Abstract

Background: Access to safe abortion care is a reproductive right for all individuals across Canada. Underserved populations are overrepresented among those with unintended pregnancies and particularly those seeking abortion. Yet, few resources exist to help health care and allied helping professionals provide culturally competent and gender-affirming abortion care to such a population group.

Objective: This project aimed to redesign and adapt an existing subscription-based medication abortion mentorship platform into a culturally appropriate and gender-affirming open-access website of curated health professional resources to promote equitable, accessible, high-quality abortion care, particularly for underserved populations.

Methods: We drew on a user-centered design framework to redesign the web platform in 5 iterative phases. Health care and allied helping professionals were engaged in each stage of the development process including the initial design of the platform, curation of the resources, review of the content, and evaluation of the wireframes and the end product.

Results: This project resulted in an open-access bilingual (English and French) web-based platform containing comprehensive information and resources on abortion care for health care providers (physicians, nurse practitioners, and pharmacists) and allied helping professionals (midwives, medical officers, community workers, and social workers). The website incorporated information on clinical, logistical, and administrative guidance, including culturally competent and gender-affirming toolkits that could equip health care professionals with the requisite knowledge to provide abortion care for underserved populations.

Conclusions: This platform contains resources that can increase the competencies of health care professionals to initiate and sustain culturally and contextually appropriate abortion care for underserved groups while clarifying myths and misconceptions that often militate against initiating abortion. Our resource also has the potential to support equitable access to high-quality abortion care, particularly for those among underserved populations who may have the greatest unmet need for abortion services yet face the greatest barriers to accessing care.

Introduction

Access to abortion is a fundamental human right and a critical component of sexual and reproductive health care [1]. Each year, approximately 56 million abortions occur across the globe—translating to 35 abortions per 1000 women. In Canada, nearly half (~40%) of pregnancies are unplanned, and one-third of women and pregnancy-capable people will have at least 1 abortion in their lifetime [2,3]. Medication abortion using mifepristone is the international gold standard for first-trimester medication abortions and currently accounts for over 50% of all abortions in most European countries and the United States. Canada's unique regulations allow nonphysician prescribers to prescribe and dispense the medication and allow people without

access to ultrasound to access medication abortion services. Despite the loosening of restrictions in Canada, timely access to safe abortion services can be difficult for historically, persistently, or systemically marginalized (HPSM) populations including racialized groups, migrants, Indigenous people, people with disabilities, homeless and underhoused people, sex workers, two-spirit, lesbian, gay, bisexual, transgender, queer, intersex, and gender-diverse (2SLGBTQI+) people, youths, and people living in rural and remote areas [4,5]. For instance, Indigenous people in Canada experience more abortion access barriers than non-Indigenous Canadian people [6]. In addition, approximately 18% of people in Canada traveled more than 100 km to access abortion services [7]. While most clinicians in Canada indicated providing abortion services to underserved populations, the majority of them did not have the appropriate cultural training to provide care to underserved populations. For instance, a recent study suggests that most clinicians in Canada who provide abortion services to underserved populations (91.2%) reported not receiving any form of training for providing care to such populations [8]. A lack of training or mentorship in culturally safe and gender-affirming care would further exacerbate barriers to accessing abortion services that already bedevil underserved populations including Indigenous people [9,10].

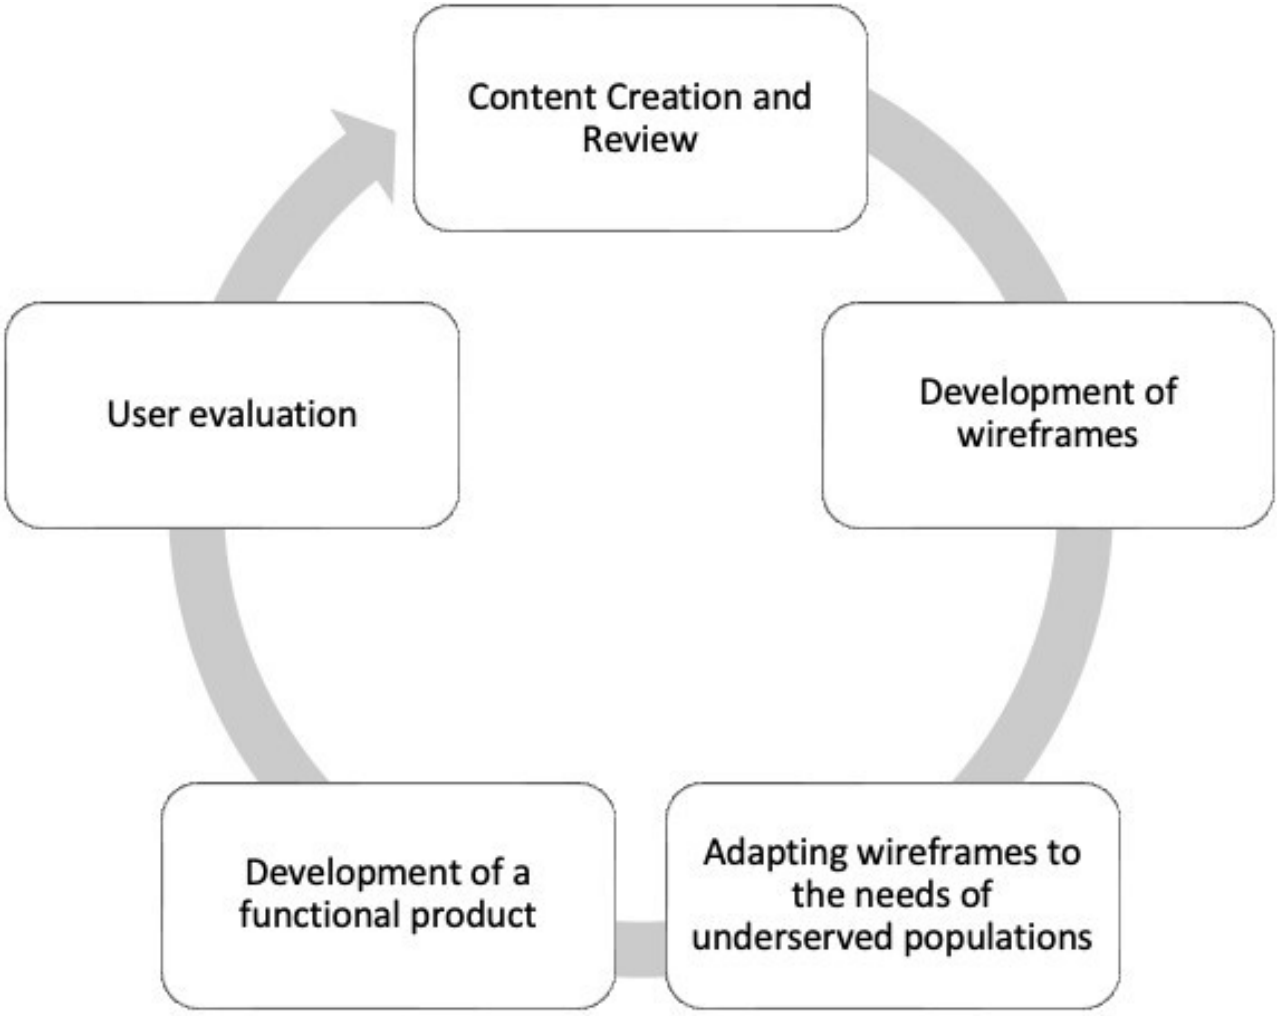
To provide culturally safe and gender-affirming abortion services, there is an urgent need to develop, evaluate, and implement training and mentorship resources that will equip health care professionals in providing equitable abortion services to underserved populations in Canada. In this paper, we reported on the processes we adopted in redesigning our already-established web-based community of practice platform into an open-access website. We also highlighted on the considerations for developing a gender-affirming, culturally appropriate, and inclusive web platform to support health professionals in providing abortion to equity-deserving populations. With the internet increasingly becoming a major source of information on abortion [11], an open-access web platform could not only help in disseminating evidence-based abortion resources to all health care professionals but also help in dispelling the myths and misconceptions that often fuel abortion-related stigmas. Furthermore, an open-access web platform could assist in countering abortion-related misinformation or disinformation that is often targeted at health professionals by antichoice groups.

Methods

Study Design

We used a mixed methods user-centered design approach in developing the content and structure of the website [12]. In compliance with the user-centered design process, we engaged with the relevant stakeholders in Canada (health professional associations and abortion advocacy organizations) in 5 iterative design phases. The five phases include (1) content creation and review, (2) development of wireframes, (3) adaptation of wireframes to end-user needs, (4) development of a functional product, and (5) user evaluation. We adopted a user-centered design process to emphasize the clinician-centeredness of the website while revealing the knowledge gaps that need to be addressed to create an inclusive web platform. Figure 1 shows a schematic presentation of the website's development process.

Figure 1. A schematic depiction of the website development process.



Ethical Considerations

This project was approved by the University of British Columbia Behavioral Research Ethics Board (approval H22-03342). All participants who took part in the interviews were provided with CAD $150 (US $103.34) honoraria.

Phase 1: Content Creation and Review

Overview

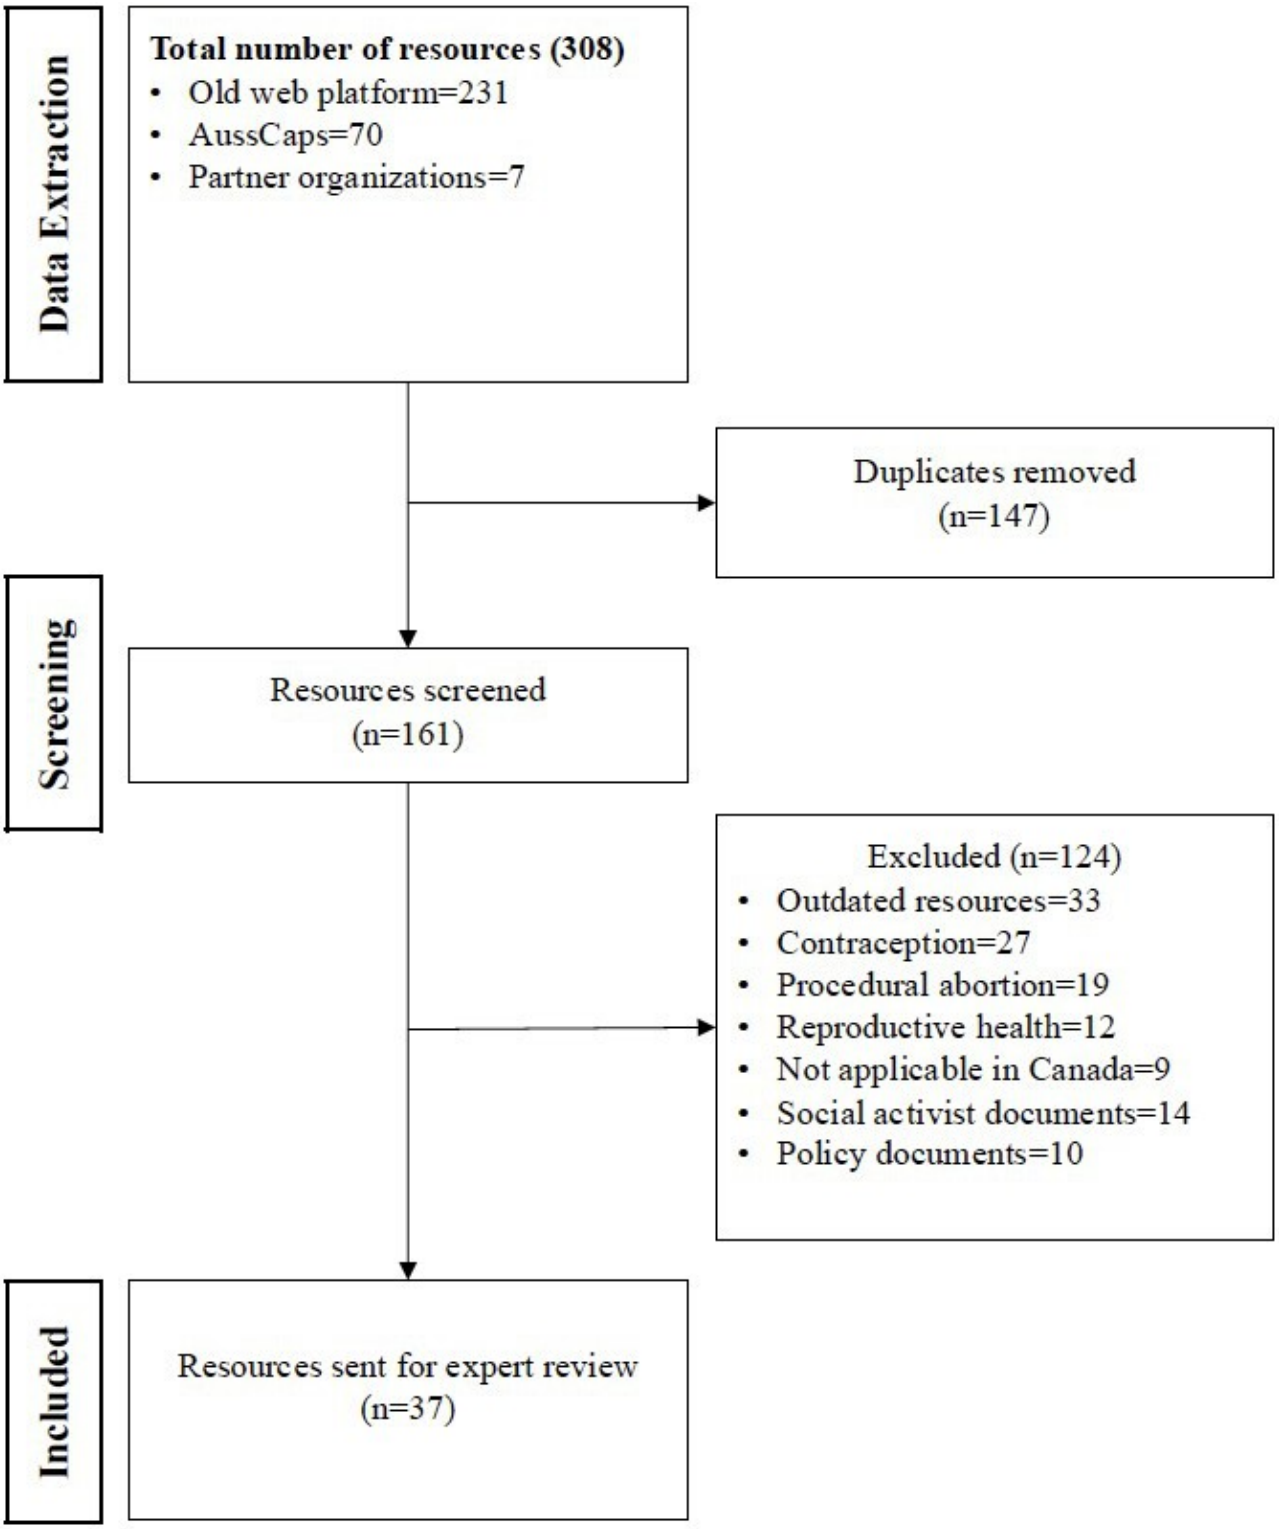
The content creation phase comprised 2 steps to ensure that the content is up-to-date and reliable. These include (1) the content curation process, in which we searched for resources that are relevant to medication abortion, and (2) the content review process.

Content Curation

We actively engaged with health professional associations, health regulatory agencies, and sexual and reproductive health advocacy organizations across Canada to curate relevant content for the website. To ensure high-quality, appropriate, evidence-based materials specific to Canadian health care professionals, we focused our content curation efforts on sources within Canada as well as trusted and reliable international evidence on medication abortion. The main sources for curating our content include the national health professional organizations (Society of Obstetricians and Gynaecologists of Canada, Canadian Pharmacy Association, Canadian Association of Midwives, and Canadian Association of Schools of Nursing) and advocacy groups (Action Canada for Sexual Health and Rights and National Abortion Federation) as well as our already-established web-based community of practice platform [13]. We examined relevant resources from a partner website in Australia (the Australian Contraception and Abortion Primary Care Practitioner Support Network) [14]. We limited our focus to medication abortion to enhance relevance and usability for clinicians looking to adopt, improve, and sustain the practice of this newly available service in Canada. After identifying the data sources and establishing a working relationship with stakeholders, we undertook focused data extraction from May 2023 to November 2023. The data extraction process yielded a total of 308 documents detailing resources on medication abortion. These were compiled into a Microsoft Excel sheet, and 147 duplicates were removed. Following this, we conducted an initial screening of the resources by examining the titles, abstracts, headings, and subheadings to determine their relevance to medication abortion. To be eligible for inclusion, each resource must be focused on medication abortion services including clinical (guidelines, protocols, checklists, and factsheets) and nonclinical services (financial, legal, and social). Since our objective was to improve equitable access to abortion among underserved populations, medication abortion resources

focusing on Indigenous populations, racialized groups, and gender minorities were included. Resources were excluded if they were dated more than 20 years ago, not relevant to the Canadian context, beyond the scope of medication abortion, or not targeted to health care providers (ie, physicians, pharmacists, social workers, and midwives). Most papers were not relevant to the Canadian context because of the constant regulatory changes regarding the prescription, dispensing, and use of medication abortion in Canada since 2017 [15-17]. We also excluded resources that were exclusively focused on procedural abortion, contraception, or general reproductive health or illnesses. Procedural abortion resources were excluded because procedural abortion demands specialized training, and we considered a web platform as an inappropriate training source for those seeking to provide this skilled task. After screening the resources against the inclusion and exclusion criteria, 124 resources were excluded, leaving us with 37 resources for a detailed expert review. Figure 2 shows the data extraction and review process.

Figure 2. Resource extraction and screening process.



Content Review

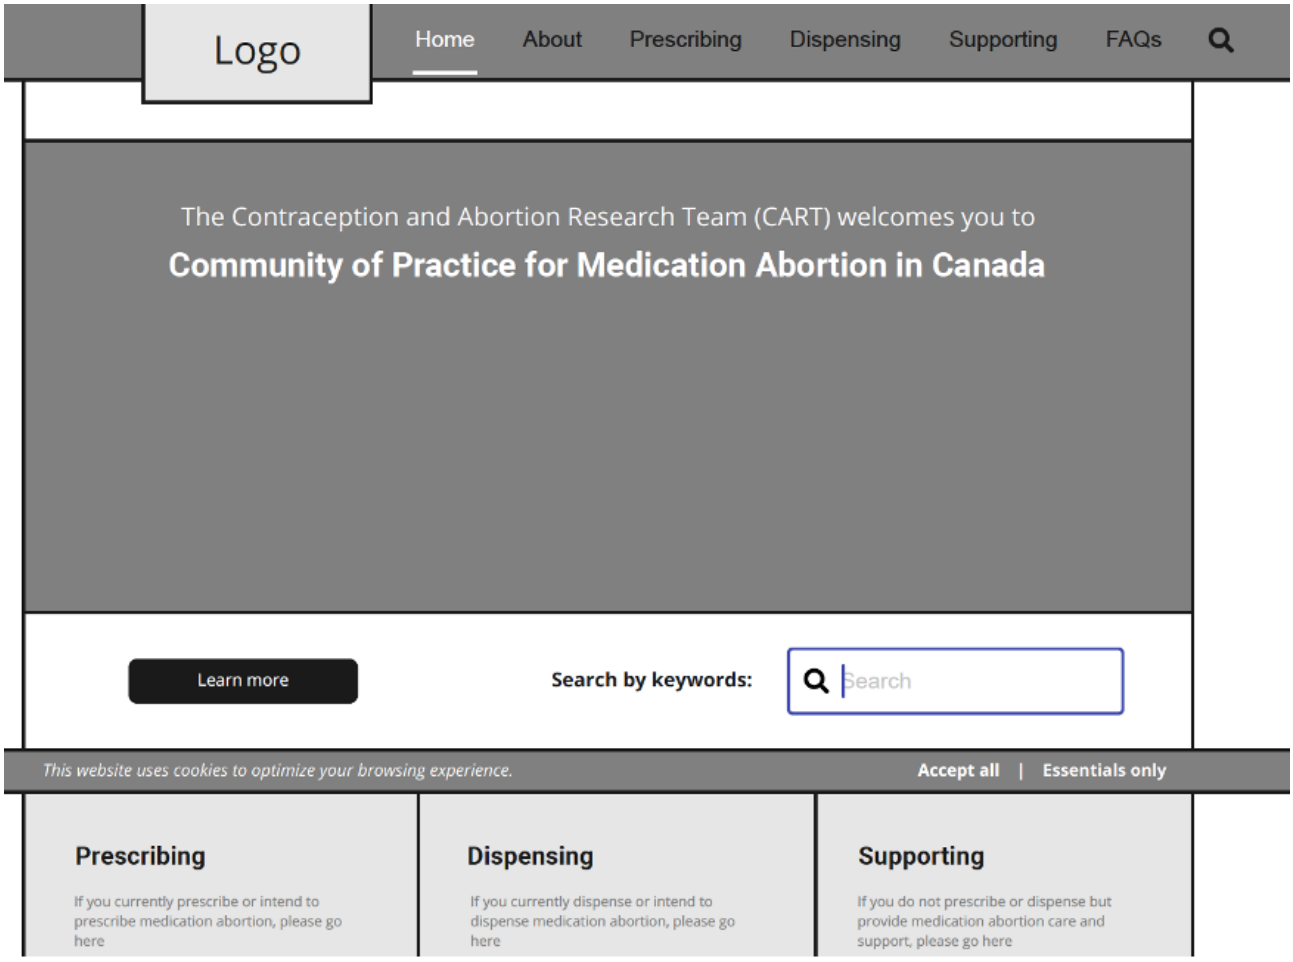
Even though the resources were extracted from credible sources, medication abortion regulations and professional practice guidelines in Canada have evolved over time, and with these changes, some of the resources might have become outdated. To ensure our website contains up-to-date resources and is in line with current practices, we engaged 10 health care and allied helping professionals providing abortion services to review the 37 resources for accuracy, currency, and relevance for providing medication abortion, particularly for equity-deserving populations. These health care professionals include physicians, nurse practitioners, pharmacists, and midwives. We asked each health care professional to review each document and respond to the following questions: (1) How do you think this resource will be relevant or useful for you to initiate or strengthen your medication abortion services and why? (2) Please indicate specific parts that you feel are most useful for your practice. (3) Please indicate specific parts that you think are out of date, not useful, or contradict your current practice.

All reviewers provided their feedback within 1 month, and all feedback was compiled into a single document. Following the review, we then engaged 2 experts in abortion care (a family physician and an obstetrician and gynecologist) to discuss and reconcile any differences or contradictory comments by the reviewers. The 2 expert reviewers resolved any differences and wrote a master document containing up-to-date resources on current medication abortion practices. The master file was organized into three main sections including (1) prescriber resources (how medication abortion works, preabortion medication evaluation, postabortion assessment, web-based and hybrid care, physician billing information, regulations, and inclusivity toolkit), (2) dispenser resources (coverage information, patient communication guidelines, checklist for dispensing abortion, and pre- and postabortion assessment), and (3) supporting resources (patient counseling before and after abortion and social worker support resources). This master document was used to inform the content of the website.

Phase 2: Development of Wireframes

Using a web-based design tool known as Figma (Figma Inc), we created wireframes of the website. A wireframe is a visual guide that shows a skeletal framework of a web interface [18]. The wireframe was designed to follow the format of the resources on the master file. The framework depicted the page layout and arrangement of content on the website including interface elements, navigational features, the range of functions to include, and the relative prioritization of content. This wireframe was reviewed by 3 experts in abortion care, and revisions were made regarding space allocation and content prioritization for each of the resource sections outlined in the master file. Following this review, the skeletal framework was then populated with the content from the master file. Figure 3 shows the wireframe of the website.

Figure 3. A screenshot of the wireframe.



Phase 3: Adapting the Wireframes to the Needs of Underserved Populations

After populating the skeletal framework with the revised content, we then conducted a focus group discussion with 14 health care professionals who currently provide, or intend to provide, medication abortion in Canada. The essence of the focus group was to understand how the wireframe can be adapted to equip health care professionals to provide inclusive, gender-affirming, and culturally safe abortions to underserved populations in Canada. We also wanted to identify potential areas for improvement before moving on to developing a functioning website.

Before the start of each focus group, we distributed a visual layout of the website containing relevant content to all participants. The participants were asked to review the visual layouts ahead of the web-based meetings. During the focus group discussions, participants were asked about (1) how the

information on the wireframe could be adapted to support them in providing evidence-based, culturally safe, and accessible abortion services to HPSM populations and (2) any additional features, functionalities, and considerations for ensuring confidentiality, appropriateness, culturally affirmativeness, and supportive resources for improving access and quality of abortion seeking experience for HPSM populations.

The focus groups were led by author AFA, with assistance from RC. Each session lasted approximately 1 hour, and the data were transcribed verbatim. The data from this focus group were analyzed thematically, and the findings (reported under the Results section) were used to modify the Figma designs before moving on to developing a functional product. The findings from the focus groups helped to minimize the design flaws and reduce the possibilities for major changes once a product was eventually developed.

