. eHealth services should, for example, include perspectives on their current everyday lives and health situations. Group 1 members often wished that eHealth services would be one service among others, smoothly integrated into everyday life. For group 2 members, more research is needed to investigate their perspectives on a suitable package of service channels and content so that they receive the same holistic support as group 1 members. The example quotes behind the need for holistically offered health and well-being support as a part of older adults' everyday lives are as follows:

I fill in crosswords, and I read when I like to. I cook, but not every day now. Things like that I get pleasure from. After all, all in all, the fact that there are not so many financial worries is a part of that balance. Everything you need is here and now. Everyone can ask themselves the question whether they are happy. [Group 1, participant U11]

For me, the most important thing in eHealth services are the right health goals considering the right information; based on researched and measured information. [Group 1, participant U7]

eHealth services help me to plan flexible schedules. [Group 1, participant U7]

eHealth services help me take care of things related to my health at once. They save time. I get e.g., lab results through a digital service. [Group 1, participant U13]

eHealth services help me get an overall picture of my health. [Group 1, participant U1]

I read a lot. Now that I've been here sick and the moments, I've been awake, I'm reading something all the time. [Group 2, participant HX6]

And then jogging with the dog. It keeps me in balance. All my social interaction now takes place there, walking the dog, because there are many dogs here, and we have lived here 45 years, so there are so many people who know dogs. [Group 2, participant S8]

The Need to be Able to Avoid Using eHealth Services But to Use Specific eHealth Functions

Older adults, especially group 2 members, need to be able to select the service channel: eHealth services or face-to-face. On the other hand, there was a need for eHealth functions. For example, group 2 members often appreciated the opportunity to look at laboratory results without having to go anywhere. The COVID-19 pandemic era might have affected this result. The following example quotes bring insights into the older adults' needs for specific functions and the possibility of obtaining health care services via service channels other than eHealth services:

In principle, they [service providers] accept to do business [face-to-face], but if you ask for some advice there, they recommend that you "go to do it online or look it up online." They don't understand that not everything works perfectly on the internet for them either. I think it's pointless for them to guide you to do business online when it can't be done there online. [Group 1, participant U8]

Or you can use a video connection to contact the nurse! They are certainly good additions to the healthcare service. [Group 1, participant U1]

It's embarrassing that I don't know how to book appointments [digitally]. I don't know how to book a time for our laboratory or X-ray. I don't know how to make an appointment. And you should know that, but when there was no need, you didn't learn. [Group 2, participant HX6]

When I imagine myself retired, and when I no longer have a work computer, and if it is difficult to get from one place to another, then of course, they [eHealth services] will be useful. And then the chat service, where you can easily ask for help or advice!

I think managing my health-related affairs should be possible in person. [Group 2, participant S8]

This means that eHealth services should be accessible: (1) devices should be available and (2) the network connection should be stable enough, and the service must be available regardless of time. The service should be offered in a multichannel manner, including personal contact, phone service, or in writing (eg, chat).

Operations related to health and well-being, such as appointment booking through eHealth services, must be clear and easy to use for all user groups. The operations and the eHealth service should support long-term and short-term health and well-being planning in terms of the content and functions available to both end users and health care professionals. It should work reliably in all situations and support older adults' empowerment in managing and controlling their current and future health situations. This is evident, for example, in the following quotes:

I think operations related to my health and well-being should be easy. [Group 2, participant HX5]

eHealth services do not help me at all. [Group 2, participant HX6]

User Needs Regarding User Experiences

The completed sentences revealed that the older adults' experiences with eHealth services varied, with some finding them easy to use and others finding them challenging. The use of eHealth services was felt to be part of everyday life and routines, and it did not produce many "peak experiences," which are the most memorable experiences producing positive

XSL•FO
RenderX

emotions [70,80]. The variation in user experiences from eHealth use is apparent in the following example quotes:

> *For me, using eHealth services is easy, and a routine.* [Group 1, participant U13]
>
> *Using them [eHealth services] makes me a little irritated.* [Group 1, participant U1]
>
> *I think managing my health-related affairs should be confidential, and the response quick and empathetic.* [Group 1, participant U11]
>
> *Using them [eHealth services] puts me in a bad mood.* [Group 2, participant HX6]

Two (25%) out of 8 participants in group 2 had worrying experiences, such as a loss of self-confidence in the use of eHealth services and an increase in concern about the use of eHealth services. These worries are reflected in the following example quotes:

> *Using them [eHealth services] makes me feel insecure.* [Group 2, participant S7]
>
> *The thing that worries or scares me the most about eHealth services is that soon you won't be able to see a doctor anymore when everything will be done digitally.* [Group 2, participant S8]

However, eHealth services especially brought peace of mind to group 1 participants, seeming to improve their well-being. For both groups, eHealth services produced important information about their current health situation. eHealth services seemed to be used in both age groups, not only out of necessity but also to obtain information and improve the flexibility of taking care of their health. eHealth services provided longer-term insights into their own health status, and information obtained through eHealth services was highlighted at different points. Finding out about their own health status seemed important. With the help of eHealth services, the level of concern about their own health condition improved. Group 2 members had more negative views of eHealth services, and they also mentioned a lack of equipment as a barrier to eHealth service use. eHealth service's role in offering information, flexibility in taking care of one's health, or role as a calming factor is reflected in the following example quotes:

> *I use eHealth services if I book an appointment with my doctor, or check my health information* [Group 1, participant U12]
>
> *I use eHealth services whenever possible.* [Group 1, participant U6]
>
> *Using them gives me peace of mind when I can book appointments and find out about health-related issues at a time that suits me.* [Group 1, participant U13]

Other barriers to eHealth services were lack of human contact, inefficiency, and challenges with its use. eHealth services divided participant opinions regarding its benefits: group 1 participants did not have as many helpful experiences with eHealth services as group 2 participants. Both groups included individuals who felt that eHealth services did not provide holistic support during life changes. At the same time, group 2 participants felt that eHealth helped them acquire information about health-related issues, supported them in planning health-related issues, and helped them commit to lifestyle changes. On the other hand, they lacked competence and felt that eHealth services (use processes and user interfaces) was too complicated. The negative experiences and use barriers are evident in the following quotes:

> *With eHealth services, I am saddened by the lack of consistency and aimlessness, as well as the lack of genuine and cheerful support.* [Group 1, participant U7]
>
> *With eHealth services, I am frustrated by delays and waiting.* [Group 1, participant U6]
>
> *With eHealth services, I am saddened by my laziness and lack of time available to study the use of eHealth services.* [Group 2, participant H3]
>
> *With eHealth services, it saddens me that I don't know how to use them.* [Group 2, participant HX6]

The most important things in eHealth services use were efficiency, ease and smoothness of transactions, access to information, planning (where group 1 members had diverse answers), and support for well-being. Participants in group 2 had the same eHealth needs as those in group 1 but they were more skeptical (Multimedia Appendix 8).

The efficiency, ease, and support for well-being via eHealth services are apparent in the following quotes:

> *Using them [eHealth services] saves my time.* [Group 1, participant U6]
>
> *Using them [eHealth services] makes me think about my health based on researched information.* [Group 1, participant U10]
>
> *For me, the most important thing about eHealth services is that I don't have to commit to a specific time or date.* [Group 1, participant U10]
>
> *eHealth services help me renewing my medicine prescriptions.* [Group 2, participant S7]

Discussion

This qualitative exploratory study aimed to gain a more in-depth understanding of older adults' needs for eHealth services as part of their everyday lives in different life stages. The data were collected with interviews and a cultural probe package, including 4 background information questionnaires, sentence completion tasks, and a diary-based exercise.

Principal Findings

Everyday Life of Older Adults

Both participant groups valued time spent at home and home-based activities as part of their everyday lives. Healthy eating habits were an especially important aspect of the participants' well-being from their own perspective. These older adults enjoyed different activities, such as jogging and Nordic walking, which is in line with other literature [31].

Older adults generally appreciated bringing health and well-being into everyday life. They had weekly or daily

XSL•FO
RenderX

activities or hobbies that supported them to reach their long-term health targets. These routines varied greatly, including exercise, good night sleep, personal hygiene, repetitive food, pet care, and housework-related morning routines. Group 1 participants reported routines and activities that partly differed from those of group 2 participants. For example, all the routines related to the gym or exercising while commuting were reported by group 1 participants. Interestingly, the only mention of reading newspapers with a tablet was reported by a participant from group 2. Furthermore, a mention of doing morning exercise with television was reported by a group 2 participant. Cleaning routines were mainly mentioned by participants from group 2.

The eHealth service can both support health self-management on a long-term basis and activate and support older adults in ad hoc type of activities and operations related to health and well-being, for example, by offering information based on the current health situation or reminding them of a (daily or weekly) hobby.

The Needs of Older Adults for eHealth Services

On the basis of the interviews and sentence completion tasks, four needs for eHealth services were identified: (1) the need for a carefree mind; (2) the need for eHealth service adaptation based on the current life situation, use contexts, and everyday life; (3) the need for a holistic perspective; and (4) the need to avoid using eHealth services but to use specific eHealth service functions. These needs should be considered when designing eHealth services that support older adults' healthy living. In addition, they generally apply to both user groups but may be emphasized differently depending on the group.

On the basis of our findings, the older adults seemed to have generally positive attitudes toward eHealth, aligning with those identified by Cabrita et al [15] and Mielonen et al [28]. The infrastructure behind eHealth services must be stable; then, eHealth services can be offered in an accessible way and without limitations for everyone, assuming that end devices are available. Owing to varying end devices among older adults, eHealth services should be scalable regardless of the service channel or devices. Therefore, the design should support the reliability of eHealth services so that they work in all situations, supporting older adults' health self-management [15,70]. Our study adds the perspective of changing time spans: the service must function smoothly for both short-term and long-term use, accommodating variations in use duration.

Well-being, sickness, health, and illness seem to be subjective personal experiences. The need for eHealth services changes due to the user's current health and well-being situation: eHealth services become unnecessary when health and well-being increase. Therefore, it must be possible for older adults to easily try out whether eHealth services will benefit them. An eHealth service may also be used less frequently at times.

eHealth services can support older adults' health and well-being, particularly when the content of the service aligns with their everyday lives and interests. Therefore, we recommend that the eHealth service work as part of an older adult's healthy routines, which might include, for example, encouraging attitudes and functions for housework and other activities.

Comparison With Prior Work

Our results show that understanding the user's life stage and the key interests at that stage is important, as found in other literature [47]. Owing to older adults' changing health and life situations [1-3,10,11,47], an individual eHealth service should function as part of a wider service offering so that the service supports and adapts to changing life situations and health statuses. For example, in this study, it was recognized that both those who are still working and those who are retired use IT and eHealth services. IT use at work might support learning new skills and sometimes even updating them [70]. In addition, eHealth service flexibility is valued [4]. The need for eHealth services to adapt to the older adult's current life and health situation is in line with the study by Reiners et al [81].

Earlier research recognized a large variation in activities that support older adults' well-being, in line with our findings: exercising; cooking; and hobbies, such as language courses [82]. Even with poor health, older adults achieve well-being and positive effects from daily activities [82,83]. In addition to physical activities, daily activities, such as reading books or watching television, can also offer relaxation [81]. Owing to the differing routines and daily activities, the need for eHealth adaptation based on the current life situation, use contexts, and everyday life was recognized in this study, and we recommend that eHealth services work as a part of older adults' daily living smoothly. Previous research supports our results behind this user need: older adults are a heterogeneous group whose activity possibilities vary regarding their living conditions or current health situation [31]. However, the importance of studying the use of eHealth service as part of everyday life has been recognized [19].

The devices with which the eHealth services are used should be considered when designing these services. Given the possible effect of the small sample size, it can be seen from the data that group 2 participants seemed to use eHealth services somewhat less than group 1 participants. One reason for that could be that older adults who are still employed might use eHealth services for work reasons, as well [70]. On the other hand, it can probably be expected that, nowadays, older adults who are retired have used at least some IT at work.

Understanding the safety of eHealth services use was important to older adults, as in earlier research [4,5,10,18]. In line with previous literature [18,70], they needed available support and training for eHealth service use. In particular, the older participants in this study also needed not to be forced to use the eHealth service. However, this varied considerably between participants, which supports earlier research results [18].

In line with an earlier study [15], one of the most important design functions is to ensure that the eHealth service conveys empathy to older adults. This can be offered via an empathic tone of voice in the services and by offering them through service channels that are especially suitable to each older adult's current situation. The whole life span, including transitions to different life phases, such as retirement, should be considered in design decisions [2,47,70]. This can be done, for example, by offering relevant content related to health and well-being to

XSL•FO
RenderX

different older adult groups and by making sure that the content is relevant to each end user's unique life and health situation.

On the basis of our findings, both those still working and those who have already retired have suitable devices and sufficient technical skills, as also reported by Mielonen et al [28]. However, eHealth services were used only by half (4/8, 50%) of the older participant group. Our findings support the observations of Kruse et al [3] regarding common barriers to eHealth use among older adults: a lack of self-confidence, a fear of making irreversible mistakes, and content that does not meet their needs. Fear can be dispelled with a clearer service concept, implementation support, user support, and instructions, as well as reassurance, such as by highlighting safety both in the service content and in the presentation of the service. In addition to minimizing fear, strengthening the self-confidence of the end user of the service plays an important role. Another phenomenon that emerged from the data was that well-being, health, and illness seem to be subjective, personal experiences.

The need for eHealth services changes due to the user's current health and well-being situation; eHealth services become unnecessary when health and well-being improve. Therefore, it should be possible for older adults to easily try out whether the eHealth service will benefit them. This can be done, for example, by offering trial versions of services, which other research [15,18,84] recommends. Being able to safely try out an eHealth service could help reduce fears, build self-confidence, and better identify the current need for the service. Another helpful option would be to group service functions into easier basic functions and possibly other more complex functions that are recommended to be familiarized with time, as is recognized in the literature [15,47]. However, based on the study findings, the end user's age or life situation does not appear to be a decisive factor in determining the need for user interface content. That said, older adults who are retired may face slightly more challenges in using eHealth services compared to those who are still working.

As also found in other literature [18,70], individual eHealth service should function as part of a wider, multichannel service package so that it adapts to changing life situations and changes in health status. It should work as a channel for end users to receive empathy in challenging health situations. This could be done with effective but sensitive communication possibilities and with empathic content. Because eHealth services should support older adults' health and well-being, it is important to look at and connect their well-being in the IT context [84]. This can be done according to content and with easy and logically functioning user interfaces. In addition, this study's participants wished for an option to not use eHealth services or specific eHealth functions. This need is in line with other research findings [85].

Limitations

This qualitative exploratory study aimed to gain a more in-depth understanding of older adults' needs. The sample was small; the participants were from 1 country, and they were likely to be more interested than average in eHealth services. Older adults are a diverse group from the perspective of, for example, cognitive, motor, or technology use abilities [61]. Therefore, completely covering the population with a representative sample was not possible. This has potentially biased the results. In addition, the COVID-19 pandemic era could have influenced the results, but this was not especially followed as a part of this study.

Regarding the adaptation of eHealth services to different life and health situations, we do not know whether the service should always be the same or differ depending, for example, on whether the health situation has changed, in which case the role and meaning of the service changes from supporting well-being to treating illness. We recommend this as a future research area, especially in long-term studies. More research is needed on the best service channel combinations for older adults to obtain sufficient holistic health and well-being support. In the future, it would be worthwhile to test the design recommendations with representatives of the designer community and older adults, for example, in co-design workshops. In this study, the older adults' needs in different life situations were not compared to those of other age groups. However, this would be valuable to study in the future.

From a methodological perspective, the cultural probe package, including diary-based and sentence completion tasks, combined with remotely conducted semistructured interviews seemed to be effective in collecting information about participants' everyday lives and in mapping user needs for eHealth services. This is interesting because, as far as we know, not many cultural probes studies on this topic are available. The working participants completed more handwriting-based sentences. Therefore, cultural probes including many handwriting exercises might fit better for them. On the other hand, the data were collected using several methods, which confirmed the findings of the study and helped identify user needs. The methods seemed to work well in remote conditions during the COVID-19 pandemic era.

Conclusions

In this qualitative study, we collected information about the everyday lives of older adults in different life situations and identified their related needs for eHealth services. The results helped us understand how older adults see and experience health care with the help of eHealth services as part of everyday life. The older adults in this study often preferred a consistent routine in their daily practices including healthy eating and exercise. eHealth services could offer time saving and flexibility within these routines. A lack of devices or skills was often mentioned as a use barrier. On the basis of the results, four main needs of the older adults for eHealth services were identified: (1) the need for a carefree mind, in which older adults could receive status information on their current health and well-being situation via eHealth services; (2) the need for eHealth service adaptation based on the current life situation, use contexts, and everyday life; (3) the need for a holistic perspective, in which older adults wished to receive support for health issues from many perspectives and through several different service channels; and (4) the need to avoid using eHealth services but to use specific eHealth service functions, in which face-to-face support for their health was especially appreciated. On the basis of the results, eHealth services should be designed such that

XSL•FO
RenderX

they fit well in older adults' everyday lives and adapt to users' everyday practices and health statuses according to content. eHealth services should be accessible and reliable.

Acknowledgments

The authors would especially like to thank the study participants. The authors would also like to thank Marina Broman for completing 3 of the interviews and Marjaana Kanervo, Annetta Kurvinen, Tytti Natunen, Kirsi Pitkälä, Sanna Pussinen, Semra Räikkönen, Reija Saarinen, Sanna Solala, Arja Sunila, and Iina Vartia for the help with the research arrangements and collaboration. The work was supported by the Strategic Research Council at the Academy of Finland (grants 352501 and 352503) and NordForsk (project 100477).

Data Availability

The datasets generated and analyzed during this study are not publicly available due to the sensitive nature of the data, but the numeric data are available from the corresponding author on reasonable request.

Authors' Contributions

The study was conceptualized by PV, SK, and RRH. PV was involved in the methodology, investigation, project administration, data curation, visualization, and formal analysis of the study. KS contributed to the formal analysis and validation of the study. PV, KS, and SK were involved in preparing the original draft of the study. SK contributed to the methodology, resources, data analysis, validation, supervision, and funding acquisition of the study. RRH also contributed to the resource collection of the study. All authors were involved in writing, reviewing, and editing the manuscript.

The visualizations used in the cultural probes were under creative commons licenses. The creators' nick names were OpenClipart-Vectors, Emmie_Norfolk, Buntysmum, Clker-Free-Vector-Images, bibin9363pbr, 1,820,796, ArtsyBee, and b0red.

Abstract

Background: The World Health Organization estimates that 1 in 4 people worldwide will experience a mental disorder in their lifetime, highlighting the need for accessible support.

Objective: This study evaluates the integration of digital peer support (DPS) into an employee assistance program (EAP), testing 3 hypotheses: (1) DPS may be associated with changes in EAP counseling utilization within a 5-session model; (2) DPS users experience reduced sadness, loneliness, and stress; and (3) DPS integration generates a positive social return on investment (SROI).

Methods: The study analyzed EAP utilization within a 5-session model using pre-post analysis, sentiment changes during DPS chats via natural language processing models, and SROI outcomes.

Results: Among 587 DPS chats, 432 (73.6%) occurred after business hours, emphasizing the importance of 24/7 availability. A matched cohort analysis (n=72) showed that DPS reduced therapy sessions by 2.07 per participant (P<.001; Cohen d=1.77). Users' messages were evaluated for sentiments of sadness, loneliness, and stress on a 1-10 scale. Significant reductions were observed: loneliness decreased by 55.04% (6.91 to 3.11), sadness by 57.5% (6.84 to 2.91), and stress by 56.57% (6.78 to 2.95). SROI analysis demonstrated value-to-investment ratios of US $1.66 (loneliness), US $2.50 (stress), and US $2.58 (sadness) per dollar invested.

Conclusions: Integrating DPS into EAPs provides significant benefits, including increased access, improved emotional outcomes, and a high SROI, reinforcing its value within emotional health support ecosystems.

KEYWORDS

digital peer support; peer support; EAPs; cost-effectiveness; SROI

Introduction

Background

The World Health Organization estimates that 1 in 4 people globally will experience mental disorders in their lifetime [1], stressing the need for a readily available treatment ecosystem. Relatedly, the increasing popularity of remote work post–COVID-19, along with work- and workplace-related stress—stemming from long hours, high workloads, an inability to disconnect, and, in particular, isolation—has contributed to a rise in mental health problems such as anxiety and depression, musculoskeletal pain, sleep deprivation, and stress [2]. These stressors impact not only employees' well-being but also presenteeism, absenteeism, and work-life balance [2-4]. Burnout, in particular, arises from chronic stress characterized by emotional, physical, and mental exhaustion, leading to reduced productivity, increased absenteeism, and higher turnover rates [3].

XSL•FO
RenderX

While the Centers for Disease Control and Prevention's National Center for Health Statistics reports a notable increase in treatment-seeking behaviors between 2019 (19.2%) and 2021 (21.6%), a significant majority of working adults may still suffer alone [5]. The proportion of working adults aged 18-44 years receiving mental health treatment grew significantly from 18.5% in 2019 to 23.2% in 2021 [5], with women (23.8% to 28.6%, respectively) continuing to outpace men (13.1% to 17.8%, respectively) [5]. By 2021, adults aged 45-64 years (21.2%) and those aged 65 years and over (18.9%) ranked second and third, respectively, in seeking treatment [5].

Employee Assistance Programs

Mental and emotional health–focused employee assistance programs (EAPs), which are confidential, voluntary, organization-sponsored, and low-cost services for employees, offer personal or work-related counseling and support. The purpose of EAPs is to help employees manage stress, enhance problem-solving abilities, and, in turn, improve work productivity, reduce absenteeism, and promote overall well-being [6]. Counseling-based EAPs provide psychoeducation, teach coping strategies, and assist users in setting achievable personal goals that build confidence and self-efficacy [7-12]. Additionally, EAPs offer training in communication skills, such as assertiveness, to improve relationships and help users navigate challenges effectively. Patient activation, which refers to an individual's knowledge, skills, confidence, and willingness to manage their health and well-being [7,8], is further supported by connecting users to resources and support networks, including health care providers and peer support groups. Finally, EAPs empower users with self-management tools, such as digital apps and resource libraries, that allow them to track their progress and independently manage their well-being [12]. Together, these strategies foster self-reliance, enhancing users' ability to manage their mental health and overall well-being [7]. Depending on the EAP, a significant return on investment (ROI) may be observed, with some organizations seeing US $3-US $10 for every dollar spent [13], largely due to positive impacts on absenteeism, productivity, and employee turnover and retention [6,13]. EAPs are well-established assets to organizations, delivering emotional benefits to employees and productivity and financial benefits to employers [6,13].

Digital Peer Support

While counseling-based EAPs are known for their advantageous returns, not every emotional concern requires counseling support. A tiered support system for individuals who are mentally well but experiencing lower-acuity emotional distress may be necessary. Simultaneously, the US health care system currently faces a shortage of mental health professionals, limiting access to adequate support [14,15]. In 2021, 5930 areas were designated as health professional shortage areas, leaving 129.6 million people without access to affordable and accessible care [15]. President Biden's 2022 White House brief highlighted this issue and called for efforts to "strengthen system capacity," including the increased use of peer support specialists and paraprofessionals [16].

Peer support interventions involve individuals with similar lived experiences offering mutual support [17]. While expert-based professional support may evoke feelings of shame, failure, and mental health stigma, peer support can normalize emotional struggles and foster connection, validation, and empathy through shared experiences [18]. This "mutual empowerment" from peer-driven interventions grants individuals greater autonomy and competency [18]. However, some Americans may not have access to digital peer services due to a lack of universal internet access and low health literacy. Approximately 24 million people in the United States lack reliable broadband service or high-speed internet [19]. Historically, lower rates of high-speed internet use have been observed in households where the owner is 65 years or older, Hispanic, African American, American Indian, or Alaska Native [19]. Furthermore, in 2021, only about 5 in 10 households with incomes below US $25K used high-speed internet [19]. Additionally, approximately 90 million American adults struggle to understand and navigate complex health- and text-based tasks accurately and consistently, exhibiting low health literacy [20]. By addressing these disparities, digital peer support (DPS) services could become even more inclusive by expanding support to those currently excluded from traditional services.

Self-determination theory, as articulated by Ryan and Deci [21], offers insight into key features that make peer support impactful. The theory states that self-determination and emotional growth are driven by 3 core elements—autonomy, competence, and relatedness [21,22]. Autonomy refers to the ability to self-direct and control one's actions, competence involves mastering new skills, and relatedness is about forming meaningful connections with others [21,22]. Peer support provides a nonjudgmental, nonstigmatizing space that fosters autonomy, as there is no professional expert directing treatment. Competence is strengthened through the normalization of mistakes shared via lived experiences, as well as the application and practice of coping strategies. Relatedness is reinforced through the verbal and emotional connections formed with similar peers [18]. Research has consistently shown that relatedness in supportive relationships contributes significantly to emotional regulation, motivation, and the overall success of interventions. By reinforcing relatedness through peer-to-peer interactions, peer support programs address a fundamental psychological need that complements autonomy and competence, further validating their essential role in the model [17,18]. The interrelatedness of these dynamic factors is believed to enhance mental health and well-being [17-22]. The introduction of DPS platforms extends these benefits by offering accessible, mutually supportive communities to help alleviate feelings of loneliness and isolation [23]. Numerous studies have demonstrated the effectiveness of these digital interventions in addressing mental health needs [23-30].

Confirmed benefits of peer support interventions are evident through self-determination theory and digital platforms [23-30]; however, a significant gap remains in understanding the ROI, particularly when integrated into counseling-based EAPs. Studies suggest that peer support may lead to direct health care savings by equipping individuals with coping mechanisms and providing emotional support, which, in turn, reduces the risk

XSL•FO
RenderX

of crises and costly subsequent interventions (eg, inpatient hospitalization, emergency room use) [31-33]. Specifically, current research does not adequately address how incorporating 24/7 DPS into EAPs translates into measurable cost-effectiveness for organizations. Traditionally, cost-effectiveness and cost-benefit analyses are used to assess the value for money of health and social interventions, but the value derived from participating in 24/7 DPS can be subtle and difficult to measure [34]. As a result, there is a paucity of research on the broader social, economic, and environmental value. This gap underscores the need for a focused study to evaluate the social return on investment (SROI) of integrating 24/7 DPS into a counseling-based EAP, assessing both the economic impact and the efficiency of these interventions.

Social Return On Investment

SROI has become a recognized method for measuring the impact, outcomes, and value created by social-emotional–focused organizations [35,36]. Broadly, SROI uses a mixed-method design to assess the value of an intervention relative to the cost of enabling it. Beyond financial metrics, which may assign limited value to a program, SROI captures social, environmental, and economic elements to generate a comprehensive "social value."

Study Aim and Hypotheses

For this study, a 24/7 US-based DPS service was integrated with a US-based counseling-based EAP firm to explore potential changes in utilization, sentiment, and the SROI of the 24/7 DPS for the EAP's clientele. The following study hypotheses were examined: (1) The introduction of the 24/7 DPS service may lead to changes in the utilization of EAP counseling services within a 5-session model; (2) participants who utilize the DPS service will experience significant changes in sentiment (eg, reduced sadness, loneliness, and stress) over the course of their engagement with the service; and (3) the integration of DPS into the EAP will produce a positive SROI, reflecting the added value of peer support services for EAP clientele. Through these key objectives, the study aims to assess the effects of DPS on EAP utilization, emotional well-being, and the social and economic value added to the EAP.

Methods

Pre- and Post-DPS Integration: EAP Services and Implementation

Using aggregated participant data, pre- and postanalyses of adding DPS to EAP services were conducted. Pre-DPS was defined as the routine care provided within the EAP, including an initial intake, screening for clinical concerns, and offering service options such as counseling, legal resources, psychoeducation, and coaching. Before the introduction of DPS, participants either accessed the EAP provider's website using a company code to explore available services or completed an initial online or phone intake. They were screened for clinical concerns, including substance use and suicidal or homicidal ideation, by licensed clinicians or clinically supervised paraprofessionals. The EAP offers a comprehensive suite of behavioral health and wellness services designed to support mental health, work-life balance, and overall well-being. These offerings include free and confidential counseling, legal and financial benefits (including Medicare and Social Security consultation), wellness coaching, work-life referral services, and an online resource library. Additional services include virtual reality programs, as well as parenting, life, career, and work performance coaching. The EAP provides managed care 24/7, with crisis support delivered by licensed mental health professionals.

An anonymous US-based DPS service that provided 24/7/365 moderated, synchronous peer group chats was integrated into the US-based EAP's client support ecosystem. The DPS service utilized artificial intelligence (AI)–driven natural language processing to match users with peers facing similar issues in small groups, each facilitated by a trained human moderator who ensured a safe environment and directed users to professional services in crises. The DPS model allows for unlimited sessions, in both duration and frequency, while the EAP's 5-session model was selected for further analysis due to the prevalence of 5-session models over other session formats.

Participants

DPS: Peer Support Users

Nonidentifying participant data from the DPS provider, collected between June 2023 and May 2024, were used to evaluate the research objectives. DPS service participants had access to unlimited peer support chats and were included in the data analysis if they utilized the chat service at least once.

EAP: Counseling Service Participants

Inclusion Criteria

Pre-DPS (June 2022 to May 2023) and post-DPS (June 2023 to May 2024) participants were selected based on having active access to the 5-session EAP model. For the analysis of total utilization, no demographic factors were matched between the pre- and post-DPS groups. However, for the utilization analysis of the 5-session EAP model and to ensure comparable groups, participants in both the pre-DPS and post-DPS cohorts were matched based on demographic and emotional concern variables. Matching was conducted using propensity score matching, adjusting for potential confounders such as age, gender, and emotional concerns (eg, anxiety or depression). Participants who had utilized the full 5-session model in both groups were selected, with efforts made to capture diverse client trajectories by including multiple participants matched on these same variables. EAP participants were employed across a wide range of sectors, including health care, education, professional services, manufacturing, construction, building trades, nonprofits, technology, service industries (eg, restaurants), unions, mining, government, and others.

Cohort Exclusion Criteria

Participants were excluded from the analysis if they had missing demographic data (age or gender) or if they exceeded the authorized number of counseling sessions (eg, >5 sessions in the pre-DPS group). These exclusions were necessary to control for confounding variables, as participants requiring more intensive mental health support (beyond 5 sessions) may have

XSL•FO
RenderX

had significantly different needs compared with those who adhered to the 5-session model. This approach ensured that the study focused on participants whose engagement with EAP services reflected typical utilization patterns.

Peer Support Moderators

Peer support moderators (PSMs) are human moderators trained in digital safety monitoring who provide real-time, text-based support. PSMs receive up to 164 hours of training within the first 90 days of hire, focusing on engaging in digital conversations, facilitating synchronous group chats, and managing the psychological safety of chat users by monitoring for and removing trolls, as well as enacting safety protocols, such as referring users who may be in active crisis to appropriate services. Additionally, PSMs receive 36 hours of ongoing asynchronous and synchronous clinical supervision and consultation per quarter.

Procedures

Overview

This retrospective study evaluated the differences in the EAP's services before and after DPS to assess the programmatic impact and added social value.

Data Variables

The primary data sources for this study were aggregated engagement variables, such as chat time, number of chats, age, gender, user struggles or presenting concerns, and national-level cost-of-service value data.

Data Extraction and Management

The data extraction process involved retrieving DPS chat data, which included digital chat records, user interactions with the platform, and usage patterns. All collected data were deidentified and anonymized to ensure participant privacy and confidentiality. Data management procedures adhered to institutional and regulatory guidelines, ensuring data security and integrity, with access restricted to authorized personnel. Measures were in place to maintain data security, integrity, and confidentiality throughout the analysis process.

Statistical Analysis

Analysis and Group Comparability

Descriptive statistics were used to summarize participant characteristics and their engagement with DPS and EAP services. To assess differences in service utilization and sentiment scores between pre-DPS and post-DPS groups, paired *t* tests (2-tailed) were conducted for continuous data (eg, session frequency), and chi-square tests were used for categorical data (eg, gender, emotional concern). As DPS is anonymous, it was not possible to directly track which EAP participants used the service. Using volunteered age and gender data from DPS participants as a starting point, propensity score matching was applied to control for potential confounders such as age, gender, and emotional concern, ensuring group comparability before DPS integration.

Mood Categorization

Clinical counseling experts reviewed the emotional concerns reported by DPS participants, categorizing them into mood categories such as depression, anxiety, adjustment, and relational concerns to align DPS participants with the presenting emotional concerns of EAP participants. The counseling experts were 2 licensed psychologists with doctoral degrees in counseling psychology and a combined 50 years of experience in the field. The clinical interpretation process, guided by the Biopsychosocial Model [37], involved categorizing participants' emotional struggles into mood categories. This model integrates biological, psychological, and social dimensions to provide a comprehensive understanding of mental health. For example, participants' reports of feeling "trapped" or "isolated" were examined through a psychological lens to identify depressive thought patterns, while work-related stress (eg, "I hate my boss") was contextualized within the social environment to classify relational concerns [38]. By incorporating these factors, the model enabled clinical experts to holistically interpret participants' struggles, ensuring that the categorizations captured the complexity of their emotional experiences. The categorization process involved initially reviewing the raw data from participants' reported "struggles" and presenting concerns in therapy individually, followed by cross-validation between the 2 experts to ensure consistency. This collaborative step helped reconcile differences in categorization and address overlapping cases. It is important to note that neither the text-based struggle data from DPS nor the presenting concerns from EAP represented formal diagnoses; rather, they reflected participants' personal interpretations of their symptoms. Keywords such as *helpless* or *sadness* were flagged for depression-related presenting concerns, while terms related to *fear, excessive worry,* or *panic* were matched with anxiety-focused concerns. In cases where symptoms overlapped (eg, depression and anxiety), the experts aligned their categorizations based on the primary presenting concern reflected in the participant's statement. For example, if a participant's statement indicated feelings of hopelessness and despair alongside anxious thoughts, the struggle was categorized as depression. Alternatively, if worry or nervousness predominated, it was categorized as anxiety. In scenarios where a specific relationship was mentioned alongside anxious or depressive feelings, the struggle was categorized primarily as a relational concern. Symptom overlap was resolved by categorizing the statement according to the dominant theme present in the participant's experience. Table 1 provides examples of these interpretations.

XSL•FO
RenderX

Table 1. Clinical interpretation of comparable emotional concerns shared on digital peer support service with employee assistance program service.

Participant's struggle	Presenting concern[a]
"I am feeling pretty suicidal and trapped. I am new to my work from home job and I need help, resources, a plan something or this will only get worse. I am trapped with no transportation, no friends or any meaningful relationships in life. Just a work schedule and I'm isolated."	Depression
"I hate my job and my boss"	Relational concern
"I've been feeling a lot of anxiety around work and my personal life"	Anxiety/stress
"Alcohol addiction"	Substance use

[a]These are not diagnoses, they are layperson understandings.

Sentiment Analysis

Peer-to-peer conversations were analyzed to produce a quantitative measure of emotional change. Each participant's chat session, referred to as a "user-chat-session" or simply "user-chat," was treated as an independent unit of analysis, regardless of whether the same participant took part in multiple sessions. As the DPS service is anonymous, each user and their experience in a given chat session were considered separately, without combining data from different sessions for the same user. This approach ensures that each user's experience is analyzed in isolation, providing a more accurate, user-centric view of emotional changes.

Each user's message was analyzed in the context of preceding messages from other users to capture their emotional journey throughout the chat session. Context was defined as the concatenation of all preceding messages from other users in the same chat, starting from the latest message of the user of interest. A user's initial struggle and first message had no prior context and were evaluated with an empty context. For example, in the following conversation:

userA: message1

userB: message2

moderator: message3

userA: message4

userB: message5

This example assumes that message1 and message2 are the first messages of user A and user B, respectively, in the chat session. User A's emotional journey was quantified by evaluating message1 with an empty context and message4 in the context of message2 + message3. Similarly, for user B, message2 was evaluated without context, and message5 was evaluated in the context of message3 + message4.

Each user's message, along with its corresponding context, was evaluated for sentiments of sadness, loneliness, and stress using a scale of 1-10, where 1 indicates low intensity, 5 indicates moderate intensity, and 10 indicates high intensity of the sentiment. The analysis focused on chat sessions where participants exhibited at least moderate sentiment intensity (score≥5) from the beginning.

A third-party, public natural language processing model from OpenAI, called GPT-4, was used to assign sentiment scores to each user message and its preceding context [39]. A few-shot learning approach was applied, where the model was provided with 10 examples representing different sentiment intensities to calibrate its interpretations [40]. GPT-4 demonstrates an advanced capacity to interpret emotion, surpassing benchmarks from the general population and offering highly congruent performance in emotion interpretation [41]. See Table 2 for examples provided to GPT-4 to predict loneliness levels.

Sentiment analysis evaluated each user's chat messages in temporal order. The quantified emotions were then interpolated and extrapolated to generate a collective sentiment trend across peer-to-peer chats of varying lengths. A one-sided Mann-Whitney *U* test was used to compare emotion scores at the start and end of the conversations.

Table 2. Examples provided to GPT-4 to interpret loneliness intensities in a few-shot manner.

Intensities	Loneliness
1=low	"Take care everyone. Thanks for the great talk"
5=moderate	"I went on Monday and today. After today's class is when I felt worse as I chatted with a lady in class who told me that she got really depressed when she retired."
10=high	"I just always feel totally alone. Like no one understands what is going on in my head"

SROI Methodology

Historically, the SROI methodology has relied on qualitative methods to identify outcome themes most relevant to participants, followed by quantitative approaches to determine monetary proxies for the identified outcomes and related values [41].

With the advent of natural language processing models, significantly larger volumes of text-based data can now be analyzed, allowing qualitative data to be graphically represented. This study utilized text-based data from peer group participants—including open-ended questions, affirmations, reflective questions, and summaries—to examine changes in sentiments such as sadness, loneliness, and stress within

XSL•FO
RenderX

peer-support chats [42]. The SROI methodology was applied to assess the social value created by integrating DPS into the EAP. Qualitative data from peer-to-peer conversations, including open-ended questions, affirmations, and summaries, were analyzed to understand sentiment changes and emotional shifts within the peer group chats. Quantitative methods were used to calculate a monetary proxy for the emotional outcomes. The Sopact SROI calculator, available on the Sopact website [41], was utilized to determine the social value generated by the DPS service, incorporating factors such as enhanced emotional well-being and cost savings from reduced therapy usage. Given the novelty of DPS and its integration into the EAP, a small sample size was anticipated. This limitation was addressed through rigorous matching techniques and statistical analyses to ensure the findings remained valid and robust despite the smaller sample size. Moreover, it is acknowledged that some participants may have preferred individual counseling services over DPS, potentially introducing selection bias among those who opted for the DPS model.

Ethical Considerations

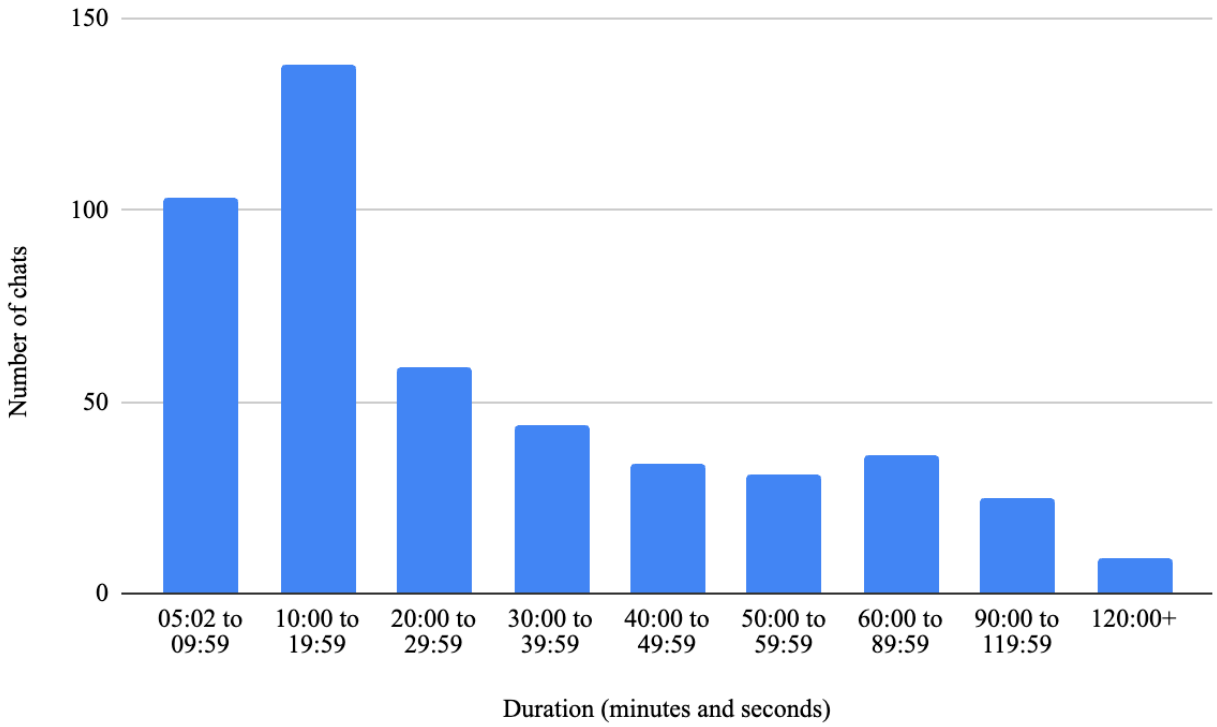
Informed consent was obtained from all participants before their involvement in the study. The consent process included clear explanations of the research's purpose, data collection methods, and the measures implemented to ensure participant privacy and confidentiality. All data collected were deidentified to safeguard participants' anonymity. The study complied with all institutional and regulatory guidelines related to data protection and participant privacy. To ensure participant safety within the DPS, real-time moderation was provided by trained human moderators specializing in digital safety monitoring. Furthermore, the Pearl Institutional Review Board reviewed and approved the study (approval ID 2024-0442).

Results

Total DPS Utilization

- Study hypothesis 1: The introduction of the 24/7 DPS service may be associated with utilization changes of EAP counseling services within a 5-session model, specifically among participants who engage with DPS.

Out of 587 total chats, 432 took place between 5 PM and 8 AM, hours when most therapy offices are typically closed. Chats lasting less than 5 minutes were excluded from the analysis, as the initial 5 minutes are generally used for introductions and setting expectations [30]. Consequently, 107 chats were omitted. A summary of the data is provided in Table 3.



When categorized by duration, the data revealed that 103 chats lasted between 0 and 9 minutes 59 seconds, 138 chats between 10 and 19 minutes and 59 seconds, and 59 chats between 20 and 29 minutes and 59 seconds. Additionally, 44 chats lasted between 30 and 39 minutes and 59 seconds, 34 chats between 40 and 49 minutes and 59 seconds, and 31 chats between 50 and 59 minutes and 59 seconds. While longer chats were less common, they occurred consistently: 36 chats lasted between 60 and 89 minutes and 59 seconds, 25 chats between 90 and 119 minutes and 59 seconds, and 9 chats exceeded 120 minutes. Refer to Figure 1 for further details.

Table 3. Peer support program utilization data.

Metric	Value
Total chats, n	480
Total messages, n	7219
Total duration, hours:minutes:seconds	254:17:57
Average duration, hours:minutes:seconds	0:31:51
Shortest duration, hours:minutes:seconds	0:05:02
Longest duration, hours:minutes:seconds	3:19:11

XSL•FO

Figure 1. Chat duration distribution.

Pre-Post Analysis

Matched Cohort Analysis

To evaluate the utilization impact of DPS on the EAP's 5-session model, semimatched cohorts were created for the periods before (June 2022 to May 2023) and after DPS implementation (June 2023 to May 2024). Because of the anonymous nature of the DPS service, only participants who voluntarily provided their age and gender were included in the matching process for analysis in the EAP's pre- and post-DPS cohorts. The matching variables comprised age, gender, and presenting emotional concerns.

Sample

Data on presenting emotional concerns were readily available based on participants' responses to the question, "What's your struggle?"—the sole query asked before matching them with the DPS service. A total of 45 unique users provided both their age and gender information voluntarily. These users ranged in age from 18 to 51 years, with a mean age of 34.97 (SD 9.71) years. Gender distribution was as follows: 18 (40%) males, 26 (58%) females, and 1 (2%) nonbinary individual.

The availability of participant age, gender, and emotional concern data from the DPS service enabled the creation of a matched pre-DPS EAP cohort. The frequency of emotional concerns in the peer support program sample is presented in Table 4.

Table 4. Emotional concern frequency in the digital peer support sample (n=45).

Emotional concern type	Value, *n* (%)
Adjustment	1 (2)
Depression	18 (40)
Anxiety	8 (18)
Posttraumatic stress disorder	2 (4)
Relational concern	14 (31)
Substance use	2 (4)

Statistical Analysis

Using age and gender data from the DPS service participant pool, a total sample of 72 EAP participants—36 pre-DPS and 36 post-DPS—was analyzed for differences. The ages of EAP participants ranged from 18 to 51 years, with a mean age of 33.86 (SD 8.18) years. Females comprised the majority of participants (n=68, 94%), while males accounted for a smaller proportion (n=4, 6%) in both the pre- and post-DPS cohorts.

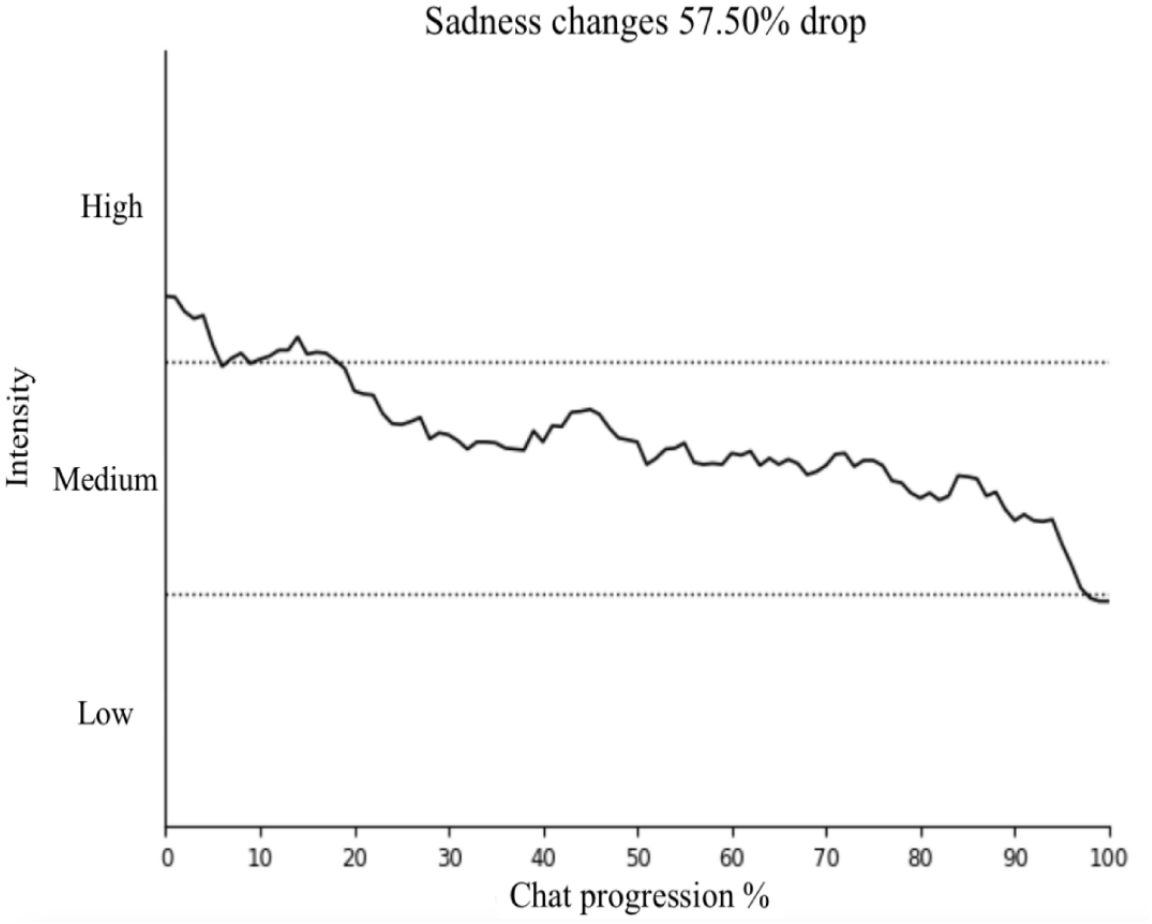
To assess the impact of the DPS addition, a paired samples *t* test (2-tailed) was performed, comparing the number of therapy

XSL•FO
RenderX

sessions utilized by participants pre- and post-DPS within the matched cohort. The analysis revealed a mean difference of –2.07 (SD 1.77) sessions (t_{71}=9.92; P<.001), indicating a significant reduction in the number of therapy sessions used after the intervention. These findings suggest that the intervention may have been associated with a decrease in therapy session utilization among the sampled participants.

Effect Size

In addition to the *t* test, Cohen *d* was calculated to determine the effect size of the intervention. Based on Cohen guidelines, effect sizes are classified as small (0.2), medium (0.5), and large (0.8). The effect size in this study was 1.77, which is considered large. This suggests that the DPS service had a substantial impact on reducing the number of therapy sessions utilized by participants.



The CI for the mean difference in therapy session utilization was calculated to be between –1.47 and –0.87 at the 95% CI level. This range further supports the reliability of the observed reduction in session utilization, providing evidence that the DPS service may have effectively decreased the number of therapy sessions used by participants in the small sample group.

- Study hypothesis 2: Participants who utilize the DPS service will experience significant changes in sentiment (eg, reduced sadness, loneliness, and stress) throughout their engagement with the service.

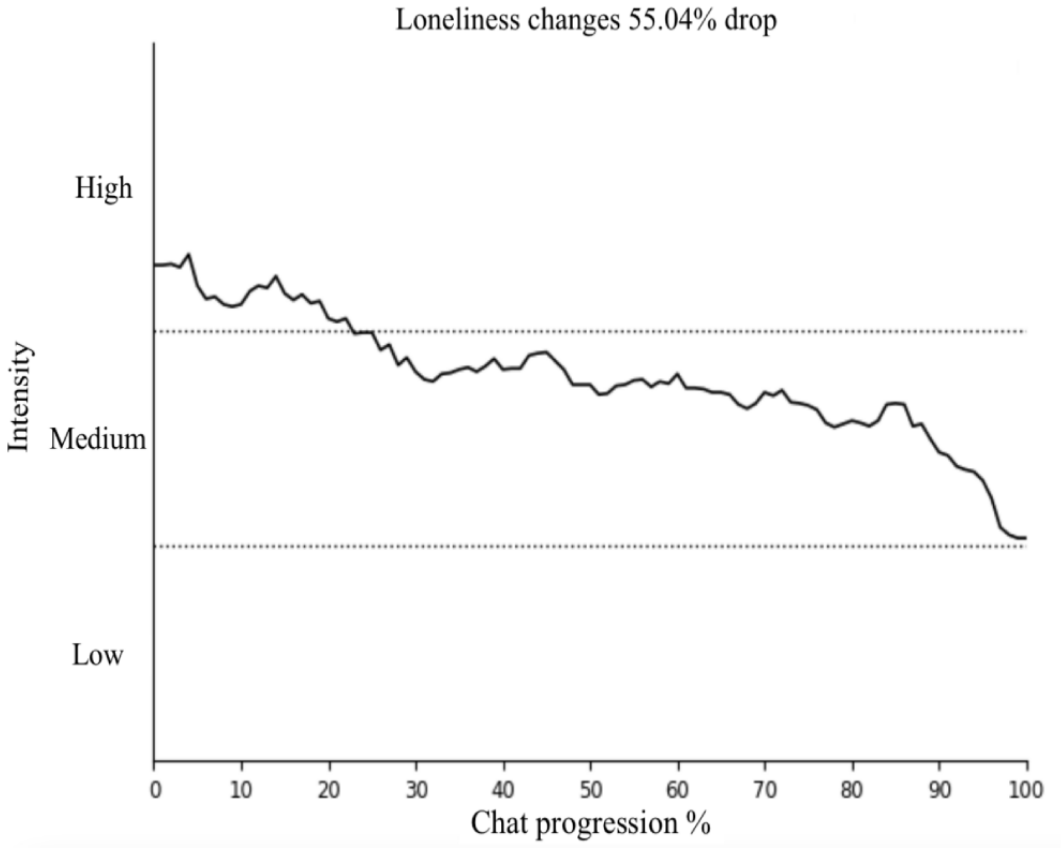
Sentiment Change

From the DPS service's sampled cohort (n=45), sentiment changes for sadness, loneliness, and stress were investigated for each user chat. The results are presented in Figures 2-4, showing the changes in sentiment for these 3 emotions. All 3 emotions demonstrated statistically significant reductions (sadness, loneliness, and stress: P<.001) in sentiment intensity during the chat sessions. The sentiment intensity levels are categorized as follows: 1-4 as "low," 4-7 as "moderate," and 7-10 as "high."

Figure 2. Significant (P<.001) changes in sadness sentiment during chats.

XSL•FO
RenderX

Figure 3. Significant (*P*<.001) changes in loneliness sentiment during chats.



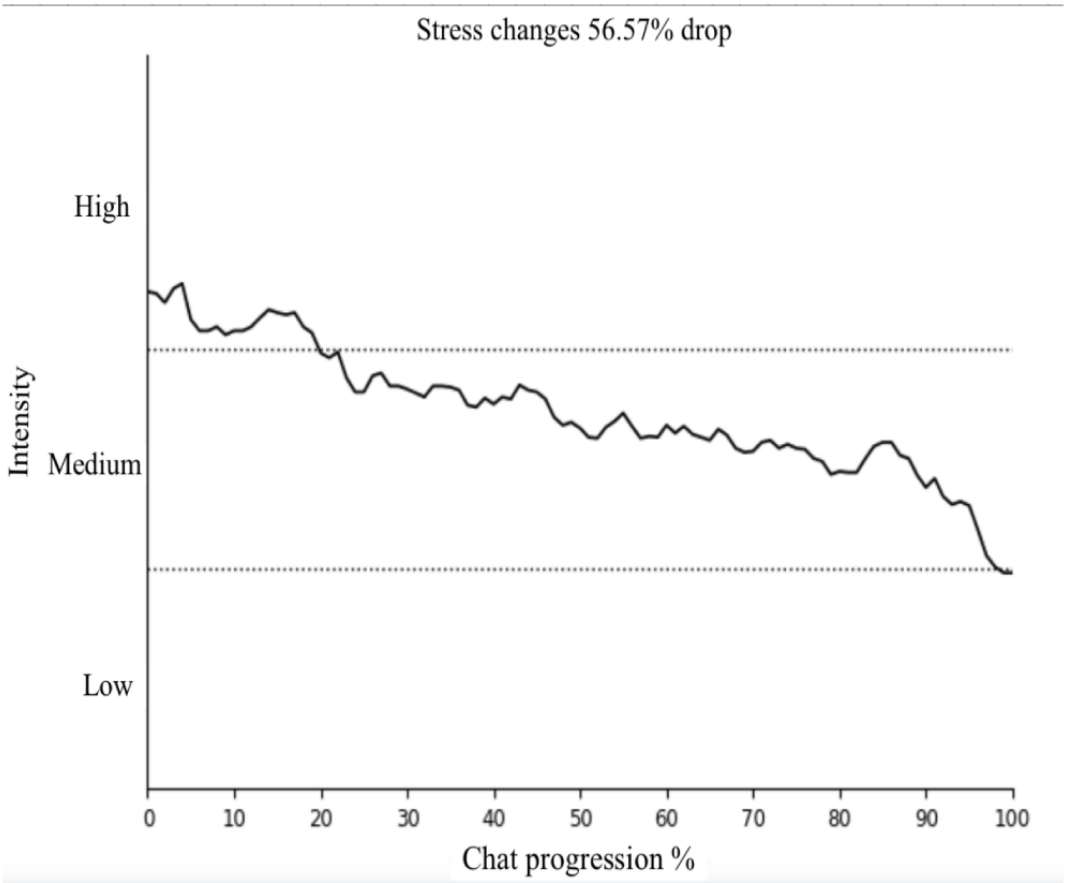


Figure 4. Significant (*P*<.001) changes in stress sentiment during chats.

Social Return on Investment Analysis

SROI assigns financial proxies to quantify the value of each identified sentiment change, enabling the attribution of a market price when no direct market value exists [41]. The proxies were carefully selected based on their relevance and supported by cited research studies to ensure the credibility of the assigned market prices. Table 5 presents the financial proxies used for each sentiment.

- Study hypothesis 3: The integration of DPS into the EAP will generate a positive SROI, reflecting the added value of peer support services for EAP clientele.

Table 5. Financial proxies for each sentiment.

Factors in which digital peer support users experience a reduction	Financial proxy	Cost
Sadness	Average unit cost of treating someone with depression (National Institutes of Health)	• PPPY[a]: US $10,074 (SD $25,694) • PPPM[b,c]: US $839.50
Loneliness and isolation	Average unit cost of treating someone with objective isolation and loneliness (National Institutes of Health)	• PPPY: US $1643 in Medicare spending (objective isolation) • PPPM: US $136.92
Stress (eg, generalized anxiety)	Average unit cost of treating someone with stress	• PPPY: US $6475 • PPPM: US $539.58

[a]PPPY: per person per year.

[b]PPPM: per person per month.

[c]PPPM calculations were made by dividing the PPPY value by 12 months.

SROI Analysis

The primary objective of this SROI analysis is to calculate and present a ratio that compares the cost of investment (US $) in an intervention with the total social, environmental, and economic value (US $) it generates. To prevent overestimation, the SROI methodology recommends certain considerations (see Table 6) [41].

The SROI analysis demonstrated that the DPS program generates positive social value, complementing overall treatment. The SROI values ranged from US $1.66 (loneliness) to US $2.50 (stress) to US $2.58 (sadness) for every dollar invested. Detailed calculations for the impact ratio are available in Multimedia Appendix 1.

Table 6. Factors considered for calculating the social return on investment impact ratio.

Factor	Description
Deadweight	A measure to describe the amount of an outcome that would have happened anyway, even if the DPS[a] service had not been offered. For example, the participants experiencing reductions in momentary loneliness may have a deadweight value of 10% from simply joining the DPS chat, but without further intervention from the peer support moderator or other peers.
Displacement	An assessment of what activities or services are displaced by the presence of the digital peer group. There was no evidence of displacement as, before the digital support option was added, there were no after-hours DPS chat services for employee assistance program members to access.
Attribution	A measure to consider how much of an identified theme is a result of the group studied or is influenced by external factors, for example, if participants also attend another service, such as counseling, which reduces their sense of chronic sadness, a conservative estimate of 20% of the identified momentary sentiment change may be attributed to the group studied.
Dropoff	The percentage of the outcome that decreases after the intervention is complete. For example, a conservative percentage of 10% re-emergence of stress may be expected after the user ends their DPS chat due to a return to their stressful environment.

[a]DPS: digital peer support.

Discussion

Principal Findings

The study examined the impact of integrating a DPS service within an EAP on utilization rates, sentiment change, and therapy session use over 1 year. Additionally, it assessed the social, environmental, and economic impact of the DPS service by estimating an SROI value. Results indicated that DPS service utilization primarily occurred after hours. In the matched sample, participants used fewer therapy sessions post-DPS integration. The SROI ranged from US $1.66 to US $2.50 to US $2.58 for every dollar invested for loneliness, stress, and sadness sentiments, respectively. These findings suggest that combining DPS with traditional EAP services may provide noncrisis

XSL•FO
RenderX

emotional support after hours, potentially reducing EAP therapy session use for lower-acuity emotional concerns. This, in turn, could allow EAPs to allocate funds toward additional ancillary support services and enable employers to benefit from a positive SROI.

The study's findings—that participants experience significant improvements in sentiment, such as reduced sadness, loneliness, and stress—align with existing literature on patient activation [7,8]. Research indicates that when individuals are activated—meaning they gain confidence and skills in managing their health—they tend to experience improvements in emotional well-being [8]. By providing peer support that fosters autonomy and self-efficacy, participants can develop coping strategies that reduce distress and promote mental health [43]. This aligns with findings that patient activation leads to better emotional outcomes through the development of personal coping mechanisms and self-management [8]. The positive SROI from integrating DPS into EAP services is also consistent with the literature on patient activation. Activated patients, who feel more in control of their health, contribute to more efficient resource utilization and improved outcomes [44]. The integration of peer support services such as DPS has been shown to enhance engagement with formal mental health services, creating value not only for individuals but also for the broader service system [44]. This supports the idea that empowering individuals through peer support can yield both personal and systemic benefits, ultimately leading to a positive SROI.

The study may also contribute to the quality of life literature, which is commonly used in cost-effectiveness studies. Health-related quality of life (HRQoL) refers to a person's physical, emotional, and social well-being as influenced by a health intervention [45]. While this study did not include standardized HRQoL assessments (eg, 36-item Short Form [SF-36] or EQ-5D) due to real-world data collection constraints and the anonymous nature of the DPS service, sentiment changes and therapy utilization could serve as HRQoL proxies [46]. Significant reductions in sadness, loneliness, and stress during DPS chats suggest improvements in emotional well-being, a core component of HRQoL. The reduction in momentary negative sentiments may indicate that participants used DPS as a coping mechanism for emotional stability. Additionally, the suggested decrease in therapy sessions implies that participants may have achieved better emotional regulation or relief through DPS, ultimately impacting their overall quality of life. Relatedly, the high utilization of DPS after hours addresses a gap in traditional mental health services and may contribute to participants' perceived control over their emotional health. Such improvements in HRQoL proxies could translate into better job performance [47] and employee satisfaction [48], while also serving as a valuable complement to therapy. This approach allows mental health providers to focus on higher-acuity cases while DPS services address lower-acuity concerns—key objectives for most EAP organizations [48]. Finally, the calculated SROI highlights tangible benefits for emotional health (eg, sadness, loneliness, stress), further demonstrating the intervention's effectiveness in enhancing HRQoL's socioemotional components.

The study's findings further align with existing literature in several key areas. The use of AI for matching participants with peers who have shared lived experiences, as well as for sentiment analysis, supports growing evidence that AI can enhance the personalization and efficiency of life struggle and nonmental health services [49-52] This study offers several novel contributions to the literature on mental health interventions and EAPs. It is among the first to demonstrate that integrating a DPS service with EAPs may enhance after-hours support, reduce the utilization of EAP therapy sessions—allowing EAPs to allocate resources more effectively for higher-acuity emotional concerns—and provide supplementary SROI. DPS services are unique within the EAP environment and may be particularly valuable for EAP participants who are not yet ready to confront the stigma or commitment often associated with therapy [53] but still benefit from peer support. By leveraging AI-driven natural language processing to match users based on their struggles and conducting sentiment analysis on chat narratives, this study highlights an innovative use of technology to enhance support for stress and life challenges. Conducted in a naturalistic setting with a diverse sample, the study's design strengthens ecological validity, demonstrating the practical feasibility and effectiveness of DPS in real-world organizational environments.

Study Limitations

This study faced several potential threats to both internal and external validity and implemented strategies to mitigate these issues. One threat to internal validity was the influence of external events (history) during the study period (June 2023 to May 2024) [54,55]. To address this, a comparison group from the previous year (June 2022 to May 2023) was used, and quarterly data monitoring helped identify and adjust for significant external changes [55]. Matched samples based on additional demographics were not possible due to the anonymity of DPS users. Future research using alternative study designs with nonanonymized data may be necessary.

Maturation effects, referring to the natural changes in participants' mental health over time, were addressed using a cohort design with propensity score matching. This approach ensured that participants in both the intervention and control groups were similar in age, gender, and presenting concerns [56]. By balancing the groups, it minimized the impact of maturation on the results [56]. Additionally, selection bias was mitigated through propensity score matching, which created comparable groups by matching participants in the pre-DPS and post-DPS periods based on key demographics and presenting concerns [57].

Experimental mortality, or dropout, was another concern. To address this, the study included multiple participants matched on the same variables, ensuring that the analysis could proceed even if some participants dropped out [57]. A diverse sample across age and gender was included to reduce the impact of selection biases on generalizability. Additionally, conducting the study in a naturalistic setting, where participants used the DPS and EAP services as they would in real life, helped minimize the reactive effects of experimental arrangements, enhancing ecological validity [55]. Furthermore, the availability

XSL•FO
RenderX

and normalization of the EAP program may have influenced participant engagement. EAP programs are voluntary for companies in the United States, Australia, Canada, and England, whereas Nordic countries have legal mandates requiring mandatory EAPs [58]. This distinction is relevant from the perspective of patient activation. Voluntary EAPs may require high awareness and active promotion to engage participants and may primarily attract individuals with higher activation or those who are more self-directed. As a result, individuals with lower activation or those in the early stages of their mental health concerns may remain underserved [58]. Additionally, factors such as program promotion and mental health stigma could contribute to uneven access across the workforce. By contrast, mandatory EAPs may help normalize access to mental health support, encourage early and preventive engagement, and promote continuity of care by integrating with public health systems, unlike the segmentation often seen with voluntary EAPs [59]. Limitations of the SROI process include the complexity of assigning financial proxies to sentiment change and the availability of data required for robust calculations, such as displacement and attribution values. A key risk in SROI analysis is an overemphasis on the ratio itself, without considering the underlying content, which provides deeper insight into the value created by different groups [58]. By acknowledging and addressing these challenges through design and analysis strategies, the study generated meaningful insights into the impact of integrating DPS services within an EAP.

Future Research

The study opens several avenues for future research. Long-term impact assessments are needed to evaluate how integrating DPS with EAP services influences therapy utilization and outcomes over extended periods. A broader demographic analysis could provide insights into how factors such as age, socioeconomic status, and cultural background affect engagement with these services. Additionally, incorporating qualitative insights may help illuminate user experiences and satisfaction, offering a deeper understanding of which aspects of the service are most effective or subjectively valued by clients.

Future research could also compare DPS with other digital mental health interventions to identify which models offer the greatest benefits in different contexts. Investigating how DPS integrates with other mental health services, such as primary care or community programs, could provide a more comprehensive understanding of its role within the broader health care system. While comparisons of single- versus multilayered support ecosystems fall beyond the scope of this study, they represent a valuable avenue for future exploration (eg, digital mental health vs in-person services or EAP vs DPS). Additionally, examining DPS's impact on different mental health conditions and conducting a detailed economic analysis of cost savings could further strengthen the case for its adoption. Moreover, this study did not calculate quality-adjusted life years; however, the observed improvements and associated cost reductions provide strong support for the intervention's economic value. Future research could explore additional methods to further quantify these benefits. These efforts would deepen our understanding of DPS' effectiveness and its potential applications across diverse settings.

Conclusions

This study demonstrates that integrating DPS services within an EAP may influence therapy utilization, allowing EAPs to serve higher-acuity clients while lower-acuity clients access supplementary support, such as DPS, for everyday emotional needs. Additionally, the research highlights the potential social, environmental, and broader economic benefits of incorporating DPS services into the emotional support ecosystem, with positive estimated SROI outcomes. By leveraging AI-driven natural language processing for user matching and sentiment analysis, the study underscores the potential of technology to enhance stress management, address life challenges, support mental health, and optimize resource allocation. The findings emphasize the need for further research into DPS effectiveness, particularly regarding long-term impacts, demographic variations, and comparative effectiveness with other interventions. Overall, this study provides valuable insights into the evolving landscape of digital mental health services, reinforcing their role in enhancing organizational wellness programs and identifying key areas for future exploration to maximize their potential.

Abstract

Background: The social media platform YouTube is a recognized educational resource for health information, but few studies have explored its value for conveying the lived experience of individuals managing chronic health conditions and end users' interactions with medical device technology. Our study explores self-care strategies and end user needs of people living with a stoma because patient education and engagement in ostomy self-care are essential for avoiding ostomy-related complications. Ostomy surgery creates a stoma (an opening) in the abdomen to alter the route of excreta from digestive and urinary organs into a detachable external pouching system. After hospital discharge, people who have undergone ostomies perform critical self-care tasks including frequent ostomy appliance changes and stomal and peristomal skin maintenance.

Objective: The purpose of this study was to systematically assess YouTube videos narrated by people who have undergone ostomies about their ostomy self-care in home (nonhospital) settings with a focus on identifying end user needs and different strategies used by people who have undergone ostomies during critical self-care tasks.

Methods: Using predefined search terms and clear inclusion and exclusion criteria, we identified YouTube videos depicting narrators who have undergone ostomies and their ostomy self-care in home settings. Using a consensus coding approach among 3 independent reviewers, all videos were analyzed to collect metadata, data of narrators who have undergone ostomies, and specific content data.

Results: There were 65 user-generated YouTube videos that met the inclusion and exclusion criteria. These videos were posted by 28 unique content creators representing a broad range of ages who used a variety of supplies. The common challenges discussed were peristomal skin complications, inadequate appliance adhesion and subsequent leakage, and supplies-related challenges. Narrators who have undergone ostomies discussed various expert tricks and tips to successfully combat these challenges.

Conclusions: This study used a novel approach to gain insights about end user interactions with medical devices while performing ostomy self-care, which are difficult to gain using traditional behavioral techniques. The analysis revealed that people who have undergone ostomies are willing to share their personal experience with ostomy self-care on the web and that these videos are viewed by the public. User-generated videos demonstrated a variety of supplies used, end user needs, and different strategies for performing ostomy self-care. Future research should examine how these findings connect to YouTube ostomy self-care content generated by health care professionals and organizations and to guidelines for ostomy self-care.

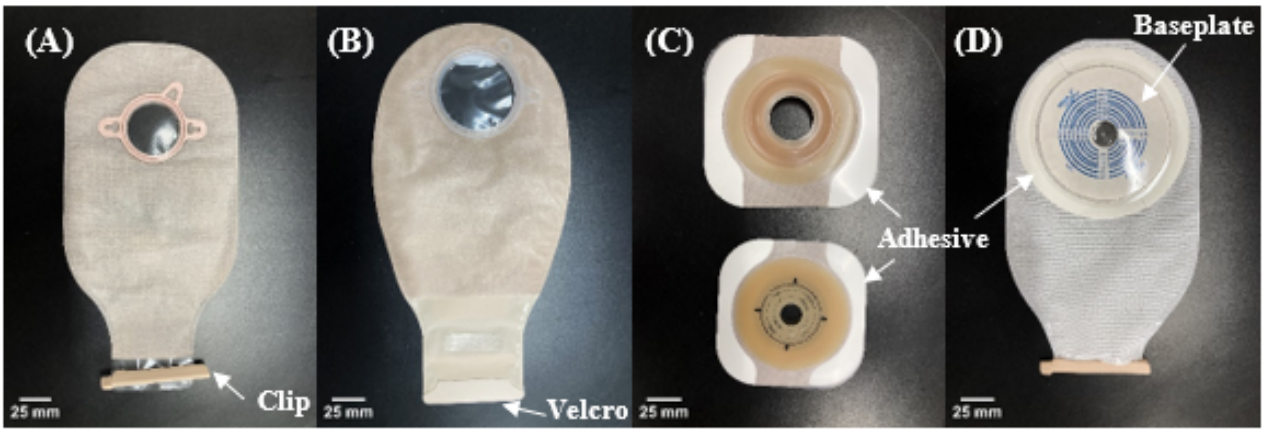
Introduction

YouTube as Health Information Resource

Individuals are increasingly seeking health-related information on the web, and in some cases, patients rely on the internet as much or more than their physicians [1,2]. Patients have also reported using web-based resources to make health-related decisions and to manage chronic conditions [2,3].

YouTube, the largest on the web video-sharing platform worldwide for streaming a variety of user-generated content with 2.5 billion users worldwide [4] is a recognized educational resource for sharing and disseminating health-related information and influencing individuals' viewpoints related to health care topics such as disease prevention, treatment therapy, or immunizations [2,3]. Several studies highlight the informational flaws and biases in a wide variety of YouTube health information videos related to clinical decision-making, diagnosing, treatment recommendation, and health promotion. The analysis in these studies generally focuses on the health information provided rather than the individual user experience with the health issue [2,5-9].

Studies involving so-called "e-patients" who are motivated to share health-related personal experiences on the web reveal that sharing their lived experience and knowledge of their disease can empower and engage others while also providing (and gaining) social support [10,11]. While many health-related government organizations such as the World Health Organization, the National Institute of Health, the Center for Disease Control and Prevention, and the American Red Cross use YouTube to disseminate health information [1], user-generated videos are also used as an educational resource. This suggests that user-generated content decreases the gap between health information delivered by health care professionals and the lived experience of dealing with a disease.



Medical Device Usability in the Home Setting

Usability studies examining the interaction between medical device technology and end users are essential for developing medical devices that are safe and effective [12]. These studies allow for actively including end users in the design process while considering end user competencies and environment, thus, continuously improving medical device design to fit user needs [13]. Capturing the real world, end user experience of people with chronic conditions and their interaction with complex medical device technology in home (nonhospital) settings is challenging [12], such as having a stoma and routinely using an ostomy appliance, and to our knowledge, these studies are limited [14].

Ostomy Surgery

There are about one million people living with ostomy in the United States and more than 150,000 Americans undergo ostomy surgery each year [15,16]. Ostomy surgery alters the route of excreta from internal digestive and urinary organs through a stoma in the abdomen and into a detachable external pouching system (Figure 1) that fits snugly around the stoma [16]. People who have undergone ostomies perform critical self-care tasks that include frequent changing of the pouching system (3-10 changes per week) and maintaining healthy stoma and peristomal skin [17]. Therefore, there is a need to understand the usability of medical device technology used by people who have undergone ostomies in ostomy appliance change procedures and self-care.

Figure 1. An ostomy appliance consists of an external pouching system that is attached to the abdomen of people who have undergone an ostomy using adhesive. There are various design features, including a (A) 2-piece pouch with clip closure, (B) 2-piece pouch with Velcro closure, (C) precut (top) and moldable (bottom) baseplate that is subsequently attached to the 2-piece pouch [in (A) or (B)] at the ring, and (D) 1-piece appliance with clip closure (pouch and baseplate being 1 part).

XSL•FO
RenderX

Ostomy Care Patient Education and Self-Management

It is widely recognized that patient education and engagement in ostomy self-care are essential for avoiding ostomy-related complications [18-20]. However, the education of new people who have undergone ostomies to gain the knowledge and skills needed for managing chronic conditions and performing self-care tasks is not well defined [18]. Ideally, according to the Wound, Ostomy, and Continence Nurses Society Clinical Guidelines and recommendations [21], new people who have undergone ostomies should obtain education from ostomy nurse specialists. Nevertheless, there is evidence of insufficient pre- and postoperative education provided to new people who have undergone ostomies related to stoma and peristomal skin care and complications [22-25]. Due to the short hospitalization trends and the limited availability of ostomy nurse specialists, there is limited teaching time and formal follow-up with the specialists [22-25]. Further, new people who have undergone ostomies may not be mentally and physically prepared for self-management of their ostomy, which requires gaining new knowledge, skills, and attitudes [26,27]. Most people who have undergone ostomies experience some long-term challenges concerning the management of daily self-care of their stoma that broadly impact their health-related quality of life and outcomes [28,29]. Peristomal skin complications are a common problem following ostomy surgery affecting over one-third of patients with ostomies within 90 days post surgery and up to 80% within 2 years [30-33]. While it is known that skin problems interfere with pouch adhesion, causing challenges with pouch leakage, and thus odor, and the necessity for frequent and unscheduled appliance changes [29], it is very difficult to study real-world responses to such challenges.

Study Objective

Given the complexity of ostomy appliance change procedure medical technology and self-care, there is a need to assess the usability of this technology and how self-management skills are developed by people who have undergone ostomies over time. We completed a systematic analysis of user-generated videos related to ostomy self-care published on YouTube and created by individuals with expertise in managing chronic conditions about ostomy self-care in home (eg, nonhospital) settings. Our objective was to identify end user experiences with ostomy medical device technology and the different strategies and procedures used by these experts to change their ostomy appliance and perform stomal and peristomal skin care.

Methods

Ethical Considerations

This study was excluded from an institutional ethics board review because it assessed only copyrighted, public source information and no individual user data was included in the manuscript.

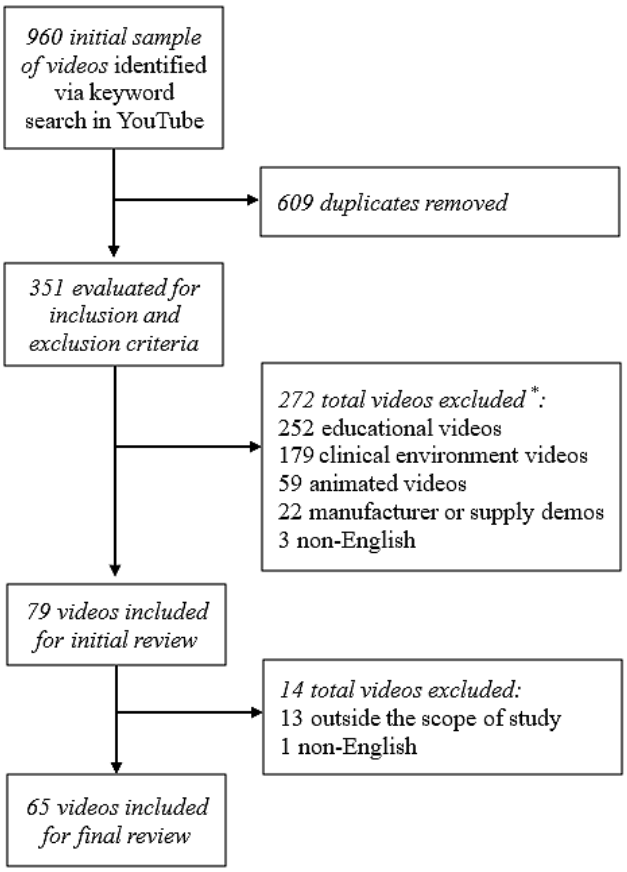
Search Terms and Search Strategy

Search terms related to ostomy self-care were defined by the research team (Table 1) for identifying videos using the search tools within YouTube. During December 2023, YouTube was searched for relevant videos using search terms and Boolean operators under the search category “videos only” tab or “video” filter. All searches were conducted using an incognito or private browser that did not retain cookies to prevent suggested related videos from appearing on search results and to ensure that the search for each term could be replicated. The first 20 videos for each search term were reviewed and documented in a spreadsheet. No videos were included in the analysis if they appeared in the YouTube search result under the “people also watched,” “shorts,” or “sponsored websites” section as these videos may or may not have met the search term criteria. The initial search resulted in 960 videos.

Table 1. Search terms used to search for relevant user-generated videos published on YouTube.

Search term category	Search terms
Ostomy pouch change procedure	[a] + (pouch OR bag) + (care OR change OR procedure)
Ostomy tips and tricks	[a] + (pouch OR bag) + (pros and cons OR tips OR tips and tricks OR empty OR cleaning OR care OR leakage OR leakage prevention)
Ostomy self-care and home management	[a] + (pouch change OR bag change) + (home OR self-care OR care)
Ostomy skincare	[a] + (skin OR peristomal skin) + (care OR treatment OR irritation OR dermatitis)

[a]Is ostomy OR urostomy OR colostomy OR ileostomy OR stoma OR colorectal cancer OR Crohn disease OR inflammatory bowel disease OR IBD OR diverticulitis OR bladder cancer OR cystectomy.



Inclusion and Exclusion Criteria

Overview

From the initial set of 960 videos, a final set of 65 videos (Figure 2) was identified for review after the removal of duplicates and the application of inclusion and exclusion criteria (Textbox 1). Duplicate videos (n=609) were identified and removed by channel grouping and comparing URLs and video titles. The inclusion and exclusion criteria were applied to eliminate educational videos (n=252), videos recorded in a clinical environment (n=179), animated videos (n=59), supply or manufacturer demonstration videos (n=22), videos in languages other than English (n=4) and those videos that were outside the scope of this study (n=13) such as broad discussions of clinical issues or ostomy support. Educational videos were defined as videos not discussing personal experiences related to ostomy self-care, for example, videos providing information related to ostomy belts.

Figure 2. Video search inclusion and exclusion process. *Some videos were excluded for multiple criteria.

Textbox 1. Specific inclusion and exclusion criteria.

Included videos

- Were found using search terms
- Included a user narrative
- Involved any channel, age, gender, race, ethnicity, year, or length
- Depicted ostomy appliance change procedures in a nonhospital setting
- Discussed ostomy self-care, tips, tricks, or challenges
- Involved a person living with a stoma as a narrator
- Were published in the English language

Excluded videos

- Were recorded in a clinical environment or were narrated by a medical professional (not having a stoma)
- Included experiences of users who have not undergone ostomies
- Were educational videos
- Were supply or manufacturer demonstration videos
- Were animated
- Duplicated videos from other search terms
- Were published in the non-English language
- Categorized as video “shorts”
- Were outside the scope of this study

Data Coding

In total, 3 categories of video-specific variables were recorded, including video metadata, narrator data, and specific content data (Table 2). The researchers used consensus coding of the included videos, which is a well-accepted method to enhance credibility and reliability in qualitative research [34]. Before video reviews, 3 general categories and 15 variables were named and defined (Table 2). Each video was then coded individually by 2 reviewers using the defined categories and any discrepancies between reviewers were discussed. If consensus was not reached, a third reviewer reviewed the video and data coding to address bias and reach consensus and to ensure accuracy in data coding. The category definitions were then revised as needed before a final consensus coding of all the included videos by 2 reviewers.

Table 2. Data coding for 3 categories of videos including specific variables, and their definition and type.