Phase 4: Development of a Functional Website

After making changes to the Figma design, we engaged our software engineers to translate the Figma design into a functioning website. To further explain the Figma design to the development team, we wrote a Systems Requirements Specification Document to further explain the Figma design to the development team. This document included a breakdown of the Figma designs into various components and specifying each design feature as contained in the guide [19]. Figure 4 shows the interface of the functional website. To make sure that the functional product reflects the Figma design and meets the knowledge needs of the end-user clinicians, the development team sought ongoing feedback from our team as well as from the health care professionals who reviewed the resources. We held biweekly consultation meetings with the software development team starting from August 2023 until we had a functional website in February 2024. In compliance with the user-centered design process, we evaluated the functional website with end-user clinicians.

Figure 4. The home page of the functional website.

Phase 5: User Evaluation

We conducted a user evaluation of the website using a think-aloud observation method with 26 health care professionals across Canada. A think-aloud observation is a user evaluation method, in which participants verbalize their thought processes as they interact with a system [20]. The purpose of the user evaluation was to determine the relevance and usefulness of the website in providing abortion services to equity-deserving and HSPM populations, understand the ease of use of the website, detect any design flaws, and make final changes before the website is launched. During the think-aloud observation, we provided participants with 5 tasks related to information retrieval on our website. As participants navigated the website, they verbalized their thought processes by commenting on aspects of the website that they found confusing, difficult to navigate, or irrelevant to their purpose. The think-aloud data were analyzed using simple content analysis. The findings (reported under the Results section) were used to revise the website.

Results

Overview

In this section, we focus on the findings from the focus group discussions of the wireframes as well as the user evaluation of the functional website. Overall, the health professionals who took part in the focus group discussions and the end-user evaluation acknowledged that our web platform was an important educational resource that would equip them with the necessary knowledge to provide abortion care. They also provided recommendations on how this web-based platform could be adapted to support them in providing inclusive abortion care to underserved populations.

Findings From the Focus Group Discussion

Overview

The participants expressed their satisfaction with the layout and the content displayed on the wireframes. They indicated that the various clinical guidelines, factsheets, and checklists on medication abortion would help demystify the myths and misconceptions associated with providing abortion. The usefulness of the resources in demystifying abortion provision was a very important feature considering participants' self-described limited understanding of medication abortion. While acknowledging the importance and potential usefulness of the wireframes, participants noted some limitations on the interfaces of the wireframes and suggested ways in which they could be adapted to improve the capacity of health care professionals to provide abortion services to equity-deserving and HPSM populations. These recommendations fell into 4 thematic areas.

Inclusive and Culturally Sensitive Content

Participants expressed the need for the website to contain inclusive and culturally sensitive language that has the least chance of causing harm to underserved populations including Indigenous, trans, and nonbinary people who seek abortion. To enable health professionals to provide inclusive abortion services to trans people, the participants suggested that the website should contain gender-neutral terms as well as handouts and factsheets on abortion and postabortion care in multiple languages. A physician who provides abortion stated:

> *A lot of my patients can speak English but there are instances [where] I get patients that cannot speak English properly. In such cases, it will be good to have some resources in their language that I can give out to them.*

Some of them also suggested having a print-out function to provide materials for patients who do not speak English. The participants also expressed the need for low bandwidth connectivity to enable health care providers in rural areas with poor internet access to access resources.

Indigenous and Gender-Diverse Resources

The participants also called for the inclusion of Indigenous and 2SLGBTQI+ resources on the website because they indicated that one of the groups facing the most barriers to accessing health services includes Indigenous groups and the 2SLGBTQI+ populations. This could be seen in one of the statements given by one of the participants:

> *it isn't just about understanding the clinical guidelines and factsheets. But we also need to understand the other aspects of Indigenous cultural safety when providing abortion to Indigenous patients like the relationship between abortion care and legacies of forced apprehension/the millennial scoop, information on the knowledge and risk of reproductive coercion (either for or against abortion) etc.*

These calls were particularly made by participants who provide services to Indigenous communities. Other participants indicated a need for a learning hub or short courses on Indigenous cultural safety, gender-affirming, and trauma-informed abortion care—arguing that these additional knowledge sources will help them to provide services to abortion seekers who experienced historical and intergenerational traumas.

Providing Resources for Noninsured Clients

The participants also indicated how the website could be a "one-stop shop" of information if they included information on how to support noninsured clients. This recommendation was made by a midwife who revealed the challenges of providing abortion services for noninsured clients such as undocumented migrants:

> *More than half of my clients were unhoused, or street-involved or living in extreme poverty, or they were refugees, recently landed immigrants, or people of color and trans communities. You know there is a significant intersection between such populations and those living in poverty so there needs to be some resources around how to make sure that these populations are also getting access to abortion services.*

Protecting the Privacy of Website Users and Abortion Seekers

The participants acknowledged the stigmatizing nature of abortion and the need to protect people's privacy. Thus, they suggested including a built-in exit button that would enable users to immediately exit the website, particularly in public places. They also indicated the need for the website to contain geolocation features that can map out nearby abortion providers and pharmacies outside of people's communities. One participant stated:

> *I provide services in a local community, and some don't feel comfortable seeking abortion services from me because I may probably know them. When this happens, it's difficult to refer because they won't even come to you. So, it will be good to have a feature on this platform where patients themselves can search for nearby abortion providers that they can approach with comfort.*

According to the participants, this will make visible nearby abortion providers that could serve as alternative sources for patients who may be reluctant to seek abortion services within

their (particularly very small) communities due to privacy concerns.

Findings From the User Evaluation

Overview

Iterative feedback from the focus group informed changes to the website, as participants serially identified gaps and problems to be addressed before it was launched. Some health care professionals indicated that the functional website felt too medical and was insufficiently focused on the social aspects of abortion. They perceived our banner image on the home page as overrepresenting physicians and not sufficiently acknowledging the role of midwives and supporting professionals. They also made recommendations on how the website could be adapted for navigability and to touch on the stories of underserved populations. The recommendations from the user evaluation fell into 3 thematic areas.

Portraying a Positive Image of Abortion via Visual Effects

Some health care professionals commented that the initial wireframes lacked a human touch and thus suggested adding more vibrant and bright colors that reflect the identities of diverse groups of health professionals and the diversity of patients. Participants felt that such adaptations could portray abortion as something that is considered normal for everyone to seek, normal for every health professional to provide or support, and to ensure the abortion-seeking experience is positive.

> *maybe some colors will be nice because I feel that when I am looking into abortion care, I just want to take this stigma away. So, having colors that are dark for me is like you are doing something bad, right? So maybe having some lighter colors and highlighting on socio-cultural aspects of abortion would be helpful. People need to feel that abortion is normal after going through this website.*

Connecting With Patients

Other health professionals explained that although the website targets health care professionals, it is ultimately about caring for people. They thus suggested that it would be great to have images of health care providers taking care of patients from diverse gender and racial backgrounds or better still include images of patients having children to remove the myth that people seeking abortion are irresponsible adults without children or families. One participant stated:

> *This website is about people getting care. So, we need to see how so many people who have pregnancy termination also have children already. So, it's not just like the unwed single woman who wants to terminate her pregnancy.*

The participants also expressed the need for the website to help health care professionals understand the patient populations most likely to seek abortion services from them. This way, the website would not only provide clinical information but also help providers to connect with the patients' stories.

Making Compromises Between Being Comprehensive and Practical

Many participants acknowledged the comprehensiveness of the website and were confident that they would be able to find relevant information should the need arise. They also acknowledged that being comprehensive might make the website a less suitable quick reference guide, particularly during clinician-patient encounters. This concern could be a challenge for high-volume providers and providers in rural and remote areas. One midwife stated:

> *the information that I'm seeing is actually really good. It's really good information, and I'm intrigued to read more about what's in here. But [it's] too much. It would be really good for like education and training, but not when you have a patient in front of you.*

While this theme was not specifically related to providing abortion to underserved populations, it highlighted the busy schedule of clinicians vis-à-vis looking for information in a dense and cluttered web platform.

Discussion

Principal Findings

In this study, we report on the cocreation of an open-access web-based abortion platform and highlight considerations for promoting access to abortion for underserved populations. This study followed an intersectionality study we conducted with end-user clinicians before embarking on the development of the website [21]. Our study incorporated rigorous engagement of end-user clinicians, and our user evaluation data demonstrated an accessible, acceptable website that could better equip health and allied helping professionals to provide equitable, culturally safe, and gender-affirming resources to equity-deserving and HSPM populations. It is important to note that many health professionals in Canada, including nurse practitioners and midwives, had not received any formal training on abortion as part of their education, leading to limited knowledge and general uncertainties in providing abortion [22]. The limited knowledge may lead to some hesitation in providing abortion, particularly for patients from underserved populations who present with complex health challenges. We believe that this mentorship platform will equip health professionals with the necessary knowledge to provide abortion to patients who face intersecting barriers to access services while also enhancing timely decision-making for health professionals in rural and remote areas. For a time-sensitive procedure such as abortion, expeditious decision-making is crucial to high-quality care for women and pregnancy-capable people who request abortion services.

In addition to information dissemination and helping with decision-making, an open-access abortion web platform may also serve to counter abortion-related misinformation and disinformation that are often targeted at health care professionals. This is important at a time when the proliferation of disinformation, together with the stigma and belief-based refusal to provide legal and appropriate abortion care, creates interpersonal tensions that make it difficult for some health

professionals to meet the reproductive needs of their patients [23,24]. Health professionals may further be disadvantaged when there are frequent changes in medication abortion guidelines and regulations [17]. These changes, together with the need for quality improvement, highlight the importance of such a web-based platform for updating the competencies of health care professionals who provide or intend to provide abortion. This is more relevant, as there is an increasing call for the timely integration of research evidence in routine clinical practice [25].

Our findings suggest that adopting a user-centered design in this project resulted in a platform that was largely considered by potential end-user clinicians as inclusive. While engaging stakeholders from diverse clinicians and organizations was quite challenging, we acknowledged that the process was essential to fulfill the principles of user-centered design. Our team believes that the active engagement of clinicians, health professional organizations, and abortion advocacy groups in cocreating this web-based platform enhanced the appropriateness of the content while facilitating clinician recruitment, dissemination, and subsequent uptake of the resource among end-user health care professionals.

It is also important to note that few digital health projects are designed from gender equity and Indigenous rights perspective [26]. In the context of abortion-related websites, intersectionality is particularly important, as it helps illuminate ways in which the website could be tailored to the needs of the population subgroups facing the most barriers in access to abortion (racialized groups, migrants, people with disabilities, homeless and underhoused people, sex workers, 2SLGBTQI+ people, Indigenous people, and youths) [21,27]. Indeed, available evidence suggests that such minority groups are overrepresented among those with unintended pregnancies and particularly among those seeking abortion [28-30]. Therefore, engaging with a group of health professionals who serve diverse populations in developing and evaluating our web platform made the website unique, as it cedes all decisions on the content and structure in the hands of the end-user clinicians who may have first-hand experience in providing services to underserved populations. This approach to developing our website supports the vision of “design justice” where the community owns the design artifacts [31]. By cocreating with health care professionals, we were able to generate website content that illuminates ways health care professionals can provide abortion services to underserved populations who present with complex, historical, and intersecting health challenges. This approach is more likely to lead to a seamless translation of the web platform into practice since the clinicians and partner organizations were more or less coowners of the end product.

Creating web platforms that are inclusive of equity-deserving and HSPM populations requires more than just technically sophisticated algorithms but a deep understanding of users’ needs and specific considerations that promote inequities in access to health care [32]. The inclusive design recommendations from the participants in this study were aimed at equipping health care professionals with the necessary tools to address inequities in access to abortion care. The integration of low-bandwidth connectivity for instance would improve accessibility of the resources to health professionals in rural and remote areas with low internet connectivity. Improved web access could help improve abortion access in rural and remote areas where medication abortion might be the only, or most accessible, option [33]. Furthermore, the recommendation for including geolocation services could help address abortion-related stigma and provide better privacy for abortion seekers in communities with conservative values around abortion. While the argument for geolocation features was seen as a way of helping patients easily locate abortion providers and pharmacists, some were concerned that geolocation services could be used by antichoice groups to target abortion providers. Additional security measures may be needed if geolocation features are to be implemented on abortion-related web platforms.

Limitations

Our study was not without limitations. Even though our objective was to design a web platform that supports health care professionals to provide equitable access to abortion for underserved populations, we did not rigorously engage abortion seekers the same way we engaged with clinicians. A future improvement would be to engage the patients’ voices in resource development to better reflect the peculiar needs of underserved populations. Our ultimate goal for this website is to empower health care professionals to provide equitable and inclusive abortion to underserved populations. However, we cannot ascertain if we have achieved that objective at the time of writing this paper. Future evaluation reports from users would tell us if the resources provided in this platform are indeed useful in providing abortion services to underserved populations. Furthermore, the participants made several recommendations in the focus group and the user evaluation that were not implemented mainly due to time and resource constraints. While we acknowledge this as a limitation, it is not uncommon to see such limitations in digital health projects, as it is practically impossible to implement all findings from user evaluation [34,35]. Finally, even though we planned to recruit health professionals who identify as or have expertise in providing abortion services to underserved populations (ie, racialized people, migrants, people with disabilities, homeless and underhoused people, sex workers, 2SLGBTQI+ people, and youths as well as those living in or providing abortion services in rural or remote areas), it was difficult to find health professionals who identify as or has expertise in all these diverse populations. Therefore, some phases were completed without adequate input from health professionals with expertise or experience in providing abortion services to underserved populations.

Conclusions

Drawing on a user-centered design approach, we cocreated a gender-affirming and culturally appropriate open-access mentorship platform with and for health care professionals to support the equitable provision of abortion in Canada. We believe that a platform of this nature would increase medication abortion awareness among health care professionals and destigmatize abortion care while clarifying the myths and misconceptions that often create tensions and foment general

uncertainties in initiating and sustaining abortion care. With underserved populations more likely to have unintended pregnancies than the general population [36,37], a website that specifically seeks to improve the competencies of health care professionals in providing abortion services to this population is important and timely. We believe that this platform has the potential to enhance the knowledge and expertise of health care professionals, particularly those in rural and remote areas on how to initiate and sustain abortion care for HPSM populations in Canada who face the most barriers in access to health services. This platform is also expected to provide the necessary resources needed to support health care professionals in providing evidence-based and culturally safe medication abortion for health care professionals in rural and remote areas.

Acknowledgments

The funding for this project was received from the Health Canada Sexual and Reproductive Health Fund under the Health Care Policy and Strategies Program. The authors would also like to acknowledge the Health Professional Association (ie, Society of Obstetricians and Gynaecologists of Canada, Canadian Pharmacy Association, Canadian Association of Midwives, and Canadian Association of Schools of Nursing), advocacy groups (Action Canada for Sexual Health and Rights and National Abortion Federation), and health care professional participants who provided diligent reviews of the resources.

Conflicts of Interest

None declared.

Abstract

Background: Assessing the daily lives of older adults, including their activities, social interactions, and well-being is essential, particularly in nursing homes, as it gains insights into their quality of life. Methods such as the Microsoft Excel-based Maastricht Electronic Daily Life Observation (MEDLO) tool are time-consuming and require extensive manual input, making them difficult to use.

Objective: This study aimed to develop an app-based version of the MEDLO using a user-centered design (UCD) and co-design approach to enhance efficiency and usability. We looked to actively involve researchers and care professionals who have used the MEDLO before, throughout the development process.

Methods: Participants included a diverse group of researchers and care professionals experienced in using the MEDLO tool. The UCD approach involved multiple iterative phases including semistructured interviews, user research sessions, and application development. Data were analyzed using a qualitative (thematic) approach of UCD and user research sessions. The app, which was preferred to the traditional Excel-based MEDLO, underwent multiple iterations. This method primed the continuous iterative development of the app, aimed for a minimum viable product (MVP).

Results: This study included 14 participants, primarily female, from diverse professional backgrounds. Their feedback highlighted the need for efficiency improvements in tool preparation and data management. Key improvements included automated data handling, an intuitive tablet interface, and functionalities such as randomization and offline data syncing.

Conclusions: The iterative development process led to an app that aligns with end-user needs, indicating potential for improved usability. Early and continuous user involvement was key in enhancing the application's usability, demonstrating the importance of user feedback in the development process.

Introduction

Assessing the daily lives of older adults, particularly in the context of nursing homes, is essential for gaining insights into quality of life [1,2]. It allows health care providers to detect and address issues related to their physical health (eg, mobility limitations, pain), mental well-being (eg, mood disturbances, cognitive decline), and social interactions (eg, isolation, engagement in activities) in a timely manner [1,3,4]. This information can then be used to personalize care plans, thereby potentially improving health outcomes and enhancing the overall quality of life of older adults [5,6].

Ecological momentary assessments (EMAs) have been developed to facilitate this process by providing real-time, on-site evaluations of an individual's well-being [5,7,8]. EMA involves collecting data on individuals' behaviors and experiences in their natural environments, which can then be used to identify patterns and inform interventions [7]. However, existing EMA tools are mainly used in research settings, and their implementation in clinical practice has been challenging due to the time-consuming nature of data collection and the complexity of the tools [9,10]. The Maastricht Electronic Daily Life Observation tool (MEDLO-tool) is designed to assess the daily lives of nursing home residents using EMA methodologies [1,4]. The tool captures real-time information across several key dimensions of daily life, including activity levels (eg, participation in communal or solitary activities), agitation, mood states, and interactions with staff, fellow residents, and visitors [1,4,11]. By systematically observing and recording these

aspects, the MEDLO-tool provides a nuanced view of residents' experiences, which can inform personalized care strategies [4]. However, the MEDLO-tool relies on Excel templates that require significant manual input and are not user-friendly for care professionals [1,4]. The complexity of the Excel-based system poses significant challenges, including data entry errors, time inefficiency, and barriers to widespread adoption in clinical settings [12,13]. This complexity can be particularly problematic in nursing homes, where staff may have limited time and technological proficiency [13].

Developing a mobile application for the MEDLO-tool could address these challenges by automating data collection processes, reducing manual input, and providing an intuitive interface for users [14,15]. An app could streamline observations, enable real-time data analysis, and facilitate immediate feedback to care providers, thereby enhancing the tool's use in clinical practice. Furthermore, considering the unique needs of residents with dementia, it is important that such an app is designed to account for cognitive impairments and communication difficulties [16,17]. The development of such an app requires a thorough understanding of the needs and preferences of the end-users. A user-centered design (UCD) approach is vital for developing software that truly meets users' needs [14,18]. UCD emphasizes involving users throughout the design process to ensure that the product aligns with their requirements and preferences [19]. This involves iterative cycles of user need assessment, design, prototyping, and testing [20].

Co-design, a component of UCD, involves direct collaboration between users and designers, requiring the active participation of users in generating ideas, making decisions, and solving problems [21,22]. This not only ensures the software's functionality but also its usability [21].

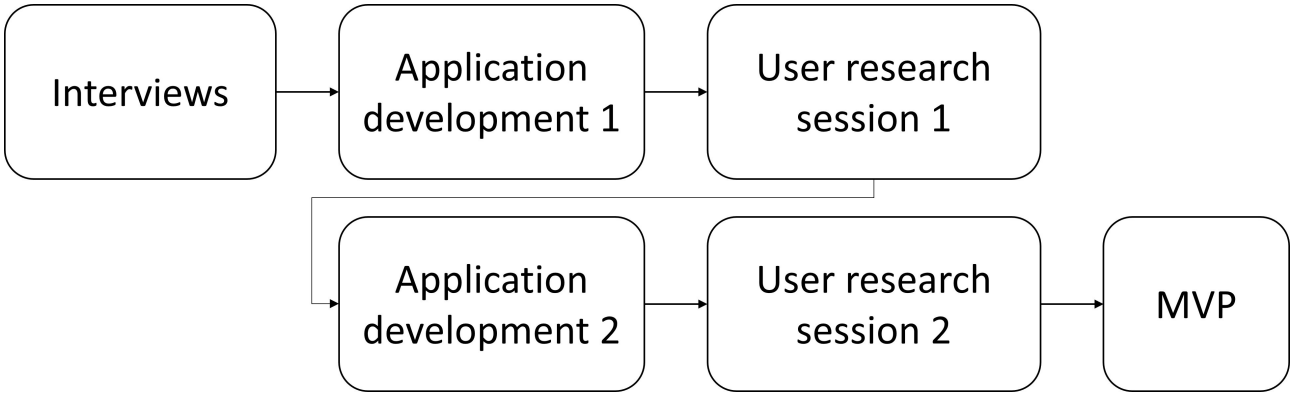
Potential barriers to implementing such technology include technological literacy among staff, user engagement, and ensuring data privacy and security [13,23]. By actively involving care professionals and stakeholders in the design process, we aim to create a tool that is both functional and user-friendly, facilitating its adoption in clinical practice and ultimately improving the quality of care for residents with dementia. Therefore, this study is aimed at developing an app for measuring the daily life of residents with dementia living in nursing homes, using a user-centered and co-design approach.

Methods

Study Design

This methodological study aimed to develop a mobile application version of the MEDLO-tool for use in long-term care facilities, using a UCD approach [24-26]. The study unfolded in multiple iterative phases, including semistructured interviews, user research sessions, application development, and comprehensive data analysis, as illustrated in Figure 1. The project culminated in the achievement of a minimum viable product (MVP).

Figure 1. The iterative process of app development. MVP: minimum viable product.



Participants

Participants were selected through purposive sampling to include individuals with experience using the MEDLO-tool. The sample consisted of researchers and health care professionals affiliated with Maastricht University and local nursing homes. Inclusion criteria were previous use of the MEDLO-tool and willingness to participate in the study. A total of 14 participants were recruited, comprising research assistants, PhD candidates, postdoctoral researchers, senior researchers, occupational therapists, research coordinators, and associate professors.

Data Collection

Data collection involved semistructured interviews and user research sessions conducted between January and June 2023.

Interviews

Semistructured interviews were guided by a comprehensive list of topics derived from available literature and consultation with the researchers who developed the original MEDLO-tool [1,4]. The interview guide can be found in Multimedia Appendix 1. The interviews aimed to gather insights into participants' experiences with the Excel-based MEDLO-tool, usability issues, functionality requirements, data analysis techniques, and general impressions [27]. Each interview lasted approximately 45 to 60 minutes and was audio-recorded with participants' consent. The audio was transcribed verbatim for analysis. The interview guide is provided in the supplementary materials.

The interview transcriptions were subjected to a 6-phase thematic analysis process, aligning with the methodologies supported by previous research [28-30]. The inductive analysis was conducted by one researcher. A second researcher reviewed

the coding to enhance trustworthiness. This comprehensive process involved familiarization with the data, generating initial codes, identifying themes, reviewing themes, defining and naming themes, and ultimately, reporting the results. The resulting report summarized the key findings, interpretations, and implications, to provide valuable insights for the next stages of the development of the app.

User Research Sessions

A total of 2 user research sessions were conducted monthly to involve participants in the iterative development process. The session guide can be found in Multimedia Appendix 2. Each session lasted approximately 2 hours and was held at Maastricht University. Participants interacted with app prototypes using tablets and smartphones provided by the research team. The sessions included guided tasks (eg, completing an observation using the app), open-ended discussions, and interactive feedback activities facilitated by researchers using prototypes and interactive demos. The structure of these sessions was informed by previous co-design methodologies [1,3,31].

Data Analysis

Qualitative Analysis of Interviews

Interview recordings were transcribed verbatim and analyzed using thematic analysis following Braun and Clarke's 6-phase approach [28]. A total of 2 researchers independently coded the transcripts to enhance reliability. Initial codes were generated and organized into potential themes. Discrepancies in coding were discussed and resolved through consensus meetings. Themes were reviewed and refined to ensure they accurately represented the data. The final themes captured key insights into the usability and functionality of the MEDLO-tool, informing the app development. The overall process of thematic analysis was guided by earlier works in this field [29,30]. The session guide is provided in Multimedia Appendix 1.

User Research Sessions

Each user research session included guided tasks (eg, completing an observation using the app), open-ended discussions, and interactive feedback activities facilitated by researchers using mock-ups and interactive demos. Feedback from user research sessions was documented through field notes and audio recordings. An inductive content analysis was conducted by one researcher, who coded feedback and categorized issues into 4 themes: layout, functionality, errors, and appearance. A second researcher reviewed the coding to enhance trustworthiness. This categorization allowed the development team to prioritize user concerns based on frequency and severity, ensuring a user-centric approach to app refinement.

Application Development

The application was developed using ".NET MAUI" (ie, a framework designed by Microsoft) for cross-platform compatibility on iOS and Android devices. The server-side (ie, where the data are sent to) used "ASP.NET Core" (ie, a framework designed by Microsoft) for a maintainable and performant application. The development process was iterative, with weekly meetings between developers and researchers to integrate user feedback from the interviews and user research sessions.

Usability testing involved participants completing specific tasks using the app prototypes while researchers observed and noted any issues. Testing sessions were conducted in a controlled environment to simulate actual usage conditions. Feedback from these tests informed further refinements and addressed potential adoption or feasibility issues.

Ethical Considerations

This study did not require formal ethics approval under the Medical Research Involving Human Subjects Act (WMO). In the Netherlands, research that collects only anonymized or nonsensitive feedback—without requiring participants to undergo procedures that affect their physical or psychological integrity—is not considered WMO research and is therefore exempt from ethics review. The guidelines provided by the Central Committee on Research Involving Human Subjects clarify that retrospective or noninvasive studies using aggregated or anonymized data do not fall under the scope of the WMO [32]. The Maastricht University Medical Center+ Research Code also confirms that studies conducted with minimal risk, such as those analyzing collective feedback, do not require formal ethical review. All participant feedback was anonymized and is presented in aggregate form to ensure confidentiality [33].

Results

Sample

The study involved 14 participants with an average age of 36 (SD 10; median 39; range 24 - 57) years, and 93% (13/14) of them were female. The participants represented a diverse range of professions, including research assistants (n=3), PhD candidates (n=4), postdoctoral researchers (n=2), a senior researcher (n=1), an occupational therapist (n=1), a research coordinator (n=1), an associate professor (n=1), and an individual who was currently unemployed. Most participants (9/14, 64%) were affiliated with Maastricht University, while others worked at health care providers (4/14, 29%) or were unemployed (1/14, 7%). The average duration of employment at their respective institutions was 6 (SD 5; median 6; range 0.5 - 16) years.

All 14 participants had previous experience with the MEDLO-tool; 12 (86%) participants had used it directly in their research, while 2 (14%) participants had used it as inspiration for developing other tools different from MEDLO. All participants had also been in contact with the developers of the MEDLO-tool. Table 1 presents the demographic information of the participants in detail.

Table . Demographic information of the participants.

Characteristic		Values
Age (years), mean (SD)		
	24 - 57	36 (7.7)
Gender, n (%)		
	Female	13 (93)
	Male	1 (7)
Time at institution, mean (SD)		
	6 months to 16 years	6 (3.3)
Use of the tool, n (%)		
	Used in research	12 (86)
	Inspiration for another tool	2 (14)
Contact with developers, n (%)		
	All participants	14 (100)
Participants' affiliations, n (%)		
	University	9 (64)
	Health care provider	4 (29)
	Unemployed	1 (7)

Interviews

The participants described the process of using the MEDLO-tool in research projects as comprising 7 distinct phases: (1) acquiring informed consent, (2) preparing the Excel sheets before the observation, (3) familiarizing themselves with the faces of the residents who would be observed, (4) conducting the observations, (5) fixing issues with the data (such as missing values or inconsistencies), (6) analyzing the data, and (7) communicating the data back to the care organizations.

Participants emphasized that the preparation of the tool and the subsequent data cleaning were particularly time-consuming and would significantly benefit from automation. One participant stated, "Every time before we do a new observation, we have to look at the participants, randomize them several times, and input all of this into the Excel sheet." Another participant highlighted the challenges faced after data collection, "After the observation is done, I have to go through the whole document to check all the fields that I didn't have time to fill out or that I didn't know how to rate." These comments reflect the manual and labor-intensive nature of the existing process, which participants found cumbersome.

Participants reported that during observations, they used separate pieces of paper to write down descriptions of each resident's appearance because the observation periods were too short to input this information into the Excel sheet in real time. They suggested that having an additional field to securely write this information directly on the tablet would make the process more accessible. One participant explained, "We usually arrive at least half an hour earlier, so we can ask the nurses which participant corresponds to which name, and write down what they look like. We do that to find them back more easily during the observation." Another participant elaborated on the logistical challenges, "The data entry process on the tablet is intuitive, but we also have to keep track of the patient names and descriptions on paper, we carry the manual, and we use a timer on our phone to ensure that we don't spend too long on any resident. This is a lot to carry around." Regarding data reporting, participants indicated that the data reported back to the nursing homes primarily consisted of quantitative measures, which could potentially be automated through a dashboard (eg, Microsoft PowerBI). Participants expressed that automating this process would reduce the time between data collection and reporting, which currently could be several months. One participant noted, "When we want to report back the numbers to the care organization, we make a PowerPoint presentation that includes aggregated numbers. This usually takes place several months after the observations." Another participant suggested: "I think some of the numbers could be reported back automatically."

Overall, participants preferred using a tablet compared to using pen and paper, citing the intuitive data entry process. However, they also mentioned that a tool compatible with smartphones would be beneficial, especially for care professionals who might find tablets less convenient. One participant remarked, "I think the tool works well, but I'm not sure if it would be usable like this for nurses."

Initial User Research Session

Based on the information gathered during the interviews and the suggested points for improvement, an initial version of the application was created and provided to the participants for the first user research session. This first draft of the application consisted of an dashboard web application and a mobile app, both of which included the core components but had limited functionality. Multimedia Appendix 3 shows the app and dashboard as they were presented to the participants. Multimedia

Appendix 4 provides a detailed overview the feedback received during the initial user research session.

During the initial user research session, participants expressed largely positive sentiments towards the concept of the application and appreciated the efforts made in its development. One participant commented, "I know we have a lot of complaints about the app, but we really appreciate the work [the development team] has done already." However, participants also identified several areas for improvement. They expressed concerns regarding certain features of the app, such as the timer functionality, which lacked a reset option. Participants noted that in their current practice, they used interval timers on their phones to manage observation times for each resident, and the app's timer did not adequately support this need. One participant suggested, "What could be nice is some kind of interval timer. That's what we currently use on our phones." In addition, participants missed the comprehensive overview provided by the Excel-based MEDLO-tool, as the prototype app had been designed primarily for phone screens and did not offer the same level of data visibility. One participant observed, "Normally, you could easily scroll back in the overview." Furthermore, there were some unclear aspects of the app, such as certain functionalities being available only through the dashboard and not within the app itself. Participants found labels on buttons to be unclear, which led to confusion during navigation. They recommended improving the screen layout for better usability and enabling easy switching between participants by a list.

Participants raised concerns about data storage and security, even though these aspects had been addressed in the app's design. They questioned how the data was stored and whether it was encrypted. It was explained to them that the data was stored on the device (ie, phone or tablet) in encrypted form and could be synced to a secure server. Regarding randomization, participants asked how it would be conducted within the app and where they could access this feature. It was clarified that randomization was performed automatically upon creating a new observation group. A participant inquired, "How do I randomize the participants in the app?" To which the response was, "That is done automatically when an observation group is added."

Participants inquired about features that had not yet been implemented but were planned for future updates. For example, they asked if the app would work offline, which was an important consideration for use in environments with limited internet connectivity. They also asked whether the data could be exported to Excel for further analysis. These features were already part of the application's development roadmap but were not yet available in the user interface at the time of the session. One participant expressed concern, "I don't know if it's an issue when I lose connection, or whether I lose my data." Another participant discussed data export capabilities, "These are the data you see when you download the Excel file. With Excel, it looks a bit different, but what you see here are all the column names."

Second User Research Session

Following the initial user research session, the app was updated to address the feedback received. Adjustments were made to the timer functionality, screen layout, language translation, and several other features as per the participants' suggestions. A second version of the application was then provided to the participants for the subsequent user research session. In Multimedia Appendix 5, the feedback received during the second user research session is detailed.

In the second session, participants expressed fewer concerns regarding the application, indicating that many of their initial issues had been resolved. However, they still provided valuable feedback on functionality and appearance. One of the main concerns was that the app was not yet fully translated into Dutch; while significant progress had been made, some parts remained in English. Participants emphasized the importance of complete translation before the app could be effectively used by nurses and other care professionals. One participant remarked, "Most of the app has been translated, but some of the texts are still only in English." Another participant added, "This all needs to be translated before we can hand this to nurses."

Participants also suggested that the criteria for showing and hiding fields during observations should be further refined based on relevance, to streamline the data entry process and reduce cognitive load. They discussed various small changes in the appearance of the app to enhance usability and visual appeal. For instance, they recommended that the "star" button used to mark important observations be made a different color to stand out more prominently. One participant suggested, "Could you make the star button orange to make it stand out a bit more?" In addition, participants found the criteria for marking an observation as "complete" to be somewhat confusing. They proposed that once an activity has been set for an observation, it should be automatically marked as complete to provide clearer feedback to the user. One participant explained, "I would prefer it if the observation could be marked as 'complete' when the activity has been set." Participants also recommended offering flexibility in the number of observation rounds that could be added, as different research protocols or care routines might require varying numbers of observations. They suggested making the process more efficient by creating a priority list or extending the default time block for certain observations that typically take longer. Furthermore, participants emphasized the importance of ensuring that the app's manual could be accessed from within the app itself. They stressed that the manual should be clear, comprehensive, and align with users' practical experiences to facilitate ease of use, especially for new users.

By the conclusion of the second user research session, participants expressed optimism about the app's potential to improve their workflow and reduce the time spent on manual data entry and processing. They acknowledged the responsiveness of the development team to their feedback and looked forward to future iterations of the app that would incorporate their latest suggestions.

Discussion

Principal Findings

This study successfully developed an app-based version of the MEDLO-tool aimed at assessing the daily life of residents with

dementia in nursing homes. By using a UCD approach, we incorporated feedback from participants throughout the development process, resulting in a minimum viable product that aligns with the needs and preferences of end-users.

The iterative development process revealed that larger issues, such as bugs and significant feature requests, were identified and addressed in the initial phases. Subsequent user research sessions showed a decrease in the number and severity of issues, indicating progressive refinement of the app. Participants expressed that the app improved upon the Excel-based MEDLO-tool by streamlining data collection and reducing manual input, thereby potentially enhancing usability.

Balancing end-user feedback with established best practices and user interface guidelines was crucial during development [34-37]. While participants provided valuable suggestions, not all could be implemented due to conflicting requests and constraints related to usability standards. For instance, some users desired a more complex timer feature, whereas others preferred simplicity. Decisions were made to benefit the majority and adhere to platform guidelines to ensure familiarity and ease of use [34,35].

The effectiveness of the UCD approach in this study aligns with previous research demonstrating its benefits in software development [38,39]. A key factor in our success was the development team's familiarity with the context of long-term care for older adults. This domain knowledge facilitated insightful conversations between developers and participants, reducing misunderstandings and accelerating the development process. Previous studies have highlighted that cognitive similarity and shared jargon can enhance team performance [40,41].

Limitations

Despite these strengths, the study has limitations that warrant consideration. The participant sample consisted primarily of researchers affiliated with the University, which may limit the generalizability of the findings to care professionals who are the intended end-users in clinical settings. While these researchers had extensive experience with the MEDLO-tool, involving a broader range of stakeholders, including nurses and other care staff, could provide additional insights into usability and practical implementation. Furthermore, the app was not tested in a real-life nursing home environment, which could have revealed context-specific challenges and opportunities.

Future Work

Future research should focus on conducting pilot studies to evaluate the feasibility and effectiveness of the MEDLO app in real-world nursing home settings. Involving care professionals in these studies would help assess the app's usability, accessibility, and impact on daily workflows. In addition, gathering feedback from residents and their families could provide a more comprehensive understanding of the app's influence on care quality.

Further development could explore integrating advanced technologies, such as artificial intelligence and machine learning, to enhance data analysis and provide predictive insights [42,43]. For example, natural language processing could be used to automate the interpretation of observational data, aiding care providers in identifying patterns and potential areas for intervention. However, implementing such technologies would require careful consideration of ethical implications, data privacy, and user acceptance.

Future research may also investigate the usability in practice, by letting nurses use the app in their daily work. This could provide valuable insights into the app's integration into existing workflows and its impact on the quality of care provided to residents. In addition, longitudinal studies could assess the long-term effects of using the app on care outcomes and staff satisfaction. This information could inform further refinements and improvements to the MEDLO app, ensuring its relevance in long-term care.

Conclusion

This study successfully demonstrates the viability and demand for an app-based MEDLO-tool for assessing residents with dementia in nursing homes. By using a UCD approach, this study addressed the limitations of the existing Excel-based system by offering a more efficient and user-friendly alternative. This study shows that involving users early on in the process and keeping them involved can have a positive effect on the usability of an application. The MEDLO app shows that a UCD approach can provide real benefits in the development of a digital tools in nursing homes.

Abstract

Background: Remote patient monitoring (RPM) aims to improve patient access to care and communication with clinical providers. Overall, understanding the usability of RPM applications and their influence on clinical care workflows is limited from the perspectives of clinician end users at a cancer center in the Northeastern United States.

Objective: This study aims to explore the usability and functionality of RPM and elicit the perceptions and experiences of oncology clinicians using RPM for oncology patients after hospital discharge.

Methods: The sample included 30 of 98 clinicians (31% response rate) managing at least 5 patients in the RPM program and responding to the mHealth usability between March 2021 and October 2021. Overall, clinicians responded positively to the survey. Item responses with the highest proportion of disagreement were explored further. A nested sample of 5 clinicians who responded to the study survey (30% response rate) participated in interview sessions conducted from November 2021 to February 2022, averaging 60 minutes each.

Results: Survey responses highlighted that RPM was easy to use and learn and verified symptom alerts during follow-up phone calls. Areas to improve identified practice changes from reporting RPM alerts through digital portals and its influence on clinicians' workload burden. Interview sessions revealed 3 main themes: clinician understanding and usability constraints, patient constraints, and suggestions for improving the program. Subthemes for each theme were explored, characterizing technical and functional limitations that could be addressed to enhance efficiency, workflow, and user experience.

Conclusions: Clinicians support the value of RPM for improving symptom management and engaging with providers. Improvements to address RPM challenges include functional changes to enhance the program's utility, such as input from patients about temporal changes in their symptoms and technical resources for home monitoring devices.

(JMIR Hum Factors 2025;12:e60585) doi:10.2196/60585

Introduction

Improving the patient's access to care and enhancing their quality of life by preventing readmission is the primary goal of posthospital care delivery, yet traditional oncology care models often lack communication and monitoring after discharge [1-5]. Consequently, re-admissions for oncology patients within 30 days of discharge for symptoms that could be mitigated with proactive, remote patient monitoring (RPM) is an opportunity for advancing oncology patient care [6-8]. Our prior research at Memorial Sloan Kettering Cancer Center (MSK) highlights the potential of RPM to facilitate transitions of care through optimized patient-provider communication and proactive engagement through digital technology [7,8]. The RPM program was designed to reduce unplanned care visits following discharge from the hospital by proactively monitoring patient status via daily questionnaires. Electronic patient-reported outcome (ePRO) assessments generated alerts for patients enrolled in the RPM that were sent to the patient's primary oncology care clinician team. Details regarding the early development and integration of the organizational RPM project, as well as the patients recruited have been previously published [3,9-11]. However, limited research exists describing the perspectives and experiences of the clinician end users regarding how digital interventions are integrated into clinical care and the influence of technological health care models on patient care workflows.

To address this gap, our team developed this study to gain a greater understanding of the influence of RPM on clinical workflows in daily practice as part of a larger institutional initiative supporting center-wide symptom management during the transition of care from the inpatient to the outpatient setting [3,9-11]. The purpose of this study is to explore the usability of the RPM program and the perceptions and experiences of oncology clinicians using RPM to care for patients in practice after hospital discharge. The broader aim was to identify the impact, perceived usefulness ease of use, user control of the RPM, and barriers and facilitators experienced during the initial RPM implementation. The Consolidated Framework for Implementation Research [12] guided this study to query oncology clinicians, the key contributors to this management strategy, about their experiences, satisfaction, usefulness, and value of RPM.

Methods

Overview

The study's design used a multi-modal case study approach, using quantitative (survey) and qualitative (interviews and focus groups) to characterize the phenomenon and context of integrating RPM into the practice setting [13-18]. This approach encourages multiple sources of evidence to understand the clinician's perspectives about the use and function of RPM in real-world clinical practice and its influence on patient care workflows.

Initially, survey methods assessed clinicians' responses to the overall usability, functionality, and value of RPM. Second, clinicians participated in semistructured interviews and focus group sessions to elicit feedback and explanations about items of concern found in the survey responses [13,14,17]. The interview sessions aimed to delve deeper into the survey concerns and examine the use of the RPM application from a clinical perspective.

Setting and Clinician Sample

This study focused on clinician end users, specifically nurses involved in clinical office practices that integrated the initial organization's RPM initiative [3,9-11] from October 15, 2018, to July 10, 2019, at MSK in the Northeastern United States. The clinicians in this study were the first group of end users involved in caring for oncology patients using RPM. The RPM program was rolled out sequentially, beginning with the oncology services that care for patients with the highest symptom burden (Table 1). Clinicians from physician office practice settings, who had experience in caring for at least 5 patients enrolled in RPM, were invited to participate in the usability survey. This criterion ensured that the clinicians had ample experience with using the RPM program. Additionally, a nested sample of clinicians who completed the survey were recruited to take part in semistructured interviews to provide further information about the challenges of the RPM identified from the survey [19-22].

Data Collection

Survey

Eligible clinicians in this study who met the study criteria were identified using the RPMs dashboard. Clinicians were recruited using the organization's email with a link to a web-based consent and m-Adapted Health Usability Questionnaire from March 2021 to October 2021. To maintain the anonymity of the clinicians, broad demographic data were collected to quantify clinicians' years of experience in their current organizational roles and use RPMs within electronic health record systems.

The m-Adapted Health Usability Questionnaire [23,24], is a 29-item self-report survey, that assessed an overall understanding of the functionality of the RPM from the perspectives of the clinician end users including the quality of work life, perceived usefulness, and ease of use, and user control of RPM in a 7-point Likert Scale (1 [strongly disagree] to 7 [strongly agree]). The questionnaire takes about 13 minutes to complete in REDCap (research electronic data capture; Vanderbilt University) [25]. The Cronbach α for all scale values was >0.7 with scores ranging from 0.85 to 0.92. Permission to use the questionnaire was not required [24].

Interview Sessions and Guide

Clinicians who completed the study's survey were also recruited through the organization's email to take part in 60-minute interviews or focus group sessions. The interview guide was developed by the research team based on understanding areas where the usability of RPM was challenging for the clinicians. Items from the usability survey where the percentage of responders who disagree, disagree, and strongly disagree exceeded 44%, informed the interview and focus group guide. Topics in the guide were broad enough to elicit narrative data describing the background and contextual characteristics related to the clinician's experience with RPM [26,27]. The interview guide was organized into four topics: (1) General understanding and information about the RPM; (2) Experiences, barriers, and challenges with using the RPM; (3) The Influence of the RPM on the current workflow; and (4) Suggestions for improvement (Table 2). Interviews and focus groups were conducted via the web by the PI (AMME) and the qualitative methods specialist (MBB) from November 2021 to February 2022. Verbal consent was obtained from clinicians to record sessions.

Table . Interview guide.

Topic	Main statements	Probe questions	Aligns survey
Topic 1: provide general information about the topic of study and ask questions related to the specific service and the specific patient needs.	• Where do you work? • Can you tell me about your work with RPM[a]? • What can you tell us/each other about RPM?	• Can you briefly describe the patient group in your office practices (patient symptom burden, any factors in this group that need to be addressed through RPM)? • Can you describe your workflow and the technology systems used in your daily work activities? • Can you describe the workflow, and the systems used when providing care? • How does the RPM fit into the care workflow?	Q[b] 3,4
Topic 2: issues and barriers that are specific to using the RPM.	• What are the strengths/barriers to using RPM from the nursing perspective? • What are the strengths/barriers to using RPM from the patient's perspective? • Do you think RPM is valuable: to nurses the patients?	• What functionality is found in the current systems and applications used during patient care activities to make caring for patients easy? • What functionality in the RPM is not working? Describe? • Do you think the patients like using the RPM? • Does the RPM provide value for the patients? Care? • Do you think patient education about the RPM helps?	Q 7,9,10,13
Topic 3: practice workflow; getting to the issue about the RPM, frequency of using the toolkit, and the influence of workflow.	• How does the RPM toolkit work with your workflow? • How do you use the RPM apps to provide care? • How do you use the RPM toolkit using the digital apps?	• Describe how you use the RPM (and patients with remote monitoring devised, ie, pulse oximetry) • How do you use the information in caring for your patients? • Can you describe the communication among practitioners using the RPM?	Q 18 - 20
Topic 4: functionality, if modified, would be meaningful and helpful for the RPM, improved workflow, user satisfaction, and improved patient outcomes.	• What are your thoughts about how RPM functions? • How could it be improved?	• If you could fix anything about the RPM, what would it be? • To what extent do you think the modifications described could influence patient outcomes that patient care? • What current functionality has the greatest influence on workflow?	Q 23 - 25

[a]RPM: remote patient monitoring.

[b]Q: question.

Data Analysis

Survey

Survey response data were extracted from REDCap [25] to a deidentified Excel spreadsheet before analysis. To ensure anonymity, demographic information was only provided for clinicians who were sent the surveys and not collected for clinicians who responded. Data responses were initially scored in REDCap [25] for the frequency and proportion of agreement or disagreement with survey items consistent with the 7-point response scale. The scale responses were then collapsed into 3 groups, disagreement (strongly disagree, disagree), neutral (neither agree nor disagree), and agreement (agree and strongly agree). The Strengthening the Reporting of Observational Studies in Epidemiology guidelines were used to report the study's quantitative findings [28].

Interviews Sessions

Data from the interviews and focus groups followed the Consolidated Criteria for Reporting Qualitative Research

guidelines and were used to report the study's findings [29]. The rigor and validity of the data were supported by clarifying participants' statements during interview sessions. The transcripts were audio recorded, transcribed verbatim, and independently reviewed by 2 reviewers using thematic content analysis [30]. Themes and subthemes were constructed based on the verbal responses from the clinicians. Team consensus was determined by agreeing upon the best representation of the data [24,26,27,30].

Ethical Considerations

This research is part of an ongoing organizational program of RPM initiatives. This research obtained ethical approval from the MSK Institutional Review Board (X20-086) as exempt research and follows the ethical principles and guidelines of the Belmont Report. All responders to surveys completed web-based informed consent to participate. Participants in focus groups and interviews provided informed verbal consent.

Results

Overview

A total of 35 clinicians participated in this study from both survey and interview sessions. Of the 98 clinicians who had experiences with at least 5 patients enrolled in RPM and received the study's survey, 30 responded (31% response rate). A nested sample of 5 clinicians (17% response rate) from this original group of 30 clinicians who completed the survey, also agreed to take part in 4 sessions (3 interviews; 1 focus group of 2 clinicians). Demographic data were not collected with the survey to maintain the anonymity of the clinician responders. However, the majority of clinicians who responded to the survey and interview sessions represented the Gastrointestinal, Thoracic, and Breast oncology services known to have the highest symptom burden. Of the clinicians who took part in the interview sessions, 3 clinicians had 5 or more years of organizational work experience, while 2 clinicians had 2 years or less of experience.

Survey Responses

Overall, the clinicians reported that the RPM was easy to use and learn and that symptoms communicated through the RPM program were confirmed during follow-up phone calls. Suggested areas for improvement included communication and practice changes related to symptom management and the clinicians' workload burden. Findings highlighting survey items with the highest frequency and proportion of survey responses are presented (Table 3).

Table . Frequency distribution of m-Adapted health questionnaire responses (n=30)[a].

Statements about remote patient monitoring (RPM)	Total responses, n	Agree/somewhat agree/strongly agree, n (%)[b]	Neither agree nor disagree, n (%)	Disagree/somewhat disagree/strongly disagree, n (%)	Unknown, n
Ease of use and functionality as easy to learn					
1. RPM is easy to use	27	18 (67)	2 (7)	7 (26)	3
2. RPM is easy for me to learn	27	18 (67)	7 (15)	5 (18)	3
3. Liked the digital interface of the patient data received through portal secure message alerts	26	8 (31)	4 (15)	14 (54)	4
4. I liked the digital interface of the patient data received through the Splunk/summary dashboard	26	7 (27)	12 (46)	7 (27)	4
5. Information in the Splunk/summary dashboard was well-organized	25	12 (48)	9 (36)	4 (16)	5
Integrating the RPM into workflows					
6. RPM has usable functions and capabilities	27	14 (52)	6 (22)	7 (26)	3
7. RPM has been appropriate for me to care for patients	27	11 (44)	1 (4)	14 (52)	3
8. Easy to integrate into my current clinical workflow	27	11 (41)	4 (15)	12 (44)	3
Acceptable for practice					
9. An acceptable way to coordinate health care services	26	9 (35)	5 (19)	12 (46)	4
10. Improved communication between my colleague's office practice teams for patient symptoms	26	10 (38)	1 (4)	15 (58)	4
11. Prompts me to refer patients to a specialist for symptom management	25	9 (36)	5 (20)	11 (44)	5
12. RPM is useful for my health care practice	26	12 (46)	4 (15)	10 (39)	4
13. Improved my ability to deliver health care services	27	7 (26)	4 (15)	16 (59)	3
14. Helped me manage my patient's symptoms effectively	27	11 (41)	5 (18)	11 (41)	3

Statements about remote patient monitoring (RPM)		Total responses, n	Agree/somewhat agree/strongly agree, n (%)[b]	Neither agree nor disagree, n (%)	Disagree/somewhat disagree/strongly disagree, n (%)	Unknown, n
RPM convenience						
	15. Is convenient for me to communicate with patients	26	10 (39)	4 (15)	12 (46)	4
	16. Had many more opportunities to interact with patients	27	11 (41)	4 (15)	12 (44)	3
	17. Felt comfortable communicating with my patients about symptoms using portal secure messaging	26	12 (46)	1 (4)	13 (50)	4
Devices and symptom management						
	18. Highlighted the high-risk symptoms (not pulse oximetry) provided the correct corresponding severity level for the patient-reported symptoms	27	10 (37)	5 (19)	12 (44)	3
	19. Highlighted symptoms related to pulse oximetry appropriately	27	10 (37)	9 (33)	8 (30)	3
	20. Patients were appropriately identified for pulse oximeter monitoring.	27	12 (44)	7 (26)	8 (30)	3
	21. Pulse oximeter monitoring enabled me to more effectively manage my patient's symptoms	26	10 (38)	8 (31)	8 (31)	4
	22. High-risk symptom alerts were confirmed upon communication with the patient by telephone	27	20 (74)	2 (7)	5 (19)	3
Satisfaction, value, and recommendations

	29. I would recommend the RPM to my colleagues	26	8 (31)	5 (19)	13 (50)	4

[a]Number of participants who answered the survey.