Category and variable	Definition
Video metadata	
Title	The title of the video by the content creator
URL	The web address of the video
Channel	The name of the page where videos are posted for viewing
Posted year	The year that video was publicly posted to the YouTube platform
Video length	The time duration of the video
View counts	The number of times the video was viewed as of January 4, 2024
Public ratings	The number of likes or dislikes as of January 4, 2024
Data of narrators who have undergone ostomies	
Presenting assumed gender	The assumed gender of the content creator based on gender markers such as physical build, voice, clothes, and hair
Presenting assumed age group	The assumed age group of the content creator mainly based on physical appearance and hair coloration
Specific video content data	
Supplies used	Any item, product, equipment, or accessory used or discussed as used by a narrator who has undergone an ostomy during the ostomy appliance change procedure
Appliance change frequency[a]	How frequently the narrator who has undergone an ostomy completed an appliance change process
Type of ostomy[a,b]	The type of ostomy disclosed by the narrator who has undergone an ostomy
Underlying condition for ostomy[a,b]	The medical condition experienced by the narrator who has undergone an ostomy and contributing to the ostomy surgery
Common challenges[a]	Description of the problems related to ostomy, ostomy appliance change procedures, and ostomy self-care
Expert tips and tricks	Advice or recommendation given by a narrator who has undergone an ostomy to the audience to address common challenges, aid in expediting or easing the appliance change process, or provide additional information to improve the overall user experience

[a]Variable was not communicated in every video.

[b]If not communicated in the video, the intro page and the about me page for the creator were reviewed.

Results

Video Metadata

After removing duplicate videos and applying the inclusion and exclusion criteria, there were 65 videos that explored different topics related to ostomy, ostomy appliance change procedures, and the self-care of people who have undergone ostomies. Included videos were posted between 2011 and 2023 and averaged about 9.5 minutes in length, over a quarter-million views, and more than 3000 likes (Table 3).

Table 3. The video metadata descriptive statistics for the videos included in the analysis.

Video metadata	Data
Posted year, n/N (%)	Between 2011 and 2023 (11/65, 17% and 12/65, 18% videos in 2020 and 2023, respectively)
Video length, mean (SD; range)	9:36 min (SD 6:30 s; 1:00-31:40 min)
View counts, mean (SD; range)	269,076 (SD 922,352; 1900-5,493,702) views
Public ratings, mean (SD; range)	3015 (SD 8761; 0-58,000) likes

Data of Narrators Who Have Undergone Ostomies

There were 28 unique content creators with several individual creators posting multiple videos. Further, 2 high volume narrators who have undergone ostomies uploaded almost half (31/65) of all the videos (24 and 7 videos from the 2 most frequent content creators). Most videos included a female narrator and a narrator in the 20-30 years age range followed by a middle-aged narrator, an older narrator, and a teenage narrator (Table 4). None of the narrators who have undergone ostomies communicated their gender or age in the videos. Therefore, the presenting assumed gender was determined by the reviewers based on the gender markers such as physical build, voice, clothes, and hair and the presenting assumed age based on the physical appearance and hair coloration.

Table 4. Data of narrators who have undergone ostomies for videos included in the final review.

Unique narrators who have undergone ostomies (n=28)	Data, n/N (%)
Presenting assumed gender	
Female	20/28 (71% narrators who have undergone ostomies)
Male	8/28 (29% narrators who have undergone ostomies)
Presenting assumed age group	
Infant[a]	1/65 (2% videos)
Teenager	4/65 (6% videos)
Aged 20-30 years	42/65 (65% videos)
Middle age	13/65 (20% videos)
Older	5/65 (8% videos)

[a]One video was presented about an infant with an ostomy that was narrated by the parent caregiver.

Specific Video Content Data

Ostomy Video Content

From the final set of 65 videos, 26/65 (40%) videos discussed ostomy self-care tips and tricks that focused most frequently on maintaining peristomal skin health, preventing leaks, pancaking, supply use, and general tips; 21/65 (32%) videos captured a full ostomy appliance change procedure and 14/65 (22%) videos included part of an ostomy appliance change procedure such as emptying, specific supply use, and skin preparation and appliance application, among others; and 4/65 (6%) videos were about the personal experience of a person living with a stoma (Table 5).

Supplies Used

The narrators who have undergone ostomies did not all use identical supplies and there was a variety of types, numbers, and frequencies of supplies used during the ostomy appliance change procedures (Table 6). Among the 35 videos that captured a full or partial ostomy appliance change procedure, 25/35 (71%) included a 2-piece pouching system, and 9/35 (26%) included a 1-piece pouching system (Table 6). In 1/35 (3%) videos, the type of ostomy appliance could not be determined. Furthermore, the baseplate was cut to fit or precut by the supplier in 25/35 (71%) videos and molded by hand in 3/35 (9%) videos. In 7/35 (20%) videos, the method for sizing the baseplate by cutting or molding could not be determined.

Further, supplies used to clean the peristomal skin and remove any remaining adhesive or output included paper towel or toilet paper in 19/35 (54%) videos, adhesive remover wipes in 17/35 (49%) videos, adhesive remover spray in 14/35 (40%) videos, dry wipes in 11/35 (31%) videos, towel or washcloth in 9/35 (26%) videos, water in 7/35 (20%) videos, and wet wipes in 4/35 (11%) videos. Supplies used to protect the skin included a barrier ring in 17/35 (49%) videos, skin barrier in the form of wipe, spray, or cream in 15/35 (43%) videos, and ostomy paste in 6/35 (17%) videos. Supplies used to treat peristomal skin disorders included stoma powder in 12/35 (34%) videos and skin treatments (eg, corticosteroids, and antifungal or other anti-inflammatory medications) in 8/35 (23%) videos. Supplies used to aid adhesion between the pouch and peristomal skin included extenders in 5/35 (14%) videos and belts in 4/35 (11%) videos. Supplies used to prevent or minimize odor issues were odor eliminators in 9/35 (26%) videos and lubricating deodorant in 5/35 (14%) videos. Other general ostomy supplies that were used included plastic bags in 19/35 (54%) to discard the ostomy appliance before disposal, scissors in 16/35 (46%) videos to cut a baseplate to match the size of the stoma, some kind of bag in 4/35 (11%) videos to carry ostomy supplies, and some type of container in 4/35 (11%) videos to rinse the pouch with water.

Underlying Condition and Type of Ostomy

One-third of the narrators who have undergone ostomies (9/28, 32%) did not disclose their underlying condition. Crohn disease was the most frequently reported underlying condition for 10/28 (36%) narrators who have undergone ostomies followed by ulcerative colitis (3/28, 11%), cancer (3/28, 11%), and unspecified inflammatory bowel disease (1/28). Further, 2 (7%) narrators who have undergone ostomies reported other underlying conditions for their ostomy surgery. Per the type of ostomy, ileostomies accounted for 79% (22/28) and colostomies accounted for 14% (4/28). Furthermore, 2 narrators who have undergone ostomies did not report their type of ostomy and no urostomy videos met inclusion and exclusion criteria for final review.

Appliance Change Frequency

More than half of narrators who have undergone ostomies (16/28, 57%) did not discuss appliance change frequency. For the remaining narrators who have undergone ostomies (12/28, 43%), there was considerable variability in ostomy appliance change frequency. In general, a majority of narrators who have undergone ostomies (n=10) reported changing their appliance within a 2-5-day interval, 2 every 7 and 15 days, and 1 when the pouch is full. Further, 1 narrator reported various changing frequencies across 4 videos (2-3 days, 3-4 days, every 4 days, and 4-5 days). Additionally, 2 narrators who have undergone ostomies commented on changing the appliance more frequently when having peristomal skin issues (every day or every other day) and emptying the ostomy appliance 5 to 8 times a day.

Common Challenges

About one-third of the content creators noted specific issues with supplies or processes that required workarounds or techniques to be implemented. Major challenges included peristomal skin complications (21/65 videos, 32%), leaks around the adhesive area (20/65 videos, 31%), inadequate appliance adhesion (13/65 videos, 20%), and no control over stoma effluent discharge making it difficult to keep the stoma and peristomal skin clean while changing the ostomy appliance (13/65 videos, 20%). Within the videos, the narrators who have undergone ostomies reported peristomal skin complications related to skin irritation and redness due to the output leakage, peristomal skin disorders such as granulomas, or allergic reactions toward specific ostomy supplies and these complications subsequently compromised appliance adhesion, caused pain, and led to further leaks.

Narrators who have undergone ostomies also expressed difficulties related to supplies in 17/65 (26%) videos. For example, supplies leaving residues on the skin compromising appliance adhesion, supplies containing alcohol causing a burning sensation on the wounded skin, variability in supplies' names causing confusion, and supplies not delivered on time or not working properly for a given individual. Challenges with the design of the ostomy appliance were noted, including the clip of the pouch being uncomfortable, difficulty with cleaning the end of the pouch after emptying, moisture absorption by the barrier ring leading to inadequate adhesion, or a 2-piece appliance being more difficult to apply. Finally, pouch pancaking with the output being trapped at the top of the pouch, pouch ballooning due to the gas accumulating in the ostomy appliance, cutting the baseplate to fit the stoma size, emptying an ostomy appliance and its cleaning, lifestyle adjustments (clothing, diet, relationships, intimacy, travelling, etc), and odor were additional challenges discussed in the videos.

Expert Tips and Tricks

The narrators who have undergone ostomies identified various strategies to address the challenges encountered. To overcome peristomal skin complications, narrators who have undergone ostomies (1) emphasized the importance of cleaning peristomal skin (eg, shower without an appliance and using adhesive remover to remove any output residue which could further irritate the skin); (2) avoided supplies containing alcohol to minimize burning sensations on the skin; (3) used a crusting technique which involves the application of stoma powder over sore skin followed by moistening the powder with skin barrier (wipe or spray), letting the powder dry, and repeating the process multiple times [16]; (4) used ostomy paste, or barrier ring to protect and allow healing of the wounded skin by creating a protective barrier between the wounded skin and appliance, or implemented more aggressive skin treatment products such as steroids or silver nitrate based on the consultation with ostomy care nurse specialists; and (5) recommended balance between changing an appliance too frequently or too rarely.

The tips of narrators who have undergone ostomies to avoid leakage included (1) properly fitting the appliance baseplate with the sizing of the opening for the stoma not to be too tight or too big; (2) using a barrier ring or ostomy paste to fill any abdominal gaps and divots; (3) using an ostomy belt, extenders, or medical tape to support the weight of the pouch; (4) trying different supplies (eg, convex pouches for retracted stomas) and different suppliers to identify supplies working properly for a given individual, while also emphasizing not using too many supplies; and (5) emptying an appliance regularly.

Narrators who have undergone ostomies believed that appliance adhesion was improved by (1) cleaning the skin properly using an adhesive remover followed by cleaning with water or some type of wipe to avoid leaving any residues that could compromise adhesion, (2) ensuring the peristomal skin is dry before applying an appliance, (3) wearing an ostomy belt, (4)

XSL•FO
RenderX

using an equalizer ring that applies an equal pressure around the stoma or ostomy paste that fills any divots or gaps between appliance and abdomen, (5) applying an appliance on a flat abdominal surface (eg, leaning backward or standing), (6) massaging the baseplate and running a finger around the stoma, and (7) using heat to stimulate baseplate adhesion to the abdomen (eg, hairdryer on low setting, heating pad, or holding hand over pouch). Narrators who have undergone ostomies also acknowledged there is not only one proper way of performing ostomy self-care and that what works for them may not work for someone else. Thus, they recommended trying different supplies and self-care strategies and consulting with ostomy nursing care specialists about supplies selection and their use for skin care.

Concerning managing a frequent and uncontrollable stoma output, some narrators who have undergone ostomies found it effective to eat marshmallows or to fast before changing an appliance to slow down the output, covering the stoma with some type of wipe, paper towel, or gauze while changing the appliance to protect the skin and make it easier to clean, and organizing or preparing all supplies and emptying the pouch before starting to change the appliance.

Narrators who have undergone ostomies conveyed strategies to prevent "pancaking" such as using a lubricant or some type of oil inside the pouch, emptying and rinsing the pouch with water, disabling an appliance filter, and blowing air into the pouch. Further, they used deodorants and "burped" (let the air out of the pouch) their appliance to prevent ballooning. They used an ostomy cover and deodorizing drops along with eating naturally deodorizing food such as kefir, yoghurt, or parsley to deal with the odor. To overcome the challenge of cutting a baseplate to the proper size, narrators who have undergone ostomies traced the stoma size with a marker on the template and saved the template with a marking for repeated use, or ordered the appliance precut from suppliers once their stoma size remained constant. Strategies used to adjust to the postostomy lifestyle included (1) finding and joining a support group, (2) talking to people who "get it," (3) learning about their stomas (eg, diversity of supplies, proper diet and hydration, or clothing tips), (4) exercising to reduce anxiety, and (5) developing an ability to perform ostomy self-care while also having someone else who can change their appliance.

Discussion

Principal Findings

This study uses a novel approach for gaining insight into ostomy care end user (person who has undergone an ostomy) experience and usability with medical device (ostomy appliance change) technology through the identification of strategies and supplies used, and common challenges and needs experienced by people who have undergone ostomies while changing the ostomy appliance and performing self-care. The needs, supply choices, and self-care strategies that people who have undergone ostomies used and discussed reflected the need to address a common challenge of peristomal skin complications following an ostomy surgery [21-23] and demonstrated characteristics of an expert understanding [24-27].

YouTube as Ostomy Self-Care Resource

This study examined YouTube videos related to the interaction of people who have undergone ostomies with medical device technology and self-care that were provided by and for the public, and the need for additional information related to long-term ostomy self-care in home (nonhospital) settings. In our study, we initially identified 960 ostomy-related videos and analyzed 65 videos with a narrator who has undergone an ostomy that met our inclusion criteria. Each of these videos was viewed 269,000 times on average, liked 3000 times on average, and posted by 28 unique content creators representing a broad range of ages and both, female and male genders. Our study supports current research suggesting that individuals are increasingly seeking health-related information on the web and patients use web-based resources to make health-related decisions and to manage chronic conditions [1-3,35,36]. Patient education and engagement in ostomy self-care are essential for performing self-care tasks and successful management of their chronic condition [18-20,35]. Nevertheless, research evidence shows the pre- and postoperative education provided to people who have undergone ostomies is insufficient [22-25] and new people who have undergone ostomies may not be prepared to gain new knowledge, skills, and attitudes necessary for self-care management of their ostomy immediately post surgery [26,27]. Therefore, our study suggests patients are looking for additional support and resources for ostomy self-care.

The video metadata and data of narrators who have undergone ostomies show that people who have undergone ostomies of various ages and genders are willing to share their personal experiences with ostomy self-care and appliance change procedures on the web and that these videos are viewed by others. Through YouTube, people who have undergone ostomies can share their stories, empower and help other people who have undergone ostomies, and develop a sense of community with other people who have undergone ostomies [10,11], which goes beyond the ability of health care providers not living with a stoma. In our study, narrators who have undergone ostomies created videos depicting ostomy self-care not to substitute health care professional guidelines and recommended practices, but rather to share a lived experience with a chronic illness, and their challenges and wins. They also commented on being able to develop a sense of community, learn from the lived experiences of other people who have undergone ostomies, and adjust to postostomy surgery lifestyle changes such as by finding and joining a support group or talking to people who "get it." Many of the narrators who have undergone ostomies made disclosures that they were not giving medical advice and commented on positive experiences with and encouraged interaction with ostomy care nurse specialists. The ostomy self-care-related videos depicted what it is like living life with a stoma, and what self-care strategies were found to be effective and what were not. This type of data would be difficult to gain using traditional observational techniques and surveys.

End User Experience With Ostomy Medical Device Technology

The narrators who have undergone ostomies used a variety of supplies at different frequencies to change their ostomy

XSL•FO
RenderX

appliance and discussed challenges related to supplies, challenges with peristomal skin health, appliance adhesion, leakage, and not having control over the stoma output which reflects their user needs. For example, peristomal skin complications were identified by narrators who have undergone ostomies in approximately one-third of analyzed ostomy self-care YouTube videos, and stoma powder (used to treat skin complications) and skin treatments were included and discussed in 12 (34%) and 8 (23%) of the videos depicting an ostomy appliance change procedures, respectively. This finding aligns with extensive research on peristomal skin complications following an ostomy surgery representing a common challenge [30,37,38] and negatively impacting the quality of life of people who have undergone ostomies [39]. The use of peristomal skin protection supplies such as barrier rings, skin barriers, and ostomy paste in 17 (49%), 15 (43%), and 6 (17%) of videos, respectively, and adhesion supplies such as extenders, ostomy belts, and skin adhesives in 5 (14%), 4 (11%), and 3 (9%) of the videos, respectively, manifests the need for properly fitting and adhering external pouching system [17,40]. Thus, the selection of supplies may have been associated with attempts to address appliance adhesion and leakage issues and thus peristomal skin complications.

Narrators who have undergone ostomies reported usability issues with supplies, such as the difficulty with out-of-package baseplate not adhering to "warm" body temperature skin, supplies that are effective in cleaning but compromise peristomal skin health and ostomy appliance adhesion and cause pain (eg, alcohol-based ostomy paste), which call for design improvements of ostomy supplies or redesign related to their properties (eg, baseplate adhesion to peristomal skin, or alcohol-free supplies).

Moldable technology is believed to improve peristomal skin health, reduce the incidence of irritant dermatitis, and be well-perceived by people who have undergone ostomies for its ease of use, ease of learning, and comfort [41,42]. However, in our study, only 3 (9%) of videos depicting the full or part of the ostomy appliance change procedure included a moldable baseplate compared to 25 (71%) of videos where the baseplate was cut to fit or precut and people who have undergone ostomies reported challenges with cutting the baseplate to size. If the stoma hole is too small, the stoma can be damaged, if the stoma hole is too big, the output is more likely to leak on the peristomal skin which in turn will lead to peristomal skin complications. Generally, there are 3 designs of baseplate, precut (cut by supplier), cut-to-size (cut by a person who has undergone an ostomy), and moldable. Moldable baseplate technology does not require cutting the baseplate with scissors but rather using fingers to roll flexible material to size and around ("turtle necking") the stoma and allows for adjusting the stoma hole to fit snuggly around the stoma while also creating a protective barrier and preventing output from reaching peristomal skin [41]. The narrators who have undergone ostomies did not elaborate on the reason for cutting versus molding baseplate to size, except for 1 video where the narrator who has undergone an ostomy had her husband change the appliance and commented on the molding being "easier to use at first." Therefore, further studies should be conducted to explain this trend and to more specifically identify user needs. Additionally, future work should determine if people who have undergone ostomies are aware of and educated on the benefits of using moldable baseplate technology versus using cut-to-fit or precut appliances and if moldable appliances are widely available to people who have undergone ostomies.

Experts' User-Generated Ostomy Self-Care Strategies

The tips and tricks discussed by the narrators who have undergone ostomies in the videos we examined provide evidence of problem-solving strategies useful for decision-making and ostomy self-management. Ostomy self-care requires complex daily decision-making to solve ostomy-related challenges such as compromised appliance adhesion, leaks, or peristomal skin complications discussed above. People who have undergone ostomies have to monitor their daily output, diet, and stomal or peristomal skin health; perform ostomy appliance changes; and plan future self-management. In previous studies of professional expertise, experts stood out in their ability to identify problems [43], understand functional relationships [44], and use problem-solving strategies [45].

Lippa et al [46] suggest that in the self-management of chronic conditions, such as diabetes, professional expertise may be useful for aiding decision-making and supporting patient's strategies. Lippa et al [46] also found that diabetic patients who used functional knowledge and problem-solving strategies reported higher levels of adherence to treatment and glycemic control and that descriptive knowledge about diabetes may not necessarily correlate with effective self-management [46]. In our study, narrators who have undergone ostomies demonstrated their expert understanding while elaborating and showing their self-care strategies and adaptation to ostomy-related challenges. These strategies relate to supplies use and organization, ostomy appliance adhesion, baseplate sizing, maintenance of healthy peristomal skin, pouch pancaking and ballooning, and adjustments to lifestyle changes.

Finally, our study of ostomy self-care and end user experiences with ostomy appliance change technology complements the "Ostomy Life Study," [47] a global effort to gain knowledge about what is it like to live with a stoma and the user experience with ostomy-related supplies. Our study identifies an efficient alternative to traditional observational and survey methods for obtaining end user data that have implications for addressing patient safety and quality of care issues.

Limitations

Several limitations should be considered when interpreting the results of this study and guiding the direction of future research. In our sample of videos, there were more ileostomies than colostomies, and there were no urostomies, therefore, our findings did not compare different types of ostomies. Further, the narrators who have undergone ostomies were essentially "performing" and demonstrating for the video, therefore, these videos may not capture the routine procedures people who have undergone ostomies use for self-care. In our data analysis, half of the narrators who have undergone ostomies were within an assumed age of 20-30 years and approximately one-third of narrators who have undergone ostomies were in their middle

XSL•FO
RenderX

age. This is likely due to most YouTube users falling between the ages of 18 and 44 years [48].

There were also limitations related to demographics in this study. All videos analyzed were narrated in English, but the global representation is unknown. This may limit the global generalizability of this study. Additionally, we did not examine any race, gender, or ethnicity differences in the experiences of people who have undergone ostomies.

Future Work

Further, it should examine differences in ostomy appliance change procedure and self-care strategies across all the types of ostomies, more specifically, whether ileostomies are more prone to peristomal skin complications considering ileostomies' output is frequent, more liquid, and high in digestive enzymes [32]; and the prevalence and decision-making of using a moldable versus cut-to-fit appliance technology among people who have undergone ostomies. Future research should also specifically study younger and older people who have undergone ostomies and their experiences, complement this work in other languages and for individuals with experiences in other health care systems, and examine if there are differences among various populations of people who have undergone ostomies.

We identified 28 individual narrators who have undergone ostomies, and their videos were widely viewed. In addition to counting likes, future research should examine who is viewing these videos, what they are learning from them, and the content of viewer comments and discussions related to the video content. The comments analysis could provide a rich discussion around the strategies and ostomy self-care provided in the ostomy self-care videos.

In our study, we purposely did not include any video content from medical professionals or health care professional organizations because it can contain different information about ostomy self-care strategies than what is practiced by people who have undergone ostomies in home settings [35]. We intended to evaluate end user experiences with ostomy self-care rather than how people engage with YouTube videos created by health care professionals. However, we recognize there is value in comparing user-generated information to what clinicians and health-related government organizations may communicate about ostomy self-care as they use YouTube to disseminate health information [1] that is considered to be the most reliable and accurate information [6]. Future research should examine the content in the ostomy self-care videos created by health care professionals and professional organizations and evaluate how they compare to the user-generated ostomy self-care YouTube videos examined in this study.

Conclusions

This study used a novel approach for ostomy care (YouTube videos) to gain insights into ostomy self-care in home settings and end user interactions with medical devices while performing self-care, which are difficult to gather using traditional behavioral techniques. Using YouTube or other publicly available content created by individuals dealing with a chronic condition is a low-cost means to identify successful strategies, potential design problems, and potential workaround for issues that would be difficult to obtain in other study designs and approaches. The analysis of 65 videos showed that people who have undergone ostomies are willing to share their personal experience with ostomy self-care on the web and that these videos are viewed by the public. The findings also identify user needs related to medical device technology and indicate that narrators who have undergone ostomies were able to use problem-solving strategies for decision-making and successful ostomy self-management. This study demonstrates the potential value of these videos for filling the gap between health information delivered by health care professionals and the lived experience of individuals dealing with a chronic condition.

Additional information related to long-term ostomy self-care in a home (nonhospital) setting and the differences between what is clinically recommended and how the procedures and supplies are actually used by individuals living with ostomies needs to be more clearly understood for the design and testing of future ostomy supplies as well as for patient education from clinicians. Future research could use these approaches to address other types of clinical information that other clinical populations need to learn or be able to access when at home as well as strategies to design better medical devices for home health care in the future.

Abstract

Background: Effective symptom identification, a key responsibility for community pharmacists, requires patients to describe their symptoms accurately and comprehensively. However, current practices in pharmacies may be insufficient in capturing patient-reported symptoms comprehensively, potentially affecting the quality of pharmaceutical care and patient safety.

Objective: This study aimed to construct a new, hierarchical symptom list derived from the Patient-Friendly Term List of the Medical Dictionary for Regulatory Activities (MedDRA) and to develop and evaluate a mobile app incorporating this list for facilitating symptom reporting by patients in pharmacy settings. The study also aimed to assess the usability and acceptance of this app among potential users.

Methods: Subjective symptom-related terms were extracted from the Patient-Friendly Term List version 23.0 of the MedDRA. These terms were systematically consolidated and organized into a hierarchical, user-friendly symptom list. A mobile app incorporating this list was developed for pharmacy settings, featuring a symptom selection interface and a free-text input field for additional symptoms. The app included an instructional video explaining the importance of symptom reporting and guidance on navigation. Usability tests and semistructured interviews were conducted with participants aged >20 years. Interview transcripts were analyzed using the Unified Theory of Acceptance and Use of Technology (UTAUT) model to evaluate factors influencing the acceptance of technology.

Results: From the initial 1440 terms in the Patient-Friendly Term List, 795 relevant terms were selected and organized into 40 site-specific subcategories, which were then grouped into broader site categories (mental, head, trunk, upper limb, lower limb, physical condition, and others). These terms were further consolidated into 211 patient-friendly symptom terms, forming a hierarchical symptom list. The app's interface design limited options to 10 items per screen to assist with decision-making. A total of 5 adults participated in the usability test. Participants found the interface intuitive and easy to use, requiring minimal effort, and provided positive feedback regarding the potential utility of the app in pharmacy settings. The UTAUT analysis identified several facilitating factors, including ease of use and the potential for enhanced pharmacist-patient communication. However, concerns were raised about usability for older adults and the need for simplified technical terminology.

Conclusions: The user-friendly app with a hierarchically structured symptom list and complementary free-text entry has potential benefits for improving the accuracy and efficiency of symptom reporting in pharmacy settings. The positive user acceptance and identified areas for improvement provide a foundation for further development and implementation of this technology to enhance communication between patients and pharmacists. Future improvements should focus on addressing usability for older adults and simplifying technical terminology.

Introduction

Patient-reported symptoms are critical indicators in health care, essential for maintaining patient safety and improving therapeutic outcomes in clinical settings [1,2]. In Japan, the Ministry of Health, Labour and Welfare launched "Pharmacy Visions for Patients" in 2015, clearly outlining the role of community pharmacies, including comprehensive monitoring of medications, as well as providing tailored drug management and guidance [3]. A key responsibility for community pharmacies in this context is to gather and monitor patient-reported symptoms, essential for identifying potential health issues and ensuring timely intervention.

For pharmacists, collecting patient-reported symptoms plays multiple critical roles in medication therapy management. First, it facilitates the early detection and monitoring of potential adverse drug reactions, enabling timely interventions to prevent serious complications. Second, comprehensive symptom information helps pharmacists assess therapeutic effectiveness and adjust medication regimens accordingly. Third, systematic symptom monitoring supports pharmacists in providing targeted patient education and improving medication adherence through a better understanding of patient experiences. These activities are fundamental to the pharmacist's role in ensuring medication safety and optimizing therapeutic outcomes.

While health care providers traditionally collect symptom information through direct questioning, a patient-centered approach that enables patients to report symptoms at their own pace using familiar terminology may improve the accuracy and comprehensiveness of symptom reporting. Such an approach acknowledges patients as active participants in their health care, potentially leading to better identification of health-related issues and more effective interventions. A cross-sectional study demonstrated that structured symptom reporting tools can help identify numerous patient-reported symptoms and their potential associations with medications, providing valuable information for medication reviews [4]. However, another previous study showed that patients often underreported symptoms to health care providers, either because they do not attribute symptoms to the medication or do not recognize the significance of the symptoms [5].

To facilitate patient reporting, various symptom questionnaires have been developed, enabling patients to describe their experiences [6]. However, many of these tools lack thorough validation. In Japan, Nojo et al [7] introduced the "Adverse Drug Reaction Signal Check Sheet," which lists subjective symptoms of side effects for patients taking high-risk drugs. Although limited to specific drugs, the sheet proved effective in prompting patients to communicate their symptoms during consultations with pharmacists. This approach suggests that selecting symptoms from a structured list can support patient reporting.

The Medical Dictionary for Regulatory Activities (MedDRA), a globally recognized dictionary of medical terminology, includes a Patient-Friendly Term List that reflects a wide range of symptoms reported by patients in safety databases [8]. MedDRA has a hierarchical structure with organ categories at the top, and its Patient-Friendly Term List is a supplementary list made up of the lowest-level terms of the MedDRA. This structured approach allows patients to progressively identify and report their symptoms. However, international research has indicated that patients do not fully use this list when reporting adverse drug reactions [9], suggesting challenges in the direct adoption of a symptom-reporting system.

This study aimed to construct a new hierarchical list of symptoms derived from the Patient-Friendly Term List of the MedDRA to simplify and facilitate incremental symptom selection by patients. Moreover, we aimed to develop an app incorporating this list to enhance communications between patients and pharmacists by facilitating more accurate symptom reporting.

Methods

Creation of the New Hierarchical, Patient-Friendly List of Symptoms

A hierarchical list of subjective symptoms was created using the Patient-Friendly Term List version 23.0 from the MedDRA. MedDRA, developed by the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use, is a standardized medical terminology used in pharmaceutical regulation. The MedDRA Patient-Friendly Term List was selected for this study due to its standardized structure and global adoption in pharmacovigilance. This list consists of patient-friendly terms derived from MedDRA, ensuring that the terminology is both medically accurate and comprehensible to nonexpert users. The structured format of this list was expected to facilitate consistent symptom categorization while remaining accessible to patients, supporting pharmacists in identifying potential adverse drug reactions (ADRs) and optimizing medication therapy management.

Terms associated with subjective symptoms were extracted from the Patient-Friendly Term List and categorized by body part. Similar terms were consolidated into "symptoms," forming the lowest level of a 3-tier hierarchical structure, with "broader site categories" and "site-specific subcategories" as the upper levels. This new hierarchical list was reviewed and refined through multiple rounds of consensus by three researchers (WS, KH, and HS). WS was an undergraduate student in the Faculty of Pharmaceutical Sciences, and KH and HS were researchers in the Faculty of Pharmaceutical Sciences.

Development of a Patient Symptom-Reporting Application

An app was developed to incorporate the newly created hierarchical list of symptoms. The app featured a symptom selection interface, an instructional video explaining the importance of symptom reporting, and guidance on how to navigate the app. To assist with decision-making, no more than 10 options were displayed on the screen at a time. In addition to the structured symptom list, the app included a complementary free-text entry, allowing users to input symptoms that may not be represented on the list or when the listed symptoms did not fit their condition. The app is intended for use in a pharmacy setting and was designed to capture a

XSL•FO
RenderX

wide range of symptoms, beyond those related to side effects of specific drugs. Apache Cordova, an open-source mobile app development framework, was used for the development. The operating system used was Android, and the app was run on a HUAWEI MediaPad T3. The content of the app was written in Japanese.

Usability Study and Interviews

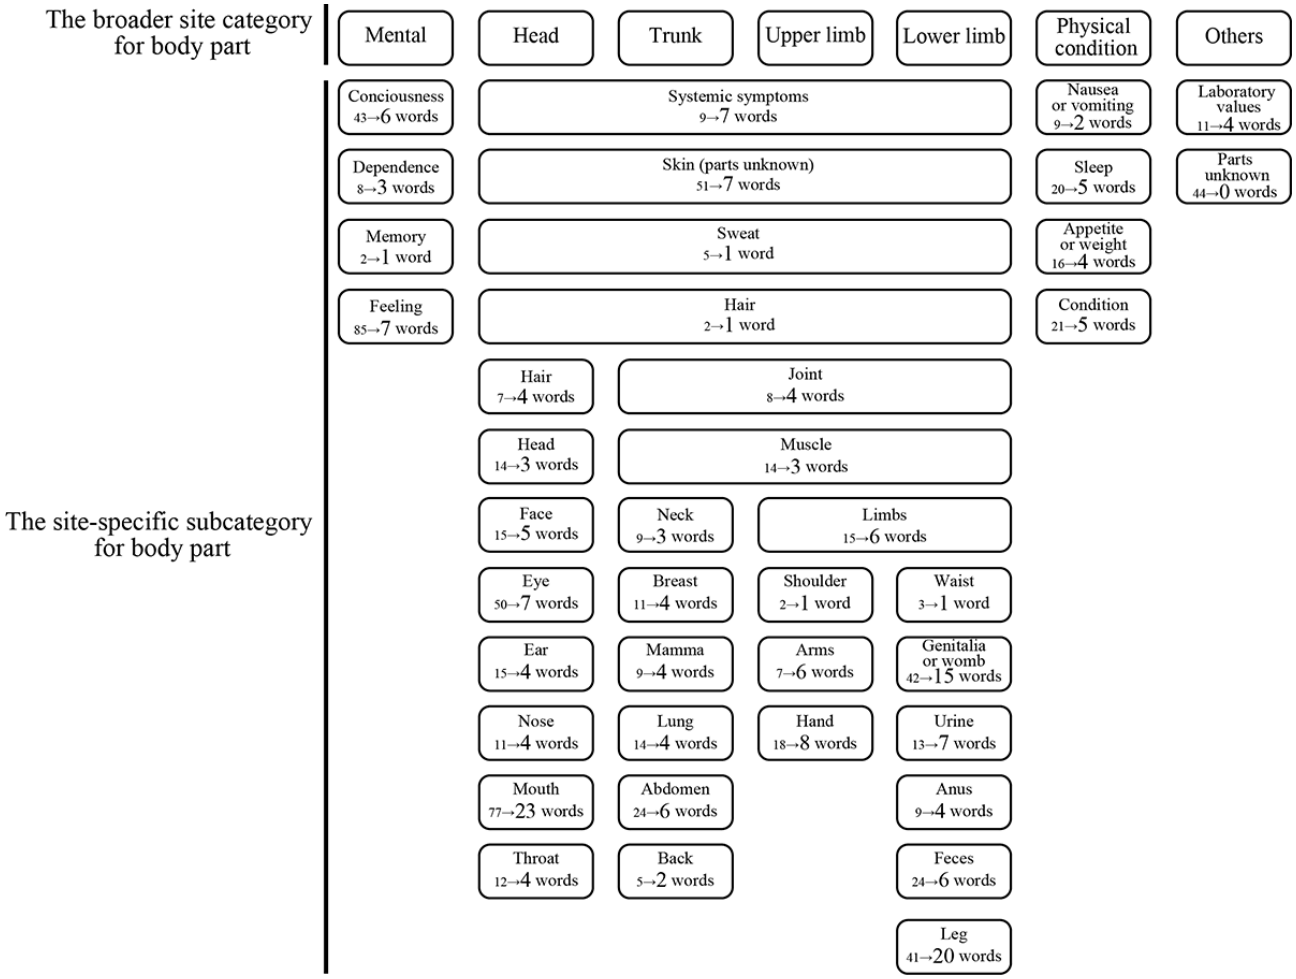
A usability study was conducted from September to October 2020 with adults aged >20 years, recruited through research flyers. Participants first completed a questionnaire on their demographics, medication use, history of ADRs, and familiarity with digital devices. They were then briefed on the purpose of the app in a pharmacy setting and the interview format. Participants tested the app on a HUAWEI MediaPad T3, entering personal and symptom data on 5 hypothetical patient scenarios (Table S1 in Multimedia Appendix 1). Following the app trial, a semistructured interview was conducted, based on the interview guide (Table S2 in Multimedia Appendix 1), to gather feedback on the app. Interviews were conducted in Japanese, focusing on impressions of the app from participants and their awareness of reporting side effects. All interviews were recorded with the consent of participants and conducted by a single researcher (WS).

Analysis of the Interview

Thematic analysis was applied to the recorded interview transcripts using a deductive and theoretical approach. The Unified Theory of Acceptance and Use of Technology (UTAUT) model was used for this analysis. Initially proposed by Venkatesh et al [10] in 2003, the UTAUT model has been widely adopted in the medical field in recent years [11]. This model is particularly useful for understanding factors influencing the adoption of new technologies. It posits that performance expectancy (expected benefits of using new technology), effort expectancy (expectations of the ease of use and understanding of new technology), and social influence (how much the user's decisions about technology are influenced by others) determine behavioral intention to adopt the technology. Behavioral intention, along with facilitating conditions, influence actual technology use. In addition, gender, age, experience with similar technologies, and spontaneity of use serve as general adjustment variables (moderators). The translation of these constructs was based on the work of Ono [12]. In total, 3 researchers conducted analyses to ensure objectivity.

Ethical Considerations

On the day of the usability study and interview, the survey content, privacy protection, and plans for publishing the research results were comprehensively explained to the participants, and written informed consent to participate in the survey was obtained. The preinterview questionnaire was self-administered anonymously. Participants received compensation in the form of a gift card (Quo Card) valued at 1000 JPY for their participation in the study. This survey was conducted after being approved by the Ethics Committee for Research Involving Human Subjects, Keio University Faculty of pharmacy, following the Ethical Guidelines for Medical Research Involving Human Subjects (200213-3).



Results

Creation of the New Patient-Friendly Symptom List

From the 1440 terms in the Patient-Friendly Term List version 23.0, duplicates with the same Japanese translations were removed, resulting in 1288 terms. Subsequently, 12 product-related terms such as "suspected counterfeit products" were excluded. In addition, 450 terms that were difficult for patients to self-identify, including those requiring a medical diagnosis or those specific to certain conditions, were removed. Another 31 terms unrelated to medications were deleted, leaving a total of 795 terms. The 795 terms were systematically sorted into 40 site-specific subcategories based on information related to the locus of impact of each word. These site-specific subcategories were grouped into 7 broad site categories: mental, head, trunk, upper limb, lower limb, physical condition, and others (Figure 1). Within each site-specific subcategory, similar terms were consolidated by grouping related symptoms (eg, various types of arm discomfort such as "arm paralysis" and "arm discomfort") and creating standardized descriptive names (eg, "tingling and discomfort in the arm") that accurately represent the consolidated symptoms. This consolidation process aimed to simplify symptom selection while maintaining clinical relevance, yielding 211 subjective symptoms (Figure 1). Finally, a hierarchical list of patient-friendly symptoms was created using the hierarchical structure of site categories, subcategories, and symptoms.

XSL•FO
RenderX

Figure 1. The broader site categories and site-specific categories for body parts, as well as the word counts before and after consolidation. The 795 terms were systematically sorted into 40 site-specific subcategories based on information related to the locus of impact of each word. These site-specific subcategories were grouped into 7 broad site categories: mental, head, trunk, upper limb, lower limb, physical condition, and others. Within each site-specific subcategory, similar terms were consolidated by grouping related symptoms (eg, various types of arm discomfort such as "arm paralysis" and "arm discomfort") and creating standardized descriptive names (eg, "tingling and discomfort in the arm") that accurately represent the consolidated symptoms. This consolidation process aimed to simplify symptom selection while maintaining clinical relevance. In this figure, the number on the left side of each arrow represents the count of terms before consolidation and the number on the right indicates the count following this unification process.

To integrate this list into the app, we designed a question flow that allowed for easy symptom selection. Broader and site-specific subcategories were modified and recombined into major site categories and site subcategories for an intuitive question flow (Figure S1 in Multimedia Appendix 1). As an example, the hierarchy under the major site category "upper limbs" and its subcategories is detailed in Table 1. The app included a free-text entry field labeled as "other" at each categorical level to capture symptoms that users could not find in the structured list. This feature was implemented to ensure comprehensive symptom reporting and to collect data for future improvements of the symptom list.

Development of a Symptom-Reporting App

The screen transition diagram and display screens for the app are shown in Figure 2. Figure 2A shows the screen transition diagram of the app. The starting screen featured an instructional video explaining the purpose of the app and the importance of comprehensive symptom reporting (Figure 2B), followed by a series of intuitive selections for symptom identification (Figure 2E-J). The closed screen signaled the end of the session, prompting the user to pass the device on to the pharmacist (Figure 2K). To minimize cognitive overload, no more than 10 options were displayed per screen, making symptom selection easier and more manageable. An instructional video was included to explain the importance of symptom reporting, providing users with essential background knowledge before using the app. In addition, a free-text entry field was implemented to allow patients to describe symptoms not covered by the structured list, ensuring flexibility while maintaining structured reporting as the primary method. These features were designed to enhance the accuracy and completeness of symptom reporting, thereby improving communication between patients and pharmacists.

Figure 2. Screen transition diagram and display screen of the app. (A) Screen transition. (B) Start and video viewing section. (C) Input of personal information, (D) Confirmation of personal information. (E) Selection of the presence or absence of symptoms. (F) The large category of body parts. (G) The small category of body parts. (H) The selection of symptoms. (I) Selection of presence of other symptoms. (J) Confirmation of the selected symptoms. (K) End. The app screen in Japanese is shown since the actual app is in Japanese. English translations of the screen elements are provided in parentheses within the figure.

Usability of the Symptom-Reporting App

In total, 5 adults participated in the usability study and interviews. Table 2 presents the demographic characteristics of the interviewees. Overall, 4 of the 5 interviewees regularly used smartphones, and 4 of the 5 interviewees had previously experienced side effects. The interviews elicited valuable opinions on the usability of the app, as summarized in Table 3, with an analysis aligned with the UTAUT model presented in Figure S2 in Multimedia Appendix 1.

Table 3. Opinions on app usability based on the Unified Theory of Acceptance and Use of Technology (UTAUT) model.

UTAUT category	Details
Performance expectancy	
Ease of consultation	• Easier to answer than to be asked • Easier to tell something than in person • Gives a chance to talk • Unclear what the app is used for
Contribution for medication	• May contribute to the treatment of others
Feedback from health care professionals	• Good to have an opinion from a pharmacist • Good to have continuous monitoring • Good to have topics related to daily life • Good to have a comfortable relationship with the pharmacist
Other functions	• Good to provide information about medication • Good to enter one's medication status • Good to be able to discuss other issues besides symptoms • Good to be linked to other systems • Good to be used outside the pharmacy • Concerns about adding too many functions
Effort expectancy	
Ease of use	• Usable without problems • Easy to use selective forms • Easy to be guided by selective forms • Negative feelings though none of the options apply to me • Difficult to enter free-text fields • Difficult to check, change, or add information • Difficult to use for older people who are not used to using smartphones or tablets
Expression of question items	• Usable without problems • Very detailed items • Many specialized words and phrases • Difficult to understand the words of the site classification • Difficult to understand the way the questions are asked
Social influence	
Influence from health care professionals	• Easy to answer if a health care provider asks about symptoms • App that can be used by pharmacists in medication instruction
Information collection and management	• Resistance to data being stored
Facilitating conditions	
Appearance	• Easy-to-read layout • Easy-to-read colors • Easy-to-read font size • Difficult reading text for older people
Device	• Difficult to use keyboard • No problems with the size of device • Easy to use the device with horizontal screen display • Probably being too small for older people
Behavioral intention	
Use of app	• Want to use the app • Should be used also outside of pharmacies • Probably not being able to be used for older people alone • Sometimes difficult to tell something even with app

In terms of "performance expectancy," participants expressed a preference for using the app to consult with pharmacists because "it is easier to answer than when being asked by a person," "it is easier to communicate than doing it face-to-face,"

XSL•FO
RenderX

and “it gives me a chance to talk to someone.” Some participants suggested that “it would be beneficial to receive expert opinions as feedback from a pharmacist.” In terms of “effort expectancy” (expectations about the ease of use and understanding of new technology), usability and expressions were both deemed “usable without problems,” while issues such as “too many technical terms” and “I feel bad when there are no applicable choices” were identified. Regarding “social influence” (the extent to which the user’s technology decisions are influenced by others), opinions included “it is easy to answer when a medical professional asks about symptoms” and “pharmacists can use it in medication guidance,” indicating that the influence of medical professionals contributes to the behavioral intention to use the technology. Regarding the “facilitating conditions,” it was suggested that there should be no problems with the design and terminal. Based on the above, all participants were positive about their behavioral intention to use the app, and some suggested that the app should be used outside pharmacies. Concerns were raised regarding the use of the app by older adults.

Several factors that did not align with the UTAUT model but significantly affected how ADRs reported to health care providers were identified. These factors included “I recognize pharmacist as a person to consult, but do not want to consult,” “I will not consult if not sure of side effect,” “I will not consult if the side effect is minor or not necessary to discuss by myself,” and “I will not consult if I think it is a side effect.” In addition, factors specifically affecting the reporting of ADRs to health care providers comprised “I recognize that it is an ADR but do not want to discuss it with a pharmacist,” “I do not discuss it unless I am sure it is an adverse drug reaction,” “I do not discuss it unless I am sure it is an adverse drug reaction,” and “I feel uncomfortable reporting an adverse drug reaction.”

Discussion

Principal Findings

In this study, we developed a hierarchical list of symptoms based on the MedDRA Patient-Friendly Term List and created an app that enables patients to easily select symptoms. The potential use of the app in pharmacies was well received, indicating that it could significantly aid patients in communicating their symptoms more effectively.

Our newly created list comprised 211 symptoms, and to improve user-friendliness, we implemented a “questionnaire flow” within the app, based on the hierarchical structure. This approach allows users to systematically select symptoms by navigating through major site categories, site subcategories, and detailed symptoms. Participants using the app in 5 hypothetical patient scenarios praised its ease of use, confirming the feasibility of using the hierarchical list of symptoms and the app for effective symptom selection. Previous research revealed that approximately 20% of reports on side effects used patient-friendly terms, with the majority opting for free-text entries [5]. By limiting displayed options to 10 or fewer, while providing a free-text input field for unlisted symptoms, our app may improve the ease of symptom identification. This design feature was further supported by the overall positive feedback from the participants. Future updates to the symptom list, informed by the analysis of real-world, free-text entries, could further streamline symptom reporting.

Participants in our study expressed their opinions about reporting usual self-aware symptoms such as “I do not discuss subjective symptoms unless I am sure they are side effects” and “I do not mention side effects if they seem minor or unnecessary to report,” which aligns with reasons reported in previous research for underreporting symptoms to health care providers [5]. These responses highlight common barriers to symptom reporting in health care settings, including patients’ uncertainty about whether symptoms are drug-related and their hesitation to mention symptoms they perceive as minor. To address these universal challenges, our app was designed with a structured interface and a hierarchical organization of symptoms, guiding patients through a systematic symptom-reporting process. The hierarchical structure of the app enables patients to progressively identify and select symptoms, potentially increasing the comprehensiveness of reported symptoms while reducing psychological barriers to reporting even minor or uncertain symptoms. Positive feedback from participants, such as “easier to answer than being asked by someone,” “easier to communicate than doing it face-to-face,” and “becomes a trigger to talk,” suggests that this structured approach could effectively address these reporting barriers. In addition, participants’ feedback indicating the app’s effortlessness (“can use without a problem”) and willingness to use (“I want to use it”) suggests its potential for successful implementation in pharmacy practice.

From the perspective of health care providers, pharmacists can review these structured patient reports before medicine consultation, enabling more focused and efficient discussions. These features, combined with the ability of the app to document patient-reported outcomes systematically, provide a foundation for continuous monitoring of therapy effectiveness and early detection of drug-related problems.

While our usability study received positive feedback regarding the potential of the app, we also identified several usability issues, particularly among older users. A participant aged 79 years expressed concerns, stating “I might not be able to use it on my own,” and other feedback pointed to specific issues such as “The size may be too small for elderly users” and “The text might be difficult to read.” Given that many customers of pharmacies are older adults, future usability assessments should focus on this population.

Implementing our app in pharmacy settings strategically aligns with the evolving health care landscape in Japan, particularly in aging societies where pharmacies are expanding beyond traditional medication dispensing [3,13]. Pharmacies offer several unique advantages as ideal implementation sites, including their high accessibility, regular patient visits, and prescription preparation waiting time, which offers a natural opportunity for symptom reporting without disrupting workflow. While the app could be valuable in various health care settings, including clinics and hospitals, pharmacies offer unique advantages. Pharmacists’ expertise in medication, combined with their frequent patient interactions, makes them ideal providers for continuous symptom monitoring and self-care

XSL•FO
RenderX

support. Their role has evolved from traditional medication dispensing and adverse effect monitoring to more comprehensive patient care support. Integrating the app into pharmacy practice could particularly support patient engagement in their own health care by enabling systematic symptom reporting in a familiar, low-pressure environment. This approach not only supports pharmacists' evolving role in comprehensive patient care but also promotes active patient participation in medication management.

Future research should systematically evaluate the effectiveness of the app in achieving its intended outcomes. Key areas of investigation include the impact of the app on the number and types of symptoms reported. Quantitative measurements will be valuable in assessing the impact on pharmaceutical interventions, including the identification of drug-related problems and subsequent care recommendations. Further research opportunities lie in evaluating improvements in the quality of patient-pharmacist communication and the effect of the app on the efficiency of pharmacy workflow. These investigations would benefit from including a larger, more diverse patient population in real-world pharmacy settings, with particular attention to older adults who represent a significant portion of pharmacy patients.

Although our sample size of 5 participants is consistent with recommendations for initial usability testing suggesting that 5 users can identify approximately 80% of major usability issues [14], this small sample size limits the generalizability of our findings. This limitation highlights the need for additional testing with a larger and more diverse user group to ensure the app meets the needs of all potential users in pharmacy settings.

Conclusions

We successfully developed a new hierarchical list of symptoms and an accompanying app. The app, designed to enable users to select symptoms from a structured list, was positively accepted and showed strong potential for improving patient behavior in symptom reporting. Future improvements to the design of the app design, particularly for older users, will further enhance its utility in both pharmacy settings and broader health care environments.

Acknowledgments

We would like to thank all the participants in this study.

Abstract

Background: Chronic kidney disease (CKD) is a common condition worldwide and home dialysis (HD) provides economic, quality of life, and clinical advantages compared to other dialysis modalities. Human-centered design aims to support the development of eHealth solutions with high usability and user experience. However, research on the eHealth needs of patients using HD is scarce.

Objective: This study aimed to support the design of eHealth for patients with CKD, particularly for patients using HD, by developing a kidney disease experience map that illustrates user needs, concerns, and barriers. The research questions were (1) what experiences do patients, particularly older adults, have in their everyday lives with CKD? (2) what user needs do patients with CKD have for HD eHealth? (3) how can these needs be illustrated using the experience map technique? The study focused on patients aged >60 years, as they are at a higher risk of chronic conditions. The study was conducted as part of the eHealth in HD project, coordinated by Hospital District of Helsinki and Uusimaa, Finland.

Methods: In total, 18 patients in different care modalities participated in retrospective interviews conducted between October 2020 and April 2021. The interviews included a preliminary task with patient journey illustrations and questions about their experiences and everyday lives with CKD. The data analysis was conducted using a thematic analysis approach and the process included several phases.

Results: On the basis of the thematic analysis, 5 categories were identified: healthy habits, concerns about and barriers to eHealth use, digital communication, patients' emotions, and everyday life with CKD. These were illustrated in the first version of the kidney disease experience map. The patients had different healthy habits regarding social life, sports, and other activities. They had challenges with poorly functioning eHealth software and experienced other factors, such as a lack of interest and lack of skills for eHealth use. Technical devices do not always meet the emotional or physical needs of their users. This caused feelings of frustration, worry, and fear in patients, yet also fostered situational awareness and hope.

Conclusions: The experience map is a promising method for illustrating user needs and communicating the patient's voice for eHealth development. eHealth offers possibilities to support patient's everyday life with chronic disease. The patient's situation and capacity to use eHealth solutions vary with their everyday challenges, opportunities, and their current stage of treatment. The kidney disease experience map will be used and further developed in the ongoing research project "Better Health at Home—Optimized Human-Centered Care of Predialysis and Home Dialysis Patients" (2022 to 2026).

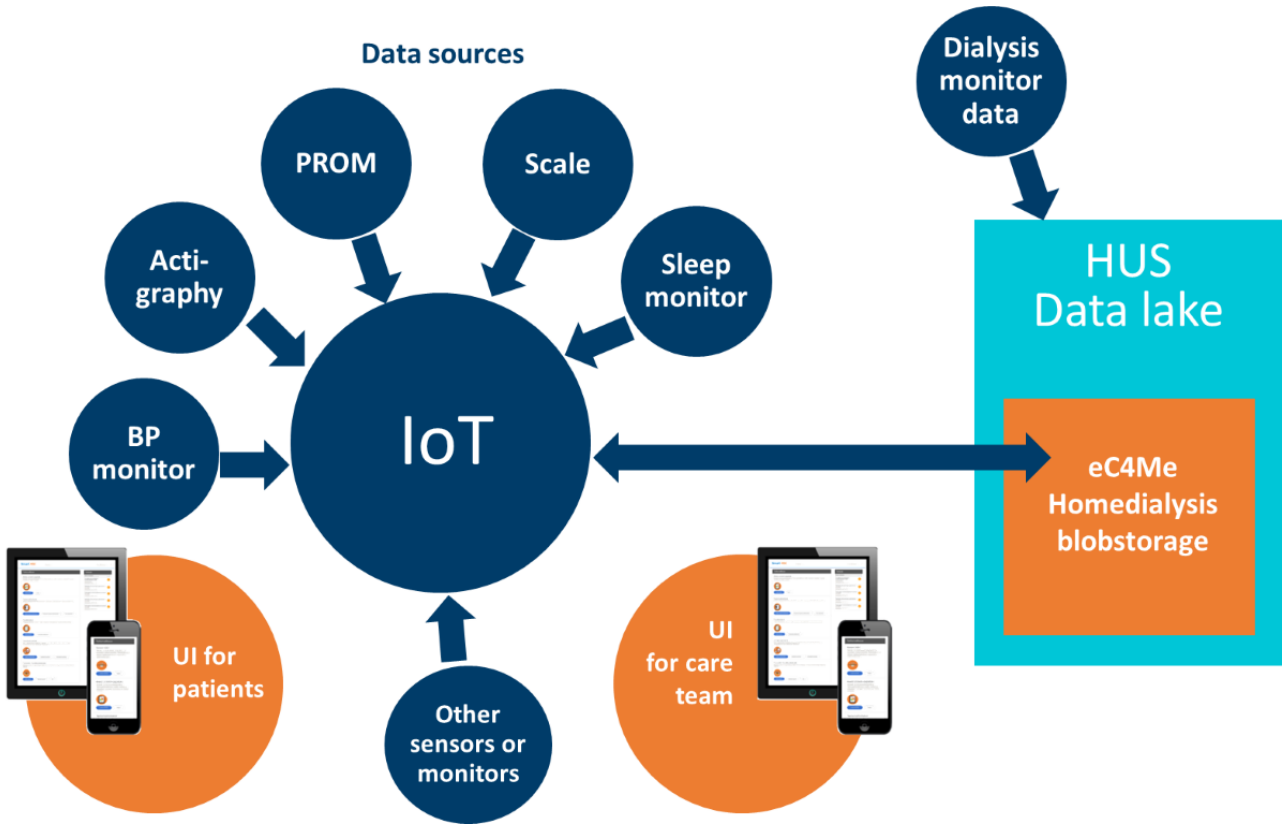
Introduction

Background

Chronic kidney disease (CKD) is a common condition worldwide. It has been estimated that 11% to 13% of the population in high-income countries have CKD. The number of patients with advanced kidney disease is growing 5% to 7% per year [1,2]. The prevalence of CKD is highest among older adults, ranging from 38% to 44% in patients aged >65 years [3,4]. In total 2.05 million people were treated with dialysis worldwide in 2010 [2]. In 2017, 1.2 million people died globally because of CKD [5].

Patients with end-stage CKD need kidney transplants or dialysis to survive. Dialysis can be performed in a dialysis unit in a hospital (ie, in-center dialysis), in a satellite dialysis unit, or at home using peritoneal dialysis or hemodialysis. The dialysis modality may vary depending on the patient's current health and life situation. Both in-center and satellite dialysis can be laborious for patients [6] and impose a heavy financial burden on medical care [7]. Therefore, home dialysis (HD) provides better quality of life and clinical advantages and empowers patients by providing them with more flexibility in their everyday lives [6,8].



Even though bringing dialysis treatment to a patient's home might be burdensome and complicated for both the patient and the health care unit [8,9], there is a common understanding that HD prevalence needs to increase [1]. HD creates opportunities to improve the patient's safety and quality of life, as well as to support self-management of health [6,10]. HD has also proven to be feasible for older adults, even though challenges such as fear of needles or doubts about handling them, or other physical limitations have been recognized [8,11,12].

Research advises a holistic eHealth design that integrates technologies, end users, and use contexts [13-15]. Using human-centered design (HCD) approach [16], our study aimed to support the design of eHealth for patients with CKD, especially those on HD care, by investigating user needs, concerns, and digital service barriers, and illustrating those in the format of a kidney disease experience map. Due to the high prevalence of CKD among older adults [8], both in Finland and worldwide [17], the focus of the study was set on the perspective of older adults. The research questions were as follows:

1. What experiences do patients, particularly older adults, have in their everyday lives with CKD?
2. What user needs do patients with CKD have for HD eHealth?
3. How can these needs be illustrated using the experience map technique?

The study was part of the eHealth in HD project ("device research") [18] coordinated by the Hospital District of Helsinki and Uusimaa in Finland from 2020 to 2022. The project aimed to create a novel eHealth solution for patients with CKD undergoing HD (named "Home dialysis eHealth solution") and research devices that support patients both before and throughout dialysis therapy by gathering monitoring data, managing HD supply orders, and facilitating communication between the patient and the health care team (Figure 1).

HCD of eHealth Solutions

HCD is an approach to interactive system development that aims to develop solutions with high usability and user experience [16]. The principles of HCD highlight the importance of involving end users in an iterative design process [16,19] and understanding their needs at the beginning of the development process [16,19].

When exploring user needs, researchers collect information, for example, about what features digital services should contain and how they should function from the perspectives of end users. The user needs exploration is important as it helps service designers to understand the role and meaning of the solutions for end users, in our case, patients using HD. eHealth is used to refer to digital health services, and health information offered through the internet or other technology solutions improving health care [20,21]. By designing in a human-centric way and involving end users in the development, eHealth can offer more value and new ways to provide health care and well-being services for patients and all citizens [13,21]. For patients with chronic illnesses, eHealth solutions can offer new communication possibilities between the patient and the health care team, as well as support empowerment and improve quality of life [21,22].

Patient Journey Maps and Experience Maps as Illustrations of User Needs

A patient journey map and an experience map are tools for 2 different purposes. In this study, patient journey maps were used as a part of patient interviews [23], and an experience map was used to communicate the results of the study holistically.

Patient journey maps as tools for visualizing patient journeys can be used to support the design of eHealth in several ways. The maps can help researchers and designers to identify how health care processes can be improved, for example, identify gaps and improve the processes by integrating eHealth solutions as part of those processes [24]. The patient journey maps sum up patients' experiences and care activities in a single, chronological, timeline-type visualization [24]. As the maps can help to explain what patients go through with their disease [23,24], they can help designers promote empathy, which is important in HCD [25-27]. Furthermore, they can help the sharing of knowledge between stakeholders as well as activate creative thinking [28].

Patient journey maps can be applied in various specialties regardless of the medical condition. For example, patient journey maps have been used to illustrate home isolation experiences of people with mild COVID-19 [29], hypertensive disorders in pregnancy [30], cancer [24], cervical dystonia [31], and kidney diseases [32]. In literature, the focus of patient journey maps varies from communicating patients' emotions and identifying process gaps to the importance of shared decision-making [33].

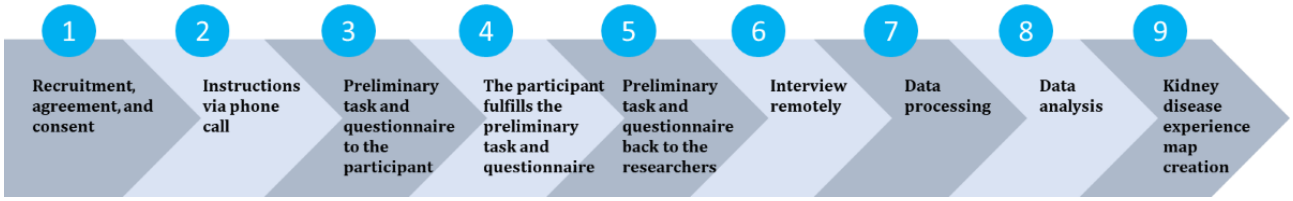
Experience maps are tools to combine situations, functions, emotions, and contacts in the same visualization [34]. Experience maps are valuable in the development of various eHealth, mobile health, and other apps, helping to communicate, for example, how cancer affects a patient's life and capturing patients' voices [35]. However, similar to patient journey maps, there is no standardized way to visualize and use them in an eHealth development context [33]. To our knowledge, no experience maps have been produced to represent the everyday life of patients with CKD using HD. Even though working with experience maps helps to identify users' needs [34], based on our literature review, few patient journey maps or experience maps focus on illustrating and communicating the needs as a basis for eHealth design and requirements specification.

Older Adults as eHealth Users

The European population is aging [36]. In Finland, >2 million citizens (ie, 36% of the population) are ≥55 years old [37]. Finnish older adults have good self-confidence in using digital services. In the 55 to 64 age group, >80% of Finns felt that their digital skills were at least on par with those of other Finns, and in the 65 to 74 age group, >60% of Finns felt the same [38]. At the same time, the number of patients in Finland who undergo dialysis, is expected to increase by >36% before 2040 [39]. Therefore, Finnish older adults seem to have both a need for and self-confidence in using CKD eHealth.

Older adults, due to an increase in diseases and complex health issues, could benefit substantially from eHealth [40]. Still, they experience several barriers to using eHealth, such as privacy concerns, lack of motivation to use digital solutions [41,42], and challenges to finding, accessing and understanding health-related information [40,43]. In addition, they have concerns about eHealth reducing the time with the physicians during appointments [42]. Although they can benefit from eHealth, they still face several challenges that could be solved with careful design.

The health situation also affects the use of the eHealth and user needs. Many eHealth tools are intended for the treatment of a specific disease. One or more chronic health conditions can lead to several regular self-management tasks [40], which can potentially affect a patient's everyday life and the use context of eHealth. Therefore, eHealth should be adapted to each user's special situation [44].



Methods

Overview

Combining different context-specific strategies is important when developing services in a complex environment, such as health care [15]. Our study on user needs of patients with CKD for eHealth used a qualitative research approach and semistructured interviews [23,45] as the primary method for data gathering. The interviews were supported with preliminary tasks, which included visualizing patient's journey in the form of a timeline drawing [23]. The procedure of the study included several phases starting from the recruitment and ending with the creation of the kidney disease experience map illustration (Figure 2).

XSL•FO
RenderX

Figure 2. Procedure of the study.

Ethical Considerations

The empirical study was conducted as part of the eHealth in HD project, which received permission from the ethical committee of the Hospital District of Helsinki and Uusimaa (HUS/1649/2020, Jarkko Ihalainen). All participants gave their voluntary, informed, and written consent. The patients' capabilities to participate in the study were ensured. While analyzing the data, the information of the patients participating in the study was pseudonymized and coded with the identification numbers. Only the researchers assigned to the study had access to the data. No compensation was paid to the participants for their participation.

Participants

In total, 18 patients aged ≥60 years participated in the study: 5 patients in predialysis phase, 4 patients in satellite dialysis, 5 patients in home peritoneal dialysis care, and 4 patients in home hemodialysis care (Table 1). Most of the participants were retired. The sample excluded in-center patients with dialysis, but included patients with dialysis in satellite units. The participants were recruited from the group of patients who were participating in the larger research project of HD eHealth solution development.

Table 1. Demographics of study participants (N=18).

Demographics	Frequency, n (%)
Dialysis	
Predialysis	5 (28)
Satellite dialysis	4 (22)
Home peritoneal dialysis	5 (28)
Home hemodialysis	4 (22)
Gender	
Woman	4 (22)
Man	14 (78)
Education	
Basic education	4 (22)
Upper secondary level	4 (22)
Bachelor's degree	5 (28)
Master's degree	3 (17)
Other	2 (11)
Technology skills (self-assessed)	
Good	6 (33)
Basic	11 (61)
Weak	1 (6)

The health care team recruited the patients by distributing materials about the study and asking about their interest in participation. Participation was voluntary and they did not get any compensation. The study participants were already familiar with the novel HD eHealth solution under development and had tested the first version of the solution. The research nurse contacted the potential participants first and informed them about the study. If the participants wanted to participate in the study, they signed the consent form, and the research nurse provided their contact information to the researchers. Then, the research material package, prepared by the researchers, consisting of a cover letter, a preliminary interview task, background information forms, and the responsible researcher's contact details were sent to the participants. After sending the package to the participants, the researcher called them to provide more detailed instructions, answer any questions, and schedule a time for the remote interview.

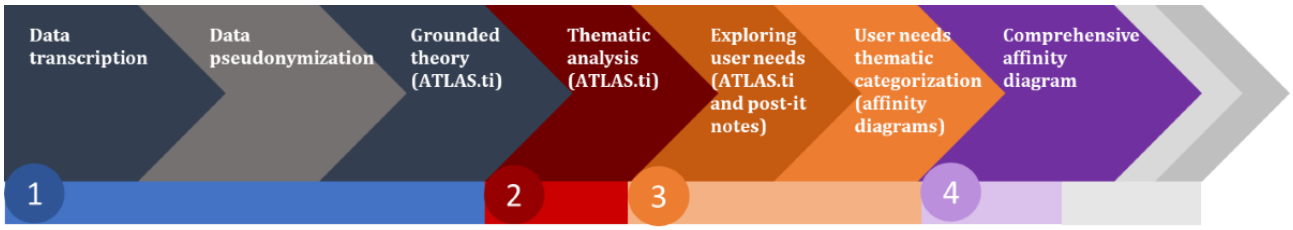
XSL•FO
RenderX

Preliminary Tasks and Retrospective Interviews

Interviews are useful in the phases of any development process related to eHealth [15]. In our study, retrospective interviews included questions about the patient's journey, treatments experiences, cooperation with the health care team, technology experiences, and visions for the future. The themes broadly covered patients' everyday experiences with the illness, practical questions, and the comprehensive timeline with CKD.

The idea of the visual timeline drawing as the preliminary task for the interview was to (1) help the interviewee to process and structure their multistage patient path even before the interview, and (2) help with communication between the interviewee and researcher during the remote interview [23]. The preliminary task was sent to the interviewees 2 weeks before each interview. In this task, patients were asked to identify and illustrate significant milestones, events, and experiences with their illness to a timeline. The patients returned the task to the researchers before the remote interview.

The interviews were conducted between October 2020 and April 2021 when the second wave of COVID-19 was underway in Finland. For safety reasons, the interviews were arranged remotely via Microsoft Teams. Two researchers were present in the interview session with the participating patient: one researcher being the interviewer and the other note-taker. Interviews were audio-recorded using recording functionality of Microsoft Teams. Data gathering was conducted in collaboration with 5 researchers (SL, NK, JV, SH, and PV): 2 doctoral researchers, 2 students, and a professor from the human-computer interaction field.



Data and Analysis

Overview

The data included recordings and notes from the interviews, as well as illustrations of patient journeys. The interview notes were finalized according to audio recordings and the transcriptions were pseudonymized. In total, the data consisted of 155 pages (ie, 58,429 words) of written notes and 18 paper-based patient journey visualizations (ie, visual timeline drawings). A total of 5 researchers (SL, NK, JV, SH, and PV) participated in the data analysis.

The data were analyzed in 4 phases (Figure 3): (1) grounded theory analysis, (2) thematic analysis, (3) user needs exploration and thematic categorization, and (4) comprehensive affinity diagram creation. The data included many different perspectives to understand the different nuances and ensure reliability, and the analysis was done in collaboration with several researchers in many phases.

Figure 3. Four phases of data analysis.

Phase 1: Grounded Theory Analysis

In the first phase [46], the pseudonymized interview transcripts were analyzed following the main structure of grounded theory [47,48] using ATLAS.ti software version 9.1.5.0 (ATLAS.ti Scientific Software Development GmbH, "ATLAS.ti") [46]. During the analysis, the interview data was coded using researcher-denoted concepts and open coding influenced by the grounded theory [46,47]. The first round of interview data analysis following grounded theory was conducted by SL.

Phase 2: Thematic Analysis

In the second phase, the principles of the thematic analysis method [48,49] were followed to analyze the interview data from 18 participants from an existentialist perspective, including references to death, well-being, and atmosphere in life (eg, emotions) [50-52]. In addition, the analysis used the holistic framework [13-15] of exploring the context of use, technology, and people.

On the basis of the analysis, 3 thematic categories were identified: healthy habits, concerns and barriers for eHealth use, and everyday life with CKD. Observations based on interview transcripts were written on post-it notes and thematically categorized following the phases of the affinity diagram method [48,49]. The data gathered using preliminary task of patient journeys were mapped in line with the interview transcripts. In addition to the initial 3 themes, 2 categories were formed based on thematic analysis: digital communication and patients' emotions. Concerns and use barriers for eHealth were investigated from the data by two researchers (PV and SH). The digital communication affinity diagram was done by three researchers (PV, SH, and JV).

The thematic analysis categories include several aspects as presented in Textbox 1.

XSL•FO
RenderX

Textbox 1. Categories of thematic analysis.

- Healthy habits: health-promoting activities and hobbies that were mentioned by interviewees, including the whole scale of activities from sports to eating habits.
- Concerns and use barriers for eHealth: observations related to everyday life challenges with the disease, use challenges and barriers of digital services, negative emotions, such as worries or dissatisfactions, and patient path challenges.
- Digital communication: observations concerning health care-related digital communication habits, channels, and experiences.
- Patients' emotions: observations of emotions and experiences interviewees mentioned in the interviews and patient journey visualizations. The emotions included the whole scale of emotions, from fear and confusion to happiness.
- Everyday life with chronic kidney disease: observations related to interviewees' thoughts, stories, and experiences of their everyday lives, including references to death. Death made the participants reflect from different perspectives: their own (forthcoming) death was compared to other deaths, the actions to avoid death were listed, and the inevitable nature of death was considered.

Finally, the frequency of observations per theme was calculated (Multimedia Appendix 1). Most of the observations were related to concerns and barriers to technology use. Emotions and healthy habits were also common topics in all the interviews.

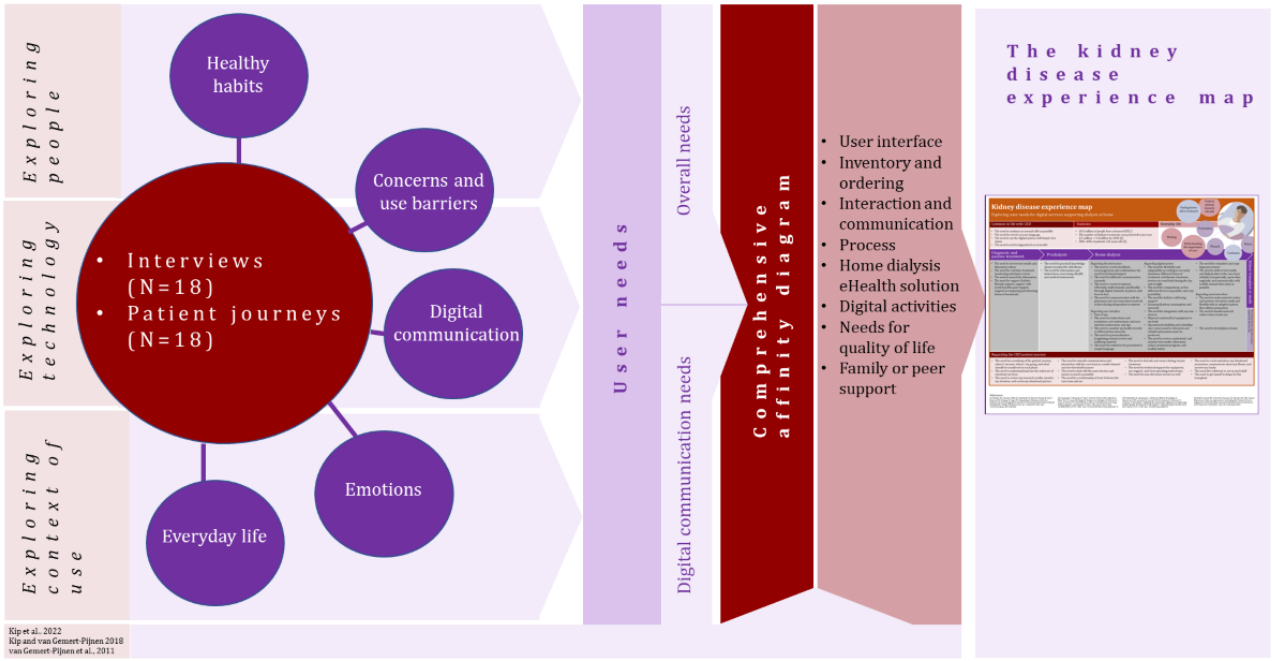
Phase 3: The User Needs Exploration and Thematic Categorization

The third phase focused on analyzing user needs. All the gathered data were explored from the viewpoint of user needs from 2 perspectives: exploring digital communication needs and exploring overall user needs for interactive solution development. In the analysis, 2 researchers (PV and SH) explored the data labeled "digital communication," "user needs," and "to eHealth solution concept" in ATLAS.ti and formulated the observations as user needs. The second round resulted in 165 needs.

After this, the digital communication affinity diagram was created in collaboration with 3 researchers (SH, JV, and PV). The user needs were written on post-it-notes by PV, and analyzed, and regrouped to the affinity diagram in collaboration with SH, JV, and PV. In the affinity diagram, the identified needs (n=165, 100%) were thematically grouped under 5 categories: overall interaction and communication (n=77, 47% of all identified needs), patients' digital activities (n=28, 17%), instruments (n=27, 16%), inventory and ordering dialysis supplies (n=19, 12%), and digital communication with the health care team (n=14, 8%). While creating the affinity diagram of digital communication needs, doubles were removed.

When exploring overall user needs, the data transcriptions of 18 interviews were analyzed using ATLAS.ti. During this analysis, the data labeled with the following codes—"user needs," "healthy habits and hobbies," "suggestion," "communication," "digital services," "tasks," "care team," "communication," "social relationships," "equipment," "challenges," "positive experiences," and "device research"—were explored and formulated as user needs. In total, 287 user needs were identified and written on post-it notes as preparation for the comprehensive affinity diagram work.

Phase 4: Comprehensive Affinity Diagram



In the fourth phase, the affinity diagrams created in the previous analysis phase were merged to form a comprehensive affinity diagram. Three researchers recategorized the post-it notes to create a comprehensive affinity diagram of user needs. The main themes of the diagram were "eHealth user interfaces," "Inventory and ordering dialysis supplies," "Overall interaction and communication," "Process," "HD eHealth solution," "Family/peer-support," "Patients' digital activities," and "Needs for improving the quality of life" (Multimedia Appendix 2). These 5 were used as the leading themes to guide the design of the first version of the kidney disease experience map. Data analysis results were discussed between PV, SH, VR, and JV.

Creation of the First Version of the Kidney Disease Experience Map

An experience map is a tool that strings the perspectives of the context of use, people, and technology, together in a holistic manner [13-15]. The maps can be used to support the communication between stakeholders and to capture a patient's voice in eHealth design [35]. The first version of the kidney disease patient experience map (Figure 4) was made by combining remarks from existing example models particularly the cancer experience map [35]. In the first paper-based template of our map, the preliminary phases from the preliminary tasks (ie, patient journey maps) were illustrated: "before diagnosis," "diagnosis and passive treatment," "treatment method selection," "beginning of treatment/training," and "home dialysis." Post-it notes from the comprehensive affinity diagram were added under those phases. The first draft of the patient experience map was created in collaboration with 3 researchers.

XSL•FO
RenderX

Figure 4. Overview of the data analysis process leading to the creation of the first version of the kidney disease experience map.

Next, the structure of the experience map was refined based on the number of post-it notes in each phase. The duplicate post-it notes were removed and the content of the map was reorganized (PV, SH, and JV). To validate the contents of the draft map further, 2 researchers (PV and SH) reexamined the post-it notes after which 4 other researchers (JV, NK, SL, and VR) gave feedback on the next version of the map. After all, in total of 6 researchers (PV, SH, JV, NK, SL, and VR) participated at least somehow in the experience map visualization process. The published version of the first version of the kidney disease experience map was finalized by PV. An overview of the multiphase analysis process which led to the creation of this first version of the kidney disease experience map is illustrated in Figure 4.

Results

Overview

As the outcome of the study, the first version of the kidney disease experience map, which illustrates the user needs, concerns, and barriers of patients with CKD for eHealth, was created. This section explores the patients (ie, people), technology, and context of use perspectives [13-15]. First, patients' healthy habits are investigated and their concerns and barriers to technology are addressed. Then, the technology is examined, concentrating on digital communication. Finally, the context of use from the perspective of patients' everyday lives is explored. Due to sensitive personal issues, research results and citations are presented without identification information to ensure complete anonymity of the participants.

Exploring the People: Healthy Habits

The patients had different needs for healthy habits regarding social life, sports, and other activities (Multimedia Appendix 3). Patients mentioned that social life and taking care of close relatives, such as grandchildren, were important to them. Incidental exercises, including gardening or shoveling snow, were popular. Being in nature, picking mushrooms or berries, fishing, and hiking, along with other everyday life activities, such as club and society activities or studying, brought well-being to the participants. Animals, for example, dogs, cats, and summer chickens, also supported the participants' well-being. Handcrafting, art, and culture were also seen as important, but COVID-19 restricted those activities. The importance of many remote social contacts was mentioned in the data, and patients had to learn new eating habits, such as losing weight or cutting down on alcohol consumption.

Exploring the People: Concerns and Barriers for eHealth Use

Patients were challenged with poorly functioning available eHealth solutions and also experienced other negative factors, such as lack of interest or lack of skills (Multimedia Appendix 4). Technical devices did not always meet the emotional or physical needs of their users. This caused emotions like frustration, worry, and fear from patients. The patients' responses covered their available eHealth solutions, not focusing especially on the HD eHealth solution.

The solution or software used by patients for their CKD care was found to function poorly in many ways. For example, the devices as a part of the HD eHealth solution did not work as expected, or they worked differently than they expected:

> *I have no control over the information. If I measure my blood pressure, I press the BT button and then it should be delivered, but I don't know if it did. The same goes for the scale, *beep*, and maybe it synchronized.* [P18]

Alongside poorly functioning devices, in some cases, the HD eHealth app also did not work well. The software content (eg, one's results or visualizations of one's health situations) was challenging to understand or find. The HD eHealth app was challenging to use with small mobile phone screens and its user interface terminology caused problems for patients:

XSL•FO
RenderX

> *There have been a few problems with the phone. There will be updates and then it will freeze somehow. I don't understand much; the basic things are in Finnish, but then they are English words so... This was at least the third time that the nurse had visited us.* [P17]

> *Others have also worked well. Even the mobile phone. You can monitor your health from it, even though it has those [health status] curves that you don't understand much about.* [P13]

The participants doubted the functionality of the HD eHealth solution, both devices and the app. With the dialysis monitor, they were worried that something would go wrong:

> *I haven't used (ie, the devices and instruments) much, I've just tried. I'm a bit lazy. I doubt whether the instrument is still in good condition. There was an error message about a month ago. There was a notification that there was still something wrong. I thought I'd let it be and fix the instrument before I started.* [P24]

> *When the first treatments started, it was so exciting. But after a month had passed, it had become routine and was no longer exciting. Then, when I moved home from hospital, I started to get excited again.* [P22]

Exploring the Technology: Digital Communication

Overview

Patients commented on digital devices and the app from many different aspects in terms of the technical functionality and the emotion they cause. The contents of the solution's user interface (Figure 1), as well as other user interfaces, were also commented on. Patients linked and communicated with the health care team through digital channels and used technology independently as a part of their HD treatment during the research.

Many Groups Communicate With the Patient

Communication within the health care team is important, but also nurses, physicians, and patients share information (Multimedia Appendix 2). To get the supplies and instruments needed for HD care, the patient also needs to be in regular contact with the pharmacy or the health care team. Relatives must not be forgotten either, as patients may want to share information with them:

> *To be able to get in touch with the on-call nephrologist or the other way around, perhaps you could organize a little more frequent meeting. I think that many patients could have questions for the doctor that the nurses cannot or are not allowed to answer. Nephrologist on-call from the computer.* [P24]

Examples of Current Communication Channels

Depending on the patients' devices and patients' capabilities to use them, HD patients use different communication channels for following their health records and CKD-specific operations. They order HD supplies once per month. Some patients have created their digital tools (eg, Excel sheets), which calculate the number of needed supplies automatically. After that, the order will be sent via email to the nurse. Still, Excel sheets or other tools for ordering dialysis supplies are not an option for everybody. Therefore, an easy-to-use solution for ordering supplies and managing inventory is needed for HD patients:

> *Orders must be sent once a month. I have an Excel sheet that automatically keeps the balances. Then, there is a page where you can automatically see what needs to be ordered. I have made Excel sheets myself. It's quite a job when there are more than 30 different supplies. Syringes... you must know their numbers. Sometimes, I also check some information. If one item is true, then so are all the others. It's automatic. I then make a .pdf list from the Excel sheet, one A4, and then it goes [by e-mail to the nurse].* [P30]

In Finland, patients follow their health records via national or local patient portals (eg, "My Kanta Pages" [53] or "MyChart" [54]). Patients with chronic illness have many laboratory tests taken. They appreciate that all their health records are found in one place, but each record is shown in detail separately, too. Therefore, easy-to-read visualizations of test results and current health situations are needed:

> *MyChart is as hopeless as My Kanta, both of which break down the lab results separately, even if they want to see them as a whole. Applying for your results is difficult.* [P37]

> *I look at the results on 'My Kanta,' all diagnoses come there, as well as laboratory test results. From there, I can see them all. The information is readable and remains stored. I think 'My Kanta' is really good. There you can also see laboratory visits from a certain period if you want to follow a limited period.* [P21]

Positive Attitude Toward Digital Communication

All patients participating in the study seemed to have a positive attitude toward digital communication tools. For example, paper-based dialysis supply orderings may be forgotten and instead, digital tools can step in and help patients with their everyday lives. Patients felt that digital solutions enabled information-seeking and offered more flexibility in meetings with the health care team and other contacts:

> *Their version is that they hand out an A4 paper. You should fill it in; it's difficult manually. The risk is that you forget.* [P30]

> *We have internet and e-mail. My wife uses them more; I just read. The wife handles banking and other things remotely. I kind of stopped using the computer when I don't need to. You could probably handle things digitally. I haven't come across anything like that. I have had to deal with a lot of paper. I have not been approached digitally. Yes, it would be even easier. You could reach the staff at any time.* [P24]

XSL•FO
RenderX

Exploring the Context of Use: Everyday Life and Emotions

Overview

The main themes related to everyday life were thinking of death, the importance of care, changes in well-being after treatment started, and emotions (Multimedia Appendix 5).