[b]Percentage of the group responses.

Usability

The RPM was easy for clinicians to use but was influenced by a shift in basic assumptions with patients now instructed to report symptoms through portal messages rather than calling the medical offices (14/26, 54%).

Integrated Workflows

The proportion of responses was fairly divided between agreement and disagreement. While 14 (52%) clinicians agreed that the RPM had usable functions and capabilities, 14 (52%) clinicians disagreed that the RPM was suitable for their patient care needs.

Acceptability in Practice

A total of 16 (59%) clinicians reported a disagreement with the notion that RPM improved their ability to care for their patients and, 12 (46%) clinicians reported that the RPM was useful in their practice.

Convenience in Patient Care

Despite similar proportions of agreement and disagreement overall, a higher proportion of clinicians (13/26, 50%) disagreed with feeling comfortable communicating with patients about symptoms through portal messages.

Symptom Management

Clinicians reported that devices were appropriately used for 12 (44%) patients and that high-risk symptoms were confirmed during follow-up phone calls to 20 (74%) patients. The responses were fairly split between agreement (10/27, 37%) and disagreement (12/27, 44%) on how well the devices provided severity levels. Additionally, 10 (38%) patients agreed that RPM helped them manage their patients.

Satisfaction and Value

A total of 21 (81%) clinicians reported that the RPM did not decrease their workload and 15 (56%) clinicians reported it did not improve job satisfaction. In addition, 14 (52%) of the clinicians were not satisfied with RPM, and 13 (50%) clinicians would not recommend the RPM to colleagues. The proportion of clinicians who neither agreed nor disagreed was similar to those who reported disagreement and was further explored in the interview sessions.

Interview Sessions

The interviews and focus group sessions consistently provided similar information about the RPM thus achieving thematic saturation [30]. All clinicians reported a limited understanding of the RPM during its implementation and suggested that ongoing educational modules and supporting technical support would enhance the RPM program for the clinician end users. Three major themes emerged from the interviews: clinician understanding and usability constraints, patient constraints, and suggestions for improvement. Subthemes were further explored (Table 4).

Table . Themes and subthemes.

Theme	Subthemes
Theme 1: Clinician understanding and usability constraints	• Clinician uncertainty • Repetitive alerts • Alignment with clinician workflows • Program value
Theme 2: Patient constraints	• Appropriate patient enrollment • Timing of enrollment • Communication during and after enrollment
Theme 3: Suggestions for improvement	• Clinical champions needed • Program modifications • Information technology support for end users

Theme 1: Clinician Understanding and Usability Constraints

Overview

Theme 1 encompasses the information given to the clinicians during their RPM orientation and how they applied the application to their current workflow. Three subthemes included clinician uncertainty, repetitive alerts, alignment with clinician workflows, and program value.

Subtheme: Clinician Uncertainty

The RPM was rolled out in stages starting with oncology services known to have patients with high symptom burdens. The clinicians involved in the initial rollout reported more knowledge and understanding about the RPM compared with clinicians who were involved later in the rollout. Clinicians joining later in the rollout reported having little training about the RPM. However, they reported that the increased frequency of using the RPM helped them navigate the program for addressing symptom management alerts and functionality.

> *I have only worked with it (RPM) for a couple of patients in the outpatient setting, but I get a notification (through) the portal … to notify us that the patient has enrolled in the RPM program…During this timeframe patients (complete) a survey every day about their symptoms and how they feel.* [R32]

Subtheme: Repetitive Alerts

All clinicians reported concerns about repetitive alerts from daily patient surveys. Each day that a patient reported a symptom and generated an alert [1,3,10], clinicians called the patient to verify it and confirm if the symptom was worse, better, or the same as the previous survey. Although they could see past patient response trends in the system, this required substantial effort and did improve the patient's care for symptoms. When alerts were consistently reported, the clinicians used their judgment to decide when to call patients for verification.

> *There are a couple of categories that we feel were a little monotonous. ie, was (the pain/symptom) worse? If they are at stage four lung cancer, (the patient) is on treatment and they have fatigue, every day… (the patient cannot modify) their answers, (for example) moderate fatigue; I am having trouble doing my activities of daily living, so they are clicking that every day.* [R11]

Subtheme: Aligning With Clinician Workflow

Clinicians reported that before implementing the RPM, patients were instructed to call the physician's medical offices to report symptoms. Although none of the clinicians reported significant changes to their clinical workflows, they all raised concerns about the shift from patients calling the medical oncology office for unrelieved symptoms through a digital portal. This change made clinicians apprehensive about potentially missing symptoms reported in patient portals.

> *Before RPM, patients were not supposed to report symptoms through the portal, but a lot of patients, ended up just doing that because they were home.* [R11]

Subtheme: Program Value

Clinicians reported that the RPM was of immense value to them and their patients and supported its inclusion in the organization's future care delivery. Patients liked that their office practice clinician proactively contacted and interacted with them after they were discharged from the hospital.

> *I do not think they (the patients) mind and love to be followed up closely, I mean my patients would love for me, a call them every day. I think patients prefer (clinicians) calling them over calling the office.* [R41]

Theme 2: Patient Constraints

Overview

The patient constraint themes involved the transition of care from the inpatient setting to RPM following discharge. Three subthemes emerged: the appropriate patient enrollment, the timing of enrollment, and communication during and after enrollment.

Subtheme: Appropriate Patient Enrollment

Nurses from the discharging inpatient unit were responsible for educating patients about using RPM and program enrollment. However, office practice clinicians stated that not all patients enrolled by the discharge team were appropriate due to a lack of technical proficiency, ability, and understanding of the purpose of the RPM. Clinicians consistently reported that they should be included in RPM enrollment decisions for their patients.

> *There is a disconnect, (between enrolling the patient and educating them about the program) and sending symptoms via the portal messaging using the patient portal. The policy is that we are given two business days to answer portal messages…clearly, we cannot do that when it is a separate message. We need to speak to that person (By phone).* [R21]

Subtheme: Timing of Enrollment

Office practice clinicians reported that the time of discharge is overwhelming for patients and inpatient unit teams have limited time to prepare the patients to leave the hospital. During this study, pandemic-related social distancing restrictions prevented caregivers and family members from taking part in the discharge process, further complicated RPM enrollment.

> *The second thing that I wanted to suggest for patients wanting to quickly leave the hospital and be discharged and suddenly just get bombarded with all this information, is to discuss the RPM program the day (before) discharge.* [R32]

Subtheme: Communication During and After Enrollment

Clinicians reported that a patient's age was not a factor in RPM enrollment, as older adults familiar with technology could engage digitally with providers. However, patients with language barriers or limited access to electronic devices needed assistance from caregivers or family members similar to findings in a prior

study [8]. The RPM assessments were intended to be completed during weekday work hours, from 9 AM to 5 PM Monday through Friday. Clinicians described receiving the surveys late in the day, or after hours added stress for the nursing team to address alerts.

> *We have a lot of foreign-speaking patients ---, you know it is not them who are filling out the survey ... and it may be one of their relatives or their daughter. But the daughter may not live with them ... so how do you know what is going on?* [R11]

Theme 3: Suggestions for Improvement

Overview

The Clinicians supported using RPM to sustain patient care posthospital discharge. From their perspective, 3 subthemes emerged, the need for clinical champions, technology support for end users (clinicians and patients), and specific RPM modifications.

Subtheme: Clinical Champions Needed

Clinicians expressed the need for continuing education and updates on RPM improvements, infrequent use required relearning the system for each new patient. While there were few Clinical Champions during the initial rollout, additional experts would have helped them navigate the program and supported novice clinicians. They also suggested developing informative slides or videos addressing specific program issues.

> *I think nursing (clinician end-user) … needs more education on the portal because it (the portal) is such a big part of our job. More training is needed for using (connecting) pulse ox to an iPhone (or other devices ie, Android).* [R11]

Subtheme: Program Modifications

Clinicians reported that patient enrollment before hospitalization or early in their hospital admission would improve the transition from inpatient to outpatient care. They also requested allowing patients to change or clarify their symptom responses within the assessment. Frequent patient alerts were seen as potentially problematic [31] and suggested that enabling patients the option to modify their assessment responses would provide more accurate symptom information to the clinical team.

> *There should be a way for them (patients) to say (respond in the survey) no changes or something… so that we don't get the same exact thing (response) that we spoke to the patient yesterday---about because it's not realistic, that I call the patient every day to talk to them about the same time (symptom).* [R42]

Subtheme: Information Technology Support for End Users

Clinicians raised concerns about the lack of integrated IT systems they use for delivering patient care. Additionally, clinicians expressed the need for greater IT support for both patients and staff. Clinicians conveyed concern about the difficulty in resolving connectivity issues and requested dedicated assistance from IT teams.

> *The patients are calling in a panic and you are trying to walk them through over the phone how to set up the device (RPM on patient's device ie, phone, tablet). If it was not set up correctly on discharge, or the device is just not working. (These issues) add more stress to the patient, but it also adds stress to you (the clinician) This becomes the added work.* [R11]

Discussion

Principal Results

This study presented the perceptions and experiences of oncology clinicians when caring for their patients using RPM after hospital discharge. Initially, clinician survey responses highlighted concerns about their understanding, perceptions, and challenges when using RPM as well as its influence on their clinical workflows. These topics were further explored in interview sessions and revealed 3 themes: clinician understanding and usability constraints, patient constraints, and suggestions for improvement. Most clinicians found the RPM easy to use and learn, allowing them to confirm the patient's reported symptoms during follow-up phone calls. They supported RPM's value for both clinicians and patients as a care delivery method in oncology practice, aligning with findings from other organizational studies using ePROs [11,31-36], as well as the challenges and limitations of addressing symptom alerts after the patient transitions from an inpatient to the home setting [7,35,36].

Challenges and Opportunities From the Clinical Setting

This research further emphasized multiple challenges faced by clinicians during the initial RPM roll-out. A major concern was the practice change in clinical workflows whereby patients reported symptoms through electronic portals rather than contacting the medical offices by phone. Despite this change, clinicians felt their comfort level would improve with more experience, and as RPMs aligned with their workflows [7]. An opportunity to improve clinician confidence includes continuing educational tutorials from the initial RPM orientation and more technical and clinical support for both patients and clinicians. These efforts would facilitate aligning clinician workflows with clinical practice, thus leading to reduced stress and improved job satisfaction when caring for oncology patients using RPM [7].

Another challenge was patient constraints and their lack of understanding of RPM, which clinicians suggested might contribute to their uncertainty in digital symptom management reporting. Some patients completed surveys late in the clinic hours making it difficult to address symptoms. In many instances, clinicians reported that family members completed the surveys instead of the patients which raised concerns about the integrity of the symptom alerts. Further research could enhance the understanding of logistical limitations involving patients and caregivers with completing postdischarge symptom assessments at home. A similar study recommended that concerns revealed by patients and caregivers postdischarge could be included in future clinical outcomes [37]. Additionally, the timeframe for enrolling patients in RPM was another

constraint identified by clinicians. Although older patients were comfortable using the RPM [38,39], enrollment at discharge was considered suboptimal. They suggested educating patients in a relaxed environment or office practices before hospitalizations would benefit patients and improve the enrollment process.

A major opportunity for RPM improvement involves addressing repetitive alerts from the daily ePRO assessments, also identified in other ePRO studies [23]. Clinicians verify all patient-reported symptom alerts. When prior symptoms are stable, these alerts could be averted to reduce their workflow burden [40,41]. To enhance effective communication with the patients, clinicians recommended adding context about symptom changes relative to the prior day's ePRO assessment to improve the integrity of alerts.

The perspectives of all clinicians involved in this study expressed a need for additional resources to improve the effectiveness of RPM and their ability to clinically support it. The RPM was initially implemented using a core team of designated clinicians for addressing patient alerts. Studies of RPM cited the inclusion of core teams for this purpose which may be a preferred approach for clinicians in other studies [42]. However, clinicians in this research preferred a hybrid RPM program with primary care clinicians in the clinical practices addressing alerts on weekdays and centralized after-hours and on weekends. Clinicians proposed that leaders provide consistent status updates and education about RPM functionality through tutorial videos in an accessible location. Additional technological support could improve data collection and relieve clinicians of the burden of providing technical support for patients at home [41,42], which is not the best use of their skills [43].

Strengths and Limitations

The consistent reports from survey responses and interviewed clinicians strengthen the study's findings and provide pragmatic recommendations for workflow redesign and enhancing access to care for oncology patients postdischarge [1,2,7,31], As a result of this study, selected modifications were implemented into practice to improve the program's experience for both clinicians and patients. These results provide important foundational work for future pragmatic trials and implementation science to enhance the usability and value of RPM in oncology practice.

The sample was limited to only clinicians who had experiences with at least 5 patients enrolled in the RPM, but typical for case studies [13-18]. They expressed strong positive or negative experiences with the RPM which may have created a selection bias. The study's design was multi-modal which could have included both interviewer and report biases. Clinicians were also employees of the organization and therefore specific demographics were not collected to ensure their anonymity. This study was conducted at one comprehensive cancer center, limiting the generalizability of results. However, the perspectives of clinician end users from oncology services with known symptom burdens can apply to similar RPM implementation initiatives in other organizations worldwide.

Conclusion

The National Cancer Institute calls for studies about cancer-related interventions, which also include program effectiveness from the perspectives of both patients and clinician end users [44]. This study contributes to the National Cancer Institute's initiatives, demonstrating that RPM is a valuable method for communicating with clinical providers and managing patient symptoms during transitions of care from inpatient to the home setting.

Acknowledgments

The authors want to thank the clinicians who participated in this study for their insight and dedication to oncology practice.

Authors' Contributions

AMME drafted the nursing perspective aspect of the proposal and conducted the interviews, transcribed and analyzed the interview data, and drafted the original manuscript. MBB conducted interviews with AMME, reviewed the transcript data, and edited the manuscript. RD is the principal investigator of the organizational protocol involving remote patient monitoring and reviewed and edited the manuscript. J Huang, CB, and JA are involved in providing protocol support for the daily activities of this study. CW was involved with drafting the manuscript and editing the study proposal. KSP, GK, and JM were involved with the organizational protocol and its development, and manuscript review. J Holland, RS, JC, and AB are involved with the organizational project development and review of the manuscript.

Conflicts of Interest

RD reports grant support from the National Institutes of Health and the Emerson Collective, participation on a data safety monitoring board or advisory board with Varian Medical Systems, and stock or stock options in Roche. The remaining authors do not have conflicts of interest to declare.

Abstract

Background: Only 15% of the nearly 30 million Americans with hearing loss use hearing aids, partly due to high cost, stigma, and limited access to professional hearing care. Hearing impairment in adults can lead to social isolation and depression and is associated with an increased risk of falls. Given the persistent barriers to hearing aid use, the Food and Drug Administration issued a final rule to allow over-the-counter hearing aids to be sold directly to adult consumers with perceived mild to moderate hearing loss at pharmacies, stores, and online retailers without seeing a physician or licensed hearing health care professional.

Objective: We evaluated the safety and usability of an over-the-counter hearing aid prior to Food and Drug Administration approval and market release.

Methods: We first conducted a formative usability test of the device and associated app with 5 intended users to identify outstanding safety and usability issues (testing round 1). Following design modifications, we performed a summative usability test with 15 intended users of the device (testing round 2). We concurrently conducted a test with 21 nonintended users (ie, users with contraindications to use) to ascertain if consumers could determine when they should not use the device, based on the packaging, instructions, and labeling (testing round 3). Participants were asked to complete 2 - 5 tasks, as if they were using the hearing aid in real life. After each task, participants rated the task difficulty. At the end of each session, participants completed a 10-question knowledge assessment and the System Usability Scale and then participated in debriefing interviews to gather qualitative feedback. All sessions were video recorded and analyzed to identify use errors and design improvement opportunities.

Results: Usability issues were identified in all 3 usability testing rounds. There were minimal safety-related issues with the device. Round 1 testing led to several design modifications which then increased task success in round 2 testing. Participants had the most difficulty with the task of pairing the hearing aids to the cell phone. Participants also had difficulty distinguishing the right and left earbuds. Nonintended users did not always understand device contraindications (eg, tinnitus and severe hearing loss). Overall, test findings informed 9 actionable design modifications (eg, clarifying pairing steps and increasing font size) that improved device usability and safety.

Conclusions: This study evaluated the usability and safety of an over-the-counter hearing aid for adults with mild to moderate hearing loss. Human factors engineering methods identified opportunities to improve the safety and usability of this direct-to-consumer medical device for individuals with perceived mild-moderate hearing loss.

Introduction

Approximately 1 in 4 people older than 12 years of age in the United States have hearing loss in 1 or both ears [1], and 30 million American adults could benefit from hearing aid use [2]. Hearing loss is associated with an increased risk for falls [3] and may lead to cognitive decline [4] and dementia [5]. Yet, only 1 in 3 older adults [6] and 15% of all adults with hearing loss use hearing aids [7]. Some barriers preventing adoption

include lack of access, stigma, and financial challenges with traditional hearing aids costing between US $1000 and US $6000 per ear [8]. Aiming to mitigate these barriers, the Food and Drug Administration (FDA) issued a final rule in 2022 [9] permitting the sale of hearing aid devices without a prescription or medical exam. Yet, there are few studies of the usability and safety design challenges of over-the-counter medical devices intended to be sold widely in consumer markets.

Over-the-counter or direct-to-consumer medical devices do not require a prescription and can be sold at retail outlets including pharmacies, big-box stores, and online. Examples include self-monitoring blood glucose test systems and at-home pregnancy tests. Typically used outside of health care settings, these devices must have (1) low potential for misuse; (2) benefits that outweigh their safety risks; and (3) sufficient labeling so that lay-users can self-diagnose their condition, self-determine that the device is appropriate for their condition, and understand how to use the device without clinician assistance or instruction [10]. To minimize use errors and their associated risks, the FDA requires premarket review of the safety and effectiveness for most direct-to-consumer medical devices. This review process includes rigorous human factors usability testing with representative users to validate that the warnings, cautions, and contraindications are transparent, assess if users can complete critical tasks of the device, and identify areas of foreseeable misuse (including use of the device by unintended users) [11].

Numerous studies have evaluated the safety and usability of clinician-facing medical devices (eg, smart intravenous infusion pumps) [12-15], as well as patient-facing medical devices (eg, glucometers, ventilators, and epinephrine injectors) [16]. Typically, clinicians still mediate the use of these patient-facing medical devices either by providing a prescription to use the device or instructions on how to use the device appropriately [17]. There remains limited research on the safety and usability of direct-to-consumer medical devices, especially those used by underserved populations (eg, people with hearing impairment) [18-20].

Compared to clinician-facing medical devices, patient-facing devices present a challenge to designers as the potential environment of use and characteristics of end users is much more diverse [16]. The usability of direct-to-consumer devices is especially important given the lack of clinical supervision to support appropriate use. For instance, over-the-counter hearing aids will be on the shelf at consumer electronics stores next to other, nonmedical devices (eg, wireless headphones) and consumers may come across the device without previously identifying a need for a hearing aid. While the risk is minimal, use of hearing aids by those with normal hearing could result in noise-induced hearing loss. In this context, the packaging of the device and communication of its intended use (and contraindications to use such as an ear infection, tinnitus, or severe hearing loss) is especially important. In this study, we evaluated the safety and usability of an over-the-counter hearing aid among adults in the United States.

Methods

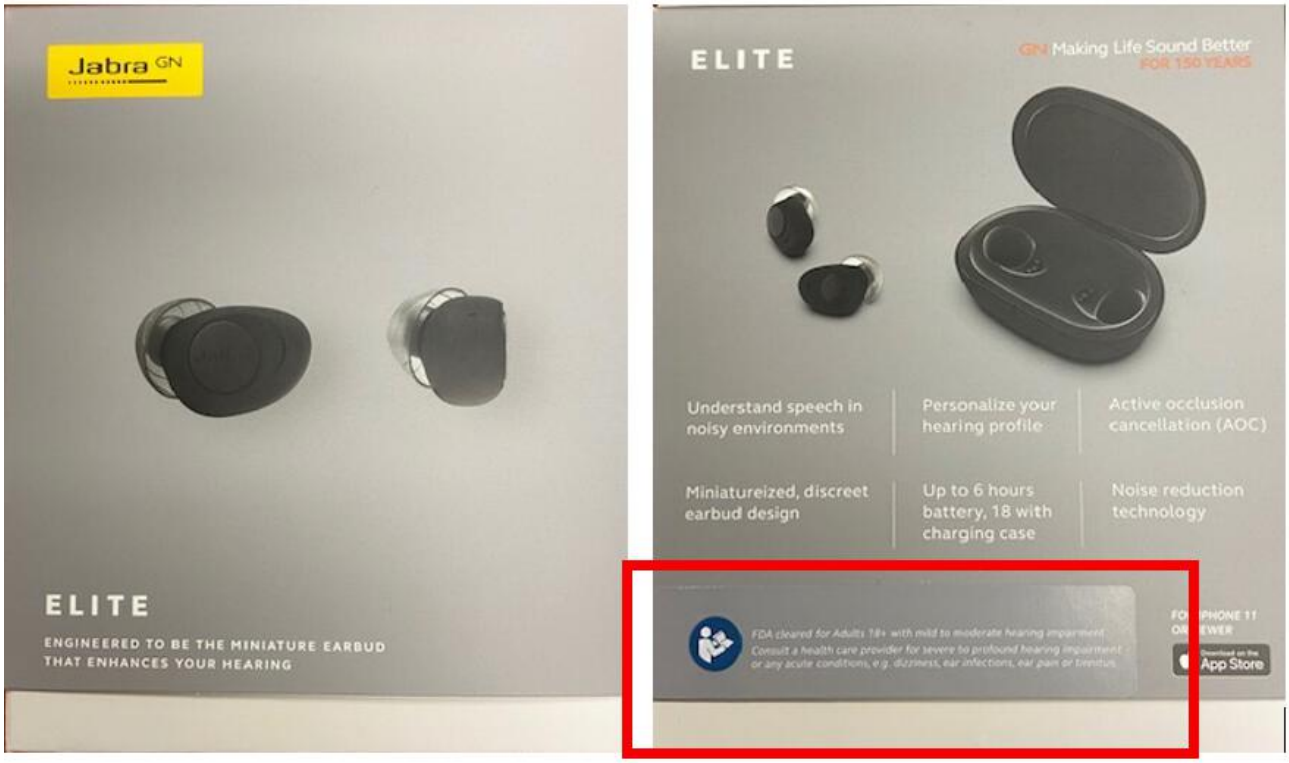
Ethical Considerations

We conducted usability testing of an over-the-counter hearing aid to evaluate the safety and usability of the device prior to market release. This study was approved by the Vanderbilt University Medical Center's institutional review board (201894). At the start of each session, we reviewed the consent document with participants and answered any questions they had. All participants provided written consent to be in the study. Data have been deidentified.

Hearing Aid

We evaluated the Jabra Enhance Plus (formerly called the "Jabra Elite" during the study), an over-the-counter hearing aid that is intended to enhance hearing but can also be used for phone calls and listening to music. Users can purchase these hearing aids at a suggested retail price of US $799 per pair. The hearing aids are physically similar to wireless earbuds with adjustable ear gels. Users can pair them to a smartphone and personalize their own hearing aid profile using a free smartphone app (ie, Jabra Enhance app). The miniaturized in-the-ear style earbuds (see Figure 1) come in a small charging case and can be used up to 12 hours on a single charge.

Figure 1. Front and back of the device box.



Participants and Setting

We conducted usability testing with production equivalent prototype devices (ie, packaging, hearing aids, charging case, and user manual) including an iPhone with the Jabra Enhance app installed. We only used iPhones in the usability testing since the Jabra Enhance app was only available for iPhones at the time of testing. We recruited two participant populations for the study, (1) intended users of the device and (2) nonintended users (Textbox 1). We identified potential participants meeting our study criteria through medical record chart review, university newsletters, and word of mouth. Eligible participants conducted a prescreening questionnaire, via phone call or email, to verify they met the inclusion criteria for the study before scheduling. The testing occurred from December 2020 to August 2021.

Textbox 1. Eligibility criteria for intended and nonintended users.

Intended users (adults aged 18+) with:

- Mild to moderate hearing impairment

Nonintended users (adults aged 18+) with:

- Normal hearing,
- Severe to profound hearing impairment, and/or
- Acute conditions including tinnitus, dizziness, ear infections, and ear pain

Intended Users

To start, we conducted usability testing with 5 intended users of the device. Based on the safety and usability issues identified in the testing round (round 1), we made recommendations for modifications to the device packaging and app screens. We then conducted round 2 of usability testing of the revised product with 15 intended users. In each usability testing session, participants were asked to complete 5 tasks (see Textbox 2) within 90 minutes. Participants received a US $50 gift card at the end of the session.

Textbox 2. Task descriptions.

Tasks for intended users (rounds 1 and 2)

- Read outer label and indicate if use is appropriate
- Set up the hearing aids and app including
- Find and open hearing aid app
- Register product and accept terms and conditions
- Pair the hearing aids
- Finalize the set up of the hearing aids
- Fit the hearing aids into ear
- Recharge the hearing aids
- Clean the hearing aids

Tasks for nonintended users (round 3)

- Read outer label and indicate if use is appropriate
- Read the inner box contents (note that the inner box contents were available to the participants, but they did not receive explicit instructions on how to read them) and indicate if use is appropriate

Nonintended Users

We conducted a third round of usability testing with 21 nonintended users of the devices to evaluate if consumers could ascertain that they should not use the device based on the external and internal labeling, user manual, and app screens. We recruited participants who were contraindicated to use the device including adults with normal hearing, adults with severe to profound hearing loss, and adults with tinnitus or severe dizziness. Round 3 participants were scheduled for a 30-minute test session, in which they were asked to complete 2 tasks (see Textbox 2). Participants received a US $20 gift card at the end of the session.

Data Collection

We conducted functional simulated use studies with end users completing real-world tasks. One human factors engineer facilitated the sessions. In line with real-world use of the device, participants received no training prior to testing. We read task instructions out loud while displaying the same instructions on a computer monitor with closed captioning. Participants were directed to complete 5 (rounds 1 and 2) or 2 tasks (round 3, see Textbox 2). After each task, participants rated how easy or difficult the task was to complete on a scale from 1 (very difficult) to 5 (very easy). After all tasks were completed, we asked intended and nonintended users 10 questions to assess their knowledge of the device and its contraindications for use (see Multimedia Appendix 1). Participants then completed the System Usability Scale (SUS), a 10-item validated survey for assessing the usability of interactive systems [21] (see Multimedia Appendix 2). To conclude the session, we conducted debrief interviews to gather additional qualitative feedback about the safety and usability of the device. The interview guide can be found in Multimedia Appendix 3. All sessions were video recorded and uploaded to Morae (TechSmith), a software suite for usability testing that supports video annotation (eg, of use errors) and logging of tasks.

Data Analysis

One researcher coded the videos in Morae, annotating areas of difficulty, confusion, safety-related issues, and errors. We analyzed the participant's path (ie, steps) through the attempted completion of each task. Any deviation that occurred in the attempt to complete the task (eg, participant clicks on an incorrect menu item or participant struggled to get the user manual out of the box) was coded as a "use error." For task 2, we specifically noted any instances where participants' workflow deviated from the expected workflow (see steps in Textbox 2). We analyzed the time spent on each task and if the tasks were (1) completed, (2) completed with difficulty, or (3) not completed (task failure). We then calculated the task success rate. A task was only scored as a success if the user was able to complete the task requirements on their own without facilitator assistance. We calculated participants' rating of difficulty for each task and the SUS scores. One researcher listened to the audio recording of each debrief interview and created a comprehensive list of feedback (eg, longer battery life) organized into two categories (1) what participants liked about the device and (2) areas for improvement. A team of human factors researchers reviewed all identified errors and participant difficulties completing tasks to develop design recommendations to improve the device, app, and packaging prior to market release. We mapped each design recommendation to specific human factors design principles, using the list of design heuristics described in Barton et al [22], which combined the commonly used heuristics for medical device design [23], interactive systems [24], and medical documents [25].

Results

Overview

Table 1 shows the participant demographics for each round of usability testing. Table 2 depicts the task success rates, number

of use errors, task durations, and difficulty ratings for each task and round of usability testing.

While we identified minimal safety concerns with the device, we identified numerous usability issues, which led to several design modifications. We outline the key issues identified from the usability testing in the following sections.

Table . Participant demographics for each usability testing round.

	Round 1 (intended users, n=5)	Round 2 (intended users, n=15)	Round 3 (nonintended users, n=21)
Hearing loss, n (%)			
None or normal hearing	0 (0)	0 (0)	18 (86)
Mild	2 (40)	7 (47)	0 (0)
Mild to moderate	1 (20)	2 (13)	0 (0)
Moderate	2 (40)	6 (40)	0 (0)
Severe	0 (0)	0 (0)	3 (14)
Tinnitus (ringing in ears), n (%)	0 (0)	0 (0)	5 (24)
Average age (years), n (range)	65 (57 - 73)	66 (56 - 79)	65 (52 - 77)
Women, n (%)	2 (40)	8 (53)	13 (62)
Education, n (%)			
High school or General Educational Development	0 (0)	5 (33)	5 (24)
Associate's or trade school	1 (20)	2 (13)	4 (19)
4-year college	2 (40)	3 (20)	7 (33)
Graduate or professional school	2 (40)	5 (33)	5 (24)

Table . Usability testing performance.

Measure and round	Task 1	Task 2	Task 3	Task 4	Task 5
Task success rate, n (%)					
Round 1	3 (60)	2 (40)	2 (40)	5 (100)	3 (60)
Round 2	12 (80)	10 (67)	7 (47)	15 (100)	10 (67)
Round 3	10 (48)	10 (48)	—[a]	—	—
Average task duration (minutes), mean (SD) [b]					
Round 1	0.72 (0.3)	9.33 (0.5)	1.37 (0.6)	0.50 (0.2)	1.08 (1.1)
Round 2	0.83 (0.5)	11.24 (4.0)	2.21 (0.9)	0.67 (0.6)	0.95 (0.8)
Round 3	—	—	—	—	—
Average difficulty rating, mean (SD) [c]					
Round 1	4.6 (0.5)	3.4 (1.2)	4.2 (0.8)	5 (0)	5 (0)
Round 2	4.87 (0.4)	3.27 (1.4)	3.73 (1.2)	4.53 (0.8)	4.67 (0.6)
Round 3	4.71 (0.6)	4.43 (0.9)	—	—	—
Number of use errors per participant, n					
Round 1	0	4	0	0	0
Round 2	0	4.9	0.5	0.6	0
Round 3	0	0.7	—	—	—

[a]Not applicable.

[b]Only includes times for participants who successfully completed the task.

[c]Scale from 1 to 5 (1=very difficult, 5=very easy).

Package Labeling

Overall, we found minimal safety issues with the set up and use of the device across all 3 rounds of testing. The one issue that presented potential, albeit minimal, concerns to safety was related to the accessibility of intended use and contraindications to use of the device. We found that the font size and color on the outside of the box made the intended use of the device hard to see and read (right side of Figure 1). Few participants saw or read this information on the box, and several participants indicated that they would not know the device was a hearing aid based on the outside of the box, stating "to know they are hearing aids, off the bat, I would have walked right by them."

A total of 3 participants in usability testing rounds 1 and 2 failed task 1 (read outer label) since they could not determine if it was appropriate for them to use the product based on the outside of the box. We identified the same problem with nonintended users of the device, with over half of the participants in round 3 stating that they did not know that the device was a hearing aid from the labeling on the outside of the box. All 3 of the participants with severe hearing loss and 3/4 of participants with tinnitus said (incorrectly) that the device would be appropriate for them to use based on the labeling on the outside of the box.

Device Pairing

The primary usability challenge with the device was setting up and pairing the hearing aids to the iPhone (task 2). In round 1, a total of 3 of 5 participants failed this task, and a fourth participant had difficulty completing it. A common challenge was that participants did not know that they needed to return to the app to complete the hearing aid set up after pairing the hearing aids to the iPhone. Rather, participants thought they were done setting up the device once they followed the Quick Guide pairing instructions (see Figure 2). The only participant to complete the task easily followed the workflow: open the Jabra Enhance app → pair the hearing aids using the iPhone → return to the app to complete the set up. As a result, we recommended design changes to the Quick Guide prior to round 2. As shown in Figure 3, the Quick Guide was revised to inform users to first go to the Jabra Enhance app before pairing the hearing aids to the phone. We further emphasized that users should return to the Jabra Enhance app after pairing to finish set up.

Figure 2. Quick guide instructions (December 2020 version—round 1 testing).

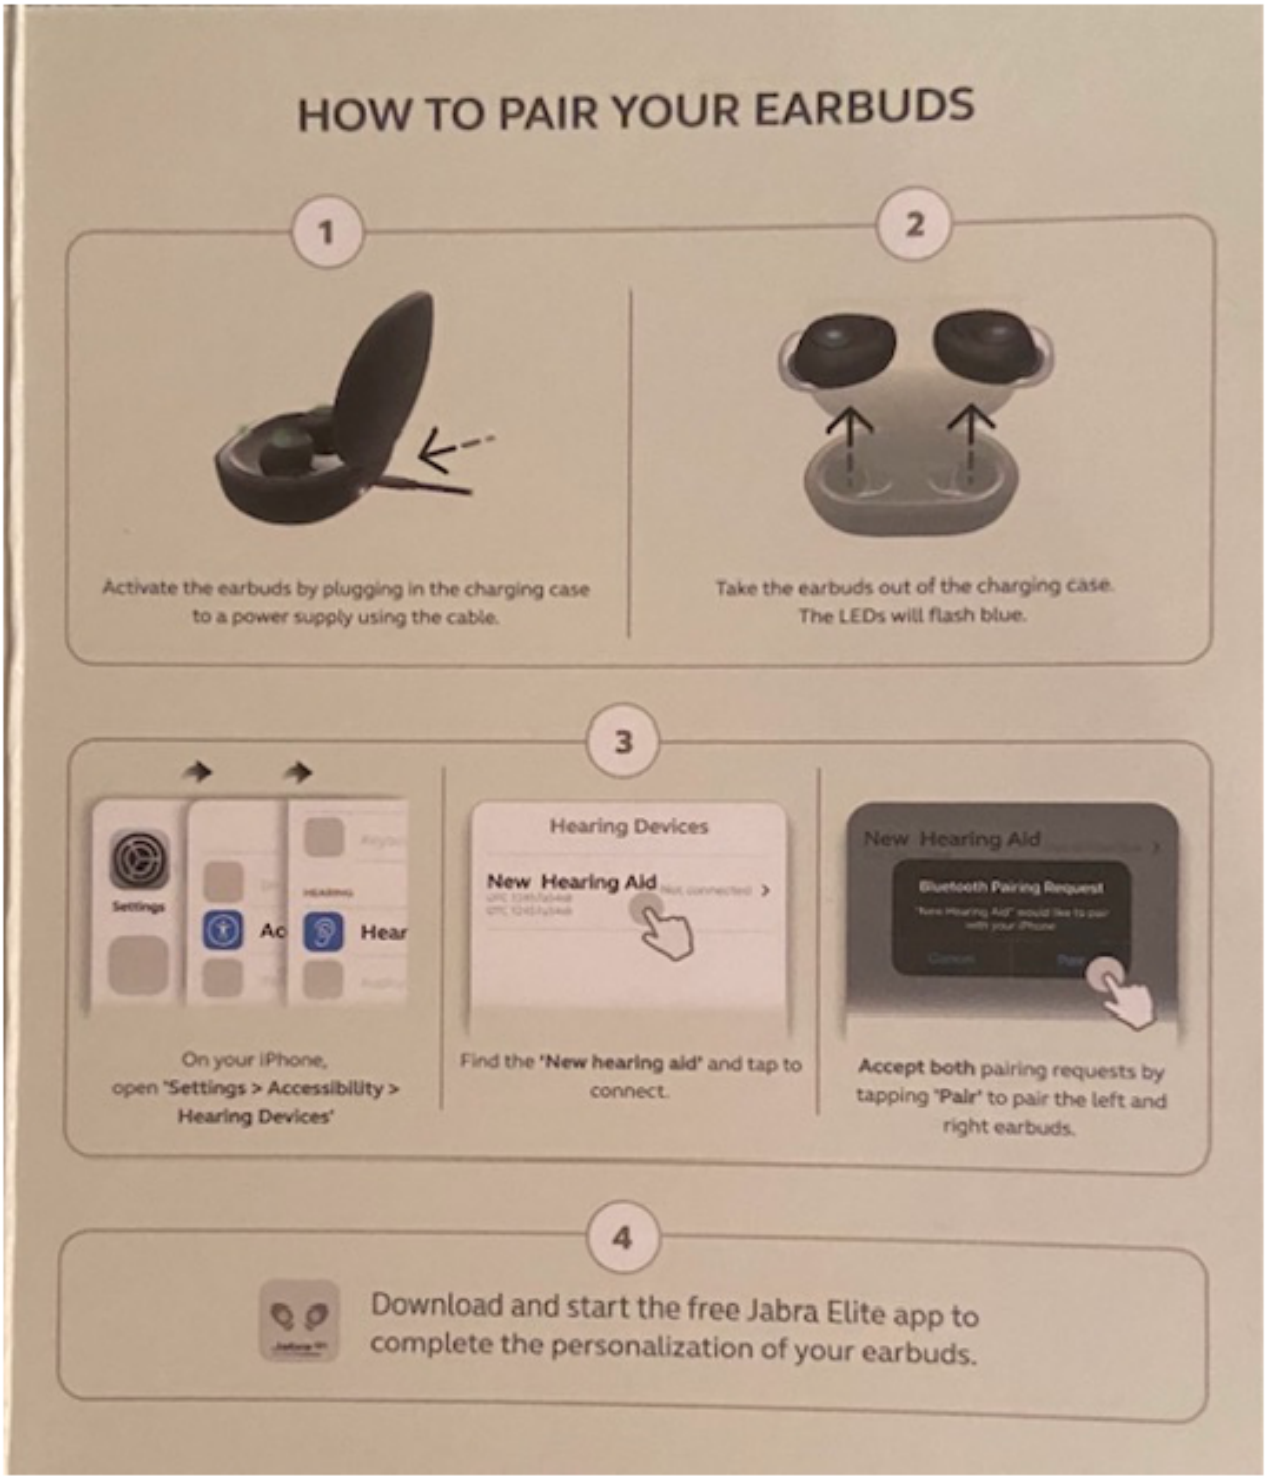


Figure 3. Quick guide (February 2021 version—round 2 testing).

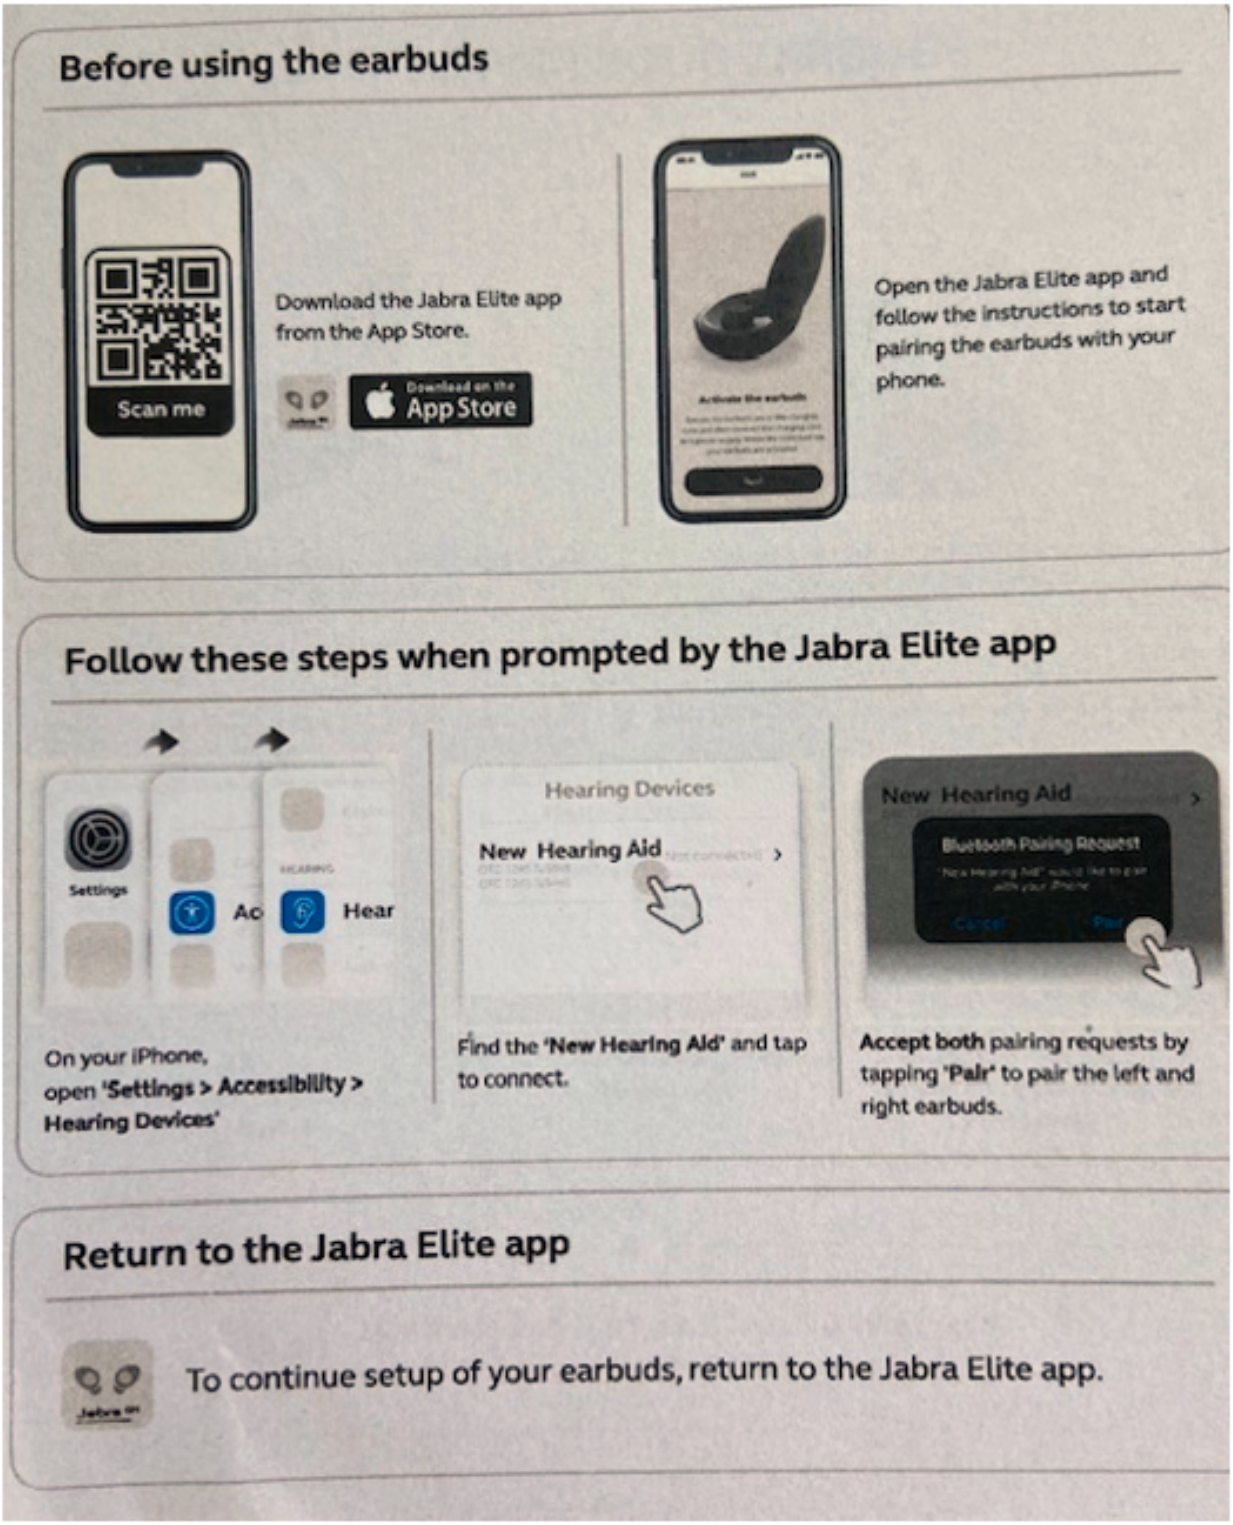

Following these design changes, task 2 success rate increased from 40% (2 out of 5 in round 1) to 67% (10 out of 15 in round 2). Yet, there were still several use errors during pairing and setting up the earbuds in round 2. For instance, 2 (13%) participants did not understand that they needed to go to an app to set up the earbuds. Several participants had trouble reading the Quick Guide instructions as the text was too small (see Figure 3). A total of 3 participants did not know what to do after pairing the earbuds to the phone. Finally, it was unclear to participants which section of the iPhone settings to use to pair the hearing aids. Some participants had difficulty finding the "Accessibility" section in the iPhone's system settings, and some participants then went to the "Bluetooth" rather than the "Hearing Devices" section to pair the hearing aids.

Distinguishing the Right and Left Earbud

Participants had difficulty determining which earbud was for the right versus the left ear. Several participants stated that they

saw a "R" and "L" on the charging case, but not on the earbuds themselves. For instance, one participant stated, "so, there's not a right and a left?" while another participant said, "I don't see a left and right, they don't indicate that right?" Some participants were eventually able to identify the "R" and "L" markings on the earbuds stating,

> *Ah, there's an R on the end, that's really hard to see. I'd make that bigger...yeah that's really hard to see.*

The inability to distinguish the right from the left earbud resulted in several use errors, including difficulty placing the earbuds in the ears and difficulty placing the earbuds back in the charging case.

User Manual

The user manual contained information about the intended use and about most of the hazards of device use. The location of the user manual at the bottom of the box led to several use errors. Several participants were not able to find the manual. Finding the user manual was challenging since the text "User manual" was partially covered by the cardboard insert (see Figure 4). One participant said,

> *it's kind of hidden though...that's a little deceiving maybe, because I would have looked at this first.*

Another participant asked, "Where are the directions?" In total, 5 (33%) participants, all of whom identified the user manual, struggled to get it out of the box. Several more participants never took the manual out of the box; it is possible that these participants could not find the manual but did not verbalize this. Additionally, in round 1 testing, we found that there was not an entry in the table of contents to indicate on which page the "intended use" and "health and safety information" was within the user manual. This was corrected prior to round 2.

Figure 4. User manual cutout in box.

Product Design

Overall, participants were very positive about the device. They liked the size and design of the charging case (eg, small and easy to put in a pocket or purse), and they liked that the device was rechargeable, and thus did not require batteries. Participants liked the sleek and modern looking design stating, "it feels high-end" and said that the hearing aids were easy to place in their ears. They appreciated the different sized ear gels and the magnets that assured that the earbuds clicked into the correct charging position in the case. Participants were excited that they could purchase the device "off-the-shelf" and stated it would be helpful to use when they were in crowded rooms. Despite observed difficulties with setting up and pairing the hearing aids to the iPhone (task 2), participants reported that the app was easy to use. Finally, participants liked that they could adjust the hearing aids' settings on their phone.

Participants recommended several areas for improvement. Most participants desired a longer battery life (which was 6 h at the time of testing) so that they could wear the hearing aids all day without needing to recharge them. They also recommended that technical terms be better explained in the manual and on the box. One participant recommended that the hearing aids come in more discreet colors (ie, skin colored) instead of black. Participants recommended some modifications to the front of the box saying,

> *it should have more on the front about like if it's better for a noisier environment or something, because I'd be more likely to use it if it said, "will improve your hearing in a crowded environment" because I have a very hard time hearing when there is background noise.*

Some participants also found the contrast of white and red text on a gray background hard to read.

Knowledge Assessment

Table 3 details the scores for each of the 10 knowledge assessment questions across all 3 rounds of testing. Participants who used the user manual performed better overall compared to those who did not access or refer to the user manual. The user manual appeared to help the most on question 9—whether someone who had a recent episode of dizziness should use the earbuds.

Table . Knowledge assessment (percent correct answers).

#	Question topic	Round 1 (n=5), n (%)[a]	Round 2 (n=15), n (%)[b]	Round 3 (n=21), n (%)[c]
1	Tinnitus	1 (20)	13 (87)	13 (62)
2	Sinus infection	0 (0)	15 (100)	15 (71)
3	Severe hearing loss	4 (80)	8 (53)	5 (24)
4	Rapid hearing loss	1 (20)	11 (73)	11 (52)
5	Preference for earbuds	1 (20)	12 (80)	15 (71)
6	Laryngitis	3 (60)	4 (27)	7 (33)
7	Sore in ear	5 (100)	13 (87)	17 (81)
8	Ear wax	3 (60)	12 (80)	11 (52)

Design Recommendations

Based on the identified usability issues, we recommended 9 design changes to the earbud system and its packaging (Table 4). We rated these recommendations as "high,""medium," or "low" priority. A total of 4 of the proposed changes (items 1, 2, 3, and 7 in Table 4) were implemented prior to subsequent testing rounds and all but 2 (items 4 and 5) were implemented prior to initial product release. Each design recommendation corresponds to a human factor's design principle (descriptions of the design principles can be found in Barton et al [22]).

Table . Design recommendations derived from the results of 3 rounds of usability testing.