The Presence of Death

With kidney disease, death is present in life. It is known that without dialysis or receiving a transplant, one dies. The logic of the disease is unequivocal: when dialysis no longer helps, the person knows they are going to die:

> *I think that the disease is deadly and must be treated.* [P21]
>
> *Everyone knows that life ends eventually, but I'm not afraid of it in any way.* [P1]

The General Well-Being of the Participants Varied

The patients understood the essentiality of treatment and often felt better after the treatment started. They wished to be able to continue life as normally as possible. One patient (P9) described experiencing leg cramps at night, which had caused them to sleep poorly. After the dialysis treatment started, the cramps stopped. They managed better than before and could even go for walks:

> *I hope I don't end up on dialysis. Of course, it is ahead, but hopefully as far as possible. It is a wish.* [P20]
>
> *It's just that now I feel like I'm getting older. I recently turned 70, so all kinds of unnecessary aches and pains will increase.* [P25]

Everyday Life Is Characterized by Waiting

The health situation of a patient can be improved either with dialysis or a transplant. Having to wait for transplant can have major setbacks; one patient (P24) had to be removed from the transplantation waiting list due to amputation and sepsis, which is why they now focus on keeping themselves in the best possible physical condition through physical activities. Patients were waiting to travel.

A Wide Range of Emotions in Everyday Life

A wide range of emotions appeared in the interview data about the patient's everyday life. Despite the challenges of the disease, most of the patients described their lives with the disease in somewhat positive terms. Everyday life with the disease seemed to go somewhat smoothly.

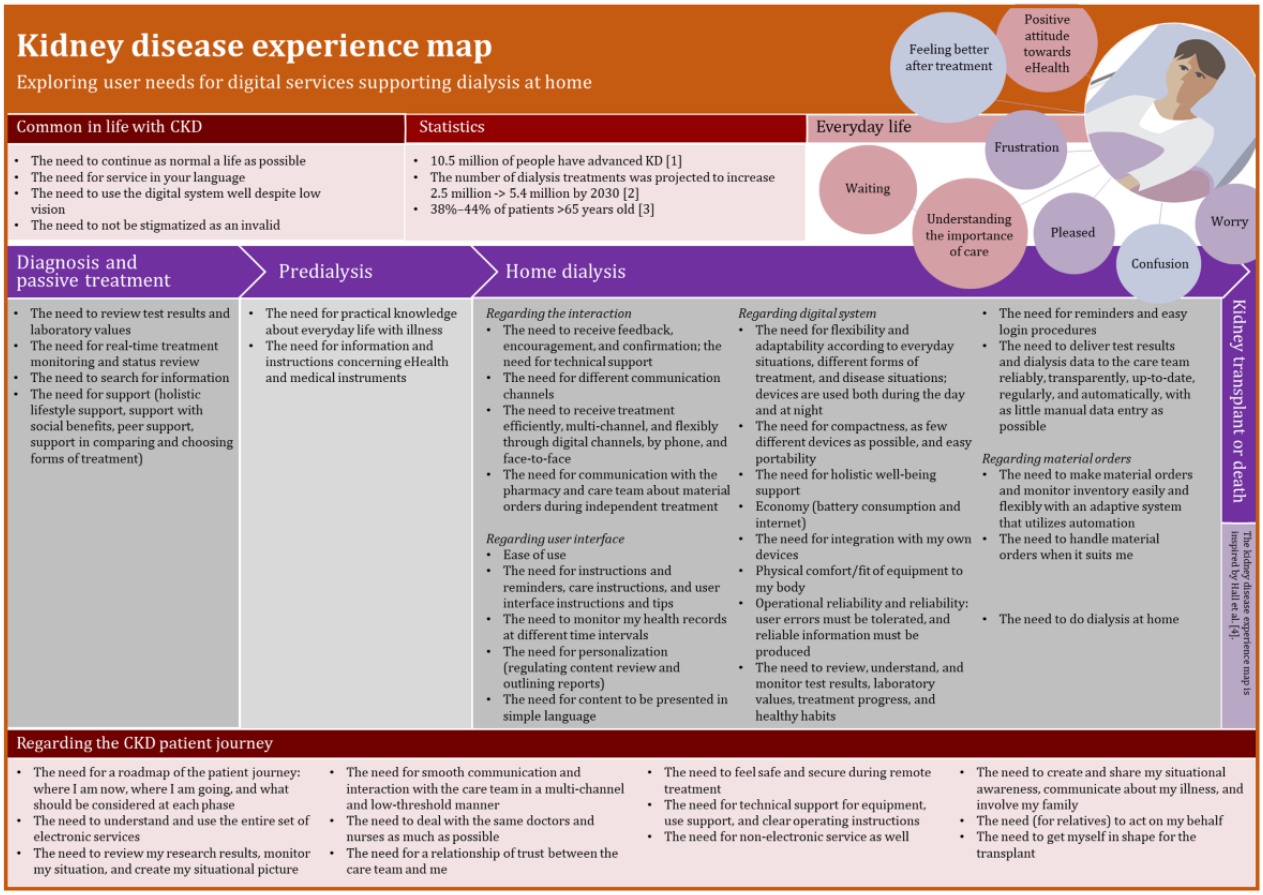
In addition to positive feelings, patients also expressed negative emotions, such as confusion, fear, irritation, anger, and frustration. Feelings of confusion were caused by changes in health status and events in the patient's journey, uncertainty of the future steps in the journey, or technology that worked unexpectedly. After receiving the diagnosis, one patient was confused because they did not fully understand what kind of disease the diagnosis was about. Several patients brought up fear in the interviews. Things related to the treatments were especially scary. Most of the patients also described irritation or anger at least sometimes during the patient journey. In addition, half of the patients reported frustration. Health challenges, the difficulty or even failure of a treatment, and the commitment to dialysis treatment were irritating. The most frustrating thing was when HD treatment did not go as well as planned. Another source of frustration was digital systems, equipment, and devices:

> *And a little fear. I am quite hopeful that I will get there on the transplantation waiting list and that it will be successful at some point. I hope that I can make it there (ie, from a health perspective), and if this continues, then there is nothing to worry about.* [P11]
>
> *Actigraphy, a part of HD eHealth solution, is inconvenient, but there is nothing wrong with the other devices, everything is fine. I have a strong belief that information will go forward. It's enough for me to see on the scale and blood pressure monitor that my weight and blood pressure are okay.* [P18]
>
> *This home dialysis takes up a lot of space. Do you see these boxes? A huge package comes once a month. The dialysis monitor also takes up quite a lot of space. And then the cabinets, where you put all the treatment consumables. And there is a bottle like this: hand sanitizer comes once a month. Quite a lot of supplies come from the hospital once a month. This room is completely reserved for dialysis.* [P30]

HD taking up too much space or other resources was both irritating and frustrating. HD requires much space at home, so some patients had to renovate their homes. However, almost half of the patients felt that their living conditions did not require changes due to HD. The patients felt it was important that the dialysis treatment could also be done at the summer cottage.

Positive emotions included joy, optimism, hope, and satisfaction. A third of the patients mentioned joy in the interviews and most patients expressed hope and optimism. They were satisfied with the professional staff and the stability of the current situation. The supportive and successful dialysis made them happy. Keeping their health situation stable was their biggest wish. Patients also mentioned their willingness to continue their hobbies.

The patients were satisfied with both their health condition and the information related to it. Half of them were satisfied with the treatment. The patients were pleased with the eHealth solution in use during the study and the HD treatment was experienced as proceeding smoothly. The nursing staff was considered friendly and knowledgeable:



> *I have been very satisfied. They, the care team, have guided me, and when I have challenged them, they have accepted challenges and promised to sort things out.* [P37]
>
> *Home dialysis has gone surprisingly well—no major problems.* [P34]
>
> *At least now, this present moment looks bright.* [P13]

The First Version of the Kidney Disease Experience Map

The first version of the kidney disease experience map (Figure 5 [1-3,35]) was developed from the perspective of user needs of eHealth. It includes their needs for everyday life with CKD (ie, "Common needs"), needs relating to 4 phases of the journey of patients with CKD, and needs in all journey phases of patient with CKD from diagnosis to kidney transplant or death. The patient journey phases, which are inspired by the experience timeline of cancer experience map [35], are "Diagnosis and passive treatment," "Predialysis," "HD," and "Preparing for kidney transplant or death." In the top corner of our map kidney disease statistics and patients' everyday life experiences with CKD are illustrated.

Figure 5. The first version of the kidney disease experience map from a user needs perspective. A higher resolution image is available in Multimedia Appendix 6. CKD: chronic kidney disease. KD: kidney disease.

The first version of the kidney disease experience map (Figure 5) includes aspects from all three perspectives [13-15]:

1. Context of use: the context of use perspective can be found especially in the patient journey phases and the "everyday life with CKD" part of the map.
2. People: information about people is available in the "statistics and everyday life with CKD" parts of the map.
3. Technology: technology aspects are mainly covered in the form of user needs.

Discussion

Principal Findings

On the basis of our study, eHealth as a part of the daily lives of the patients with CKD was perceived as being useful, but the patients also had challenges with devices and apps. Acknowledging that CKD is a long-lasting journey, it is essential to consider long-term user experiences. Finally, several user needs in different phases of the journey of patients with CKD were identified and illustrated with the first version of the kidney disease experience map.

Answers to Research Questions

Overview

This study had three research questions: (1) what experiences do patients, particularly older adults, have in their everyday lives with CKD; (2) what user needs do patients with CKD have for HD eHealth; and (3) how can these needs be illustrated using the experience map technique?

XSL•FO
RenderX

What Experiences Do Patients, Particularly Older Adults, Have in Their Lives With CKD?

Three key experiences related to daily life of patients with CKD were identified as depicted in Textbox 2

Textbox 2. Key experiences related to daily life of patients with chronic kidney disease (CKD).

- Patients' healthy habits: patients with CKD must adapt to the changes in their everyday lives resulting from dialysis care. For example, patients must learn new routines for their treatment at home. Patients felt that CKD limited their lives, but they dealt with it in different ways: some were frustrated and others continued to live as normally as possible. However, they understood the necessity of the treatment and continued the treatment as usual. Similar findings were reported from a study involving cancer patients [35], who expressed concerns with unknown, life-threatening, and life-changing experiences.
- Patients' concerns and barriers to use for eHealth: patients had challenges with user interface and technical devices, including dialysis monitors and research devices of HD eHealth solution (Figure 1), that did not always meet the users' needs.
- Digital communication: digital communication opportunities via the eHealth solution play an important role for patients. Digital solutions made information-seeking possible and offered more flexibility when meeting the health care team and other contacts. Information gaps did not accumulate as easily as for cancer [24].

What User Needs Do Patients With CKD Have for HD eHealth?

In our study, both general needs and needs related to different patient journey phases were identified and illustrated in the first version of the kidney disease experience map (Figure 5). We found that CKD was different from day to day, and thus the use context of eHealth varied. Poor usability burdens the everyday life of a person with disease even more. Similar observations were reported in the case of digital independent living supporting systems of older adults [34]: designers were important to understand the treatment stage, the transition from health to illness, and statuses between them. Furthermore, the needs and experiences of patients with cancer were found to vary during the care process [35].

The HD eHealth solution is targeted to all patients with CKD, as well as individuals with disabilities, such as low vision or even amputated limbs. The solution is to be used during the entire patient journey, which may last for years. Considering this, the HD eHealth solution is observed to play a remarkable role in the patient's life and highlights the need for research on long-term user experience.

How Can the User Needs Be Illustrated Using the Experience Map Technique?

Typically, user needs are illustrated with use cases or user needs tables, and they can be processed further to requirements format [55]. Findings from user research can also be presented as user profile illustrations, such as personas [15,34], stakeholder maps [15], experience maps [34], and visualizations of stakeholders [34].

In our study, we used the experience map method to illustrate user needs. As with the cancer experience map [35], we identified the phases of care and relevant themes for grouping the findings. We considered the experience map technique applicable for illustrating not only the phases but also the eHealth related needs of the patients. We found a group of general needs, which are common for all phases of care, but also needs that arise from specific phases of care. Understanding the care process and how user needs evolve is important for the designers and also for the health care team, who are responsible for introducing the services to patients and training them. Experience maps help to ensure the care continuum in service development [34].

In this study, the created experience map represents a common higher-level experience map, which can illustrate a specific persona, or the timeline could be narrower (ie, 1 month or 1 day). In the first version of the kidney disease experience map, the HD eHealth solution covers different wearable solutions and the software (ie, including the wearable solutions and software connected to the dialysis monitors); however, different physical dimensions (ie, dialysis monitors, packing materials of supplies ordered) are not covered.

Experience mapping can be seen as a promising but laborious method for illustrating user needs and communicating a patient's voice holistically to eHealth development, especially in a case where the experience map is based on extensive qualitative data. Following the example of cancer experience map [35], we captured patient's voices with their quotes. Similarly, we also focused on reporting patient quotes in the paper instead of the experience map. Therefore, the first version of the kidney disease experience map can be used both separately and with the paper. Our interpretation is that similar to the integrated patient journey map for hypertensive disorders in pregnancy [30] and the cancer experience map [35], the kidney disease experience map can help developers build effective eHealth solutions and promote empathy and shared understanding between the developing team members. It can also help empower patients and help with shared decision-making [33]. Like the patient journey map [24], the first version of the kidney disease experience map has the potential to help simplify and optimize processes for better health outcomes. In addition to that, similar to the cervical dystonia patient journey map [31], it can help to communicate the different phases of the care to the patients and help them to understand their needs at each phase.

Relevance of the Research

In the study, the experience map describing the patient's experience was formed based on the qualitative data from retrospective interviews and preliminary tasks. This first version of the kidney disease experience map can be used as a basis for other experience maps related to kidney diseases in the future. In addition, it can also bring perspective to the experience maps of other chronic diseases.

XSL•FO
RenderX

The presented results can be used to support the further development of HD eHealth. The results have already been used in HD eHealth solution development project in Finland (eg, to inform the redesign of the solution user interfaces).

Experience maps, such as the map created in the study, can help researchers, designers, and developers to empathize with the patients with chronic illnesses, and to understand their needs and use contexts for future eHealth innovations. We see our kidney disease experience map and other similar maps having the potential to help design the solutions from a more holistic perspective compared to currently prevailing practices [13,21], as well as to create a base for the new ecosystems and new ways to offer health care in the future [21]. We continue the work in the ongoing research project "Better Health at Home—Optimized Human-Centered Care of Predialysis and Home Dialysis Patients" (2022 to 2026).

Evaluation of the Study

Our study had some limitations. First, exploring the context of use was not allowed at patients' homes due to COVID-19 restrictions. Therefore, we needed to collect data remotely. This was partly problematic because the patient's home is the main context of using HD eHealth. In contrast, due to the patient journey preliminary task and participants' open-minded attitude during the interviews, we were able to gather rich data about user needs and the context of eHealth use. In our study, the possible impact of the COVID-19 period was considered.

Our sample size is quite small, however, typical for a qualitative interview study. The representativeness of our sample can be questioned as it is divided from a larger patient group based on age and treatment methods. To find as comprehensive a sample as possible, while ensuring the safety of the participants with their ongoing treatment, the health care team helped researchers in recruiting participants for the research study.

Due to the personal nature of health information and privacy, we could not release the participants' background information, such as specific ages or treatments in this paper. In addition, the indirect identifiers have been removed from the paper. The relative satisfaction of the patients in their lives despite CKD could have been influenced by various factors, besides the HD eHealth solution. First, the target group in this study included only active patients with relatively good physical conditions for research ethics reasons. Second, many of them were waiting for a kidney transplant, which brought them hope with the disease. Overall, there was a lot of variation in emotions, but deep gloom appeared in the data only rarely.

The first version of the kidney disease experience map was created based on a reasonable amount of qualitative data of the everyday lives on patients aged ≥60 years in Finland. Before participating in this study, the patients already knew that the study covered new eHealth solution testing. Therefore, perspectives from patients whose condition is very weak and those whose attitude is not open to new technology are missing in this study. In contrast, research shows that HD is optimal for those who live in areas with long distances to travel to an in-center dialysis unit [6,7]. In part, this can also be seen in the first version of the kidney disease experience map: the study did not include patient experiences during the kidney transplant phase—meaning that the user needs related to this essential phase of the patient journey are missing from our map. In future, the introduced version of the kidney disease experience map can be updated by including motivational issues for HD.

The study was conducted as an integrated part of the patient's normal CKD treatment, so the research setup was organized in line with the patients' typical daily conditions and treatments. The study included participants who started using the HD eHealth solution shortly before the interviews but also those who had already been using the solution for several months. Thus, the study covered both novice users and more experienced users. Patients' reported technology skills varied from weak to good.

Further Research

This study provided initial experiences of creating an experience map to illustrate patients' needs for eHealth. In addition, the patients' experiences from the HD eHealth solution development can offer important perspectives to other development projects regarding patients with CKD. Further research is needed to gather more experience about the applicability of the method. We aim to continue the research with patients with CKD and HD eHealth designs. We will use the illustrated first version of the kidney disease experience map and the listed user needs in further analysis, which will aim to describe design principles and guidelines for HCD of eHealth for patients using HD and other patients with chronic illnesses.

The outcome of the first version of the kidney disease experience map offers insights to the different phases of the patient journey for patients with kidney disease at the HD care. Due to the diverse experiences of patients in different phases of the care process, different types of kidney diseases could also be studied and visualized with experience maps. In addition, the next versions of the kidney disease experience maps could focus on specific days and months. The next versions of the kidney disease experience maps could also be created from the health care team's perspective.

The content of the first version of the kidney disease experience map was collected with qualitative research methods, which made the consideration of the many different nuances possible. Due to the qualitative nature of the data collection for the first version of the kidney disease experience map, we did not prioritize the available content, for example, based on the amount of the post-it notes. However, without careful prioritization, there is always a risk that the map is too challenging to use as a part of the practical software development work. Therefore, we will involve the patients, as well as the health care team, designers, and software developers, in prioritizing the content of the map in the future.

The perspectives of patients using in-center dialysis are missing from that data, which was the base of the first version of the kidney disease experience map. However, we believe the creation of experience maps for the eHealth needs of patients using in-center dialysis is important for the future as the dialysis modalities might change depending on the patient's health and life situation.

XSL•FO
RenderX

Our study pointed out the need for further research on the existentialism perspectives of the patients with chronic illnesses using eHealth. Deeper understanding is required on user needs and the role of eHealth as a part of patients' everyday lives, even when life is nearing its end [50-52].

Conclusions

eHealth offers possibilities to support the key needs of patients with chronic diseases, such as CKD; however, digital services need to adapt to a wide variety of situations and user needs because kidney diseases are unique to each patient. Patient experiences vary both between and within the stages of treatment. In addition, the patient's situation, needs, and capacity to use eHealth vary with everyday challenges and opportunities. Furthermore, with older adult patients, the problems that come with age increase the spectrum of barriers to use eHealth and associated challenges.

eHealth should enable proactive communication between the patient and the health care team. Furthermore, awareness of the status should be formed for both parties in real time, as much as possible. In this way, the patients feel safe, are more motivated in their treatment, and take responsibility for themselves.

The experience map is a promising method for illustrating user needs for eHealth, communicating a patient's voice and describing the longitudinal patient journey to support eHealth development. Our first version of the kidney disease experience map combines people, context of use, and technology perspectives holistically and illustrates the eHealth needs of patients with CKD for the future.

Acknowledgments

The project eHealth in Home Dialysis was part of the CleverHealth Network ecosystem and the project (eCare for Me Homedialysis) was funded by participating companies, the Hospital District of Helsinki and Uusimaa, and Business Finland. We thank our project partners Tiina Puurtinen and Pirgit Silvast-Äikäs from Helsinki University Hospital and Malin Ekholm from Helsinki University, and the patients who participated in this study.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the ethical reasons as stated in the research permit application.

Authors' Contributions

The study was conceptualized by PV, SL, SH, NK, VR, and JV. Data were collected by five researchers (PV, SH, SL, NK, and JV). PV, SL, and SH were involved in the methodology, investigation, project administration, data curation, visualizations, and formal analysis of the study. PV finalized the experience map. JV contributed to the resources, validation, supervision, project administration, and funding acquisition of the study. VR contributed to funding acquisition, project administration, resource collection, supervision, and results' validation. All authors were involved in writing, reviewing, and editing the manuscript.

Abstract

Background: Telehealth has grown, especially during the COVID-19 pandemic, improving access for those in remote or underserved areas. However, its implementation faces technological, practical, and interpersonal barriers.

Objective: The aim of this study was to identify and consolidate best practices for telehealth delivery, specifically for video call sessions, by synthesizing the insights of health care professionals across various disciplines.

Methods: We first identified 15 common telehealth barriers from a preceding scoping review. Subsequently, a modified Delphi method was used, involving 9 health care professionals (physiotherapists, speech and language therapists, dietitians, and midwife) with telehealth experience in qualitative interviews and 2 iterative rounds of web-based surveys to form consensus.

Results: This study addressed 15 telehealth barriers and identified 105 best practices. Among these, 20 are technology-related and 85 concern health care practices. Emphasis was placed on setting up telehealth environments, ensuring safety, building relationships and trust, using nonmanual methods, and enhancing observation and assessment skills. Best practice recommendations for dealing with patients or caregiver skepticism or lack of telehealth-specific knowledge were developed. Further, approaches for unstable networks and privacy and IT security issues were identified. Areas with fewer best practices were the lack of technology skills or technology access, unreliability of hardware and software, increased workload, and a lack of caregiver support.

Conclusions: This guide of best practices serves as an actionable resource for health care providers to navigate the complexities of telehealth. Despite a small participant sample and the potential for profession-specific biases, the findings provide a foundation for improving telehealth services and inform future research for its application and education.

Introduction

Video call–based telehealth refers to the use of information and communication technologies to deliver health care services remotely and synchronously, bridging the gap between patients and health care providers [1]. Over the past few years, telehealth has seen an increase in adoption due to its potential to improve access to health care services, particularly for individuals living in rural or remote areas [2]. The COVID-19 pandemic has further accelerated this trend, as the need for remote health care solutions to reduce the risk of infection transmission has become more urgent [3]. As a result, telehealth has emerged as an essential part of modern health care delivery, offering new opportunities and challenges for both patients and health care providers.

Telehealth has the potential to offer numerous advantages and benefits for patients, health care providers, and the overall health care system. Benefits summarized in previous reviews include, for example, increased access and convenience, cost savings, improved family involvement, and better management [4]. Increased access refers particularly to individuals living in remote or underserved areas [2], as well as to those with mobility limitations or chronic conditions that require frequent monitoring [5]. Furthermore, telehealth enables patients to receive care from the comfort of their own homes, reducing the need for travel and waiting times associated with in-person appointments and providing a more convenient way of service provision [6]. By reducing travel costs, decreasing hospital readmissions, and minimizing the need for in-person consultations, telehealth might also have the potential to reduce health care costs for both patients and providers [7,8].

Despite its numerous advantages, telehealth also faces several challenges and barriers that can hinder its successful implementation. Recent studies and reviews have highlighted various obstacles to delivering care via real-time video consultations. These include technical issues such as unstable internet connectivity [4,9,10], lack of technology skills among both patients and providers [4,9,11], and concerns over privacy and data security [9,12]. Moreover, health care professionals have reported challenges in establishing rapport and trust with patients via video call [9,11], and there exists skepticism about the effectiveness of remote care compared to in-person sessions [9]. Addressing these barriers is especially critical when considering the rapid shift to telehealth prompted by the COVID-19 pandemic, which has underscored the potential benefits of video consultations but also exposed the need for clearer guidelines to ensure quality of care [9,13]. Despite growing evidence on these challenges, the literature lacks a comprehensive set of actionable best practices to mitigate barriers associated with video consultations. This study therefore aims to fill that gap by drawing on multiple health care disciplines and using a modified Delphi process to achieve expert consensus on best practices to maximize the potential benefits of video call–based telehealth for patients, health care providers, and the overall health care system [14].

Methods

Overview

In this study, we used a modified Delphi method [15] to identify best practices to overcome common barriers in video call–based telehealth. The reporting follows the proposed Delphi reporting guideline by Spranger et al [16].

Research Paradigm

The epistemological positioning of this study is based on a pragmatic paradigm that recognizes the value of diverse viewpoints and the importance of practical solutions to real-world problems. Pragmatism has been identified as relevant and useful for qualitative research on organizational processes [17], as well as in patient-oriented research [18]. This approach also aligns with the goals of the modified Delphi method, which aims to synthesize expert knowledge into actionable best practices. It acknowledges the dynamic and iterative nature of knowledge creation and embraces subjective experiences to address the complex challenges of telehealth implementation.

Study Design

Our modified Delphi method was characterized by 2 main adaptations to the traditional Delphi process. First, we used preliminary expert interviews to gather an initial pool of best practices. These interviews guided the development of a list of 131 practice statements and 15 barriers, which were then presented to the expert panel for rating. Second, our survey structure diverged from a classic Delphi by using (1) a 4-point Likert scale and (2) an additional response option “This practice is not relevant for my profession.” This allowed professionals from various health care disciplines to opt out of rating statements they found inapplicable. We also set specific thresholds for acceptance (≥80% agreement after round 1; ≥75% agreement after round 2) to ensure each item reached a robust consensus without necessitating a third round. These modifications provided a more streamlined approach and helped account for the diverse professional backgrounds of the participants and time and resource limitations.

Recruitment

We recruited participants via a combination of email invitations, professional social media groups, and a snowball sampling strategy. Known telehealth practitioners were first contacted directly by the research team and then invited to share the invitation within their professional networks. To ensure broad representation across allied health professions, we distributed the study invitation to professional associations and specialized digital communities. To be eligible, participants had to (1) have at least 2 years of professional experience in a non-physician health care field (eg, nursing, dietetics, occupational therapy, speech-language therapy, physiotherapy, orthoptics, or

XSL•FO
RenderX

midwifery), (2) have delivered a minimum of 10 video call–based telehealth sessions in the preceding quarter, and (3) have excellent German language proficiency. All participants were given detailed information about the study objectives, procedures, and time commitments.

Participants

A total of 9 health care professionals (4 physiotherapists (PTs), 3 speech and language therapists (SLTs), 1 dietitian, and 1 midwife) were purposively recruited based on their experience with telehealth. All participants were licensed and currently practicing health care professionals with at least 2 years of experience in their field. They each had conducted a minimum of 10 video-based telehealth sessions in the preceding quarter and practiced in an area where telehealth is applicable. Their professional experience ranged from 2 to 32 years, and encompassed diverse health care settings such as neurorehabilitation, musculoskeletal care, adults, and pediatric care, bariatric medicine, mixed practice settings, respiratory therapy, independent midwifery, and pelvic health. In total, 4 panelists were female and 5 were male.

Interviews

The expert interviews were conducted using Zoom videoconferencing software (Zoom Video Communications) in September 2022. Specifically, 4 interview sessions took place: 3 small-group focus groups and 1 individual interview. Focus group 1 included 2 PTs and lasted 1 hour 34 minutes; focus group 2 included 2 SLTs and lasted 1 hour 3 minutes; and focus group 3 included 2 PTs, 1 SLT, and 1 dietitian, lasting 1 hour and 32 minutes. The one-on-one interview was conducted with a midwife and lasted 29 minutes. We used a semistructured interview guide to help focus the discussions, which was based on commonly reported barriers with video call–based telehealth, found in the existing research for these health care fields (Multimedia Appendix 1). All interviews were conducted by the lead author (LR), who is experienced in qualitative research methods and trained in facilitating interviews and focus groups.

The barriers discussed during the expert interviews were identified through a preceding scoping review [9]: Lack of technology access, unstable internet connections, lack of privacy & IT security, lack of technology skills, unreliability of hardware and software, reluctance of patients or caregivers to use telehealth, decreased establishment of relationships and trust, decreased validity of observations and assessments, lack of hands-on methods, decreased quality and effectiveness, lack of telehealth training, increased workload, lack of support for patients from caregivers, increased safety risks for patients, and unsuitability of setting for telehealth. Experts were asked to provide insights and best practices for addressing these barriers, based on their experience.

Each interview was transcribed verbatim by the lead author (LR) with support from an automated transcription software. After automated transcription, LR reviewed the transcripts to ensure accuracy and fidelity to the original recordings. The final transcripts were analyzed using qualitative content analysis, following the framework proposed by Kuckartz and Rädiker [19]. The first author (LR) conducted the initial deductive coding by extracting passages that contained strategies for overcoming telehealth barriers. These excerpts were then assigned to the corresponding barriers. For each identified strategy, the main characteristics and essential elements were extracted to form a clear and actionable statement. To enhance the reliability of the coding, the research team engaged in multiple team rounds to discuss the initial findings. During these sessions, the team identified similarities across different strategies, combined overlapping or related strategies to reduce redundancy, and formulated precise statements that accurately captured the essence of each strategy. Through iterative discussions, codes were refined and adjusted to better represent the data, thereby enhancing the credibility of the findings.

Ethical Considerations

Prior to participation, all individuals provided informed consent, thereby ensuring ethical compliance and voluntary engagement in the study. The ethics committee confirmed the adherence to ethical principles, and an ethical approval was not required as the study involved only expert consultations without collecting or processing sensitive patient data. All participants gave informed consent, and data collection did not involve patient data. The Ethics Committee for Research Activities of FH Campus Wien, University of Applied Sciences, confirmed that no formal approval was needed for this study (EK 243/2025). The participants did not receive any financial compensation.

Delphi Rounds

Following the qualitative interviews, we conducted Delphi rounds to achieve expert consensus on best practices for video call–based telehealth. The Delphi process was carried out in 2 rounds. Round 1 was initiated at the beginning of November 2022 and remained open for 2 weeks. During this round, panelists received a web-based survey containing a demographic data section, including name and profession, and 15 sections on barriers and corresponding strategies. Round 2 was conducted at the end of November and beginning of December 2022, also open for 2 weeks. In this round, panelists were presented with a survey of 11 sections with the remaining best practices that were lacking consensus.

Barriers

Barriers were rated for their perceived magnitude (1=very small barrier, 2=rather small barrier, 3=rather big barrier, 4=very big barrier) in round 1. Frequency distributions were calculated to determine the perceived magnitude of each barrier among panelists. These results serve to contextualize the forthcoming best practice recommendations.

Analysis of Best Practices

Best practices, on the other hand, were rated for their perceived helpfulness (1=not helpful, 2=rather not helpful, 3=rather helpful, 4=very helpful). In recognition of the diverse professional backgrounds of the panelists, the survey items included an additional response option: “This practice is not relevant for my profession.” Additionally, the survey invited the panelists to contribute further comments and propose new best practices not previously covered, thereby contributing to a more comprehensive dataset.

XSL•FO
RenderX

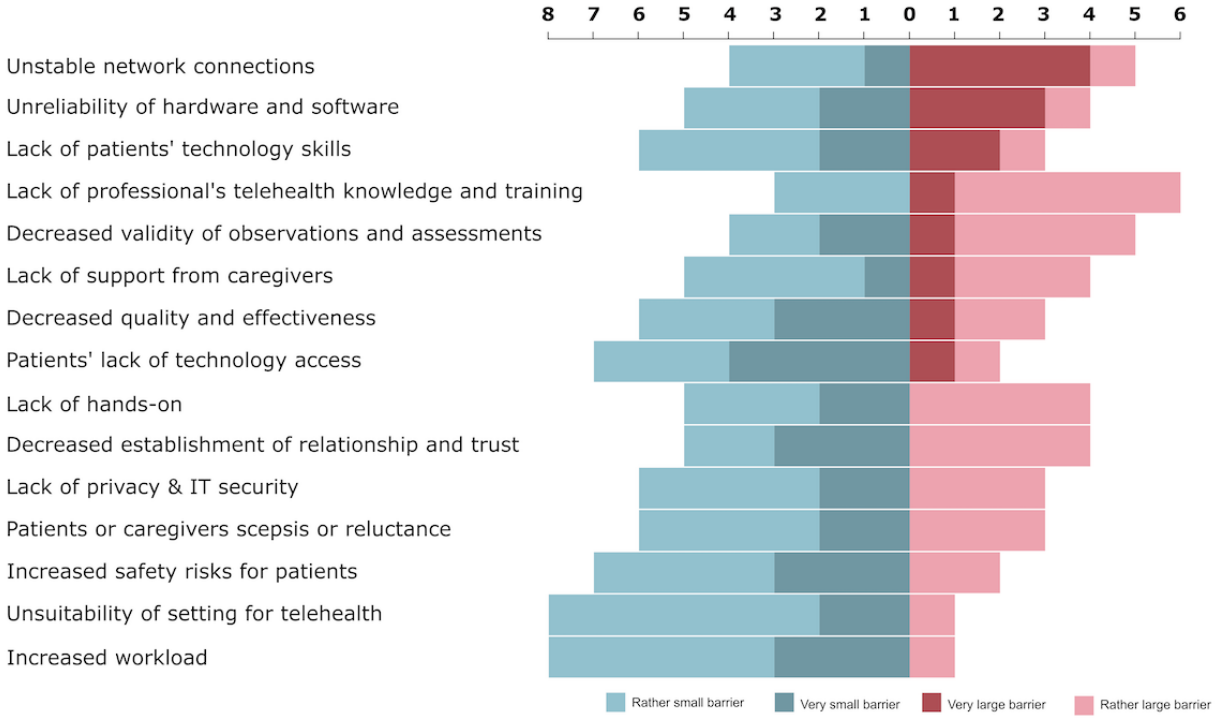
Response percentages were calculated, and the perceived helpfulness of each practice was quantified using frequency distributions for each response category. Following the first survey round, any practice that received a "helpful" or "very helpful" rating from ≥80% of participants and elicited no comments was automatically included in the final guide. Practices with ratings between 50% and 79% or those that received substantive comments moved on to the second round for reevaluation. Regarding practices rated "helpful" or "very helpful" by <50% of participants, we weighed the risk of prematurely discarding potentially relevant items against the need to maintain focus on practices demonstrating at least a minimal level of acceptance by the panel. After careful consideration, the study team decided to exclude these practices immediately following round 1, rather than carrying them forward. However, participants were given opportunities to propose modifications or new practices at the end of each round, ensuring that any critical practice could be reintroduced or reframed if panelists believed it had merit. The research team discussed all received comments and considered if any rephrasing based on the comments should be made. In case the comments led to a rephrasing of a best practice, both the original and revised versions were presented in the second round for further evaluation. During this round, panelists were provided with the remaining best practices along with the percentage of previous agreement and anonymized comments for each best practice in December 2022. Participants were offered 2 response options: "This practice should be included in the best practice guide" or "This practice should not be included in the best practice guide." When 2 variations of a practice were presented, panelists could select their preferred version or "none of both." Practices that carried over from round 1 required at least 75% agreement among participants to be included in the final best practice guide [20]. This slightly lower threshold accounted for the fact that these practices already showed moderate support or warranted further discussion due to comments. In case 2 versions of a best practice existed, the version receiving the higher preference was selected.

Results

Barriers and Best Practices

The qualitative content analysis on the expert interviews yielded a total of 422 coded text segments. From this process, an initial set of 131 practices was developed. The association of the practices with the discussed barriers can be found in Table 1, and the perceived importance of the 15 presented barriers is shown in Figure 1.

In the first Delphi round, 108 practices exceeded the 80% approval threshold for perceived helpfulness; 83 of these practices had no comments and were therefore included directly. In total, 48 practices met the criteria to proceed to the second round: 23 practices rated as "very helpful" or "helpful" by 50%-79% of the experts; 18 without changes but with comments from the first round; and 7 practices with alternative revision based on comments. One entirely new strategy was introduced (Figure 2). Upon completion of the second round, the final best practice guide emerged with 105 practices, covering practices addressing 5 technology barriers and 10 practical barriers (Table 2 and Textbox 1).



In total, we identified 105 best practices addressing 15 telehealth barriers, with 20 aimed at technology challenges and 85 focused on practice issues.

Table 1. Demographic characteristics of the panelists.

Panelist number	Gender	Profession	Years of professional experience	Professional experience
1	Male	Physiotherapist	15	Orthopedics, traumatology, neurolrehabilitation
2	Male	Physiotherapist	3	Orthopedics, musculoskeletal, training
3	Female	Speech and language therapist	20	Swallowing disorders, functional voice disorders
4	Female	Speech and language therapist	2	Childhood speech development disorders
5	Male	Physiotherapist	32	Orthopedics, respiratory therapy
6	Female	Dietitian	4	Bariatrics
7	Male	Speech therapist	2.5	General speech therapy, respiratory therapy
8	Female	Physiotherapist	20	Pelvic floor therapy
9	Female	Midwife	28	Birth preparation, support, and aftercare

Textbox 1. Best practice guide for barriers to telehealth via video call.

Best practices to address technology barriers

A. Unstable network connections

1. Every participant should choose a location with a stable network connection for video call sessions. This should be communicated to the clients in advance.
2. Other devices, persons, or activities should not use the same network connection during the video call session.
3. In case of an unstable network connection, the device may be exchanged.
4. In case of an unstable network connection, switching off the camera for a short time could help.
5. In case of network disconnection, the client should be informed about further steps by telephone (full agreement from all participants).
6. In case of audio transmission problems, an additional phone connection can be used.

B. Unreliability of hardware and software

1. The video call software used should be installed and tested in a timely manner by all participants before the start of the session.
2. If clients experience technical issues, possible solutions can be discussed and solved directly during the video call session or via telephone (full agreement from all participants).

C. Lack of technology skills

1. Health care professionals should gain digital literacy skills in using different devices and video call software, as this can help in solving common technical problems encountered by patients (full agreement from all participants).
2. For technically non-proficient individuals, user-friendly video call software should be selected. Getting started via a direct link without prior installation should be favored (full agreement from all participants).
3. Telephone support can help inexperienced individuals get started with video call software (full agreement from all participants).
4. As required, the operation of the video call software can be supported at the beginning or ongoing by relatives or other persons on site.

D. Lack of privacy & IT security

1. Software used should ensure encrypted data transmission (full agreement from all participants).
2. One's own decisions regarding the handling of client data should be made and communicated in accordance with current data protection laws.
3. Written consent from clients should be obtained in advance.
4. When using video call software, access should only be possible for invited individuals (full agreement from all participants).
5. If software has not been recommended by a certification body for use in health care, it should be reviewed concerning its data processing.

E. Lack of technology access

1. Providing a checklist of minimum technical requirements for video call sessions can optimize conditions in advance.
2. Availability of equipment should be confirmed prior to the beginning of the session.
3. For sessions that focus on visual demonstration or perception, it is recommended to use a device with a large, high image quality screen.

F. Lack of telehealth knowledge and training

1. Watching video call software tutorials can provide information on available functions and give confidence in handling.
2. Learning by doing can help to gain confidence in conducting video call sessions.
3. A test run with individuals from the private environment can provide confidence in using the technology (full agreement from all participants).
4. Materials for use in video call sessions can be researched on the internet (full agreement from all participants).
5. Reading current articles on the topic of telehealth can increase knowledge (full agreement from all participants).
6. Exchanging experiences with colleagues about the use of video units can expand one's own repertoire (full agreement from all participants).

G. Decreased validity of observations and assessments

1. Important assessments should be conducted in a supplementary face-to-face unit if specific information cannot be gathered via a video call session.
2. Clients should be informed that their clothing of choice should allow detailed observations of the body (full agreement from all participants).
3. Cameras should be positioned in a way that enables a stable image (full agreement from all participants).

XSL•FO
RenderX

4. Detailed and guided instructions on how to position the body or involved body parts in front of the camera should be given to ensure high-quality observations (full agreement from all participants).
5. The background should provide visual reference points for guiding and observing movements.
6. The observation quality of details can be improved by moving the corresponding body section closer to the camera (full agreement from all participants).
7. The observation quality of details can be improved with targeted lighting (full agreement from all participants).
8. Assessments can be adapted with the help of using objects in the client´s room during video call sessions (full agreement from all participants).
9. Increased attention should be given to small nonverbal signals of the clients.
10. Involving self-observation and self-perception of clients can supplement limited on-screen observation possibilities (full agreement from all participants).

H. Lack of support from caregivers

1. Ensuring that a support person is within reach can help to run a video call session smoothly (full agreement from all participants).

I. Lack of hands-on

1. Education about functional deficits and how to deal with them in everyday life should be emphasized in video call sessions.
2. Training self-awareness and empowering clients in their self-efficacy can be part of video call sessions to achieve lasting effects (full agreement from all participants).
3. Proven effectiveness of therapy interventions aiming at lifestyle modifications should be explained to clients (full agreement from all participants).
4. Exercises that can be performed by the clients independently should be selected (full agreement from all participants).
5. Exercises should be guided verbally in such a manner that they can be understood even if visual guidance is limited (full agreement from all participants).
6. In advance, material needed for the video call session should be communicated to the clients or relatives, and it should be prepared in a timely manner (full agreement from all participants).
7. Selected self-treatments can be taught to clients during the video call session (full agreement from all participants).
8. Clients should be given specific advice for performing self-control of guided exercises (full agreement from all participants).
9. Clients' self-awareness can be promoted by feeling movements or structures with their own hands, wherein possible misinterpretations should be considered.
10. Material required for a video call session should be communicated in advance with clear information, for example, on size, quantity, and weight.

J. Patients or caregivers scepsis or reluctance

1. Clients can be offered a combination of presence and video call sessions (full agreement from all participants).
2. It can be explained to skeptical clients that some therapy content is suitable for video call sessions, others not (full agreement from all participants).
3. Demonstrating video call software and discussing a possible video call session can reduce insecurities and help with decision-making.
4. A single video call session for familiarization can be offered to skeptical clients, followed by a discussion about the experience and further procedure.
5. After a few face-to-face sessions, video call sessions can be suggested again.
6. Involving relatives or the social environment can be facilitated with video call sessions.
7. The reduction of travel and increase in time flexibility can be used as an argument for using video call sessions.

K. Decreased establishment of relationship and trust

1. Authenticity and professionalism can be conveyed through conscious design choices and insight into the premises in the background (full agreement from all participants).
2. Optimally adjusted lighting of one's face can create a friendly atmosphere and convey mimic information well (full agreement from all participants).
3. A well-adjusted camera angle and optimal positioning in front of the screen support communication on an equal footing (full agreement from all participants).
4. Facial expressions and gestures during a video call session should be used consciously (full agreement from all participants).
5. Since real eye contact is not possible via the screen, this can be imitated by consciously looking into the camera.
6. Maintaining one's own appearance can promote authenticity in front of the camera (full agreement from all participants).
7. Conscious choice of clothing supports the professional appearance.

XSL•FO
RenderX

8. Seeing one's own camera image can be used as feedback about one’s own appearance (full agreement from all participants).
9. Framing a video call session with introductory words and a deliberate end can provide orientation (full agreement from all participants).
10. Spontaneous playful elements and humor can loosen up video call sessions and promote the relationship (full agreement from all participants).

L. Decreased quality and effectiveness

1. Clients who can benefit from video call sessions should be selected purposefully (full agreement from all participants).
2. The limitations of video call sessions for certain medical conditions should be clearly communicated to clients (full agreement from all participants).
3. The use of video call sessions should be evaluated regularly and adjusted if necessary.
4. Strategies to ensure whether elements learned in the session can be implemented independently should be used.
5. Video call sessions can be used to maintain a regular appointment frequency (full agreement from all participants).
6. By collecting relevant health parameters at the beginning and the end of the session, the effectiveness of treatment interventions can be evaluated.
7. At the beginning of a video call session, expectations should be gathered. At the end they should be compared with the session's content and success.
8. The role of relatives in the treatment process can be strengthened through targeted counseling during video call sessions.
9. By setting a clear focus and sequence for the video call session and individualizing the duration, one’s ability to focus can be considered (full agreement from all participants).
10. The video call session should take place during a time of the day when clients have a good ability to focus (full agreement from all participants).

M. Increased safety risks for patients

1. Clear exclusion and termination criteria for video call sessions for clients with safety-critical characteristics should be established and adhered to (full agreement from all participants).
2. Competent relatives can increase clients’ safety.
3. For video call sessions with children, a legal guardian should be present at the child's side (full agreement from all participants).
4. Clients or family members should be educated about making the environment as safe as possible to reduce potential hazards such as tripping, falling, or slipping (full agreement from all participants).
5. Client’s pets that may interfere with free movement in the room should be kept out of the client's room during video call sessions.
6. Exercises instructed via video call sessions should be chosen according to clients' abilities (full agreement from all participants).
7. Video call sessions should not include unfamiliar exercises that may jeopardize client safety.
8. Exercise difficulty should be increased only step by step, adapted to the client (full agreement from all participants).
9. In case of uncertainties regarding perceived health parameters, referral to specialists should be made (full agreement from all participants).
10. In psychologically tense situations, one’s own voice can serve as an instrument for calming down (full agreement from all participants).
11. The daytime of the video call session, and therefore a potentially limited suitability of certain measures, should be taken into consideration.

N. Unsuitability of setting for telehealth

1. A quiet room without distractions should be chosen for video call sessions (full agreement from all participants).
2. Background noise from people, pets, or household equipment should be reduced (full agreement from all participants).
3. For video call sessions, a room with good sound quality and reduced hall should be chosen (full agreement from all participants).
4. The speaker used should be tuned sufficiently loud (full agreement from all participants).
5. Balanced lighting conditions allowing good contrasts should be selected (full agreement from all participants).
6. Devices should be positioned stable to not produce blurry images (full agreement from all participants).
7. If a tablet or smartphone is used, it should be positioned at a 90-degree angle to the surface with a suitable mount (full agreement from all participants).
8. Clients should be guided in the optimal camera setup and positioning in front of it (full agreement from all participants).
9. The camera section should be chosen so that only things that one is willing to share are visible in the background (full agreement from all participants).
10. Other people in the household or work premises should be informed that a video call session is taking place to ensure privacy (full agreement from all participants).
11.

XSL•FO
RenderX

It should be discussed with the clients in which area of their premises the video session will take place in order to avoid the concern of giving insight into things they want to keep private (full agreement from all participants).

12. Windows and doors should be closed.
13. High-quality microphones and headphones can improve acoustic transmission.
14. Advice should be given on how to use built-in or external microphones to ensure good transmission and avoid noise interference.
15. Doors in the camera's field of view should be avoided to prevent unwanted privacy intrusion.
16. A dedicated therapy location—for example, at a table—can promote attention and concentration.
17. Marking one or more places where the camera is well positioned facilitates a sustainably working set-up.
18. If the video call session involves movement across the room, a flexible camera setup for rapid changes should be facilitated.

O. Increased workload

1. Using quick-to-use treatment or exercise methods that require little pre-planning and explanation can reduce preparation time.
2. By combining preparation time for several video units, one's own working time can be used efficiently.

Best Practices to Address Technology Barriers

In total, 20 best practices were selected by the participants to address the barriers of unstable network connections, unreliability of hardware and software, lack of technology skills, lack of privacy and IT security, and lack of technology access (A-E in Textbox 1). For optimal video call sessions, each participant should ensure a stable network connection, free from other devices and activities that might compete for bandwidth. When issues such as an unstable connection arise, switching devices, temporarily turning off the camera, or making a phone call can provide continuity and effective communication. Participants should install and test the video call software well before the session, with technical issues being addressed directly during the call or via telephone if necessary. Health care professionals should develop digital literacy for various devices and software to assist patients with technical issues. For less tech-savvy individuals, user-friendly software with direct links, telephone support, as well as on-site help from relatives, can facilitate the use of video call applications. To ensure data privacy and security, video call software must encrypt data transmission and comply with data protection laws. Informed consent should be obtained from users, and access should be restricted to invited participants. If software has not been recommended by a certification body for use in health care, it should be reviewed concerning its data processing. To optimize video call sessions, a checklist of technical requirements should be provided, and equipment availability should be confirmed beforehand. For visually intensive sessions, a high-quality large screen is recommended.

Best Practices to Address Health Care Practice Barriers

Overall, 85 best practices addressed practice issues such as lack of telehealth knowledge and training, decreased validity of observations and assessments, lack of support from caregivers, lack of hands-on, patients or caregivers scepsis or reluctance, decreased establishment of relationship and trust, decreased quality and effectiveness, increased safety risks for patients, unsuitability of setting for telehealth, and increased workload (F-O in Textbox 1).

Reviewing current telehealth publications and internet resources to search for material to use in telehealth sessions, as well as watching software tutorials, can enhance proficiency and confidence in conducting video call sessions, complemented by practical experience and sharing knowledge with colleagues.

For comprehensive assessments in telehealth, certain procedures may need to be supplemented with in-person visits. Clients should be guided on how to prepare for video sessions with appropriate clothing, camera positioning, lighting, and background setup to enhance the quality of observations. Additionally, using objects for adapted assessments, paying attention to subtle nonverbal cues, and involving clients in self-observation can maximize the efficacy of remote evaluations. Having a support person readily available can facilitate a smooth video call session.

In video call sessions, educating clients on functional deficits and self-management in daily life is crucial, with a focus on training self-awareness and self-efficacy for sustainable outcomes. For effective video call sessions, exercises that clients can perform independently should be chosen, and clear verbal guidance for exercises with limited visual cues should be given. This can be added with the training of self-treatments, advice for self-control during exercises, and the promotion of clients' self-awareness through tactile experiences while addressing potential misinterpretations. Clear communication and preparation of materials is necessary.

To address skepticism, clients can be offered a blend of in-person and video call sessions, emphasizing the suitability of certain therapy contents for remote delivery, with demonstrations and trial sessions helping to alleviate skepticism and showcasing the convenience and flexibility that video calls offer. To convey professionalism and authenticity in video calls, one should make deliberate design and setting choices, ensure optimal lighting for a friendly atmosphere, and use a camera angle that supports equitable communication. Conscious use of facial expressions, gestures, and clothing, along with looking into the camera to simulate eye contact, enhances authenticity. Additionally, framing the session with a clear beginning and end, along with the use of humor, can improve the interaction.

XSL•FO
RenderX

Purposeful selection of clients for video call sessions is essential, with transparent communication regarding their limitations for certain conditions. Regular evaluations should be conducted to assess effectiveness and determine if expectations are being met. Strategies to ensure whether elements learned in the session can be implemented independently should be used. Sessions should be structured in a way that they have a clear focus and sequence, an appropriate duration, and are scheduled for when the client's focus can optimize the session. Incorporating relatives into the treatment process via video call sessions can provide targeted counseling. Establishing clear criteria for excluding or terminating video call sessions is vital for clients with safety-critical concerns. Competent relatives can enhance safety. Guardian presence for children, safety education, and gradual exercise progression can ensure the clients' well-being during remote sessions.

For effective video call sessions, it is essential to choose a quiet room with as little background noise as possible, ensuring good sound quality and balanced lighting. Proper camera setup, privacy considerations, and guidance on microphone use enhance the session quality. Additionally, creating a dedicated therapy location and facilitating flexible camera setups can improve the overall experience and engagement during sessions. Efficient use of time in video sessions can be achieved by opting for quick and easy treatment methods and combining preparations for multiple video units.

Discussion

Principal Findings

The findings from this study, which encompassed expert interviews and a modified Delphi process, provide a best practice guideline for telehealth in health care. The key results underscore the importance of addressing the challenges of technology accessibility, enhancing observations and assessments, creating a professional setup, building relationships and trust, and ensuring privacy and IT security. Although the majority of the panelists were PTs and SLTs, their combined professional experiences—spanning areas such as neurorehabilitation and pediatric care—have facilitated a comprehensive exploration of these practices across various health care settings, thereby complementing the aims and findings of previous studies and guidelines [21-25].

The best practice guideline offers a starting point towards a unified guide to improve telehealth across various health care settings. Prior publications have established telehealth frameworks in disciplines such as occupational therapy, physiotherapy, and speech and language therapy [21-24], which partially align with our findings. A high level of agreement is seen in these existing frameworks, particularly regarding fundamental principles of telehealth delivery. However, there remain clear gaps in the current literature on how to manage these barriers through concise best practice statements [24]. Grogan-Johnson [25] discusses the challenges of maintaining engagement in virtual settings but provides limited guidance on how to address this. Our best practice guide suggests trust-building strategies, such as non-verbal communication enhancements, environmental adjustments, and interactive session structuring. Davies et al [13] outline the importance of technological proficiency for PTs but do not provide detailed practices for managing unstable networks or unreliable hardware, where our study adds explicit recommendations for overcoming technological challenges, including strategies for low-bandwidth settings, selecting robust hardware, and providing patient education on basic troubleshooting. Other studies limit their focus to specific populations or pathologies [22,25]. Cottrell and Russell [22], for instance, provide an in-depth analysis of pre-implementation considerations and practical steps specifically within the domain of musculoskeletal physiotherapy. Their work examines technological and operational challenges, offering targeted strategies to enhance the successful deployment of telehealth services. Other guidelines have delineated key technical principles health care professionals are expected to follow to ensure a smooth and secure telehealth experience [26,27], focusing on adherence to laws and regulations and the implementation of privacy and security measures. Our study extends these principles by proposing practical, applicable strategies and emphasizes dual-focused education, targeting both health care providers and patients. It includes specific methods to address skepticism and enhance digital literacy, particularly for populations unfamiliar with telehealth.

Notably, our research revealed a strong consensus on the effectiveness of specific strategies across health care settings, such as providing detailed technical guidelines, enhancing visual and audio components of telehealth sessions, and incorporating elements that foster a sense of connection and trust between health care providers and clients. These findings offer new insights into the practical implementation and adaptation of telehealth services in diverse health care contexts.

In examining the distribution of best practices identified to address various barriers, we found notable differences. "Unsuitability of setting for telehealth" yielded the largest set of best practices despite being rated as a relatively small barrier. This contrast likely arose because many aspects of the setting (eg, lighting, device positioning, noise reduction) are easily modified by health care professionals. These direct, practitioner-driven solutions help frame the barrier as "small," in that it can be quickly addressed through practical steps. In other words, the perception of a barrier's magnitude may reflect how empowered providers feel to remedy it: settings are simpler to adjust, whereas more systemic issues (eg, workload, limited technology access) require external interventions and may thus seem more significant.

Additionally, a significant collection of best practices has been identified to address practical implementation barriers such as "increased safety risks for patients," "decreased validity of observations and assessments," "lack of hands-on," "decreased establishment of relationship and trust," and "decreased quality and effectiveness." These best practices provide pragmatic strategies to navigate the range of challenges presented by telehealth, ensuring a higher standard of patient care and treatment integrity. On the other side, there were barriers that received fewer best practices to address them, such as "lack of support from caregivers" and "increased workload," both at the lower end, with 1 and 2 identified best practices. These issues

XSL•FO
RenderX

likely require organizational or systemic changes that are beyond the immediate control of the individual practitioner. Similarly, "lack of technology access" and "unreliability of hardware and software" are countered by only 3 best practices each, possibly indicating a gap between the technological requirements of telehealth and the ability of health professionals to influence these parameters.

Reflections on the Delphi Method

Our modified Delphi approach relied on 2 rounds, underpinned by preliminary interviews that generated a well-defined set of barriers and best practices. This groundwork contributed to a high level of initial consensus—83 of 108 items achieved ≥80% agreement in round 1. While we acknowledge that time constraints and difficulty finding sufficient participants limited the scope of our panel (n=9), each participant brought substantial experience: all met strict inclusion criteria (eg, minimum 2 years' professional practice, at least 10 video-based telehealth sessions in the previous quarter), ensuring specialized and recent expertise.

We employed a 2-threshold system: items achieving ≥80% agreement in round 1 were immediately included, while items carried forward required ≥75% agreement in round 2. This tiered approach balanced efficiency and adaptability by refining practices with moderate support without burdening participants with repeated rounds. Items garnering <50% agreement were excluded after round 1, given their limited traction; however, participants could introduce revisions or propose new items if they felt critical information was overlooked. Although this may appear stringent, it enabled us to produce a focused, consensus-driven guide for reducing barriers to video call–based telehealth within the time and resource constraints of our project.

While our study does not claim to capture every possible facet of telehealth across all health care contexts, the methodology employed aligned with recommended standards.

Limitations

This study still has several limitations that need to be acknowledged. First, the sample size was small, consisting of only 9 eligible experts in specific health professions. Our participant sample was relatively small, yet it was purposefully recruited to encompass diverse professional backgrounds and extensive telehealth experience. This approach generated a robust consensus on best practices for video call–based telehealth. Future studies with larger or more varied panels could further enhance and validate the findings, but our current methods provide a strong foundation for ongoing research and practical implementation. Second, the heterogeneity of the participants' professions may be both an advantage and a disadvantage. On the one hand, it allowed for a broader range of perspectives and strategies to be considered than if we would have focused on only one profession. On the other hand, it could also have resulted in the exclusion of profession-specific strategies that may be essential for a successful telehealth implementation, which could be studied in the future. Each profession uses telehealth differently based on their specific clinical needs and methods. For instance, PTs may focus more on movement assessments and exercise guidance, whereas SLTs might emphasize communication techniques and auditory assessments. This variation means that certain best practices identified may be more applicable to some professions than others, potentially limiting the universal applicability of the recommendations. The small number of distinct professions included in the study may have resulted in the exclusion of specialized best practices pertinent to each field. Essential strategies unique to specific clinical scenarios or patient interactions within each profession might not have been fully captured or emphasized, thereby affecting the comprehensiveness of the best practice guide for individual disciplines.

Moreover, the findings reflect the current state and must be interpreted as such. They likely are subject to change due to the continuous evolution of professional expertise in health care and ongoing technological advancements that are likely to shape the future landscape of telehealth. Furthermore, this study relied on self-reported data from the experts. While this method is commonly used in qualitative research, it is important to acknowledge that the data collected may be subject to bias or limitations in recall. Another important consideration is the length of the final best practice list. Although it represents a comprehensive set of potential solutions, its sheer number may pose challenges for day-to-day clinical application.

Implication of Findings

The study's findings offer valuable insights for various stakeholders within the telehealth ecosystem, promoting enhanced effectiveness, accessibility, and sustainability of video call–based telehealth services. The best practices serve as a practical guide for clinicians to optimize telehealth delivery. Implementing these strategies can improve care quality, strengthen patient-provider relationships, and increase patient satisfaction while reducing operational burdens through streamlined session management and technical troubleshooting. Using enhanced privacy measures and user-friendly technologies ensures a secure and confident telehealth experience for patients, particularly those in remote or underserved areas. Insights from this study can also inform the development of regulations and standards that promote equitable telehealth access. By addressing practical barriers and supporting measures such as technology funding and training programs, policy makers can facilitate the broader adoption and integration of telehealth into standard health care practices. Finally, incorporating these best practices into health care curricula ensures that future practitioners are equipped with the necessary digital literacy and remote communication skills. Training programs can emphasize technical competencies and patient engagement strategies specific to telehealth, preparing health care workers for modern care delivery.

Further Research

While this Delphi study provided insights into potential solutions, it would be beneficial to evaluate the impact of these strategies on the successful implementation of telehealth in different real-world settings by exploratory and confirmatory studies. For example, while this study focused on barriers and solutions in the selected health care professions, other health care specialties and settings may face different challenges and

XSL•FO
RenderX

would come up with different best practices when implementing telehealth. Evaluating these barriers and solutions in different contexts would provide a more comprehensive understanding of telehealth implementation. Moving forward, further research could investigate strategies to streamline or prioritize these recommendations, identifying which are most beneficial for specific professional groups or patient populations. Further, it would be interesting to create educational programs to see how teaching these strategies to students would increase their telehealth proficiency.

Conclusions

This publication presents a modified Delphi study that compiles best practices for overcoming barriers in video call–based telehealth. It includes insights from various health care professionals and focuses on enhancing telehealth's quality and effectiveness. The study emphasizes technology accessibility, professional setups, and patient-centered care. Limitations include a small sample size and self-reported data, suggesting future research should assess these strategies' real-world effectiveness, explore barriers in different health care specialties, and develop educational programs to increase telehealth proficiency.

Abstract

Background: Social determinants of health (SDOH) are the conditions in which people are born, grow, live, work, and age, encompassing social and economic factors that shape health outcomes. There is an increasing call to leverage digital health technology (DHT) to address SDOH and health-related social needs and establish connections to resources and services.

Objective: This study aimed to (1) identify the DHT-related characteristics of DHT users with low socioeconomic status (SES), (2) determine the needs and preferences of DHT users with low SES, and (3) explore how current SDOH-DHT addresses these needs and preferences in addressing their health-related social needs.

Methods: We used a multiphase, mixed method, user-centered design approach. In phase 1, we developed a user profile based on a literature review, aggregate data, interviews with 26 low-SES individuals, and focus groups with 28 professionals. In phase 2, we conducted a landscape analysis of 17 existing SDOH-DHTs.

Results: DHT users of low SES had diverse social and technology characteristics. Five key themes emerged regarding user needs and preferences: (1) user-centered design, including multilingual support, visual guidance, and customization; (2) efficient, solution-based assessment of social risks, assets, and needs; (3) e-caring support features; (4) user education and feedback mechanisms; and (5) trust, privacy, and security. The landscape analysis revealed that current SDOH-DHT features do not adequately meet these needs.

Conclusions: Discrepancies between target user needs and current DHT features represent missed opportunities in developing user-centered tools for individuals of low SES. Findings underscore the importance of inclusive, empowering, and responsive design in SDOH-DHT to bridge health disparities and advance public health.

Introduction

Background

Social determinants of health (SDOH) are "the conditions in which people are born, grow, live, work, and age," encompassing social and economic factors that shape health outcomes [1]. These determinants can function as assets or risk factors, with individual-level adverse social conditions being defined as social risk factors [2]. "Health-related social needs" (HRSN) differ from social risk factors by reflecting both the presence of risks and individuals' preferences for addressing them [2]. These immediate needs, such as food insecurity and social isolation, stem from upstream SDOH, including economic stability, education, health care access, and the physical environment [3]. The resulting social gradient creates a corresponding health gradient with particular impact on lower socioeconomic status (SES) populations [4-6].

Studies have highlighted the impact of SES on both health outcomes and technology use, underscoring the importance of considering SES in health technology research [4,7,8]. A broad definition of "low SES" includes a lack of resources (eg, education and income) or measures of poverty (eg, food insecurity and income-to-needs ratio) [9]. Individuals of low SES often lack the knowledge or resources to respond to social needs and maintain health [6]. Bourdieu's theory of capital—economic, social, and cultural—provides a useful framework for understanding how these determinants operate [10]. Economic capital refers to financial resources, social capital to networks and relationships, and cultural capital to knowledge and dispositions that confer social value. Each form of capital can impact health outcomes and access to health care [11]. Unmet social needs are closely associated with disparities in health outcomes, quality of life, and life expectancy, disproportionately affecting marginalized communities [12]. While SES, typically measured by income, education, and occupation, is a key social determinant of health, SDOH encompasses a broader range of social and environmental conditions beyond individual-level SES [9]. SES and related SDOH significantly impact health outcomes, with studies estimating that they contribute to around half of health outcome variation, while health behaviors account for about a third, and clinical care accounts for about a fifth of variation in health outcomes [13-15].

There is an increasing call to leverage technology, specifically digital health technology (DHT), to support social needs and establish connections to resources and services. DHTs such as mobile health (mHealth) apps, telemedicine and telehealth services, health information technology (HIT) systems, and virtual reality (VR) and augmented reality (AR) technologies play increasing roles in the modern health care system. mHealth apps provide accessible platforms for health monitoring and management [16], telemedicine and telehealth offer remote health care access [17], HIT systems facilitate the integration of social needs data with medical care [18], and VR/AR technologies enhance training and patient engagement [19]. These technologies can systematically identify and tailor resources to individual needs, promoting personal health care management and reducing health disparities among low-SES populations [20]. Ideally, DHT should focus on increasing factors that promote health-related behaviors (eg, education) and decreasing factors discouraging health-related behaviors (eg, resource access barriers).

A compelling case exists for targeting individuals of lower SES as SDOH-DHT primary users. This study focuses on SDOH-DHT among low-SES populations to capture the complex interplay of social, economic, and environmental factors influencing their health and health-related technology use. Although individuals of low SES have traditionally had limited access to digital technology [21], recent studies show a growing use of technology, particularly mobile phones, and mHealth apps among this population [8,22]. While the development of DHT apps has substantially increased, many do not meet the needs of people of low SES [8]. For example, engagement with digital health systems generally requires a basic level of digital health literacy, which is still in its early stages for many individuals of low SES [23]. Digital health literacy is "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem [24]." Moreover, there is not currently a universal framework for assessing the effectiveness and usability of DHT in this population [8]. Furthermore, many SDOH-DHT apps are designed to address a single domain on SDOH, mostly commonly food and housing, but individuals of low SES must often address multiple SDOH domains that fluctuate throughout their lives [25] (Figure 1).

XSL•FO
RenderX

Figure 1. The 12 domains of social determinants of health (SDOH) used in this study.

Objectives

The manuscript aims to identify the characteristics, needs, and preferences of individuals with low SES using DHT to address HRSN. For digital SDOH management tools to best serve individuals of lower SES, we must use a user-centered design (UCD) approach that incorporates characteristics specific to the target user population, including contextual situations, preferences, and capabilities, to develop system requirements, goals, and design features [26,27]. In technology development, developers may be unfamiliar with the target user group, especially when specific user groups have historically been excluded from the design process [27,28]. UCD aims to shift developers' focus from their own mental models to those of the targeted users [28]. This allows for a more user-empathetic, inclusive, and flexible approach to DHT development so that the functions, features, and aesthetics of SDOH-DHT meet the target user group's needs [28].

Few studies have leveraged UCD to inform DHT addressing social needs among low-SES populations. In response to this gap, the first phase of this study uses UCD methods (eg, interview and focus group) and tools (eg, user profile) to address the following questions:

1. What are the DHT characteristics of SDOH-DHT users of low SES?

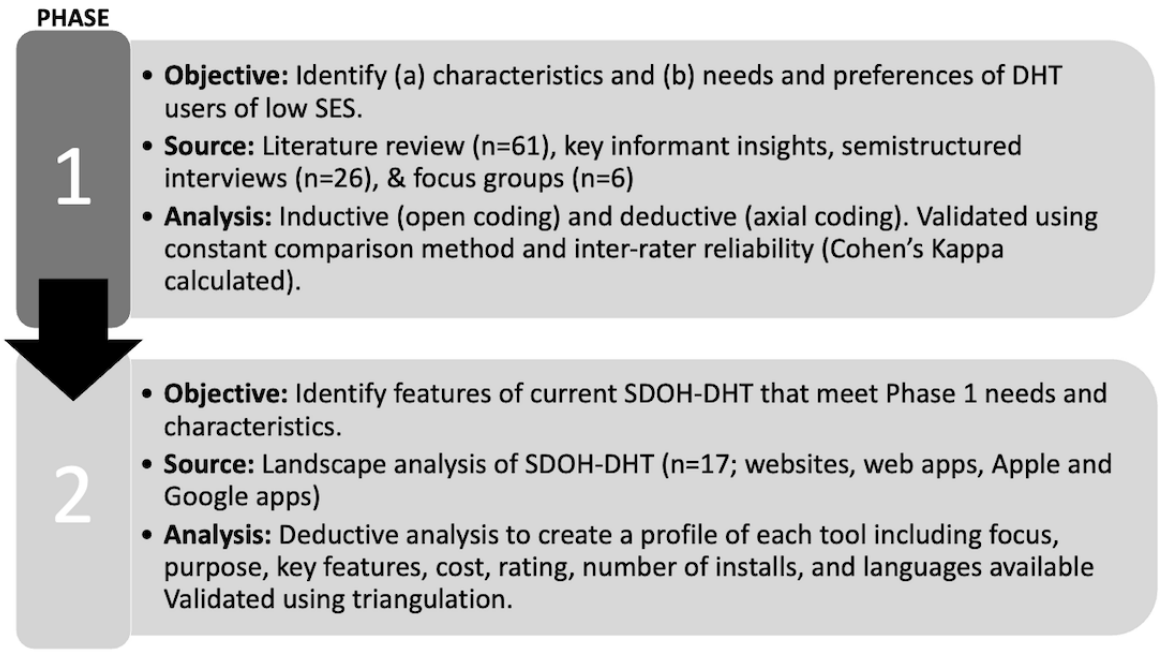
2. What are the needs and preferences of SDOH-DHT users of low SES?

The application of insights gained from exploring the characteristics, needs, and preferences of SDOH-DHT-targeted users raises the question of whether the current SDOH-DHT tools meet users "where they are." Thus, we explore the following research question in the second phase of the study:

3. What identified needs and preferences do current SDOH-DHT address?

XSL•FO
RenderX

We then discuss how our findings can be applied to developing SDOH apps, particularly referencing the Florida International University (FIU) Thrive app currently being developed.



Overall, this study promotes an enhanced understanding of the target user population, desirable SDOH-DHT features and functions, and the status of existing SDOH-DHT in addressing those features and functions, and a discussion, with illustration, of how to collectively address desirable features with some focus on addressing differences between identified and current features and functions. As a result, findings and insights pave a pathway to advance SDOH-DHT design science and DHT product design.

Methods

Study Design

We used a multiphase, mixed method UCD approach following the consolidated criteria for reporting qualitative research (COREQ) [29] to address our research questions (Figure 2 depicts an illustration of the methods). UCD seeks to incorporate all relevant stakeholders in developing system requirements, goals, and design features [26].

Figure 2. Mixed method approach including objective, data source, and analysis for each phase. DHT: digital health technology; SDOH: social determinants of health; SES: socioeconomic status.

Ethical Considerations

As this research involved human participants, ethics approval was obtained from the Institutional Review Board at FIU (IRB-22-0206). After the screening process for the interviews and focus groups, participants received an information sheet detailing the study procedures, risks, and benefits. At the beginning of each interview, the interviewer explained the study procedures, reaffirmed verbal consent for participation, and invited questions from participants. Participants were informed that they were free to withdraw from the study at any time. The data obtained from participants have been anonymized and are not identifiable. Following their participation, interview participants received compensation of US $25 in the form of a gift card.

Phase 1: Understanding Users and Their Needs

Phase 1 occurred in the context of FIU Thrive, a trans-disciplinary design science research (DSR) study to use mHealth to address social risks and resulting disparities in vulnerable populations. DSR is a problem-solving approach that creates novel technologies and associated knowledge [30-32]. In this study, we report on our UCD efforts, which are integral to the more extensive FIU Thrive DSR study.

Phase 1 addressed our first 2 research questions on the characteristics, preferences, and needs among individuals of low SES for SDOH-DHT. Leveraging the expertise of UCD experts on our team and digital health literacy models (eg, Digital Literacies Domains and Relationships [33], ICT Digital Framework [34], and A Review of Digital Literacy Assessment Instruments [35]), we developed user profiles describing our target users based on their characteristics, prior experiences, and anticipated behavior to guide design choices [36]. The user profile was organized based on demographics, health/SDOH-related characteristics, and DHT-related characteristics of interest for this study and the overall FIU Thrive project (Multimedia Appendix 1 [8,35,37-77] shows categorized characteristics).

As a first step to completing the user profile framework, we conducted a focused narrative literature review to obtain generalized insight into the characteristics of interest for our target user population. Using multiple interdisciplinary databases

XSL•FO
RenderX

(eg, Web of Science and PubMed), our search parameters combined low-SES terms with targeted characteristics or characteristic types aligning with our SDOH domains (eg, technology, wellness, health care, and health education; Figure 1) or SDOH terms (eg, social risk and social need). We performed a full-text review of each study to ensure relevance to our profile characteristics of interest.

To add detail to our user profile, we used aggregated data (eg, demographics and some social and health characteristics) from the records of The Green Family Foundation Neighborhood Health Education Learning Program (NeighborhoodHELP), a university-led community program providing interprofessional household-centered care for individuals who face challenges addressing social needs and are open to assistance [78,79]. These program members were targeted as the initial FIU Thrive pilot users. Our study population closely aligned with the literature's definition of low SES: individuals or groups with limited income, education, and occupational prestige, often resulting in reduced access to resources and opportunities. NeighborhoodHELP aims to address social needs and maintain community connections, allowing us to address current and past priority needs with our participants. We aimed to leverage the firsthand experiences, needs, and preferences of individuals enrolled in the program to develop SDOH-DHT that effectively addresses their needs.

Guided by findings from our literature review and aggregate data, we tailored the development of target user interview and outreach worker focus group protocols to areas needing deeper exploration and gaps to be explored.

We constructed a semistructured interview protocol to explore SDOH-DHT user needs and preferences, adding depth and breadth to the user profile. We recognized three key aspects in developing a phenomenological interview guide: (1) contextualization, asking general questions related to participants' general SDOH/social needs experiences and their management of these concerns; (2) apprehending the phenomenon, asking questions focused on participants' experiences with using DHT to manage health and wellness concerns; and (3) clarifying the phenomenon, exploring areas for improvement in DHT for social concern management.

We developed a parallel structure for focus groups with targeted co-users, primarily NeighborhoodHELP outreach staff. The focus group protocols emphasized the attributes and deficits of currently used tools, the information needed to perform their jobs effectively, and their perception of the digital health capabilities of those they served.

The resulting interview and focus group protocols were reviewed and refined by a multidisciplined team involved with the Thrive project. This team included a researcher with substantial qualitative methods expertise (focused on information systems and health informatics) and familiarity with the study constructs, a primary care medical provider engaged in community outreach, a sociotechnical community health researcher experienced in developing technological platforms, and several team members with experience focused on UCD. A consensus was reached on the final protocols.

Participants (n=26, ages 20-71 years, mean age 50 years) were selected through purposive sampling to ensure representation across age decades within the lower SES demographic. The decision to include a diverse age range was guided by the recognition that age can significantly impact one's perspective on socioeconomic challenges and resilience strategies [80,81]. By incorporating voices from younger and older individuals, we aimed to capture a broader spectrum of experiences and insights related to lower SES. NeighborhoodHELP outreach staff were trained in the purposes of the study and recruited program members to participate in the interview process, verifying that age (between 18 and 75 years) and capability (basic technical skills and English comprehension) inclusion criteria were met. For those who had difficulty with technology, the outreach specialist provided support to access Zoom. Participants whose primary language was Spanish or Haitian Creole were included if they could speak enough English to complete the pre-enrollment questions in English. Before each interview, recruiters obtained information from qualified and consented participants via telephone to characterize the nature of participant information technology (IT) use questions. This preliminary information provided insight and helped set the appropriate starting point for interview inquiries regarding technology.

We conducted 26 one-hour semistructured interviews with individuals of low SES via Zoom to obtain the end user perspective. Sample size guidelines for qualitative research suggest that having at least 20 participants is sufficient for data saturation, where incremental learning is minimal [82,83]. Interviews were conducted by 2 trained team members, one serving as lead and the other as scribe. The scribe could interject clarifying questions periodically during the interview to facilitate a comprehensive understanding. The scribe also provided a summary of interview highlights at the end of each interview, inviting participant comments regarding accuracy, omissions, and further explanation (ie, member check) [84].

For the focus groups, we recruited NeighborhoodHELP care providers aged 18 to 75, including clinical, outreach, administrative, faculty, and student divisions. These individuals have experience using a variety of electronic medical records (EMRs) and IT systems, including the university's homegrown outreach health risk profile and outreach portal. Their familiarity with the challenges of collecting, maintaining, and reporting social risks, needs, goals, and patient-reported outcomes provided valuable insight into developing technological solutions. As with the focus groups, 2 research team members conducted the interviews as lead and scribe, performing a collective member check.

We conducted 6 confidential focus groups with a total of 28 participants. Typically, 3 to 5 focus groups per project are sufficient for achieving saturation [85]. We reached saturation by the fifth focus group, but conducted a sixth to ensure data saturation. Participants included physicians, outreach specialists, program coordinators, and social workers with an average of 3.8 years of experience working in the program. Most participants had prior experience working with underserved populations through other programs.

RenderX

Data Analysis

To enhance the reliability of the results, we performed member checks at the end of each interview and focus group by sharing interview summaries and highlights [84]. During these checks, we presented participants with highlights of our initial data analysis for feedback on accuracy and resonance with their experiences [86]. Deidentified interview and focus group transcripts were uploaded to Dedoose (Sociocultural Research Consultants) qualitative analysis software.

We used a hybrid thematic analysis approach using inductive and deductive coding [87]. Following guidance from King [88], we developed an a priori coding schema consisting of high-level concepts (ie, categories of the user profile and functional categories of the planned FIU Thrive app) for deductive coding (eg, member characteristics, areas of need -risk factors; SDOH data intake survey; app mock-up reactions; promoting app awareness, and implementation of app). These high-level concepts were applied to conceptually meaningful sections of the transcripts (aka slips) [89]. For instance, if participants discussed their perception of the Thrive DHT mock-up screen, we used app mock-up reactions.

Next, we further analyzed the selected slips of transcript texts coded at the deductive level using an inductive, open-coding approach to provide a more detailed and specific understanding of each high-level concept [90] (eg, details of technology use and reactions to screen mock-up). Specifically, we re-examined relevant portions of the text previously coded deductively under each high-level concept to create more discreet, detailed subcodes needed to provide a depth of insight into our first 2 research questions through an open coding approach.

Finally, we used axial coding to organize the discrete codes related to our first 2 research questions (user characteristics and SDOH-DHT needs and preferences) into broader, generalizable categories of the core themes presented in our results section [91].

We aimed to capture the rich, diverse narratives of participants and ideas as a collective set of data without subordinating or elevating the importance of any particular narrative or group of narratives (narratives belonging to a particular demographic group), providing valuable insights that can inform policy and practice aimed at addressing the challenges faced by this subpopulation. Therefore, while we may have had more individuals in a certain age group than others (or other demographic bin), data from each individual transcript was considered towards building an aggregated data set.

To ensure the trustworthiness of thematic analysis (ie, internal validity and reliability), we used Guba's [84] strategies and Weber's [92] recommendations for conducting a rigorous qualitative research study. These include peer debriefing (ie, code review), the code-recode procedure, and researcher triangulation. Table 1 summarizes these procedures.

Table 1. Summary of validity and reliability procedures.

Trustworthiness criteria and procedures	Description
Internal validity	
Peer debriefing (code review)	A health communication expert reviewed high-level codes, their contextualized definitions, alignment between high-level codes and subcodes, the conceptual integrity of the coding schema, and 20% of data.
Reliability	
Reproducibility	A graduate assistant (not involved in data collection/analysis) coded 15% of the excerpts using high-level coding schema. Cohen κ value was 0.99, indicating a high level of agreement.
Stability	The lead researcher recoded 15% of data from the first 3 interviews approximately a month after coding. Cohen κ was 0.99, indicating a high level of coding stability.

Phase 2: Landscape Analysis

Phase 2 involved a landscape analysis that included a structured review of available SDOH management technologies to identify whether their features aligned with the needs and preferences of health consumers, as identified in phase 1. This analysis did not involve direct usability testing, but rather examined publicly available information (eg, product descriptions and user documentation) to infer alignment with the needs and preferences identified by our target population. This approach is consistent with UCD methodologies that emphasize understanding the current design landscape from the mental model of users to inform new solution development [93]. For example, a recent study on diabetes self-management tools used a similar strategy to map available features against user needs as part of a UCD process [94]. Notably, as part of UCD, landscape analyses are critical to understanding the existing market of DHTs and identifying missing features and design elements that should be incorporated into new DHT designs [93-95].

To understand the current environment for SDOH apps and tools, we searched for website tools and web apps, as well as the Google Play and Apple App Stores using the search criteria presented in Table 2.

XSL•FO
RenderX

Table 2. Social determinants of health digital health technology (SDOH-DHT) search strategy.

	Web-based tools	App
Search Terms	One or more of these SDOH term permutations: • Social determinants of health • Social services • Social services referral system • SDOH • Social Risks • Social factors • Social risk factors • Social determinants • Health - related social needs • Health - related social problems • Social needs • Social needs-informed care • Social needs-targeted care **AND** One or more of these digital term permutations: • Digital health intervention • Digital health technology • Client communication system • Community-based information system • Digital health tools • Interactive tools • Tool • Technology interventions • E-health • Website • App • Mobile health/mhealth • Platform • Connect	One or more of these SDOH term permutations: • Social determinants of health • Social services • Social services referral system • SDOH • Social Risks • Social factors • Social risk factors • Social determinants • Health - related social needs • Health - related social problems • Social needs • Social needs-informed care • Social needs-targeted care
Inclusion criteria	• Tool addresses more than one SDOH domain. • Primary target user includes those experiencing a social needs consumer directed • Interactive human-computer interaction (HCI) features included to provide SDOH education and awareness, assess social needs, obtain services, or manage social needs.	• Tool addresses more than one SDOH domain. • Primary target user includes those experiencing a social needs consumer directed • Interactive-(HCI) features included to assess needs, obtain services, or manage needs.
Exclusion criteria	• Tools that limit scope to one SDOH domain (eg, just health care needs). • Tools that target primarily policy makers, community leaders, and health care providers or administrators (eg, tools that provide data sets and strategies for community health improvement)	• Tools that limit scope to one SDOH domain (eg, just health care needs). • Tools that target primarily policy makers, community leaders, and health care providers or administrators (eg, tools that provide data sets and strategies for community health improvement)

We followed several steps to identify the available SDOH technology tools targeting people with social needs. For website tools and resources, we performed an internet search using permutations of "SDOH technology tools" as a search term (Textbox 1 contains a complete listing). Search terms were identified through team discussion and literature search of relevant terms (eg, SDOH lexicon work by Alderwick and Gottlieb [2]). We included websites that included an interactive SDOH feature or specific training or guidance on implementing or evaluating SDOH-based programs. Websites that only provided general education about SDOH without targeted tools were excluded.