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
1	High	Yes	Yes	• Increase the font size of the text in the Quick Guide	Readability (font and capitalization)
2	High	Yes	Yes	• Revise the Quick Set-up Guide and user manual to clearly show the following steps: • Download Jabra Enhance app from app store • Open the Jabra Enhance app (show a picture of the app) • Register and set up the hearing aids following the steps on the app • Pair the hearing aids with the iPhone (show pictures to show the steps of going to settings > accessibility > hearing devices), select "New Hearing Aid" device, accept both pairing requests • Return to the Jabra Enhance app (show picture of returning to app)	Organization (order)
3	High	Yes	Yes	• Add a section in the user manual's table of contents for "Intended use and warnings"	Organization (navigation tools)
4	High	No	No	• Add a screen in the app that lists the contraindications of use (eg, severe hearing loss, tinnitus, and dizziness). This could be a screen after the registration in the app that participants acknowledge they understand reasons they should not use the device.	Content (emphasis)

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
5	Medium	No	No	• Increase the font size of text about contraindications and intended use on the outside of the box.	Readability (font and capitalization)
6	Medium	No	Yes	• More clearly indicate on the box that the device is to support those with hearing loss. It may be helpful to add the below text from the user manual, page 1, somewhere onto the outside of the box: "This product may help you, if you: • Strain to follow conversations in both quiet and noisier environments • Miss important information during conversations • Have trouble hearing at a distance • Have trouble understanding the television or telephone calls"	Content (clarity of content)
7	Low	Yes	Yes	• Revise the app name and other aspects in the app and user materials to have a consistent term for the Jabra earbuds, for example, "Jabra Elite," "Jabra earbuds," and "Jabra hearing aid."	Comprehensibility (terminology)
8	Low	No	Yes	• Make the cut-out in the white box bigger so that the entire "User Manual" text can be seen (Figure 4), and add text directing users that the user manual is under the white box. Could say "User Manual" with an arrow pointing below the box.	Readability (layout and position)
9	Low	No	Yes		

#	Priority	Addressed before round 2 testing?	Addressed before product release?	Design recommendation	Corresponding human factors principle
				• Add a note on the "manual pairing" page of the user manual that participants should refer to the "first time use" section if it is their first time setting up the device: "if this is the first-time use, please refer to page X."	Organization (navigational tools)

Device Packaging

We recommended that the warnings and intended use information on the outside of the box be better emphasized (eg, larger font size and more color contrast) to ensure appropriate use. Due to participants' difficulty finding the user manual and getting it out of the bottom of the box, we recommended placing the user manual on the top so the user sees and touches it before accessing the product. This could improve safety as the user manual contains most of the warnings and intended use information about the device.

Pairing the Device

To better support the pairing of the device to the smartphone, we recommended that the Quick Guide be revised. Despite modifications after round 1 testing, participants still could not read or follow the Quick Guide instructions due to the small text size. We recommended that the font size in the Quick Guide be significantly increased given the older population intended to use this device. We also recommended modifying the Quick Guide to clearly outline the pairing steps (eg, go to "Settings" then "Accessibility" then "Hearing devices"). As participants did not know to return to the app to complete set up after pairing the earbuds to the iPhone, we recommended that the steps in the Quick Guide be more clearly sequentially marked (eg, 1, 2, 3,... or a, b, c,...).

Discussion

Principal Findings

In this study, we evaluated the safety and usability of an over-the-counter hearing aid for people with mild to moderate hearing loss. We conducted usability testing with 20 intended and 21 nonintended users of the device. We identified numerous usability issues hindering the optimal use of the hearing aid, and generated design recommendations to mitigate use errors and improve the overall design of the device.

This work expands our understanding of the safety and usability of novel, over-the-counter hearing devices [18,26]. Overall, we found minimal safety-related issues with the device. The primary safety risk is that the diagnosis and treatment of a serious condition, such as sudden deafness due to infection, may be delayed due to the lack of medical screening prior to the device use [27]. Consistent with this, the main challenge we found was related to the lack of understanding by nonintended users, including those with tinnitus and severe hearing loss, that they should not use the device. This issue underscores the importance of ensuring that device contraindications and safety warnings are clearly displayed and legible, preferably on the outside packaging. Further, redundant messaging should be incorporated; we recommended a verification dialog in the phone app during device set up to ensure that users understood device use contraindications.

Usability testing identified numerous usability issues with the device, which largely related to violations of human factors design principles. Some examples of violations of the principle, readability (font and capitalization), were the small font size of the contraindications on the outside of the box, the Quick Guide, and the markings of "L" and "R" on the hearing aids. We also identified issues with comprehensibility (terminology), as the device was referred to by different terms (eg, "Elite" and "Rogue") throughout the packaging and app. Based on our design recommendations, there were significant improvements in the usability of the device between the testing rounds. Human factors design principles [23,24], including those developed specifically for patient-facing medical documents [22,25], should be incorporated into the design of patient-facing medical devices. In hearing care, specific design guidelines for older adults (eg, use 12-14 pt font sizes, write in third-sixth grade level) [28] should be followed to maximize the ease of use of these devices given the substantial diversity in patients' physical and cognitive attributes and abilities, experience, and background.

We observed appreciable tension between the goals of designing for safety and designing for ease of use, aesthetics, and marketability. For instance, from a safety perspective, the device's contraindications for use (eg, tinnitus) should have been displayed in a large font such that they covered much of the back of the box. However, this would not be aesthetically appealing and there were concerns that it would deter customers from purchasing the device. Similarly, from a safety perspective, we recommended adding a hard stop in the app setup to ensure that the user understood the intended use of the device. However, this would have decreased the ease of pairing the earbuds to the phone. With over-the-counter medical devices, both product safety and aesthetic appeal are important [16] and

it can be challenging to achieve both concurrently resulting in trade-off decisions. For devices with greater safety risks, safety should be prioritized.

We found that participants were excited about an over-the-counter hearing aid and appreciated this product's design attributes. Similar to prior studies [18,26], participants liked the earbuds' discreet size and form factor, which made hearing aid use less obvious, especially given the growing general use of earbuds for listening to music or talking on the phone. Participants also liked that the device did not require batteries and that it had a small carrying case that could easily fit in a pocket or purse. Our study identified excitement about the device from the intended user population, which may result in increased access to and use of hearing aids.

We uncovered challenges in conducting usability testing with nonintended users of the device. One goal of the FDA device approval process is to identify areas of foreseeable misuse including use of the device by unintended users [11]. This is a unique issue with over-the-counter devices, as there is no clinical mediation to ensure appropriate use. During testing, we found that only 50% of nonintended users were able to determine that they should not use the hearing device. While the design of the device and packaging likely contributed to this, another challenge is that participants may have assumed they should use the device since they were recruited to participate in the study. In essence, participants may have been "tricked" into thinking they should use the device due to the nature of usability testing. Future research should explore additional methods or approaches for eliciting information from nonintended users of over-the-counter medical devices.

Another limitation of this study is that the findings are based on users' interaction with the device over only a short period of time; it is possible that as users learn to use the device, ease of use would increase or alternatively, new usability issues may emerge over prolonged use that we did not observe. We only used iPhones for testing and some of the participants were Android users. Despite diversity in participants' age, hearing ability, comfort with technology, and education level, our sample may not have included the full range of end user cognitive abilities, experiences, and backgrounds. In the real environment of use, older adults may rely on adult children or other family members to assist with device pairing and set up; our study highlights the usability issues encountered by older adults setting up the device on their own, without assistance. We also did not test actual use of the hearing aid to enhance participant hearing so we cannot draw conclusions on the function of the hearing aid technology. Future studies should evaluate the use of the hearing aid in the real environment over time to determine if it supports users' needs. There is increasing evidence, however, demonstrating efficacy of over-the-counter hearing aids in comparison to prescriptive devices [29,30].

Conclusions

This study describes the safety and usability of an over-the-counter hearing aid for adults with mild to moderate hearing loss. Based on the usability testing, we proposed human factors design recommendations to enhance the usability and safety of the device. For instance, the intended user group and contraindications for use (eg, tinnitus) should be clearly displayed on the outside of the box, as well as throughout the set up materials. Clear step-by-step guidelines should be available to support user set up and pairing of the device. We identified challenges to the design and testing of direct-to-consumer devices. As the population ages and technologies continue to pervade every aspect of our lives, the direct use of medical devices by laypersons will continue to expand. This study lays the foundation for future studies on best practices for the user interface design of direct-to-consumer medical devices.

Abstract

Background: Falls in hospitalized patients are a serious problem, resulting in physical injury, secondary complications, impaired activities of daily living, prolonged hospital stays, and increased medical costs. Establishing a fall prediction scoring system to identify patients most likely to fall can help prevent falls among hospitalized patients.

Objectives: This study aimed to identify predictive factors of falls in acute care hospital patients, develop a scoring system, and evaluate its validity.

Methods: This single-center, retrospective cohort study involved patients aged 20 years or older admitted to Shizuoka General Hospital between April 2019 and September 2020. Demographic data, candidate predictors at admission, and fall occurrence reports were collected from medical records. The outcome was the time from admission to a fall requiring medical resources. Two-thirds of cases were randomly selected as the training set for analysis, and univariable and multivariable Cox regression analyses were used to identify factors affecting fall risk. We scored the fall risk based on the estimated hazard ratios (HRs) and constructed a fall prediction scoring system. The remaining one-third of cases was used as the test set to evaluate the predictive performance of the new scoring system.

Results: A total of 13,725 individuals were included. During the study period, 2.4% (326/13,725) of patients experienced a fall. In the training dataset (n=9150), Cox regression analysis identified sex (male: HR 1.60, 95% CI 1.21 - 2.13), age (65 to <80 years: HR 2.26, 95% CI 1.48 - 3.44; ≥80 years: HR 2.50, 95% CI 1.60 - 3.92 vs 20-<65 years), BMI (18.5 to <25 kg/m²: HR 1.36, 95% CI 0.94 - 1.97; <18.5 kg/m²: HR 1.57, 95% CI 1.01 - 2.44 vs ≥25 kg/m²), independence degree of daily living for older adults with disabilities (bedriddenness rank A: HR 1.81, 95% CI 1.26 - 2.60; rank B: HR 2.03, 95% CI 1.31 - 3.14; rank C: HR 1.23, 95% CI 0.83 - 1.83 vs rank J), department (internal medicine: HR 1.23, 95% CI 0.92 - 1.64; emergency department: HR 1.81, 95% CI 1.26 - 2.60 vs department of surgery), and history of falls within 1 year (yes: HR 1.66, 95% CI 1.21 - 2.27) as predictors of falls. Using these factors, we developed a fall prediction scoring system categorizing patients into 3 risk groups: low risk (0-4 points), intermediate risk (5-9 points), and high risk (10-15 points). The c-index indicating predictive performance in the test set (n=4575) was 0.733 (95% CI 0.684 - 0.782).

Conclusions: We developed a new fall prediction scoring system for patients admitted to acute care hospitals by identifying predictors of falls in Japan. This system may be useful for preventive interventions in patient populations with a high likelihood of falling in acute care settings.

KEYWORDS

falls; inpatient falls; acute care hospital; predictive factor; risk factors

Introduction

In 2022, the proportion of the population aged 65 years or older in Japan reached a record high of 29% [1]. A 2017 survey by the Ministry of Health, Labour and Welfare of Japan revealed that patients aged 75 years or older accounted for 41.5% of all patients admitted to acute care hospitals [2]. Given the trend in population aging, it is projected that the number of older adult

patients with a high risk of falling will further escalate in the future. Falls are not limited to older adults, and falls in hospitalized patients can lead to severe physical injuries, secondary complications, a marked decline in activities of daily living (ADL), and even death in extreme cases [3,4]. Therefore, fall prevention has become an important issue to protect patients' lives and quality of life [5].

Interventions for fall prevention must be strategically targeted to populations with a high risk of falling during hospitalization. Furthermore, previous studies have emphasized the importance of patient exercise therapy [6,7] and education for both patients and health care providers in fall prevention [8-12]. Educating patients about the risks of falls and strategies to mitigate these risks is crucial in reducing the incidence of falls in hospitalized patients. To effectively conduct patient education, it is imperative to construct a fall prediction model for the accurate identification of these high-risk patients. Currently, fall prevention measures in hospitals include fall prediction models using information from electronic health record (EHR) systems [13-22], as well as predictive models that analyze patient information from EHRs and nursing records using artificial intelligence [15,23]. Here, we present several fall prediction models that can be used with EHRs [17-20]. The STRATIFY scale [17] uses a history of falls, visual impairment, mental status, frequency of elimination, and ability to transfer and move as factors in a prediction model. The Morse Fall Scale [18] includes 6 items related to a history of falls, comorbidities, use of walking aids, intravenous fluids, ability to walk and move, and mental status. The Medication Fall Risk Score and Evaluation Tool [19] assesses the medication-related fall risk. This tool considers a patient's use of medications as predictors, classified according to the associated risk levels. Tago et al [20] reported 8 predictors of falls in people with disabilities in Japan: age, sex, emergency hospitalization, admission to neurosurgery, use of sleeping pills, history of falls, independence in eating, and level of independence in daily living.

Although fall prediction tools are widely used in Japanese hospitals, existing models vary in predictors and are often difficult to apply due to differences in facility and patient characteristics. Many hospitals also rely on tools that lack a strong evidence base [24,25] and are not well integrated with EHR systems. In our clinical environment, we found it challenging to implement existing models due to their reliance on numerous variables that are either difficult to extract from the EHR or unavailable. Therefore, we aimed to develop a streamlined fall risk assessment tool that considers facility-specific factors and can be seamlessly integrated with EHR systems, enabling real-time insights and more efficient fall prevention strategies.

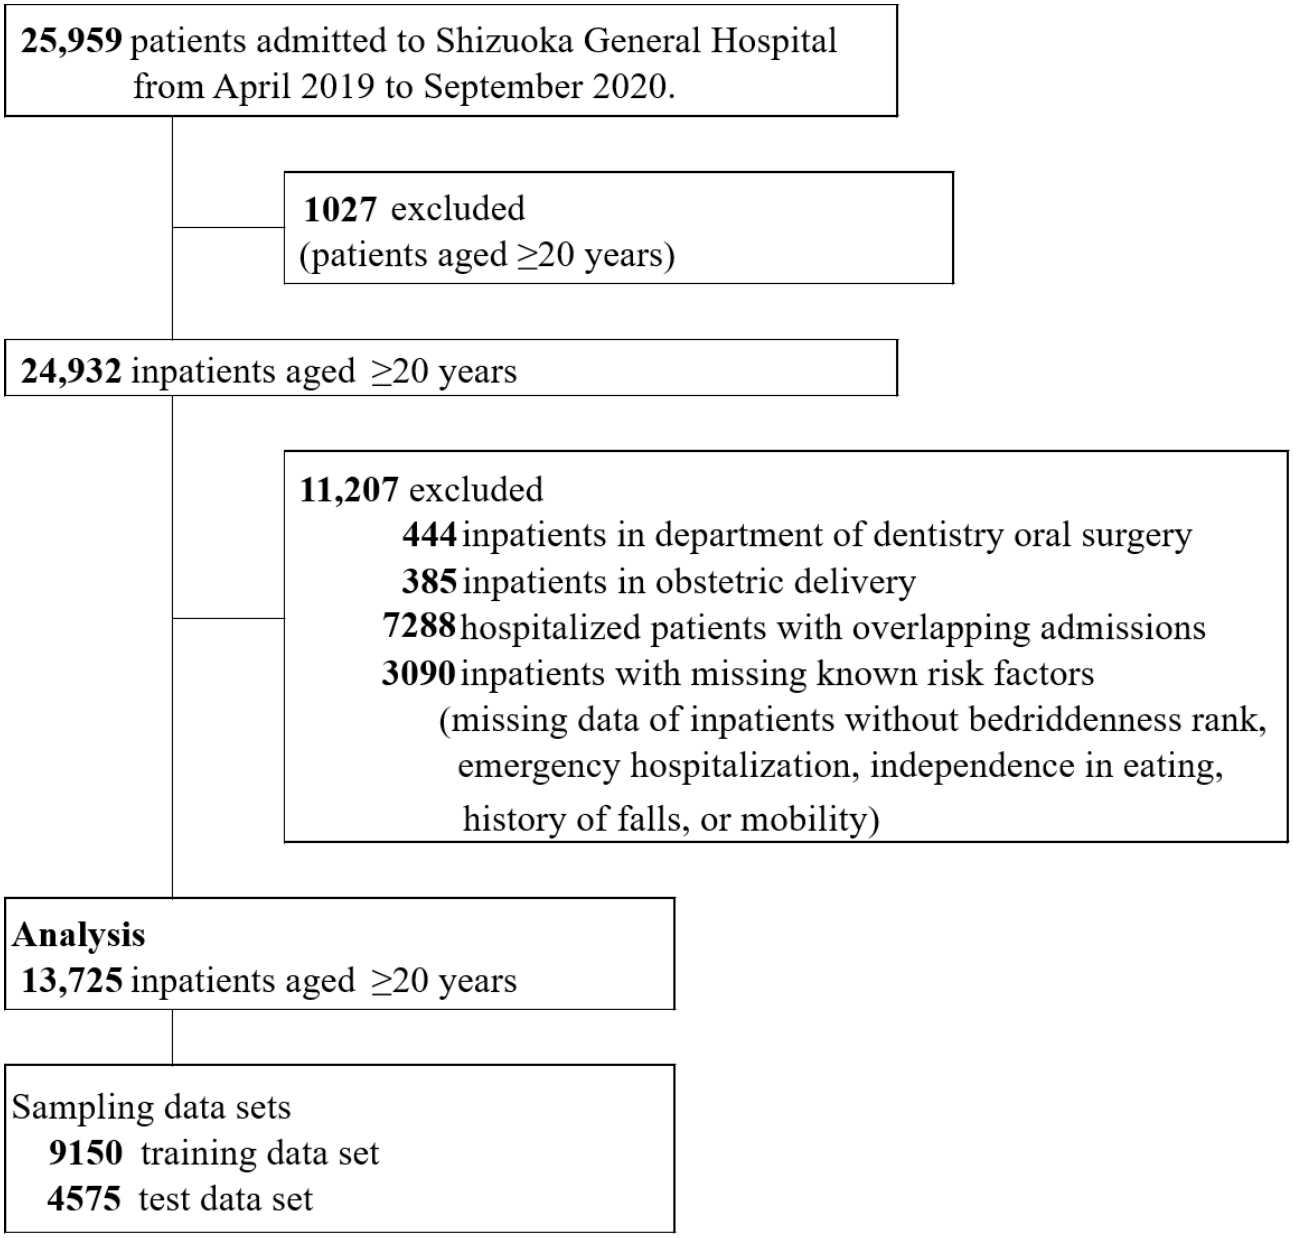
The purpose of this study was to identify predictive factors for falls in patients admitted to an acute care hospital as well as to develop a scoring system using these factors and evaluate its validity.

Methods

Participants and Study Design

We conducted a retrospective cohort study of patients aged ≥20 years admitted to Shizuoka General Hospital between April 2019 and September 2020. Inpatients excluded from the study included those not covered by the Diagnosis Procedure Combination system, such as dental and oral surgery patients and obstetrics and gynecology inpatients during pregnancy, childbirth, and postpartum. In addition, inpatients lacking data on known risk factors such as the degree of independence in daily living for the older adults with disabilities, bedriddenness rank (BR), emergency admission, dietary independence, mobility, and history of falls in the past year were also excluded, as illustrated in Figure 1.

Figure 1. Flowchart illustrating the study population.



Variables at Hospitalization as Candidate Predictive Factors

All data used in this study were extracted from patients' medical records as of February 3, 2022. Preadmission medical history variables included dementia [5,6], Parkinson disease [7,26], stroke [6], visual impairment (with or with no diagnosis of glaucoma or cataracts) [4,5], history of falls [5,16,20,27], and use of sleep medications [20,28-30]. The following variables at admission were also collected: age [6,16,20,27], sex [20,27,28], BMI [31-35], date of admission [20], disease name at admission, department [20], mode of admission, ambulance transport, consciousness disorders [16,23,28], requirement for nursing care, good sleep condition, use of sleeping medication [20,28,30], status of medication management, BR [20,36], Cognitive Function Scores [5,6], ADL at admission (eating, transferring, dressing, toilet transfer or use, bathing, level walking, stair use, changing clothes, defecation management, and urinary management) [17,18,20], fall assessment end points at admission (history of falls or falls within 1 year, inability to stand without holding on [28], impaired judgment and comprehension, toilet assistance, and use of portable toilet), and presence of physical restraint screening at admission.

The BR [20,36] is an official assessment tool in Japan's long-term care insurance system [37]. The BR is an assessment of the degree to which a person's daily life is restricted; this degree is mainly assessed in terms of mobility in daily life, such as whether the person is independent, in a wheelchair, or bed bound. The Ministry of Health, Labour and Welfare ranks the degree of BR based on evaluations by nurses and other health care professionals according to the daily care they provide during hospitalization, as well as on reports from family members. The procedure for assessing BR and its reliability have been reported [20,36].

Falls During Hospitalization as an Outcome

The primary end point was the time from the date of admission to a fall at incident level [38] 2 or higher (hereafter referred to

as “fall”), which requires medical resources. For patients who died during hospitalization and those who did not have a fall, the date of death or date of discharge, respectively, was used as the censoring date. The classification of incident levels is shown in Table S1 in Multimedia Appendix 1.

Statistical Analysis

Demographic data and potential predictors at the time of hospital admission were summarized as follows. Continuous variables are described using mean (SD) or median (range), considering the distribution type. Categorical variables are summarized as frequency (%). For comparisons between the groups with and with no fall occurrence, *t* tests were used for continuous variables and chi-squared tests for categorical variables. The Kaplan-Meier method was applied to estimate the fall rate.

We explored predictors of falls and constructed a predictive model using two-thirds of the total cases, randomly selected as the training group, with the remaining one-third serving as the validation group for the scoring system. In the training group, predictive factors were identified using the Cox proportional hazards model, and we calculated hazard ratios (HRs), 95% confidence intervals (CIs), and *P* values. Predictive candidates that were significant ($P<.05$) in the comparison of backgrounds among patients with and with no falls, along with known predictors, were included in a multivariable model. Factors with *P* value of <.2 in this model were identified as predictors of inhospital falls. Independence between explanatory variables was confirmed using an absolute value of Spearman rank correlation coefficient of >0.4. Among 2 correlated variables, 1 was chosen based on ease of collection or clinical significance; this variable was then included in the multivariable model. According to the identified predictive factors, a score was created for each HR, and these scores were summed. We used a method called “conditional inference tree analysis” to categorize patients into 3 groups based on their risk of falling. This approach works by first dividing the data into 2 groups based on their overall scores. Then, a statistical test is performed to see whether these 2 groups are significantly different, and the variable that shows the strongest difference (the one with the lowest *P* value) is used to split the groups. This process is repeated within each subgroup until no further meaningful divisions can be made or the smallest group size allowed is reached. The predictive performance of this score and the fall risk groups in the validation group were evaluated using the c-index.

The significance level of the 2-tailed test was set at .05. Missing values were not imputed in the analyses. All analyses were performed using R (version 4.1.1; The R Foundation for Statistical Computing), EZR (version 1.54; Saitama Medical Center, Jichi Medical University) [39], and IBM SPSS (version 28; IBM Corp).

Ethical Considerations

This study conformed to the Ethical Principles for Medical Research Involving Human Subjects issued by the Ministry of Health, Labour and Welfare and the Ministry of Education, Culture, Sports, Science and Technology of Japan. Following these guidelines, the Shizuoka General Hospital research ethical committee determined that individual patient informed consent was not required because we analyzed existing information in this study, and patients were given the right to refuse participation via disclosure. After obtaining committee approval (SGHIRB #2020075; January 15, 2022) and publishing the disclosure document on Shizuoka General Hospital’s website, the information for each individual was anonymized, and the analysis was conducted.

Results

Patient Background and Falls at Incident Level 2 or Higher on Admission

From April 1, 2019, to September 30, 2020, a total of 24,932 inpatients aged 20 years or older were admitted to Shizuoka General Hospital. We excluded 3.3% (829/24,932) of patients not covered by the Diagnosis Procedure Combination, 29.2% (7288/24,932) with duplicate admissions, and 12.4% (3090/24,932) with missing known risk factors of falls. Consequently, 55% (13,725/24,932) of patients were included in the analysis (Figure 1).

During the observation period, defined as the length of hospital stay (median [range]: 13 [1-271] days), 3.6% (489/13,725) of patients experienced falls across all incident levels, of which 2.4% (326/13,725) falls were classified as incident level 2 or higher. For this study, we used fall data meticulously managed by the hospital’s medical safety department, ensuring accuracy and reliability. The details are shown in Table S2 in Multimedia Appendix 1. The median age (range) of the patients included in the analysis was 66 (20-103) years, with 52.1% (7150/13,725) male patients, and the median BMI (range) was 22.8 (9.6 - 58.1) kg/m^2. Table S3 in Multimedia Appendix 1 shows the results of the comparison between the backgrounds of patients in the training and test datasets. In a univariable analysis of the training dataset (n=9150; two-thirds of the study population), we compared patient backgrounds according to the presence of falls (Table 1).

[a]Between-group comparisons were made using *t* tests and χ^2 tests for continuous and categorical variables, respectively. The *P* value was calculated using the Wald test. Bedriddenness rank J=independent or autonomous, rank A=housebound, rank B=chair, and rank C=bedridden.

Predictors of Falls

In the training dataset, univariable Cox regression analysis compared patient backgrounds based on the presence or absence of falls and identified factors affecting the time from admission to the date of fall (Table 2, left side). Correlations between explanatory variables were checked using Spearman correlation coefficients, and independent explanatory variables were entered into a multivariable regression model. The variables were narrowed down by applying a high absolute value of the Spearman correlation coefficient (>0.4) (Table S4 in Multimedia Appendix 1). Among the 21 variables that were significant in the univariable analysis, 5 variables (age, sex, BMI, department, and history of falls within 1 year) were not correlated with each other. Sixteen variables (including 12 ADL-related variables, emergency admission, and consciousness disorders) had a correlation coefficient of 0.4 or higher. From the correlated variables, BR was ultimately chosen. This decision was influenced by the fact that 12 other ADL variables showed correlation, and BR could potentially explain physical severity, including factors such as emergency transport and impaired consciousness. The variables were chosen based on ease of collection or clinical significance.