Next, we searched for smartphone tools and resources on the Google Play Store and the App Store using permutations of SDOH search terms (Table 2 contains a complete listing). We also reviewed apps suggested on the pages of other apps. Additionally, if we found an app on one platform (eg, Google Play Store), we searched for the same app on the alternative store (eg, App Store). We included any app that assisted professionals and community organizations in providing education, raising awareness, or alleviating more than one domain for people facing social challenges.

RenderX

Textbox 1. Summary of social determinants of health digital health technology (SDOH-DHT) included in landscape analysis.

Mobile app (Apple):

- Providers: EBT, debit, & more (Propel, Inc)
- What I Need (WIN) (OurCommunityLA)

Mobile app (Apple and Android):

- myCOMPASS PA (Pennsylvania State Government)

Website and mobile app (Apple and Android):

- FindHelp.org (FindHelo)
- HelpSteps (Boston Children's Hospital)
- Your Texas Benefits (TX Health and Human Services Commission)
- ebtEDGE (Fidelity National Information Services, Inc)

Website:

- ACCESS Florida (Florida Department of Children and Families)
- Washington Connection - Your link to services (Washington Connection)
- Washington Healthplanfinder (Washington Healthplanfinder)
- 211.org (United Way Worldwide)
- Benefit Finder (US Government)
- HHS.gov Social Services (US Department of Health and Human Services)

Web app:

- ACT.md (Activate Care)
- NowPow (As of July 2024, the NowPow website states that the platform is no longer supported and available.) (Unite Us)
- Pieces (Pieces Technologies)
- WellSky Social Care Coordination

Three rounds of the search process were performed during the study to account for the inclusion of recently released tools in the final results. Two authors (CL and PD) conducted the final searches and data extraction during October 2024. It is of note that many tools were excluded as they only covered one domain. Indeed, we discovered that most existing apps and websites designed for at-risk individuals connect users to social services that address only a narrow range of social issues, leading those with more than one social need to choose to use technology tools to rely on multiple DHTs to meet their needs. The search process resulted in analyzing 17 DHTs (Textbox 1). Further details of these tools can be found in Multimedia Appendix 2.

We assessed each app based on the inclusion of clearly identifiable features from phase 1. In some cases, we were not able to gain full accessibility to some tools reviewed for inclusion due to privacy features (required a health provider registration and identification). In these instances, we consulted reference material on the tool features to help assure that we were not missing key features in our analysis.

Results

Overview

Our results provide insights into the characteristics of SDOH-DHT users and how currently available SDOH-DHT addresses their needs and preferences. First, we highlight insights regarding target user SDOH-DHT characteristics in detail in our user profile (Multimedia Appendix 1 [8,35,37-77]). Next, we review our findings regarding the needs and preferences of SDOH-DHT users and the associated landscape analysis results. This analysis is organized according to 5 themes: UCD; efficient solution-based assessment of SDOH risk/need; trust, privacy, and security; e-caring and support; and user feedback and education. To support the general themes and findings from the interviews and focus groups, we provide a detailed evidence trace table in Multimedia Appendix 3, moving from theme to associated open codes to representative quotes.

Target User Characteristics

We defined our targeted profile based on the literature, focusing on individuals who experience a lack of resources such as food, education, income, and transportation, resulting in social risks and challenges. Phase 1 results revealed the DHT characteristics

XSL•FO
RenderX

and needs of DHT users with low SES, particularly early adopters, allowing us to complete the comprehensive user profile in Multimedia Appendix 1 [8,35,37-77]. We augment this artifact with the highlights and extended descriptions provided below.

Demographics

Our interview participants include individuals enrolled in NeighborhoodHELP to help address unmet social needs and risks. Table 3 contains the demographic information of our participants collected during screening.

Table 3. Interview participant demographic information.

Demographics	Values
Age (years), mean (range)	50 (20-71)
Household income, mean	US $18,519
Number of household members, mean	4
Sex, n (%)	
Male	8 (31)
Female	18 (69)
Ethnicity, n (%)	
Hispanic or Latino	5 (19)
Non-Hispanic or Latino	21 (81)
Race, n (%)	
African American	18 (69)
White	5 (19)
Mixed race	2 (8)
Asian	1 (4)

The age range of participants for our study was between 20 and 71 years, including representatives from each age decade to ensure a comprehensive understanding of how age influences the experiences of individuals within the low-SES population. The mean household income was US $18,519, and the average household size was 4 members. While English-speaking was required for interview participation, linguistic diversity is present within the overall NeighborhoodHELP population. Among the NeighborhoodHELP population, 40% of members primarily speak Spanish and 14% speak Haitian Creole. Educational attainment varied, with 77% having completed at least high school.

The Social Needs Landscape: Insights From Participants and Professionals

Participants reported a wide array of social needs, reflecting the complex challenges low-SES populations face. These needs spanned financial instability, food insecurity, housing concerns, transportation difficulties, unemployment, educational barriers, limited health care access, and inadequate social support. Interviewees provided examples of how issues in the social domains, such as education, finances, and food insecurity, negatively impacted their physical and emotional health.

Participants indicated that they attempted to address their social needs through various resources, such as governmental programs, churches, and local nonprofits. When trying to address these needs, participants encountered several obstacles, including fragmented services, burdensome application processes, financial constraints, and competing life demands that made it challenging to navigate support systems effectively. Participating professionals indicated that successful care plans addressing social needs must include a triad of individual patient priorities, the feasibility of meeting specific needs, and evidence-based guidelines. They also noted that identifying the target user's strengths alongside risk areas is beneficial as these strengths can serve as leverage points and motivators.

DHT Use

Studies show that individuals with low SES often struggle with IT literacy, making it difficult to adapt to new tools. However, our research reveals that during the COVID-19 pandemic, many reported improved digital health use. Focus group participants highlighted various programs that promoted the use of technology, particularly for completing applications and checking statuses. Despite low SES, participants demonstrated significant engagement with digital technologies. Most (81%, n=21) reported daily internet use, and 81% (n=21) regularly used smartphone apps. However, self-assessed digital skills varied widely among participants, indicating a range of comfort levels with technology. Still, about half of the study participants used DHT for various health-related social activities, including scheduling health care appointments, completing social need applications, reading health care reviews, monitoring symptoms, accessing EMRs, retrieving medical records, completing health surveys, and using health-related apps (Multimedia Appendix 4).

User Needs, Preferences, and Current Technology Solutions

Our user profile work and detailed qualitative analysis resulted in 5 key themes related to user needs and preferences: UCD,

XSL•FO
RenderX

solution-based assessment of social needs, trust, privacy and security, e-caring and support, and education and user feedback. The following sections explore these themes identified through qualitative analysis of target user needs and preference data and share the presence of features associated with these themes in current DHT offerings. Table 4 highlights key comparisons from our landscape analysis, showing how current DHT aligns with or diverges from the identified needs and preferences. This comparative narrative addresses our research question on how the current landscape meets—or fails to meet—these needs. Multimedia Appendix 2 includes detailed descriptions of each SDOH-DHT we explored for a cohesive depiction of the landscape.

Table 4. Overview of themes from literature review, interviews, focus groups, and landscape analysis.

User needs and preferences	Current DHT[a] identified
User-centered design	
Multilingual	Few offer language translation beyond Spanish (eg, Creole)
Use of images, icons, and videos over text to help address literacy and add to aesthetics	Limited use of images and videos; most DHTs are text-based with few illustrations
Customized needs prioritization, goal setting, messaging (eg, reminders and progress tracking with incentivization/encouraging messages)	No DHTs found that allow easy assessment and prioritization of needs and goals; users often cannot choose notification timing
Self-paced, streamlined survey completion process that meets users where they are and their schedules	DHTs break questions into sections but do not allow users to save progress; few offer prefilled responses to streamline processes
Efficient, solution-based assessment of social risk/need	
One-stop access to resources addressing multiple social domains; cross-domain referencing	No DHTs surveyed include guidance to assess and navigate all health-related social domains with direct access by users; users need multiple DHTs, specific ideas about what services they need, or a case manager to assess needs and address barriers
Multiple referrals filtered by goals, geography, open hours, eligibility, etc.	Resources are searchable by keyword or domain area; some offer zip code filtering
Track progress over time with outreach workers/administrators	Program-focused DHTs track eligibility, application progress, and benefits status but are limited to those receiving formal assistance
Easy sharing of data with health care providers/social service professionals	Patient SDOH status integration into other systems (eg, EMRs) is generally unavailable for patient use
E-caring and support	
Use of empathetic and cooperative tone and language; motivational messaging	Few DHTs show evidence of an empathetic tone or motivational messaging
Option for continued contact with outreach workers; surrogate users (household, friends, outreach workers)	Several DHTs are designed for health care providers, not the general public; some offer training/resources for addressing social needs, while others only provide search functionality for services
User education and feedback	
DHT skill training (eg, swipe function) and health information searching; education on taking action on social needs	Few DHTs offer education on taking action to address social needs or risks; existing training is often limited to basic use of DHT or provider training
Review existing feedback (reviews and ratings) and add personal feedback	Most SDOH-DHT apps have user reviews in app stores; few include feedback from users and outreach workers on past service experiences
Trust, privacy, and security	
Trustworthy DHT platform and sponsor; evidence of safeguards against hackers, scams, and spam	Few current SDOH-DHTs prominently display privacy and data security policies or trust language
Information is optional, particularly for sensitive topics, unless required for app processes	Many DHTs do not allow users to skip sensitive questions

[a]DHT: digital health technology.

User-Centered Design

The UCD process tailors app design and development to the needs and capabilities of the target user population. Our data highlighted 3 key areas of UCD needs and preferences: inclusiveness, customization, and human-computer interaction efficiency. Although some existing apps addressed 1 or 2 of these areas, most apps in our landscape analysis lacked comprehensive attention to all aspects of UCD.

XSL•FO
RenderX

Inclusiveness

Participants strongly emphasized the need for inclusive design in SDOH-DHT. They expressed a desire for multilingual options, particularly highlighting the importance of Spanish and Haitian Creole translations alongside English. This linguistic inclusivity was seen as crucial for ensuring that diverse user groups could effectively engage with the technology. Our participants preferred apps in English, Spanish, and Creole. While several DHTs offer Spanish translations (eg, Your Texas Benefit, ebtEDGE, myCOMPASS PA), very few include Creole (eg, ACCESS Florida).

Additionally, participants stressed the importance of using simple, accessible language to accommodate varying literacy levels within the target population. Participants also noted that simpler terminology could reduce on-screen text and suggested that icons, graphics, and videos could further enhance usability. Some participants used sites like WebMD for their illustrative content, but few SDOH-DHTs include such features. For instance, ACCESS Florida (Florida Department of Children and Families) offers limited visuals, and while ACT.md (Activate Care) and WellSky Social Care Coordination (Wellsky) provide videos, these are general overviews rather than guides for accessing specific services. Most DHTs in our analysis were text-heavy, offering questionnaires or service lists with minimal visual aids (eg, Benefit Finder).

Customization

Customization emerged as another critical aspect of UCD. Participants wanted the ability to prioritize their needs within the app, set personalized goals, and receive customized messaging. Current SDOH-DHTs for individual use often fail to account for personal factors and prioritized needs.

Participants envisioned features such as reminders and progress tracking accompanied by encouraging messages, which they felt would enhance their engagement and motivation to address their social needs. While many existing SDOH-DHTs, especially mobile apps, offer notifications, they often lack options for users to choose when notifications should appear. For example, the "Providers: EBT, debit, & more" app (Propel, Inc) allows users to receive notifications for benefits, offers, tax filing, and promotions, but does not let them customize the frequency of these alerts.

Efficiency

Efficiency in interactions was also a key concern. Participants expressed a preference for a self-paced, streamlined survey completion process. They indicated that ideally, survey sessions should be limited to 10-30 questions and last no more than 20 minutes. This preference reflects the time constraints and competing priorities many individuals of low SES face. However, some SDOH-DHTs, like the Benefit Finder (US government), require up to 30 minutes to complete a questionnaire, which does not align with these preferences. While about one-third of current SDOH-DHTs avoid repetitive and lengthy data collection, some still take up to 30 minutes to complete.

Furthermore, participants stressed the importance of completing surveys at their own pace, starting with the most critical sections and saving their progress to continue later. The ability to save progress helps avoid repeating processes, which participants found essential. However, most web-based DHTs do not allow users to save their progress. For example, ACCESS Florida (Florida Department of Children and Families), Benefit Finder (US Government), and Washington Connection require users to fill out entire questionnaires without the option to save and return later. While some DHTs, like ACCESS Florida (Florida Department of Children and Families), break down questions by sections (eg, household, income, expenses), they still do not allow users to save partially completed questionnaires.

Efficient Solution-Based Assessment of Health-Related Social Risks, Needs, and Goals

Users articulated a strong desire for comprehensive tools integrated with practical solutions. They envisioned a "one-stop" platform that could address multiple social domains simultaneously, recognizing the interconnected nature of many social needs. For example, one participant faced food insecurity but could not access a food pantry due to a lack of transportation. Others were ineligible for services because of their immigration status. Participants expressed frustration with fragmented services and saw great value in cross-domain referencing within a single platform. Tools with a broader scope of social needs typically cover housing, food, employment, health care, transportation, and childcare services. For example, FindHelp (FindHelp) spans domains including food, housing, transportation, health, money, education, work, and legal services.

Social needs navigation professionals also emphasized the importance of tracking progress in addressing specific social needs. However, current DHTs typically do not integrate social needs assessments with service referrals or track progress over time. Some platforms, like Pieces (Pieces Technologies), use artificial intelligence and advanced analytics to automate screening and address SDOH issues through predictive modeling of at-risk patients in EMR systems. Unfortunately, these advanced algorithms and processes are inaccessible to the general low-SES population.

Another key preference was the ability to receive filtered referrals based on specific criteria. Users wanted to be able to narrow down service options based on their personal goals, geographic location, service hours, and eligibility criteria. This level of customization was seen as essential for making the platform truly useful in addressing individual needs. Most SDOH-DHTs provide lists of service referrals for specific needs and guide users to access a single service, but do not automatically filter resources based on user eligibility and practical considerations like access. More comprehensive tools, such as HelpSteps (Boston Children's Hospital) in Massachusetts and FindHelp (FindHelp) nationally, serve as central resources for individuals but are primarily designed for resource searching rather than automatically filtering resources based on eligibility. These tools allow users to search for help by directly finding and connecting with services like food,

XSL•FO
RenderX

housing, health care, and other types of support available nearby, usually by entering a zip code.

Participants also emphasized the importance of easy data sharing with health care providers and social service professionals. They recognized the potential for improved care coordination if their social needs data could be seamlessly integrated with their medical care. Administrators and outreach workers suggested that integrating this functionality with EMR systems could be an effective solution. While some DHT platforms are already integrated with EMRs, these are typically designed to assist providers rather than directly support low-SES patients. Certain platforms, such as NowPow (Unite Us) and WellSky Social Care Coordination (WellSky), focus on building networks among community care providers.

E-Caring and Support

The concept of "e-caring" also emerged as a significant theme in our discussions. Participants valued an empathetic and cooperative tone in all interactions within the app. They expressed a desire for motivational messaging, particularly when completing tasks or reaching milestones, as a way to maintain engagement and boost morale. However, our landscape analysis revealed that few existing DHTs offer motivational messaging when users complete questionnaires or select different services.

Many participants also highlighted the importance of having options for continued contact with outreach workers or support from surrogate users, such as household members or friends. This human element was seen as a crucial complement to the digital platform, providing personalized support and guidance when needed. During our landscape analysis, we identified ACT.md (Activate Care), an app that integrates with EMRs. The ACT.md platform enables health care providers to manage patient needs and coordinate care with community partners by sharing tasks, messages, and data across organizations. Care teams can view patients' unmet social needs and collaborate with community organizations to address those needs. However, these platforms are only accessible to providers and patients within health care systems that have purchased them. Additionally, they are primarily designed for health care providers rather than individual users.

User Education and Feedback

Participants showed interest in educational content within the SDOH-DHT, but with a specific focus on actionable information. Rather than basic facts about SDOH, they wanted practical guidance on how to address their specific social needs. Practical guidance references included a desire for DHT skill training (such as instruction on navigation functions) and advice on how to search for health information effectively. Existing digital health technologies tend to focus on offering general information across various social domains (eg, Your Texas Benefits, HHS.gov Social Services) or screening users for eligibility for certain benefits (eg, Benefit Finder, Washington Connection - Your Link to Services) without providing step-by-step guidance on how to address the identified needs and risks effectively.

The ability to engage with feedback was another important aspect for users. Participants wanted to be able to review existing feedback, including ratings and reviews of services, as well as contribute their feedback based on their experiences. This 2-way flow of information was seen as valuable for making informed decisions about services and contributing to community knowledge. While most SDOH-DHT apps feature user reviews on the technology itself in the app store, only 2 apps included feedback from both users and outreach workers on past service experiences. For instance, ACT.md, a platform that enables health care providers to manage patient needs and coordinate care with community partners, includes a page dedicated to client experiences. This page details how the platform has assisted its clients and features quotes from clients about their experiences with the programs.

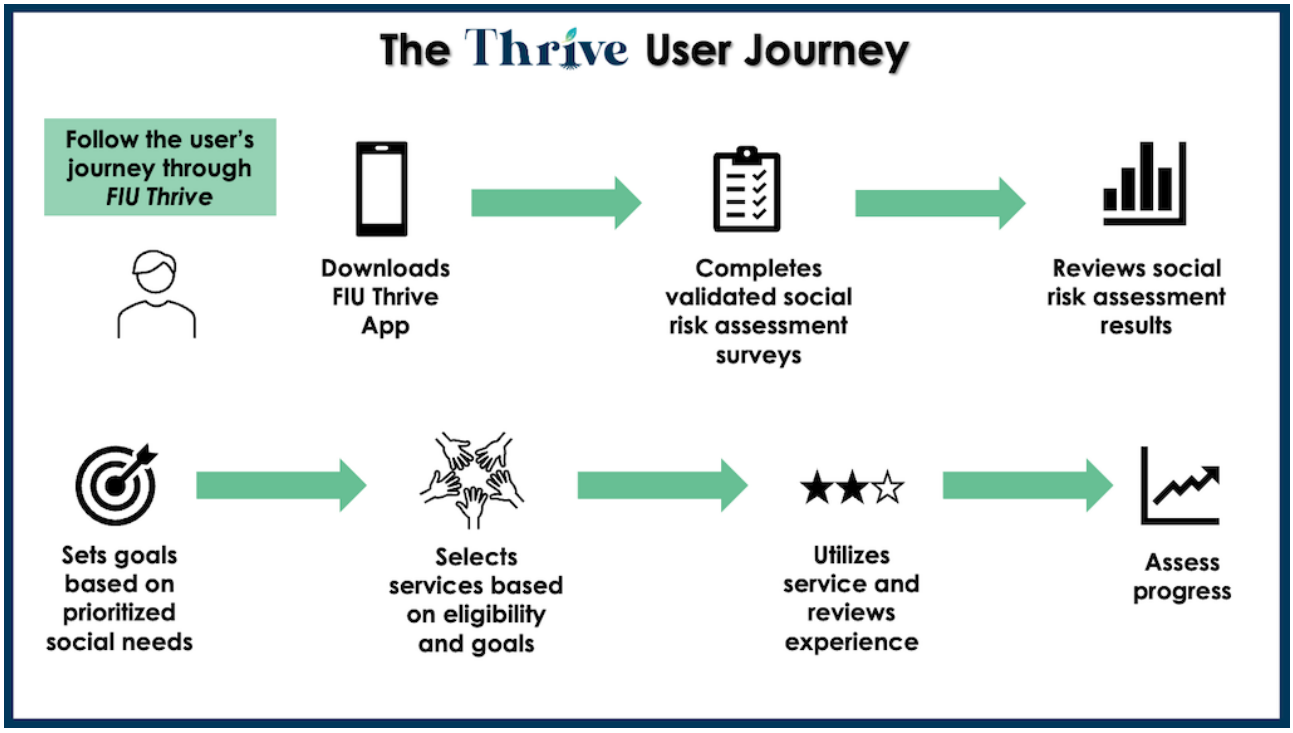
Trust, Privacy, and Security

Trust, privacy, and security emerged as foundational concerns for potential SDOH-DHT users. Participants emphasized the need for clear evidence of safeguards against possible threats such as hackers, scams, and spam. They were particularly sensitive to the possibility of personal information misuse leading to unwanted solicitations. Our landscape analysis showed that only a few current SDOH-DHTs prominently feature clear privacy and data security policies. One exception is the Pieces DHT, which offers users a dedicated page outlining its data privacy policy and contact information for any questions or concerns.

Regarding data sharing, participants strongly preferred granular control over their information. They wanted the option to selectively disclose sensitive information, with mandatory fields limited to only what was absolutely necessary for specific processes. Existing DHTs, especially those using questionnaires, often do not allow users to skip these sensitive questions. For example, the Benefit Finder (US government) requires users to disclose citizenship status, annual income, and employment status before allowing them to proceed with selecting services. This mandatory disclosure can deter some users from using the platform. Transparent privacy policies were seen as essential for building trust in the platform.

Discussion

Principal Findings



Our study reveals the characteristics, needs, and preferences of individuals of low SES using SDOH-DHT and how current DHTs align with or diverge from these needs and preferences. Our results, identified across the key themes such as UCD, solution-based features, e-caring support, education and feedback, and trust and security, have important implications for the effectiveness, adoption, and equity of digital health interventions targeting SDOH. The pervasive message users have communicated is the need for continuity across all themes.

The insights gained from this study are crucial for informing the iterative design process of the FIU Thrive mHealth tool. FIU Thrive aims to maintain continuity in addressing social needs by creating the user journey. This mHealth tool uniquely emphasizes identifying and addressing users' health risks, needs,

XSL•FO
RenderX

priorities, and goals. It integrates these elements into actionable insights, creating individualized care plans that enhance self-knowledge and empower individuals. Users can connect with recommended services based on their specified social risks, goals, and geographic area. FIU Thrive aims to address risks and needs across multiple SDOH domains. Overall, the FIU Thrive user will embark on a journey to understand their social needs and risks better and find evidence-based and personalized solutions to address them. The FIU Thrive User Journey is presented in Figure 3.

Figure 3. Thrive user journey. FIU: Florida International University.

FIU Thrive also seeks to address the needs and preferences of users of low SES within the different themes. Based on this UCD study, features designed into FIU Thrive to address the needs and preferences of our target users are presented in Textbox 2 and further described below.

The gaps in current SDOH-DHT may perpetuate barriers to access and engagement for individuals of low SES, who often face language, literacy, and cultural challenges [8,23,24,26-28]. Features for improving aspects of UCD to tailor app design and development to the needs and capabilities of the intended user population include multilingual support, use of graphics for visual guidance, customization, and self-paced and streamlined data collection. By interviewing participants aged 20-71 years, we captured a broad spectrum of experiences and insights related to lower SES. Decreased DHT adoption can be attributed to biopsychosocial factors that can be generalized to many age groups, including cognitive and physical impairments, lack of familiarity with technology, or lack of device access [96,97]. Based on current literature and our results, strategies to accommodate these needs include technology features such as larger font size and instructional videos, voice-to-text functions, and increased support from family, caregivers, or health care providers [96,97].

The fragmented nature of current SDOH-DHT resources, coupled with limited integration of referral and tracking features, may impose additional burdens on individuals of low SES who often navigate complex and disconnected social service systems [5,98]. The absence of comprehensive, coordinated support can lead to unmet social needs, delays in accessing care, and poorer health outcomes [3,27,99]. Improving solution-based assessment of HRSN by offering integrated, one-stop access to a wide range of social services, personalized referrals, eligibility screening for social services, and progress monitoring (for managing social risks) could help streamline connecting users to appropriate resources and support [6,20,100].

The lack of empathetic support and action-oriented education in existing tools may also undermine user engagement and motivation, particularly among individuals facing multiple stressors, competing priorities, and limited social support [27-29,99]. While using DHT platforms, our users emphasized the importance of conveying sensitivity, empathy, and motivation, as positive in-person interactions with health care providers do. Participants reported that features conveying e-caring included using empathetic and cooperative language, motivational messaging, and web-based chat or support group features.

Textbox 2. Florida International University (FIU) Thrive app features.

The FIU Thrive mHealth app is designed to address the specific needs and preferences of low socioeconomic status users identified in this study. The app is designed to incorporate the following features:

1. Multilingual support (user-centered design [UCD])

- In-app language selection option (eg, English, Spanish, and Haitian Creole)
- Automatic language detection based on the user's device settings

2. Simple and intuitive user interface (UCD)

- Clean, uncluttered design with minimal text
- Use of icons and visual cues to guide navigation

3. Customized user experience (UCD)

- Customizable user profile
- Ability to set personal goals and priorities
- Tailored content and recommendations based on user's social risks/needs assessment results

4. Solution-based assessment of social risk/need

- Brief, user-friendly questionnaires for each social domain
- Progress tracking and visualization using color-coded SDOH wheel
- Option to complete assessments in multiple sessions

5. Integrated referral system

- Personalized referrals to local resources and services based on social needs assessment results
- Detailed information about each referral, including eligibility criteria, contact information, and user ratings
- Ability to save and track referrals within the app

6. E-caring support features

- In-app messaging with outreach workers and peer support groups
- Encouraging notifications and reminders to support goal progress
- Web-based coaching and educational content tailored to user's needs

7. User education and feedback mechanisms

- User feedback on referral services
- In-app feedback form to report issues or suggest improvements
- Regular prompts to share progress and successes with outreach workers

8. Robust privacy and security measures

- Secure user authentication and data encryption
- Granular privacy settings to control data sharing
- Clear, concise privacy policy and terms of service

Regarding references of e-caring to their current technology, commonly used apps manifesting some aspect of e-caring that impacted our participants' health and wellness were spiritual and fitness apps. Participants reported continual use of spiritual and fitness apps because of the encouragement and motivation they received through notifications and messages, ensuring the user that they are moving in the right direction and imparting a sense of accomplishment. Participants reported that these messages helped them feel cared for and as if they received individualized attention to their actions, reducing the monotony of the DHT interaction. Ultimately, our participants appreciated that these messages allowed them to obtain reassurance and affirmation without physical interactions from a provider. Some participants commented that these elements of e-caring were an essential component of the long-term use of DHT. Our study supports that designing for e-caring and support (eg, "individualized attention"), which combines technology's efficiency with human interaction's empathy, may be particularly valuable in building trusting relationships and promoting sustained engagement [101].

XSL•FO
RenderX

Incorporating increased user education and feedback enhances engagement and impact of SDOH-DHT for this population [8,102,103]. For example, participants indicated that they desired the apps to enhance their knowledge and skills and provide useful feedback in the following areas: IT skill training, education on taking action to address HRSN, and a feedback/rating mechanism for social services consulted.

Privacy and security concerns emerge as a critical barrier to trust and adoption of SDOH-DHT among users of low SES who may have heightened sensitivities around the protection of their personal information, given experiences of discrimination, stigma, or exploitation [104,105]. The absence of clear privacy policies, granular data-sharing controls, and secure communication channels in many current tools may exacerbate these concerns and deter engagement [106]. Developing SDOH-DHT with robust privacy safeguards, transparent data practices, and user control over information sharing is essential to fostering trust, buy-in, and long-term use among low-SES populations [107,108].

Our findings highlight the importance of addressing HRSN among low-SES populations through various DHTs. mHealth apps provide accessible health monitoring and management platforms, crucial for low-SES populations facing barriers to traditional health care [16]. Telemedicine and telehealth services offer remote health care access, addressing transportation barriers and improving care for underserved communities [17]. HIT systems facilitate the integration of social needs data with medical care, enabling providers to better address the social determinants affecting patients' health [18]. EHR interoperability is crucial in achieving seamless communication and coordination of care. While VR and AR technologies are increasingly used in surgery [109] and occupational health to enhance training and patient engagement [19], their direct application to addressing HRSN among low-SES populations may be less clear. VR has been used in education related to SDOH to help providers recognize situations and increase empathy in management [110]. However, incorporating e-caring support features and personalized feedback mechanisms can improve the user experience and effectiveness of VR and AR applications for low SES populations [111].

In low and middle-income countries, barriers to DHT implementation include infrastructure limitations (unreliable electricity, limited internet), insufficient resources, and poor digital literacy among patients and providers [112,113]. Key facilitators include continuous on-the-job training, strong stakeholder commitment, and technologies designed with user-friendly interfaces [113]. Simpler DHTs such as telemedicine, mHealth, and EMR (including patient portal access or printouts) may be best initial DHT options in low and middle-income countries as they are easiest to implement due to lower infrastructure requirements, and easier integration into workflows [112]. Current literature has shown that efforts to bring DHT to such countries have been successful in improving the standard of health care service delivery, data management for decision-making, and boosting attendance at health facilities and use of services [112,113]. Therefore, we see promise in adapting our results in many settings, including low and middle-income countries, with adaptation as needed.

Overall, future work should focus on developing and evaluating SDOH-DHT that incorporates the user needs and preferences identified in this study. This could involve the creation of new tools (eg, FIU Thrive) or adapting existing platforms to better align with the requirements of those with low SES. Importantly, these development efforts require a solid commitment to UCD principles and the meaningful engagement of diverse individuals as co-designers and cocreators throughout the process to facilitate usability and acceptance. By involving target users as active partners in the conception, design, and iteration of SDOH-DHT, we can ensure that these tools are aligned with their unique needs, values, and lived experiences [37]. This participatory approach can help to identify and address potential barriers to adoption and use, enhance the cultural responsiveness and contextual relevance of the tools, and ultimately, improve their acceptance, usability, and impact among populations with low SES [114-116].

Furthermore, the development and implementation of SDOH-DHT must be situated within a broader ecosystem of supportive policies, programs, and partnerships that address the root causes of health disparities [3]. Digital tools alone cannot solve the complex, systemic issues that contribute to health disparities. Still, they can play a valuable role in connecting individuals to resources and facilitating communication and coordination among service providers [117].

Limitations

The purposive sampling method, while effective for ensuring representation, may limit the generalizability of our findings to the broader population of lower SES individuals. Additionally, the qualitative nature of the study means that the findings are inherently subjective and may not reflect the experiences of all individuals within this demographic. Limitations of our study also include the focus on participants speaking at a threshold level of English (speaking enough English as a primary or secondary language to complete the pre-enrollment questions in English) and the potential for incomplete identification of relevant SDOH-DHT given sample limitations. While we aimed to include a diverse sample of target users, the lack of non-English speaking participants may limit the generalizability of our findings to populations with limited English proficiency. Future research should use a cross-sectional design study with a larger and more representative sample of North American populations, including First Nations individuals and African immigrants, to capture the unique needs and preferences of a diverse patient population.

Additionally, despite our systematic search strategy, it is possible that some relevant SDOH-DHT were not identified or included in our landscape analysis. Moreover, due to the proprietary nature of some of the systems, we were unable to access some parts of some systems and include functionality of these parts (beyond what was described and referenced in information materials) in our landscape analysis. As the field of digital health is rapidly evolving, new tools and platforms may have emerged since our data collection in May 2024. Ongoing research should continue to monitor and evaluate the SDOH-DHT landscape to ensure that the most current and relevant tools are considered.

XSL•FO
RenderX

Conclusions

This study identifies characteristics, needs, and preferences related to SDOH-DHT among individuals of low SES compared with the current DHT landscape. Five themes emerged from our analysis: UCD, solution-based assessment of social risks and needs, e-caring and support, education and feedback, and trust, privacy, and security. This study also identified gaps between the needs and preferences of individuals of low SES for comprehensive social needs support and the features of current SDOH-DHT. Discrepancies between target user needs and current DHT features represent missed opportunities in developing user-centered tools to assist individuals with self-management of social needs. These findings underscore the need to design SDOH digital health interventions that are inclusive, empowering, and responsive to the unique challenges faced by these populations.

By creating digital health interventions that strive to truly meet the needs and preferences of users with low SES, we can harness the power of technology to bridge health disparities and promote public health. However, the development of user-centered SDOH-DHT is just one piece of the puzzle. We can only create the enabling environment needed for SDOH-DHT to achieve its full potential in advancing health and reducing health disparities by working together across disciplines, sectors, and communities.

Acknowledgments

The authors acknowledge Nancy Napolitano, Jessica Vallejo, and Carolina Cardenas for coordinating recruitment for this study. They also acknowledge Troy Stefano, Andres Rodriguez, Staci Morris, Rodolfo Padron, Nicholas Chung, and the rest of the College of Medicine IT team for their work in developing the FIU Thrive app platform. They also acknowledge Troy Stefano's leadership in conceiving and funding FIU Thrive. They also acknowledge Gabriela Torres' contribution to data analysis for the UCD project. Last, the authors recognize the Green Family Foundation Neighborhood Health Education Learning Program (NeighborhoodHELP) outreach team and household members without whom this program and study would not have been possible. Funded in part by CDC-RFA-OT21-2103, the National Initiative to Address COVID-19 Health Disparities Among Populations at High-Risk and Underserved, Including Racial and Ethnic Minority Populations and Rural Communities, through Florida Department of Health in Miami-Dade contracts DEX87 and DEY50.

Authors' Contributions

KLH contributed to the writing of the original draft and its review and editing, as well as to investigation, data curation, and analysis. CL contributed to conceptualization, administration, and supervision, and participated in the writing of the original draft and its review and editing, investigation, data curation, and analysis. PD contributed to the writing of the original draft and its review and editing, investigation, data curation, and analysis. MPDC contributed to the review and editing of the manuscript, investigation, data curation, and analysis. DRB contributed to conceptualization, administration, and supervision, and participated in the writing of the original draft and its review and editing.

Abstract

Background: Digital health tools such as smartphone apps have the potential to improve supportive cancer care. Although numerous smartphone apps for supportive care are available, few are designed using a user-centered approach. Such an approach is crucial for successful implementation, as it may improve user engagement, usability, and adoption in clinical settings.

Objective: This study aimed to co-design and develop a digital health app for supportive cancer care in collaboration with patients with cancer and health care professionals and to explore factors influencing its future acceptance.

Methods: We conducted a participatory study with the major stakeholders at the University Hospital Zurich. Workshops, individual qualitative interviews, and focus groups were held with health care professionals, survivors of cancer, and patients with cancer. The co-design process was divided into 3 phases: predesign, generative phase, and prototyping. User-centered design methods included scoring cards and think-aloud protocols to co-create design ideas, identify important functionalities, and test usability. Qualitative data were analyzed using thematic analysis.

Results: Patients and health care professionals emphasized the need for a digital health app to improve patient–healthcare professional communication, digitalize supportive care screening and processes, and enhance self-efficacy. The resulting app, OncoSupport+, was co-designed and integrated into the clinical workflow for supportive cancer care. It consists of (1) a patient dashboard to record patient-reported outcome measures and to provide access to personalized supportive care information and contact details, and (2) a nurse dashboard to visualize patient data, which can be used during nursing consultations. Potential facilitators for adoption included ease of use, workflow integration, introduction by health care professionals, and technical support, whereas internet anxiety may be a potential barrier.

Conclusions: Collaborative development with patients and health care professionals is crucial for creating digital health tools that can be implemented successfully. Future research should evaluate the feasibility of long-term implementation and the real-world usability and effectiveness of OncoSupport+ for improving communication, self-efficacy, and quality of life.

KEYWORDS

cancer; digital health; mHealth; patient-reported outcome measures; supportive care

Introduction

Cancer is a highly prevalent condition with increasing incidence rates and is the leading cause of death worldwide [1]. As improvements in diagnosis, treatment, and surveillance have led to better survival rates, patients with cancer are living longer [2], though a considerable portion of patients experience significant morbidity and symptoms related to both the cancer and its treatment. Patients with cancer often exhibit physical, emotional, social, spiritual, and informational needs, also known as supportive care needs, and the aggregated impact may ultimately contribute to exacerbated health outcomes and diminished quality of life [3]. Supportive care, which focuses on the prevention and management of cancer symptoms and cancer treatment–related symptoms, has been widely acknowledged as an essential component of comprehensive cancer care [4]. It includes the management of physical and psychological symptoms and side effects across the cancer care trajectory from diagnosis through treatment to posttreatment care. Examples of supportive care include management of symptoms such as nausea, nutritional and exercise support, psychological support, and practical assistance for concerns such as transportation [4].

Several cancer centers have established specialized supportive care services, employing the expertise of a multidisciplinary team with diverse medical specializations such as nutritionists, physiotherapists, and psychologists. Supportive care has been shown to improve quality of life [5], tolerability of cancer treatments, survival, and systemic health economic benefits [6]. However, studies continue to report unmet supportive care needs, such as physical and informational needs, indicating that significant efforts are still required to ensure the effective implementation of evidence-based supportive care in clinical practice [7]. Specifically, the Multinational Association of Supportive Care in Cancer has emphasized the routine collection of patient-reported outcome measures (PROMs) to facilitate timely, individualized supportive care and empower patients through evidence-based education [7]. Commonly used PROMs include the European Organization for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) [8] and the National Comprehensive Cancer Network (NCCN) Distress Thermometer [9]. In this context, digital health tools, particularly mobile health (mHealth) apps, have emerged as promising solutions for delivering patient-centered supportive care interventions [10].

A growing number of digital health applications offer mental health support, symptom self-management, and educational resources. Among these, digital symptom monitoring and electronic patient-reported outcome measures (ePROMs) are commonly integrated interventions for supportive cancer care [11,12] and provide advantages over traditional paper-based PROMs or retrospective questionnaires, which are often limited by recall bias and low completion rates [13,14] . As digital health apps enable the remote collection of symptoms and supportive care needs in daily living environments, these tools allow for a more timely and accurate assessment of patient well-being. Research has shown that such applications can improve communication with health care professionals, facilitate connections with other patients, and enhance self-efficacy, thereby complementing clinical care [15]. Systematic reviews and meta-analyses have further suggested that digital health interventions may improve symptoms and quality of life [11,15]. Despite these findings, their implementation and adoption remain limited, particularly in cancer care [16]. A key reason is the limited involvement of key stakeholders, including patients and health care professionals, during development, leading to suboptimal adoption and effectiveness [10,11,17].

Co-design has been identified as a promising approach to ensure that digital health interventions are patient-centered, clinically relevant, and technically feasible [18]. By incorporating participatory and iterative stakeholder engagement, co-design can help tailor digital health interventions to meet the needs and preferences of both patients and health care providers while facilitating the early identification of implementation barriers and factors influencing adoption and long-term engagement. However, despite its potential, co-design is not always rigorously applied in digital health research, as studies often lack structured methodologies, fail to systematically integrate diverse stakeholder input, and do not adequately assess long-term feasibility [19]. Addressing these gaps is crucial for developing user-centered and sustainable digital health interventions in supportive cancer care.

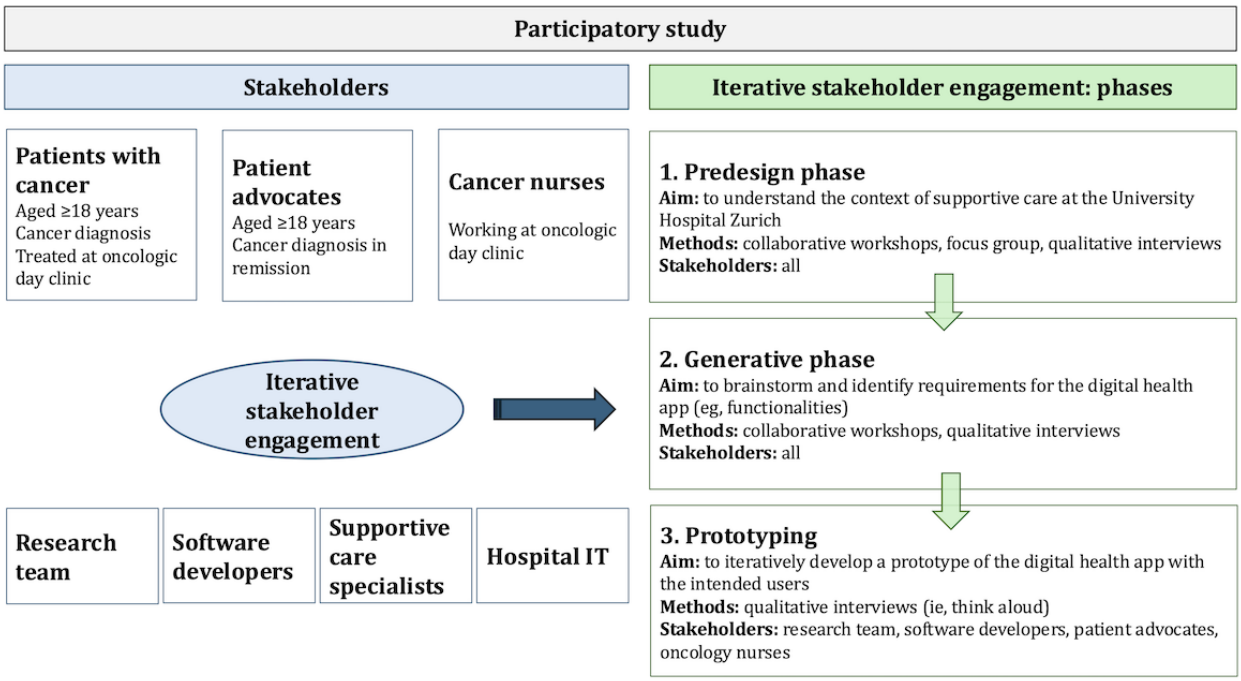
The overall aim of this study was to collaboratively design and develop a digital health app for supportive cancer care together with the relevant stakeholders (patients with cancer, survivors of cancer, and health care professionals). Specifically, the first objective was to map the context of supportive cancer care at the University Hospital Zurich, including challenges and needs. The second objective was to identify specific functionalities and features of the app and gather the patients' and nurses' perspectives; as part of this objective, we also explored factors that can potentially influence the uptake and implementation of the digital health app for supportive cancer care. Finally, the third objective was to design and develop the prototype and user interface of the digital health app to be technically implemented.

Methods

Ethical Considerations

This study was reviewed by the Ethics Committee of the Canton of Zurich, which determined that it did not fall within the scope of the Swiss Human Research Act and therefore did not require formal approval (Req-2023-01095). According to the Swiss Human Research Act (SR 810.30), ethical approval is required for studies involving health-related personal data, biological material, or clinical interventions. This study involved collecting opinions and experiences from patients, advocates, and nurses to inform app development; no health-related personal data were analyzed. Patients, patient advocates, and nurses received written

XSL•FO
RenderX



and oral information about the study objectives and procedures, and written informed consent was obtained before participation. Data were collected in a pseudonymized manner. Transcripts and digital records were deidentified before analysis, and all personal identifiers were removed. Access to study data was restricted to the research team. As patient advocates were part of Swiss Group for Clinical Cancer Research (SAKK), they received financial compensation for their contribution. No quotes or materials that could identify individual participants are included in the manuscript or supplementary materials.

Study Design

This participatory study was conducted between May 2023 and October 2024 as part of the Digital Health Zurich initiative [20]—a collaboration between the University of Zurich, the University Hospital of Zurich, and the Zurich University of Applied Sciences. The overarching goal of Digital Health Zurich is to create a sustainable, data-driven, and cross-institutional digital ecosystem by fostering collaboration between patients, health care professionals, technology developers, and researchers in Zurich and beyond. The initiative aims to translate research into real-world digital health solutions, with a strong focus on patient and provider needs, participatory development, cross-institutional cooperation, and innovation within the health care system. As a use case, this study was conducted at the University Hospital Zurich in collaboration with the Department of Oncology and Hematology and the Comprehensive Cancer Center Zurich.

The stakeholders included in the study were patients with cancer and patient advocates, cancer nurses, supportive care specialists, oncologists, and the research team; more details are listed in the Study Participants and Stakeholders section. Figure 1 shows an overview of the study design, using iterative stakeholder engagement, user-centered approaches, and design thinking techniques. The study can be divided into different phases, similar to the framework suggested by Noorbergen et al [18] for co-designing mHealth systems, which is a novel extension of the work by Sanders and Stappers [21]. The predesign phase aimed to understand the context of supportive cancer care at the University Hospital of Zurich, including the challenges faced by cancer nurses and patients in accessing supportive cancer care. The generative phase focused on brainstorming digital health app functionalities, as well as identifying potential factors that may impact future uptake of the technology. The prototyping phase, taking into account the findings from the previous phases, aimed to iteratively develop a prototype of the digital health app by gathering feedback from the intended users. Between June 2023 and October 2024, the research team held collaborative workshops, focus groups with cancer nurses, and qualitative interviews with patients and patient advocates.

Figure 1. Participatory study design using iterative stakeholder engagement, divided into 3 phases: predesign, generative, and prototyping.

Study Participants and Stakeholders

Patients With Cancer and Patient Advocates

Patients with cancer and patient advocates were recruited for the study. Inclusion criteria for patients with cancer were: (1) current treatment for cancer at the oncologic day clinic of the Department of Oncology and Hematology, (2) age ≥18 years, and (3) ability to speak German, Italian, or English. As patients with cancer often experience fatigue and may face challenges in participating in research activities, patient advocates from the SAKK (today Swiss Cancer Institute) were also included. These advocates were survivors of cancer in remission, enabling them to contribute insights from both patient and survivor perspectives. Their ability to engage more actively made them valuable contributors to the research. Inclusion criteria for patient advocates were (1) history of cancer, (2) age ≥18 years, and (3) ability to speak German, Italian, or English.

XSL•FO
RenderX

Cancer Nurses

Cancer nurses were included in the study. Inclusion criteria were employment at the Department of Oncology and Hematology of the University Hospital Zurich.

Supportive Care Specialists

Supportive care professionals, including a supportive care nurse, a nutritionist, 2 physiotherapists, and medical doctors with specializations in oncology, palliative care, and complementary medicine, were engaged in the participatory study to share their expertise and ensure that the app aligned with clinical practices in supportive cancer care.

Research Team

The research team consisted of one cancer nurse and one oncology doctor, researchers in digital health, computer science, computational health, and medical informatics, as well as a user experience designer. Two of the computer science researchers also contributed as software developers for the digital health app. Digital health researchers were responsible for organizing, moderating, and conducting the research activities. One of the computer science researchers supported data collection.

Recruitment of Patients With Cancer, Patient Advocates, and Cancer Nurses

Patients with cancer were recruited by cancer nurses from the Department of Oncology and Hematology at the University Hospital Zurich. Potential participants were introduced to the study through an informational flyer describing the study procedures and offering the option to participate in interviews while receiving systemic antineoplastic therapy at the oncologic day clinic. Interested patients could provide their contact details and suggest a convenient date and time for an interview with a researcher. Of the 8 patients who provided their contact details, a total of 6 agreed to participate in the study. Patient advocates were identified by the coordinator of patient advocates at SAKK, and 4 agreed to participate. A total of 5 nurses were recruited by a project team member who also works as an oncology nurse at the day clinic.

Study Procedure

Between June 2023 and October 2024, data were collected through collaborative workshops, focus groups with oncology nurses, and qualitative interviews with patients with cancer and patient advocates. Interviews and focus groups were conducted in German, English, or Italian, while workshops were held in English, the working language of the project team. Focus groups and interviews were audio-recorded, whereas workshops were documented by 2 researchers who took notes, cross-checked them, and shared the notes with the wider team.

Phase 1: Predesign

The predesign phase consisted of a collaborative workshop with the research team, one focus group with cancer nurses, and individual qualitative interviews with patients and patient advocates. The initial workshop aimed to map the context of supportive cancer care at the hospital and define the study problem statement. The subsequent 1.5-hour focus group with cancer nurses was guided by questions on their experiences with supportive care, challenges in daily practice, and opportunities for digital health to enhance supportive care. In parallel, interviews with patients with cancer and patient advocates explored their experiences with supportive care services and their views on how digital health tools could support their needs.

Phase 2: Generative

The generative phase included a second collaborative workshop with the research team, qualitative interviews with patients with cancer and patient advocates, and a workshop with supportive care specialists. Informed by the predesign phase, the research team specified potential functionalities for integration into the app. During the interviews, patients and patient advocates were asked to reflect on potential app functionalities, suggest additional features, and discuss factors that might influence the uptake of digital health interventions. To prioritize functionalities, a scoring exercise was included in which participants rated each feature on a scale from 1 to 10, with 10 indicating a “must-have” functionality. The collaborative workshop with the research team focused on brainstorming digital health solutions and proposing an initial structure for the app. As the preceding step highlighted the need to personalize supportive care for patients with cancer, a 2-hour workshop was conducted with supportive care specialists and digital health researchers, during which participants co-designed a rule-based algorithm to tailor supportive care.

Phase 3: Prototyping

From July to October 2024, the prototyping phase was conducted. Based on insights from the previous phases, a digital health researcher iteratively developed user requirements and specifications documented in Confluence [22], which were then translated into user interface designs with Figma [23] by the user experience designer. A user flow was created to outline app navigation, and this flow was tested by 2 cancer nurses and 4 patient advocates. The prototype of the user interface was subsequently developed and iteratively reviewed by the same group. Participants were encouraged to verbalize their impressions, identify challenges in navigation, and comment on the clarity and usefulness of the proposed functionalities. Finally, a workshop involving health care professionals and the research team was held to evaluate and further refine the prototype.

A meeting between the software developers and the IT department of the hospital was also held to assess different digital solutions and explore how these could potentially be integrated into the IT system of the hospital.

Data Analysis

The qualitative data from interviews and focus groups were transcribed, translated, and analyzed using thematic analysis, following Braun and Clarke [24] methodology.

All audio recordings were transcribed orthographically using OpenAI Whisper [25], performed locally to ensure data security. Transcripts were translated to English, initially using Whisper and then manually checked and corrected by bilingual researchers who conducted the interviews, ensuring high-quality transcription and translation. The corrected transcripts were

XSL•FO
RenderX

used for analysis. Thematic analysis was conducted following the six-step process [24]: (1) familiarization with the data, (2) generating codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing a report. To reduce bias, analyses were conducted by the first 2 coauthors of this study. During familiarization, the first 2 coauthors read transcripts multiple times and highlighted text segments relevant to 5 aspects: app and dashboard functionalities, barriers and facilitators to use, challenges with the health care system and supportive care, and experiences with digital devices. Initial codes were generated using an open coding approach, capturing meaningful segments without predefined categories. Codes were then grouped based on similarity to identify patterns and inform preliminary theme development.

Themes were iteratively reviewed, refined, and organized into coherent subthemes, with disagreements resolved through discussion between the first 2 coauthors. Theme names were defined to accurately reflect core concepts, and data extracts were used to support each theme. Results were summarized with mind maps, journey maps, and frequencies of reported themes. Median and ranges were reported to summarize scorecards on functionalities.

Unified Theory of Acceptance and Uptake of Technologies

As it is important to identify factors influencing acceptance early in the design phase to guide design choices and improve engagement, the Unified Theory of Acceptance and Use of Technology (UTAUT) framework was used to guide reporting of the results [26]. Originally developed to predict technology acceptance in organizational settings, the framework has been validated in health care contexts [27] and adapted for mHealth adoption in cancer care [28]. The validated framework by Philippi et al [28] identifies 3 key predictors of acceptance: performance expectancy, effort expectancy, and social influence. Internet anxiety moderates their effects.

Performance expectancy refers to the extent to which an individual believes the technology will be beneficial and is considered the strongest predictor of acceptance. Effort expectancy describes the perceived ease of use of the system, with higher effort expectancy (ie, lower ease of use) negatively impacting acceptance. Social influence refers to the degree to which users perceive that significant others encourage system usage, positively influencing adoption. Internet anxiety moderates the relationship between effort expectancy and social influence, potentially hindering adoption. Specifically, the UTAUT was used to report the identified themes related to barriers and facilitators to uptake.

Sample Size and the Principle of Saturation

Although the study initially aimed to enroll approximately 30 participants for qualitative interviews and focus groups, the principle of thematic and design saturation was applied [29]. Recruitment was stopped once no new themes emerged, ensuring that data collection was both rigorous and meaningful without overburdening participants. For instance, when 2 or more consecutive interviews or focus groups did not reveal new themes or suggest new design features, the recruitment was stopped. This approach is consistent with co-design studies in digital health, where sample sizes are often small and vary widely; a recent umbrella review reported that as few as 2 participants have been included in some co-design projects [30]. In addition, as mentioned by Arcia at al [31] what matters most is not the absolute number of participants, but the iterative design process and achievement of thematic and design saturation, both of which were ensured in this study.

Results

Demographics, Experience With Digital Tools, and Other Characteristics of Patients With Cancer, Patient Advocates, and Cancer Nurses

A total of 6 patients with cancer and 4 patient advocates participated in the study (Table 1). Their ages ranged from 29 to 75 years, with a mean of 50.3 years. Four participants were female. Most held advanced university degrees, with 6 out of 10 having completed a bachelor's degree or higher (ie, master's or PhD). None were employed full-time at the time of the study; 4 worked part-time, and 2 were retired. All participants owned both a smartphone and a computer. While all reported daily smartphone use, 7 also used a computer daily, and 6 owned a tablet. Half of the participants rarely needed assistance when using digital devices, 4 required help occasionally, and 1 needed assistance daily. All nurses who participated in the study were female, aged between 37 and 53 years, with at least 10 years of experience in oncology nursing.

Phase 1 (Predesign): Supportive Care Pathway, Challenges, and Opportunities for Digital Health

Figure 2 shows the supportive care pathways at the University Hospital Zurich. Patients may access supportive care services through oncology nursing consultations, physician consultations, or direct contact. At the initial nursing consultation, supportive care needs are assessed using standardized paper-based PROMs, specifically the EORTC QLQ-C30 [8] and the NCCN Distress Thermometer [9]. Based on these assessments, nurses provide referrals to one or more of the 12 supportive care services offered, and patients additionally receive a supportive care brochure.

The predesign phase revealed 4 major themes regarding challenges and opportunities for digitalization in supportive cancer care at the University Hospital Zurich (Figure 3). Nurses, patients, and patient advocates highlighted the need for digitalization and standardization of supportive care, suggesting that digital platforms could replace paper-based PROMs, improve screening rates, and allow consultations to focus on discussing patient responses. As one cancer nurse explained:

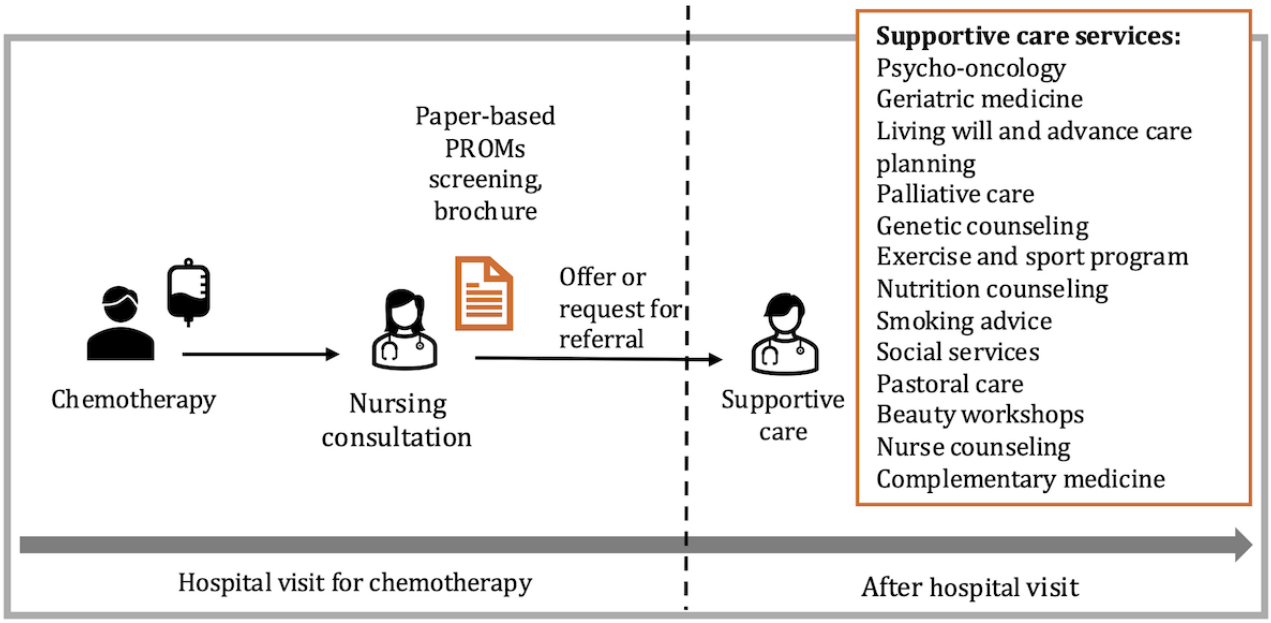
> *At the moment, we give patients a paper-and-pencil version of the screening when they come to the hospital. […] So, the digital screening should actually improve this by allowing patients to answer in advance […]. This way, patients can complete it at home, and we can spend more time discussing their responses during the consultation.* [Cancer Nurse 2, focus group]

Communication challenges were also emphasized, including difficulties in reaching doctors, treatment-related fatigue, and language barriers. One patient advocate noted:

> *It's difficult [the communication with healthcare professionals] ... most of the time, my oncologist answers quite quickly. But sometimes he has too many things to do.* [Patient Advocate 3]

XSL•FO
RenderX

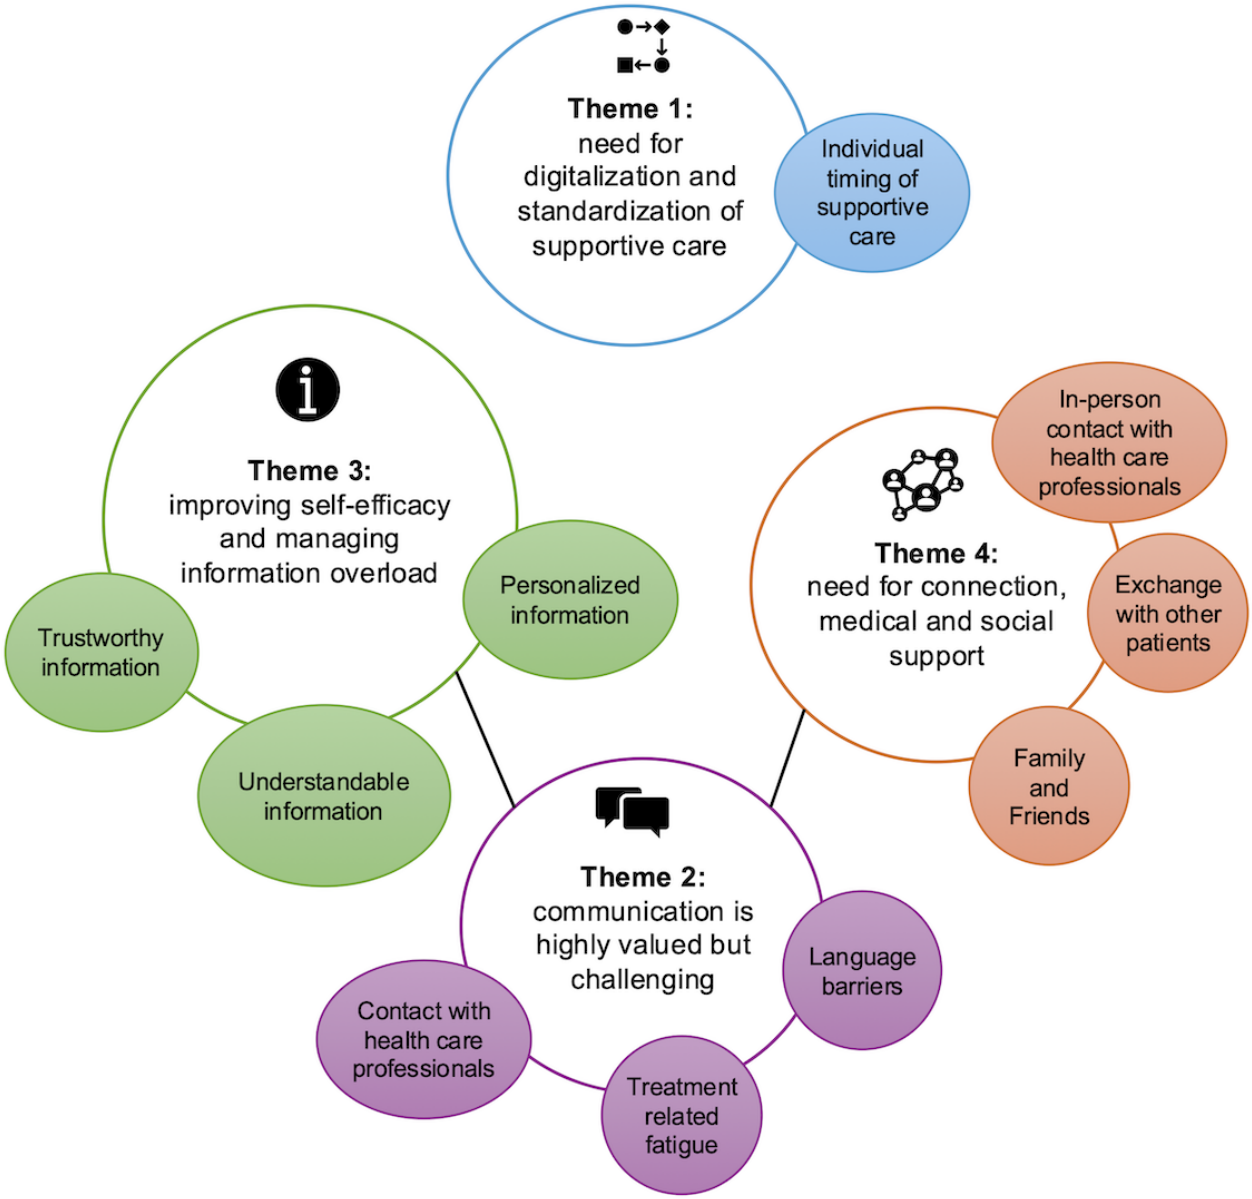
Patients reported information overload, describing the volume of paper-based brochures and consultations as overwhelming, and expressed a preference for simplified, trustworthy, and personalized digital resources.



> *I have read a few things but, in the end, I was so overwhelmed with the conversations. Before each surgery, you have a conversation with the surgeon or the radiologist and then with the anesthetist and then again, a conversation and then you get a few more documents […]* [Cancer Patient 6]

Finally, the importance of connection and social support was highlighted. Patients valued peer support and digital opportunities to connect, but also emphasized that face-to-face consultations remain indispensable.

> *If I had an app for my illness, it would be good, but it would make everything so virtual, and you still need to connect with people in real life.* [Cancer Patient 4]



These themes and their relationships are summarized visually in Figure 3. More illustrative quotes can be found in Multimedia Appendix 1.

Figure 2. Mapping of supportive care pathways at the University Hospital Zurich.

XSL•FO
RenderX

Figure 3. Challenges and opportunities for digitalization in supportive cancer care at the University Hospital Zurich. Themes were derived from interviews and focus groups with patients with cancer, patient advocates, and oncology nurses, and informed subsequent app functionalities.

Phase 2 (Generative): Functionalities and Integration in the Supportive Care Pathway

Table 2 summarizes the functionalities of the digital health app, named OncoSupport+, that were either proposed by the research team or suggested by patients, mapped to the related themes identified in phase 1 (Figure 3). Functionalities developed by the research team were rated by patients on a scale from 1 to 10, where higher scores indicated greater perceived importance. Personalized information on supportive care (median 9.5) and digital PROMs screening (median 9.0) were rated as the most relevant features. Other functionalities, including self-help group information, a diary for consultations, and PROMs visualization, also received favorable ratings (all medians ≥7). Patients suggested several additional functionalities, including patient–health care professional chat (proposed by 6 participants), patient–patient chat (5 participants), self-management advice and symptom checking (5 participants), proactive contact from health care professionals (4 participants), reminders (4 participants), sharing data with family and friends (3 participants), information about cancer types (3 participants), patient stories (3 participants), and supportive care information for relatives (2 participants). Several of these patient-suggested features were integrated into the app (eg, reminders, patient stories, cancer type information, and peer support links), while others were not implemented due to scope limitations or regulatory considerations.

XSL•FO
RenderX

Table 2. Proposed functionalities for OncoSupport+, by source (research team vs patients), with brief descriptions, related themes identified in the predesign phase (Figure 3), ratings by patients and patient advocates.

Functionality	Description	Related theme (phase 1)	Median (range)	Frequency of suggestions,n	Included (yes/no)
Digital PROMs[a] screening[b]	Scheduled digital assessment of supportive care needs using standardized instruments: EORTC QLQ-C30[c] and NCCN[d] Distress thermometer (ePROMs[e]).	Digitalization and standardization; communication	9.0 (6-10)	—[f]	Yes
Personalized information on supportive care[b]	Personalized list of relevant supportive-care services and contact details generated from the patient profile and ePROMs results.	Information overload and self-efficacy	9.5 (7-10)	—	Yes
Self-help group information[b]	Link to verified cancer self-help and peer-support groups.	Information; connection, and peer support	7.5 (2-10)	—	Yes
Diary for consultations[b]	Free-text notes to record symptoms not captured by ePROMs and questions for nursing consultations.	Communication	7.5 (3-10)	—	Yes
PROMs visualization[b]	Dashboards for patients and cancer nurses displaying ePROMs and trends over time, with integration of diary notes.	Communication; self-efficacy	7.0 (2-10)	—	Yes
Patient–Health Care Provider chat[g]	Messaging between patients and cancer nurses.	Communication	—	6	No
Patient–patient chat[g]	Link to a peer-support platform provided by the cancer association.	Connection and peer support	—	5	Yes
Symptom checker and self-management advice[g]	Personalized symptom management advice based on reported symptoms and ePROMs results.	Self-efficacy	—	5	No
Proactive contact from health care provided (phone or email)[g]	Nurse-initiated outreach (phone or email) triggered by digital PROMs screening.	Communication	—	4	No
Appointment and PROMs reminders[g]	Automated reminders for clinic appointments and ePROMs completion by email, SMS, or mailed letter.	Self-efficacy	—	4	Yes
Sharing data with family and friends[g]	Patient-controlled sharing of selected PROMs summaries with family members and friends.	Social support	—	3	No
Information about cancer types[g]	Evidence-based educational content on cancer diagnoses, treatments, and common side effects.	Information overload; self-efficacy	—	3	Yes
Patient stories and experiences[g]	Positive stories and experiences from patients and survivors to support coping with cancer.	Emotional support and connection	—	3	Yes
Supportive care information for relatives[g]	Resources for relatives on available services and practical guidance.	Social support	—	2	No

[a]PROMs: patient-reported outcome measures.

[e]ePROMs: electronic patient-reported outcome measures.

[f]Not available.

[g]Patient suggestions.

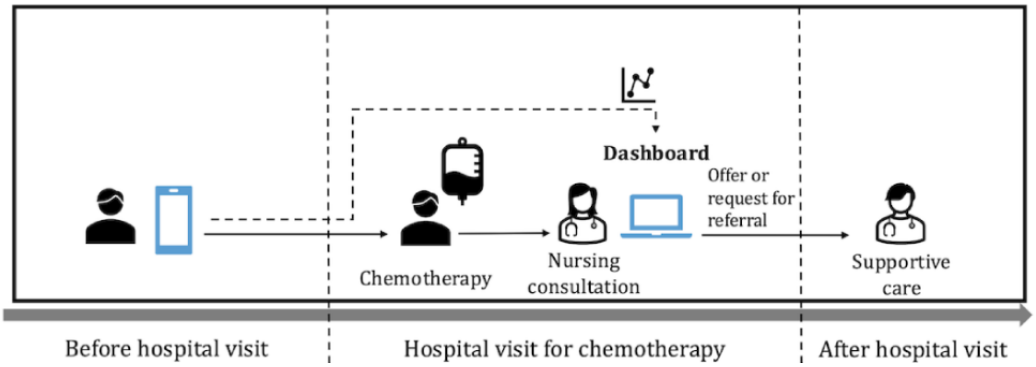

Figure 4 summarizes how OncoSupport+ and the included functionalities are integrated into the supportive care pathway. Patients complete digital PROMs screenings (Multimedia Appendix 2 lists the entire digital screening questionnaires, including the EORTC QLQ-C30 and the NCCN Distress Thermometer tool) in the week before their consultation, after which the app provides personalized supportive care information and other more general information, such as self-help groups and the peer-support platform. During the consultation, nurses access a dashboard displaying PROMs, diary notes, and

XSL•FO
RenderX

personalized information for supportive care and can recommend supportive care services. During the cancer treatment journey, patients use the app at least 3 times: at the beginning, halfway through treatment, and at the end.

To provide personalized supportive care information based on digital PROMs screening and the patient profile, a rule-based algorithm was developed in collaboration with supportive care specialists at the hospital. This algorithm prioritizes supportive care services and provides personalized information based on the symptoms and needs reported by patients and is based on medical knowledge and published scientific literature. For example, psycho-oncology is prioritized if a patient reports a distress score ≥5 on the NCCN Distress Thermometer and rates at least one emotional or social functioning item as "very much." A detailed description of the algorithm and its rules is provided in Multimedia Appendix 3.

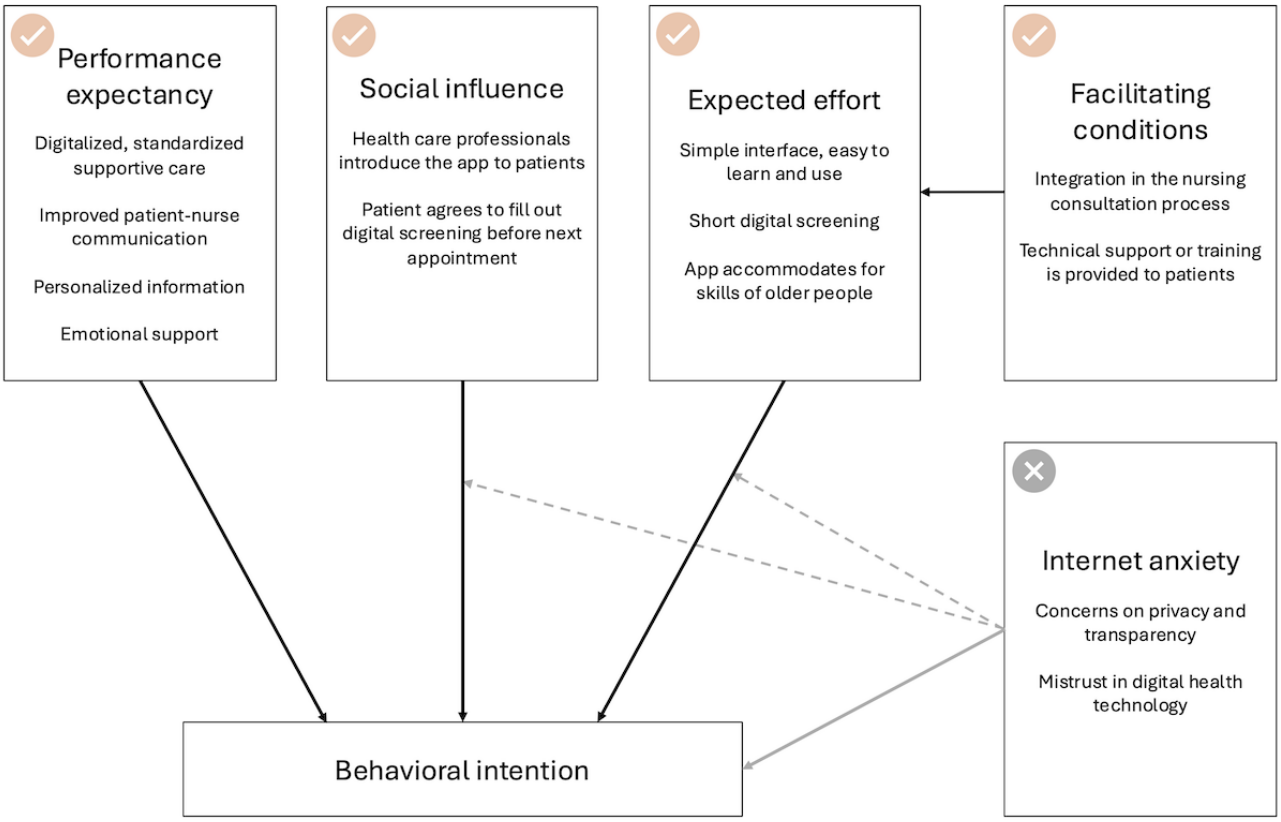

Figure 4. Integration of OncoSupport+ into the supportive care pathway.

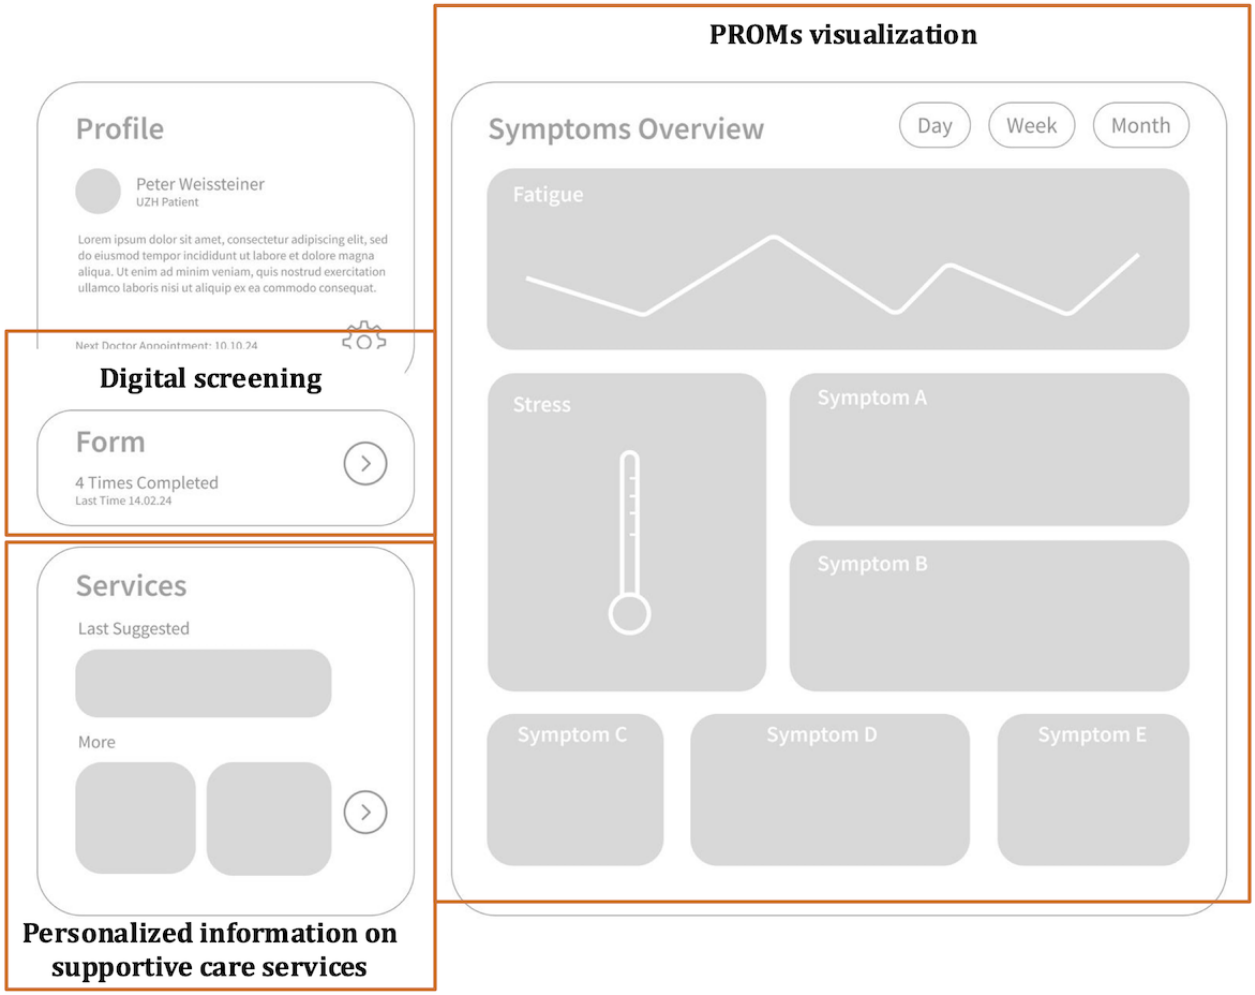
Factors Potentially Impacting the Uptake of the Digital Health App OncoSupport+

Factors influencing the potential uptake of OncoSupport+ were mapped to the UTAUT framework (Figure 5; Multimedia Appendix 1 shows supporting quotes). Improved communication with health care professionals was the strongest driver of performance expectancy. Social influence was also important, as patients indicated they would be more likely to use the app if recommended during consultations. Effort expectancy was reflected in the preference for a simple, intuitive interface, particularly among older users or those with lower digital literacy. Facilitating conditions included integration into routine nursing consultations and the availability of technical support. Conversely, privacy concerns and internet anxiety emerged as barriers that may limit adoption.

Figure 5. Unified Theory of Acceptance and Use of Technology model illustrating factors affecting acceptance of OncoSupport+. Performance expectancy, social influence, and expected efforts positively correlate behavioral intention (black lines), whereas internet anxiety negatively correlates with behavioral intention (gray line) and moderates the relationships between social influence and expected effort (gray dotted line).



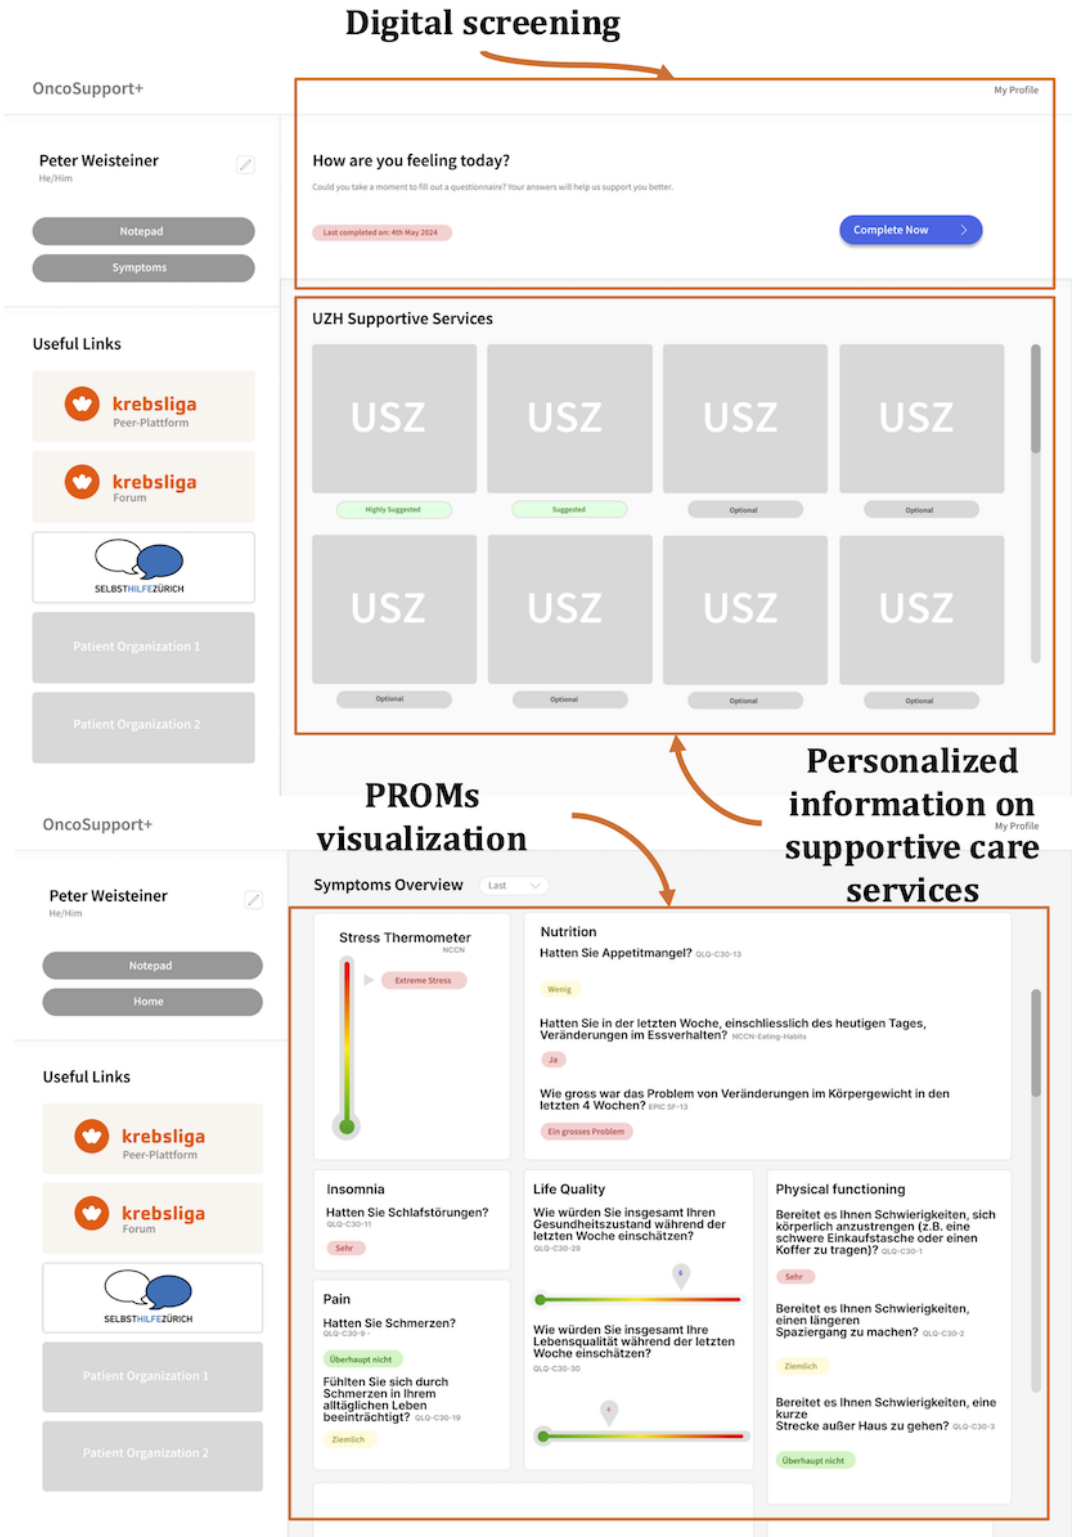
XSL•FO
RenderX

Prototyping

In the prototyping phase, the requirements identified in earlier stages were translated into user interface designs and iteratively refined with patient advocates and cancer nurses. A user flow was first created to map the patient and health care professional (ie, cancer nurses) journey through the app. Patients can self-register, whereas cancer nurse accounts, which allow access to multiple patient records, can only be created by the OncoSupport+ development team to ensure proper verification and compliance with data security protocols.

The first low-fidelity prototype (Figure 6) underwent usability testing, where some patient advocates expressed discomfort with frequently viewing symptom trajectories. This led to relocating the symptom overview to a dedicated section, while the digital screening and personalized information sections were emphasized.

Figure 6. First version of the low-fidelity prototype displaying the main functionalities: digital screening, personalized information on supportive care services, and patient-reported outcome measures (PROMs) visualization.



A second low-fidelity prototype (Figure 7) underwent further feedback from patients and one cancer nurse. The cancer nurse recommended replacing red and green color schemes with neutral tones and adding bar charts to facilitate intuitive interpretation of symptom trends. Patient advocates suggested replacing clinical images with neutral, calming visuals and simplifying terminology.

Based on this feedback, a high-fidelity prototype (Figure 8) with responsive design was developed, compatible with both smartphones and laptops. A landing page was introduced to increase transparency about data storage and use and to highlight the key benefits of the app, particularly its potential to enhance communication between patients and health care professionals. Calming images were also integrated to improve the user experience. More details about the IT infrastructure can be found in Multimedia Appendix 4.

Discussion

Principal Results

This study reports the end-to-end co-design of OncoSupport+, a supportive cancer care app developed with patients with cancer and cancer nurses. The co-design approach identified challenges in supportive care and opportunities for digital health technology, generated a set of functionalities to address these challenges, and iteratively produced a prototype. As improving patient–health care professional communication and standardization and digitalization of supportive care were primary challenges, the OncoSupport+ app was designed to integrate a digital PROMs screening for supportive care using standardized oncology questionnaires (ie, EORTC QLQ-C30 and the NCCN Distress Thermometer) into the supportive care pathway. In addition, as enhancing self-efficacy, managing information overload, and receiving support from peers and

XSL•FO
RenderX

health care professionals appeared to be very important, OncoSupport+ prepares patients for in-person nursing consultations by providing personalized information, access to supportive care services, and links to self-help groups, patient-to-patient chats, and stories from other patients with cancer. These features may prepare patients effectively for consultations, thereby improving the overall quality of the interaction between patients and health care professionals and their sense of empowerment. While meeting the performance expectations of patients and health care professionals is a primary driver for the uptake of the technology [28], the development of an easy-to-use app, its introduction by health care professionals, and the provision of technical support may be critical for improving overall adoption. However, concerns related to interacting with a digital environment (eg, internet anxiety) may hinder this adoption. Future usability and feasibility studies will further evaluate the implementation feasibility, real-world usability, and acceptance of OncoSupport+ in clinical practice.

Comparison With Previous Work

The challenges identified in this study highlight the critical role of communication between patients and health care professionals, a domain where digital health technologies may play an important role. These technologies are not intended to replace health care professionals but rather to enhance and facilitate interactions with patients [32]. Consistent with previous research and systematic reviews [3], effective communication has been recognized as a key supportive care need. Not surprisingly, effective communication in cancer care has long been associated with improved medical and psychosocial outcomes, including reduced distress and increased satisfaction for both patients and clinicians [33]. Moreover, the European Society for Medical Oncology supports the integration of digital symptom monitoring, including the assessment of PROMs, as a vital element of cancer supportive care [34]. Evidence suggests that the use and digitalization of PROMs significantly enhance communication between patients and health care professionals [35]. For instance, a systematic review by Yang et al [35] suggests several mechanisms through which PROMs influence communication. These include increasing symptom awareness for both patients and health care professionals, prompting discussions (eg, addressing patient fears or uncertainty about disclosing symptoms), streamlining consultations (eg, using PROMs as a guide to direct health care professionals toward key patient-reported symptoms), and facilitating interprofessional communication between health care professionals (eg, enabling standardized patient tracking and optimizing the transfer of information). These mechanisms illustrate how PROMs may be a valuable tool for improving the quality of communication and, thereby, potentially enhancing clinical outcomes.

The findings of this study suggest that improving empowerment and self-efficacy in patients with cancer may be an important aspect of digital interventions in supportive care, consistent with previous research in this field. Recent systematic reviews [36,37] have indicated that digital health interventions, such as mobile apps and web-based platforms incorporating educational resources, interactive tools, medication reminders, and self-management features, may encourage patients to actively engage in their health care by enhancing empowerment and increasing self-efficacy. This enhanced sense of empowerment has been associated with better adherence to treatment regimens and more proactive health behaviors [37]. However, while digital health interventions that incorporate educational resources and self-management tools have been more consistently associated with increased self-efficacy, their direct impact on clinical outcomes, such as symptom reduction and improvements in quality of life, remains inconsistent across studies [38]. Although OncoSupport+ includes features related to informational and educational resources, appointment reminders, and tools to facilitate patient interaction, future research may explore the integration of self-management advice for symptom management to further enhance patient empowerment [39]. Additionally, while chat functions and telemedicine tools could further improve communication and self-efficacy, these features were not feasible for implementation in OncoSupport+. As patients value such tools, future research may focus on exploring the role of telemedicine solutions or artificial-intelligence–based chatbots in enhancing patient outcomes.

The digitalization of supportive care screenings and processes presents both significant opportunities and considerable challenges for hospitals. Digital transformation is reshaping health care by enhancing clinical workflows and promoting patient-centered care [40]. Implementing digital tools can improve efficiency and the quality of care, thereby reducing waste in health care costs. For instance, as reported by health care professionals interviewed in our participatory study, a separate study has shown that digital questionnaires significantly reduce the administrative burden on nurses compared to traditional paper-based questionnaires, allowing them to dedicate more time to patient care and resulting in substantial reductions in paper consumption [41]. Similarly, the adoption of electronic health record systems has been shown to facilitate better patient data management and streamline workflows. However, the transition to digital systems is not without challenges. Hospitals often face issues such as interoperability, strict data security regulations, the need for comprehensive staff training, and potential resistance to change among both health care professionals and patients [40]. This has been shown for cancer care as well [42]. Additionally, the lack of standardization across different IT systems at the hospital can hinder the seamless integration of digital tools. For example, the unsuccessful implementation of a nationwide digital patient dossier in Switzerland highlights the difficulties associated with a fragmented health care infrastructure and the absence of standardized frameworks [43]. Therefore, while digitalization offers promising benefits, careful consideration and strategic planning are essential to effectively navigate the associated challenges.

This study explored factors influencing the future acceptance of digital health apps like OncoSupport+, aligning with the UTAUT framework, which has been validated using quantitative data from digital health interventions [28]. An interesting finding concerns internet anxiety and the observation that age does not appear to be a barrier to technology acceptance. Internet anxiety,

XSL•FO
RenderX

defined as the fear or discomfort individuals experience when using online technologies, can hinder the adoption of digital health solutions [28]. Previous research indicates that while age is not a significant predictor of health technology acceptance [44], it correlates with internet anxiety—an important factor in adoption. Moreover, individuals with lower digital literacy [45] tend to exhibit higher levels of internet anxiety. Although these results appear to be in line with previous literature, a larger and more representative sample may confirm the role of internet anxiety in relation to digital health technology acceptance in patients with cancer. However, providing adequate training and support can help alleviate these concerns, thereby enhancing the adoption of digital health technologies.

Strengths and Limitations

This study has both strengths and limitations that should be considered when interpreting the results. The relatively small sample size (N=10 patients with cancer and patient advocates) may limit generalizability. However, the principle of thematic saturation was applied to ensure that no new themes emerged, supporting the adequacy of the sample. In addition, the inclusion of a significant number of female participants may account for gender-related biases in digital health acceptance. The patient group may not fully represent the broader population of patients with cancer, as most participants were aged below the average age of people with cancer and had a tertiary education level, higher than the Swiss national average. As education level correlates with digital literacy and some participants were highly experienced with digital health tools, acceptance of OncoSupport+ may differ in populations with lower digital experience. While individual interviews provided valuable insights, future research may benefit from workshops involving different user groups (eg, patients, nurses, family members, and caregivers) to foster mutual understanding and refine the co-design process. Although this study primarily examined user acceptance using the UTAUT framework, future implementation studies may apply frameworks such as Nonadoption, Abandonment, Scale-up, Spread, and Sustainability framework [46] or the Consolidated Framework for Implementation Research [47] to explore technology, organizational, and system-level factors affecting implementation and adoption. A key strength of this study is the direct integration of perspectives of patients, ensuring that OncoSupport+ is aligned with user needs and expectations, and the use of a structured co-design framework to guide development.

Conclusion

This study highlights the feasibility and importance of collaborative design in developing digital health applications and interventions, emphasizing the need for direct involvement of patients and health care professionals in the development process. The findings suggest that digital interventions such as OncoSupport+ may include features and functionalities to enhance patient–health care professional communication, facilitate the digitalization of supportive care screenings, and support patient empowerment and self-efficacy by providing personalized information on supportive care services, promoting connection with other patients, and offering self-management advice. However, while OncoSupport+ appears to meet the performance expectations of both patients and health care professionals, future research is needed to evaluate its implementation feasibility and determine whether it can effectively improve communication, enhance self-efficacy, and ultimately lead to better health outcomes, such as improved quality of life.

Acknowledgments

The authors thank Helén Johanna Luedtke for her assistance with the recruitment phase at the Department of Oncology and Hematology of the Zurich University Hospital and Bruno Ceolin Argenta for his help in creating Figma prototypes in the prototyping phase. We also thank the supportive care specialists working at the Zurich University Hospital who participated in our workshop and contributed to creating the knowledge-based algorithm: Maja Zenz, PhD; Prof Dr med David Blum; Christina Gassmann; Nicola Greco; and Anastasios Manettas. This study was supported by the Digitalization Initiative of the Zurich Higher Education Institutions (DIZH).

This study used OpenAI Whisper AI to transcribe qualitative data. To ensure accuracy, researchers manually reviewed and verified transcripts by cross-checking them with the original audio recordings. Additionally, generative AI–assisted tools were used solely to support grammar correction and language refinement, with the goal of improving readability. No content, data interpretation, or results were generated by AI. All final decisions regarding the wording, content, interpretation of results, and conclusions were made by the research team. The authors take full responsibility for the integrity and accuracy of the work presented.

The funder had no involvement in the study design, data collection, analysis, interpretation, or the writing of the manuscript.

Data Availability

The dataset generated and analyzed during this study is not publicly available because it is being used for the ongoing development of the digital health app OncoSupport+ at the University Hospital Zurich, but it is available from the corresponding author upon reasonable request.

Abstract

Background: The utilization of the Internet of Things (IoT) can significantly enhance health care. However, successful implementation of IoT requires a holistic approach including factors beyond technology alone.

Objective: This paper seeks to advance understanding of the factors influencing the successful implementation of IoT solutions in the health care sector, expanding beyond a purely technological focus.

Methods: Using data from 22 semistructured interviews with a diverse group of stakeholders—including health care professionals, researchers, municipal and regional officials, and private companies—this study examines 5 leading IoT projects in Sweden.

Results: Grounded in sociotechnical systems theory, the research identifies five critical subsystems impacting IoT implementation: (1) laws and regulations, which present challenges due to their complexity and misalignment with rapid technological advances; (2) organizational support, highlighting the essential commitment and resources from management to drive innovation; (3) user focus, emphasizing the importance of engaging end-users—such as patients and health care providers—in the design and implementation of IoT solutions; (4) resources, encompassing both financial investments and human capital needed for effective deployment; and (5) infrastructure, which addresses the technological foundations required to support IoT systems reliably.

Conclusions: By shifting attention from adoption to the complexities of implementation, this study fills a critical gap in the literature, which has largely emphasized adoption and technical aspects over practical implementation challenges. The findings provide a nuanced understanding of the primary factors influencing IoT implementation in health care, illuminating both the challenges and potential avenues for successful integration. Ultimately, this research advances the sociotechnical systems theory and also offers valuable insights for managers and policymakers tasked with driving digital transformation in health care systems.

Introduction

Background

The Internet of Things (IoT) and technologies, such as artificial intelligence, big data, and cloud computing [1], can significantly enhance the quality of health care [2]. IoT is a network of intelligent sensing devices and physical objects that are digitally connected for the collection, monitoring, and control of health care data [3]. It enables tracking, identification, authentication, data collection, and sensing [4]. These features can lead to improved patient outcomes, increased efficiency, remote monitoring, and enhanced collaboration between health care providers [5]. They are essential to addressing rising demands, such as an aging population, an increase in long-term conditions, limited resources, and growing expectations for personalized health care [6].

However, in exploring IoT's potential in health care, it is essential to distinguish between adoption and implementation. Adoption refers to the decision to use an innovation, while implementation involves the actual use of that innovation [7]. This distinction is often overlooked, as the 2 terms frequently used interchangeably or without clear differentiation [2,8-11]. IoT adoption and its influencing factors have been widely researched, typically focusing on technology [12-14], but also covering aspects related to individuals and the surrounding environment [15]. Adoption studies typically draw on frameworks such as the technology acceptance model (TAM) [16,17] and the Unified Theory of Acceptance and Use of Technology (UTAUT) [18,19].

XSL•FO
RenderX

A recent sociotechnical analysis of factors influencing IoT adoption in health care, based on a literature review and carried out by the Swedish researchers; Kronlid et al [20] identified a broad array of factors, 94 in total, that impact IoT adoption in health care. The comprehensive literature review by Kronlid et al serves as a starting point for this article, as it responds to previous calls for a deeper sociotechnical understanding of IoT adoption within health care and proposes a specialized sociotechnical systems framework tailored specifically to IoT adoption in health care settings. The review found no studies on the actual implementation of IoT in health care and only a few focusing on IoT adoption. Kronlid et al call for more rigorous empirical research on IoT adoption and implementation, grounded in frameworks that reflect sociotechnical realities.

Other previous research has shown that successful implementation requires consideration of factors beyond technology [21]. As early as 1951, Trist and Bamforth [22] emphasized the importance of social factors in realizing the full potential of technological innovations. Earlier research on implementing medical innovations shows that influencing factors extend beyond technical considerations to include managerial, clinical, financial, legal, and individual elements [23,24]. However, research exploring IoT implementation in health care through a sociotechnology lens remains scarce [20].

Rogers [7] defines adoption as "a decision to make full use of an innovation as the best course of action available," emphasizing the importance of the decision-making process. Research on IoT adoption in health care began to gain traction around 2013, with a predominant focus on technological aspects [25]. Dantu et al [25] identified 5 main topic clusters for adoption: security and privacy, cloud and smart health, wireless network technologies, data, and applications. IoT solutions in health care rely heavily on the transfer of large volumes of data (ie, big data) and device-to-device communication, making high-speed internet a crucial requirement [26]. A review of studies on IoT in elderly care also highlighted bandwidth and network connectivity (eg, WiFi) as essential preconditions for IoT adoption [27]. In addition, cloud services play a significant role in IoT adoption, providing big data storage and access, often described as the "backbone" of IoT solutions [12]. Several studies have explored the benefits and risks associated with cloud services [13,14,28-31].

The literature addressing nontechnical aspects of IoT adoption in health care is relatively limited, and the lack of focus on the social dimensions of IoT adoption has been noted by several researchers (eg, [8,25]. In a review of IoT adoption in health care [15], categorizing the factors influencing IoT adoption into 5 groups: individual factors (eg, social influence), technological factors (eg, perceived ease of use), security factors (eg, trust), health factors (eg, perceived health risk), and environmental factors (eg, financial cost). Many of the included studies applied the TAM or the UTAUT1 and UTAUT2 [15].

An interesting finding is that Alraja [32] found that gender influences the intention to use IoT technology among Generation Y, but not among Generation X. Furthermore, concerns about privacy risks did not impact the decision to use IoT technology. Additionally, Huarng et al [33] developed a model for the adoption of health care wearable devices, identifying data privacy, perceived ease of use, and perceived usefulness as key influencing factors. The review by Kronlid et al [20], which found 94 factors influencing IoT adoption, was grouped into eight subthemes: (1) financial circumstances (eg, reimbursement), (2) infrastructure (eg, data management), (3) people (eg, attitudes and feelings), (4) procedures (eg, capability development), (5) regulatory frameworks (eg, security and privacy), (6) stakeholders (eg, commercialization challenges), (7) technology (eg, complexity), and (8) other factors (eg, conflicts of interest). Of these, 34 factors were related to technology and infrastructure, accounting for approximately 42% of the total. The categories people and regulatory frameworks each counted for around 20%. Thus, this highlights technology, infrastructure, people, and regulatory frameworks as the most important areas. Notably, many of these factors were identified from research in low- and middle-income countries [20], raising questions about their relevance in high-income settings.

IoT Implementation in Health Care

Implementation occurs when an individual or organization actively begins using an innovation [7] and can be understood as "a deliberately initiated process, in which agents aim to bring into operation new or modified practices that are institutionally sanctioned and performed by themselves and other agents" [34]. A recent review did not find any studies specifically addressing IoT device implementation [20]. Moreover, distinctions between adoption and implementation are often blurred or unclear in the existing literature [20]. To gain insights into the range of nontechnical factors influencing IoT implementation, it is useful to consider findings from related fields, such as telemedicine, where technology integration in health care shares similarities with IoT [3]. In telemedicine research, the difference between adoption and implementation is more distinctly delineated; see, for example, Broens et al [35].

Telemedicine implementation is a well-established research area, with several reviews summarizing key findings. Broens et al [35] identified 5 primary factors influencing telemedicine implementation: technology (eg, quality), user acceptance (eg, attitudes), financial considerations (eg, reimbursement structure), organizational aspects (eg, work practices), and policy and legislation (eg, standardization). Scott Kruse et al [23] identified 5 common barriers to telemedicine implementation globally: technically challenged staff, resistance to change, cost, reimbursement issues, and demographic factors such as patient age and education. Recent studies validate these findings; for example, Khodadad-Saryazdi [24] emphasized that successful implementation requires adaptability in technology, strategy, and culture. Similarly, Cannavacciuolo et al [36] affirmed the 5 factors initially outlined by Broens et al [35]. Overall, successful implementation is a mix of technical and nontechnical factors.

Most previous empirical research on IoT implementation in health care is quantitative, using surveys to collect data [2,8,9,15] combined with adoption theories such as TAM or UTAUT. While useful, there are drawbacks that we have identified in previous research. The combination of quantitative

XSL•FO
RenderX

methodologies and adoption theories limits the research, as it lacks the capacity to include unexpected aspects of IoT implementation. We thus see the need to broaden the literature both in terms of methodology and theory: methodologically, with more qualitative studies that have more flexibility to let the data guide the research, and, theoretically, to identify and make sense of, for example, organizational and contextual factors that can play a major role in the implementation of IoT.

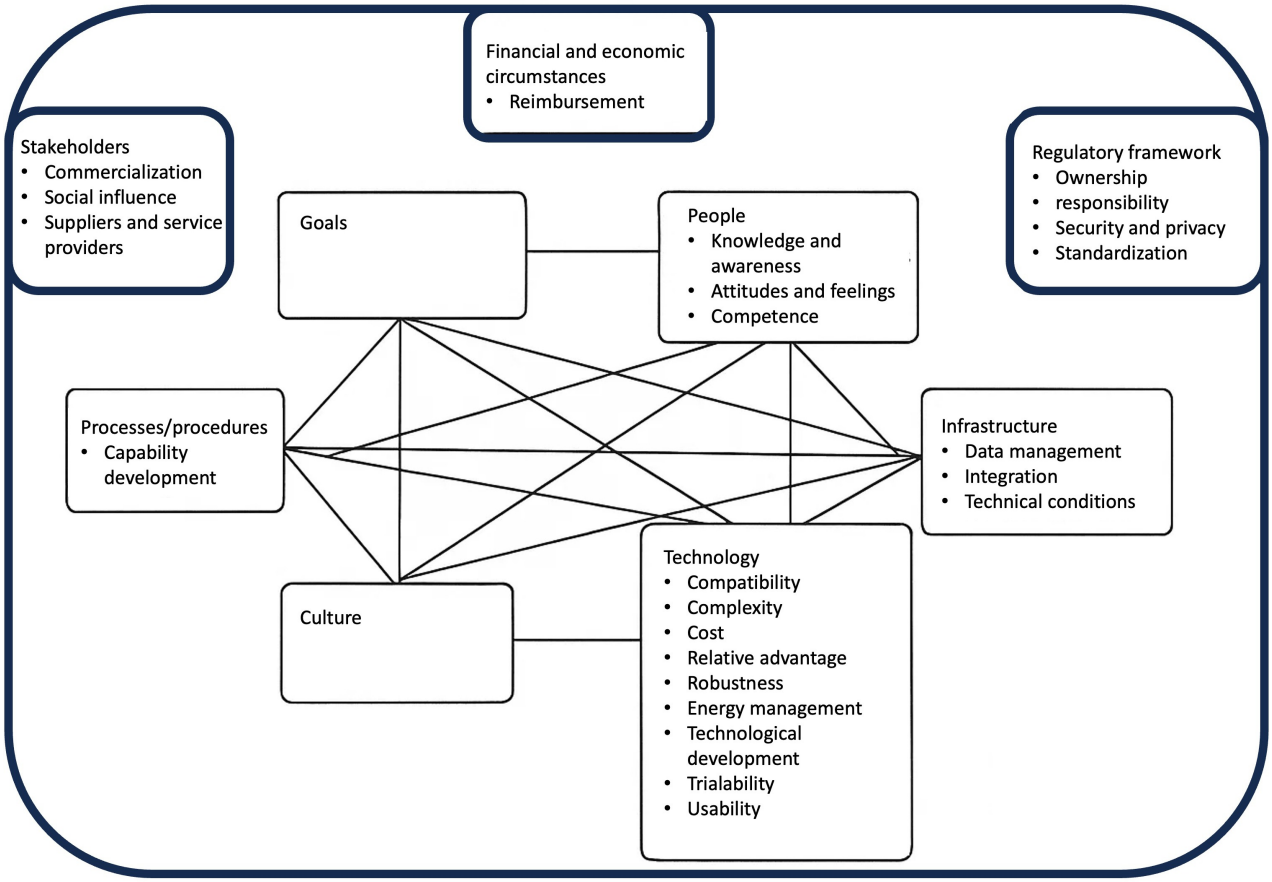
In summary, research demonstrates the importance of considering many factors when implementing new health care technologies. This highlights the need for more empirical studies on IoT implementation that draw on a sociotechnical systems framework to account for the complex interplay of these factors.

The Sociotechnical Systems Model

This study builds upon the sociotechnical systems framework proposed by Kronlid et al [20], which categorized key factors influencing IoT adoption in health care settings (see Figure 1). The framework is informed by and aligns with implementation research in related fields, such as telemedicine [23,35], thus providing a solid foundation for analyzing the multifaceted challenges and enablers associated with IoT implementation in health care.

The sociotechnical systems model, grounded in the work of Leavitt [37], highlights that any system is composed of multiple, interdependent subsystems. Changes in one subsystem, such as technology, will invariably impact others, including organizational culture, infrastructure, or processes. A more modern version of this approach, developed by Davis et al [38], outlines 6 key subsystems within an organizational system: goals, technology, culture, people, infrastructure, and processes. These subsystems interact with an external environment that includes regulatory contexts, financial factors, and other stakeholders. While this model has proven useful in many areas, Kronlid et al [20] propose that specific modifications might be needed in health care. Their review showed that the "culture" and "goals" subsystems of the model have not been well studied in health care research.

This study investigates the key factors influencing IoT implementation in health care, based on empirical evidence from 5 state-of-the-art IoT projects in Sweden. These projects were pilot projects; the focus of the study was on the early stages of the implementation process.



We explored how various factors, particularly organizational and societal, contributed to successful implementation of IoT. Using a comparative case study approach, we analyzed the key mechanisms driving the integration of IoT in health care. Through this analysis, we also aimed to refine sociotechnical systems theory as it pertains to IoT implementation in healthcare.

We moved beyond traditional adoption studies that often rely on frameworks like UTAUT, which, while useful, do not capture the complexity of implementing new technology in practice. Instead, we applied the 7 subsystems proposed by Kronlid et al [20], tailored for health care but flexible in terms of specific influencing factors within each subsystem. Since their framework was developed from a limited number of adoption-focused studies, we did not predefine factors within each subsystem. Instead, we remained open to identifying new factors, allowing a more comprehensive understanding of IoT implementation in health care.

In this article, we aimed to deepen theoretical insights into the critical factors affecting the early phase of implementation. We identified factors influencing the first phases of IoT implementation in health care through the lens of sociotechnical systems theory. Accordingly, our research questions were: (1) What are the most important factors that influence the early phase of implementation of IoT in health care? (2) How can sociotechnical systems theory contribute to understanding IoT implementation in health care?

Methods

Study Design

The study uses a qualitative multiple-case approach [40], suitable for generating new insights and contributing to theory development. This approach is particularly useful for studying emerging areas such as IoT implementation in health care when an in-depth understanding of the phenomenon is needed [40,41]. Using multiple cases allows for replication logic where cases are compared with each other to create robust and reliable insights [41,42].

Case Selection

To identify appropriate sources of information, we reviewed 72 state-of-the-art IoT development initiatives funded by a Swedish agency specializing in IoT solutions. By analyzing the applications and mid-term reports, we identified 20 initiatives directly related to IoT applications within health care. Among these, 5 initiatives were selected as relevant for studying implementation.

These 5 cases represent small-scale IoT pilots, each testing practical applicability in health care. The pilot nature of these projects, with varying numbers of end users (patients), provided insights into implementation factors under controlled conditions before any larger-scale deployment. We initially aimed to include full implementation cases; our review showed that none had reached that stage. Instead, these pilots served as the closest point to practical implementation available for study.

Notably, none of the used IoT technologies had undergone the public procurement process required for broader implementation within Sweden's health and social care systems. Multimedia Appendix 1 provides an overview of these 5 cases.

Data Collection

We started the data collection by first reviewing the existing documentation (eg, grant applications and follow-up reports) concerning each of the projects to map all partner organizations in each of the projects and identify the key players and the project managers leading the initiative. Then, we conducted semistructured interviews with the project managers in each project and regarded them as key informants [43]. We also asked the project managers to identify other relevant partner organizations that we should interview to obtain a broad picture [41]. We conducted 22 interviews altogether, which lasted between 22 and 57 minutes. We followed an interview guide that covered background questions, questions concerning the initiative, and possible factors influencing implementation. The interviews were recorded and transcribed. Table S2 in Multimedia Appendix 2 provides an overview of interviews.

Data Analysis

The analysis of the transcribed interviews was conducted using an abductive method [44]. We started with an inductive systematic thematic analysis [45] to identify patterns grounded in the participants' perspectives. These identified themes were then organized according to the 7 subsystems proposed by

XSL•FO
RenderX

Kronlid et al [20], allowing us to relate the empirical findings to the theoretical framework.

The process involved the following 7 stages. First, following Braun and Clarke [45], we familiarized ourselves with the data by thoroughly reading and rereading the transcripts. This stage aimed to gain a comprehensive understanding of the content and context of the participants' responses, noting initial ideas and recurring topics that emerged throughout the interviews. Second, we identified and generated initial codes from the transcribed interviews. This involved systematically coding segments of text that reflected factors influencing the implementation of IoT solutions in health care. Each segment was labelled with a code that encapsulated its essence. The coding process was flexible and data-driven, ensuring that the codes emerged directly from the participants' responses rather than from preconceived notions. Two researchers coded the transcripts independently to capture diverse interpretations and perspectives, which were then discussed to reach consensus.

Third, we grouped the initial codes into broader themes. This involved examining the codes for patterns and relationships and identifying clusters that represented similar ideas or concepts. The entire research team collaborated to discuss and refine these potential themes, ensuring they accurately reflected the data and contributed to addressing the research questions. Fourth, once the initial themes were established, we engaged in a thorough review process to refine and validate them. This involved checking whether the themes accurately represented the coded data and aligned with the overall dataset. The researchers revisited the interview transcripts to ensure the themes were robust and reflective of the diversity of participant experiences. Any inconsistencies or gaps were addressed through discussions and iterative adjustments. Fifth, after finalizing the themes, we aligned them with the sociotechnical subsystems by Kronlid et al [20] to the extent possible. However, we used inductive labeling, which provided a more accurate reflection of the data. As a result, the findings are structured around five adapted subsystems drawn from Kronlid et al [20] framework: (1) regulatory framework, (2) organizational support, (3) user focus, (4) financial and economic circumstances, and (5) infrastructure. The remaining 2 subsystems in the original framework, "technology" and "stakeholders" [20], did not emerge from the data and are therefore not included in the findings.

Sixth, to identify the specific factors influencing implementation of IoT in health care, we revisited the data within each of the 5 subsystems. This allowed us to break down the data into distinct factors linked to each subsystem. For details, see Table S3 in Multimedia Appendix 2.

Seventh, we compared the subsystems and factors across cases, identifying similarities and differences [41]. Finally, we compiled the data into a coherent findings section, aiming to convey the rich insights derived from the analysis and highlighting how various factors influence the implementation of IoT solutions in health care.

Ethical Considerations

The Swedish Ethics Review Authority made a rejection of the request for ethical review as they considered that ethical review was not necessary, which means that a favorable ethical decision was obtained (exemption number: Dnr 2022-01259-01). The data were collected through interviews, and the participants chose to agree to the interviews. The original consent covered secondary analysis without additional consent. Data were anonymized. No compensation was provided to participants.

Results

Our findings show that factors within 5 subsystems influence implementation of IoT in health care.

Regulatory Framework

Respondents from all but one of the cases we studied identified laws and regulations as major factors influencing the implementation process. In the IoT Older Adults Home Care project, challenges related to laws and regulations were identified early on, and the project was designed for straightforward implementation. The primary issue concerned informed consent from the older adults. The project targeted older adults, including individuals with neurocognitive disorders such as dementia; the implementation faced difficulties due to the inability of older adults to provide informed consent. In one participating municipality (Municipality A), this was taken into account when selecting participants, and no major issues arose. However, in another municipality (Municipality B), the decision was made to include older adults who could not provide informed consent, which led to a failed implementation in that municipality.

> *But you could say that [Municipality B] actually failed due to issues with consent and so on. So, we made installations in [Municipality B], but it didn't work out. Because they wanted to include a user group that couldn't give their consent. Legally, it fell through because they couldn't study the individuals they wanted to include in the project.* [Respondent 11, IoT Older Adults Home Care & IoT Older Adults Care Home projects]

This issue, where those who might benefit the most from IoT technology are unable to provide informed consent, may stem from laws and regulations that have not kept pace with recent technological advancements. One respondent specifically mentioned that the laws and regulations are "outdated," emphasizing how this discrepancy creates challenges from a user perspective.

> *If you look at how laws are written and changed, the time we've had digital tools is very short compared to how long we've had the Patient Data Act. We have several... quite... or very strict laws that we work under when working in healthcare, and they are outdated when it comes to... […] Patient safety and user-friendliness don't really go hand in hand. So that's one of the major obstacles when talking about [IoT] implementation.* [Respondent 16, IoT CF project]

XSL•FO
RenderX

Some strategies were used to navigate existing laws and regulations. This was particularly evident in the IoT CF (cystic fibrosis) project, where creative approaches were used to deliver IoT services to patients and collaborate with companies. One approach involved "hiding behind studies," using ongoing research studies as a way to test and implement IoT technology. Research studies have less demanding regulatory requirements, so hospitals could not object to the activities conducted within them. In addition, the involved companies were not permitted to integrate with specific health care systems. As a workaround, they used the diabetes registry, which operates under different rules.

> *And we hid behind studies. Studies have much lighter requirements, and you can test all the technology. So, it turned out that we started new studies, and we have several ongoing studies because the hospital couldn't say anything. That way, we could hide behind them with the technology. […] My actual research is in something else. This is not my research area, even though I conduct studies, but it's just to hide behind them. As we said, it makes it easier to get around these technical...* [Respondent 15, IoT CF project]

In the IoT LTC (long-term condition) project, respondents emphasized the challenges of handling and securing data in compliance with relevant regulations. Ensuring that data was collected, stored, and used according to legal standards was crucial for maintaining both trust and legality. Meeting certification standards was necessary for the project's legitimacy and acceptance, but obtaining these certifications was a complex process that required careful attention to detail. In the IoT Older Adults Care Home project, there was uncertainty about how the technology should be classified and, consequently, which laws and regulations would apply. The technology captured a clear image of the older adult, which was later blurred on a server. Since a clear image was initially captured, the municipality determined that the camera surveillance law was applicable, leading to the shutdown of the technology testing and a change in the project's direction. After extensive discussions with the municipality's legal team, it was concluded that they should have used a camera instead of a sensor. Had the camera blurred the image immediately, or if the server had been located within the same facility, a different decision might have been reached.

> *So, we use motion sensors and... yes, employ a different interpretation pattern around it or under the radar, you could say that the data you collect about the person is essentially the same. But in our case, it's the camera law that applies.* [Respondent 14, IoT Older Adults Care Home project]

In the IoT CF, IoT Bedwetting, and IoT LTC projects, the public procurement process was identified as a significant challenge. The difficulty lay in ensuring that procurement was conducted legally while still allowing for an innovative approach, which was critical to the success of these projects. The IoT CF project described the procurement process as very slow, with the risk that the product would become outdated during the procurement process. In the IoT LTC project, respondents highlighted how procurement remains a challenging issue, with the belief that the continued implementation of IoT solutions almost always stalls once it reaches the procurement stage. Several respondents suggested that this issue is linked to lawyers' reluctance to test new procurement techniques, driven by a fear of potential legal risks.

> *Then you get into the procurement issues concerning regions and municipalities, and it becomes very, very challenging in many ways. Not least, there is a fear from the actors in, for example, this project. Are they allowed to participate in a procurement, or do they know too much now about the customers in different ways, making them disqualified from the procurement? That risk always exists. So, this procurement step is very, very difficult in the next stage.* [Respondent 21, IoT LTC project]

Organizational Support

Respondents from all the cases we studied emphasized the importance of organizational support in creating an enabling environment for IoT implementation. In the 2 projects, IoT Older Adults Home Care and IoT Older Adults Care Home, both initiated by the same municipality, it was clear that the municipal management had made a firm decision to support digitalization initiatives. This decision, coupled with its effective communication, was considered highly beneficial to the success of these 2 projects. The IoT project manager received strong backing from various levels of organizational leadership. The municipality itself was "very focused on introducing various types of technology within the care services" (Respondent 13, IoT Older Adults Home Care & IoT Older Adults Care Home projects). In the Older Adults Care Home project, managers and staff at the facility where the technology was being tested were particularly enthusiastic and supportive.

> *The housing manager, department manager, and many within the organization are truly passionate about this and are very driven, visionaries, and willing to take risks to make it as good as possible for the individuals. So, we really see that as a success factor in the project.* [Respondent 12, IoT Older Adults Home Care & IoT Older Adults Care Home projects]

Both the IoT CF and IoT LTC projects also highlighted the importance of support functions, such as IT services, administrative assistance, and training, in ensuring successful implementation. The IoT CF project further illustrated the challenges of advancing IoT implementation when facing resistance from organizational stakeholders and a lack of support and resources necessary to establish a more permanent solution. In this case, the IoT project manager encountered significant pushback from colleagues, management, and support functions like the IT department.

> *There are many parts of the IT structure, and we had everyone against us, I must say. Everyone thought it was good, but many thought it was wrong [some technical aspects were deemed illegal by the IT department]. Many didn't think we should do what we did, but then [if we did it] be held accountable for it.* [Respondent 15, IoT CF project]

XSL•FO
RenderX

Several respondents across all cases noted that the level of prioritization within the organization directly impacted a project's progress and success. A common observation was that organizational priorities and decisions outside the project's scope often had a negative influence. For example, in the IoT Older Adults Home Care project, one respondent raised the influence of the political planning: "There's a political agenda that usually follows a 4-year cycle, a planning horizon for operations. So, there are many other factors that govern what actually happens [in projects like this]" (Respondent 7, IoT Older Adults Home Care project). Several respondents also highlighted the difficulty that lower-priority projects had in gaining momentum.

> *The third is getting priority in the regions to obtain staff and resources to assist in the projects is almost impossible, so even if the staff wants to, it is very difficult for them to, well, take care of these projects.* [Respondent 18, IoT LTC project]

Additionally, one project raised an aspect crucial to its success but not mentioned by any other project: organizational readiness for implementation. Respondents from the IoT Older Adults Home Care project emphasized that the level of knowledge regarding implementation varied significantly among managers at different organizational levels, influencing the feasibility of implementing the IoT solution.

> *There is a large variation in maturity levels [knowledge of implementation] among our operational managers. And when I say operational managers, I mean everyone from those at individual care facilities, group homes, to the highest leadership. They don't have a unified understanding [of what to do and how to do it]; it's quite diverse.* [Respondent 6, IoT Older Adults Home Care project]

User Focus

Another major success factor identified in all the cases we studied was having a strong user focus, which encompassed both patients and health care staff.

> *It originates from the staff and patients from the start, and they have been involved throughout and have had a say in how it should look [like], how the tool should look [like], what functionality we should have, and what the priorities should be.* [Respondent 21, IoT LTC project]

In the IoT LTC project, it became clear that involving users (ie, health care staff) not only helped the service developer improve the usability of their service but also increased the likelihood of successful implementation. Respondents noted that while the service developer initially had a vision for how the service should function, there was often a disconnect between the engineers' perspective and how patients, relatives, and health care staff perceived the service. In the IoT CF project, the team had initial ideas about the effects and benefits the technology would bring to patients, but additional benefits were identified by both patients and their relatives.

> *So, we made the technology available to everyone, instead of making decisions like "you think," "we need," or similar. And we saw quite clearly that it's very difficult to guess who will benefit from the technology. [...] I think that [involving patients] was a success factor because we said, "This doesn't mean it should replace one or the other," but we let our patients choose instead of healthcare professionals making the choice.* [Respondent 15, IoT CF project]

In addition to involving immediate users (ie, caregivers and patients), it is also essential to include a broader range of users, as demonstrated in the IoT CF project. This project engaged health care staff both directly and indirectly connected to patient care, such as medical secretaries, nurses, dietitians, psychologists, physiotherapists, and counsellors. This extensive involvement was highlighted as a key success factor. However, some respondents also pointed out the complexities that IoT technology introduces to caregiving, noting that health care staff may feel that the more technology is introduced, the further they move away from their core role as caregivers. This creates a paradox, as many choose to work in health care precisely to be close to the patient.

> *We have gained a lot of insight into the technology frustration that exists [i.e, the complex role of technology in caregiving] and that, as it is today, they [the health care staff] feel they are moving further away from their caregiver role than they would like [to].* [Respondent 12, IoT Older Adults Home Care project]

A match between user instructions and user capabilities is also crucial in IoT implementation projects. Both the IoT CF and IoT Older Adults Home Care projects emphasize the importance of clear communication with users and adjusting the complexity of instructions to suit their abilities. Additionally, one project (IoT Bedwetting) highlighted the role of national guidelines—care guidelines from authorities that outline best practices in different clinical areas—in the success of IoT implementation. Respondents from the IoT Bedwetting project suggested that if national guidelines recommend IoT solutions, this could become a critical factor in achieving successful outcomes.

Financial and Economic Circumstances

Securing sufficient resources for implementing IoT solutions was highlighted as a challenge in several interviews across the IoT LTC, IoT CF, and IoT Older Adults Home Care projects. These resources primarily include financial support. Shorter projects are often insufficient to drive meaningful change, as it takes considerable time—and therefore money—to alter established practices. There is often ambiguity around who should bear the costs for the necessary time, resources, and ongoing maintenance of the services.

> *No one wants to pay. Everyone thinks someone else should pay. But now I have no... But now I'm a little... Now we're shutting down if the hospital doesn't step in and pay. So I've set some demands. And everyone thinks this group is good and should continue, but it's... everyone thinks someone else should pay.* [Respondent 15, IoT CF project]

XSL•FO
RenderX

Infrastructure

Respondents from 3 cases emphasized that infrastructure is crucial for successful IoT implementation. They noted that the process was often hindered by either insufficient or unstable WIFI connections, as well as concerns over the use of cloud services. In the IoT Older Adults Care Home project, for example, the IoT solution had already been procured by the region for other applications. However, when installation began, it became clear that WIFI coverage was inadequate to get the technology fully operational.

> *Exactly, it's another project that is implementing the equipment we intend to use in this project. In that project, I perceive that the staff has some resistance because there have been infrastructure issues that have prevented it from working as expected. For example, the WIFI hasn't had the coverage they thought it would, and when the equipment lost network connectivity, it resulted in false alarms, in reality.* [Respondent 12, IoT Older Adults Home Care & IoT Older Adults Care Home projects]

In the IoT Older Adults Home Care project, WIFI access was also a significant issue. Here, older clients were responsible for their own WIFI, complicating the service provider's efforts to install the necessary infrastructure. In the IoT Bedwetting project, concerns about the security of cloud services also created challenges.

> *...I have been in contact with [the region], and there the IT department flatly said no, that "we cannot agree to this because we do not consider cloud services to be secure." So, that... those are the things I think are the problem, that there are many smart technical solutions, but in many cases, the healthcare system is not quite ready to embrace them.* [Respondent 4, IoT Bedwetting project]

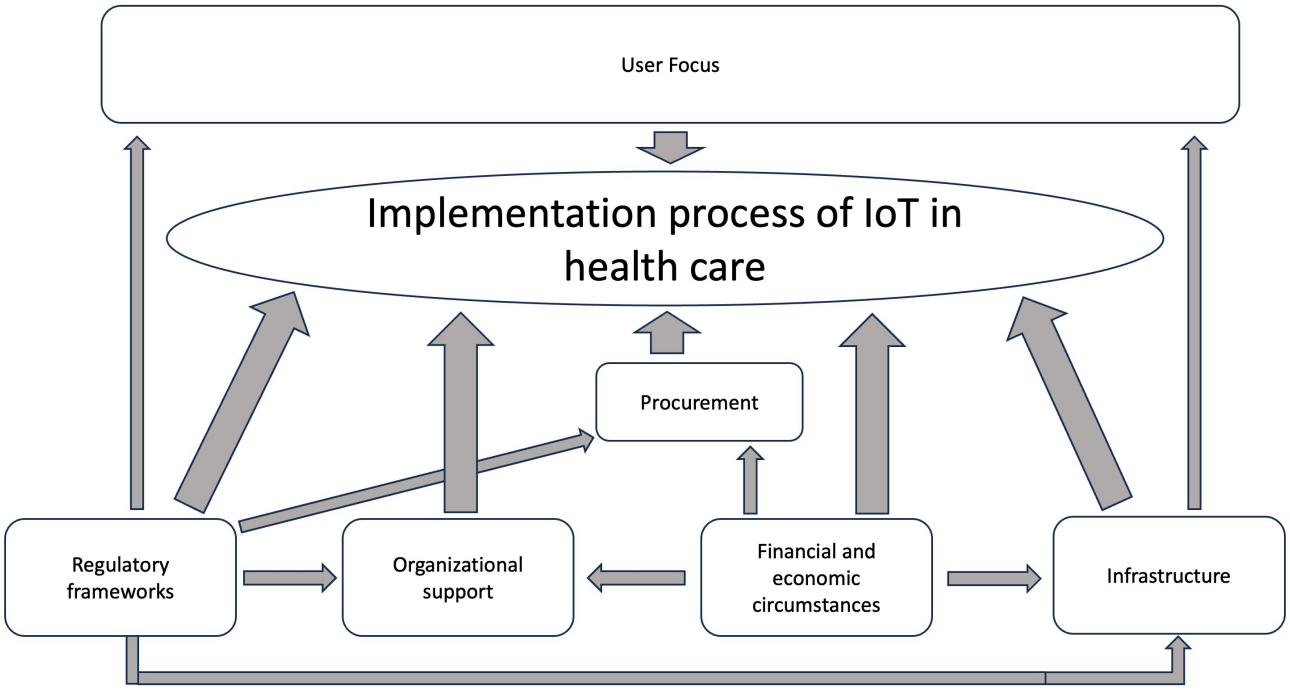
In the IoT Older Adults Home Care project, stakeholders such as the IT department seemed unaware of local cloud solutions and declined to consider them without further investigation. In contrast, the IoT Older Adults Care Home project successfully addressed potential security concerns by contracting with a local cloud provider.

In addition, communication tools play a critical role in supporting implementation. Our findings suggest that when communication tools are not properly aligned with the IoT solution, they can obstruct the implementation process.

> *Then there are these contextual factors. For example, the staff currently use fairly old phones to receive their alarms, and this means that it takes quite a while... Every time an alarm comes in, it takes quite a long time for them to access their phones. They need to enter their code every time, open an app, and then turn off the alarm. And it takes quite a long time.* [Respondent 12, IoT Older Adults Home Care & IoT Older Adults Care Home projects]

Another important aspect of communication tools is the use of web-based meetings. Our findings indicate that well-functioning web-based meetings can greatly facilitate implementation. In the IoT CF project, secure web-based meetings were essential for delivering the service. These meetings were facilitated centrally through a national service called "1177," the primary digital platform for health care services in Sweden.

Discussion



Principal Findings

This study investigates the key factors influencing IoT implementation in health care by examining 5 state-of-the-art IoT projects in Sweden. It addresses the pressing need for more empirical studies on IoT implementation [20], as well as the need for an approach that goes beyond purely technical factors, focusing instead on a broader range of influences within organizational and social contexts [8,25].

Figure 2 illustrates our theoretical contributions and proposes a sociotechnical systems model tailored to IoT implementation in health care. It is difficult to determine the exact causality between the different factors, but based on the interviews, Figure 2 illustrates our interpretation of the main relationships between the factors.

XSL•FO
RenderX

Figure 2. The most important factors that influence the implementation process of Internet of Things (IoT) in health care. The broader arrows represent a direct impact on the IoT implementation process in health care, while the narrower arrows represent an indirect impact—from one factor to another factor that in turn affects the ability to implement IoT in health care.

Our research contributes to the growing discourse on IoT in health care, which has predominantly focused on the adoption phase [5,15,25]. While prior studies emphasize technical factors as primary considerations during adoption [25,26], our findings underscore the importance of organizational and societal factors in the implementation phase. Through our study, we advance sociotechnical systems theory by demonstrating how its components interact in real-world health care settings, particularly in the context of IoT. Our findings reveal complex dynamics between technological potential and social structures, identifying key gaps, tensions, and interdependencies that impact implementation. Below, we discuss 5 primary ways in which our study contributes to applying sociotechnical systems theory to health care IoT implementation.

First, by applying the Kronlid et al [20] model, we identify specific refinements to the sociotechnical systems model necessary for the health care sector. Of the 4 core factors—people, infrastructure, technology, and processes or procedures [20]—our findings support 3. We relabel "people" as "user focus" and "processes or procedures" as "organizational support" to better reflect its relevance in health care. Infrastructure remains unchanged. The subsystem, "technology," was not observed in the 5 cases we studied.

Second, our study confirms 2 of the 3 external factors in the sociotechnical systems model, financial circumstances and regulatory frameworks [20], but did not observe evidence for the third factor, stakeholders. More importantly, we suggest that financial circumstances and regulatory frameworks should be viewed as internal organizational factors because of their interconnectedness with other internal elements, particularly organizational support. For example, financial resources significantly influence organizational support: when funding is adequate, organizations can prioritize IoT projects, allocate resources, and provide leadership backing. Conversely, limited funding can restrict support and hinder even promising projects. Regulatory frameworks similarly shape user engagement by setting boundaries around privacy and consent, which are critical in health care. Regulations that protect vulnerable users can inadvertently restrict participation in IoT projects [46]. Thus, we propose that the sociotechnical systems model should reposition these factors as internal dynamics within health care IoT implementations.

Further research could examine whether the remaining subsystems from Kronlid et al [20], technology and stakeholders, are relevant to IoT implementation in health care beyond Sweden. Regarding the technology subsystem, the affordability and technical challenges of IoT solutions may vary across countries. In low-resource settings, such as parts of Africa, the high costs of IoT devices, infrastructure, and maintenance can hinder adoption. In contrast, high-income countries like the United States and Germany may face greater challenges in integrating IoT into existing health care systems, requiring significant investment in interoperability and cybersecurity.

As for the stakeholders' subsystem, the commercialization of IoT solutions is shaped by regulations, market demand, and funding availability. In countries with strict health care regulations (eg, the European Union [EU] under General Data Protection Regulation), compliance costs can make it difficult for startups to scale their solutions. Meanwhile, in developing markets, a lack of investor confidence and infrastructure limitations may slow commercialization, even when there is strong health care demand.

Third, our findings highlight the essential role of health care workers' attitudes and patient involvement in harmonizing social and technical elements of IoT adoption. The observed frustration among health care staff with certain technologies supports the

XSL•FO
RenderX

sociotechnical systems theory assertion that social environments such as attitudes, values, and identities strongly influence technology use [47]. This insight suggests that future adaptations of sociotechnical systems theory could benefit from explicitly addressing the emotional and identity-related impacts of technology, particularly in health care, where professional identity often ties closely to user autonomy and caregiving roles.

Fourth, our study reveals that regulations often lag behind technological advances, creating obstacles to IoT implementation. Rather than facilitating adoption, regulatory complexity can become a barrier, consistent with previous findings on medical device regulations [48]. Health care's rule-driven culture fosters a cautious approach, limiting the adoption of emerging technologies [49]. Our findings further indicate that existing procurement structures can impede innovation, as traditional processes stifle creative thinking necessary for IoT implementation. Although innovation-based procurement strategies are promoted in the EU [50], none of the cases we examined identified these as practical solutions. To enable effective IoT adoption, managers must understand legal and regulatory constraints while collaborating with legal teams, a rarely studied area in management research [51]. Without this collaboration, legal departments may adopt overly cautious stances, leading to project rejections, while support departments may resist due to anticipated increases in workload. In one case, the organization strategically managed data by using local servers to avoid EU data-sharing restrictions [52,53], demonstrating that creative solutions can help navigate regulatory challenges. The respondents mentioned that they were hiding behind academic studies, ie, using ongoing research studies as a way to both test and implement IoT technology. It indicates a certain level of frustration regarding the lack of flexibility in the organizational structures.

Finally, the technical complexity of IoT systems, coupled with the need for simplicity in user interfaces, underscores the principle that technology and human systems must evolve together [54,55]. While IoT technologies provide advanced capabilities, their complexity can alienate users, particularly in health care, where ease of use is critical. This observation suggests a vital revision for sociotechnical systems theory: usability should be prioritized as a co-evolutionary requirement within sociotechnical design, not as an afterthought. This aligns with theories of sociomateriality, supporting the idea that intuitive, user-friendly design is essential in fields with high cognitive and emotional demands [54]. Thus, even if our study did not specifically address user engagement strategies tailored to vulnerable groups, such as individuals with cognitive impairments or mobility limitations, we recognize this as critical for future research. Practical methods such as participatory design and co-creation techniques should be used to ensure that IoT solutions are inclusive and accessible [56]. A stronger focus on user experience design will enhance the relevance, equity, and effectiveness of implementation efforts in health care.

Practical Implications

This study reveals several practical implications for managers involved in health care IoT implementation, highlighting the importance of collaboration, financial strategy, training, and regulatory awareness. First, close engagement with legal departments is crucial. Developing a collaborative relationship with legal teams allows managers to address complex regulatory concerns upfront, avoiding overly conservative stances that could stifle innovation. To facilitate smoother project approvals, it may also be beneficial to provide legal teams with training specific to IoT technologies, helping them understand the unique aspects of these projects. Second, demonstrating the economic benefits of IoT initiatives is equally essential. Managers can strengthen organizational support by conducting detailed cost-benefit analyses that clearly illustrate potential financial gains. This approach not only helps in securing initial funding but also promotes a culture that values and supports innovative solutions. Third, investing in comprehensive training programs is also vital for successful implementation. By providing targeted training across all staff levels, including frontline workers, support departments, and management, managers can build the technical competencies necessary for IoT integration. Moreover, fostering cross-functional collaboration by forming interdisciplinary teams encourages the sharing of expertise, which can lead to more effective problem-solving and innovation.

Fourth, ensuring that patients, health care providers, and other stakeholders are involved in the implementation process can significantly enhance the relevance and acceptance of IoT solutions. Addressing the needs and concerns of these users from the outset ensures that solutions are practical and user-centered. Developing clear protocols for managing informed consent is particularly important when technologies involve sensitive components like sensors or cameras. Special attention to accessibility, especially for patients with cognitive disabilities, further reinforces the inclusivity of the implementation. Finally, engaging with policymakers to advocate for flexible and supportive regulatory frameworks is crucial. By working together, managers and policymakers can create a balanced approach that safeguards patient safety and privacy while fostering a regulatory environment that encourages digital innovation in health care. This proactive stance helps to create a foundation for sustainable IoT implementation, aligning technological advancement with patient care priorities and organizational objectives.

Limitations and Further Research

Our study has 2 main limitations. First, it examines only 5 IoT pilot implementation cases, which, while allowing for a deep exploration of IoT implementation factors, limits the generalizability of our findings. The small sample size may mean that our conclusions are less applicable to other health care settings, particularly those outside Sweden. However, we believe that the results may very well be relevant for countries with similar demographics and systems for social and health care. Expanding future research to include a broader and more varied set of cases across different regions or countries would help to enhance generalizability. However, as shown by our sampling process, identifying numerous relevant IoT cases can be challenging. Second, each case we studied was in the pilot implementation stage, with none yet reaching full-scale public procurement or integration into Sweden's health care system. This limitation restricts our insights into the long-term

XSL•FO
RenderX

challenges and sustainability of IoT implementation in health care. Consequently, our findings do not fully capture the issues and opportunities associated with later stages of implementation, such as public procurement, scaling, and long-term use.

Building on these limitations, several avenues for further research emerge. One area needing exploration is the adaptation of health care laws and regulations to better support IoT implementation. Future studies might investigate how regulatory frameworks and procurement models, such as innovation-based procurement, could be refined to foster IoT implementation. Research could also focus on best practices for aligning health care regulations with the rapid advancements in IoT technology. Future research could also aim to identify actionable solutions to the challenges that have been identified.

Since this study is based on pilot projects, there is also a need for longitudinal research that extends beyond the pilot phase. Examining the full-scale implementation of IoT solutions would provide insights into additional challenges and opportunities, including public procurement, solution scalability, and sustained use over time. Further, expanding the scope to different regions or countries would enable comparative studies to assess whether factors influencing IoT implementation are universally relevant or specific to certain national or health care system contexts.

Another critical research direction involves deepening our understanding of effective user involvement in IoT design and implementation. Future studies could explore best practices for managing informed consent, especially for vulnerable populations, like individuals with cognitive disabilities. These studies could help shape policies that ensure the full benefits of IoT technologies reach all user groups, reinforcing the patient-centered approach essential to health care innovation.

Conclusions

In conclusion, this study explored 5 IoT pilot implementation projects in Sweden, shedding light on key factors that influence the deployment of IoT solutions in health care. By responding to the demand for empirical research on IoT implementation, our findings contribute to an understanding of the practical challenges and organizational dynamics involved, expanding beyond the adoption-focused literature. While IoT has the potential to significantly enhance health care delivery, several barriers remain, especially concerning regulatory complexity and rigid legal frameworks. These findings underscore the importance of ongoing collaboration between managers and legal teams to prevent regulatory constraints from hindering innovation. Our study also highlights the necessity of strong leadership in championing IoT projects within health care organizations. Managers play a pivotal role in clearly communicating the economic value of IoT through cost-benefit analyses and fostering a collaborative, cross-functional culture to tackle implementation hurdles. Adopting a user-centered approach—one that involves health care providers, patients, and families throughout the process—emerges as essential for achieving broad acceptance and success of IoT solutions. Additionally, managing informed consent, particularly for vulnerable populations such as individuals with cognitive disabilities, is crucial for the ethical deployment of these technologies. Overall, our study underscores the need for thoughtful strategies that prioritize regulatory alignment, economic rationale, and user involvement to realize the full potential of IoT in health care.

Abstract

Background: Co-design is recognized for its potential to enhance the usability of products through active user participation. However, participation alone does not guarantee the effectiveness of the resulting product. Understanding participants' engagement during co-design activities can provide valuable insights into their motivations, concerns, and contributions, which are critical to achieving successful outcomes.

Objective: This study aims to analyze participant engagement in a digital health co-design parent project focusing on developing a tool to facilitate support-seeking for elderly caregivers.

Methods: The parent project included 74 participants from 3 categories: caregivers, health care and social service professionals, and community workers. Testimonies for this study were collected from 20 participants using the self-confrontation interview methodology. Engagement was analyzed qualitatively using the course-of-action framework. The engagements were organized into emergent themes. The analysis focused on variations in engagement patterns across participant categories and sessions.

Results: A total of 3 themes of engagement were identified: tool design, participant needs, and contextual situations. Engagement was distributed similarly across themes, except for community workers, who were more focused on needs (52/94, 42%) than tool design (25/62, 20%). There was significant variation in engagement over sessions, with tool design being more prominent during specific sessions (co-design sessions CoD5, CoD7, and CoD8) and less important during others (CoD4, AC2 [advisory committee session], CoD6, and AC3). Activities directly tied to design tasks significantly enhanced engagement with tool design. These results underscore the influence of activity types in shaping participants' focus and involvement.

Conclusions: This study highlights the role of affordances in co-design activities to balance engagement across design, collaboration, and participation dimensions. By strategically leveraging affordances, future co-design projects can optimize engagement and ensure more effective outcomes.

Introduction

Background

Digital health can improve access to and quality of health care, lower costs, and provide a personalized experience for patients, but it also raises ethical challenges [1], usability problems [2], and, as seen, few successful implementations [3]. Involving end users in the creation of digital health solutions can minimize usability and accessibility problems [4]. Although co-design has several theoretical virtues, it does not guarantee positive outcomes. A total of 2 systematic literature reviews identified mixed and even negative outcomes, including communication problems, misunderstandings between users and the development team leading to conflicts, higher user expectations, and a negative influence on data quality [5-7]. What factors lead to better results?

For example, there is a great diversity of activities conducted during co-design sessions: interviews, advisory council meetings, focus groups, surveys, deliberative methods [8], and plenary sessions [9]. Gray literature also offers a wide range of techniques for collaborative sessions, problem-solving, and

XSL•FO
RenderX

ideation that can be used in co-design [10-12]. How does the type of activity affect outcomes?

Extra time is needed when involving patients in health research [13]. To date, research on co-design in digital health is still seldom described, evaluated, or empirically tested, raising questions about the cost-effectiveness of user contributions compared to the investments required in time, effort, and money [8]. This paper contributes to the body of work on co-design initiatives with a focus on what drives participants—namely, their engagement—in a co-design project, based on a strong theoretical lens on human activity and empirical results provided by the participants themselves.

Positioning Engagement and Co-Design Through a Theoretical Lens

Co-design in this study aligns with the perspective of Sanders and Stappers [14], which involves users (or potential users) in the development of knowledge, concepts, and idea generation. For us, co-design lies at the intersection of 3 dimensions: design, collaboration, and participation. First, participants engage in "design as a reflective practice," following Schön [15], to reflect on their situation and contemplate potential solutions to improve it. The second dimension is collaboration, where actors engage in mutual learning [16-20], leveraging each other's knowledge and experience to better understand the situation and co-create the solution. The third dimension is participation, which involves how actors act, speak, and think [21], and how they may ultimately benefit from their participation beyond the co-design project's objectives [22]. We perceive participation and collaboration as interrelated dimensions rather than levels on a ladder [23].

Engagements of participants can help understand participation in co-design by providing insights into what motivates or concerns a person to participate (act, speak, or think; see Textbox 1). For example, an actor might have concerns about the capability of users with low digital literacy. These engagements affect their participation and their willingness to engage in design as a reflective practice and in mutual learning about the situation. They can influence the potential for collaboration, creativity, and ultimately the innovative, useful, and usable potential of the proposed solution.

Textbox 1. Plain language summary.

- Affordances: perceptual cues in the environment that suggest specific interactions.
- Course-of-action framework: theoretical and analytical framework for activity analysis that focuses on understanding an individual's lived experience by examining their actions in context, including their intentions, concerns, perceptions, and adaptations over time.
- Engagement: what motivates or concerns a person to participate (act, speak, and think).
- Pragmatism paradigm: a paradigm that is not committed to any sort of philosophical stance and oriented toward what works.
- Self-confrontation interviewing: one-on-one discussion in which participants are shown excerpts of recordings from a recent activity to stimulate reflection and verbalization about their actions and experiences.

Participant engagements in co-design initiatives, particularly in the digital health domain, are crucial but come with inherent challenges. These challenges include the multifaceted nature of digital health implementations, the lack of empirical evaluations [8], and the need for a precise understanding of engagement based on participants' perspectives and theoretical frameworks.

Previous Work

The concept of engagement is often blurred with involvement [8,24-26] or remains unclear [7,27,28]. In both cases, engagement seems to be defined by how actors were involved in the projects. A total of 3 studies provide concise definitions, positioning engagement as involvement: "actively collaborate" [29]; "partnership, collaboration or consultation" [13]; and engagement type: co-production, co-design, and co-creation [30]. These are extrinsic considerations, not necessarily focusing on the motivations or concerns from the actors' perspectives.

Jolliff et al [31] used an existing framework proposed by the Patient-Centered Outcomes Research Institute [32], including extrinsic but also intrinsic considerations, such as engagement quality (perceptions of actors) and partners' outcomes (effects for actors). Peters et al [33] also associated quality of engagement with emotional and cognitive factors.

Some studies report on engagement without referencing co-design or participative design, instead focusing on patient partners [27] or patient and community involvement in research [7,13,29]. While actors were involved in these projects, they were not engaged in the co-creation of the solution, which does not align with our perspective on co-design. Empirical studies focusing on engagement [7,25,27], along with literature reviews on engagement [8,13,26,29], provide insights into factors affecting engagement and offer recommendations based on the results.

Among the problems affecting engagement, power distribution or tokenism (symbolic participation) was reported in all papers except in O'Connor et al [26], whose literature review included only 4 papers discussing co-design. Papers also mentioned:

- Levels of expertise, lack of skills, or limited knowledge [7,13]
- Unclear contribution to the project [13]
- Expectation of the degree and level of involvement not clearly articulated, leading to a lack of motivation [7]
- Communication issues [7,13]
- Personal life, values, and the engagement and recruitment approach [26]
- Limited availability of actors, lack of awareness and understanding of guiding frameworks and validated methods, and resource constraints (time and money) for adequate planning [29]

XSL•FO
RenderX

Papers mentioned positive emotional outcomes for actors (targeted end users), such as increased confidence in their daily lives [8], a sense of pride and accomplishment, feeling empowered, an increased knowledge and skills [8,13]. Most papers conclude with recommendations for future research, including:

- Clear communication [7,8,27]
- Clear end-user expectations and clearly defined roles for all parties involved in co-design [8,29]
- Engaging actors as early as possible and continuing engagement throughout the process [7,28-31,33]
- Allocating sufficient time to achieve objectives [8,27]
- Fostering a positive environment and mutual respect [29]
- Providing orientation, support, education, and training to help actors participate [8,27,29,31]
- Authentic design participation focused on "designing with" rather than "designing for" [25]
- Evaluation of engagement [29,31,33]

There was still a lack of empirical results or insufficient reporting of methodology across all the papers. Most papers did not provide detailed information about the co-design activities, except for reviews of wireframe workshops [7] and a design charrette [25]. Slattery et al [8] noted that the most frequent activities in their review were interviews or advisory councils, which do not explain how actors contributed to the co-creation process.

Objective of This Study

Despite the critical role of participant engagement in co-design for achieving fruitful outcomes, discussions on engagement remain predominantly focused on extrinsic factors, blurred with involvement, and are poorly empirically described. While the insights are useful for optimizing the co-design process, connecting them to participants' motivations or concerns from their perspective remains challenging.

In this study, engagement is considered differently, based on what participants found significant from their own perspective, aligned with the course-of-action framework [21]. This article aims to address this gap by providing an intrinsic description of participant engagements in a co-design situation.

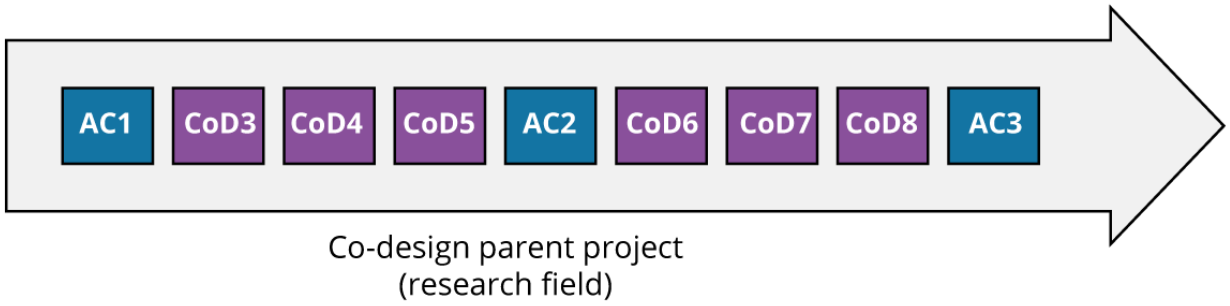
Methods

Study Design

Overview

We used a mixed-methods approach [34], within the pragmatism paradigm [35]. In our study, the pragmatism paradigm provided various perspectives on participants' engagements, each building upon the other [36]. Most of the methodology was guided by the course-of-action framework [21].

Engagement in the Course-of-Action Framework



The course-of-action provides a strong theoretical and analytical framework for documenting participant experiences in digital health co-design initiatives [37]. Within the course-of-action framework, engagement represents the actor's significant concerns or motivations related to the elements considered in the situation [38]. Engagements are shaped by participants' histories and what is meaningful or significant to them at that moment [39]. Engagement is also directly linked to expectations, as expectations modulate engagement. Concerns and motivations lead actors to expect that something will happen in relation to them. Engagement is also influenced by the referential (knowledge and experience) of the actors. In a co-design situation, we examine how the participants' engagements evolve, what motivates them to think, speak, or act (participate). Expectations related to engagements can hinder the actor's participation if they are engaged by other elements in the situation, diverting them from the task [40,41].

Study Setting: The Co-Design Parent Project

This engagement study is embedded in a larger multisite co-design parent project (from May 2017 to June 2018), whose objective was to develop a tool to facilitate the search of resources for caregivers of seniors experiencing loss of autonomy. A complete description of the co-design study protocol is available in Latulippe et al [42], and the results of the approach are presented in 3 articles [43-45].

Data collection was conducted as part of a co-design project aimed at designing a tool to facilitate resource searches for caregivers of seniors experiencing loss of autonomy. A total of 8 co-design sessions (CoDs) were held from May 2017 to June 2018. These sessions were interspersed with 3 advisory committee sessions (ACs) (see Figure 1).

Figure 1. Co-design sessions (CoD) and advisory committee sessions (AC) of the parent project.

XSL•FO
RenderX

The following describes the CoD workshops and the AC meetings:

- Regional CoD workshops (n=8): Conducted in 11 administrative regions of Québec, each workshop gathered local caregivers, health and social service professionals (HSSPs), and community-organization staff to surface region-specific needs and generate design ideas. As attendance was location-based, membership naturally differed from one CoD workshop to the next.
- AC meetings (n=3): Convened in Québec City, the AC also gathered local caregivers, HSSPs, and the community-organization staff. Its mandate was to ensure alignment between the progress of the tool's design and the data collected during the co-design sessions, resolve outstanding design questions, and steer iterative prototype development. The participants in the AC sessions were generally the same individuals, as all these sessions took place in the Quebec region.

The co-design process culminated in the creation of a prototype website with 2 main sections: one for caregivers to search for resources and another for service providers to offer resources. The prototype was the subject of a study based on the triangulation of 3 frameworks in usability and user experience [46].

Ethical Considerations

The parent co-design project received institutional review board approval before the first workshop began (Université Laval #2017 - 103, issued April 20, 2017). The initial certificate covered the core workshop activities and brief contextual questionnaires completed by HSSPs and community-organization staff; these questionnaires informed the broader design effort but are not analyzed in this engagement study.

An amendment adding video-recorded participatory observation and postsession self-confrontation interviews was submitted in June 2017 and was approved on July 17, 2017, after CoD1 (May 2017) and CoD2 (early July 2017) had already taken place. Consequently, no postsession interviews were conducted for those 2 early workshops; full data collection commenced with AC1 and CoD3 and continued through AC3 and CoD8. All participants involved in the amended protocol provided written informed consent specific to these additional procedures and received a nominal compensation of CAD $20 (US $16.45). Data were anonymized for this study.

Recruitment for This Study

Participants for this study were recruited during the sessions. A caregiver serving on the AC was interviewed twice—immediately after AC1 and again after AC3—to capture how his engagement trajectory evolved over the life of the project. Retaining both interviews enabled a longitudinal within-person analysis consistent with the course-of-action framework; discarding the second interview would have forfeited this analytic leverage.

Data Collection

This co-design project served as the research setting for our study, which aimed to describe the engagements of participants in a cyberhealth co-design project. Data collection occurred in 5 steps (see Textbox 2).

Textbox 2. The 5 steps of the data collection.

Ethnographic data collection: internet-based questionnaires for HSSPs and community organizations, along with semistructured interviews with caregivers. Conducted under the parent codesign project; not analyzed in this study.

- Participatory observation of the sessions: video and audio recordings (3 h) of the sessions to capture data on participants' activities during the session.
- Partial chronicles (extrinsic description): the day following the session, a synthesized transcription of the complete session was made using the recordings to reconstruct the sequence of events with the help of time markers. Significant moments for participants (interpreted by the researcher) were selected.
- Self-confrontation interviews: interviews of approximately 1 hour conducted mostly within 2 days after the activity. Participants were presented with portions of recordings representing key moments of the session, aiming to obtain verbalizations about their activities during the session. The partial chronicle was used to structure the interview with the temporal sequence of the session, allowing the researcher to question the participant and identify significant moments expressed by the participant. Video and audio recordings were made during the interviews.
- Complete chronicles: transcriptions of the self-confrontation interviews were used to complement the partial chronicle of the session with participants' verbalizations (intrinsic description).

Data Analysis

The analysis was conducted in 2 stages by the primary author. The first stage (deductive) involved reconstructing the participants' course-of-action in the complete chronicle. Engagements and expectations were mostly identified by paraphrasing participants' statements to clarify the researchers' understanding, while in some cases, verbatim excerpts were used to stay as close as possible to participants' experiences.

These documents were then used in the second stage (inductive), conducted using the qualitative and mixed methods analysis software MAXQDA 2020 (VERBI Software). Engagements were organized into emergent themes [47], describing the nature of the engagements.

We subsequently cross-referenced the themes with variables, including participant categories (caregivers, HSSPs, and organizations) and sessions. This step allowed us to generate tables presenting the frequency with each theme. This quantitative analysis was useful for selecting data based on what appeared significant to a larger number of participants, from their perspective, and for maintaining analytic validity by

XSL•FO
RenderX

guarding against potential biases when selecting data to present [47].

Results

Participants

The co-design project included 74 participants. We collected testimonies from 20 participants, including caregivers (n=9), HSSPs (n=4), and community workers (n=7; see Table 1). We conducted 21 interviews (1 AC participant was interviewed twice).

Table . Session's location and participants.

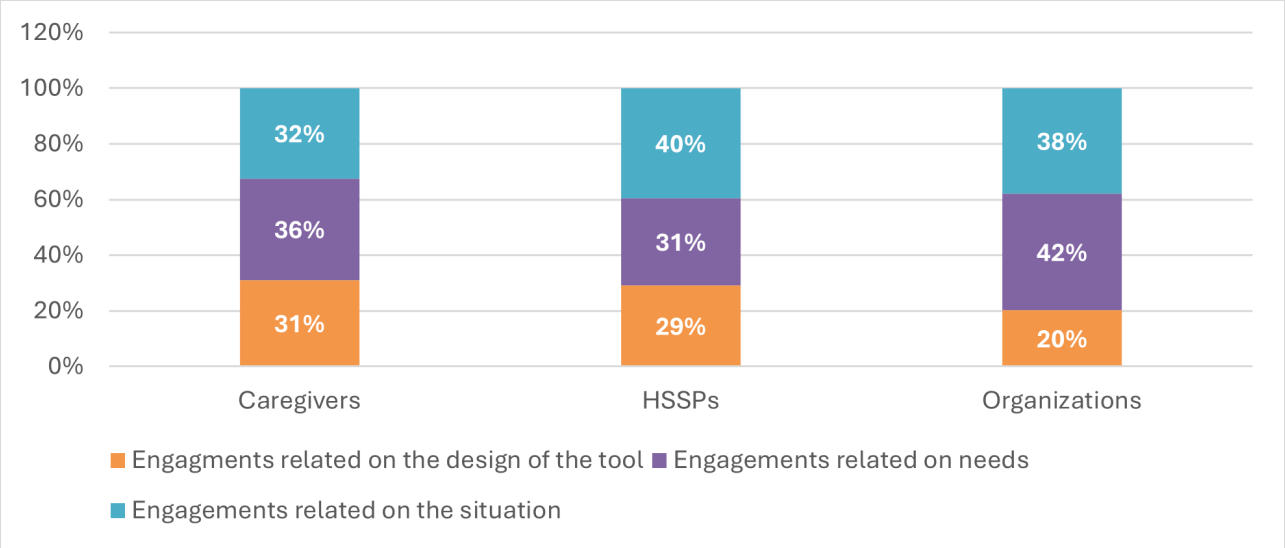
Session	Location	Participants
AC[a]1	Centre-du-Québec	• Caregiver (n=1) • HSSP[b] (n=1)
CoD[c]3	Saguenay	• Community worker (n=1)
CoD4	Bas-Saint-Laurent	• HSSP (n=1) • Community worker (n=1)
CoD5	Outaouais	• Caregiver (n=2) • Community worker (n=2) • HSSP (n=1)
AC2	Centre-du-Québec	• Community worker (n=1) • Caregiver (n=1)
CoD6	Montréal-Laval	• HSSP (n=1) • Caregiver (n=1)
CoD7	Mauricie	• Caregiver (n=2)
CoD8	Montérégie	• Caregiver (n=1) • Community worker (n=1)
AC3	Centre-du-Québec	• Community worker (n=2)

[a]AC: advisory committee meeting.

[b]HSSP: health and social service professionals.

[c]CoD: co-design session.

The AC sessions were conducted entirely in plenary, where participants were invited to express their positions on specific issues where consensus had not been reached during the CoD sessions. All CoD sessions began with a plenary presentation outlining the project, the objectives of the session, and other relevant information. Subsequently, participants were divided into small workshops of 3 to 4 people, each facilitated by a member of the research team and typically focused on a different subcomponent or angle of the session's main objective, allowing for complementary contributions to the overall session goal.



A distinctive feature of CoD5 was that all small groups worked collaboratively on the same specific task: creating a paper prototype. In contrast, other sessions (CoD1 to CoD4 and CoD6 to CoD8) explored the session's objective through more diverse or exploratory angles within subgroups. Participants had the freedom to choose their workshops, resulting in subgroups that were sometimes homogeneous and sometimes heterogeneous in terms of participant categories. Activities varied based on the session objectives, the progress of the tool design, and the specific goals of the subgroup workshops. The analysis revealed 3 main themes of participants' engagements: engagements related to their needs (personal and professional), engagements related to the situation, and engagements related to the design of the tool.

Nature of Engagements Per Participant Category

The distribution of engagement was quite similar among caregivers and HSSPs across themes (see Figure 2). However, the engagement of organizations (community workers) was significantly less focused on tool design.

XSL•FO
RenderX

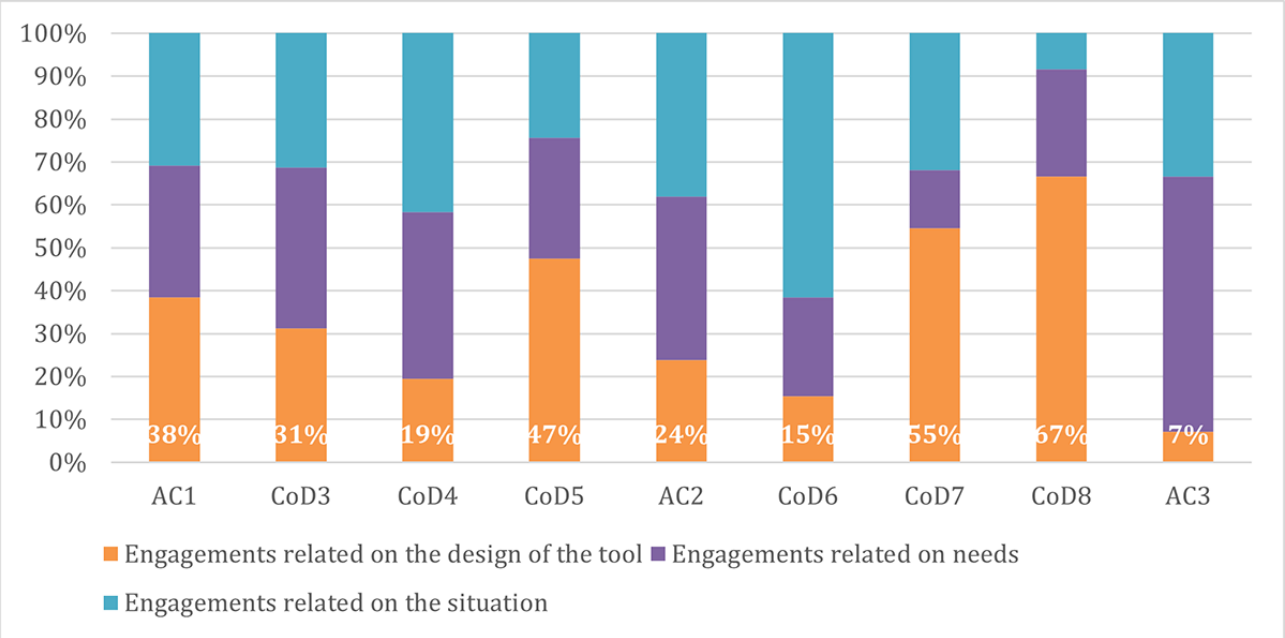


Figure 2. Distribution of engagement by participant category. HSSP: health and social services professional.

Nature of Engagements Per Session

Figure 3 shows that the nature of engagements also varied greatly throughout the project. For instance, engagements related to the design of the tool were more significant during specific sessions (CoD5, CoD7, and CoD8), while they were noticeably less important during other sessions (CoD4, AC2, CoD6, and AC3). A significant majority of the engagements related to the situation involved interaction with others, which is inherent to co-design, as interaction with others is a fundamental characteristic of the process. Figures 2 and 3 suggest that the nature of engagement varied depending on participants' categories and sessions.

Figure 3. Evolution of the nature of engagement by session. AC: advisory committee meeting; CoD: co-design session.

Example of Data Per Session

Below are examples of empirical data from each session (see Table 2), including session objectives and the methods and materials. The verbatim excerpts are enclosed in quotation marks.

XSL•FO
RenderX

Table . Session's location and participants.

Session	Objective	Methods and materials	Data examples
AC[a]1	Validate the design decisions made during the first 2 co-design sessions regarding user needs and address conflicting results.	Plenary discussion with a Microsoft PowerPoint presentation reporting the results of previous co-design sessions and addressing questions about conflicting results.	Situation: • Understand the process previously used to compile the list of needs (HSSP[b] 11 - 5). Design of the tool: • Determine what will work from the start and understand what caregivers are likely to use. (HSSP 11 - 5).
CoD3[c]	Identify user needs already addressed by other tools and determine the functionalities and content requirements related to those needs.	Comparison of existing cyberhealth tools for caregivers (2 websites, 1 app, and 1 video) conducted through small group workshops using a speed dating approach.	Professional needs: • Discover tools that can be suggested to the clientele (CW[d] 3 - 3). Design of the tool: • Avoid "losing" the caregiver through a complex and challenging resource search process (CW 3 - 3).
CoD4	Identify functional and content requirements for needs not addressed by existing tools.	Plenary brainstorming session (1.5 h) followed by small group workshops (1 h) using paper and pens.	Professional needs: • Ensure that everyone understands that for CW, the client is not the caregiver but the person receiving assistance (CW 4 - 2). • Ensure that the health services network can meet the demands of caregivers generated by the tool. "There are two problems. ONE, sometimes you're entitled to it, but you refuse the service, and TWO, there is a lack of time and resources to provide everything. If people become aware of the services, they will request them, and it will cost too much." (CW 4 - 2). Situation: • Redirect the discussion to the intended topic, as participants only had 3 hours, and the conversation had deviated from addressing the primary question (CW 4 - 2).