[a]Between-group comparisons were made using *t* tests and χ^2 tests for continuous and categorical variables, respectively. The *P* value was calculated using the Wald test. Bedriddenness rank J= independent or autonomous, rank A=housebound, rank B=chair, and rank C= bedridden.

[b]HR: hazard ratio.

[c]Not applicable.

In multivariable analysis, age (65 to <80 years: HR 2.26, 95% CI 1.48 - 3.44; ≥80 years: HR 2.50, 95% CI 1.60 - 3.92 vs 20 to <65 years), sex (male: HR 1.60, 95% CI 1.21 - 2.13), BMI (18.5 to <25 kg/m²: HR 1.36, 95% CI 0.94 - 1.97; <18.5 kg/m²: HR 1.57, 95% CI 1.01 - 2.44 vs ≥25 kg/m²), BR (rank A: HR 1.81, 95% CI 1.26 - 2.60; rank B: HR 2.03, 95% CI 1.31 - 3.14; rank C: HR 1.23, 95% CI 0.83 - 1.83 vs rank J), emergency department (internal medicine: HR 1.23, 95% CI 0.92 - 1.64; emergency department: HR 1.81, 95% CI 1.26 - 2.60 vs department of surgery), and history of falls within 1 year (yes: HR 1.66, 95% CI 1.21 - 2.27) are shown as predictors of inhospital falls (Table 2, right side).

Construction of a Fall Scoring System

Based on the results of multivariable analysis using the training set, we weighted the scores based on each HR (Table 2, right side) and formed 3 fall-risk groups (low risk: 0-4 points, moderate risk: 5-9 points, and high risk: 10-15 points) using conditional inference tree analysis (Figure S1 in Multimedia Appendix 1). The new fall prediction scoring system built on this basis is shown in Figure 2. As a predictor of the performance of these 3 classifications of fall prediction, the c-index in the validation set (n=4561) was 0.733 (95% CI 0.684 - 0.782). The cumulative fall incidences in training and test datasets are

shown, with Kaplan-Meier curves presented for the training dataset (Figure 3A) and the test dataset (Figure 3B).

Figure 2. Fall prediction scoring system to be implemented at the time of admission.

Predictive score for falls at admission		
Sex		
☐ Female		0 points
☐ Male		2 points
Age		
☐ 20 to < 65 years		0 points
☐ 65 to < 80 years		3 points
☐ ≥ to 80 years		4 points
BMI		
☐ ≤ 18.5 kg/m^2		2 points
☐ 18.5 to < 25 kg/m^2		1 points
☐ ≥ to 25 kg/m^2		0 points
Bedriddenness rank		
☐ Rank J		0 points
☐ Rank A		2 points
☐ Rank B		3 points

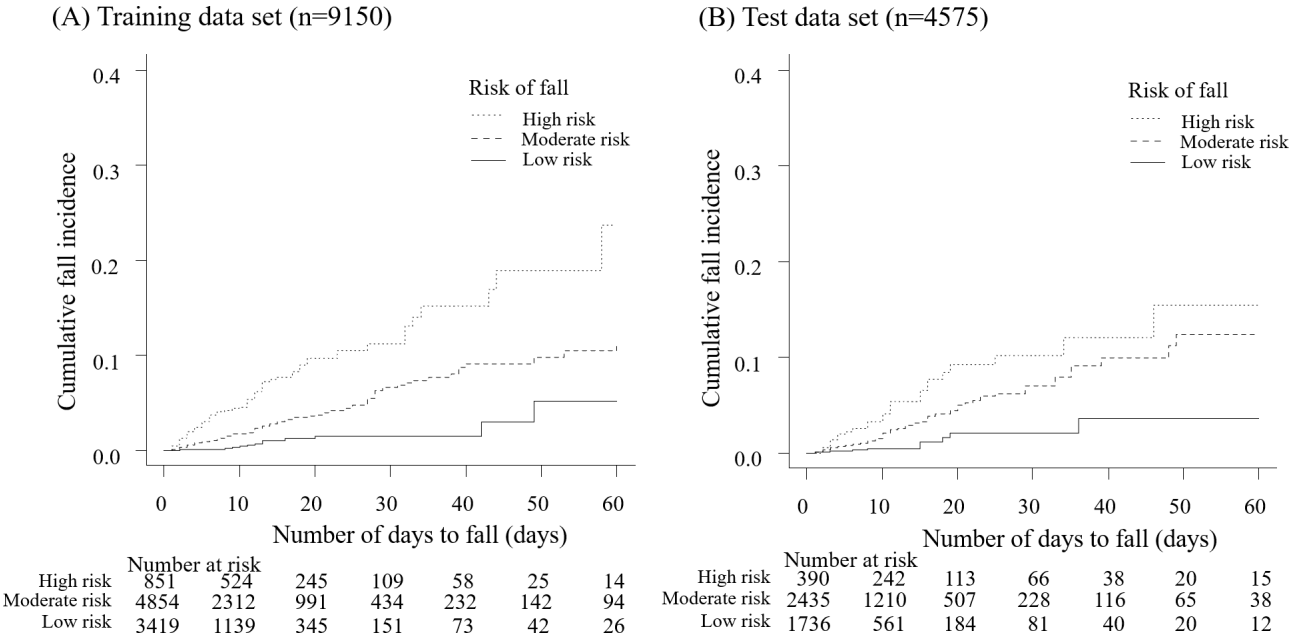
☐ Department of surgery		0 points
☐ Emergency department		2 points
History of falls with in 1 years		
☐ Absence		0 points
☐ Presence		2 points
Sum of the points		____points
Risk of fall	0-4	Low risk
	5-9	Moderate risk
	10-15	High risk

Figure 3. Fall risk classification-specific cumulative fall incidence. Cumulative fall incidences classified by fall risk scoring are shown for the training dataset (**A**) and test dataset (**B**).



Discussion

Principal Results

This study was a retrospective cohort investigation conducted at an institution specialized in acute inpatient care, aimed at identifying the risk factors for falls using the time from admission to fall as the outcome variable. Fall risk factors included age, sex, BMI, BR, emergency department, and history of falls within 1 year. Specifically, the study found that older patients (aged 80 years and older) had a higher risk of falls, with men being more at risk than women. Patients with a BMI of <18.5 and those admitted through the emergency department had an increased risk. In addition, those with a history of falls within the past year were particularly vulnerable. We constructed a new predictive scoring system for falls by weighting scores based on each HR according to the results of multivariable analysis and using statistical methods to classify fall risk groups into 3 categories (low risk: 0-4 points, moderate risk: 5-9 points, and high risk: 10-15 points). The present fall prediction scoring system could facilitate preventive interventions for high-risk patients, potentially reducing the likelihood of falls among the most susceptible patient populations and improving patient safety and care in the hospital environment.

Comparison With Prior Work

In terms of age-specific fall incidence, it was evident that a higher proportion of falls occurred among people aged 65 years and older. This result is in alignment with previous reports [6,16,20,22,27,40] identifying advanced age as a predictive factor for falls. Consistent with past studies [5,16,20,22,40], a history of falls was determined to be a predictive factor.

Previous reports on predictors of falls have shown that sex can be a predictor for both men and women. In this study, being male was identified as a risk factor. In addition, men have been found to experience multiple falls more frequently [27]. Past reports indicating that being male increases the risk of falls [20,28] have focused on hospitalized patients whereas those suggesting an increased risk for women [41,42] have focused on community-dwelling individuals. These differences may be owing to the different characteristics of the study populations, that is, relatively healthy community residents and patients in health care facilities. This may be related to the fact that hospitalized patients tend to have reduced physical activity, which increases the risk of falls. However, the relationship between sex differences and fall risk factors in the hospitalized population remains unclear, and further research is needed to elucidate these aspects.

A systematic review targeting community-dwelling older adults showed that a low BMI (<17 kg/m^2) is associated with a greater risk of falls, when using 23.5 kg/m^2 as the baseline [34]. In addition, some reports indicate that both high (25 - 35 kg/m^2 or above) and low (below 18.5 kg/m^2) BMI values are associated with increased fall risks [31-33,35]. These findings suggest that extreme BMI values influence the risk of falling. However, in our study, we identified low BMI (below 18.5 kg/m^2) and normal BMI (18.5 - 25 kg/m^2) as risk factors for falls, using high BMI (25 kg/m^2 or above) as the reference category. This divergence in results might be attributed to the fact that in our Japanese study population, few patients met the international high BMI criterion (>30 kg/m^2). In the study, because only 5.7% (6/741) of people in this training category fell, BMI >30 kg/m^2 was not able to be included as the category for a categorical variable BMI.

The BR degree, which is strongly correlated with ADL, was identified as a risk factor for inhospital falls. This finding aligns with several fall prediction models [17,18,20], demonstrating the significant role of a decline in ADL, as it is known that exercise therapy is effective in fall prevention [6,7]. This underscores that impaired ADL is a crucial factor in determining the outcomes of patients who experience falls. In addition,

because the overall assessment of ADL is predominantly based on mobility, a substantial correlation [43] between ADL and BR has been observed. In our study, of the 15 variables that showed a correlation with BR, 12 were related to components of ADL.

Being admitted to the emergency department (as an inpatient department) was identified as a risk factor for inhospital falls. The emergency department inpatient population comprises patients who have been transported to the emergency department or who otherwise came voluntarily to the emergency department. This population typically has more severe illness, which may explain why emergency department admission is a risk factor for inhospital falls. Moreover, a history of falls within the past 1 year was identified as a risk factor for inhospital falls. This result was similar to previous reports that identified a fall history as a risk factor for subsequent falls [17,18,20].

Falls are internationally recognized as a serious health issue [3,30], and various efforts to prevent falls are undertaken worldwide. Particularly in Japan, where rapid aging is prevalent, fall prevention has become an increasingly critical issue. Education for patients and staff is considered a fundamental approach to addressing this problem [8,10-12,44], and the introduction and enhancement of educational programs in Japanese hospitals are desirable [10]. To achieve this, it is essential to identify high-priority patients among inpatients and implement fall prevention measures as a high-risk approach. Multifactorial interventions to comprehensively assess and address multiple fall risk factors have proven effective [10]. However, some tools for evaluating fall risk have been criticized for their time-consuming nature and limited effectiveness [45-47], necessitating judicious selection and effective use. Recent research supports these multifactorial interventions and highlights the importance of tailored educational programs and effective risk assessment tools. Guidelines from the United Kingdom's National Institute for Health and Care Excellence offer specific approaches for fall prevention [48], which could serve as valuable references for fall prevention strategies in Japan. In the approach to fall prevention in Japanese hospitals, international insights and guidelines should be considered while also tailoring unique approaches according to facility characteristics, health care delivery systems, and patient backgrounds.

Statistical Validation and Clinical Application of Risk Categorization

In our research, we used the conditional inference tree method for statistical analysis to categorize patients into low-, middle-, and high-risk groups, as detailed in Table S4 in Multimedia Appendix 1. This methodological choice ensured that our risk stratifications were based on solid data analysis, avoiding arbitrary determinations. In addition, this scoring approach permits adjustment of cutoff values based on each health care facility's resources and circumstances, enhancing its applicability in diverse clinical settings. Our aim is not to change the patient's fall risk level based on resources but to adjust the intensity of preventive interventions according to available resources. The fall risk classification is based solely on clinical characteristics, while resource availability guides the prioritization and distribution of these interventions.

For patients identified as high risk for falls according to our predictive model, it is important to recognize that identifying these individuals is only the first step; providing effective interventions is a separate and critical challenge. Based on prior research demonstrating their effectiveness, we recommend several interventions tailored to implement fall prevention measures as a high priority. Here, we outline interventions such as increased monitoring, personalized environmental adjustments, nonslip footwear, assistive devices such as walkers or canes, one-on-one support, and immediate assistance. In addition, patient education and rehabilitation are crucial components. Educating both patients and health care providers about fall risks and preventive strategies, combined with physical therapy to enhance strength and balance, can significantly reduce the risk of falls [6-12]. However, it may be necessary to adjust these cutoffs based on sensitivity and specificity considerations to enhance the accuracy of patient risk identification, aligning more closely with practical prediction practices in health care.

The fall prediction tool we developed integrates seamlessly with a hospital's EHR system. Upon a patient's admission, it automatically retrieves EHR data and calculates a fall risk score based on various predictors. This integration allows all health care providers, including emergency and trauma physicians, to easily access the patient's fall risk assessment. Emergency or trauma physicians can use this tool to quickly identify patients at high risk for falls and implement appropriate interventions. This proactive approach can significantly reduce the incidence of falls and enhance patient safety in fast-paced and high-stress environments such as emergency departments and trauma centers.

Limitations

This study has several limitations. First, owing to the identification of inhospital fall predictors based on the characteristics of the facility and patient population in an acute care hospital, generalizing the findings to other all hospitals may be challenging. While the generalizability of our model is not fully guaranteed due to the lack of external validation, hospitals with similar facilities and patient characteristics might find the identified predictors and scoring system developed in this study applicable to their setting. Second, our study did not examine psychiatric symptoms, including delirium, as a potential predictive factor [49,50]. Because previous studies have shown that psychiatric symptoms can be a risk factor for falls [17,18,28], it can be necessary to reconstruct the prediction model by including additional predictors of falls, including psychiatric symptoms such as delirium, in future studies. Third, we did not examine the association between medications and falls. Previous studies have shown that taking sleeping pills [19,20,28-30,51] and the number of medications [42,52-54] are risk factors for falls. At the time of our study, limitations in our EHR system made it difficult to collect accurate medication data. This prevented us from including medication type and number as predictors. Since then, our EHR system has been upgraded, and we can now reliably obtain medication data. We

plan to incorporate these variables in future studies to enhance the accuracy of our fall prediction model. Fourth, we could not compare the results of our model with those of existing fall prediction models. However, we believe that our newly developed fall prediction model is highly useful in that it is easy to apply in many Japanese hospitals with acute care settings, similar to that in this study.

To further enhance the practical application of our fall prediction scoring system, we plan to integrate it into our hospital's EHRs to gather real-world evidence. This will allow us to evaluate its usability, accuracy, and impact on reducing inhospital falls. Future research will include multisite longitudinal studies to validate the tool's effectiveness across different health care settings.

Conclusions

We successfully identified predictors of falls within a patient population admitted to an acute care hospital and developed a novel prediction model in Japan. This model could serve as an effective tool to guide preventive interventions for both individual hospitalized patients and high-risk populations in many hospitals with acute care settings.

Acknowledgments

We thank Motoe Yumioka, Satomi Unno, Kazuyo Okushio, Sumiko Sano, Hideko Mochizuki, and Kazue Sano for their guidance in conducting this study. We thank Ms Etsuko Nagahashi and Mr Hiroki Ueda of the Information Support Office of Shizuoka General Hospital for assistance with data acquisition. We thank Katherine Thieltges and Analisa Avila, MPH, ELS, from Edanz for editing a draft of the manuscript. This study was supported by a grant-in-aid for Medical Research Promotion from the Shizuoka Prefectural Hospital Organization and a research instruction budget from the Shizuoka Graduate University of Public Health.

Data Availability

The datasets generated and analyzed during this study are not publicly available since the authors failed to obtain informed consent regarding the disclosure of raw patient data at the start of the study, which means the data in the manuscript, supporting information files, or public repositories cannot be freely accessed. However, the datasets are available from the Clinical Trial Management Office at Shizuoka General Hospital, located at 4-27-1 Kita-ando, Aoi-ku, Shizuoka, Japan 420-8527 (chiken-sougou@shizuoka-pho.jp), on reasonable request.

Authors' Contributions

CS and EN contributed to study concept and design and data analysis; CS and KH contributed to data acquisition; CS, EN, HS, NEK, MT, and KH did data interpretation; and CS contributed to first draft of the manuscript. All authors read drafts of the manuscript and approved the final version.

Conflicts of Interest

None declared.

Abstract

Background: The opaque nature of artificial intelligence (AI) algorithms has led to distrust in medical contexts, particularly in the treatment and monitoring of atrial fibrillation. Although previous studies in explainable AI have demonstrated potential to address this issue, they often focus solely on electrocardiography graphs and lack real-world field insights.

Objective: We addressed this gap by incorporating standardized clinical interpretation of electrocardiography graphs into the system and collaborating with cardiologists to co-design and evaluate this approach using real-world patient cases and data.

Methods: We conducted a 3-stage iterative design process with 23 cardiologists to co-design, evaluate, and pilot an explainable AI application. In the first stage, we identified 4 physician personas and 7 explainability strategies, which were reviewed in the second stage. A total of 4 strategies were deemed highly effective and feasible for pilot deployment. On the basis of these strategies, we developed a progressive web application and tested it with cardiologists in the third stage.

Results: The final progressive web application prototype received above-average user experience evaluations and effectively motivated physicians to adopt it owing to its ease of use, reliable information, and explainable functionality. In addition, we gathered in-depth field insights from cardiologists who used the system in clinical contexts.

Conclusions: Our study identified effective explainability strategies, emphasized the importance of curating actionable features and setting accurate expectations, and suggested that many of these insights could apply to other disease care contexts, paving the way for future real-world clinical evaluations.

atrial fibrillation; explainable artificial intelligence; explainable AI; user-centered design; prevention; postablation monitoring

Introduction

Background

While the role of artificial intelligence (AI) in health care is growing, concerns about its reliability and transparency remain largely unaddressed [1]. The opaque nature of AI algorithms challenges trust, particularly in cardiology, where the lack of interpretability in deep learning models limits their adoption and utility [2,3]. This has led to increased interest in developing explainable AI models that offer accurate predictions along with clear explanations of the rationale behind the predictive results [4].

Our study explored the advantages and challenges of using AI models in cardiovascular treatment, focusing on designing an explainable AI system to aid posttreatment care for patients with atrial fibrillation (AF) after catheter ablation. There were >3 million new cases of AF, a common arrhythmic disorder [5], in 2017, with numbers expected to rise due to aging [6]. Although often undetected, AF is a significant risk factor for severe conditions such as stroke or heart failure [7] and can greatly impact patients' quality of life [5,8]. While catheter ablation is effective, AF can recur after ablation, requiring careful monitoring of risk factors [9].

Several machine learning models, from screening algorithms [10,11] to those predicting AF recurrence after ablation [12], have been developed, but integrating them into health care remains challenging. Physicians often require detailed justifications due to prediction uncertainties. While explainable AI algorithms [5,13] could assist, a more holistic approach is needed in posttreatment scenarios to effectively integrate additional information, which remains poorly understood in real-world care contexts (discussed in the next section).

To better integrate a machine learning model into the ongoing decision-making ecosystem and identify unmet clinical needs beyond performance optimization, we used a user-centered, iterative design approach to develop AF'fective, an explainable AI system for posttreatment monitoring of patients with AF. By conducting semistructured interviews, design sessions, and focus groups with 23 cardiologists, we aimed to identify key principles for the effective design and use of explainable AI in real-life cardiac treatment and management. In this section, we first review the development of explainable AI in relevant fields in the second subsection and summarize our first 2 study stages in the third subsection. We then detail and discuss our final-stage findings and conclude with reflections on the study's implications and the generalizability of our insights.

High Accuracy but (Still) Rejected: Machine Learning Models in Cardiology

Cardiology is one field of medicine that has seen extensive use of AI to aid in medical practice. Various machine learning models have been developed and used to assist in a wide range of tasks, from helping predict the prognosis or readmission after heart failure [14,15] to detecting various cardiovascular diseases from medical images [16]. In the area of arrhythmia, previous studies have focused particularly on two key areas: (1) prevention, which involves assisting in the early detection of various arrhythmic conditions; and (2) monitoring, which involves supporting the management of such conditions after treatment [17]. In the preventive area, researchers have shown how machine learning models could be developed and used to detect irregular conditions using electrocardiography (ECG) signals [18] or even through photoplethysmography sensors from commercially available smartwatches [19,20]. In most cases, such models were able to diagnose these irregular conditions with a high degree of accuracy (97%) [20]. However, the potential for a high rate of false positives when implemented through commercial smartwatches has triggered concerns among researchers, and as a result, they have cautioned against using such systems for population-wide screening and emphasized maintaining the 12-lead ECG as the gold standard [21]. Given the prevalence of AF, several of the developed models in this domain have chosen to focus specifically on this condition, with various deep learning ECG models being developed to help screen people for AF, stratify patients based on their risk level, and even predict the chances of the condition occurring in the future (see the study by Sehrawat et al [21] for a comprehensive review).

In the monitoring area, to support posttreatment care, previous studies have developed models capable of predicting patient mortality or echocardiographic response after procedures such as cardiac resynchronization therapy [22]. Other studies have even shown how the risk of recurrence for conditions such as AF could be predicted using patient demographics and 3D computed tomography images of the left atrium [23]. Similarly, several studies have demonstrated how the recurrence of AF or 30-day hospital readmission after catheter ablation can be predicted using various deep learning and non–deep learning strategies (eg, convolutional neural network [CNN] and Extreme Gradient Boosting) [12,13,24]. In other cases, deep learning algorithms have also been developed to detect an AF episode 4.5 minutes before onset, thus enabling prompt interventions to prevent their occurrence [25].

Overall, while the findings of these studies all appear to demonstrate significant potential for implementing predictive models to support AF treatment, we have encountered substantial pushback from clinical partners when attempting to implement such a model in clinical practice. Despite the promising performance of the model in the study by Nishimura et al [26] (area under the curve of 0.72 with 83% sensitivity and 58% specificity), there was still strong resistance from physicians regarding trusting the predicted outcomes. Such hesitation and resistance to adopting machine learning models among clinical staff have also been frequently identified in previous studies [1,27]. Given the delicate and often critical nature of treatment in this field, it is not surprising that the lack of interpretability undermines trust in these models, preventing clinicians from using them in medical treatment (see the study by Petch et al [2]). Moreover, the opaque process raises concerns regarding how mistakes could be rectified, not to mention that it may cause potentially disruptive emotions when discussing such results with patients. Therefore, at present, the high accuracy, accessibility, and (possibly) low cost of machine learning models often do not lead to their adoption in medical practice.

Explainable AI in AF

Recently, explainable AI has gained attention as a potential approach to address these issues of transparency and interpretability [28-30]. In the context of AF treatment, ECG data are generally used as a main data source for screening irregular rhythm and predicting the risk of AF recurrence, and as such, explainable AI techniques such as Shapley Additive Explanations (SHAP) have been used with the ECG data to identify features contributing to the predictive outcomes [31]. In previous studies, researchers have proposed an explainable deep learning model that not only detects AF but also describes the reasons behind their decisions and visualizes key regions within the ECG signal identified as important predictors using techniques such as Gradient-Weighted Class Activation Mapping (Grad-CAM) or a deep visual attention [29,32,33]. Building upon earlier models, researchers such as Raza et al [34] incorporated federated learning techniques alongside explainable AI to preserve patient ECG data privacy. In more recent studies, explainable models have even been created that are capable of identifying patients at high risk after catheter ablation and highlighting the features (eg, type of AF, age, and left atrial diameter) that the model used to decide on the risk level for each patient [30]. The use of "explainable" models in this manner has been argued to have the added benefit of allowing clinicians to better understand the relationship between each contributing factor and the predicted outcome of an individual case, helping clinicians justify their decisions and treatments more effectively [35].

While explainable AI techniques are believed to enhance the interpretability of algorithms, incorporating them to truly improve patient outcomes in real-life medical contexts remains challenging [36]. Understanding of the strengths and limitations of these approaches in different use cases and how human and AI-based diagnoses can complement each other is still lacking [36]. Deploying these models effectively requires a thorough examination of the patient journey and adapting the explainable strategy accordingly. Recent studies [37,38] have begun to address these issues by examining the use of explainable AI in more realistic settings with various stakeholders to ensure safe adoption in clinical practice.

Overall, although the integration of explainable AI into medical contexts holds great promise, it requires a concerted effort to address technical, ethical, and practical challenges. Insights from near-live and real-life case studies can help develop best practices and trustworthy methods for implementing such systems in clinical settings, thereby enabling users and professionals to fully benefit from AI technology.

Early Study Stages and Findings in a Nutshell

In this section, we summarize and report the in-depth insights from the 2 early stages of interviews (partially reported as a poster in the study by She et al [39]) and group design sessions to conceptualize and pilot-test our design strategies and prototype. We chose to include some key findings from these early stages to enhance readers' understanding of our design decisions in developing the final prototype for evaluation.

Stage 1

Overview

In the first stage, we conducted semistructured interviews with physicians to gain insights into their experiences and best practices for posttreatment care of patients with AF. Physicians were asked to share their positive and negative experiences, communication strategies, and effective procedures for monitoring posttreatment patients with AF. To sensitize and prepare participants, we provided a 1-week workbook with reflection exercises sent 1 to 2 weeks before the interview. Each interview lasted approximately 45 minutes and was fully recorded with the consent of the physicians.

Participants

We invited 8 physicians from different specialties, such as emergency medicine, internal medicine, and cardiology, to join us for interviews at Kyoto Prefectural University of Medicine in Japan. We made sure to include a mix of experience levels and backgrounds in cardiology to obtain insights that could be more broadly generalized to other medical contexts.