XSL•FO
RenderX

Session	Objective	Methods and materials	Data examples
CoD5	Design the information architecture.	Paper prototyping conducted in small group workshops using cardboard, pens, and small pieces of paper to represent options for functionalities and content requirements.	Design of the tool: • Avoid information overload by preventing it from becoming a "monster" and ensuring it remains "simple but understandable." (Caregiver 5 - 8). Situation: • Assist the caregiver in responding to the facilitating researcher who asked about a filter that could limit search results for resources in their region. He knows that older adults often do not understand computer logic; to them, a filter is akin to a coffee filter (CW 5 - 1).
AC2	Decisions on conflicting requirements.	Plenary discussion (3 h) involving both in-person and remote participants, using 2 documents: a 13-page table of results from all previous sessions and a 16-page summary table of requirements to meet the needs (results from the previous session).	Personal needs: • Understand the research project and provide relevant interventions, as she lacked sufficient information before the meeting to fully grasp the project (Caregiver 11 - 11). Situation: • Have a positive experience of participation. "I didn't fully understand my discomfort during the meeting, but I thought about it, and I realized I had become so anxious because I didn't want to mess anything up. I reflected a lot on whether I wanted to continue participating in the research because, for sure, with the way I had experienced it, I didn't want to anymore..." (Caregiver 11 - 11).
CoD6	Information design.	Plenary presentation and discussion (1 h), followed by small group brainstorming workshops (1 h and 45 min) using activity sheets for each group.	Personal needs: • Be prepared to achieve the objectives. She needed to make a choice but was unable to prepare because she had not received any information about the planned activities (HSSP 6 - 6). Situation: • Have sufficient time to achieve the objective. "At that moment, I knew we wouldn't finish our mandate. Instead of pushing forward and trying to say... at that point, I decided to disengage" (HSSP 6 - 6).
CoD7	Validation of the information architecture and interaction design.	Small group brainstorming workshops using activity sheets for each group and an interactive low-fidelity prototype (version 1).	

XSL•FO
RenderX

Session	Objective	Methods and materials	Data examples
			Situation: • Ensure that a common goal is pursued. "I felt that she [a CW] was attacking your project... [...] Meaning to say: 'You don't need to do that, we're already doing it!'" (Caregiver 7 - 7). Design of the tool: • Feel welcomed and guided by the homepage, "But caregivers need this... They're tired, they don't know where to go, they don't know what to do" (Caregiver 7 - 7).
CoD8	Comparison of homepage proposals, examination of the search results page, and validation of questions designed to help identify needs.	Small group brainstorming workshops followed by a usability discussion using an interactive low-fidelity prototype (version 2).	Design of the tool: • Ensure that visually, it immediately captures attention (Caregiver 8 - 9). • Avoid returning search results with no findings (Caregiver 8 - 9).
AC3	Decisions on conflicting results. Obtain feedback on the latest version of the prototype before website programming.	Presentation of a medium-fidelity prototype (version 3) in small groups (30 min), followed by a plenary discussion (2 h).	Professional needs: • Ensure that the language and terms used are appropriate. "I always have a concern about the language and terms that we use." (CW 11 - 6). Situation: • Take a stance without fear of judgment. "We're taking a stance on this, and that's okay. We don't have to be judged for it. [...] Can we have our approaches without getting jumped on?" (CW 11 - 6)

[a]AC: advisory committee meeting.

[b]HSSP: health and social service professionals.

[c]CoD: co-design session.

[d]CW: community worker.

Discussion

Principal Findings

Our objective was to obtain an intrinsic description of engagement, encompassing what motivates and concerns actors in a co-design situation, from their perspective. The chosen methodology, grounded in a pragmatic paradigm and informed by the course-of-action framework, allowed us to foreground participants' lived experiences and situated knowledge. This approach privileged perspectives that are often underrepresented in more top-down design processes. By adopting a co-design approach supported by self-confrontation interviews, we were able to access not only what participants said during the sessions but also how they made sense of their own engagement. These perspectives influenced both the iterative refinement of the design and our interpretation of the engagement dynamics.

The results might not appear surprising, yet it seems we are still encountering the same challenges in co-design projects. The contribution of this paper is to emphasize these results with a detailed description of the methodology and empirical data evaluating participant engagement, as recommended by Manafo et al [29] and Slattery et al [8]. This includes describing what was significant in participants' overall experience, from their perspective. Our analysis highlights that the nature of participants' engagement during the sessions went far beyond the design of the digital health tool for caregivers, even though that was the reason they were invited to participate. This aspect has not been discussed in other studies.

Comparison With Previous Work

Among the commonly discussed findings, our study revealed that actors need preparation (personal need) to understand their role, which enhances their sense of relevance and their ability to contribute meaningfully [7,8,27,29,31]. Service providers were also engaged in increasing their knowledge (professional

XSL•FO
RenderX

needs) [8,13]. A unique finding was the engagement of community workers, who sought to ensure their distinct concerns—differing from those of HSSPs—were understood. This is particularly relevant in Quebec, where community organizations operate under a model of entrepreneurial governance, with private foundations influencing their mission and work [48]. These engagements related to professional needs eventually led to engagements related to the situation (interaction with others).

Several engagements related to the situation mirrored those identified by Zowghi et al [7]. Unlike common issues of power distribution reported in other studies, our research did not encounter such conflicts between researchers and participants. However, we observed tensions between HSSPs and community workers, particularly during the final session (AC3), highlighting the need for a positive environment, mutual respect [29], and a shared vision [8]. Participants emphasized the importance of having sufficient time to achieve objectives [8,27].

The Nature of Activity as an Affordance of Action and Engagement

The concept of affordance [49] highlights perceptual cues in the environment that suggest specific interactions. From this perspective, we propose that the activities offered to participants shaped the nature of their engagement in this project. Plenary discussions generally fostered engagements related to personal and professional needs, as well as situational aspects. In contrast, design-centric activities primarily directed engagements toward the tool's design.

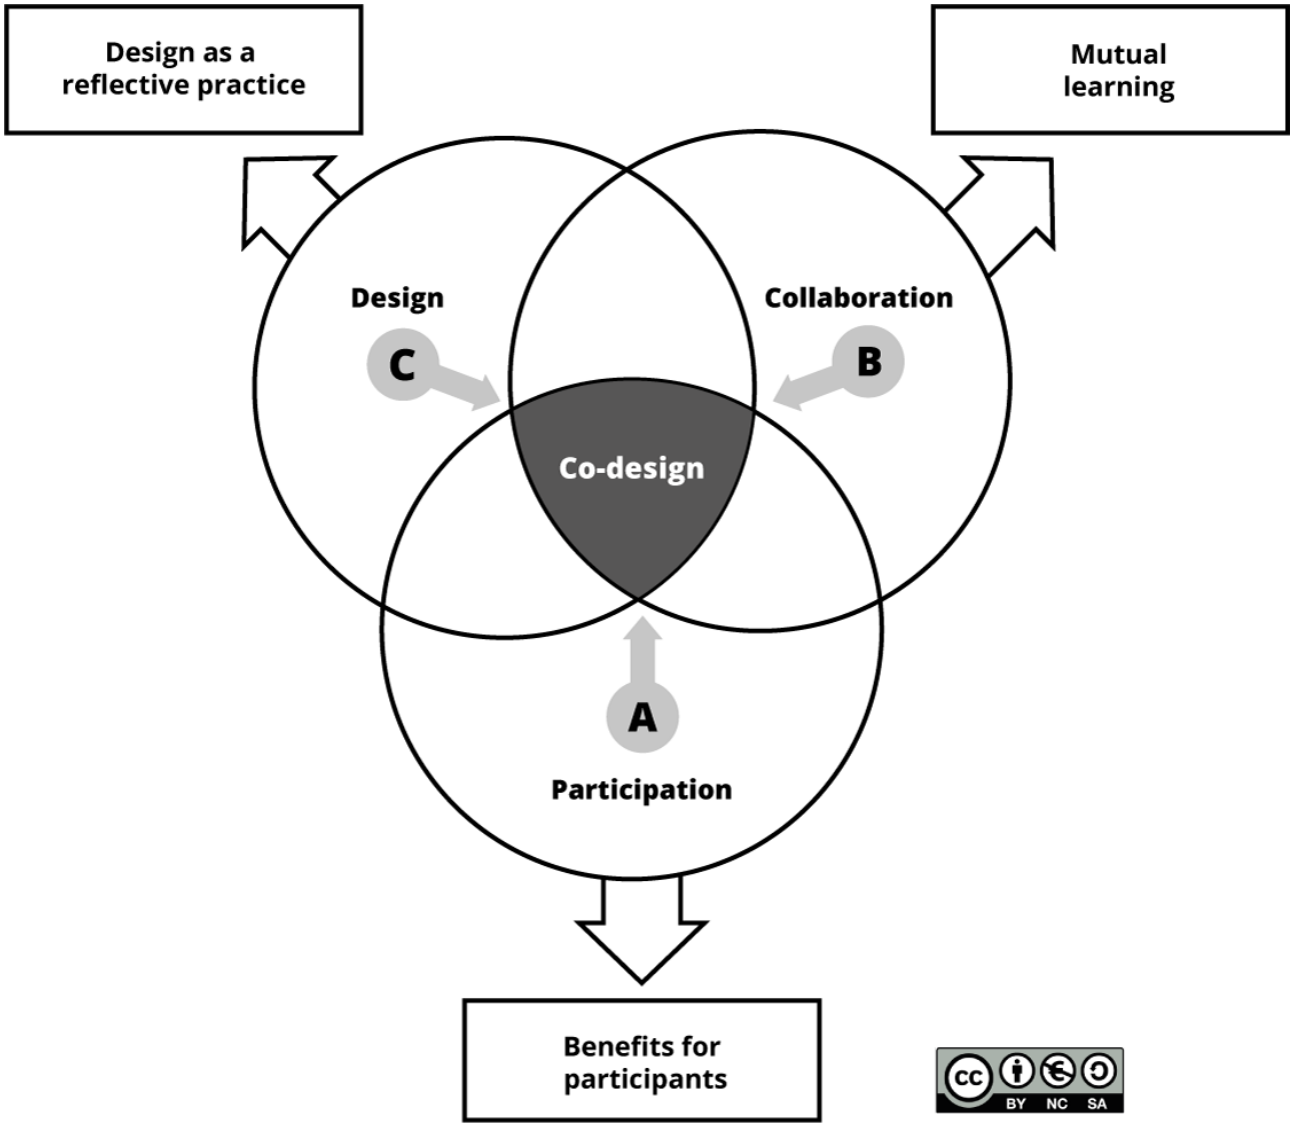
Participants in our study who were more engaged in the tool's design participated in typical design activities, such as paper prototyping (see Figure 4), mockups, clickable prototypes, and usability testing. These activities, which enhance creativity and direct involvement, acted as affordances by guiding appropriate actions, driving engagement, and directing participation (acting, thinking, or speaking) toward the tool's design. Effective facilitation of co-design sessions should emphasize design practices [50,51], aligning with best practices in this field, as reviewed by Mosely et al [52]. This approach supports the "designing with" philosophy rather than "designing for," as suggested by Howard and Somerville [25].

Figure 4. Paper prototyping activity.

Establishing an Engagement-Focused Approach

Grasping the essence of engagement is key to understanding participation in co-design, a core element of participatory research. However, the question arises: participation in what, exactly? From a researcher's viewpoint, participation implies committed involvement in co-designing a product or service. Yet, our findings suggest that participants perceive participation differently, emphasizing the diversity of engagement. This includes concerns, situational considerations, and the mobilization of their participation. In terms of research ethics and co-design, we should consider engagements that prioritize participants' needs and the situation. Adopting a compassionate stance to meet their expectations allows them to derive benefits from engagements that appear more significant to them. Based on our results, we recommend that researchers and designers using a co-design approach establish conditions that respect the diverse nature of participant engagements. To meet expectations tied to participants' personal needs and enable them to benefit from their involvement [22], we propose exploring the following avenues (see Textbox 3).

XSL•FO
RenderX



As mentioned earlier, co-design, for us, lies at the intersection of 3 dimensions: design, collaboration, and participation. These dimensions are closely related, resembling a Venn diagram. The tensions between these dimensions will impact the center (co-design). The suggested affordances (A, B, and C) could help balance these tensions (see Figure 5).

Textbox 3. Affordances that enable participants to benefit from their participation.

1. Consider participants' personal and professional engagements:
   - Recognize that participants pursue personal and professional goals that may extend beyond the intended design objectives for which they were invited to contribute.
   - Allow participants to express their personal and professional engagements (or expectations) by dedicating a specific period during sessions.
   - Endeavor to address expectations related to personal and professional engagements to honor the goals they pursue through their participation.
2. Address expectations related to the situation:
   - Ensure a shared objective from the outset by identifying and including all interest holders from the beginning.
   - Embrace a flexible approach to achieve objectives by allocating sufficient time and offering a satisfactory experience to participants.
   - Enable participants to comprehend the discussed elements by ensuring they have the necessary knowledge, such as by sending them a preparatory sheet before the session, for example, as the flipped classroom approach in education.
   - Ensure the maintenance of a positive environment characterized by mutual respect during all sessions.
3. Configure activities as affordances that suggest appropriate actions:
   - Prioritize design activities that guide participants' actions toward tool design.
   - Prompt participants to engage in action quickly during sessions (active mode) and avoid prolonged presentations (passive mode).
   - Adopt best practices in design facilitation.

Figure 5. Balancing the tensions between the dimensions of co-design.

Limitations

Participants varied in each co-design session. Analyzing the engagement of individuals who participated throughout the entire process using the course-of-action framework might yield different results. Comparing our findings with those of continuous participation could enrich the discussion on engagement by exploring the similarities and differences arising from the methodological choice of isolated versus continuous or multiple participation.

Conclusions

In this study, we explored the concept of engagement among 3 categories of potential users—caregivers, HSSPs, and organizations—who participated in a cyberhealth co-design process. We used a robust methodological approach based on the course-of-action framework to document participant engagements, addressing a gap in the scientific literature [8]. Our findings reveal that engagement extends beyond the immediate goals of tool design, encompassing broader concerns and motivations shaped by individual needs and the dynamics of interaction. In my professional co-design practice, I have integrated these recommendations by adopting a compassionate stance that prioritizes participants' perspectives and by configuring activities as affordances to support meaningful engagement. This approach has consistently led to more inclusive and impactful co-design processes, as evidenced by the quality of participation and the relevance of the outcomes generated. Our analysis highlights the importance of balancing design, collaboration, and participation to address the inherent tensions in co-design projects. Ultimately, this study underscores the value of tailoring co-design practices to respect and leverage the unique contributions of all participants, thereby advancing both the process and outcomes of collaborative innovation.

Abstract

Background: We co-designed the novel multicomponent CAPS (Care Assistant and support Program for people after Stroke or transient ischemic attack) to augment the secondary prevention of stroke.

Objective: Following completion of a feasibility study, we sought feedback from Australian clinicians and service provider representatives (the potential deliverers of CAPS) regarding their perceptions of CAPS for secondary prevention and the pathways to real-world adoption.

Methods: This was a qualitative descriptive study of clinicians and service provider representatives involved in the delivery of stroke care around Australia. A pragmatic convenience sample was obtained by contacting previous CAPS co-design study participants; leveraging professional networks (eg, LinkedIn); and distributing study flyers and newsletters via primary health care networks, general practitioner (GP) networks, and social media posts (Commonwealth Scientific and Industrial Research Organization's LinkedIn pages). Semistructured interviews and focus groups were conducted virtually with clinicians and representatives of the Stroke Foundation (Australia). Qualitative content analysis was undertaken.

Results: Overall, 18 clinicians and 3 Stroke Foundation representatives participated from 5 Australian states, including medical specialists, GPs, nurses, and allied health professionals. We collected their perceptions of CAPS, categorized as potential benefits of the program for secondary prevention, and the considerations for facilitators and challenges to real-world program implementation. The perceived benefits of supporting self-management for patients and facilitating informed decision-making for clinicians were identified. Discussions regarding program implementation included program initiation and duration, patient support considerations, and workflow alignment, which involved consideration of the barriers and enablers to uptake within primary care practice and Stroke Foundation outreach support programs.

Conclusions: There was support from participants for the potential of CAPS to improve the secondary prevention of stroke. However, approaches for addressing the challenges raised by participants, including further implementation and integration considerations, such as sustainability of the model of care, are likely required for CAPS to be successfully embedded within clinical settings.

Introduction

Globally, stroke is a leading cause of death and disability [1]. In Australia, a stroke occurs every 11 minutes, with over 400,000 people with a history of stroke now living in the community [2]. Those who survive their stroke are at high risk of a recurrent vascular event (13% - 40% cumulative risk at 10 years) [3,4], as are those who experience a transient ischemic attack (TIA) [5]. This risk can be reduced through the use of secondary prevention strategies [6]. It has been estimated that up to 80% of recurrent events could be prevented through uptake of healthy lifestyle behaviors (eg, exercise) in conjunction with the use of medication (eg, antihypertensives) [7]. However, the uptake and adherence to these prevention strategies remain suboptimal. Barriers cited by survivors include issues of access to services, lack of awareness or education following stroke, and psychosocial difficulties [8,9]. Further exacerbating the issue is the limited support provided to people following their stroke and discharge into the community [10].

Using digital health as a modality to deliver secondary prevention programs may be a method to improve long-term support and patient outcomes. Certain technologies (eg, smartphone apps) have been associated with improved management of chronic health conditions, including diabetes mellitus [11] and hypertension [12]. However, evidence for the use of digital health to improve the secondary prevention of stroke remains limited [13]. To ensure digital health programs are fit-for-purpose, end-user involvement in their design and development is crucial [14]. Engaging clinicians in this process ensures the resultant program is relevant to their work, aligns with their workflows, and may lead to better uptake in practice [15].

Consequently, we developed the novel CAPS (Care Assistant and support Program for people after Stroke or transient ischemic attack). The program was co-designed with people living with stroke or TIA and clinicians from different disciplines involved in delivering stroke care [16]. This iterative process included assessment of user needs from both patient and clinician perspectives, and user experience workshops. The resultant multicomponent program combines clinician-led, person-centered goal setting with the person living with stroke and facilitates risk factor monitoring through a remotely accessible clinician portal. Behavior change is supported through SMS text messages aligned to goals. Patient end users also access a purpose-built smartphone CAPS app and a commercial wearable device for tracking health-related measures.

The feasibility of CAPS was evaluated in a 12-week, single-group, open-label, pretest-posttest pilot study among 33 people after stroke or TIA [17]. The program was highly acceptable and satisfactory to people living with stroke or TIA, with evidence of potential improvements in cardiovascular and psychosocial health [17]. Participant feedback was generally focused on program modifications to improve usability.

In addition to seeking input from people living with stroke or TIA [17], it was important to collect feedback from clinicians and health service provider representatives as the potential deliverers of CAPS, if found to be effective. While patient experiences and perspectives regarding digital health are frequently explored, further work is required to understand clinicians' perspectives and experiences [18]. Therefore, we sought to understand the perceptions of clinicians and service provider representatives regarding the overall program for the secondary prevention of stroke, as well as the potential pathways to the future adoption of CAPS into real-world use as a health promotion program. In this preimplementation study, we present the synthesis of the participants' feedback to guide future development of CAPS and explore potential future models of care.

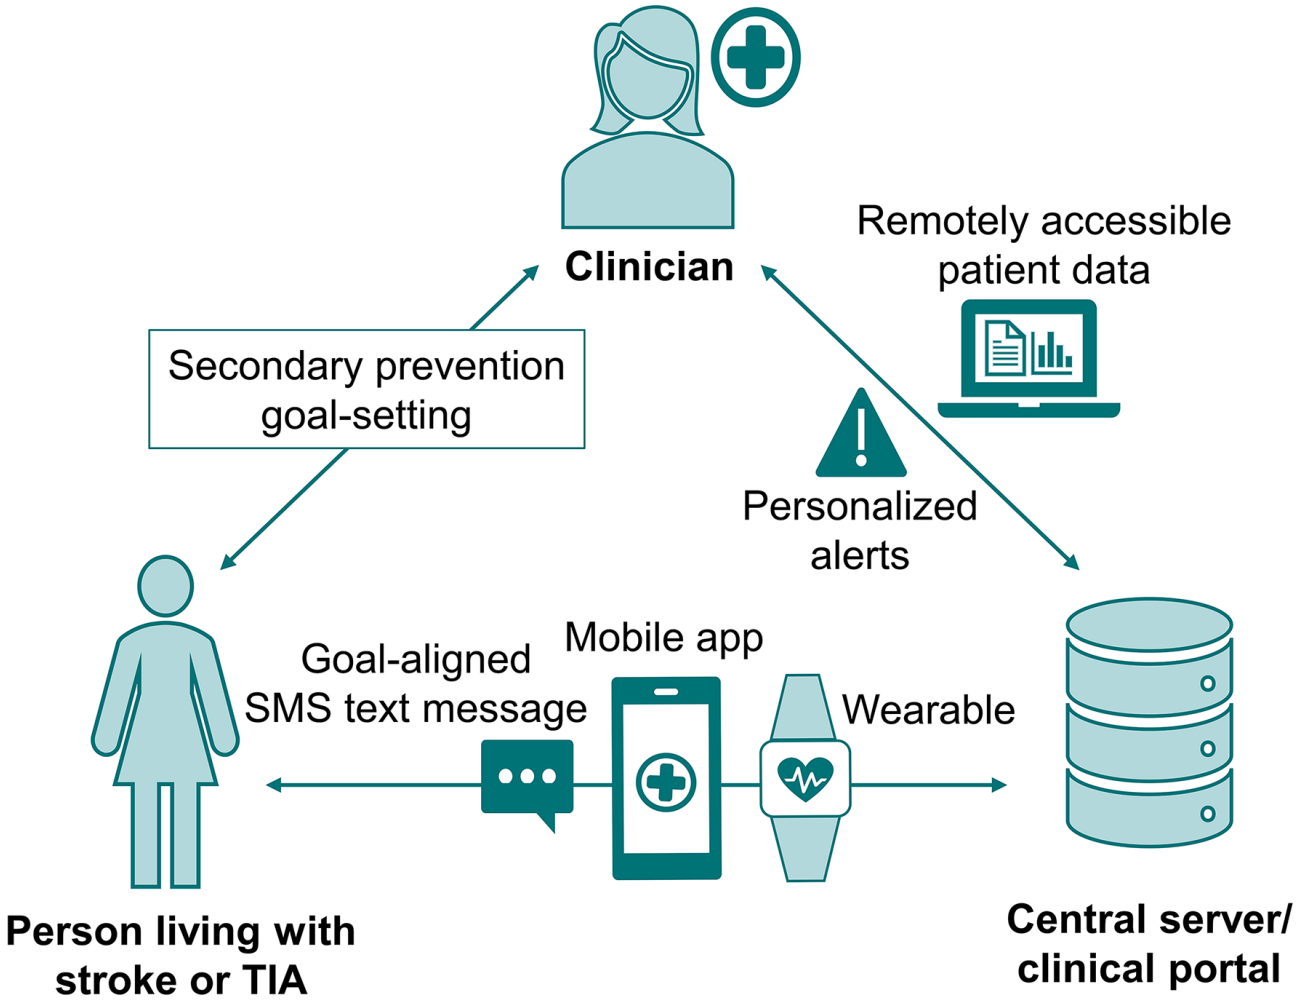
Methods

Study Design

A qualitative descriptive design was adopted, using semistructured interviews and focus groups. Methods and results are reported against the Consolidated Criteria for Reporting Qualitative Research (COREQ) (Checklist 1) [19]. This study was conducted following the feasibility study in which the digital health program was evaluated among people living with stroke or TIA (September 2022 to May 2023) [17]. A snowball recruitment process was used, where feedback from the first group of participants informed the selection of the appropriate cohort for the second group.

Ethical Considerations

The interviews and focus groups conducted as part of this study were approved by the Monash University Human Research Ethics Committee (30521) and the Commonwealth Scientific and Industrial Research Organization (CSIRO) Health and Medical Human Research Ethics Committee (2021_118_RR). Consent was collected electronically prior to commencement. All data were stored securely according to institutional guidelines. Participants were provided a gift card to acknowledge their contribution; amounts were recommended by our institution and stakeholder advisory groups. To maintain privacy, participants were given pseudonyms for data analysis and reporting.



CAPS Components

The CAPS components are described in detail in previous publications [16,17]. In brief, participants used a standardized process to set 1-2 secondary prevention and person-centered goals using the SMART (specific, measurable, achievable, realistic, and timebound) format [20]. The template and procedures for this process were adapted from a phase III randomized controlled trial (RCT), which involved using SMS text messages to support goal attainment across the domains of secondary prevention, activities of daily living, self-management, psychosocial health, and accessing health care [21,22]. The clinician-facing technology consisted of a remotely accessible web-based portal (Figure 1). Patient profiles were created and tailored using personalized health measurements and alert thresholds, upload of SMART goals, activation of SMS text messages aligned to goals adapted from the above study, and education links. Alert messages within patient profiles were activated for measures outside thresholds sourced from clinical guidelines (eg, systolic blood pressure

XSL•FO
RenderX

>140 mmHg). This process also included an automated email to the monitoring coordinator and SMS text messages to the participant. Patient-facing technology consisted of 3 components. The first was motivational goal-aligned SMS text messages, sent at a rate of 2 messages per goal per week, with some containing educational hyperlinks. The second was the purpose-built smartphone CAPStroke app, where patients entered health data daily (with different measures selected through the portal) and could review their health data, enter journal notes (audio, text, and images), activate medication reminders, and access education resources. The third was a Bluetooth-synchronized smartwatch or fitness tracker that passively collected patient data with automatic upload to the portal and app.

Figure 1. Components of CAPS (Care Assistant and support Program for people after Stroke or transient ischemic attack). TIA: transient ischemic attack.

Participants

A pragmatic convenience sample of different clinicians involved in the delivery of stroke care from various parts of Australia was invited to participate in this qualitative study. Several recruitment strategies were used. For the first group, we sent invitations to participants who were involved in the co-design of CAPS and had expressed a willingness to contribute further to this research, and also reached out to our existing professional networks (eg, LinkedIn) between May and June 2023. For the second group, various methods were used to recruit stakeholders who were identified by participants in the first group as important in providing or responding to features of CAPS. These included general practitioners (GPs) and representatives of the Stroke Foundation (Australia), who provided in-reach support services to people living with stroke, including advice on secondary prevention. The recruitment strategies for the second group included distributing study flyers, internal organization newsletters, and personal invitations over a 4-month period (January to April 2024) via primary health care networks (PHNs) (Tasmania & Gippsland), Monash Health GP Liaison Unit, Monash University Practice-based Research and Education Network (MonREN), and GoldNet Research. A marketing post was also made on CSIRO's LinkedIn pages targeting GPs, and individual GP clinics were contacted via email or directly through their website.

Data Collection

Online semistructured interviews and focus groups were conducted separately with clinicians and service provider representatives based on their availability and preference to meet. During semistructured interviews and focus group sessions, participants were provided with a background of the purpose of the study and then an overview of the program, including video demonstrations of the CAPStroke smartphone app and clinical portal. Following this, participants were asked

XSL•FO
RenderX

a series of open-ended questions regarding their perceptions of using CAPS for the secondary prevention of stroke and the potential adoption of CAPS into real-world use. The questions posed within the semistructured interview guide were adapted from previous work and subsequently refined with input from the research team. This was to ensure that all important concepts, specific to the project objective, were captured (Multimedia Appendix 1) [23,24].

For the first group, sessions were conducted remotely via the Cisco Webex video conferencing system (May and June 2023). Four researchers were involved in facilitating the sessions, with 2 researchers present in each (JC: female, PhD, clinician researcher; DS-T: male, PhD, digital health researcher; JL: female, PhD, digital health researcher; LPA: male, BSc, PhD candidate). For the second group, the sessions were conducted remotely via Microsoft Teams video conferencing (March and June 2024). Two researchers were involved in facilitating the sessions, one of whom was involved with the first group (TP: female, PhD, clinician researcher; JL). Some researchers were known to some participants from the co-design process or from professional relationships.

Sessions lasted approximately 60 minutes and were audio-video recorded with consent, using Webex or Microsoft Teams. Notes were taken by the researchers during each session. Audio recordings were professionally transcribed verbatim.

Rather than basing the sample size on data saturation, in this study, we focused on achieving adequate information power by using purposive sampling, having clear objectives, and obtaining rich, detailed interview data [25]. According to this framework, the more relevant the cohort is to the study aim and the more specific the analysis, the fewer participants are needed.

Data Analysis

To minimize potential bias, a semistructured interview guide was used, and coding was completed by 2 researchers (JL and LPA) who did not have prior relationships with the participants. Qualitative content analysis was undertaken by 2 researchers (JL and LPA), using NVivo software (QSR International) [26]. As this was a preimplementation study in which potential modifications to the program and future models of care were explored, this approach was used to systematically organize the data and generate practical insights [26]. Analysis of the first group occurred prior to recruitment of the second group, with all data combined. Preliminary initial codes were established based on the interview questions and feedback received during sessions using an integrated approach, which involved applying deductively derived codes based on the interview questions with inductively derived codes from session transcripts [27]. Coding was cross-checked and discussed between the 2 researchers prior to the second round of the coding process and writing of the results. For the second group, additional steps included discussing and reviewing initial notes taken during the interviews and focus groups among 3 researchers (TP, JL, and LPA). The categories and subcategories generated in the second group were reviewed by a third researcher (TP) and visualized using Miro software (RealtimeBoard, Inc). Coding was cross-checked and discussed among the 3 researchers prior to the second round of the coding process and writing of the results. Final coding for both groups was discussed with 2 additional authors (JC and DS-T), following the writing of the results. Disagreements were resolved through consensus.

Results

Participant Characteristics

Eighteen clinicians and 3 Stroke Foundation representatives participated (Table 1). Eleven participants attended one of the focus groups, ranging from 2 to 3 participants per session. Ten participants had one-on-one interviews. The participant flowchart is provided in Figure 2. Clinicians had various clinical backgrounds, including specialists, GPs, nurses, and allied health professionals. Clinician experience spanned the stroke continuum of care. They were working in various settings, including acute care (n=4), rehabilitation (n=3), and primary practice (n=9). One clinician also worked in community-based care as an adjunct to their acute role. Stroke Foundation representatives worked across various primary and secondary prevention services offered by the provider. All 3 representatives also had clinical backgrounds (nursing and allied health).

Categories and Subcategories

We present the results and subcategories related to the categories of "*perceived benefits*" *of CAPS for secondary prevention* and *considerations for real-world "program implementation*," including facilitators and barriers to future program uptake (Table 2).

Table . Summary of categories and subcategories.

Major category	Subcategories
Perceived benefits	• Overall perceptions of the program and technology • Benefits to the patient - Supporting patient self-management and accountability - Appropriateness of the program technology • Benefits to the clinician - Facilitating informed decision-making
Program implementation	• Program initiation and duration • Patient support considerations - Encouraging patient ownership and accountability - Barriers to patient engagement • Workflow alignment within existing programs and models of care - Alignment with Stroke Foundation services - Alignment with primary practice • Practical factors affecting program delivery - Barriers to uptake in primary practice - Reimbursement and funding considerations • An independent model of care

Perceived Benefits

In this section, we describe the perceptions regarding the overall program and the potential benefits to the patient and the clinician.

Overall Perceptions of the Program and Technology

The majority of clinicians saw the value of CAPS as a "comprehensive" program that "integrates" multiple functions for health monitoring and tracking. They also praised the program as a novel product "a few steps above what is currently available in the market" for people living with stroke or TIA in the community. Many clinicians indicated that the technological components appeared to be "very user-friendly" and "well-designed," making them easy to navigate.

> *I'm part of a clinical entrepreneur program at the moment and […] there's so much happening in this space. I certainly haven't seen anything similar to this around secondary prevention of stroke and TIA.* [Participant #6, GP]

Some GPs also raised the wider applicability and potential use of CAPS in the primary prevention of stroke and across different chronic conditions, given that the risk factors for stroke prevention are relevant to many other disease states and health conditions.

> *It's almost like it could just be a generic patient thing, not even condition specific. And if you had enough individualized goals, I mean I think it could be nearly for everyone.* [Participant #18, GP]

Benefits to the Patient

Supporting Patient Self-Management and Accountability

The potential benefits of CAPS as an option for improving self-management and "optimizing" the secondary prevention of stroke through its emphasis on self-management were raised. Clinicians indicated that the program could be used to enhance postdischarge care, providing clear instructions, support, and information to patients in a "straightforward" way. This was seen as preferable to overwhelming them at a time when they are often feeling "lost" or vulnerable after discharge from an acute hospital. Participants saw CAPS as useful for encouraging patient self-management, with the data collection serving as a motivational tool to support accountability to themselves and to their health care provider. A GP suggested the program could provide a safety net, particularly for patients who might be deterred from presenting to their GP, and could help "pick up" patients with worsening health.

> *[CAPS could help] in one or two ways, [for the patient that has] kind of completely changed their ways and are highly motivated […] this type of program no doubt would facilitate that [self-management] for them. And then some patients obviously spiral the other way and get quite depressed and, you know, fall into a bit of a hole so, but this, you know, this might be useful to give them something tangible to hold on to.* [Participant #12, GP]

> *[…] to have this recommended, just so [patients] don't feel like they've just literally been kicked out the door and that their stroke didn't matter, I think it will help them to accept some of that and process some of those changes and actually set up good life skills going forward. I think it's - it just literally would be a safety blanket for them, but a positive safety blanket.* [Participant #1, registered nurse]

Appropriateness of the Program Technology

Feedback regarding the patient-facing components of the program indicated that the measures collected through the app from the daily check-in were "all valid" for patient management. However, a few of the specialists (a neurologist and stroke consultant) noted that including subjective measures, such as mood or distress, was less important for the secondary prevention of stroke and that objective physiological measurements, such as blood pressure, should be the main focus of the program, suggesting the daily check-in to be "pared back." Conversely, GPs stated that while those physiological parameters were very important, subjective psychosocial measures were also important in long-term patient management and well-being.

> *I think a lot of patients don't realize once you've had a stroke, there's a higher chance you'll be depressed, so I think it's good for them to be thinking about it, so maybe they can be more proactive about it as well.* [Participant #18, GP]

Clinicians also recommended tailoring the frequency of each measure for patients (rather than being exclusively daily) and taking advantage of the electrocardiogram features of some of the wearable devices for monitoring atrial fibrillation.

> *[smartwatches having] the capacity to do an ECG […] that's going to completely transform diagnosis of AF into the future.* [Participant #6, GP]

Benefits to the Clinician

The benefits of using CAPS for the clinician were discussed less often, with a few of the clinicians stating that the program would have more benefits for the patient than it would for the clinician.

Facilitating Informed Decision-Making

Most of the GPs mentioned that they could leverage the rich data provided by CAPS to improve patient care and better target the risk factors of concern. This included enhanced monitoring of psychosocial well-being, highlighted as an important factor in improving patient treatment "outcomes and compliance." Clinicians emphasized the value of accessing longitudinal data that can offer greater clinical insights than the limited data that might be collected in a single consultation (eg, blood pressure readings). One GP also indicated that the potential of improved patient outcomes would be motivating for clinicians to use the program for patient management.

> *I guess the things that I would find beneficial is just having more data […] having more blood pressure readings, having more information […] if they come in and they've got all this information just available for us, we can make much more informed decisions much quicker.* [Participant #18, GP]

XSL•FO
RenderX

The importance of presenting the data in an accessible way in the clinical portal was raised, for example, using a traffic light or matrix system to easily identify data outside of clinically recommended parameters (eg, hypertension and hypercholesterolemia). By doing so, the clinician could "very quickly" get an idea of the current health needs of the patient and use the "tangible" data to target areas of improvement (eg, blood pressure).

> *[…] I'd love to just be able to type in total LDL [low-density lipoprotein], HDL [high-density lipoprotein] ratio, triglycerides and then they can just sort of see […] how well are [they] in the green?* [Participant #10, nurse practitioner]

> *I don't want a data kind of avalanche coming our way, it would be more tangible bits of information that we can move the needle with.* [Participant #12, GP]

Program Implementation

A major focus of the focus groups and interviews was to understand the potential adoption of CAPS into real-world use. In this section, we present themes related to the optimal time for delivering such a program, patient-level considerations, and the identification of potential models of care. We also explore the facilitators and perceived barriers to program uptake at the clinician level.

Program Initiation and Duration

Clinician sentiments for a suitable program initiation time after stroke were varied, ranging from immediately upon discharge to slightly longer follow-up periods (ie, a few weeks to a few months after discharge). However, the general consensus was that patients would receive the most benefit from the program if delivered within 3 months of discharge from the hospital. This aligned with feedback provided by patient participants [17].

When queried, nearly half the clinicians noted that the program should be delivered upon or soon after discharge, particularly after having been seen by specialists such as neurologists and cardiologists. They felt this was an appropriate time given that patients and their family members are "quite motivated" to implement changes and are more "susceptible to behavior change" and to learning healthy "habits." This could be done by introducing CAPS as part of the Stroke Foundation's MyStrokeJourney, a resource provided to patients to support the "transition from hospital to home" [28].

> *CAPS really has value [delivered] very acutely after an incident, when patients are more likely to engage.* [Participant #14, GP]

However, the other half of the clinicians felt it would be more appropriate to introduce CAPS a few weeks to within 3 months after discharge, with 3 elaborating that waiting a period of time after discharge was ideal. This is because patients are often overwhelmed and need further information and support at this time.

> *[…] we do a three-month follow-up in all the strokes […] that to me that would be the sweetest spot to introduce this […] they are overwhelmed, there are multiple competing demands, multiple things to still get their head around. Three months the patient already comes with a list of questions, and I see that as a nice time.* [Participant #4, neurologist]

A more flexible model of care was also suggested by a few of the clinicians, with the possibility of introducing the program at any time to patients who were discharged directly from hospitals and who have been unable to access other support services. They also felt it would be appropriate to offer the program to patients who were not given enough education about the secondary prevention of stroke at the time of their event, as identified by their GP.

> *It really depends doesn't it, if it's a TIA, they've had a fright and they're very motivated to stop that from ever happening again or stop them from ever having a stroke. If they've had a major stroke then […] they've got a whole grief process and a rehab process, so I think it needs to be individualized […].* [Participant #6, GP]

Patient Support Considerations

Encouraging Patient Ownership and Accountability

Clinicians expressed clearly that the onus should fall on the patient to self-manage for secondary prevention, rather than assuming and relying on the oversight of clinicians, who are likely to be monitoring the data sporadically. This entails patients being "empowered" to take "ownership" of their health and being "confident" in knowing when to seek help from their primary carer. However, several GPs raised concerns about patients interpreting their clinical information without the support of a clinician, feeling it "opened up a can of worms."

> *[…] there has to be an expectation put on the patients around how much responsibility they take for their health; you know they can't completely load that back on the clinicians.* [Participant #12, GP]

> *I think […] most people are trying to take more responsibility for their health and something like this could definitely help them along the way. And I think allows them to […] take that ownership. I would think they would enjoy it.* [Participant #5, occupational therapist]

Barriers to Patient Engagement

Clinicians raised some challenges patients could experience with accessing and using the program. There were concerns that some people with stroke would be unable to access the program due to not owning the right technology and that some elderly patients may lack the technological literacy for the program. Additionally, the potential difficulties in providing equitable access to the program were emphasized, particularly in culturally and linguistically diverse communities, including Aboriginal and Torres Strait Islander people. However, it was raised by 3 clinicians that patients could be supported and trained to use the technology relatively easily.

> *Of course, there is going to be a proportion of patients who can't manage a smart phone, don't speak*

XSL•FO
RenderX

> *English, don't know their Apple ID [identification] or password. Those sorts of things are a challenge and those people are already the least well served of our population, particularly people who don't speak English.* [Participant #10, nurse practitioner]

> *I think some people might be a little IT [information technology] illiterate, but […] I wouldn't say that you couldn't teach someone how to do that pretty easily.* [Participant #18, GP]

Some of the clinicians noted that CAPS would predominantly benefit motivated patients, who would find the program "exceptionally helpful," but that less-motivated patients may struggle to engage. Similarly, there were discussions about the difficulty of patients to adhere to programs, with barriers to engagement, such as fatigue or depression, as well as previous challenges with requesting patients to complete data input for extended time periods.

> *[…] those people who are motivated will probably engage in this and those who probably need it are maybe less inclined to engage for reasons. That's always a battle.* [Participant #16, GP]

Workflow Alignment Within Existing Programs and Models of Care

Clinician opinions regarding who could best deliver the program varied. In the first group, most clinicians recommended a GP-shared model of care, feeling the program aligned with the purpose of primary practice. Most clinicians highlighted the benefits of including multidisciplinary care professionals (nurses and allied health professionals) for supporting secondary prevention. Given the current service provision by the Stroke Foundation, the alignment of CAPS with their existing programs was considered. In the second group, perceptions of the GPs regarding the potential model of care and workflow alignment varied, and several challenges to the program being GP-led were raised. This concept was explored with GPs, and further information about their perceptions is provided below.

Alignment With Stroke Foundation Services

Some of the services provided by the Stroke Foundation, relevant to CAPS, include the Living Well After Stroke program and the Stroke Navigator service. The first is a secondary prevention program delivered via telehealth to improve self-management and education for people after stroke. The Stroke Foundation representatives indicated that no objective measures (eg, blood pressure) are taken by the Living Well After Stroke program, with more focus on supporting participants to achieve their program goals and equipping them with a toolkit for self-management. In the second service, the Stroke Navigator, patients are contacted by staff following discharge from the hospital to support the access of various services for managing recovery and secondary prevention. Given this, the representatives were asked if they felt the Stroke Foundation could and would include CAPS as a service in their current model. The Stroke Foundation representatives indicated that while CAPS aligned with Living Well After Stroke and the purpose of foundation activities, there was currently no bandwidth for it to be incorporated as a Stroke Foundation–led service. However, 2 representatives felt that the Stroke Navigator service could be used as a referral or registration pathway for people living with stroke returning to life in the community. When queried regarding the placement of the program, 2 of the 3 representatives indicated the importance of partnering with GPs to deliver CAPS.

> *[…] that's their key, that's where their medical care, their recovery is mainly managed […] in general practice.* [Participant, Stroke Foundation representative]

Alignment With Primary Practice

Most GPs pointed out that CAPS aligned well with GP Management Plans currently used to facilitate chronic disease management (CDM) in primary practice [29]. These plans are described in further detail in the subsection *Reimbursement and Funding Considerations*. It was raised by 1 GP that frequent touchpoints with clinicians, as required in CAPS, which could be facilitated by aligning with these care plans, are highly beneficial for patients in programs such as these and can support continued "motivation" and "achieving goals."

> *[...] a lot of this is based on personalized goals... and this is how this could be integrated into...I could see how this could make those plans just amazing...and this program sort of goes for 12 weeks, and I was just thinking that would fit with those GP management plans so much better. And the goals that are in the app are almost exactly the goals that I write for my patients now […] adding more work is often not encouraged by GPs, but I think how this could integrate into general practice, that would be really useful.* [Participant #18, GP]

There was variability reported in the perceptions of who would potentially be involved in the various tasks of onboarding and delivering CAPS. Some GPs felt that practice nurses were best equipped to onboard participants into the program, including familiarizing them with the various technologies. It was also mentioned that nurses could support patients to set secondary prevention goals. One GP stated a preference for their practice nurse onboarding patients but they themselves [the GP] setting goals with the patient. Another GP noted that either the GP or a nurse could onboard patients, depending on the practice (eg, GPs in small practices without a nurse). One GP also raised the possibility of referring patients to an external service for registration and onboarding, and then having an "agreed shared care" model with the external entity.

> *I could see how a practice nurse involved in this could be really helpful, because they have a little bit more flexibility on time […] getting the nurses to set up this with the patient would […] take that pressure off the GP doing it.* [Participant #18, GP]

GP opinions regarding who was best equipped to monitor the data were split between GPs and practice nurses. Some indicated that both were potentially viable options in the interviews. Those of the opinion that it should rest with GPs felt that it should be their responsibility as they are the primary point of "medical care" and are managers of "recovery" for patients after stroke.

XSL•FO
RenderX

> *They'd [GPs] definitely be able to do the monitoring side of things.* [Participant #18, GP]

Others noted that the practice nurses had the "skill set" and more availability to monitor patients and would be able to "spend more time" than the doctors supporting patients. It was also mentioned that the nurses could then act as a "filter" or could triage patients and "flag" particular concerns with the GP when patients attended appointments.

> *[…] we do health assessments, data gathering, practice nurses are fully trained to do that in our clinic. We do care plans, […] falls assessments and so forth, things that take time and I don't have that. My practice nurses do it on my behalf.* [Participant #13, GP]

Practical Factors Affecting Program Delivery

Barriers to Uptake in Primary Practice

A number of challenges to embedding CAPS in primary practice were raised.

The majority of GPs highlighted the lack of time they currently have available with an "insurmountable" workload, without the addition of a "high touch" monitoring program. They expressed concerns about the increased workload, potential for missed alerts, and legal implications of managing the additional information, especially outside regular hours. Additionally, 1 clinician raised the lack of support for GPs, particularly those in rural locations.

> *[…] there's a whole other workload attached to GP workload with no more remuneration or care because if the public system is suffering, then it's, we have this finite plate of things we have to do and people just keep adding, adding, adding, there's CAPS, there's obstetrics, there's psych, there's – but the job is still, you know 40 hours a week, so unfortunately some things are going to fall off the plate if you keep adding without creating a new job or adding more capacity or hiring new GP's or nurses.* [Participant #17, GP]

Some of the GPs raised issues with timeliness in responding to alerts activated within the portal when patient measurements are outside guideline-based thresholds. This included consideration of alerts being activated during periods where GPs are away, "out of hours," or not accessing the information until an extended time afterwards. One GP shared a method for addressing this current issue in their practice, where out-of-hour patient telephone calls are forwarded to after-hours medical clinics, allowing patients to still be treated. However, this comes with the caveat that the after-hours clinics cannot access clinical information from the GP and vice versa.

> *[…] they sort of just get redirected to after-hours […] if they need to see a doctor then as well. There's pretty much no access to our notes, like those afterhours doctors can't see our file at all.* [Participant #18, GP]

Most of the GPs interviewed and one other clinician (registered nurse) had concerns regarding the duty of care and medico-legal responsibility associated with the expectation from patients that there is a clinician responding to alerts in a timely and appropriate manner. An example situation provided was an alert being activated while a GP is on leave or "out of hours," which does not get actioned and leads to a medical emergency, and the liability of the GP in that situation. Several GPs felt that adopting the program could lead to increased insurance premiums. These legal and cost implications were highlighted as deterrents to the uptake of the program.

> *I think in terms of, from the medical legal point of view, it opens up conditions to being liable for clinical information that comes across your desk, because if you see something that's abnormal and you're on leave or you're away and it doesn't get actioned and then the patient subsequently has a stroke or something like that then who is at fault?* [Participant #17, GP]

Interoperability with the current medical software was raised as critical in the adoption of CAPS by most of the GPs interviewed and another clinician (nurse practitioner). Two GPs raised the challenge of using an additional interface in the time-poor environment. To access and use the information collected in CAPS, the GPs stated that the data would need to be automatically "integrated" into the patient's medical file in the practice software. According to them, this could include "populating" the patient file in the practice management software or providing "downloadable data." One GP felt that being able to integrate with the practice software would be "game-changing." Another suggestion was to include a link to the CAPS clinician portal within the patient profile in the practice software for seamless access.

> *[…] as a GP I want it all in the one thing, I want it all in best practice, I want it all in medical director.* [Participant #18, GP]

> *I think as soon as you're asking GPs to go outside their medical software and log on to another web page, they're not going.* [Participant #12, GP]

Another concern raised by a few of the GPs was the management and storage of patient data on an external platform. Citing "privacy issues," they flagged that GPs often worry about sending data to third parties and desire clear "labeling" of how their patient data are being stored and used. One GP indicated that backing from a trusted organization, for example, data being hosted and protected by the CSIRO (a federal government research organization) or elsewhere by the government, would help allay those concerns.

Some GPs highlighted cost and reimbursement as major barriers to implementing the program in primary practice. This is explored further below.

Reimbursement and Funding Considerations

Aligning consultation and management of patients under the Medicare Benefits Scheme (Medicare), Australia's universal health care insurance program, was suggested by most GPs. This could be done by aligning the program delivery (including onboarding) and associated consultations under the CDM services provided by the GP. CDM services were introduced to provide further Medicare subsidized support to patients with chronic medical conditions [29]. By doing so, the nurses

XSL•FO
RenderX

involved in supporting the delivery of CAPS could be reimbursed via existing Medicare rebates within the management plan codes for their time and consultations, which was highlighted as vital with the "razor-thin" margins of a GP practice.

> *[…] you can probably fall within the same consult as the GP management plan, like a chronic disease management plan, because that also requires goal setting to do it correctly.* [Participant #14, GP]

Similarly, some GPs indicated they would privately bill the patients, referencing the "undercurrent" in the general practice of continued reductions in bulk billing (where Medicare benefits fully subsidize health services).

> *[…] if we created a job and we paid someone to be monitoring it possibly, but there would be, it would be a paid service and the patient would have to foot the bill for it.* [Participant #17, GP]

Another GP raised the possibility of using private health insurance to cover the sessions, given that the insurers are "incentivized" to reduce members using health services and having recurrent events. This could be used to then incorporate health coaches into the program to support and guide the patients and take the burden of monitoring from GPs. However, they acknowledged that this could exclude patients who do not have private health insurance.

> *[…] the private health insurers can pay the health coaches to actually help patients through this journey and […] the app can actually be part of the private health insurer hospital prevention program to say, a tool that health coaches can use […] set goals for [the patient] and the alerts will streamline where the alerts go, or will help [the patient] with when is it relevant to see a GP.* [Participant #14, GP]

An Independent Model of Care

An alternative proposal by several GPs was that the program could be run independently as a standalone private service, providing a solution to the current barriers GPs face. One GP mentioned that this could lead to more "feasible," "efficient," and cost-effective care by training independent clinical staff to solely onboard, monitor, and respond to data. These staff could then link in with GP services to share the information collected. Another GP highlighted how previous programs supported by a PHN have worked, for example, having independent clinical staff travel to different clinics, provide heart health checks, and then feed that information back to the GP.

Discussion

Principal Findings

We have described the perceptions of Australian clinicians and Stroke Foundation representatives regarding CAPS. This included their opinions regarding the potential perceived benefits, and the facilitators and challenges to the future adoption of this novel digital program as a health promotion program delivered in the community. We report that clinicians from different disciplines and the continuum of stroke care saw the value of a digitally delivered multicomponent secondary prevention program, which was discussed as a potential model of care. We present their insights into the challenges of integrating these types of programs into primary practice.

Both the clinicians interviewed in this study and the end-user participants living with stroke or TIA in the feasibility study felt the program could provide essential support if delivered shortly after discharge [17]. While secondary prevention begins in the hospital with medications, care plans, and risk factor education, not all patients receive these. In 2023, 30% of patients discharged from Australian hospitals did not receive a care plan, and 28% were not educated regarding risk factor management [30]. The transition from hospital to home is often poorly supported, leading to unmet needs, particularly in healthy lifestyles and uptake of secondary prevention [31]. The lack of support provided may contribute to many people living with stroke reporting long-term unmet needs, particularly in the areas of healthy lifestyles and secondary prevention [32,33]. CAPS could be used to provide essential information for self-management and ensure patients feel better supported after discharge [34].

Clinicians identified issues of accessibility, particularly "digital exclusion", as a potential barrier to patient uptake of the program. Digital access is now a key social determinant of health [35], which can be affected by factors such as digital literacy, age, education, and cultural diversity [36,37]. People with lower digital literacy, including those from culturally diverse backgrounds, are less likely to access and use digital technologies for their care [38]. To bridge the digital divide, interventions should be made accessible through various methods, such as using simple language, offering alternative formats (eg, audio or icons rather than text) [38,39], providing devices [13], co-designing interventions to ensure they are fit-for-purpose [13,38], and offering individual training in the use of technology [40]. In the CAPS feasibility study, training was provided via an image-based step-by-step manual, a tutorial video, and a telephone call. This may have contributed to the high level of participant satisfaction with the usability of the smartphone app and wearable device [17].

An additional barrier identified was the challenge of engaging patients who lack motivation to improve their health. While we observed sustained technology usage in the feasibility study [17], that finding was among people who chose to participate in digital health research. The broader stroke population may be less incentivized to engage with a digital health program and less motivated to improve their health. However, previous studies have found that particular features, such as the ability to review the data and active participation in health management, can improve motivation and engagement [41-43]. Person-centered goal-setting also increases motivation among people living with stroke [44]. While these features are part of CAPS, the program needs further evaluation in a larger, more representative population to assess motivation and adherence.

Several barriers to the adoption of a digital health program into clinical practice were identified. Stroke Foundation representatives noted limited availability for integration with existing services in their stroke-specific models. In particular,

XSL•FO
RenderX

barriers of adoption into primary practice were discussed. Scarcity of resources was a major concern of the clinicians interviewed, with limited time and personnel to regularly monitor and respond to patient data. Previous studies have also shown that mobile health technology (eg, smartphone apps), telemonitoring, and self-management tools can increase clinician workload [45], hindering the implementation of evidence-based stroke care guidelines [46]. Digital health programs should support, not disrupt, workflows, and clinicians must be involved in their development to ensure they are effective and fit-for-purpose for both patients and clinicians [47].

The first group of clinicians noted that GPs were the best placed health care providers to deliver a program such as CAPS. However, the GPs cited a number of barriers, as explored above, that raise challenges in delivering CAPS in the current primary practice setting. As such, a GP-led model of care may not be feasible at scale. Involving nurses (for example, the specialist nurses in the New South Wales Chronic Disease Management Program) [48] to support a shared model of care may be more plausible. Previous research has indicated that nurse-led remote patient monitoring is feasible and has positive clinical outcomes [49].

With training, a nurse could develop patient-centered goals, monitor and respond to data, and provide action points or feed important information back to primary care. This also leverages an existing workforce that is trained in health promotion, CDM, and patient monitoring. As suggested, delivering CAPS as an independent nurse-led service, where clinical summaries are securely fed back to primary practice, could alleviate some challenges of integration with the various practice management software. Given the fragmentation of management software used across Australia, integrating CAPS into each would be technically and financially challenging. Data sharing through secure formats (eg, HL7 or encrypted PDF reports) to primary practice could be a more practical approach.

Consideration of the sustainable implementation and delivery costs of CAPS is vital, given that they are key barriers to the uptake of digital health programs [50]. While aligning the program under the Australian Medicare–subsidized CDM plan as a potential reimbursement model was discussed, this funding is predominantly used for allied health services, such as podiatry [29]. Furthermore, there is no current funding mechanism for remote patient monitoring or the delivery of a digital health program through Medicare [51]. As such, alternative forms of funding are likely to be required. Funding through PHN initiatives or private health insurance may provide pathways for sustainable reimbursement. State-level funding may also be viable, with precedent from the South Australian government supporting the sustained delivery of a virtual clinical care model [52]. Sustainable delivery of CAPS will require investment in training, technical infrastructure (eg, servers, product updates, and cybersecurity), and secure integration with primary practices. Scalability of the program will also require addressing interoperability barriers across diverse practice management systems, ensuring workforce availability and readiness, and improving digital health literacy among both clinicians and patients [53]. Demonstration of downstream cost benefits from program delivery (eg, reduced hospitalization) will also be essential to attract continued funding.

Identifying successful digital programs, which have been uplifted into a health service, can highlight factors that facilitate implementation. However, there is limited reporting on this process, and many programs face large implementation challenges [54]. A successful Australian example is Cardihab (Cardihab Pty Ltd) [55], a cardiac rehabilitation program offered via a smartphone app and clinician-facing portal. The program was evaluated in an RCT for effectiveness before implementation [56], and it is now offered to patients in multiple Australian states through private health insurance and certain private and public health services [55]. Medly, delivered in Canada, is another example of a mobile phone–based telemonitoring program for heart failure. Developed through a user-centered design process, the program was evaluated for effectiveness in an RCT [57,58]. Medly is currently offered through 9 health services throughout Toronto, supported by the University Health Network and Boehringer Ingelheim Canada [59]. The successful implementation of these digital programs indicates the importance of conducting an RCT in order to progress through the implementation pipeline. Data from this study will inform the future design of an RCT, including modification of CAPS technology and the model of care to be evaluated.

The strengths of our study included the diverse range of clinicians and wider service providers with expertise across the continuum of care, including those involved in acute, rehabilitation, and primary care. Given their mention by GPs during the interviews, practice nurses and practice managers could have been interviewed to understand their perceptions of adopting CAPS into primary care. However, we feel that our pragmatic convenience sample of content experts provided sufficient information power related to the richness and relevance of the data [25]. We used standardized procedures to demonstrate the program components and capabilities, with clinicians asked a similar set of questions to enhance dependability and consistency while still permitting flexibility to explore their views and experiences. Analysis of the data was undertaken by researchers independently with collaborative cross-checking and oversight of a third researcher in the second group. We demonstrated the capabilities of the program for patient end users, including self-monitoring and tailored support for goal attainment. However, we did not have the opportunity to involve clinicians in using and delivering CAPS to demonstrate enhanced management of actual patients. This means their perceptions and interpretations were purely conceptual, based on the demonstration provided during the focus groups or interviews. As such, a number of clinicians made assumptions and provided comments about a program they were not fully familiar with. The current lack of interoperability with practice management software or electronic health records makes integration of CAPS challenging. The current program design, which relies on regular review and response to patient-entered data, may impact clinical workflows and workload. Furthermore, the use of CAPS requires some level of digital literacy and the ownership of compatible devices among patients, as well as digital competence among clinicians,

XSL•FO
RenderX

which may limit equitable use and adoption. Interviews for the first and second groups were conducted by different researchers; however, a consistent semistructured interview guide was used across all interviews, and the facilitators were experienced. Data analysis was also conducted by the same 2 researchers, and all the other researchers were involved in the discussion of the results.

The data collected regarding clinician perceptions will be integrated with the prior patient feedback collected [17]. This will be used to guide amendments to the program components (both patient and clinician facing; eg, patient traffic-light summaries) and updates of the technology. Their feedback will also guide the future model of care to be evaluated in a mixed-methods RCT, where patient participants will be recruited earlier in their recovery as recommended, and clinicians will be involved in the delivery of the program. We will also collect information to facilitate an economic evaluation of the program, a critical component of future implementation.

Conclusion

Clinician perspectives regarding the use of CAPS for improving the secondary prevention of stroke indicate the potential of the program to address gaps in care. Participant feedback indicated a need to consider a viable and sustainable model of care that includes primary care without detrimentally impacting associated workloads. Further evaluations of the program regarding effectiveness in phase II and III RCTs are warranted.

Acknowledgments

This research was funded by a STOPstroke Pilot Project grant and the Commonwealth Scientific and Industrial Research Organisation Precision Health Future Science Platform. LPA acknowledges scholarship support from Monash University and the Australian e-Health Research Centre, CSIRO. NAL acknowledges fellowship support from the Heart Foundation of Australia (#106762). DAC acknowledges fellowship support from the National Health Medical Research Council of Australia (#1154273).

The authors would like to acknowledge support in participant recruitment from A/Prof Seana Gall, Primary Health Tasmania, Gippsland Primary Health Network, MonREN (Monash University Practice Based Research Network), GoldNet (the Gold Standard in Primary Care Research), the Department of General Practice at Monash University, and the University of Queensland General Practitioner Network.

Abstract

Background: The rapid expansion of virtual care during COVID-19 accelerated the development of virtual hospital-at-home models, which deliver hospital-level care in patients' homes through remote monitoring, virtual communication, and in-person support when required. While the virtual hospital-at-home model offers the potential to improve patient-centered care and health equity, rapid implementation often overlooks culturally diverse and underserved populations, including South Asian communities who experience disproportionate chronic disease burden and barriers to accessing culturally relevant services. Strategies are needed to ensure equitable design and adoption of virtual hospital-at-home models.

Objective: This study used an experience-based co-design (EBCD) approach to engage patients, caregivers, clinicians, and community organizations in shaping a regional virtual hospital-at-home strategy within the Fraser Health Authority, British Columbia, Canada. The aim was to identify barriers, facilitators, and equity-focused solutions to inform future implementation.

Methods: We conducted a five-stage EBCD quality improvement process in the Fraser Health Authority, British Columbia, including (1) forming a multidisciplinary steering committee, (2) reviewing health care provider experiences, (3) interviewing South Asian patients and caregivers, (4) hosting a co-design workshop to develop solutions, and (5) sharing back findings.

Results: Participants identified barriers, including digital literacy, language, and trust in virtual care. The co-designed solutions focused on culturally tailored education, hybrid digital training, caregiver inclusion, and community-driven engagement strategies.

Conclusions: EBCD enabled the development of inclusive and actionable strategies to improve virtual hospital-at-home services. The findings highlight the importance of ongoing community collaboration to ensure equity in virtual care innovation.

Introduction

Background

The rapid expansion of virtual care delivery in response to COVID-19 has paved the way for the development of virtual hospital-at-home models, which are models of care that mirror the structure and functions of traditional inpatient wards, but enable eligible patients to receive hospital-level care in their own homes through a combination of remote monitoring, virtual communication, and in-person support when needed [1]. Unlike general telemedicine or outpatient virtual visits, which typically provide episodic or consultative care, the virtual hospital-at-home model aims to deliver a continuous and integrated alternative to acute hospital care.

Virtual hospital-at-home services hold promise in improving patient-centered care and enhancing health equity within communities [2]; however, the rapid implementation of virtual care during COVID-19 lacks comprehensive patient-centered development and evaluation, potentially marginalizing already underserved populations (eg, older adults, people with disabilities, and culturally diverse communities) [3]. Without effective strategies for continuous improvement, virtual care risks perpetuating inequitable and low-quality care, undermining the very goals they aim to achieve [4]. In Canada, South Asian

XSL•FO
RenderX

communities represent a significant proportion of residents who have historically been underserved and experience substantial barriers related to language, cultural relevance, and access to health services [5]. South Asians in Canada have higher rates of chronic diseases compared to other racialized groups, including cardiovascular disease, diabetes, and hypertension [6,7]—partly due to social determinants of health (eg, access to education, employment opportunities, food security, experiences of discrimination, and access to culturally appropriate care) [8-10]. Given the inequities and disparities faced by South Asian community members within Canada, innovative care strategies are needed to enhance access to culturally relevant care and improve health outcomes.

Challenges

Key virtual care challenges include the following: (1) the digital divide: disparities in technology access and digital literacy disproportionately exclude vulnerable populations, such as older adults and culturally diverse communities, from the benefits of virtual care [11,12]; (2) workforce strain: clinicians face challenges navigating new technologies and workflows and often lack the time to learn new systems and technologies contributing to burnout and hindering virtual care adoption [13]; (3) rapid technological evolution: virtual health requires continuous innovation and adaptability to ensure sustainability, interoperability, and alignment with patient needs [14,15]. In this paper, we specifically address challenges related to equitable access and patient-centered engagement in virtual hospital-at-home services.

Fraser Health Setting

These challenges are particularly salient within the Fraser Health Authority, the largest regional health authority in British Columbia, Canada, which provides care to more than 2 million residents across 20 diverse communities [16]. Fraser Health serves 75% of the South Asian residents in the province, and 1 in 5 Fraser Health residents identifies as South Asian [17]. Considering Fraser Health's diverse population and geographical spread, the virtual hospital-at-home model has the potential to improve care quality and access while alleviating pressure on hospital resources. Fraser Health is designing a regional program and strategic implementation guidelines for a virtual hospital-at-home service with five primary objectives: (1) increase overall system capacity, (2) improve patient flow and efficiency, (3) reduce hospital-acquired harm, (4) enhance patient and essential care partner experience, and (5) enhance clinician experience.

At the time of this study, the only active unit was the virtual psychiatric unit (VPU), launched in fall 2022 [18]. The VPU virtually provides hospital-level psychiatric care, but the long-term vision for Fraser Health's virtual hospital-at-home strategy is to expand to other clinical areas (not yet specified). This project did not evaluate the VPU directly, but instead sought to engage community members in shaping the design of future virtual hospital-at-home models across a range of clinical areas.

This Project

This study uses a design thinking approach, experience-based co-design (EBCD) [19], to help inform the development of the Fraser Health virtual hospital-at-home service. EBCD is a participatory, user-centered approach to quality improvement that engages those closest to the area for improvement. In this project, patients, caregivers, clinicians, and decision-makers were included to explore areas for improvement and to co-design service improvements based on lived experiences. EBCD is based on the premise that co-design can lead to experience-focused health care services, which can result in improved outcomes in clinical effectiveness and safety [20]. This multistage service improvement approach captures the experiences and emotions of service users by understanding key events or "touchpoints" during their service journey [20].

Importantly, EBCD has been recognized as a vehicle for patient empowerment and equity, shifting traditional power structures by positioning patients as co-producers in health care improvement [21]. In public health, more broadly, co-creation models such as EBCD have been intentionally used to address health inequities by involving marginalized communities across all phases of intervention development, from agenda-setting to evaluation [22]. In addition, EBCD has been shown to help flatten epistemic inequities by equally valuing all users' experiences and dismantling entrenched power imbalances in co-design processes [23]. By centering on the lived experiences of patients and caregivers, particularly from underserved communities, EBCD ensures that service improvements prioritize equity alongside quality and safety.

Methods

Overview

EBCD is a quality improvement methodology that is typically structured into 6 stages [19]. This study adapted the traditional 6-stage EBCD framework into 5 stages, as the final celebratory event was integrated into steering committee debrief sessions rather than conducted as a stand-alone event. A core component of EBCD is the creation of a short film based on interviews with participants, which is used to spark discussions between those providing and receiving care at a co-design event. This study consisted of 5 stages, and this paper describes the process of using EBCD to help inform the Fraser Health virtual hospital-at-home service (Table 1).

XSL•FO
RenderX

Table . Stages of the experience-based co-design approach.

Stage	Key activities	Participants	Key outputs
Stage 1: setting up and steering committee	Established steering committee and monthly meetings	PICS[a] society, SAHI[b], Virtual Health, EDI[c] team, and researchers	Guidance on study approach and culturally relevant methods
Stage 2: observing service delivery and staff experiences	Interviews with health care providers	7 staff (n=5, 71% physicians and n=2, 29% nurses)	Insights on barriers and opportunities for virtual hospital-at-home models
Stage 3: gathering patient experiences and touchpoint film	Interviews with South Asian community members and film creation	20 patients and caregivers (9 in film)	Short touchpoint film highlighting key experiences
Stage 4: co-design event	Workshop using film to guide problem-solving	Patients, caregivers, clinicians, and steering committee	Solutions for 5 key themes: patient-centered care, technology, training, community engagement, and process improvement
Stage 5: post–co-design analysis and uptake	Thematic analysis and follow-up meetings	Steering committee and the virtual hospital development team	Recommendations shared, implementation planning, and reflections

[a]PICS: Progressive Intercultural Community Services.

[b]SAHI: South Asian Health Institute.

[c]EDI: Equity, Diversity, and Inclusion.

Stage 1: Setting Up and Establishing a Steering Committee

Members from the Progressive Intercultural Community Services (PICS) society, Fraser Health's Virtual Health department, Fraser Health's South Asian Health Institute, Fraser Health's Equity, Diversity, and Inclusion team, and researchers were invited to join the steering committee. These groups were chosen for their understanding of the underserved communities (particularly South Asian communities), their roles in the health care system, and their experience with virtual care services and community-based research methods, ensuring a comprehensive perspective for the project. The committee met monthly to discuss project updates, provide feedback on the research approach, and assist in refining the study's methods.

Stage 2: Observing Service Delivery and Gathering Staff Experiences

To contextualize the development of virtual hospital-at-home services within Fraser Health, we incorporated findings from a previous qualitative study with 7 health care providers (n=5, 71% physicians and n=2, 29% registered nurses) regarding their experiences with existing remote patient monitoring services. We conducted approximately 30-minute, semistructured one-on-one interviews with health care providers across Fraser Health. The semistructured interview guide was developed in consultation with the Virtual Health department to ensure that the questions were relevant, actionable, and aligned with the information needs of the remote patient monitoring program. Interviews explored health care providers' experiences referring patients to remote patient monitoring programs, barriers encountered, perceived advantages and disadvantages of referral, and suggestions for program improvements. These interviews were included to inform this study, as remote patient monitoring is an integral aspect of virtual hospital-at-home models. Remote patient monitoring allows clinicians to track patient status in real time and supports proactive care delivery. For full details on the methods used, refer to the study by N Moghaddam, M Montenegro, and M MacPherson (unpublished data, 2025).

Stage 3: Gathering Patient Experiences and Creating Touchpoint Film

Overview

Qualitative interviews were conducted with 20 South Asian community members in multiple languages to better understand the attitudes, experiences, and perceptions of patients and caregivers toward virtual hospital-at-home models. South Asian communities are among the largest racialized groups within the Fraser Health region. These interviews identified perceived barriers and preferences regarding virtual hospital-at-home models. Moreover, 30- to 60-minute, one-on-one semistructured interviews were conducted virtually via Microsoft Teams. Technical support was available through the PICS society to ensure participant access. The topic guide was adapted from previous Fraser Health Virtual Health workshops, revised with feedback from South Asian community members, and reviewed by the plain language team for clarity. The guide covered perceptions of and attitudes toward the virtual hospital-at-home model, including perceived benefits, concerns, and strategies for community engagement. During the consent process, participants were asked if they agreed to have their interviews audio and video recorded and if they would like to be contacted for potential participation in the co-design event. For full details on the methods used, refer to the study by MacPherson [24].

Creating the Short Film

Following the interviews, a short film was created featuring interview clips to highlight key "touchpoints" or themes and outline experiences within the patient journey. Only participants who consented to their video being used were included in the study. Following thematic analysis, salient quotes were identified, and the corresponding video clips were spliced into a 10-minute film created by Fraser Health's Virtual Health department. The film is an essential element of the EBCD approach, which captures patient experiences to help facilitate

XSL•FO
RenderX

conversation in stage 4, and is an effective tool to communicate patient experiences to health care providers.

Stage 4: Co-Design Event

Interview participants who consented to be contacted, steering committee members, and clinicians were invited to an in-person co-design workshop where the touchpoint film from stage 3 was presented to stimulate discussion on improving virtual care. The film highlighted key experiences and themes identified in the interviews, providing a foundation for the co-design discussions. Community members were introduced to the principles of co-design and engaged in collaborative problem-solving activities to address 6 key challenges: language barriers, digital literacy, comfort and convenience, suitability, quality of care, and awareness of available services.

These 6 challenges were derived from thematic analysis of participant interviews conducted in stages 2 and 3, representing the most salient and recurrent themes reported by participants. The steering committee reviewed and confirmed these challenges before the workshop to ensure that they accurately reflected participant priorities. Discussion prompts and structured design thinking exercises were specifically aligned with these areas, ensuring that participant contributions addressed the most relevant issues for improving the virtual hospital-at-home service.

Participants contributed ideas through structured design thinking exercises, including the “5 Whys” technique and “Crazy 8’s” brainstorming method. The “5 Whys” is a root cause analysis method that involves asking “why” iteratively (typically 5 times) to drill down to the underlying cause of a problem [25]. “Crazy 8’s” is a rapid ideation exercise in which participants sketch 8 distinct ideas in 8 minutes, promoting creative thinking and diverse solution generation [26,27]. Both methods facilitated active engagement and helped structure participant feedback. The proposed solutions were analyzed and subsequently shared with the virtual hospital-at-home development team for further consideration.

Stage 5: Co-Design Analysis, Follow-Up, and Internal Uptake

Although a formal celebration event (stage 6 in the traditional EBCD model) was not conducted, several postworkshop activities were carried out to ensure continuity and uptake of insights. Ideas generated during the co-design event were thematically analyzed by the research team to identify crosscutting recommendations. These recommendations were then shared with the virtual hospital-at-home development team, who reviewed and discussed the feasibility of incorporating them into ongoing service planning.

In addition, follow-up debrief sessions were held with the steering committee to reflect on the process, discuss next steps, and disseminate knowledge products (eg, the touchpoint film and a summary of co-design insights). Informal celebrations occurred during these meetings, where the steering committee members acknowledged the value of the process and its outcomes.

Ethical Considerations

This project received ethical approval from the Fraser Health Research Ethics Board (FHREB; approval IDs H23-03144 and H23-00463). All participants provided written informed consent prior to participation, including separate consent for video recording, for inclusion of video footage in a short film shared at the co-design event, and for potential follow-up contact regarding subsequent co-design activities. Participants were informed of the purpose and procedures for each stage of the project, as well as their right to withdraw at any time without consequence.

All data were treated confidentially and stored on secure, password-protected servers accessible only to the research team. Identifying information was removed or anonymized in transcripts and reports to protect participant privacy. Video recordings were used solely for analysis and, where consent was provided, for inclusion in the co-design film. The film was shown only to event participants and was not distributed beyond that setting.

No financial or other forms of compensation were provided for participation in the co-design event.

Results

Stage 1: Establishing a Steering Committee

A total of 13 individuals participated in the steering committee, representing a range of end-user groups, including representatives from the PICS society; Fraser Health’s South Asian Health Institute; Fraser Health Virtual Health; Fraser Health’s Equity, Diversity, and Inclusion team; and academic researchers from across Canada. Over the course of 12 months, the committee held 8 meetings, with an average attendance rate of 8 members (61% of the committee).

Early discussions focused on refining the research approach, with members advocating for culturally relevant interview questions within stage 3 and the inclusion of language support services to improve accessibility. As data collection progressed, committee members played a critical role in interpreting the findings, offering insights that contextualized patient experiences within the broader health care system.

Stage 2: Observing Service Delivery and Gathering Staff Experiences

As reported in the study by N Moghaddam, M Montenegro, and M MacPherson (unpublished data, 2025), 7 staff interviews (n=5, 71% physicians and n=2, 29% registered nurses and n=5, 71% women and n=2, 29% men) highlighted both opportunities (extended assessment time and stronger therapeutic relationships) and barriers (limited involvement in early development stages) in remote monitoring. These findings reinforced the importance of engaging clinicians in program design and informed subsequent co-design discussions in this project.

XSL•FO
RenderX

Stage 3: Gathering Patient Experiences and Creating a Short Film

As reported in the study by MacPherson [24], 20 interviews with South Asian community members identified as patients or caregivers explored attitudes, barriers and facilitators, and suggestions for enhancing awareness and improving virtual care services. While participants were generally open to virtual hospital-at-home models, they identified barriers related to trust, limited awareness, and challenges in access.

From these interviews, a 10-minute touchpoint film was created to highlight the key experiences and themes identified by participants. Of the 20 participants, 9 (45%) consented to inclusion (n=6, 67% women and n=3, 33% men; aged between 19 and 69 y), with 3 (15%) opting for audio-only contributions. Participants included patients (n=3, 33%), caregivers (n=2, 22%), and those who identified as both patients and caregivers (n=4, 44%). Video and audio clips were selected to represent the most salient themes identified in the interviews, such as building trust in virtual care, addressing language barriers, and ensuring equitable access. The film, produced by Fraser Health's Virtual Health department, served as a central EBCD tool to ground the subsequent co-design event in authentic patient and caregiver voices.

Stage 4: Co-Design Event

Overview

A total of 46 individuals were invited to participate in the co-design workshop, including interview participants from stage 3 who consented to be contacted, steering committee members, and clinicians. Participants with divergent views, including those who were initially skeptical of virtual care, were purposefully included in the co-design session to ensure a broad range of perspectives and stimulate rich discussion. Ultimately, 11 participants from stage 3 attended, alongside 6 steering committee members, a physician, 2 clinical nurse specialists, a learning consultant for Virtual Health, the manager for clinical operations for the VPU, and a coordinator for the South Asian Health Institute.

This workshop aimed to generate solutions to the problem areas identified during the interviews in stages 2 and 3, addressing the five key themes described here: (1) patient-centered and equitable care; (2) technology, innovation, and digital literacy; (3) training and education; (4) community engagement and outreach; and (5) process improvement and data use.

Patient-Centered and Equitable Care

While many participants appreciated the structure and direct interactions of hospital-based care, they emphasized the importance of ensuring that virtual hospital-at-home models provide the same level of time, reassurance, and guidance. However, ensuring equitable access to care requires addressing cultural and linguistic barriers, which go beyond interpretation and using plain language to include cultural nuance and understanding. For example, some South Asian families may not trust virtual care as "real" care, especially in serious conditions. They may believe that the patient is being dismissed too early or not taken seriously. Therefore, health care providers may need to explain the concept in culturally resonant terms—perhaps likening it to home visits from trusted family physicians in culturally familiar contexts. Community consultations and continuous feedback mechanisms were highlighted as essential to ensuring that health care services align with patient needs.

Participants suggested that health care models should incorporate family caregivers, including younger family members who may play a significant role in patient support. Furthermore, addressing technical concerns and ensuring that digital health care solutions are user-friendly with 2-way communication channels can alleviate patient anxiety, fostering a seamless integration of innovative care models.

Technology, Innovation, and Digital Literacy

Digital literacy emerged as a critical factor influencing virtual health care access and engagement. Participants acknowledged that while artificial intelligence and other digital technologies could enhance health care services, discomfort or unfamiliarity with new technology remained a significant barrier. Many patients expressed the need for hybrid digital literacy training that incorporates both online and in-person instruction, ensuring that those unfamiliar with technology can develop confidence in using digital health tools.

The use of body mapping tools with glossaries of translations, accessible via tablets or other digital devices, was suggested as a way to improve communication for patients experiencing language barriers. Participants also emphasized the need for a 24/7 patient support line to assist with technological issues, ensuring continuous access to health care services, particularly in case of an emergency while at home. Transparency in wait times and care escalation pathways, particularly through online queue systems or digital "call bells" (ie, digital notification systems for patients to request timely assistance remotely, similar to a call bell used in hospital), was seen as a potential strategy for improving patient trust and engagement in digital health care solutions.

Training and Education

Participants highlighted the need for enhanced training and education for both health care providers and patients. Digital resources, such as instructional videos, were identified as effective tools for increasing accessibility to health care information. Simulation-based learning was widely recommended, with participants advocating for hands-on training before patient discharge to ensure they understand their care plans and expectations. Training for health care providers should also emphasize virtual health competencies, equipping them with the skills necessary to navigate virtual care and digital platforms effectively, ultimately improving patient care.

Cultural competency training was another key recommendation, ensuring that health care providers can communicate effectively with diverse patient populations. To address health literacy challenges, participants suggested the use of multilingual training manuals with visual aids and simplified language to enhance patient comprehension. Participants also recommended updating patient training modules continuously based on current questions and concerns. Addition, structured patient education

XSL•FO
RenderX

that clarifies health care processes was seen as essential for helping patients navigate the complexities of the health care system, with a need for clear, step-by-step education, especially regarding the "entry points" of the health care system.

Community Engagement and Outreach

Participants underscored the importance of community-driven approaches to health care engagement and education. Meeting patients where they are, through initiatives such as community pop-ups, outreach in long-term care facilities, and targeted engagement in hospice settings, was identified as a key strategy for increasing health care accessibility. To build motivation to try virtual hospital-at-home models, participants recommended engaging in transparent discussions with patients as to why the virtual hospital-at-home model would be most suitable to their individual circumstances.

Peer learning was also seen as an effective method for knowledge transfer, particularly among older adults who may feel more comfortable learning from their peers. Social media and online communities were highlighted as valuable platforms for sharing health care experiences, testimonials, and educational content. Addition, participants suggested leveraging community champions and patient testimonials to promote new health care models and build trust in virtual health solutions. Media and promotional campaigns, particularly in South Asian media networks, were also recommended to increase public awareness and encourage informed decision-making about health care options.

Process Improvement and Data Use

Participants emphasized the role of research, data collection, and continuous feedback in improving health care processes. Both qualitative and quantitative data collection were seen as essential for refining care models and ensuring that they meet patient needs. Global information sharing was recommended as a way to integrate best practices from different health care systems. Participants also stressed the importance of transparency in care escalation processes, ensuring that patients understand when and how to seek additional support. Determining the appropriate fit between hospital-based and virtual care was seen as crucial for optimizing resource allocation and patient outcomes. Additionally, surveys and patient reviews were suggested as mechanisms for evaluating health care experiences and identifying areas for improvement. By bridging the gap between traditional and digital health care models, participants believed that the health care system could become more efficient, accessible, and responsive to patient concerns.

Stage 5: Post–Co-Design Analysis, Follow-Up, and Internal Uptake

Thematic analysis of workshop data resulted in a set of actionable recommendations, which were shared with the virtual hospital-at-home development team. Internal team discussions helped prioritize feasible ideas for implementation. While a formal evaluation was not conducted, follow-up meetings with the steering committee provided an opportunity to reflect on the success of the project and explore future applications of co-design. Members expressed appreciation for the participatory nature of the process, and the knowledge products were circulated for a broader impact. One participant shared that the co-design event was the first time they felt truly heard by the health care system, and it motivated them to explore a career in health care—a powerful testament to the impact of the process.

Discussion

Principal Findings

This study demonstrates the value of using an EBCD approach to inform the development of a patient-centered and equitable virtual hospital-at-home model within a large, culturally diverse regional health authority. By meaningfully engaging patients, caregivers, health care providers, and community organizations across 5 structured stages, the project not only surfaced critical insights into patient experiences but also helped shift traditional power dynamics by positioning patients and caregivers as partners in the design process. This participatory approach generated equity-focused recommendations that highlight how virtual hospital-at-home services can be more responsive to the needs of underserved communities.

Consistent with previous evidence showing that virtual hospital-at-home models improve outcomes and reduce hospital use [2], our findings confirm the promise of this care model. However, we also extend previous research by showing that successful and equitable implementation requires more than technology alone. Participants emphasized that access is contingent on culturally safe, linguistically appropriate, and caregiver-inclusive approaches. For example, as described in the stage 3 interviews, some South Asian families perceived virtual care as less legitimate than hospital-based services, underscoring the importance of culturally resonant communication strategies.

Digital literacy, caregiver inclusion, and culturally competent communication emerged as pivotal enablers of trust and adoption. Participants in the stage 4 co-design event proposed innovative solutions, such as hybrid training that combines online and in-person instruction, the use of body mapping with multilingual glossaries, and caregiver-centered education modules.

Similarly, digital literacy and caregiver involvement emerged as critical enablers of trust and engagement, reflecting themes raised in the stage 4 co-design workshop. Participants' proposals, such as hybrid digital literacy training, multilingual educational tools, and caregiver-centered education, illustrate how community-driven insights can translate into practical solutions. These grassroots innovations, surfaced through authentic engagement, demonstrate how EBCD operates not only as a design thinking framework but also as a platform for empowerment, amplifying voices that are often marginalized in top-down service planning.

At the same time, perspectives from clinicians and health system staff revealed important implementation challenges. As seen in stage 2 interviews, while health care providers valued the potential of virtual care (eg, extended assessment time and earlier intervention), many reported feeling excluded from initial

XSL•FO
RenderX

design processes, which limited their confidence in making referrals. This disconnect reflects a broader challenge in virtual health: aligning patient-centered priorities with operational realities. Previous research highlights that clinician engagement early in design processes is critical to ensuring that virtual care integrates seamlessly into workflows [28]. Our findings reinforce this point, suggesting that virtual hospital-at-home models cannot succeed without parallel attention to patient and health care provider perspectives.

Implications for Practice and Policy

This study highlights 5 practice and policy implications to support equitable virtual hospital-at-home implementation, grounded in our findings and supported by the existing literature.

Culturally Responsive Design

Virtual models must be co-developed with, not simply for, cultural communities. Tailored communication, education, and engagement strategies are necessary to build trust and legitimacy. This aligns with previous work emphasizing that digital health interventions must be culturally adapted to reduce health inequalities [29] and that co-design uncovers culturally resonant strategies that improve uptake [22].

Hybrid Digital Literacy Support

Bridging digital divides requires blended approaches that combine in-person training, peer-led instruction, and multilingual resources. As recommended by stage 4 participants, hybrid digital literacy models ensure that those unfamiliar with technology are supported while maintaining flexibility for more experienced users. Evidence suggests that such models enhance confidence and adoption among populations with limited previous exposure to digital tools [30,31].

Ongoing Feedback Loops

Embedding continuous feedback mechanisms (eg, community consultations, patient surveys, and user analytics) ensures that services remain responsive to evolving needs. This is consistent with evidence that iterative engagement strengthens program equity and sustainability [32].

System Integration and Escalation Clarity

Clear care pathways and escalation protocols are essential for patient safety and trust. In our study, participants requested transparent communication about when and how to escalate concerns, echoing previous research demonstrating that virtual hospital models can be sustainably embedded into broader care systems through shared “digital front doors,” referral pathways, and record sharing that support continuity of care [33].

Caregiver Inclusion

Caregivers were consistently identified as central to the success of virtual hospital-at-home models. Equipping caregivers with tools, training, and access to participate directly in care planning not only supports patients but also reduces barriers related to language and technology. Previous studies confirm that caregiver involvement, including proxy access to digital platforms, enhances access and equity for underserved groups [34-36].

Broader Policy Recommendations

Beyond these practice implications, broader policy action is needed. Standardizing culturally competent practices, investing in multilingual digital tools, and establishing mechanisms for community governance in digital health initiatives are critical next steps. As frameworks for patient-centered telemedicine suggest, community involvement and cultural adaptation must be embedded as core policy principles rather than optional add-ons [37].

Limitations

This study has several limitations. First, the interviews focused exclusively on South Asian communities. Although intentional, given the demographic composition of the Fraser Health region, future work should include additional cultural and linguistic groups to ensure broader applicability. Second, the co-design process produced recommendations but did not include a formal evaluation of their implementation or impact. Assessing the outcomes of these interventions will be essential for determining their sustainability and effectiveness. Finally, at the time of data collection, Fraser Health had only launched a single virtual hospital-at-home service, the VPU, and had not yet determined which other clinical populations would be prioritized for future expansion. Consequently, our findings do not speak of the implementation of a specific model beyond psychiatry. However, this early engagement with patients and caregivers was intentional; by eliciting perspectives before clinical parameters were finalized, the co-design process generated insights that can shape a more patient-centered and equitable foundation for service development across diverse populations.

Reflections and Challenges of Implementing EBCD in a Health System Context

Implementing EBCD in a large and complex health system context such as Fraser Health presented unique challenges and valuable learning opportunities. While the process effectively centered on patient voices and stimulated rich discussions, it also disrupted the status quo. Recruiting physician participants proved difficult, despite outreach efforts; only one physician (an acting Medical Information Officer) attended the co-design session. This highlights the tension between clinical demands and the time investment required for meaningful engagement in participatory design.

In addition, this project was not embedded within the core design cycle of the virtual hospital-at-home program, which limited the extent to which recommendations could be immediately integrated. Some suggestions generated during the workshop also fell outside the direct influence of the Fraser Health team, highlighting the need for stronger system-wide support for patient-driven ideas and cross-organizational collaboration.

Nevertheless, the project demonstrated the value of partnership with community organizations and the importance of cultural and linguistic accessibility in participatory research. Language accommodations during interviews improved accessibility, and the use of a video touchpoint film was particularly effective in centering patient stories and perspectives during the workshop. Divergent views, such as a participant strongly opposing virtual care, proved essential in challenging assumptions and

XSL•FO
RenderX

underscoring the diversity of opinions within the patient population. These perspectives enriched the discussion and ultimately strengthened the relevance of the proposed solutions.

A final lesson learned was that for many health system users, engaging in a process without a guaranteed "end product" (such as a finalized service design) was a leap of faith. Although the impact of the workshop was palpable, participants expressed feeling heard, empowered, and connected. For some, it was a transformative experience, reinforcing the need for participatory approaches in health service design that go beyond consultation to foster real collaboration.

Future Directions

Building on this foundational work, future efforts should prioritize piloting and evaluating co-designed interventions across diverse populations and clinical settings. There is also a need to explore how EBCD can be embedded as a routine part of virtual service development rather than used episodically. As technology continues to evolve, virtual care systems must be supported by ongoing, rather than one-time, engagement processes to remain equitable, culturally relevant, and trusted by the communities that they aim to serve.

Conclusions

This project illustrates how EBCD can serve as an empowering approach to guide the development of equitable and patient-centered virtual hospital-at-home services. By engaging patients, caregivers, health care providers, and community leaders throughout the co-design process, the project identified both barriers and actionable strategies for improving virtual care delivery. These findings underscore the importance of integrating cultural competence, digital literacy, caregiver inclusion, and systems-level coordination into virtual care models, particularly when serving diverse populations. As virtual hospital-at-home programs continue to expand, intentional and participatory approaches such as EBCD will be essential to ensuring that these innovations are not only effective but also inclusive, sustainable, and trusted by those they are designed to serve. To ensure that virtual care achieves its full promise, future initiatives must embed equity and patient partnership as core, not optional, design principles.

Acknowledgments

This work was supported by Health Research BC and the Health Research Foundation of Innovative Medicines Canada Team Grant in Virtual Care. The funders had no role in the study design, data collection, analysis, interpretation, writing of the manuscript, or the decision to submit the paper for publication. The authors sincerely thank the South Asian community members who participated in this study and shared their experiences, as well as the steering committee for their guidance and support throughout the project.

Abstract

Background: The rapid advancement of telehealth has led to the emergence of avatar-based psychotherapy (ABP), which combines the benefits of anonymity with nonverbal communication. With the adoption of remote mental health services, understanding the efficacy and user experience of ABP has become increasingly important.

Objective: This study aimed to explore the user experience and therapeutic relationship formation in short-term ABP environments, focusing on psychological effects, user satisfaction, and critical factors for implementation.

Methods: This qualitative study involved 18 adult participants (8 women and 10 men). Participants engaged in two short-term ABP sessions (approximately 50 minutes per session) over 2 weeks, using an ABP metaverse system prototype. Semistructured in-depth interviews were conducted with both the participants and therapists before and after the ABP sessions. The interviews were conducted via an online platform, with each interview lasting approximately 30 minutes. The key topics included the sense of intimacy, communication effectiveness of avatar expressions, emotions toward one's avatar, concentration during sessions, and perceived important aspects of the ABP. Data were analyzed using thematic analysis.

Results: The analysis revealed 3 main themes with 8 subthemes: (1) reduction of psychological barriers through avatar use (subthemes: anonymity, ease of access, self-objectification, and potential for self-disclosure); (2) importance of the avatar–self-connection in therapeutic relationship formation (subthemes: avatar self-relevance and avatar–self-connection fostering intimacy and trust); and (3) importance of nonverbal communication (subthemes: significance of nonverbal expressions and formation of empathy and trust through nonverbal expressions). Participants reported enhanced comfort and self-disclosure owing to the anonymity provided by avatars, while emphasizing the importance of avatar customization and the role of nonverbal cues in facilitating communication and building rapport.

Conclusions: This pilot study provides valuable insights into the short-term ABP user experience and therapeutic relationship formation. Our findings suggest that ABP has the potential to reduce barriers to therapy through anonymity, ease of access, and potential for self-disclosure, while allowing for meaningful nonverbal communication. The avatar–self-connection emerged as a crucial factor in the effectiveness of ABP, highlighting the importance of avatar customization in enhancing user engagement and therapeutic outcomes. Future research and development in ABP should focus on improving avatar customization options, enhancing the fidelity of nonverbal cues, and investigating the long-term effectiveness of ABP compared with traditional face-to-face therapy.

Introduction

Rapid advancements in information technology have led to significant developments in telehealth, particularly in addressing mental health issues, such as anxiety, depression, and stress-related disorders [1]. The COVID-19 pandemic has accelerated the transition from traditional face-to-face clinical services to telehealth solutions [2]. This shift has created new opportunities for individuals with difficulty accessing in-person psychotherapy owing to geographical constraints or personal reservations [3]. Avatar-based psychotherapy (ABP) has gained attention because of its unique ability to combine the benefits of anonymity and nonverbal communication. Recent research has demonstrated the potential effectiveness of metaverse-based counseling approaches compared to traditional in-person settings [4].

The therapeutic relationship between the client and psychotherapist is crucial for successful therapeutic outcomes. However, the dynamics of this relationship in ABP environments require further investigation [5]. Self-disclosure, a key element in relationship building, may be facilitated differently in ABP settings than in traditional face-to-face or video-based online therapy [6]. The concept of avatar–self-connection, which refers to the psychological link between users and their digital representations, may play a significant role in the effectiveness of ABP [7].

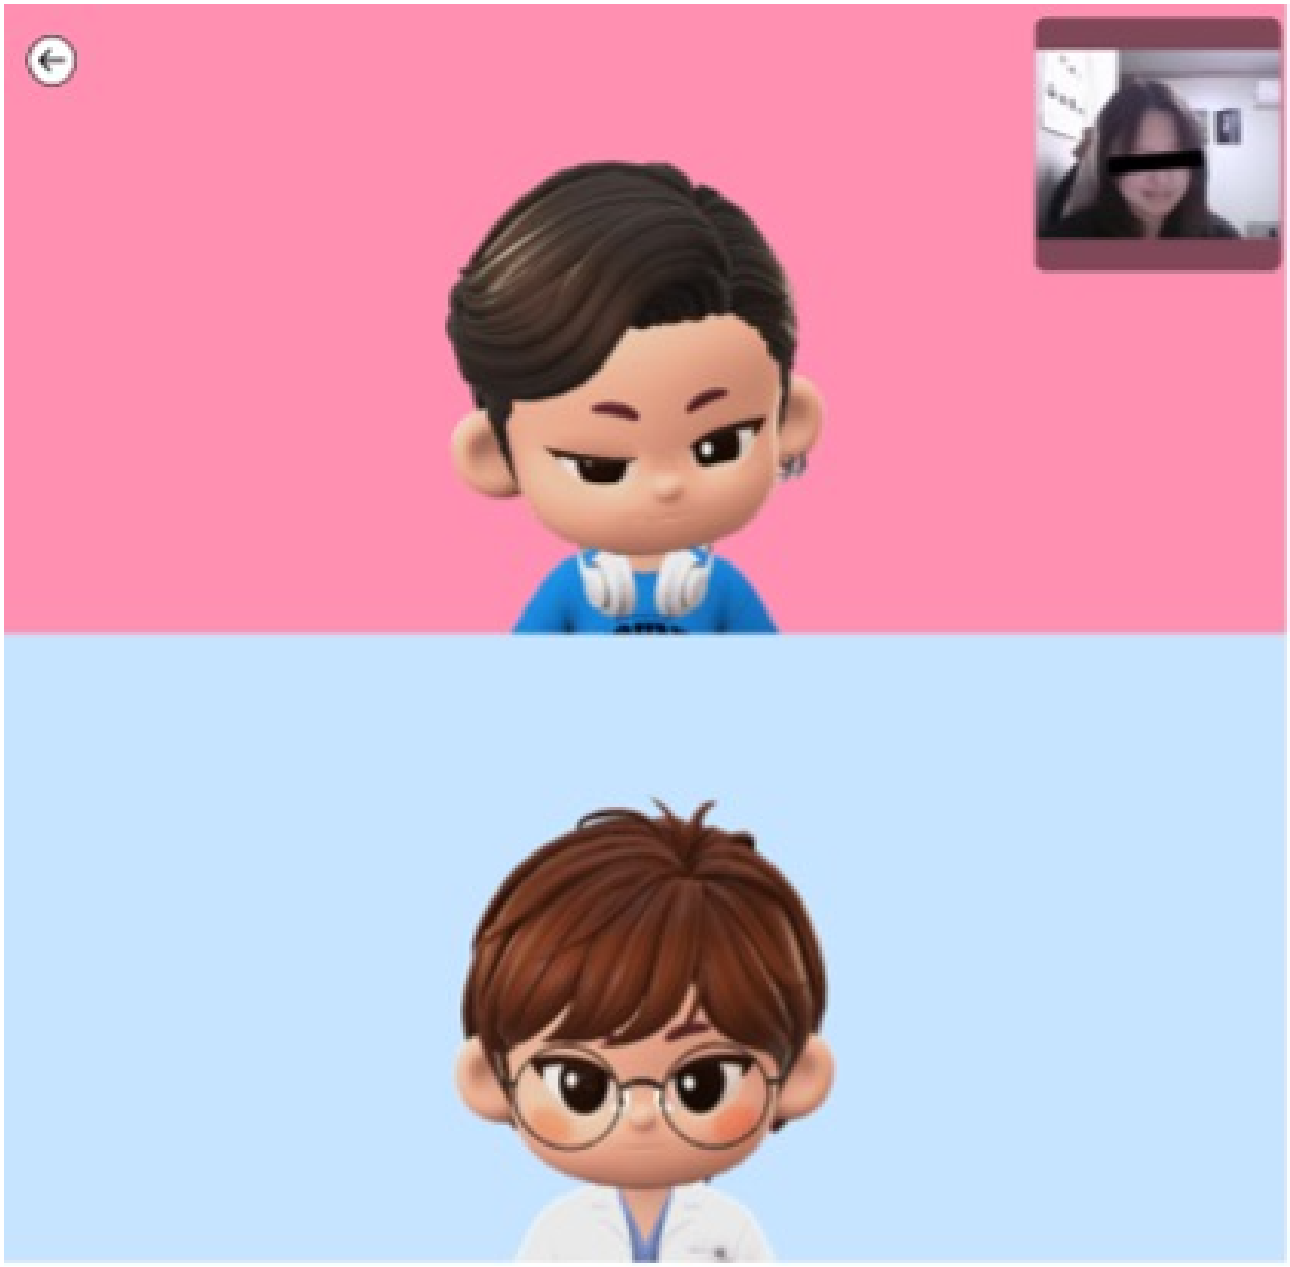
This study aimed to explore the user experience and therapeutic relationship formation in short-term ABP environments. Specifically, we sought to understand the psychological effects and satisfaction levels of users engaging in ABP and to identify critical factors to consider when implementing ABP systems.

Methods

Ethical Considerations

This study was conducted in accordance with the principles of the Declaration of Helsinki and approved by the Institutional Review Board of Korea University Anam Hospital (IRB No: 2023AN0504). All participants provided written informed consent before participation. Participants were informed that their participation was voluntary and that they could withdraw at any time without consequences. All interviews were audio-recorded with prior consent and subsequently transcribed for analysis. The data collected in this study were anonymized to ensure the privacy and confidentiality of all participants. This manuscript and its supplementary materials do not include any images or identifiable features of research participants.

Study Design and Data Collection



This study was designed as a short-term intervention pilot study to explore initial user experiences with ABP. The two-session format was chosen to capture immediate reactions and early therapeutic relationship formation in the ABP environment. We conducted a qualitative study to gain an in-depth understanding of user experiences in ABP sessions. Eligible participants were adults aged 19 - 70 years who self-reported their need for psychological health management and had no previous experience with avatar-based counseling. We excluded individuals with intellectual disabilities, organic brain damage, or those currently receiving psychiatric treatment for major mental disorders (including major mood disorders, anxiety disorders, and schizophrenia spectrum disorders). Additionally, participants were required to have access to and the ability to use smartphones or computers.

An avatar that reflected facial movements in real time was established using a metaverse system prototype (Figure 1). This system allowed participants to engage in psychotherapy sessions through avatars, enabling verbal and nonverbal communication. Eighteen adult participants (8 women) were initially recruited in Seoul, South Korea. The participants engaged in two ABP sessions (approximately 50 minutes per session) over 2 weeks.

Semistructured in-depth interviews were conducted with both the participants and psychotherapists before and after the ABP sessions. These interviews, each lasting 30 minutes, were conducted using the Zoom platform (Zoom Video Communications, Inc.). The key topics included the sense of intimacy and communication effectiveness of avatar expressions, emotions and feelings toward one's avatar, concentration during the session, and perceived important aspects of the ABP sessions.

XSL•FO
RenderX

Figure 1. The avatar-based psychotherapy metaverse system prototype. Top avatar: participant; bottom avatar: psychotherapist. The real face box at the top can be turned off; in a real psychotherapy session, the real face is turned off and is conducted with only the avatar.

Data Analysis

We employed thematic analysis to analyze the data, using ATLAS.ti software (Version 23; ATLAS.ti Scientific Software Development GmbH, Berlin, Germany) [8]. The analysis was conducted in 6 phases: familiarization with the data, generating initial codes, searching for themes, reviewing themes, defining and naming themes, and producing reports. Four researchers (JB, HL, JH, and CHC) participated in the initial familiarization phase and carefully reviewed the transcripts before individual coding. The 174 initial codes were systematically categorized through iterative analysis. Through team discussions, these codes were refined and consolidated into 3 main themes of psychological barriers (41 codes), avatar–self-connection (29 codes), and nonverbal communication (38 codes). The remaining codes were excluded as they did not directly address the research questions.

Results

The thematic analysis revealed 3 main themes with 8 subthemes, as shown in Table 1. The 174 initial codes were systematically categorized through iterative analysis. Through team discussions, these codes were refined and consolidated into 3 main themes of psychological barriers (41 codes), avatar–self-connection (29 codes), and nonverbal communication (38 codes). The remaining codes were excluded as they did not directly address the research questions.

Table . Thematic framework of user experiences and therapeutic relationship formation in avatar-based psychotherapy: main themes, subthemes, code counts, and representative codes.

Main themes	Subthemes	Code counts	Representative codes
Reduction of psychological barriers through avatar use	1.1 Anonymity	12	• Anonymity reduces social anxiety. • Sense of security through anonymity. • Honest communication enabled. • Anonymity prevents judgment. • Reduced fear of personal recognition.
	1.2 Ease of access	10	• Flexible scheduling. • No travel required. • Accessible from anywhere. • Easier therapy initiation. • Reduced logistical challenges.
	1.3 Self-objectification	8	• Detached view encourages self-reflection. • Avatar mirrors emotional state. • Enhances self-awareness. • Observing oneself via the avatar. • Identifies overlooked emotions.
	1.4 Potential for self-disclosure	11	• Easier to discuss sensitive topics. • Safe space for expression. • Encourages honest sharing. • Enables communication without barriers. • Reduces hesitation in disclosure.
Importance of avatar–self-connection	2.1 Avatar self-relevance	15	• Personalized avatars foster comfort. • Realism enhances connection. • Reflects personal identity. • Improves immersion. • Mirrors user's traits effectively.
	2.2 Fostering intimacy and trust	14	• Facilitates faster rapport. • Acts as a conversational bridge. • Builds therapeutic trust. • Supports meaningful dialogue. • Encourages emotional openness.

XSL•FO
RenderX

Main themes	Subthemes	Code counts	Representative codes
Importance of nonverbal communication	3.1 Significance of nonverbal expressions	20	• Gestures enhance communication. • Nonverbal cues reduce misunderstandings. • Expressive avatars improve immersion. • Adds emotional depth. • Reinforces communication effectiveness.
	3.2 Empathy and trust formation	18	• Mirrors emotions effectively. • Conveys empathy through gestures. • Builds trust via nonverbal cues. • Enhances emotional understanding. • Reduces virtual communication gaps.

Theme 1: Reduction of Psychological Barriers Through Avatar Use

Theme 1, the reduction of psychological barriers through avatar use, emerged as the most prominent theme with 41 codes. These codes were distributed across 4 subthemes: anonymity (12 codes), ease of access (10 codes), self-objectification (8 codes), and potential for self-disclosure (11 codes). Participants reported that the use of avatars in psychotherapy sessions helped lower psychological barriers primarily through 3 mechanisms.

Subtheme 1.1: Anonymity

The anonymity provided by avatars was frequently mentioned as a key factor in facilitating open and honest communication. One participant noted, “Knowing that the therapist does not know my real face gives me a sense of security. Even if we met in real life, they would not recognize me, which is reassuring in a way.”

Subtheme 1.2: Ease of Access

The convenience of accessing ABP services through a metaverse platform was highlighted as a significant advantage. One participant stated, “The fact that psychotherapy sessions can be done from anywhere makes it more accessible and easier to form a rapport. I think anonymous ABP is more effective in this regard.”

Subtheme 1.3: Self-Objectification

Avatars facilitated self-objectification, allowing participants to view themselves from a detached perspective. One participant observed, “When I occasionally looked at my avatar, I noticed that I was not smiling much. It made me think, ‘I look a bit pitiful.’ This showed me how I appeared.”

Subtheme 1.4: Potential for Self-Disclosure

Avatars facilitated self-disclosure. One participant noted, “For people who want psychotherapy without revealing themselves too much, expressing themselves through an avatar in the metaverse can make it easier to talk honestly with the therapist.”

Theme 2: Importance of Avatar–Self-Connection in Therapeutic Relationship Formation

The importance of avatar–self-connection in therapeutic relationship formation emerged as the second major theme, comprising 29 codes. These were distributed between 2 key subthemes: avatar self-relevance (15 codes) and avatar–self-connection fostering intimacy and trust (14 codes). The results showed that the degree of connection between users and their avatar played a crucial role in the therapeutic relationship formation within the ABP environment.

Subtheme 2.1: Avatar Self-Relevance

Participants expressed a desire for their avatars to reflect aspects of their real selves. One participant noted, “If I could customize the avatar more to my liking and feel that it truly represents me, I think I would feel more completely connected to it.”

Subtheme 2.2: Avatar–Self-Connection Fostering Intimacy and Trust

A strong avatar–self-connection enhanced the sense of intimacy and trust in the therapeutic relationship. One participant shared, “When I felt that this avatar was really me, I could immerse myself more deeply in the session and form a stronger therapeutic relationship with the therapist.”

Theme 3: Importance of Nonverbal Communication

The importance of nonverbal communication emerged as a significant theme with 38 codes, distributed across 2 subthemes: significance of nonverbal expressions (20 codes) and formation of empathy and trust through nonverbal expressions (18 codes). The thematic analysis highlighted the significant role of nonverbal communication in ABP, emphasizing its impact on self-expression, empathy, and trust-building.

Subtheme 3.1: Significance of Nonverbal Expressions

The participants emphasized the importance of nonverbal cues in enhancing communication. One participant stated, “If the avatar could show hand gestures or body language, I think it would be even better. These physical movements can have psychological significance.”

XSL•FO
RenderX

Subtheme 3.2: Formation of Empathy and Trust Through Nonverbal Expressions

Nonverbal communication through avatars enhanced empathy and trust in the therapeutic relationship. One participant shared, "I think the avatar helped by expressing my gestures and expressions to some extent. This somewhat overcomes communication errors that can occur when we are not face-to-face."

Discussion

Study Findings and Comparison With Previous Findings

This study provides critical insights into ABP, highlighting 3 interconnected dimensions: psychological barrier reduction, avatar–self-connection, and the role of nonverbal communication in metaverse therapeutic systems.

The anonymity, accessibility, and potential for self-disclosure provided by avatars create a unique therapeutic environment that lowers the resistance to mental health engagement, consistent with previous research on online self-disclosure [5]. A novel finding of this study was the self-objectification through avatar use, suggesting a potential mechanism for enhanced self-awareness that resonates with self-distancing theories in psychology [9]. This indicates that ABP may offer a natural pathway for adaptive self-reflection, a key component in many therapeutic approaches.

The self-objectification observed in this study demonstrates an interesting contrast with findings from video conferencing research, which found that viewing one's actual image during video conferences can lead to greater cognitive burden and negative psychological effects, particularly for individuals with high public self-consciousness [10]. However, our findings suggest that avatar-mediated self-observation may offer distinct advantages. Unlike video conferencing where users see their actual image, avatar representation creates a beneficial psychological distance that facilitates more objective self-reflection while maintaining emotional engagement. This unique characteristic of avatar-mediated interaction may explain why participants in our study reported enhanced self-awareness without the negative psychological impacts often associated with direct self-viewing in video conferences. The avatar-mediated environment provides a unique balance between self-awareness and psychological comfort, potentially making it particularly suitable for therapeutic contexts where self-reflection is crucial but emotional safety needs to be maintained.

Furthermore, the avatar–self-connection played a crucial role in the therapeutic relationship formation, extending previous work on avatar realism [7]. Our findings directly linked this connection to the quality of the therapeutic relationship, underscoring the potential significance of avatar customization in fostering engagement and improving outcomes. The avatar may serve as a bridge between the client's inner world and the therapeutic space, facilitating deeper exploration of personal narratives.

Our observations of nonverbal communication in ABP expand on previous research, highlighting how even limited nonverbal cues can significantly impact the therapeutic process [11]. This adaptability suggests that ABP taps into fundamental aspects of human communication, offering a rich alternative to traditional face-to-face therapy.

The interplay among these elements in ABP creates a unique therapeutic ecosystem that balances self-disclosure and self-protection. As we continue to explore the potential of ABP, it is crucial to consider its place within the broader context of mental health care. ABP can be viewed as a complementary tool that can lead to more comprehensive and accessible care, potentially reaching individuals who might otherwise not receive treatment [12,13].

Strengths and Limitations

The findings of this study have several implications for clinical practice. First, ABP may be particularly beneficial for clients hesitant to engage in traditional face-to-face therapy because of social anxiety, stigma, or geographical limitations [14]. The anonymity and ease of access provided by ABP could serve as a stepping stone for these individuals to transition to other forms of therapy, if needed. Second, clinicians using ABP should be aware of the importance of the avatar–self-connection and consider ways to enhance this connection during therapy sessions. This might involve discussing the client's choice of avatar and exploring how it relates to their self-perception or therapeutic goals. However, although ABP offers many advantages, clinicians must be aware of its limitations. The reduced nonverbal cues in ABP compared with face-to-face therapy require clinicians to develop new skills in reading and interpreting client expressions and emotions through avatars.

Conclusion

These findings not only contribute to the growing body of knowledge on telehealth interventions, but also prompt us to reconsider the nature of the therapeutic relationship in the digital age. As technology continues to reshape our modes of interaction, ABP stands at the forefront of a new paradigm in mental health care that harnesses the power of the virtual world to foster real-world healing and growth.

Authors' Contributions

JH and CHC are cocorresponding authors and are responsible for the data and materials, manuscript submission, peer review, publication process, authorship details, and ethics committee approval. EKK, JH, and CHC conceived and designed the study. JB, CY, HL, JH, and CHC performed data analyses. JB, CY, HL, JH, and CHC wrote the first draft of the manuscript. JB, HL, EKK, JH, and CHC participated in data collection. All authors edited all versions of the manuscript. All authors were involved in interpreting the results and have read, commented on, and approved the final version of the manuscript.

Conflicts of Interest

EKK is a member of Kakao Healthcare, the company that developed the avatar-based psychotherapy metaverse system prototype used in this study. The other authors declare no conflicts of interest.

Abstract

Background: Digital health innovations provide an opportunity to improve access to care, information, and quality of care during the perinatal period, a critical period of health for mothers and infants. However, research to develop perinatal digital health solutions needs to be informed by actual patient and health system needs in order to optimize implementation, adoption, and sustainability.

Objective: Our aim was to co-design a research agenda with defined research priorities that reflected health system realities and patient needs.

Methods: Co-design of the research agenda involved a series of activities: (1) review of the provincial Digital Health Strategy and Maternity Services Strategy to identify relevant health system priorities, (2) anonymous survey targeting perinatal care providers to ascertain their current use and perceived need for digital tools, (3) engagement meetings using human-centered design methods with multilingual patients who are currently or recently pregnant to understand their health experiences and needs, and (4) a workshop that brought together patients and other project partners to prioritize identified challenges and opportunities for perinatal digital health in a set of research questions. These questions were grouped into themes using a deductive analysis approach starting with current BC Digital Health Strategy guiding principles.

Results: Between September 15, 2022, and August 31, 2023, we engaged with more than 150 perinatal health care providers, researchers, and health system stakeholders and a patient advisory group of women who were recently pregnant to understand the perceived needs and priorities for digital innovation in perinatal care in British Columbia, Canada. As a combined group, partners were able to define 12 priority research questions in 3 themes. The themes prioritized are digital innovation for (1) patient

XSL•FO
RenderX

autonomy and support, (2) standardized educational resources for patients and providers, and (3) improved access to health information.

Conclusions: Our research agenda highlights the needs for perinatal digital health research to support improvements in the quality of care in British Columbia. By using a human-centered design approach, we were able to co-design research priorities that are meaningful to patients and health system stakeholders. The identified priority research questions are merely a stepping stone in the research process and now need to be actioned by research teams and health systems partners.

Introduction

The digital health sector continues to expand after being an integral part of health care delivery during the COVID-19 pandemic, resulting in a growing interest in digital health research and innovation. Digital health provides an opportunity to reduce health disparities by addressing barriers and facilitators to health care access and improving the health and lifestyle of those who use it [1]. Digital innovation is also essential to offering value-based health care, which involves changes in health systems that are measured by improvement in patient outcomes per unit health care expenditure [2]. Core to achieving improvements in value-based care is establishing an understanding of what value is based on identifying outcomes that matter to patients themselves.

Human-centered design (HCD) is an approach to problem-solving that can be used to increase value in health care by focusing on problems and outcomes of interest to patients. HCD also has a role in improving health equity [3,4]. Core characteristics of an HCD approach include an iterative process of empathy and discovery to identify the core problem and then systematic brainstorming of solutions where the human experiencing the problem plays a central role [5]. The HCD approach goes beyond simply working with the end user to focus on their interaction with the technology and considers the broader social context in which the technology is used and other partners who may indirectly be impacted by the use of the technology [4,5]. The result of working in partnership with people under these assumptions using the HCD approach is meant to be a product or service that meets real human needs and reflects their values. This approach has been used to solve complex health care challenges, such as improving pediatric patient experience in acute care [6] and increasing adherence to self-care practices for chronic conditions [7,8]. In a perinatal health setting, these methods have been used to develop digital interventions for gestational diabetes [9].

The perinatal period encompasses a person's experiences from conception to the first year after delivery including pregnancies that end in miscarriage or stillbirths. The majority of patients receiving perinatal care in British Columbia has access to a mobile device and the internet and are increasingly looking to digital technologies to inform and support their care [10,11]. Using digital technology in health care can improve the quality of care and health outcomes for patients and infants during this early stage of life. The use of digital health tools in perinatal care has already been shown to result in lower and healthier gestational weight, lower smoking rates, increased physical activity, and lower rates of maternal and infant morbidity (eg, fewer preterm births, gestational diabetes, and pre-eclampsia), leading to fewer planned and unplanned visits to health care facilities [1,12-14]. Digital health has also been demonstrated to reduce the practitioners' workload as well as relieve some of the resource strains on an overburdened system [15]. Due to the vast potentiality of digital health and opportunities for further innovation, it is important to engage with patients who have received perinatal care and care providers as end users to identify emerging priorities for future innovations and research that are informed by actual needs [16]. By identifying and responding to real patient and care provider needs, we can optimize the implementation, adoption, and sustainability of perinatal digital health solutions, create value, and ensure existing health inequities are not exacerbated [16,17].

In this paper, we report on the Research Agenda for Perinatal Innovation and Digital Health (RAPID) project [18], which was led by the BC Children's Hospital Research Institute and Women's Health Research Institute in partnership with the Provincial Health Services Authority (PHSA) and Perinatal Services BC (PSBC) with the aim of codeveloping research priorities with patients and care providers.

Methods

Ethical Considerations

This project was run as a knowledge translation initiative, and no research ethics board approval was required. The engagement activities conducted with partners were classified as quality improvement activities rather than systematic investigations to advance knowledge. Based on these distinctions, our institutional research ethics board determined that the project falls outside of the scope of research subject to ethics review, and a waiver was granted. All workshop and survey participants consented to the anonymous collection of their opinions. Members of our patient advisory committee were compensated hourly according to local standards to reflect their equal standing to research team members within the project.

Project Design and Setting

The patient and health system partners with whom we worked were partners in the research priority setting through co-design and were compensated for their time. All final workshop

XSL•FO
RenderX

participants provided consent to the collection of their opinions and views during the workshop and through the follow-up survey.

The objectives of the RAPID project were to facilitate activities that bring key partners and existing knowledge together to (1) identify gaps in the perinatal continuum of care that can be addressed with digital innovation to improve patient and family health and (2) define current barriers to optimal adoption of digital health interventions for perinatal health care from the patient and health system perspectives. This knowledge was then used to define research priorities and codevelop research questions to motivate digital innovation informed by care needs and addressing barriers.

Recruitment of Partners and Governance

Following guidance outlined by Concannon et al [19], we developed an engagement plan for our activities that describes an analysis of which partner groups should be involved, their roles and modes of participation, and sampling strategies (ie, snowball sampling). Partners to include in engagement activities were grouped as (1) people with lived experience of perinatal care who were pregnant or recently delivered a baby; (2) perinatal health care providers including nurses, midwives, physicians, and other allied health; and (3) health care decision makers who are involved with the design or delivery of perinatal health care in British Columbia.

This project was governed by two primary groups: (1) a steering committee and (2) a patient advisory committee (PAC). Using snowball sampling, starting with a core group of experts at BC Children Hospital Research Institute and Women's Health Research Institute, we identified key partners with expertise in research, innovation, and implementation processes related to perinatal, maternal, or digital health services to form the steering committee. The core group was involved from the initiation of the project including during the development of the funding proposal. This core group included 4 health system decision makers as research users and 4 researchers. Additional partners identified for the steering committee included 2 clinical care providers and 2 additional researchers. The final steering committee included 5 researchers, 3 health care providers, and 4 health system decision makers. The purpose of the steering committee was to oversee project objectives and align efforts to each of their organizations' known digital health priorities and ongoing work.

Patient partners for the advisory committee were recruited through social media and the local hospital patient engagement office. The criteria for participation were (1) multilingual and (2) pregnant or a caregiver of a child younger than 2 years of age. There were 15 respondents to the recruitment advertisements, 9 of whom responded to our invitation to complete a 15-minute informal interview so we could learn more about their background, and they could also learn more about our project. After the interviews, the steering committee was able to select 4 participants who were willing and able to commit the time required by the project and who had diverse perinatal experiences (based on type of care provider and mode of delivery), geographic location in British Columbia, and backgrounds (language spoken and profession). The PAC met separately with only 4 members of the study team and steering committee during the initial activities of the project. This was done to create a safe space that would limit the impact of known health system hierarchies and preserve the authentic patient voice in the identification of perinatal health system pain points and the development of initial insights related to these pain points [20]. Once initial insights were defined with the patient advisors, all partners were brought together in a final workshop to collaborate and build consensus on research priorities as described in more detail below.

Engagement Activities

A series of engagement activities with each distinct group of partners was completed before a final workshop that brought all partners and results together to reach a consensus on final research priorities.

Perinatal Care providers

Perinatal care providers across British Columbia including physicians, midwives, nurses, and allied health were invited to share, rate, and explore their thoughts on digital perinatal health using a ThoughtExchange (version 6.4; Fulcrum Management Solutions Ltd). ThoughtExchange is a web-based survey tool that allows participants to share their thoughts in response to a prompt, which can be anonymously viewed and ranked by other participants. The platform then creates weighted rankings of the thoughts on the prompted topic to show participant priorities. The care providers were asked to respond to the following prompt: "What digital health tools are most valuable to your delivery of perinatal health care currently, and what do you think are the greatest areas of opportunity for digital innovation going forward?" The survey was promoted through all British Columbia health authority internal staff newsletters and through member email lists at Doctors of BC; Family Doctors of BC; and University of British Columbia Faculty of Medicine alumni, School of Midwifery, Departments of Obstetrics and Gynaecology, Pediatrics and Family Medicine. Three rounds of promotion were completed. Once the advertised deadline passed, the highest-ranked thoughts were reviewed by 2 research members of the steering committee (BAP and SXC), and key messages were developed through an inductive approach. Basic descriptive statistics were used to analyze the ranking of thoughts.

Health System Partners

Steering committee members from the British Columbia Ministry of Health (MoH), the PHSA, and the PSBC were each asked to review their organizations' recently published reports outlining their strategies for addressing current gaps in health. The reports reviewed were the BC Digital Health Strategy (BCDHS) [21] and the PSBC Maternity Services Strategy (MSS). Access to the MSS was provided through confidential personal communication with PSBC Director Robert Finch. These reports were presented at a steering committee meeting within the first 3 months of the project to identify priorities and alignments specific to perinatal digital health within these documents. The steering committee members from each organization outlined ongoing digital innovation projects in perinatal care and priorities specific to digital health solutions

XSL•FO
RenderX

for improving perinatal care. Each report, postpresentation, was summarized in lay terms to highlight priorities. These summaries were reviewed and edited by the health system partners to ensure that summaries were comprehensive, not leaving out key information.

Patients

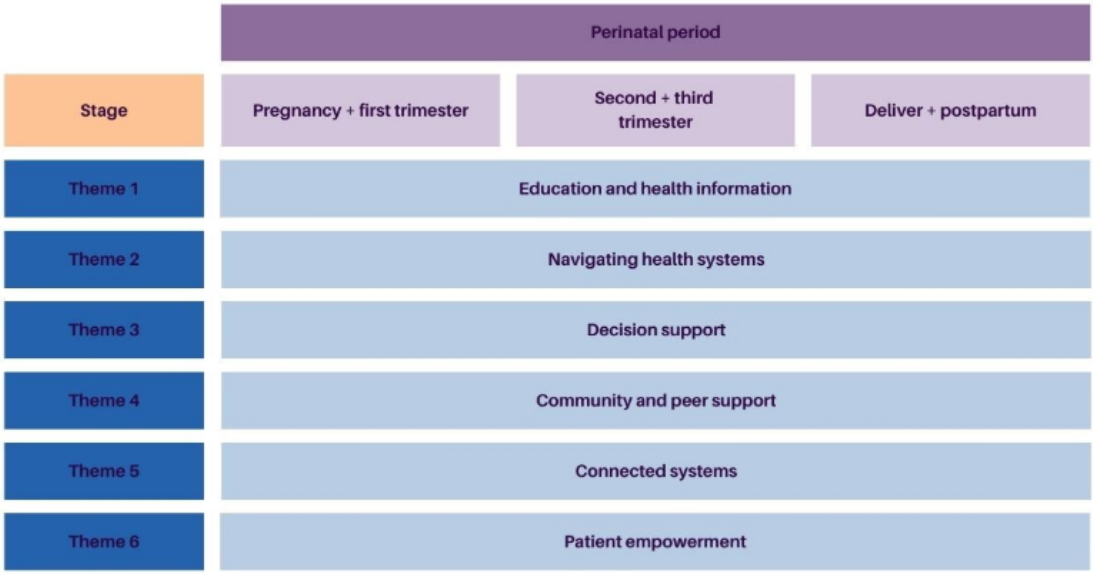
A series of four 90-minute PAC meetings were held and recorded over Zoom (Zoom Video Communications). They served to ascertain current digital health use and perceived need for new innovation as well as to inform workshop development from a patient perspective. The meetings included a series of HCD and user-experience research activities, participatory discussions, and postmeeting homework that typically took an hour to complete. The first meeting served as an introduction to all members; the following 2 meetings were developed to allow patients to share their experiences and understand how they interact with the health care system in order to identify gaps, common touchpoints with health care systems and services, and needs (Table 1). For the final meeting, the PAC was provided the lay summaries from the engagement with other partners prior to the meeting. They were asked to review these and share their reflections during the meeting. In addition, they were asked to develop insight statements that identify a need or gap. All meetings were facilitated by the core research team consisting of BAP, SXC, HA, and MV, who were also steering committee members. Activities were carried out on Miro (version 2.0; Miro), a web-based collaborative workspace. Meeting notes were collected and circulated to all participants for review and input. After each meeting, study team members also recorded reflective notes.

Table 1. Patient engagement meeting plan.

Session number	Objective	Presession activity	Activities
1	Establish an environment where patients feel safe and comfortable sharing their experiences	• N/A[a]	• Ice breaker • Introduction to digital health • Empathy mapping activity
2	Gather patients' perspectives and experiences in the health system during pregnancy and after birth	• Complete an empathy map [22] and a 30-minute reflection on their experiences in perinatal care	• Share empathy map and experiences • Introduce user journey activity
3	Identify health system touchpoints and potential areas with opportunities for improvement	• Complete a user journey [23] • Reflect on fellow participants' empathy maps and reflections	• Open discussion regarding user journey and experiences • Introduce insightful statements
4	Prepare for workshops with patients	• Review summary of ThoughtExchange and health systems' report summaries • Insightful statements worksheet [24]	• Comment on summary results • Go over insightful statements • Plan workshop

[a]N/A: not applicable.

Final Consensus Workshop and Analysis



A final 90-minute workshop was held to bring together all the partners and interested parties to share and align on challenges and priorities collected from earlier engagement sessions. This workshop was composed of both existing members of each partner group: patients, clinical care providers, researchers and health system decision makers as well as additional participants recruited through snowball sampling.

In preparation for the workshop, the core study team (BAP, SXC, HA, and MV) reviewed insight statements from the patients, and using a combination of deductive (using the guiding principles of the BCDHS as a starting point) and inductive analysis, placed these into overarching and emerging themes and then further grouped statements based on relevance to a stage of the perinatal period as described in Figure 1. This grouping was done to make the review and brainstorming session more feasible to complete within our limited 90-minute time frame. Research representatives from the steering committee, BAP and MV, developed 2 example research questions for each thematic area to prime the workshop discussion. These questions were developed to prompt discussion during the workshop, considering many participants do not have a background in research.

Attendees were divided into the 3 perinatal stage–based groups based on their expertise. For example, an attendee who is a neonatologist was assigned to the delivery+postpartum group. Each group contained at least 1 member from each of the partner types in order to facilitate collaboration across groups and consensus building. Each group was asked to reflect on and revise the provided insight statements and example research questions as well as develop their own research questions in order to identify research priorities based on their knowledge and experience. At the end of the session, each group was asked to identify 3-5 priority research questions from their brainstorming exercise. Each group then presented their priority research questions to the full workshop, and collectively, all attendees further discussed and ranked the research questions in order of priority.

XSL•FO
RenderX

Figure 1. Workshop groups and themes.

After the workshop, the research team reviewed meeting recordings, notes, and research question rankings to finalize a list of priority research questions that reflected workshop consensus. These research questions were then reviewed a final time by the PAC to ensure patient needs were at the forefront. This final list of research questions was converted and deployed as a REDCap (Research Electronic Data Capture; Vanderbilt University) survey to all workshop attendees. Respondents were asked to select 3 research questions they believed to be of the highest priority for perinatal care. Survey rankings were summarized descriptively to identify priorities from within the defined research questions.

Results

Engagement activities occurred between September 15, 2022, and August 31, 2023. The steering committee met monthly during this time to review progress and plan adjustments to the strategy, as new knowledge was developed.

Thought Exchange With Clinical Care Providers

A total of 125 perinatal health care provider participants responded, 102 of whom shared what provincial health authority they were affiliated with. British Columbia is split by geographic regions into 5 regional health authorities with an additional province-wide authority focused on Indigenous health and the PHSA that provides oversight for all regions. Most participants came from PHSA (n=25, 24.5%), Fraser Health (n=19, 18.6%), Vancouver Coastal Health (n=16, 15.7%), or Island Health (n=16, 15.7%). There were no participants from the First Nations Health Authority, and 7 participants did not affiliate with any of British Columbia's 7 health authorities.

Of the 125 participants, 55 responded with 80 different thoughts; 51 participants rated the thoughts of their colleagues, resulting in a total of 1108 ratings. Analysis of the thoughts based on the built-in functions of the ThoughtExchange platform identified the highest-ranked themes, which were grouped and summarized. Five key takeaways were identified under the themes of health education and connected systems from the ThoughtExchange:

1. There is an urgent need to create more inclusive, responsive, and accessible digital health tools. The end user (patient or health care provider) must be involved in the design of these tools to make sure that they are useful and can solve the right problems.
2. Among all current digital health tools shared, "Zoom," which is a tool that allows videos and remote health visits, and the "Hyperbilirubinemia risk assessment tool," which is a way for doctors to check if a baby is at risk of developing a condition where their skin and eyes turn yellow, are the highest ranked. "Up to Date," a web-based platform that keeps clinicians up-to-date with the latest medical research and guidelines (the United States only), was mentioned but ranked lower. A tool like "Up to Date" that provides the latest guidelines specific to Canada was identified as a current need to support high-quality care.
3. Important clinical areas that were identified as being priority topics for digital innovation were postpartum lactation support and mental health services. There is a demand for innovation in these areas to be accessible to individuals residing in rural regions.
4. A 2-way communication system is needed to support sharing health information across the province and between patients and providers; this means patients should have equal access to their electronic medical records as their health care providers. Patients should also be able to freely share their information between various levels of health care units at their own discretion.
5. Provincially standardized, free, evidence-based, and user-friendly prenatal patient education was identified as a need that could be solved with digital innovation. Accessible prenatal education would support high-quality perinatal care for all patients in British Columbia.

XSL•FO
RenderX

Health System Partner Engagement

A review of the MoH and PSBC digital health reports and strategies with health system partners in the steering committee meetings identified opportunities where perinatal innovation could be used to improve the quality of the health care system in British Columbia.

The MoH report, BCDHS, identified the following gaps in care across British Columbia: lack of coordination between health care services, poor communication systems, and inadequate follow-up. Therefore, their digital health priorities include (1) empowering patients through participation in their health journey (eg, inclusive, trusted, and equitable health content provided digitally), (2) increasing the capacity for providers to deliver high-quality care (eg, improving digital literacy and promoting the use of digital tools), (3) establishing a connected health system that allows for the sharing of data (eg, interoperability across health authorities and provider level and collaborating on clinical solutions), and (4) infrastructure and business processes streamlined for efficiency (eg, modernizing British Columbia's health supply chain, data flow, asset tracking, and analytics). To accommodate these strategies and goals, PSBC is working on developing a digital platform that acts as a central place for patient information. Based on the identified gaps, strategies, and needed tools, three potential areas for research were identified: (1) What is the best way to use telecommunication and information technologies to provide health care services during pregnancy and childbirth remotely? (2) What is the best design and implementation strategy to enable a shared electronic antenatal health record that can be accessed by any health care provider and patient during pregnancy? (3) Can we validate the use of wearable devices that can track and monitor health data during pregnancy and childbirth (ie, remote blood pressure for hypertension in pregnancy and blood glucose monitoring for gestational diabetes)?

PSBC's MSS report focuses particularly on addressing modifiable factors such as maternal weight and nutrition, substance use, mental health, diabetes, infant sleep, and breastfeeding. They currently have a series of projects in progress, and those specific to digital health solutions include a personalizable information and tool resource hub for providers and patients, a single source of data that can be shared across multiple systems, leveraging access to clinical data for quality improvement, allowing for enhanced digital training opportunities, increasing access to telemedicine care, and updated screening protocols and quality control. Based on these approaches five areas for future research were identified: (1) With the implementation of new technologies, what gaps and biases arise that impact their inclusivity and equity? (2) Although we can assess the immediate and short-term benefits of these technologies, how do we assess their long-term impact on maternal and child health? (3) How do we improve interoperability between different digital platforms to enable seamless data sharing and communication? (4) What policies would need to be put in place to ensure that patient data and privacy are protected? How would this integrate patient consent? (5) How do we understand the needs of the user (patients and health care service providers) and design resources that are user-centered? How do we ensure that users will engage with these resources?

Patient Engagement Sessions

The 4 members of the PAC varied in languages spoken (1 Mandarin, 1 Cantonese, 1 Spanish, and 1 Arabic), age of their children (1 still pregnant at the start of the project, 1 younger than 6 months, and 2 between 6 months and 1 year), mode of delivery (2 vaginal birth and 2 cesarean section), and location of their birth experience (2 Vancouver Coastal Health, 1 Fraser Health, and 1 Interior Health). Over the course of our 4 group meetings, we completed empathy maps, user journeys (Multimedia Appendix 1), and insight statements and collected reflective notes and recordings of live discussions. Common challenges were experienced among all patient partners navigating the perinatal period. For example, all patient partners described difficulties in understanding the different types of perinatal care providers and how to find an available midwife or doctor in their region. They all also spoke of challenges in navigating the transition from pregnancy to early newborn care, particularly when they had nonurgent concerns about their new baby because many available health care resources focus on urgent and emergency conditions.

In the final PAC meeting, we reflected on the summaries of the ThoughtExchange, MSS report, and BCDHS to identify recurring themes, priorities, and gaps that were also expressed by patients, which were then presented in a master list of insight statements (Textbox 1). These insights were divided into 6 themes: education or health information, navigating health systems, decision support, community or peer support, connected systems, and patient empowerment. Overall, over the 4 meetings, patients clearly expressed that they wanted digital innovation that would support their confidence and ability to navigate the health system in all regions of the province of British Columbia where health care is currently distributed and often fragmented. This should come in the form of free and accessible educational resources and tools to navigate the perinatal health journey. All patient partners discussed how stressful it is to navigate the current system and the frustration of having to communicate their health information to different care providers repeatedly. Almost all of our patient partners moved during the course of their pregnancy and experienced challenges finding maternity care providers both initially and after they moved. Another universal experience was the challenge presented by our current system, which does not allow for the pairing of the mother's and infant's health records. This often resulted in logistical challenges in navigating postpartum and postnatal follow-up that were borne entirely by the new parents. As a result of the success of these sessions, the research team worked with the PAC to develop a toolkit for patient engagement that was made available for use by other research teams (Multimedia Appendix 2).

Textbox 1. Final list of insight statements.

Reliable health information is needed

- Patients who are accessing perinatal care are overwhelmed by navigating an abundance of resources, and they are not sure which ones are accurate to follow.
- When seeking health-related information on the internet, information is often conflicting or misleading.
- When seeking health information on the internet, information is only in English and can be difficult to understand or communicate to multilingual family members.
- Health information provided is in technical terms that patients are unfamiliar with leaving patients confused.
- Patients often rely on informal peer support, which adds to the conflicting information they receive, leaving them more confused and unsure of what information to trust.
- Due to the abundance of information available on the internet, patients feel like they are wasting or spending too much of their time filtering through the information.
- Patients indicated that it is challenging to understand the difference between an obstetrician and a midwife especially for newcomers or immigrants from a different health care system; they do not know how to choose the right professional for them.

Lack of supports

- Due to the duration between pregnancy and a patient's first obstetrician gynecologist appointment being too long, patients are left with the responsibility of seeking information independently.
- There are limited perinatal classes that are poorly advertised and are not free; therefore, not all patients have the means to access them.
- Patients are navigating aspects of the health care system during their perinatal journey that they have never had to use before; this often comes with little guidance and doubts about what steps need to be taken.
- Patients who are pregnant for the first time do not know where and what services to seek, leaving them feeling helpless and guilty if complications occur.

Need for continuum of care

- Patients' care is interrupted by the transfer of care to a different care provider especially after delivery. These periods of interruption leave patients uncertain and lost.
- After being discharged after delivery or from midwives, patients feel like their only support is the emergency room, especially if they do not have a family doctor.

Mental health challenges

- Complications during the perinatal period leave patients feeling incompetent and highly anxious about their own situations.
- Patients wanting to seek mental health support are discouraged because they are unaware of how to access them or told they are not in need of them.

Emergency screening

- Due to the long wait times in the emergency room and lack of knowledge of problems arising either during prepartum or postpartum, patients indicated a need to have an emergency screening process tailored to pregnant and newborn mothers by using the digital platform before they head to the hospitals to save or rule out unnecessary visits.

Uncoordinated transitions of care

- It was challenging for patients to find an appropriate obstetrician or midwife in a timely manner; they had to call a list of clinics on their own or find one through word of mouth in order to be accepted.
- When patients find out they are pregnant, they are frustrated by a lack of information on available care providers in their region.
- Patients are confused about when to choose a midwife or other type of doctor and why they may need to switch providers during pregnancy.
- Mom and baby's care is not coordinated in the health system after the birth of the baby because they are treated as 2 distinct patients.
- There is no standardized system to share health records between perinatal care providers, which leaves patients with the responsibility to communicate their health information when multiple types of caregivers are needed to support their pregnancy.
- When accessing care, services, or resources across different health authorities, health authorities do not follow standardized structures or guidelines acting as an additional barrier for patients as they learn to navigate a new health authority.
- There is a lack of communication and awareness among health authorities, therefore, interrupting patients' care.

Poor patient-centered care

XSL•FO
RenderX

- Care providers are dismissive of patient concerns and thoughts, resulting in patients advocating for themselves and leaving them stressed and isolated.
- Patients feel uninvolved in their health because they are often told what to do without direct and clear explanations or guidelines from their providers.
- Patients have to manage multiple appointments with different providers instead of an integrated care team, meaning that they often wait long periods of time before their needs are addressed.
- Patients would appreciate more visits and opportunities to meet with their care providers or a trusted source in order to discuss their concerns and ask questions.
- Patients want to hear follow-up from their care provider after every test, even if it is normal.

Final Workshop

The workshop had a total of 20 attendees: 4 core project team members, 4 patient partners, 2 researchers, 5 clinicians, and 5 health system partners. The workshop was held over Zoom. During the workshop, 3 research themes were chosen as priorities through the discussion process including patient autonomy and support, educational resources for patients and providers, and access to health information (Figure 2). Attendees chose to frame the final research questions around broad transformative goals rather than specific clinical care concepts or processes to make the final agenda broadly applicable across health settings in the British Columbia public health system. For example, although patients and clinicians identified a need for lactation support earlier in the engagement process, a decision was made not to name this clinical concern specifically, as it was felt to narrow the scope of the recommendations. Similarly, patients and care providers identified a need for more accessible support for nonurgent health concerns. Suggestions were made to create more digital resources, but in discussion, the group agreed that more foundational knowledge on the type of digital technology that would be found most usable and effective for providing health information is needed. This resulted in final research questions such as 1.3 and 2.3. A total of 12 final research questions to be included in the research agenda were developed to reflect the identified priorities and patient perspectives (Figure 3).

Figure 2. Three priority themes for perinatal digital health research.

XSL•FO
RenderX

Figure 3. Final list of priority research questions. RPM: remote patient monitoring.

A follow-up REDCap survey was sent to a total of 35 individuals, including all workshop participants, steering committee members, and patient partners, and we received 20 responses. Respondents included 5 researchers, 5 health system decision makers, and 6 perinatal health care providers with 4 patient advisors. When asked to select the top 3 priority research questions, respondents prioritized questions 1.4, 1.2, and 3.3 (Textbox 2). All of these questions focus on supporting patients' decision-making with better information and fall within the themes of improving patient autonomy and access to information. When comparing the priority of the overarching themes, overall questions from theme 1: patient autonomy and support were the most selected; however, if we adjust for the number of questions per category, questions from theme 3: access to health information were the most selected.

XSL•FO
RenderX

Textbox 2. Prioritization of research questions.

Number of times prioritized: 9

- Question 1.4: What aspects of perinatal care can be monitored, administered, or assessed using mobile devices (ie, remote patient monitoring, digital health visits, and peer support) to support empowered self-care? How do we implement these without widening the access to care gap experienced by already disadvantaged populations?

Number of times prioritized: 7

- Question 1.2: What digital tools and information can support patients' decisions in identifying and connecting with the right maternity care provider? What information do patients need to identify the right maternity care provider? How do we support this decision with digital tools?
- Question 3.3: How can the integration of patient-reported outcomes in a patient's record contribute to quality improvement and shared decision-making?

Number of times prioritized: 5

- Question 1.5: How do we monitor the mental health patients receiving perinatal care in order to provide timely support when needed and improve health outcomes and perinatal recovery?
- Question 2.1: What resources can be compiled into a starter kit to guide patients through their pregnancy? What resources can be compiled into a starter kit to guide patients who have just delivered their child? How do these resources impact patient and child health outcomes?
- Question 2.3: How do patients prefer to view and access health information and educational resources (eg, type of format such as audio vs video vs website)? How can we engage patients and providers in developing and designing these resources? Are there existing resources we can expand in function to meet patient needs (eg, 811 response, peer support, chatbots, or SmartMom)?
- Question 3.1: What is the effect of more transparent access to provincial dashboards such as HealthGateway (for both parent and child and linked together) on care quality, and access to care in both urban and rural or remote settings?

Number of times prioritized: 4

- Question 3.2: Can improved data access for patients and care providers lead to an increase in British Columbia's status against global benchmarks for health care quality?

Number of times prioritized: 3

- Question 2.2: What are the individual, organizational, and policy barriers and facilitators to providing standardized multilingual prenatal and postnatal education in British Columbia?

Number of times prioritized: 2

- Question 1.1: How do we best measure patient autonomy in the perinatal period?
- Question 1.3: What services and resources exist within British Columbia that support patient mental health, self-care, and patient autonomy in decision-making? How do we ensure providers are aware of them? How do we emphasize connecting patients to them?

Number of times prioritized: 1

- Question 2.4 What implementation strategies will work to make educational resources accessible across regions in British Columbia? How do we measure impact?

Discussion

Research Priorities and Implications for Practice

The RAPID project resulted in the co-design of a comprehensive research agenda for perinatal digital innovation that reflects provincial strategies and patient experience in British Columbia. During the project, a series of engagement activities allowed us to ascertain the current gaps and needs for digital health interventions for perinatal care and develop a research agenda that will address these needs. Our research agenda provides a foundation for identifying, developing, and implementing digital solutions that are responsive and feasible within the current British Columbia health care system landscape. The RAPID research agenda identified a core set of research priorities under 3 interdependent thematic areas that, if addressed, could lead to meaningful improvements in patient and clinician experience and health outcomes in the perinatal period. The priority themes identified are patient autonomy and support when navigating the health system, patient and provider access to education resources, and patients' ability to access health information. These themes align with the BCDHS and have broad support from health system leaders.

The research themes identified and research questions prioritized in this project suggest that further innovation is needed to properly leverage digital health tools to support perinatal care in British Columbia. Priority research questions and a major area of discussion with our patient partners focused on a need for better digital tools to support self-care and decision-making across the entire perinatal period, from pregnancy to the end of the first year of the infant's life. The ThoughtExchange also highlighted that, within the British Columbian health system, there is a limited number of tools in use that clinicians view as

XSL•FO
RenderX

valuable to care. This results in patients accessing numerous external digital resources that are not always of quality and relevance to their care. This agenda can be used to advocate for change at the provincial level and support the incorporation of digital health into the health system. Addressing research priorities identified by RAPID would improve the patient experience by providing needed solutions that allow patients to safely interact with their health care professionals through web-based platforms or through their mobile devices, access self-care tools and applications, use smartphones or other devices to manage and monitor their health, and adopt technology in their health plans.

Digital health innovation as suggested by our research agenda is appealing because it is not restricted by time or place [13] allowing for patient empowerment as well as patient participation in the decision-making of their own health. Addressing the RAPID research priorities can also improve the continuity of care and delivery of essential services, something that all partners in the RAPID project would clearly value. There is already evidence that digital innovation in perinatal care can lead to improved health outcomes for both the woman or pregnant person and their infant [1,12-14]. This agenda highlights that the perceived value of digital innovations for patients receiving perinatal care and their families cannot only be determined by traditional health outcomes. Digital innovations should also be measured against their ability to improve confidence and autonomy in decision-making, self-care, information sharing, and patient and clinical experience.

The digital health sector receives enormous investment, making available a vast number of solutions varying in quality and capabilities [17]. The existing literature has provided a broad understanding of the feasibility, acceptability, and effectiveness of digital tools outlining advantages and disadvantages [1,12]. However, this continued growth in digital solutions does not guarantee or equate to an increase in solutions that can be implemented to meet the actual existing needs of patients, providers, and health systems [17]. In this project, we used HCD methods to identify patient needs and priorities for digital innovation that are aligned with clinical care providers and health system priorities, but our identified priorities cannot exist in isolation from the current knowledge of socioecological factors. Although the RAPID priority research questions are defined based on need, these must be explored with consideration for the facilitators and barriers that contribute to engagement with digital health solutions. Previous research on digital health use has identified barriers and facilitators to implementation such as infrastructure, equipment, network access, motivation, and usability [25,26].

The effort was made to integrate the knowledge of barriers and facilitators to engagement and uptake of digital health innovations throughout the research agenda, such as geographic settings, data-security concerns, and diversity in health concerns. However, considerations for these barriers and facilitators should continue beyond what the questions have defined, as we work to action the agenda. Issues such as connectivity, user motivation, social support, digital literacy, user-friendly design, and credibility should continue to be examined throughout subsequent digital health research.

Strengths and Limitations

This project's use of a human-centered approach prioritized patient voices and provided the space for collaborative co-design of the final research questions. Limiting the number of patient partners and restricting the number of researchers in the patient advisory meetings allowed for better quality engagement through intimate and extensive discussions. The diversity of partners from across British Columbia allows for more generalizable results. However, a significant limitation was our lack of engagement with Indigenous clinical care providers or patients. There is a need to engage with Indigenous people's voices within all of the partner groups before moving research forward from this strategy. Related to this, although we were able to collect a diverse group of partners' opinions and bring these together to design a comprehensive research agenda, running the project under a knowledge translation initiative restricted the amount of data we could collect on engaged participants. As a result, it may be more difficult for others to apply this knowledge outside of the British Columbia health system. We also cannot explore if participant characteristics such as age or experience level (for health care providers) had any impact on their opinions of digital health priorities. An additional strength is our engagement with health system partners throughout the project, aligning in strategy and garnering early support from decision makers. As a result, outcomes of research informed by this agenda are more likely to be implemented and achieve long-term impact. There was strong collaboration throughout the project between researchers and knowledge users, allowing us to lead this work within the health system, leveraging developed partnerships, and articulating alignment with organizational goals and patient research priorities.

This HCD approach prioritized patient voices in developing research priorities; yet, our multipartner codevelopment approach recognizes that the ownness should not be on patients alone to identify a solution to the complex issues of perinatal health care delivery. The emphasis on people solving their own problems that is core to the HCD approach cannot be directly assumed in a health care context due to the complexity of the system and the multitude of interested parties that will be impacted by any system changes. In positioning our work to address patient needs while still aligning with health system priorities, we have aimed to support value-based care efforts in the British Columbia health system. Focusing further research and innovation efforts to address the RAPID research priorities can support improvements in value-based care, as they would improve outcomes and processes that matter to patients without an unreasonable increase in health care expenditure.

Conclusions

This project identified clear support and enthusiasm across partners for digital innovation to improve the quality of perinatal care in the province of British Columbia. Our research agenda highlights the need for better patient education and health information systems that are more accessible to patients and care providers with the overarching need for digital resources that can increase patient autonomy in decision-making throughout pregnancy and the transition to newborn care. Co-design of this research agenda is a first step in the research

XSL•FO
RenderX

process. Our priority now is to take action on identified research priorities. Action can occur through traditional research funding pathways but also by advocating to our health system partners to directly address needs identified by the RAPID research agenda within the health system.

Acknowledgments

The authors gratefully acknowledge that our project could not have been possible without the invaluable contributions of our patient partners AE, KJH, JMG, and LY. The authors thank Joanne Hepplewhite from the Provincial Health Services Authority Transformation development office for her support with the ThoughtExchange. This project was funded through a convening and collaborating grant (#C2-2022-2969) from the Michael Smith Health Research BC.

Abstract

Background: Patient-derived biospecimens are invaluable tools in biomedical research. Currently, there are no mechanisms for patients to follow along and learn about the uses of their donated samples. Incorporating patients as stakeholders and meaningfully engaging them in biomedical research first requires transparency of research activities.

Objective: In this paper, we describe the use of participatory design methods to build a decentralized biobanking "de-bi" mobile app where patients could learn about biobanking, track their specimens, and engage with ongoing research via patient-friendly interfaces overlaying institutional biobank databases, initially developed for a breast cancer use case.

Methods: This research occurred in 2 phases. In phase 1, we designed app screens from which patients could learn about ongoing research involving their samples. We embedded these screens in a survey (n=94) to gauge patients' interests regarding types of feedback and engagement opportunities; survey responses were probed during 6 comprehensive follow-up interviews. We then held an immersive participatory design workshop where participants (approximately 50) provided general feedback about our approach, with an embedded codesign workshop where a subset (n=15) provided targeted feedback on screen designs. For phase 2, we refined user interfaces and developed a functional app prototype in consultation with institutional stakeholders to ensure regulatory compliance, workflow compatibility, and composability with local data architectures. We presented the app at a second workshop, where participants (n=25, across 9 groups) shared thoughts on the app's usability and design. In this phase, we conducted cognitive walkthroughs (n=13) to gain in-depth feedback on in-app task navigation.

Results: Most of the survey participants (61/81, 75%) were interested in learning the outcomes of research on their specimens, and 49% (41/83) were interested in connecting with others with the same diagnosis. Participants (47/60, 78%) expressed strong interest in receiving patient-friendly summaries of scientific information from scientists using their biospecimens. The first design workshop identified confusion in terminology and data presentation (eg, 9/15, 60% of co-designers were unclear on the biospecimens "in use"), though many appreciated the ability to view their personal biospecimens (7/15, 47%), and most were excited about connecting with others (12/15, 80%). In the second workshop, all groups found the app's information valuable. Moreover, 44% (5/9) noted they did not like the onboarding process, which was echoed in cognitive walkthroughs. Walkthroughs further confirmed interest in biospecimen tracking, and 23% (3/13) had confusion about not finding any of their biospecimens in the app. These findings guided refinements in onboarding, design, and user experience.

Conclusions: Designing a patient-facing app that displays information about biobanked specimens can facilitate greater transparency and engagement in biomedical research. Co-designing the app with patient stakeholders confirmed interest in learning about biospecimens and related research, improved presentation of data, and ensured usability of the app in preparation for a pilot study.

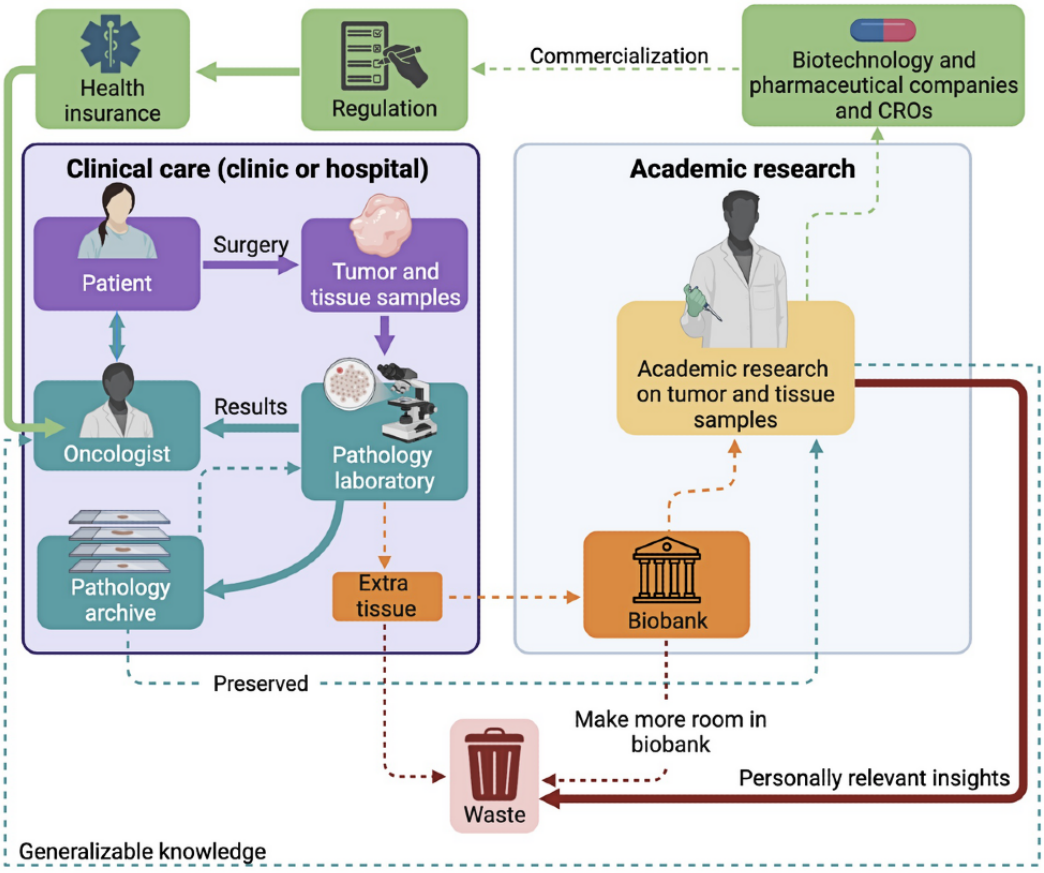
Introduction

Background

Samples of blood, tissue, urine, and other biological products, collected from patients during a medical procedure, are invaluable tools in biomedical research. Reviews estimate that >600 research biobanks exist in the United States, housing tens of millions of samples from tens of millions of patients [1,2]. Biospecimens are used in a vast array of foundational, translational, and clinical research [3-6]. Research on biospecimens shows exceptional promise in studying cancer and developing new cancer treatments [4,7,8]. Cutting-edge specimen preservation methods offer high-fidelity disease models for genomic analysis, high-throughput drug testing, advanced imaging, and more.

Typically, leftover surgical samples are collected after a 1-time informed consent process per the federal Common Rule in the United States, where patients receive information about the proposed research [9]. The terms of this consent include no expectation to follow up with pertinent research results after the form is signed and samples are collected [10]. In the transition from clinical by-product to banked research sample, patient identifiers are removed from biospecimen data [11]. Deidentification is meant to protect patient privacy by removing identifiable information; however, its conditions preclude scientists from sharing follow-up information about if, when, and how they use biospecimens for research [12]. Scientists receive deidentified biospecimens from the biobank and have no mechanism to directly communicate personally relevant insights or engage with the people whose samples they have received (Figure 1) [10]. Thus, while clinical results from pathology reports are communicated to patients, information on how their biospecimens are used and associated research findings are never shared.



Incorporating patients as stakeholders and meaningfully engaging them in biomedical research is increasingly recognized as critical to more ethical and effective scientific advancement [13]. Patients' lived experiences can help guide research questions, priorities, and methodologies, ensuring that the resulting knowledge aligns with their and their community's priorities. Various innovative technologies and techniques have enhanced patient engagement in research [14,15]; for instance, the James Lind Alliance method facilitates collaboration among clinicians, the public, and additional stakeholders, enabling their opinions to converge and inform the establishment of research priorities [16,17]. Digital platforms that assemble citizens from different backgrounds to share experiences and actively codevelop innovative health strategies have been proposed [18]. However, improving transparency surrounding the nature and extent of research activities is a prerequisite to achieving true patient engagement.

Decentralizing biobank information and empowering biospecimen donors with knowledge about how their samples are used lays the foundation for fostering trust and transparency in biospecimen research [19]. This is particularly vital in rebuilding trust with communities considered marginalized, which have historically been subject to exploitation and unethical research practices [20]. Building trust lays the foundation for further participation by diverse communities and ensures that research endeavors are accountable to those whose biospecimens make the research possible [21].

In previous work, we have demonstrated that there is unmet patient demand for increased transparency surrounding biospecimen research use [22]. We surveyed patients with breast cancer (n=109) about their interest in learning about biobank research and their individual biospecimens [22]. This survey measured patient interest in a broad range of information that they could theoretically learn about research on their samples. Notably, survey respondents were interested in learning information that is readily available within in local biobank and research databases, such as whether their samples had been used in research (66%), details about research conducted on their samples (53%), and the ability to see images of their biospecimens if available (68%).

RenderX

Figure 1. Biobanking ecosystem: biospecimen supply chain from clinical by-products to institutionalized assets. In the current biobanking paradigm, personally relevant insights and extra tissue are often wasted, representing lost opportunity to advance patient care and maximize value from donated biospecimens. CRO: contract research organization.

Objectives

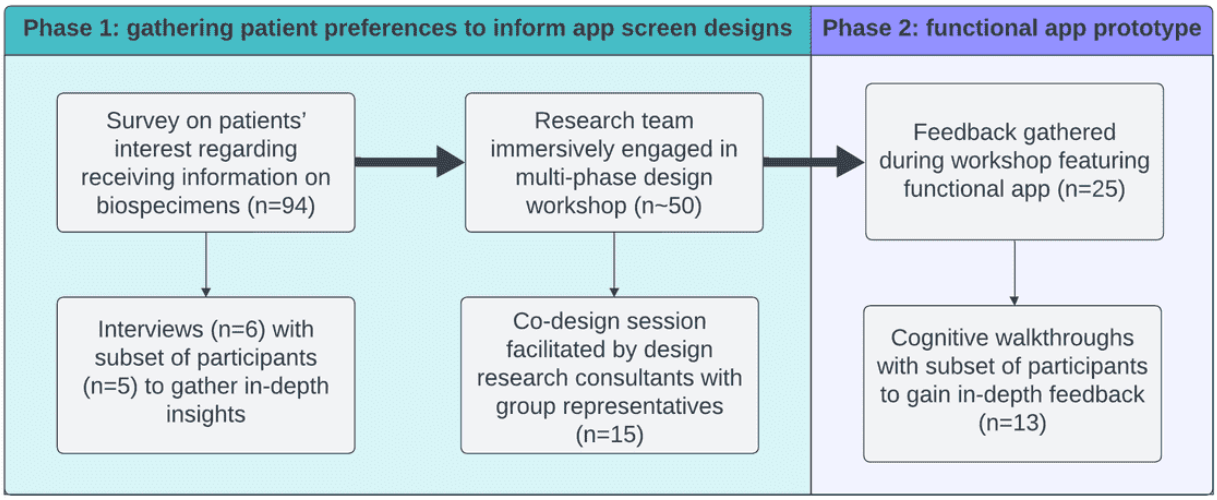
To address the unmet need for greater transparency and engagement between biobanks and patients, we sought to build an initial decentralized biobanking app—"de-bi"—to serve as a patient's "window" into an established biobank database. We aimed to build a composable platform that would be accessible and valuable to patients while being compliant with existing regulations, composable with data architectures and compatible with established workflows [23]. By viewing biobank data, patients can be empowered to "track" what happens to their biospecimens [24]. A patient-facing mobile app could overlay and display existing data, serving as a technological tool for increasing the transparency of research activities and as a mechanism for directly engaging with patients who have contributed to research, all within the current frameworks of consent and deidentification. Composability with institutional databases would also serve as a source of efficiency, easing the burden of the initial manual data transfer to an app interface and setting up easier future automation and scalability. This tool could then be piloted to measure its impact on patient participation, understanding, and attitudes about biobanking and biospecimen research and begin to answer outstanding empirical questions about effectively fulfilling obligations of transparency and engagement.

Including patients in the design phase was imperative to the future pilot's success. Before the tool was deployed, we sought to ensure that it was interesting, accessible, understandable, valuable, and easy and ideally pleasant to use. Here, we describe the process and results of using participatory design methods to define, design, and deliver a mobile app that enables patients to learn about their biospecimens collected for research, the status of the biospecimens' use in research protocols, and overall biobank collections, as demonstrated in a breast cancer biobank setting.

Methods

Overview

This multiphase participatory design study was conducted among patients of a breast cancer clinic at a large US academic institution. It consisted of surveys of patients (n=94), six semistructured in-depth follow-up interviews with five survey respondents (5/94, 5%), immersive design workshops with patients (workshop 1: approximately 50 participants, focusing on a subset of 15 codesign participants), workshop 2: n=25), and cognitive walkthroughs with individual patients (n=13) [25]. The data being presented represent a subset of broader participant engagement, including additional workshops and encounters with the local community of patients with breast cancer.



This research occurred in 2 phases (Figure 2). In phase 1, we designed smartphone screens containing different information that patients could learn about biobank and research activities

XSL•FO
RenderX

involving their samples. Embedding these screen designs in a survey, we sought to gauge patients' interest in receiving information about research or their biospecimens. We engaged a subset of survey respondents in short web-based interviews to discern their views on the importance of having this information and their opinions on its presentation and design. We held a design workshop at which participants gave feedback on the screens and suggested improvements.

For phase 2, we refined the user interfaces and developed a functional app prototype. As we developed the app, we consulted institutional stakeholders to enhance compatibility with regulations and composability of core app features, with one another and with local data architectures. We then distributed the app at a second design workshop, where participants shared thoughts on the usability and design of the app. In this phase, we conducted cognitive walkthroughs with individual participants to observe their success in using the app and to gain in-depth feedback on its functionality [26].

Figure 2. Overview of study methods.

Phase 1

App Screen Design

We used Whimsical and Figma for the initial wireframes and Flutter and Adalo for prototyping to develop the initial screen designs [27,28]. The content of these designs was informed by previous engagement with this patient population and limited by the content available within institutional biobank or research databases and publicly accessible research content. Previous survey results identified important data points to include in our patient-facing display and informed its design [22]. Working with investigators on the biobanking research protocol, their data managers, and the University of Pittsburgh Institutional Review Board, we selected data points that would be feasible and acceptable to return to patients in a future, functional solution. We then created a sample screenshot presenting a model set of samples and the corresponding hypothetical data points.

We designed 3 initial app screens presenting information about a hypothetical user's collection of biospecimens in the biobank (Figure 3). These screens were meant to be viewed sequentially, with increasing specificity of information presented about individual biospecimens in the biobank. The interface was inspired by the term "biobanking" and designed to resemble many banking apps where users first view a summary of their accounts and can click through to increase specificity about each one. Our first screen contained a summary list of a hypothetical individual's inventory of donated samples, including pictures of each. The second screen displayed high-level demographic information about each individual biospecimen: an image, its location, and the date it was collected. The third and final screen showed more details about each individual sample, such as its ID number, the medical procedure from which it was collected, the number of the freezer where it was stored, and more.

A fourth screen was created for potential users to learn about the biobank collection as a whole (Figure 4). This screen, called "connect," showed a list of subcommunities of biobank donors sorted into groups by their diagnosis code, including summary statistics indicating how many donors to the biobank shared a diagnosis (eg, invasive ductal carcinoma). The design suggests that users might be members of ≥1 of these groups (called "labs") and might use their membership to "connect" with other users, patients, or scientists.

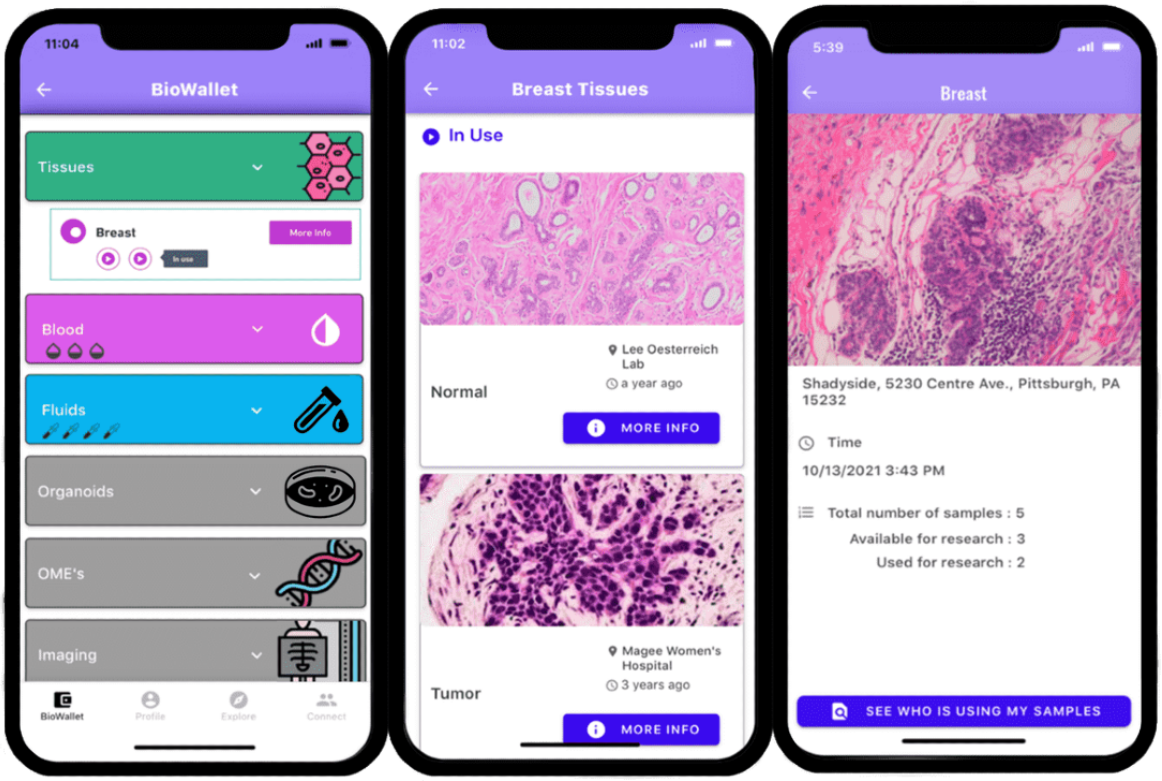
Figure 3. The 3 "biowallet" screens, as developed in Adalo and featured in the survey, presenting different categories of specimens using accordion unfolding and individual sample–level details.



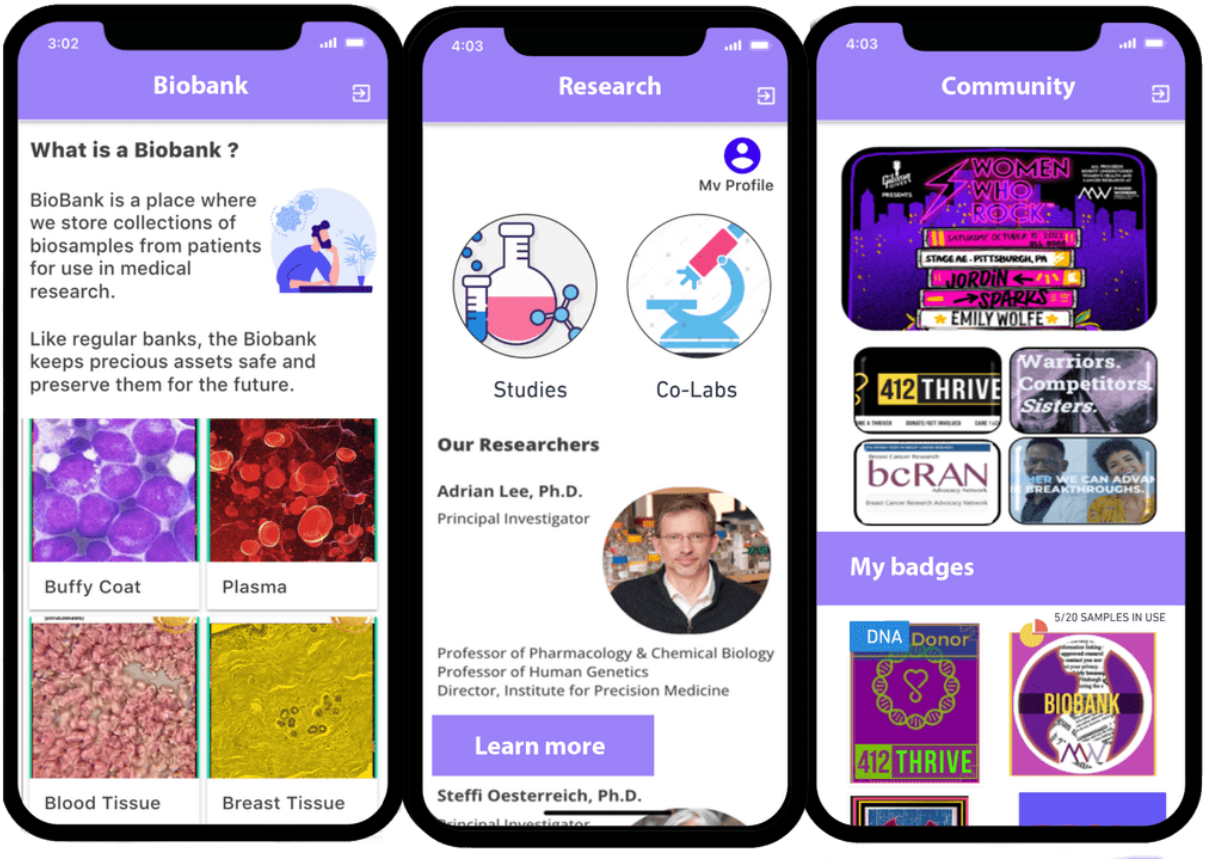


Figure 4. Biobank, research, and community screens. These screens, developed with Adalo, illustrate features explored in surveys, interviews, and workshops, including opportunities to learn about biobanking and specific specimens, follow scientists and learn about individual research programs, and connect with fellow donors and scientists.

XSL•FO
RenderX

Surveys and Semistructured Interviews

After developing the initial app screens, we embedded them into a survey to gather further evaluation and feedback from patients [29]. We conducted the survey in 2023 with a convenience sample, recruiting patients via flyers posted in breast care clinics across the health system. Participants took the survey on their own devices. IP addresses were used to identify duplicate entries from the same users. At the end of the survey, participants were invited to participate in an optional follow-up semistructured interview to discuss their survey answers. Survey content was iterated and rotated as app screens were finalized and in response to saturation of data from responses and follow-up interviews. Thus, survey data are presented with the denominator reflecting the number of participants who received each specific question and chose to reply. In total, 94 participants completed the survey, of whom 5 (5%) participated in the follow-up interviews (one participant was interviewed twice; once before and once after her cancer diagnosis). Demographics of the survey respondents, including age, race, and cancer stage, are presented in Table 1. The "Unknown" category represents participants who chose not to answer that question.

The survey asked participants their level of interest in the information presented on the app screens. After viewing the "biowallet" screens, participants were asked which of the presented data points were of interest to them. After viewing the "connect" screen, patients were asked whether identifying and belonging to a subcommunity of donors to the biobank would be of interest to them and, if so, how they might want to use the app to connect with others; for example, they were asked whether they were interested in connecting with researchers who used their samples from the biobank and, if so, what information they would like to exchange with them. They were also asked about their interest in connecting with other, similar patients who might be members of the same subcommunity (eg, have the same diagnosis code) and, if so, how.

In the follow-up semistructured interviews, participants and members of the research team viewed the participants' survey responses via screen sharing on an audio-recorded web-based call. The participant's survey responses were walked through one at a time, and the participant was asked to go into further detail about their reasoning for their answers. These interviews were meant to validate the survey questions by identifying any confusing language or images and to gain a deeper understanding of the motivations, preferences, interests, and concerns of participants. Each interview lasted 35 to 45 minutes. Interview participants were selected to represent key subsegments of the survey population, for example, age, education, and time from diagnosis.

Survey responses were analyzed, and summary statistics are presented. Transcripts of the follow-up interviews were coded for emergent themes in response to each set of screens. The results from both analyses informed changes to the presentation of biobank data and adjustments to the design of the screens to meet participant preferences and clarify content.

Design Workshop 1

We sought feedback on the "biowallet" screens, the "connect" screen, and 2 additional screens: "explore" and "profile." The "connect" feature was expanded to include 3 screens showing a list of all "lab" groups and subcommunities, a description and membership details of 1 specific "lab," and an action button to "add my samples" to a "lab." The screen called "explore" contained additional biobank-level data about the collection of biospecimens. The last addition, "profile," contained a hypothetical user-chosen avatar to represent themselves, as well as a collection of hypothetical achievement badges representing activities that users might be able to complete both in the app ("claimed my biowallet") and in research participation ("signed a consent form"). It also contained a progress bar indicating the users' completion of in-app tasks and achievements. We presented the second iteration of the screens to approximately 50 members of a local support group for patients with breast cancer in an embedded participatory design workshop. Members of the research team presented the screens, gave a short overview of their contents, and explained the overall intent of decentralized biobanking as well as the purpose of the dedicated app codesign workshop.

Participants provided feedback about the overall approach during a three-day participatory engagement event where the research team presented to and engaged with the local breast cancer patient and previvor population in an immersive setting. In this paper, we focus on describing results for 15 group representatives who attended a professionally facilitated in-person codesign workshop where they provided detailed feedback on individual app screen designs. Participants were given printed images of the screens, along with stickers—thumbs up or a heart to signify something they liked, a question mark to signify something they were confused by, and an exclamation point or a frowning face to signify something they did not like. Participants were asked to discuss the screens as a group and to place stickers on the printed images, either to signal their reaction to the entire screen or specific parts of the image. Some groups wrote on the images or in the margins to elaborate on their responses. As not all participants responded to all app screens, workshop data for all subsequently described workshops and cognitive walkthroughs are presented with the denominator reflecting the number of participants who provided written feedback on a given screen, page or design element.

The printouts were collected after the workshop, and the research team performed a content analysis of the sticker placements and notes left by participants. The identified themes were considered along with design research synthesis from expert consultants, as well as analysis of survey responses, semistructured interviews, and immersive engagement. Taken together, these themes informed further design changes that were then incorporated into a functioning mobile app prototype.

Phase 2

App Prototype Development

We developed a functional mobile app using Flutter [30]. The front-end patient-facing interfaces contained 4 sections: "biowallet," "explore," "connect," and "profile." We also developed a backend data architecture in which real biobank data could be imported into the app so that users could see personalized, real-time information about their biospecimens contained in the biobank collection. During the app's development, we consulted with institutional stakeholders to ensure regulatory compliance and compatibility with existing data resources to minimize burdens on researchers and data managers. Elsewhere, we describe a "digital honest broker" approach that enabled pilot participants to be connected directly to their own deidentified biospecimens [31].

Design Workshop 2

We held a second design workshop with a second local advocacy and support group for patients with any cancer type. A total of 25 participants attended. Members of the research team presented the app screens, gave an overview of their contents, and explained the intent of the workshop. Participants were then instructed to access the app on their personal devices and given a sample log-in leading to a deidentified demonstration account with biobank-level data and individual biospecimen data populated. Participants were given a sheet of paper with three columns—"Things I Liked," "Things I Didn't Like," and "Didn't Meet Expectations"—and were asked to write corresponding reactions as they explored the app freely by themselves or with one or two other participants. The papers were collected from nine small groups. Content analysis was performed to identify common areas of interest, enjoyment, displeasure, and dissatisfaction.

Cognitive Walkthroughs

During the second design workshop, members of the research team invited individuals at random to participate in a cognitive walkthrough to evaluate the usability of the application. Of the 25 workshop participants, 6 (24%) completed the walkthrough exercise. Participants were asked to perform several in-app tasks and seek specific information presented in the app while narrating out loud what they were doing. Members of the research team observed them using the app and took notes about their narration, evaluating their success in completing the assigned tasks.

We held seven additional cognitive walkthroughs with users recruited from participants in the phase 1 survey who agreed to be contacted about future research. These participants were

XSL•FO
RenderX

patients at the collaborating health system and were guided through the onboarding process that connected them to their own biospecimen information, if any existed. All users were able to see the "explore" and "profile" screens. Users who had also consented to the biobanking protocol (which was manually verified by the research team) were able to see the "connect" screen. If the user had samples in the biobank, they could see the "biowallet" screen populated with real data about their samples. Participants were led through the same cognitive walkthrough and asked to complete tasks and seek out specific information while they narrated their process as researchers observed and took notes.

Cognitive walkthroughs measure usability by collecting qualitative, experiential data from users directly. Researchers can infer usability by noting whether the users understand the task and are trying to achieve the right outcome, whether they take the appropriate action to achieve their intended outcome, and whether they correctly identify their success or the information sought from them. By having a mix of participants viewing uniform, hypothetical data and those viewing personalized data, we were able to gain generalized insights into usability, as well as insights into the personal value and added joy or frustration when engaging with one's own data. Both sets of participants were asked to create an account; perform the necessary authentications to populate their biospecimen data; identify how many of their samples had been used in research and how many were available; and to find a protocol that had used their samples, or, if their samples were unused, to find a protocol that studied their particular diagnosis.

Ethical Considerations

This study was approved by the University of Pittsburgh Institutional Review Board and quality improvement committees (IRB22010118, IRB22020035, and QRC3958). Participants provided informed consent before engaging with the study. The voluntary nature of the study was emphasized, including that their decision to participate in the study would have no impact on their care. Participants were able to skip questions or withdraw at any time. To safeguard privacy, data were stored on a secure institutional server, with survey responses deidentified and stored separately from personal information. Survey participants were paid US $10 for their participation upon completion. A subset of survey participants who agreed to participate in the follow-up interview were paid an additional US $20.

Results

Phase 1

Surveys

In reaction to the "biowallet" screen, participants were asked about their interest in using such an app to track their biospecimens donated to research. Of the 89 respondents, 20 (22%) were extremely interested, 22 (25%) were moderately interested, 24 (27%) were neutral or not sure, and 23 (26%) were not interested. Survey questions presented potential app features related to sample tracking, research feedback, and community engagement (Table 2), and follow up questions drilled down on preferences regarding specific design elements and user priorities.

We next assessed participants' interest in receiving updates regarding how, and by which researchers, their samples were used (Table 2). Participants (61/81, 75%) were most interested in learning "the outcomes of studies that use my tissues, like publications or new discoveries." Of these 61 participants, 14 (23%) provided qualitative details in optional open-ended follow-up questions, describing how or why they were interested in learning about research on their samples. For example, one respondent noted "I believe research participants should have full access to the data that is collected from them...The idea that my genetic data is setting in a lab for a variety of research studies, but I have no access to any of that data or the related information generated by that data is not fair or in my best interest."

The second highest area of interest concerned learning the status of their biospecimens regarding whether they had been used in research (45/81, 56%). Only 23% (19/81) of the participants were interested in seeing how many samples they had compared to other patients with the same diagnosis. Other data points of interest were the medical procedure from which their sample was collected (12/27, 44%), the current location of their sample (11/27, 41%), and collection details (when, volume, etc; 10/27, 37%).

Subsequently, we asked participants about their broader preferences for updates from researchers using their biospecimens with respect to scientific findings, new developments, and modes of communication (Table 2). Participants (47/60, 78%) expressed the greatest interest in receiving patient-friendly summaries of scientific information. Updates on new drugs or tests that become commercially available (39/60, 65%) and findings that may inform care (38/60, 63%) were also highly valued. Fewer patients were interested in updates on new publications (28/60, 47%), patient-friendly videos (22/60, 37%), study enrollment numbers (19/60, 32%), and new research grants (15/60, 25%).

In reaction to the "connect" screen, respondents expressed interest in connecting with other patients. Participants were most interested in connecting with patients with a similar type of breast cancer to theirs (41/83, 49%) and patients in their age group (36/83, 43%). Of the 83 respondents, 24 (29%) were not interested in connecting with any others. Table 2 details additional areas of interest.

XSL•FO
RenderX

Table 2. Interest in potential app features: biospecimen tracking, research updates, and community engagement[a].

App feature interest	Survey responses, n (%)
Sample tracking ("biowallet") features (n=81)	
Outcomes of the studies that use my tissues, like publications or new discoveries	61 (75)
Learning if/when my biospecimens are shared with researchers	45 (56)
Seeing how my own samples look under the microscope	35 (43)
Learning about the individual researchers who are studying my biospecimens	27 (33)
Seeing how many samples I have compared to patients with the same diagnosis as me	19 (23)
None	12 (15)
Other	3 (4)
Research updates ("scientist labs") (n=60)	
A patient-friendly summary of the scientific information	47 (78)
If there are new drugs or tests discovered that become commercially available products	39 (65)
If there are findings that might help my doctor and I make decisions about my care	38 (63)
When new publications come out (with access to that publication)	28 (47)
Short patient-friendly videos describing the research	24 (40)
How many patients are included	19 (32)
If there are new grants awarded to that research	15 (25)
Community engagement ("donor labs") (n=83)	
Similar type of breast cancer	41 (49)
Patients in my age group	36 (43)
Patients in the same research study	30 (36)
Similar stage of breast cancer	25 (30)
None	24 (29)
Similar genetic risk of cancer	18 (22)
Patient advocates	12 (14)

[a]These are not the only survey questions posed, but represent three key areas that were included in the survey. Where appropriate, questions were iterated to include screenshots of the app designs or concepts as they were refined.

Semistructured Interviews

While learning the outcomes of research on their biospecimens was identified as a high priority, concerns arose in the follow-up interviews. Of the 5 participants, 3 (60%) expressed concern about imposing additional burdens on busy scientists. They had expressed interest in learning about research on their specimens but clarified in interviews: "only if it doesn't take away from the work" and "I don't want to bother researchers, who are very busy" (Table 3). However, participants valued the opportunity to learn more about their samples; participant 3 expressed how specimen tracking can provide transparency about "what it's [biospecimen] being used for," implying how transparency may build trust.

In the follow-up interviews, 3 (60%) of the 5 participants expressed an interest in and need for communities that connect patients to research in general, stating that existing patient organizations were focused on emotional support, living with cancer, and survivorship rather than on biomedical research or the latest advances in treatments. Participant 2 expressed frustration with the lack of medical and scientific expertise in many patient support groups (Table 3): "...It's frustrating sometimes to get the kind of information you're looking for as a patient...with metastasis."

One participant undergoing diagnostic workup for cancer expressed interest in an additional support group, but without the granularity of connecting with other patients involved in the same studies. In contrast, one interview participant with a longer duration of cancer survivorship expressed that they did not have a need for additional patient connections. Multiple participants (3/5, 60%) expressed an interest in contributing additional information to scientists to provide additional context to their biospecimens. This included integrating data from genetic tests (eg, 23andMe), wearable devices (eg, Fitbit), and personal medical histories to support scientists. The motivation for doing so seemed to stem from the opportunity to "help...the scientific community, the research for cancer" (Participant 1) and elucidate "genetic links to breast cancer" (Participant 5). Participant 3 expressed interest in being informed about "a list of studies" they might qualify for, indicating a proactive approach to supporting biomedical research.

RenderX

Table 3. Qualitative interview insights. The interview quotes are organized around feature categories of biobanking education, specimen tracking, connecting with others, and dynamic data sharing. Key standout phrases are italicized,

Proposed features ("naming convention") and interview quotes	Emerging themes
Learn biobanking ("biobank")	
• "I *totally geek out* on this stuff, so as much as you guys are willing to share and whatever level detail, I'm all about it." (Participant 1, Interview 2) • "I would want to know outcomes of the studies. I am kind of *a science geek*, like that's my interest, it's not the field that I'm in whatsoever, and I was not educated in that, but I'm very interested. I've read a lot about science and especially like bioscience, so I would say, I would also like to know outcomes, with the studies that use my tissues." (Participant 3)	Valuing scientific knowledge and approaches
• "Whatever you guys are willing to share is perfectly fine...*I just don't expect that detailed level of personal information* about the researchers, but if they're willing to share...it's fascinating...it's just not one of the absolutely necessary things, I feel." (Participant 1, Interview 2) • "*I don't expect to have the ability*, or even the need to identify specific researchers who I can go to. It's like as many people can use that tiny little tumor that you guys got out of me as possible it's fine, so what, for whatever purpose and whoever needs it, for whatever reason, is fine." (Participant 1, Interview 1) • "It was my pre-op...my surgeon, and a nurse, she just had a whole pile of papers. It [the biobanking consent form] *was just one more paper she needed to get signed*." (Participant 3)	Recognized unfamiliarity with biobanking, limited expectations and agency of donors within in current model
Specimen tracking ("biowallet")	
• "I don't need to know about all the researchers and everyone who's touching it. Just in general, like *what you're looking at and...what you're doing with it.*" (Participant 1, Interview 2) • "I don't feel the need to have control over any of that stuff—You guys can do with it what you see fit." (Participant 1, Interview 1) • "I *don't want to bother researchers*, who are very busy." (Participant 2) • "It would be interesting to see my samples, and my tissue, but not necessary, I guess. So, sort of like an added bonus." (Participant 5)	Balancing gaining personalized insights versus resource constraints for scientists
• "I mean, worst case scenario, like these are my few... last few minutes on earth... It would bring meaning...I'm *suffering but I'm suffering for a reason.*" (Participant 4) • "...People are fearful of having their information being used in nefarious ways; I think *this is a way of being super transparent and also involving the candidate*...like it's personal, it's something [very] personal, especially for women with breast tissue, very personal." (Participant 4)	Recognition for personalized contributions as a source of purpose and meaning
Community engagement ("labs")	
• "Probably in the lines of a support group kind of thing, it would be kind of neat to see...what other people were experiencing and going through, but not necessarily with regards to the study itself." (Participant 1, Interview 1) • "You have questions in there, 'Do you want to be connected with other donors?' and [in the survey] I said no, 'I don't use social media,' but I would use this, and perhaps if I do have to get surgery or I...perhaps [have cancer]... *it's like people who have dogs from the same litter, you know it's like, 'How's your pup doing?'*" (Participant 3) • "You know, now that I am talking this through, I would also...need...the type, the stage, the genetic risk of patients in my age group. I might want any one of those options. I am thinking futuristically now that it's become an actual reality or possibility...*I would be more open to connecting to others...beyond the same research.*" (Participant 3)	Some felt existing support groups were adequate, while others sought camaraderie and citizen science
• "One of the limitations with the patient advocacy groups that I've been in so far is that *there is limited expertise in the groups*...so it's frustrating sometimes to get information you're looking for as a patient...for example, drugs for preventing metastasis...what are the researchers recommending at this point [for people like me]." (Participant 2) • "I think the research is important and I'm just interested in knowing what research is going on, just because I think it's interesting, but *I wouldn't necessarily need to know what's happening with other patients* and their stuff."(Participant 5) • "I want to help, do whatever is possible to help research continue, but I don't feel the need to use something like this to connect with other people [i.e., patients]." (Participant 5)	Unmet need for direct connection with scientists, as opposed to other patients

XSL•FO
RenderX

Proposed features ("naming convention") and interview quotes	Emerging themes
Data sharing ("profile")	
• "I have the ancestry/23andMe, I do Fitbit stuff, so yeah, that'd be very cool to be able to incorporate all that...Anything that would help in any way... the scientific community, the research for cancer, anything, advanced in any way, for whatever reason, whatever purpose." (Participant 5) • "There's so much that's not known in terms of...genetic links to breast cancer...*I would share more information if it would help.*" (Participant 5) • "I would like to see a list of studies that I might qualify for, *I would provide details about my medical history or treatment.*" (Participant 3) • "[If] you guys need additional information or stats or blood or anything from me, I'm more than happy to help." (Participant 1, Interview 1)	Eager to contribute more specimens and data
• "I keep throwing out those ads for...'All of us' *because they won't give you anything...that's my reason for not participating*...[since] you have all my genetic information, you have no idea where it's going to be five years from now...But you won't let me have any access to it." (Participant 2) • "I think it's brilliant and I also think that *more people would participate if this were available*...Because I've had opportunities in the past, and...the biggest question that I have, and other people have, even when we're asked, 'Would you donate organs'...is the lack of knowledge about what it's being used for...that's what makes people suspicious and, especially, in an era where we both have like open source, you can find out information about everyone." (Participant 3)	Demand for greater reciprocity and accountability for data exchange

Design Workshop 1

Participants of the first design workshop (n=69) confirmed their interest in the concept of the app as well as the content of the app screens and provided valuable feedback on its presentation. A subset of 15 participants who participated in a dedicated codesign session documented their reactions to individual app screens. The "biobank" screens were appreciated by participants who liked the ability to view the entire collection of one's personal samples (7/15, 47%), as well as the sample-level details under the individual "biowallet" (4/15, 27%), with several emphasizing the linkage between samples and other medical or genetic data. Some were confused or upset by the technical details presented about each individual sample and about some of the terminology related to their biospecimens (eg, questioning what it means for a sample to be depicted as "in use"; 9/15, 60%). Of 15 co-designers, 4 (27%) noted that they would have preferred their samples to be organized chronologically, corresponding to their lived experience of appointments and procedures as specimen collection events, rather than initially stratified by sample type (tissue, blood, urine, organoids, etc.). For example, one co-designer emphasized: "Everything is timeline for us [patients with cancer]."

Moreover, 80% (12/15) of co-designers provided positive reactions to the "connect" screens, where they hearted the framing of virtual "lab" groups as 'patient-led' (5/12, 42%) and appreciated that there seemed to be actions that a user could take, such as joining a virtual "lab" and adding their samples to the group (6/12, 50%). Of the 12, 4 (33%) expressed confusion about the "lab" groups, including who is supposed to join them and for what purpose, while 3 (25%) expressed concerns about the legitimacy of *patient-led* "labs" because they might relate to actual future research on their samples, and they worried about the potential for unmoderated, off-topic, and illegitimate activity, with 1 participant stating "It should not feel like social media. To me it should feel more like science."

The "explore" screen, showing high-level information about the entire biobank collection of samples, prompted the most confusion. Of the 14 co-designers who were able to review this screen, 12 (86%) were confused by ≥1 terms on this page (eg, "consent" and "protocols"), and 2 (14%) suggested the addition of a glossary to help users understand. Other co-designers (3/14, 21%) incorrectly assumed that the "explore" page contained information about an individual's samples instead of the entire collection.

Participants also generally misunderstood the intended features of the "profile" page. Of the 11 co-designers who reviewed this page, 7 (64%) expressed confusion or dislike of the badges feature, with concerns that they were "useless," "not important," or excessively similar to features on social media sites, which they did not like. Finally, 18% (2/11) of the co-designers expressed concerns about the visibility of individual profile data, similarly worried about the parallels to existing social media, where all users can see individual profile pages.

Phase 2

App Prototype Development

Taking participant feedback from phase 1 activities, we developed a functional app prototype with 4 sections corresponding to the screen designs. The "biowallet" screens had been well received, and minimal changes in content were made. We removed the diagnosis code from the "biowallet" page to avoid triggering negative memories and emotions in users. We maintained sample organization by type (tissue, blood, urine, etc) to more closely resemble the structure of biobank data, where the type of sample and medium of preservation are more valuable than the collection date. However, to address participants' desire for a chronological arrangement, we listed

XSL•FO
RenderX

samples from the most recently collected to oldest *within* the sample type category. The "biowallet" page also showed a record of the users' informed consent to join the biobanking protocol. Users could click on individual samples to find information such as size, location, date collected, freezer number, and more. A generic picture of the corresponding sample type (eg, a picture of urine crystals under a microscope) accompanied each sample. Users could see whether each sample had been used in a research protocol or whether it was still available in the biobank.

The "connect" feature included patient-led "labs" organized by diagnosis, as in the original designs. We added a second class of "researcher-led labs" based on individual researchers who had used the patients' samples. Due to the structure of deidentification of the initial biobank data, the names of the researchers and details about their work were blinded, with just a numerical code representing individuals (eg, principal investigator 4); summary statistics of their work (eg, 6 protocols using 75 samples); and similar blinded, summary information about specific research protocols using patient samples (eg, "Your samples were used in protocol #4, which used 25 samples"). Importantly, displaying this information did not impose any additional workload or data input responsibilities on researchers. The patient-led and researcher-led "labs" featured some cross-referencing. A patient-led group with a shared diagnosis was linked to researcher "labs" studying this diagnosis and to protocols using samples with this diagnosis. Using existing databases, we sorted individual users into the appropriate patient-led and researcher-led "labs," adding a third section, "My Labs," where users could view just the groups of which they were members. These 2 new groups of "labs" were developed to satisfy phase 1 participants' enthusiasm for learning about research both in general and specifically about their samples, while maintaining maximum interoperability with existing biobank databases and protocols.

We updated terminology on the "explore" page in response to widespread confusion expressed by participants at the design workshop. Rather than relying on institutional terms such as "informed consent," we framed participation in the biobanking protocol as being a "member." For each sample category, we clarified how many patients were represented and how many samples there were in response to participants' confusion about whether they were looking at 1 person's samples on the "explore" page or the entire biobank's samples. The "explore" page contained expandable information about the entire biobank collection, organized by sample type (eg, breast tissue, blood, and urine).

On the "profile" page, users could view the deidentified code that links their account on the app to the biobank database, populating their sample information. Rather than showing a hypothetical set of badges that users might be incentivized to collect, which were not well received, we showed just 1 indicator of whether users had successfully been connected to their sample collection. On the "profile" page, we also developed short questionnaires about potential future research topics of interest. This feature served as proof of concept for how the app might be used to engage participants in research design or be used as a data collection tool.

Design Workshop 2

The second participatory design workshop aimed to further validate the clarity and value of the information presented in the app. In addition, we received feedback on the user experience of navigating the live app.

All 9 groups of patients participating in this workshop (consisting of 25 patients total) liked learning the information presented to them on the app. Of the 9 groups, 3 (33%) specifically mentioned the "real-time" nature of the information, with one-third (n=1, 33%) stating that they liked being able to "follow along" with research. Of the 9 groups, 5 (56%) noted that they would prefer or require more information before using the app, such as background materials or guided onboarding, to better understand the information presented; 7 (78%) wished for more information (eg, details about research protocols); and 4 (44%) wished for more capabilities (eg, a search bar or the ability to make their biospecimen data more or less visible to others).

Of the 9 groups, 7 (78%) noted that the app was easy to use. However, 7 (78%) of the 9 groups also noted usability and navigation as something they disliked. Of the 9 groups, 4 (44%) noted that the onboarding process—downloading the app, creating an account, logging in, and verifying the user's identity—did not meet their expectations or was not liked; 6 (67%) did not like a design feature of the app (eg, the choice of icon and the order in which the screens appeared); and 3 (33%) listed unmet accessibility expectations, including the desire for use on a larger screen or the preference for a web platform rather than a mobile app.

Echoing concerns from the first workshop, of the 9 groups, 3 (33%) were dissatisfied with the lack of explicit security assurances or data use terms, while 1 (11%) liked the fact that users' identities were not featured on the app and were instead represented by a unique deidentified code.

Cognitive Walkthroughs

Cognitive walkthroughs with 13 patients also gauged the usability of the app. The walkthroughs illuminated an onerous and confusing onboarding process, where participants had to create an account and submit information to link their biobank data, after which they received a notification and request for more information once their biospecimen data were populated in the app. For users who were participants in the biobank, the interim waiting period for biospecimen data was as long as 1 week, and users often mistakenly thought they had done something incorrectly. Nearly all walkthrough participants expressed confusion and uncertainty about the onboarding and biospecimen data verification process, even when completed successfully.

Once they successfully logged in and were able to view biospecimen data, most of the participants successfully described their biospecimen data, including how many of their samples were available for research. Those participants who were members of the biobank, viewing their own biospecimen data, were curious as to why their samples had not been used and expressed a willingness to take action to ensure that their samples were used in research (eg, by offering to donate more

XSL•FO
RenderX

samples or to pool samples with other participants). Overall, the success rates of completing this task indicated the usability of the app. Lower usability, namely the inability to identify successful completion of the task, arose in specific contexts applicable only to those participants who were attempting to view their own biobank data. Of the 13 participants, 3 (23%) had consented to participate in biobanking, but none of their clinical biospecimens made it to the biobank. Thus, their "biowallet" page showed no samples, although their "membership" was verified. This was a source of confusion, and participants incorrectly assumed that they had made a mistake in the onboarding process.

Participants were able to correctly identify a protocol that had used their samples or that had studied their disease. These participants successfully navigated from the "biowallet" screen to the "connect" screen and correctly understood the information presented about the protocol they identified. Some of the participants (7/13, 54%) expressed disappointment in the limited amount of information presented about the protocol or the associated researcher. Consistent with the initial survey findings, participants were most interested in learning the details and outcomes of the research conducted on their samples or their disease. In sum, the cognitive walkthroughs showed the usability of and interest in the app and revealed the need to improve the onboarding process and to better explain less intuitive scenarios, such as having no banked samples as a consented biobanking participant. The walkthroughs also confirmed participant interest in learning what happened to their biospecimens and about research on banked biospecimens.

Discussion

Key Findings

Throughout the design process, participants indicated a strong interest in and demand for learning about biobanking. They found intuitive value in the ability to track their own biospecimens. Indeed, participants positively received almost all of the information presented and commonly expressed a desire for more. In all phases, participants were most interested in learning about the research being conducted on their disease or specifically using their biospecimens, including the results of this research. They noted that they were not able to find this information on their own and were not able to satisfy general curiosity about research by participating in existing patient advocacy and support groups. These findings add to existing literature confirming public interest in greater transparency and engagement in biomedical research [32-36].

Mixed responses about the usability of the app demand further research and attention. Overall, participants in all stages were interested in using the app, although the content and presentation of information needed improvement. Some of the participants sought language and design similar to that of their medical records. Presenting research information in this way may make it more intuitively understandable but may also contribute to therapeutic misconception by misleading participants into believing that the research information and participation are of a similar clinically actionable quality. Thus, careful onboarding and framing of research information must ensure participant understanding and offer opportunities to overcome confusion.

Participants expressed a demand for a "legitimate" platform that did not suffer from what they saw as the risks and ills of social media: data misuse, a lack of privacy, and the potential for negativity or misinformation. While mobile phones and apps are widely used [37], concerns about mobile apps may make them an unacceptable platform for some. An additional facet of building trust with participants can be achieved through transparency surrounding how their biospecimens are being used. An interview participant expressed the following:

> *The biggest question that I have and other people have even when we're asked you know, would you donate organs...is...the lack of knowledge about what it's being used for.*

This approach to rebuilding trust reflects ongoing movements in biomedical research aimed at improving transparency and accountability, such as interactive and accessible "data walks" designed to engage communities and stimulate dialogue [38].

However, the de-identification of biospecimens presents challenges for direct transparency and engagement. Other challenges exist as well—meaningful transparency and engagement with patients is time and labor intensive [39,40]. Even when community engagement is required or encouraged, there are few tools or guidelines for success, and interactions may be transient and transactional [40]. Biobanking and scientific research are deeply technical disciplines that historically have minimally interfaced with the public, and require extensive time, skill, and technology to translate into accessible, meaningful plain language [39]. Finding relevant patient communities and sustaining meaningful, collaborative relationships with them might prove beneficial to biobanks, or scientists themselves, but this is not required, supported, or incentivized by traditional academic reward systems or many institutions [41-43]. Engaging patients in biobanking might fulfill obligations of respect; however, evidence of its long-term impact on research participation, understanding, and attitudes is the subject of ongoing work [40].

Our experience confirms the need for specialized skills and dedicated time and resources to deliver transparency and engagement effectively and safely. New technologies, eg blockchain and generative artificial intelligence, are essential for these endeavors to be more efficient and scalable, but their development remains time and labor intensive. Participants were largely unfamiliar with biobanking, research processes or related jargon. Thoughtful, readily digestible and personalized education about each unique research context may be a critical aspect of the app onboarding process. Participants were confused about less intuitive but common scenarios, such as having consented to biobanking but having no samples in the bank. While this confusion may stem from a lack of recall or understanding of the initial informed consent for biobanking, delivering follow-up information about actual participation (or lack thereof) presents new risks of misunderstanding that must be managed.

XSL•FO
RenderX

While our study focused on patients with breast cancer, the demand for transparency and engagement may extend to other medical fields. We found that the survey participants (61/68, 90%) were most interested in learning the outcomes of research using their tissue samples. Thus, conditions with active research and strong patient interest in new treatment paradigms, such as additional cancer types and sickle cell disease, are potential areas where this platform may be effective. Further research is needed to assess the feasibility, acceptability, and effectiveness of this platform across diverse medical contexts and patient demographics.

Finally, in light of the strong reception and demand by participants, it must be acknowledged that returning deidentified, individual-level research information to participants is uncommon and unaccommodated by existing paradigms. Existing data architectures are built for a research enterprise from which participants are intentionally excluded. Working to disrupt the paradigm by allowing participants to view research data and activities presented both technological and regulatory implications. While participants were unaccustomed to receiving this type of information and, as a result, sometimes struggled to understand it, biobanks were also unaccustomed to sharing this type of information and, as a result, were sometimes hesitant to do so. Any technological tool aiming to enable transparency and engagement in research must be acceptable to all stakeholders. Careful and inclusive co-design is imperative.

Limitations and Next Steps

The patient population we engaged in this work consisted of only women due to the nature of breast disease. Our participants were mostly White (64/94, 68%) and were more educated and had higher incomes than the national average, although they more closely resembled local demographics. Our participant population may also reflect self-selection bias—those interested in learning about research on their biospecimens or in general may have been more likely to participate in any research, including ours. Our technology was intended for piloting among this group and was therefore tailored to their preferences. For these reasons, further research will be necessary to validate interest in and usability of the technology in other patient populations (eg, men and healthy individuals).

Moreover, most of the patients we engaged with throughout all stages of design and development were unfamiliar with the term "biobank." This underscores a key challenge associated with delivering an accessible and patient-friendly biobanking app. This variation in patient knowledge regarding biobanking, even among those who already consented to biospecimen donation, limits the ability to fully capture and address diverse patient preferences.

Across the surveys and workshops, questions and app content were iterated upon as app screens were finalized, new topics were raised by participants, and data saturation was reached through survey responses and follow-up interviews. As a result, the sample size of participants exposed to specific materials varied, leading to disproportionately lower sample sizes for certain areas of inquiry. Additional work is needed to investigate a larger sampling of patients' design preferences. New technologies can facilitate meaningful transparency in biomedical research to patients in a personalized yet efficient way. This research showed that patients desire transparency and revealed the specific information they were interested in learning about their biospecimens. By deeply engaging patients and other stakeholders in participatory methods, siloed and specialized research data can be translated into meaningful patient engagement. We worked to design a mobile app that allows patients with breast cancer to track and learn about their donated biospecimens. Surveys, interviews, design workshops, and cognitive walkthroughs helped to make the app maximally valuable and usable for patients while maintaining efficient integration with existing data assets.

By creating this decentralized biobanking app, we built a platform upon which methods of transparency and engagement can be tested in subsequent pilots; for example, further research can measure the app's impact on patients' willingness to consent to biobank research, to remain enrolled and engaged longitudinally, and to actively participate in community-engaged research.

Acknowledgments

The authors thank Diana Mendoza Cervantes, Sneha Vaidhyam, and Dmitriy Babichenko, as well as Raelynn O'Leary and Ashley Deal of Dezudio, for their contributions to study design and execution. The authors also thank Sam Moatz, Jen Kehm, the members of 412Thrive, and the members of Cancer Bridges. Finally, the authors express utmost gratitude to the participants of this study: "Your openness, honesty, and trust motivate all that we do."

Conflicts of Interest

Abstract

Background: In health care, the use of nursing technological innovations, particularly technological products, is rapidly increasing; however, these innovations do not always align with nursing practice. An explanation for this issue could be that nursing technological innovations are developed and implemented with a top-down approach, which could subsequently limit the positive impact on practice. Cocreation with stakeholders such as nurses can help address this issue. Nowadays, health care centers increasingly encourage stakeholder participation, which is known as a bottom-up cocreation approach. However, little is known about the experience of nurses and their managers with this approach and the innovations it results in within the field of nursing care.

Objective: This study aims to explore nurses' and their managers' experiences with a bottom-up cocreation approach in order to assess the impact of this way of working and the resulting nursing technological innovations in an academic hospital. This insight can also inform decisions on whether the bottom-up cocreation approach should be more widely disseminated.

Methods: A qualitative study using semistructured interviews was conducted with 15 participants, including cocreator nurses, end-user nurses, and their managers. First, the data were thematically analyzed. In addition, a strengths, weaknesses, opportunities, and threats analysis was conducted.

Results: The various experiences of the participants were described in 3 main themes: enhanced attractiveness of the nursing profession, feeling involved due to a cocreation environment, and experienced benefits and challenges in using cocreated products. In addition, numerous strengths and opportunities perceived by the participants were identified as associated with the bottom-up cocreation approach and resulting useful products within nursing care; for example, cocreation contributed to job satisfaction and substantially contributed to the ease of use of the innovations that were developed.

Conclusions: The findings underscore that cocreation with nurses enhances the appeal of the nursing profession and aligns nursing technological innovations with practical nursing challenges. Embracing a culture of cocreation has the potential to foster a culture of continuous improvement and innovation in nursing care.

Introduction

Background

Nowadays, technological products and other innovations are being used more frequently in the health care sector [1-3] to minimize physical strain, such as lifting patients or transporting beds, and encourage ergonomic approaches during nursing tasks. Nurses need to use these innovations during patient care to manage various health care challenges, such as the increasing demand and complexity of health care [4,5]. An example of a technological product, which will be referred to as a "nursing technological innovation" in this paper, is the TrulyEasy clamp, designed for convenient 1-handed adjustment of the arterial line to the correct height [3]. Another example of a technological product is LineConnector, a product designed to efficiently organize infusion lines and prevent tangling [3].

Unfortunately, technological solutions aimed at solving nursing issues do not always align with daily nursing practice [2,6]. A potential explanation for this lies in the top-down approach used during the development and implementation of many innovations. Policy makers may prioritize regulatory and payment interests, while technicians focus on the functionality of innovations, without fully understanding the user perspectives and the nursing context [6-8]. Consequently, some solutions may inadequately align with the needs of the nursing profession, leading to limited impact on nursing practice [2,6]. Improving the adoption of innovations in nursing practice can be addressed in the development and implementation phase of these innovations through stakeholder participation [1,5,9-12].

A growing number of health care centers are facilitating an environment that allows stakeholders to participate in the development and implementation of nursing technological innovations [1,6,9,10,12]. This involvement, also called cocreation [13], with a bottom-up approach [8], involves an interaction in which various stakeholders work together to produce an outcome that is valued by all stakeholders involved [13]. The bottom-up approach allows stakeholders to share their knowledge or opinions about issues presented in daily activities and suggest potential solutions [8,14]. This approach can support the development of nursing technological innovations that may have an impact on nursing care [1,5,9-12]. FlushEgg is an example of a cocreated nursing technological innovation. Nurses reported experiencing challenges and discomfort while flushing the narrow central lines in neonates. Therefore, a syringe attachment was designed to enhance comfort in the palm during the application of pressure [3]. Another example of a cocreated nursing technological innovation is KoosGuard, which includes a holder that can be placed in the bed through which the cables and infusion lines are guided without becoming tangled or pinched [3].

However, the bottom-up approach requires nurses to invest time, which is challenging considering many nurses face time constraints [15,16]. If these nursing technological innovations lack the required quality, this could result in decreased application in nursing practice [2,6]. Furthermore, a poorly developed nursing technological innovation could lead to resistance from nurses, resulting in a negative attitude toward these innovations [9,17]. To fully use the potential of innovations in nursing practice, the innovations need to be adequately designed, which requires the involvement of nurses [9,18]. Despite the increasing involvement of nurses in the cocreation of nursing technological innovations, little is known about how this approach and its resulting innovations are experienced by nurses. Therefore, this study seeks to explore the experience resulting from the bottom-up approach of cocreation with nurses and the resulting nursing technological innovations developed through this approach. The perspectives of nurses, both as cocreators and end users, and their managers are key to understanding the impact of this collaborative process. These results could offer a deeper insight into how nurses, both as cocreators and end users, along with their managers, perceive the bottom-up cocreation approach and its resulting nursing technological innovations. A comprehensive understanding of their experiences, both positive and negative, can significantly contribute to the overarching goal of enhancing patient care and nursing practice, making it safer and more effective.

Aim

This study explores nurses' and their managers' experiences with a bottom-up cocreation approach in order to assess the impact of this way of working and the resulting nursing technological innovations in an academic hospital. This insight can also inform decisions on whether the bottom-up cocreation approach should be more widely disseminated.

Methods

Study Design

This study used an exploratory, descriptive, qualitative research design using individual interviews conducted at an academic hospital in the Netherlands between February and April 2023. This design facilitated the exploration of participants' experiences, which were further analyzed through a thematic analysis and subsequently through a strengths, weaknesses, opportunities, and threats (SWOT) analysis [19]. The methods and subsequent results were reported according to the Consolidated Criteria for Reporting Qualitative Research (COREQ) checklist [20].

Population and Setting

The study population consisted of three subgroups: (1) nurses with experience in cocreation, (2) nurses with experience as end users, and (3) health care managers from the nursing departments at an academic hospital where the innovations were implemented. In addition, all eligible nurses and managers were required to have at least 1 year of experience within the nursing department where the innovations were implemented. The 1-year experience criterion ensured that nurses and managers were

XSL•FO
RenderX

sufficiently familiar with the innovations and context. The setting comprised an innovation department established within the academic hospital.

Sampling Strategy and Recruitment

To gain more understanding and in-depth information from a broader perspective, a heterogeneous group of nurses and their health care managers were included through purposive sampling [19,21,22]. Potential nurse cocreators and managers for this study were recruited and informed via an email by OH about participating in the interviews. Interested individuals were required to actively contact SvS by email. Upon receiving an email, SvS responded with a participant information letter and an informed consent form. Once participants agreed to participate in the study, interviews were scheduled at a mutually convenient time. For the nurse end users, SvS visited the nursing departments where nursing technological innovations were integrated into nursing practice. Interested nurse end users were able to participate in an interview during their shifts at a time convenient for them. The nurse end users were informed via a participant information letter. After informed consent was given, the interviews started. The face-to-face interviews were conducted at the academic hospital.

Sample Size

A total of 14 to 20 participants were required to obtain saturation of knowledge with a heterogeneous sample group [19]. Therefore, the aim of this study was to include at least 14 participants [19]. The study involved 15 participants, including 10 (67%) women and 5 (33%) men.

Data Collection

Data were collected through semistructured interviews using an interview guide based on literature and expert opinions [19]. The interview guide covered various topics (Table 1), including the participants' attitude [23] toward technology, the bottom-up cocreation approach, and the nursing technological innovations developed through this approach. It also explored the acceptance [9,10,23], usability [12,23], and adoption [10,23] of these innovations in nursing care as well as their impact on patient care and nursing practice [1,11,12,24]. Demographic characteristics (age, gender, and specialization), along with the adoption rate, provided an overview and background information of the participants in this study. The adoption rate proposed by Rogers [25] allowed the measurement of individuals' attitudes toward innovations, providing valuable insights into how the participants generally perceive and approach innovations. The adoption rate according to Rogers [25] was measured by asking the participants which category they identified with. They could choose one of the following five categories: (1) driven by change and introduction of innovations, (2) leading in adopting innovations, (3) deliberately adopting innovations, (4) adoption is an economic necessity and a response to social peer pressure, and (5) have a traditional view and are more skeptical about innovations [25]. A pilot test was conducted to refine the interview guide and involved expert assessment and field testing with one participant. After the interviews, the first author created memos recording thoughts that arose due to the interviews [19]. The interviews were audio recorded and conducted by SvS, a nurse with no prior experience at the hospital where the research took place. SvS was trained in conducting interviews. Throughout the data collection process, discussions were held with the research team, including investigators SvS, TvH, and OH, to refine the interview questions and ensure that they effectively addressed the research question.

Table 1. Interview guide topics and prompt questions.

Topics	Prompt questions for nurses (end users)	Prompt questions for cocreator nurses	Prompt questions for managers
Attitude	• What are your impressions regarding the fact that a coworker from your department contributed to this nursing technological innovation? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?	• Can you elaborate on how the cocreation process began and how it evolved? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?	• What are your thoughts on the fact that a nurse from the nursing department has made a substantial contribution to this nursing technological innovation? • What is your opinion on dedicating time to enable nurses to create and execute nursing technological innovations for nursing care?
Acceptance	• What were your initial impressions of the nursing technological innovation when you first began working with it?	• What were your initial impressions of the nursing technological innovation when you first began working with it?	• What responses did you observe from nurses when they were introduced to the nursing technological innovation for the first time?
Adoption	• In what ways do you integrate the nursing technological innovation into your daily nursing tasks and responsibilities?	• In what ways do you integrate the nursing technological innovation into your daily nursing tasks and responsibilities?	• What are the viewpoints within the department regarding the utilization of the nursing technological innovation?
Usability	• What is your experience with the nursing technological innovation at work?	• What is your experience with the nursing technological innovation at work?	• What are the experiences of the nurses regarding the use of the nursing technological innovation?
Nursing practice	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?	• What transformations do you observe in nursing practice as a result of the application of the nursing technological innovation?
Patient care	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?	• What changes do you perceive in patient outcomes as a result of the application of the nursing technological innovation?

Data Analysis

The semistructured interviews were transcribed verbatim [19]. A 6-step thematic analysis approach (Table 2) was applied using ATLAS.ti software (version 23; Lumivero) [26]. Open coding and constant comparison techniques were used during the analysis [19]. An iterative process was used between data collection and data analysis. Refining the interview questions made the collection of the data more focused and specific as the process developed [19]. Audio recordings were transcribed, read, and reread by SvS in order to become familiar with the data. Data were initially coded using open coding by SvS. The 1st, 3rd, 6th, and 10th transcripts were coded separately, both by SvS and TvH. The initial codes of SvS and TvH were compared and discussed until consensus was reached. Main themes were generated through an iterative process, including constant comparison, and further elaborated and finalized by SvS, TvH, and OH. A codebook was used for insights into coding and code development [19].

XSL•FO
RenderX

Table 2. Thematic analysis.

Phase	Explanation
Phase 1: familiarization with the data	SvS conducted interviews with the participants and transcribed them. Transcripts were read and reread by SvS to familiarize herself with the data and obtain an overall impression.
Phase 2: generation of initial codes	Data were extracted from the transcripts and initially coded using open coding by SvS. The 1st, 3rd, 6th, and 10th transcripts were coded separately, both by SvS and TvH. The initial codes of SvS and TvH were compared and discussed until consensus was reached. The memos were processed systematically. Codes remained linked to the transcriptions (quotes) and the data extracts, using ATLAS.ti (Lumivero).
Phase 3: broader levels of themes	SvS developed broad potential main themes by comparing the initial codes. During meetings with SvS, TvH, and OH, consensus was reached, resulting in potential main themes derived from the data. During follow-up meetings with SvS, TvH, and OH, a description of the potential main themes was created and deliberated upon.
Phase 4: reviewing and refining the candidate themes	SvS compared the potential main themes with the coded data extracts and the raw data (transcriptions), discussing inconsistencies with TvH and OH. This process led to the identification of the main themes, which were visualized with a thematic map. The themes were refined by SvS and peer reviewed by TvH and OH.
Phase 5: defining and naming themes	SvS revisited the data extracts to define the content of each main theme. In meetings, SvS, TvH, and OH discussed the essence of each theme and developed the overall story line, resulting in the final naming of the main themes.
Phase 6: producing the report	SvS drafted the report and included detailed examples and quotes supporting the main themes. TvH and OH provided feedback, and adjustments were made accordingly. Final recommendations were implemented in the report.

In addition to the thematic analysis, we performed a secondary analysis using the SWOT matrix. This secondary analysis was carried out to make the data more accessible for the readers and support strategic changes within an organization. The SWOT analysis has been shown to be a valid method in previous studies for facilitating data interpretation for readers and informing strategic planning and decision-making in practice [27,28]. In several meetings, detailed examples of the results, with related quotes of the main themes, were discussed and analyzed and subsequently linked to a component of the SWOT matrix.

Rigor and Reflexivity

Different techniques were used to enhance trustworthiness [19]. The credibility of this study was established by the investigators by creating a nonjudgmental ambiance during the semistructured interviews to obtain the participants' perspective. The chance for bias was reduced by transcribing the content of the interviews verbatim. Member checking was used to ensure the accuracy of the transcripts, with participants reviewing the transcripts to validate their thoughts and ideas [19]. The performed member check resulted in minimal textual changes to the data.

Memos were reported during data collection and analysis to support the investigation process and the thoughts that had occurred to the investigator. The conformability of the interpretation and credibility of the data were both enhanced by investigator triangulation during the data analysis and peer feedback during researcher meetings, including the investigators SvS, TvH, OH, and HSMK. Due to peer feedback, potential meanings and a wider range of perspectives were revealed. Reflexivity, ensured by the investigator's critical view of the interview process and comments from other investigators, increased depth and improved accuracy.

A thick description was pursued to ensure the transferability of this study through the diversity of the population base, the number of participants, and the length of the interviews for imitability. To enhance the reflexivity and transparency of the investigators, a logbook was kept, detailing all changes and decisions made throughout the process of this study [19].

Ethical Considerations

Throughout this study, the principles of the Declaration of Helsinki and the code of conduct for health research were followed [29,30]. The study was examined and approved by the medical ethics review committee of the Erasmus Medical Center for a nonmedical scientific research application (MEC-2023-0021). Participants were informed and invited to the study by OH. They received the investigator's email and had 1 week to express interest. Nonresponders received a reminder. The investigator sent a participant information letter and informed consent upon contact. Participants could ask further questions via email. Interviews were scheduled after participants confirmed their approval. Before the interview, they provided written informed consent. The participants did not receive any compensation for their participation in the study. During the study, data collection was conducted with confidentiality, and data were processed anonymously according to the European Union General Data Protection Regulation [29]. Only the investigators SvS, TvH, OH, and HSMK had access to the source data.

Results

Characteristics of the Participants

The duration of the interviews ranged from 26 to 62 minutes, with an average duration of 44 (SD 10.8) minutes. Participants' ages ranged from 20 to 67 years. Various departments, including the intensive care unit, children's ward, and the recovery department, were represented in the study. Table 3 presents detailed demographic information, including gender, age range, department, adoption rate, number of nurses participating as cocreators and end users, and the number of health care managers.

XSL•FO
RenderX

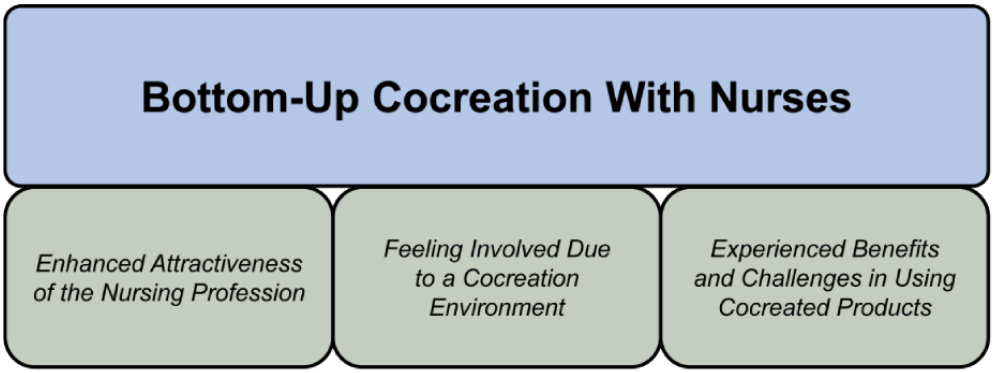
[c]Driven by change and introduction of innovations.

[d]Leading in adopting innovations.

[e]Deliberately adopting innovations.

[f]Adoption is an economic necessity and a response to social peer pressure.

[g]Laggards have a traditional view and are more skeptical about innovations [26].



Bottom-Up Cocreation With Nurses

Overview

The thematic analysis uncovered the following three main themes concerning the participants' experiences with the bottom-up cocreation approach and resulting nursing technological innovations: (1) enhanced attractiveness of the nursing profession, (2) feeling involved due to a cocreation environment, and (3) experienced benefits and challenges in using cocreated products. Figure 1 provides a visual representation of the main themes.

XSL•FO
RenderX

Figure 1. Thematic map with the 3 main themes.

Enhanced Attractiveness of the Nursing Profession

All participants experienced that the bottom-up cocreation approach with nurses contributed to the overall attractiveness of the nursing profession. The nursing profession's attractiveness was enhanced as participants were enthusiastic about participating in cocreation, finding it enjoyable and engaging. Moreover, some participants felt that they were taken more seriously as nurses as they were the ones who actually experienced the problems in practice and were given an opportunity to use their expertise to address these challenges and drive improvements in nursing practice:

> *It makes work more enjoyable. You feel taken seriously as a nurse. You can share your ideas. You can use your expertise to improve something. So I think that's a lot of fun and very inspiring, and it also leads to something useful in the end.* [P11, cocreator]

Some participants emphasized the importance of having affinity with cocreation. Most participants felt a sense of pride in having a cocreation department within the organization and being a part of a cocreation process. A few participants expressed modesty about contributing to the cocreation product:

> *Well, I think we were genuinely proud to be able to offer the product to the patient. It was a joint effort and of course it was also very important for us that our name was set out on the product. So another team could not say, "Look at this!" It really makes you feel good if you, if you can make something that you really like to use, then that is actually really nice.* [P8, end user]

In addition, nurses were more attracted to the profession because they assumed multiple roles during cocreation. They acted as developers among designers, students, and the nursing department, actively contributing ideas and promoting products within the departments. Some participants expressed that the opportunity to become involved in cocreation made their work more interesting, and, due to this, they did not look for employment elsewhere. Cocreation with nurses was also inspiring for some participants. It motivated other nurses to address practical problems encountered during their work and explore possibilities for solving them:

> *But you're then involved in care in just a slightly different way than in standard care. And that also gives new energy and new ideas. And maybe other colleagues could also get new ideas and think, well, I have seen it a few times now, so what if I can come up with some ideas like this. Then they might think, oh well, perhaps this is something that we can also work on. This could also inspire others.* [P13, cocreator]

Feeling Involved Due to a Cocreation Environment

All participants reported enhanced collaboration through bottom-up cocreation involving various stakeholders. Collaboration included clear communication and teamwork among nurses, designers, and technically oriented students. Most participants mentioned that collaboration within the organization increased their willingness to adopt certain products that were aligned with nursing practice. One participant preferred internal product development but acknowledged that external innovations could still benefit end users:

> *If you get everyone involved, then you will have much more support and that is also the case with new things. I have experienced a few times in my life that we were getting an email on Sunday night. "From Monday we will do it like this." Well, then nurses will be digging in their heels. Whereas if you say, we're working on this, and who wants to contribute their views? Then you create support; much more people will then be willing to take it from there.* [P9, cocreator]

> *I like it when the product comes from us, I like that, but it does not necessarily have to come from us.* [P8, end user]

Some participants highlighted that collaboration among nursing departments, other hospitals, and organizations contributed to knowledge exchange, product distribution, and external production. However, one participant mentioned poor communication among nursing departments concerning new developments within the organization:

> *But we, we do note things, and we share them. It's important that you know this. We're not all working in separate groups.... On the contrary, a lot of information is shared among the four of us. Because we have to intervene and know what the other thinks.* [P10, manager]

XSL•FO
RenderX

> *No, that is also very poorly communicated. And the same applies to these products.* [P9, cocreator]

Some participants mentioned encountering practical problems but found it challenging to address these problems without the support of an innovation department with a cocreation group. The presence of such a department allowed the active participation of nurses and patients in creating specific products. Furthermore, a subgroup of participants engaged in cocreation with both patients and their parents, resulting in products tailored to their specific desires and needs. Patients were enthusiastic and felt heard, leading to the active use of end-user products:

> *Yes, parents have been involved in the co-creation process. That is, in the entire process of designing, they were not just allowed to give input, but were also able make direct choices, about what benefits them the most.* [P12, manager]

An aspect experienced by most participants was the need for support during the cocreation process. Several participants emphasized the importance of a supportive manager in facilitating and allocating dedicated time for the cocreation process. They noted that cocreation was unlikely to occur without managerial backing. Participants reported that supportive managers who recognized the value of cocreation and its potential to save time in nursing care were more proactive in addressing and resolving practical problems:

> *Managers can stimulate it. I think that people working in healthcare can be very creative, but often think, what shall I say, in boxes, because it's not possible, because we're too busy. But actually that is such a shame, because we just have a lot to offer and we have the knowledge and experience to be able to create something beautiful. And I think if a manager who (A) stimulates and (B) gives the space that is required, this will ensure that people are more motivated to contribute. Because they're aware that improvement is possible.* [P11, cocreator]

Experienced Benefits and Challenges in Using Cocreated Products

Benefits

Participants found the products resulting from the bottom-up approach to be highly practical and user-friendly when used during their nursing tasks. All participants expressed immediate positivity toward the product due to its straightforward design. They could use the product without needing special training. Nurses also immediately experienced positive outcomes during their tasks. For instance, one participant mentioned that a newly created clamp for placing pressure transducers at the correct height on infusion poles improved nursing efficiency. They also reported that this clamp alleviated wrist complaints:

> *It is faster, yes, you press it and put it on the pole, loosen it and put it back on the transport cart.* [P6 end user]

Some participants found that the products improved their ability to organize and manage nursing tasks. For example, a product named KoosGuard contributed to an improved organization of patient monitoring wires, providing enhanced structure during nursing care. Another product, the cannula emergency bag, ensured that nurses, patients, and parents had all the materials neatly arranged in case of an emergency, enhancing preparedness and efficiency:

> *Overview yes, you immediately have a clear overview. Because it's easy to open it, everything is in place and it's compact. And because it was developed together with the parents and the nurses, of course, they really like that. It fits their needs.* [P12, manager]

Several participants emphasized the importance of the products' quality and safety. Participants highlighted that the professional appearance of the product and its suitability for nursing practice served as indicators of quality. Participants reported that these well-suited products reduced the need for makeshift solutions, resulting in fewer inconvenient situations during their work:

> *Yes, the well-known example is that we often use band-aids and things, but that is to help you out for the time being. But practice has already shown that there are much more convenient solutions.* [P11, cocreator]

Certain participants emphasized the role of the products in enhancing patient safety. Participants noted that a specific product effectively prevented infusion line entanglement and tension, thus reducing the risk of accidental removal. In addition, participants mentioned a product designed to decrease the risk of postsurgery wound contamination, promoting improved healing outcomes:

> *You really want those lines to be properly arranged. To make sure that not one of them is hidden from your view, because if one of those lines is pulled, the infusion may accidentally get disconnected or the patient can accidentally end up lying on top of that line because you can't see it.* [P14, manager]

Challenges

In addition to the benefits of the products, participants also experienced some challenges in their use. Some participants mentioned that some product designs had flaws, which hindered their effectiveness. For example, a participant heard from some patients that they still thought that the cannula emergency bag was too large to be used conveniently, and, due to this, it was no longer used. In addition, it was indicated that some products looked disposable, so nurses threw them away:

> *The only negative feedback came from a patient. She just thought the bag was too big.* [P8, end user]

A few participants pointed out that some products were prone to getting lost or becoming untraceable. It was emphasized that these products should be readily available to nurses at designated and standardized locations. Otherwise, the product will be used less or not used at all. Furthermore, some participants shared their struggle with making changes, leading to a heightened risk of reverting to old routines:

> *Then it takes a lot of time anyway. And you think: well, I'll just do it in the old-fashioned way, using a gauze.* [P3, end user]

SWOT Analysis Findings

Detailed examples of the main themes were divided into the 4 components of the SWOT matrix. Multimedia Appendix 1 presents an overview of all the main themes, along with detailed examples, illustrative quotations, and the corresponding SWOT categorization. The “strengths” and “weaknesses” encompass the experienced advantages and disadvantages associated with the bottom-up cocreation approach and the products developed through this approach. The “opportunities” and “threats” are examples that could be associated with potential future opportunities and challenges of the bottom-up cocreation approach and developed products. Most of the examples were connected to the components “strengths” and “opportunities.”

Discussion

Principal Findings

In this study, we sought to explore hospital nurses’ experience with a bottom-up cocreation approach and the resulting nursing technological innovations developed through this approach. Notably, through a SWOT matrix, we mainly revealed positive experiences of participants cocreating nursing technological innovations, with several strengths and opportunities. Participants’ experiences can be described in 3 themes: enhanced attractiveness of the nursing profession, feeling involved due to a cocreation environment, and experienced benefits and challenges in using cocreated products. The findings indicate that participants found the nursing technological innovations easily applicable in nursing practice due to their user-friendly design, the ability to enhance nursing efficiency, patient safety, and time-saving potential during nursing work. A collaborative culture may lead to higher work satisfaction among nurses, inspire cocreation, and promote nursing pride.

Comparison With Prior Work

This study shows how cocreating nursing technological innovations positively impacts the attractiveness of the nursing profession. The attractiveness of the nursing profession was enhanced by nurses finding joy in their roles, feeling a sense of pride, and being taken seriously in their work. This aligns with findings from a cross-sectional study, which emphasizes the significance of decision-making involvement in health care services, such as equipment, technologies, and processes for employment preferences of nursing students [31]. In addition, it aligns with a systematic review indicating that an increase in career opportunities and challenges positively impacts nurse retention. It reduces nurses’ desire to leave a particular workplace [32].

Furthermore, this study emphasizes several collaboration advances due to a cocreation environment within the organization, such as clear communication and teamwork among nurses, designers, and technically oriented students. Moreover, a cocreation environment within the organization contributed to knowledge exchange, product distribution, and external production. An in-depth case study [14] reinforced the importance of an innovative environment within the organization. It could increase the diffusion of nurse-led innovations within and outside the organization. Particularly, managers seem to have an important role in collaborating and communicating with each other about innovations and supporting working methods in nursing departments. Existing literature [33,34] reinforces the notion that supportive leadership is crucial for fostering a culture of innovation and enhancing the sustainability and impact of health care innovation settings.

In addition, this study shows that innovations cocreated with nurses led to multiple benefits for nursing practice. Cocreated nursing technological innovations were described as user-friendly, highly practical, and easy to integrate into nursing tasks, consistent with findings from a quasi-experimental study [35]. In this quasi-experimental study, trained innovative nurses were able to identify issues in nursing practice and apply creative thinking strategies to create innovative products that matched their nursing work routines. Furthermore, the cocreated nursing technological innovations met nursing quality requirements and reduced the need for improvised solutions, thereby minimizing inconvenient situations in nursing practice. Patient safety was also enhanced by the cocreated products, which prevented issues such as infusion line entanglement and reduced the risk of wound contamination. The incubator traffic light is an example from the literature of a cocreated nursing technological innovation that meets quality standards and enhances patient safety. The incubator traffic light features a visual feedback system for neonatal incubators designed to enhance hand hygiene compliance [1,2]. Incubators with the incubator traffic light visual feedback system demonstrated significantly higher compliance with the correct drying times compared to those without this feature. This could potentially enhance patient safety by reducing infection rates in neonatal intensive care units [1]. Although the cocreated nursing technological innovations offered several advantages, the study also encountered certain challenges in their use, for example, flaws in the design of the innovations, which hindered their effectiveness or ability to make changes in the nursing routines. This study shows that changes in nursing processes may increase the risk of reverting to old routines, which aligns with findings from a cross-sectional survey that indicated how changes in nursing work processes could influence established work habits [36].

While this study did not include patients or parents directly, the participants acknowledged the significance of their perspective during the innovation process. It was mentioned that some of the cocreated innovations were developed in collaboration with patients and parents, resulting in innovations aligning with their expectations and needs. This is consistent with existing literature, where patients, family caregivers, and clinicians cocreated a mobile health app for heart failure self-management tailored to the specific health care context [37]. Furthermore, it matches with a qualitative co-design article including family, physicians, researchers, patients, and industry partners. The study revealed important differences between the participants’ preference for functional requirements of a mobile health app [38].

Limitations

Limitations of the study include its single-site focus on a specific academic hospital and limited transferability to other health

XSL•FO
RenderX

care settings [19]. Furthermore, there may be a sampling bias, as interested individuals were required to actively contact the investigator via email to participate in this study. These individuals might have been more likely than other professionals to embrace the innovations and encourage their adoption within their teams. In addition, all the participants scored themselves above average on the adoption rate scale (Table 3), and 10 (67%) of the 15 participants considered themselves to be "innovators" [25]. Literature shows that only 2.5% of the population belongs to the group of innovators [25]. This suggests a potential bias in the participant group. Including nurses as cocreators may have introduced selection bias, as their enthusiasm and assertiveness toward innovations may have influenced the results in a more positive manner [39]. Finally, the sample size consisted of 6 (40%) nurses as cocreators, 5 (33%) nurses as end users, and 4 (27%) managers. The limited insights from the managers' perspective may affect the comprehensiveness of the findings in the study [19].

Implications and Further Research

The findings of this study suggest several implications. Health care organizations could consider adopting the bottom-up cocreation approach with nurses as it has the potential to enhance nurses' work satisfaction, a sense of pride among nurses, and adoptable nursing technological innovations in nursing care. Furthermore, cocreation can contribute to accessible collaborations between stakeholders inside and outside the organization. In addition, cocreation with nurses has the potential to facilitate the development of innovations that enhance the efficiency of nursing work. Simple, professional, and time-saving innovations created through this approach could improve nursing practices.

Further research is recommended to explore the impact of the bottom-up cocreation approach and the resulting nursing technological innovations in other health care centers, aiming to improve the transferability of this way of working. Moreover, to better address patients' expectations and needs during the cocreation process and resulting innovations, further research is recommended to investigate their experiences throughout the cocreation process and its outcomes.

Conclusions

This study highlights substantial positive experiences of cocreating nursing technological innovations in nursing care. The findings underscore that cocreation with nurses enhances the appeal of the nursing profession. Participants perceived cocreation as enjoyable, leading to heightened work satisfaction and a sense of pride in their nursing role. Moreover, cocreation with nurses fosters the development of nursing technological innovations that align with nursing practice challenges, thereby facilitating their adoption within nursing care. Ultimately, embracing a culture of cocreation has the potential to foster ongoing improvements and innovations in nursing care, further contributing to the professionalization of the field.

Acknowledgments

The authors extend their appreciation to Myrthe van der Zanden, MSc, nursing scientist, for reviewing the interview guide and participating in the pilot interview.

Data Availability

The datasets generated or analyzed during this study are not publicly available due the participants involved in this research did not authorize the public dissemination of their data through written consent.

Authors' Contributions

SvS contributed to conceptualization, writing the original draft, data curation, formal analysis, investigation, methodology, project administration, and visualization. OH contributed to recruitment, conceptualization, reviewing and editing the manuscript, formal analysis, investigation, methodology, project administration, and supervision. HSMK contributed to conceptualization, methodology, and reviewing and editing the manuscript. TvH contributed to conceptualization, reviewing and editing the manuscript, data curation, formal analysis, investigation, methodology, project administration, and supervision.

Conflicts of Interest

None declared.

Abstract

Background: Subjective report of pain remains the gold standard for assessing symptoms in patients with chronic pain and their response to analgesics. This subjectivity underscores the importance of understanding patients' personal narratives, as they offer an accurate representation of the illness experience.

Objective: In this pilot study involving 20 patients with chronic low back pain (CLBP), we applied emerging tools from natural language processing (NLP) to derive quantitative measures that captured patients' pain narratives.

Methods: Patients' narratives were collected during recorded semistructured interviews in which they spoke about their lives in general and their experiences with CLBP. Given that NLP is a novel approach in this field, our goal was to demonstrate its ability to extract measures that relate to commonly used tools, such as validated pain questionnaires and rating scales, including the numerical rating scale and visual analog scale.

Results: First, we showed that patients' utterances were significantly closer in semantic space to anchor sentences derived from validated pain questionnaires than to their antithetical counterparts. Furthermore, we found that the semantic distances between patients' utterances and anchor sentences related to quality of life were strongly correlated with reported CLBP intensity on the numerical rating and visual analog scales. Consistently, we observed significant differences between individuals with low and high pain levels.

Conclusions: Although our small sample size limits the generalizability of these findings, the results provide preliminary evidence that NLP can be used to quantify the subjective experience of chronic pain and may hold promise for clinical applications.

chronic pain; pain narratives; natural language processing; semantic distance; digital phenotyping

Introduction

The most recent 2020 International Association for the Study of Pain definition of pain emphasizes that pain is "always a personal experience" and is distinct from nociception, involving learning "through life experiences." In line with this definition, the biopsychosocial model of pain [1] also stresses that pain is "a personal experience emerging from the dynamic interplay between biological, psychological, and social factors." Despite this modern understanding, the everyday clinical approach to

XSL•FO
RenderX

pain still predominantly focuses on its location or injury-related causes, while monitoring pain primarily through subjective reports [2]. The "injury model" approach is incomplete, as it overlooks the affective and personal dimensions of the pain experience, which can have a significant negative impact on treatment response and long-term outcomes [3-5].

Chronic low back pain (CLBP), the most common chronic pain condition, is a typical example of the inadequacy of the "injury model" in explaining the origin of pain, the long-term outcomes, or response to treatment [5-7]. In fact, considerable variability exists among patients with low back pain, yet the most common subdivision still relies on peripheral symptom assessment, such as back pain with and back pain without radiculopathy [8,9]. The lack of understanding of this variability makes generalizing results from clinical trials to clinical practice very challenging because the observed effects in a heterogeneous population of patients do not necessarily translate to individual patients with specific phenotypes [10]. Clinical approaches that are able to capture different aspects of the "personal experience" of back pain, without relying solely on the traditional medical examination, are therefore needed to improve precision in characterizing and, consequently, treating subgroups of patients [11,12]. Experts agree that the absence of such approaches may be one of the reasons for the disappointingly poor outcomes of clinical trials for chronic pain conditions [13,14]. In addition, if these markers are affordable and easily implemented in a clinical setting, they could help generalize research results to clinical practice [13].

To date, there are no automated, quantitative tools that can both reliably assess patients with chronic pain [15] and provide clinicians with timely, clinically useful information about their pain experience. Rather, patients rely on verbal and nonverbal communication to convey their complaints. In everyday clinical practice, tools such as the numerical rating scale (NRS, 0-10), or self-administered pain questionnaires, including the McGill Pain Questionnaire (MPQ) [16] or the Patient-Reported Outcomes Measurement Information System (PROMIS) instruments, may be used. However, their utility is limited by the time constraints of busy clinical settings and by the restricted scope of information they provide. For example, an NRS rating of 4/10 does not capture the differences in the pain experience between a patient with low back pain and one with knee osteoarthritis. Therefore, patients rely on language to convey these differences to clinicians.

The language patients use can provide a valuable window into their personal experience of pain and the emotions associated with living with it. The recent advent of large language models (LLMs), which can analyze human-generated texts, offers a unique opportunity to probe the different dimensions of the chronic pain experience. Quantitative approaches of this kind are now beginning to emerge. LLMs have been applied to the analysis of clinical notes [17,18] and patients' pain narratives [19-21]. For example, one study on patients with CLBP [20] investigated the language features that distinguished between responders and nonresponders to placebo treatment using a posttreatment interview. Another study analyzed written narratives obtained from patients with fibromyalgia and found significant agreement between LLM-based assessments and those of expert clinicians, supporting the use of LLM in the clinical evaluation of patients with pain.

Here, we used patients' personal "pain stories" obtained during recorded interviews, along with natural language processing (NLP) tools, to derive quantitative measures of their pain experiences. We aimed to provide evidence that NLP can be used to analyze patients subjective accounts of their personal pain experiences and that the derived linguistic features are directly related to core phenotyping domains assessed using measures recommended by the Initiative on Methods, Measurement, and Pain Assessment in Clinical Trials (IMMPACT) and the National Institutes of Health minimal dataset for CLBP [13,22].

The interviews can be conducted in both clinical and nonclinical settings, and they are relatively inexpensive to obtain, thereby increasing accessibility for a broader patient population. The "pain story" is elicited through open-ended questions by a laboratory member without formal clinical training. It aims to capture not only a description of the physical symptoms but also how pain affects the patient's functionality, interactions with others, and overall life trajectory and meaning. This rich dataset expands upon the information typically collected during clinical encounters, which are often constrained by time.

NLP is a novel approach for identifying or distinguishing patients with various psychiatric disorders, such as major depression or psychosis, where standard diagnosis relies on subjective reports of symptoms and the impression of clinical experts [23]. It involves a set of tools built using an extensive corpus of language available on the World Wide Web and machine learning methods to determine the various aspects (eg, meaning and emotion expressed) of words and sentences used in a text by situating them in the multidimensional linguistic space. NLP has been successfully used to distinguish patients with various mental health and neurological conditions [24-27].

Methods

Participants

This study was not registered before data collection. Data were collected between December 15, 2022, and June 8, 2023. A total of 514 individuals responded to advertisements posted on social media and flyers distributed within the Rochester community. Of these individuals, 21 patients with CLBP were recruited for this study between February and June of 2023; however, 1 patient did not show up for the testing session.

Patients were first screened over the phone. To be included, they had to be aged ≥40 years; this cutoff was chosen because the prevalence of low back pain is highest in individuals aged 40 to 80 years [28]. Patients had experienced low back pain for more than 1 year below the thoracic T10 vertebra [12], with an average pain intensity greater than 4/10 on the NRS. CLBP must be the primary pain condition. At screening, patients completed the Telephone Interview for Cognitive Status (TICS) [29] and were excluded if their TICS score was less than 33. We used TICS as a screening tool to avoid bringing patients to the laboratory who might have cognitive impairments that were not detected during the screening phone call. Patients were also

XSL•FO
RenderX

excluded if they had a history of other significant pain conditions, such as fibromyalgia or migraine headaches; chronic unstable medical conditions affecting any bodily organ system; a history of traumatic brain injury; substance misuse; or mental illness. All patients, except 1, reported less than mild depression symptoms on the Montgomery-Asberg Depression Rating Scale (score <19) [30]. Patients were either opioid-naive or had not taken opioids for more than 2 weeks in the previous year. Table 1 presents the clinical and demographic characteristics of the CLBP sample; additional demographic and clinical characteristics are provided in Table S1 in Multimedia Appendix 1.

Table 1. Demographic and clinical characteristics (N=20, 10 males and 10 females).

Measure	Values, mean (SEM)
Age at screening (y)	58.3 (2.4)
BMI (kg/m^2)	29.9 (2.1)
Years of education	14.9 (0.6)
NRS[a] pain	4.0 (0.7)
VAS[b] pain	35.1 (6.1)
MPQ[c] total score	13.2 (2.8)
MPQ sensory score	11.1 (2.1)
MPQ affective score	2.2 (0.8)
PCS[d]	11.6 (4.1)
PDQ[e]	4.2 (2.1)
CSI[f]	33.9 (5.3)
VAS depression	16.1 (5.8)
MADRS-S[g]	7.9 (1.9)
HADS[h]-depression	4.4 (1.4)
HADS-anxiety	6.2 (1.2)
RMDQ[i]	8.9 (1.5)
TICS[j]	39.0 (1.0)
NEO[k] personality inventory	200.1 (7.1)

[a]NRS: numerical rating scale.
[b]VAS: visual analog scale.
[c]MPQ: McGill Pain Questionnaire.
[d]PCS: Pain Catastrophizing Scale.
[e]PDQ: PainDETECT Questionnaire.
[f]CSI: central sensitization inventory.
[g]MADRS-S: Montgomery-Asberg Depression Rating Scale–Self-Report.
[h]HADS: Hospital Anxiety and Depression Scale.
[i]RMDQ: Roland-Morris Disability Questionnaire.
[j]TICS: telephone interview cognitive status.
[k]NEO: neuroticism, extraversion, and openness.

Ethical Considerations

All participants provided written informed consent, and the study was approved by the University of Rochester Medical Center Institutional Review Board (00007633). Data protection was ensured using several layers of security in accordance with the Health Insurance Portability and Accountability Act and under the oversight of the University of Rochester Institutional Review Board . Participants were instructed not to mention their names during the interview, and their data were deidentified. All computer-based materials and data, including voice and video recordings, were stored in a password-protected server managed by the University of Rochester IT Department and protected by the university firewall. All clinical and demographic data were entered directly by the participants into the REDCap (Research Electronic Data Capture; Vanderbilt University), where the code numbers were associated with the data records. REDCap is a free, Health Insurance Portability and Accountability Act–compliant web-based application used for the electronic management of research data.

Data Collection

Interview

On the day of the interview, after obtaining consent, participants provided a urine sample to screen for drugs of abuse using a NexScreen LLC drug screen cup. Drug screening was performed because drugs of abuse are known to alter pain perception [31,32] and language output [33,34], and misuse was one of our exclusion criteria. Next, the research coordinator reviewed the inclusion and exclusion criteria with the participants and explained the study procedures. Interviews were conducted via Zoom (Zoom Video Communications, Inc) to capture voice recordings on separate channels for the patient and the interviewer. Patients were seated in front of an iPad in a quiet room, while the coordinator was in an adjacent room. All patients were interviewed in the same room by the same female coordinator (AT), with a male laboratory member present in the coordinator's room during the interviews. We included both male and female examiners during the interview to minimize bias in the patients' responses related to sex. Although this bias has not yet been examined in the context of language-based studies, in other pain-testing contexts, the sex of the examiner has been shown to influence pain-related outcomes [35-37].

The interview questions, provided in Table S2 in Multimedia Appendix 1, served as a guide for the interviewer. The questions were piloted by AT, JG, and PG during the mock interviews. PG is a trained psychiatrist with extensive experience in interviewing patients in clinical settings. However, the interviewer did not have to adhere strictly to the interview questions and asked patients open-ended questions to elicit a subjective, patient-centered narrative of pain. As shown in Table S2 in Multimedia Appendix 1, the questions were inspired by previous NLP work in chronic pain [20] and by the general biopsychosocial model of chronic pain [1].