Measurements and Study Apparatus

A week before the interview, each physician received a toolkit to reflect on their clinical practice. The toolkit included a workbook with 7 daily assignments on their experiences and patient interactions as well as stickers featuring emotional words and contextual images to help express their thoughts and feelings.

Study Process

We asked physicians to reflect on their process for diagnosing patients and explaining treatment plans, especially in difficult situations such as delivering bad news. They were also asked to share strategies for handling uncooperative patients or those who rejected treatment. Physicians were encouraged to use the 2 sticker sets to respond to workbook questions or use them as interview resources. During the interview, physicians were guided through the workbook to discuss their specific approaches, experiences, motivations, stressors, and methods for negotiating treatment plans.

Analysis

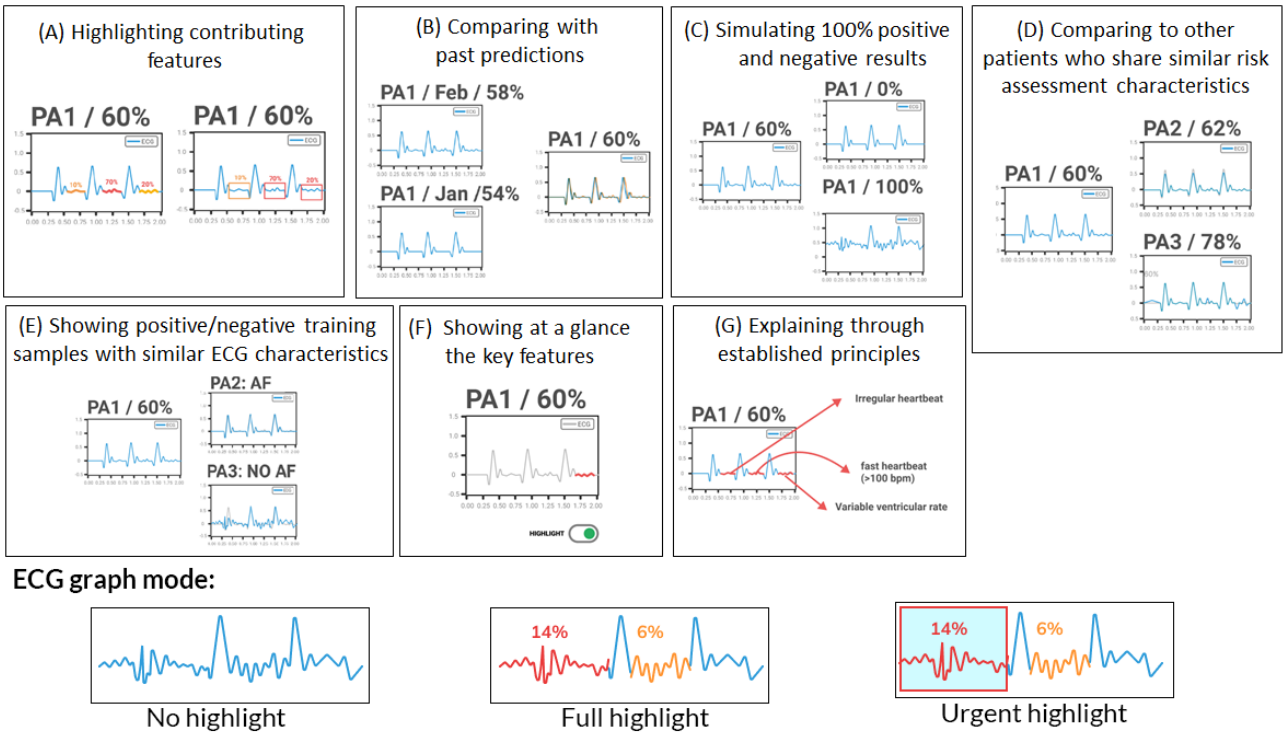
In total, 2 researchers from the human-computer interaction (HCI) field and a cardiologist analyzed the interview data, with all recordings fully transcribed. The HCI researchers developed design strategies through thematic analysis, whereas the cardiologist reviewed and selected strategies for further evaluation in stage 2.

Results

Our initial interviews with 8 physicians produced 2 key outputs: 4 physician personas (*teamworker*, *minimum effort professional*, *the veteran*, and *self-actualizer*) and 7 design strategies for explainable prediction. Each persona included pseudodemographics and progress bars depicting their personalities across 4 parameters: *passionate/realistic*, *rookie/veteran*, *work-oriented/life-oriented*, and *individualism/collectivism*.

The research team discovered that participants had common concerns about self-efficacy in patient treatment, feeling validated when treatments succeeded but disempowered when seen as incompetent. This insight led to the development of 7 design strategies for explainable prediction. Participants emphasized the need to justify decisions by clearly explaining issues such as ECG results to patients. We reviewed and adapted explainable AI strategies from previous studies [40] for cardiology. The seven strategies were (1) highlighting key ECG features (strategy A), (2) comparing with historical predictions (strategy B), (3) simulating extreme ECG outcomes (strategy C), (4) comparing with similar patients (strategy D), (5) showing similar training examples (strategy E), (6) providing an at-a-glance mode (strategy F), and (7) explaining through established ECG principles (strategy G; Figure 1 [39]).

Figure 1. The 7 explainable artificial intelligence strategies (A-G) that were examined in the initial 2 stages of the study, expanded from the previous publication [39]. AF: atrial fibrillation; bpm: beats per minute; ECG: electrocardiography; PA1: patient 1; PA2: patient 2; PA3: patient 3.



Stage 2

Overview

In the second stage, we evaluated the feasibility of the 7 design strategies from the first stage, focusing on those that could be implemented using explainable AI. Physicians first described their usual process for assessing recurrence risk and discussed the potential role of predictive models and explainable AI. We then introduced the explainable AI strategies and gathered detailed feedback on which would most effectively clarify predicted outcomes for other physicians and patients.

Study Process and Findings to Guide the Prototype Development

We conducted 2 group design sessions with 8 cardiologists to critically review and assess our design strategies. Initially, 5 cardiologists were asked to evaluate the advantages and disadvantages of each strategy, describe scenarios in which they would be useful, and reflect on their concerns regarding implementing such explainable features.

From the 7 proposed strategies, we selected 4 (strategies A, B, D, and G) for further development into a web-based prototype using a high-fidelity explainable CNN model with real patient data. In total, 3 cardiologists reviewed the prototype using the concurrent think-aloud approach [41] and provided feedback. They also discussed concerns about using AI during posttreatment care, specifically on whether the explainable features enhanced their trust in the AI system and how the system might add or reduce value in their practice.

Participants

A total of 5 cardiologists with experience treating AF were recruited from Kyoto Prefectural University of Medicine to assess the explainable AI strategies. In addition, 3 cardiologists from the same institution were brought on to evaluate a web-based prototype.

Results and Study Apparatus Development

The 4 effective design strategies identified were highlighting contributing features (strategy A), comparing with past predictors (strategy B), comparing with other patients (strategy D), and explaining through established principles (strategy G). Participants' choices were guided by 3 principles: discernibility (highlighting relevant noteworthy parts), comparability (intra- and interpersonal comparisons), and evidence-based approaches (derived from diagnostic examples or clinical literature).

Strategies to avoid included non–evidence-based methods and those showing only partial graphs.

In general, physicians were highly receptive to the AF'fective prototype, particularly its explainable features, which they found useful for evaluating treatment effectiveness in posttreatment monitoring. On the basis of their feedback, we advanced to web-based prototyping.

The web-based prototype was developed using Figma (Figma, Inc), a popular tool among user experience (UX) designers for creating high-fidelity and web-based prototypes at minimal cost during the development process. Our prototype comprised 2 main screens: a patient overview screen and an individual health record dashboard (to avoid repetition of similar images, we share the screenshots from the final system in this paper instead; Figures 2 and 3).

The overview screen displays patients' demographic details and predicted recurrence risks, allowing cardiologists to sort by various demographic and risk factors. The health record dashboard displays (comparable and evidence-based) health information gathered from a patient's previous visits. Our predictive model will automatically extract and highlight keywords or risk factors based on the patient's visits and health data. In addition, the model differentiates the importance of the risk factors and offers 3 tiers of ECG result presentation based on the level of urgency for physicians: no highlight, full highlight, and critical highlight only.

In critical highlight mode, only urgent health information is shown, whereas the full highlight mode displays all details, including less urgent AI highlights. Validated risk factors are listed as diagnostic keywords in the right panel, helping physicians quickly identify the main contributors to the predictive outcome.

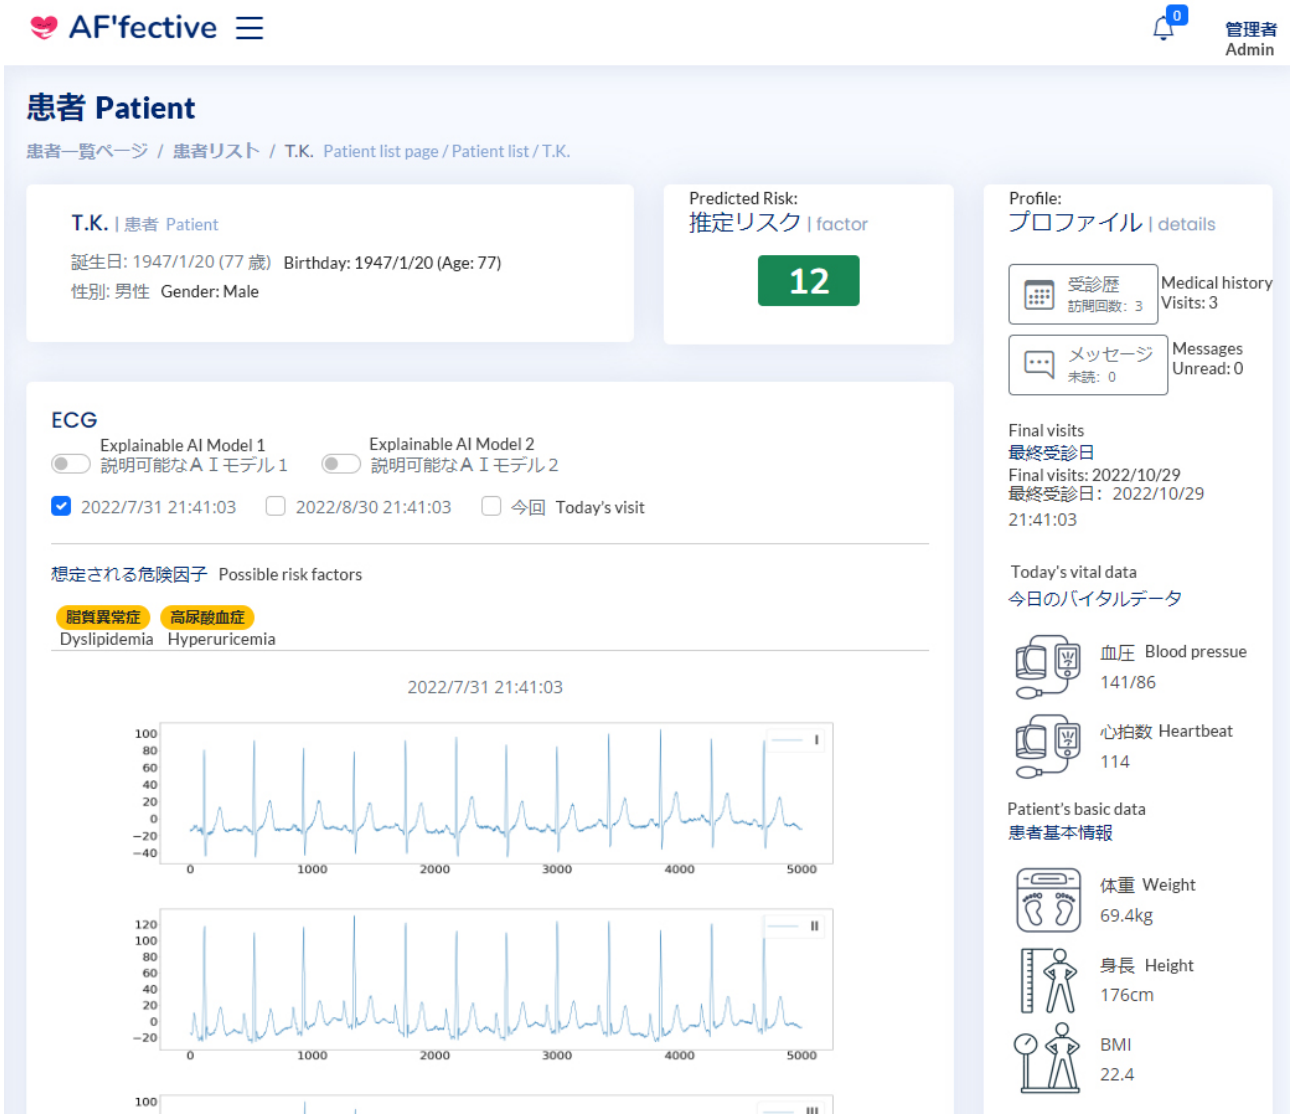
Figure 3. Screenshot of the patient page, including extra risk factors. ECG: electrocardiography.



Methods

Overview

Our research followed a 3-phase approach collaborating with stakeholders familiar with AF management. In the first phase, we conducted semistructured interviews with 8 cardiologists to explore potential explainable AI strategies for postablation care. From these insights, we developed 7 design concepts, which were then critically assessed and refined by another 8 cardiologists in the second phase. This process led to the selection of 4 explainable strategies. In this section (the final phase of the study), we built a functional prototype incorporating real patient data and invited a third group of 7 cardiologists to evaluate its effectiveness and feasibility in clinical settings.

Ethical Considerations

This study received ethics approval from the relevant institutional review boards (IRBs) in Japan, including the Kyoto Institute of Technology IRB (2021-08) and the Kyoto Prefectural University of Medicine IRB (ERB-C-2014). Informed consent was obtained from all participating physicians, who volunteered to take part in the study without receiving any compensation. To ensure the privacy and confidentiality of patient health data, all personally identifiable information, including patients' names, was removed and replaced with unique codes. This anonymization process ensured that no data could be traced back to individual patients.

Stage 3

The web-based prototype from the previous stage was developed into a fully functional progressive web application (PWA) prototype, which was then tested and evaluated by cardiologists.

Patient Data

A total of 11 postablation patients consented to provide data for the prototype. Protected health information, such as names and birthdays, was masked or replaced due to IRB requests, but other health data (eg, ECG, body measurements, blood pressure, and visit history) were used to closely resemble the original patient health data for a realistic prototype.

Participants

In total, 7 cardiologists involved in the treatment of AF were recruited from the Kyoto Prefectural University of Medicine in

Japan. All of them had experience diagnosing patients with AF and performing catheter ablation.

Measurements and Study Apparatus

In total, 3 widely adapted UX-related questionnaires were implemented in our study: the User Experience Questionnaire (UEQ), technology acceptance model (TAM), and Mobile App Rating Scale (MARS). The rationales for including these questionnaires are explained in the following sections.

UEQ Inclusion Rationale

The UEQ, developed by Laugwitz et al [42] in 2008, consists of 26 items across 6 dimensions: attractiveness, perspicuity, efficiency, dependability, stimulation, and novelty. The scale ranges from −3 (*most negative*) to +3 (*most positive*). Scores closer to 0 are considered "neutral." A data analysis tool is provided for interpreting the results, with benchmarks in 5 tiers: excellent, good, above average, below average, and bad [43]. Our goal during prototyping was to achieve above-average ratings. The English version was translated into Japanese.

TAM Inclusion Rationale

Previous research suggests that a user's intention to use is the primary predictor of actual system use [44]. To ensure that our PWA was both useful and usable in a medical context, we implemented the TAM to assess user acceptance and intention to use our explainable AI system. Originally developed by Davis et al [45], the TAM is a key model in new technology development. We adapted it for our PWA evaluation focusing on 3 dimensions: efficiency (perceived usefulness), ease of use (perceived ease of use), and intention to use (behavioral intention to use). For the TAM, a 7-point Likert scale is used, ranging from 1 (*strongly disagree*) to 7 (*strongly agree*). A score of 4 represents neutrality.

MARS Inclusion Rationale

Despite its name, the MARS is widely used to assess the quality of health applications across various types of digital platforms. It evaluates 4 dimensions: engagement, functionality, esthetics, and information quality [46,47]. We selected the MARS to assess the information quality of our PWA using the Japanese translation by Yamamoto et al [48]. The MARS uses a 5-point Likert scale ranging from 1 (*inadequate*) to 5 (*excellent*). Scores of >3 are considered above average.

AF'fective: The Web-Based PWA

A fully web-based PWA was developed using the Ionic framework (Drifty) for the front end and Python (Python Software Foundation) for the back end. Access was strictly controlled through an authentication system to ensure data security. The PWA included 2 main pages that were developed based on our explainable strategies: a patient overview screen (corresponding to strategy D) and an individual health record dashboard (corresponding to strategies A, B, and G). One noteworthy change was made to our predictive model, which also influenced our explainable features. On the basis of physicians' feedback, we omitted direct highlights on the raw ECG graph in stage 2 (using Grad-CAM; see the demonstration in Figure 1 [39]) and, instead, used the 7-item features derived from the standardized clinical interpretation of ECG graphs (corresponding to strategies A and G in particular; see the demonstration in Figures 4 and 5). In particular, we replaced the explainable AI model used in previous stages with a SHAP model [49], which was constructed to highlight the extent to which different key clinical features—commonly used as established interpretation principles in AF prediction for ECG data (eg, maximum P wave duration and augmented vector right [aVR]/first precordial lead [V1])—contributed to the decision-making process for strategy G. Therefore, the predictive model was updated from a CNN model (image based) used in the previous 2 stages to a Cox regression model (feature based) [26] to accommodate the introduction of 7 standard features for prediction (and, later on, SHAP for explaining). While physicians were not shown the Cox regression model's performance to avoid biasing them, it achieved strong evaluations, with an area under the curve of 0.72, sensitivity of 83%, and specificity of 58%. The model was trained on data from 502 patients, with an average follow-up of 6.2 (SD 3.5) years. A total of 13.1% (66/502) of the patients developed new-onset AF [26].

These standardized clinical explainable features are included in the following list. These features were derived from the interpretation standards that cardiologists commonly apply when reading an ECG graph and assessing a patient's risk level. As indicated in our previous studies, while directly highlighting sections of the ECG graph that contributed to the predictive model's output can explain the model's prediction, it does not aid physicians in interpreting the graph. To enhance the interpretability and physician-friendly explanation, we asked cardiologists to standardize their interpretation of the ECG graph into higher-level features that are more straightforward and easier to understand for their fellow cardiologists. Our previous work [26] provides details on training a predictive model based on these new features:

1. Max P wave duration >125 ms: whether the maximum P wave duration is >125 ms
2. aVR/V1<1: whether the amplitude ratio of the P wave is <1
3. Amplitude V1≥10: whether the P wave amplitude in V1 is >0.1 mV
4. Amplitude aVR<4=0: whether the P wave amplitude in the lead aVR is <0.04 mV
5. PAC on ECG=1.0: whether there was one or more supraventricular ectopies during recording (removed in the latest model for simplicity from the work by Nishimura et al [26])
6. RV5SV1≥2.2=0: whether the amplitude (height) of the R wave in the fifth precordial lead plus the amplitude (depth) of the S wave in V1 is >2.2 mV
7. PR≥185=0: whether the interval between the P and R waves is >185 ms

The individual health record dashboard (as shown in Figure 3) also allowed physicians to check past visit ECG graphs and explainable features (corresponding to strategy B). The physicians can obtain an overview of the basic patient data in the top left corner and then proceed to the raw ECG graph. In the main graph section, they can choose between 2 types of explainable models (see Figures 4 and 5 for the corresponding

graphs) and add data from the patient's history for comparison. The right panel provides additional patient correspondence data and physical measurements such as weight and blood pressure. The standardized features made it easier to compare patients when physicians navigated the patient overview board (corresponding to strategy G).

We also developed 2 interfaces to summarize the explainable features. The first interface (Figure 4) was developed using SHAP, a popular tool for explaining the outcomes of machine learning models [49]. It features a single bar chart that shows the combined influence of risk and protective factors. The second interface uses a pie chart to show the relative importance of the 7 items and their risk or protective contributions to the predictive outcome (Figure 5). Cardiologists were advised to access it using a computer, although the site is also available on mobile devices, to simulate their normal use context.

Figure 4. Screenshot of the explainable items and how they were displayed in the system—explainable model 1. ECG: electrocardiography.

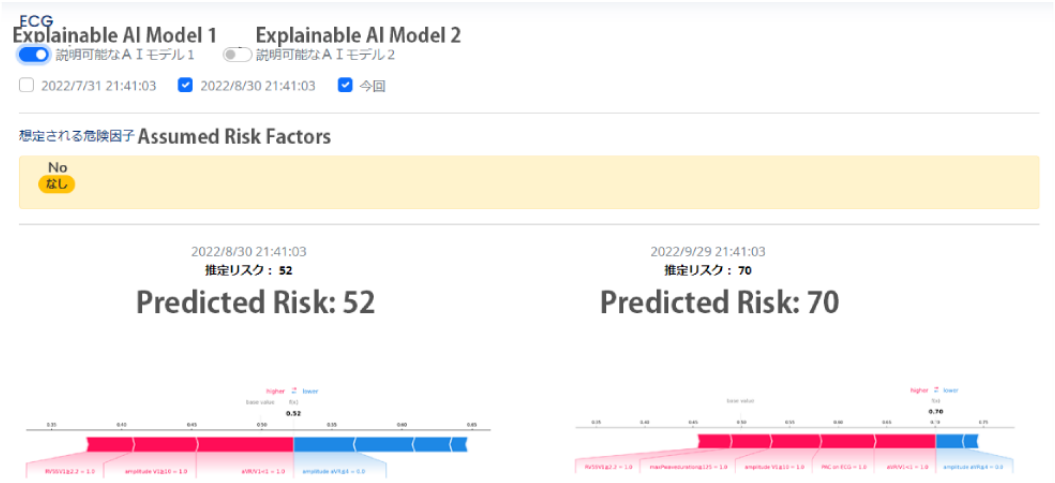


Figure 5. Screenshot of the explainable items and how they were displayed in the system—explainable model 2. aVR: Augmented Vector Right; ECG: electrocardiography. PAC: Premature Atrial Contraction; PR: PR Interval (the onset of the P wave to the start of the QRS complex).

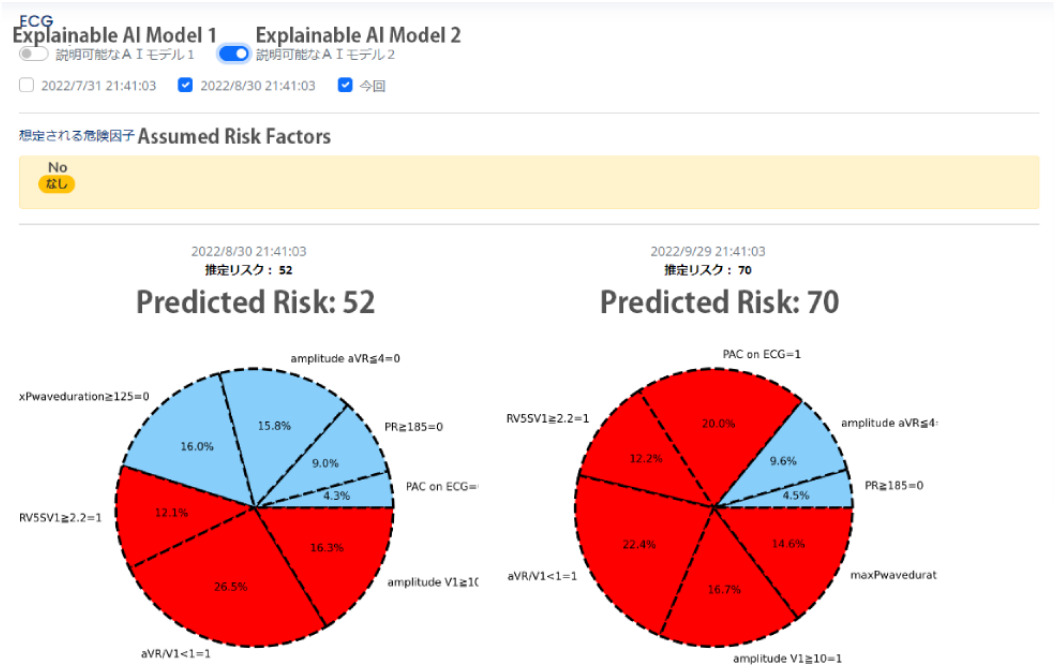

Study Process

Each cardiologist participated in a 1-on-2 interview with an HCI researcher and a cardiologist. Before the interview began, the HCI researcher set the scene for the cardiologist using the following statement: "You have 11 patients that you are currently caring for. You can see a list of them in the AF'fective system, which indicates their risks levels for recurrence." Participants were first briefed on the system and then asked to test it by imagining the following four scenarios: (1) viewing a patient's status, (2) checking a patient's ECG graph, (3) viewing explainable model 1, and (4) viewing explainable model 2. We then asked the cardiologists to complete the study measurements (UEQ, TAM, and MARS, as described in a previous section)

and began the semistructured interviews. Each interview lasted 45 minutes to an hour. All the interviews were conducted in Japanese and fully recorded, including screen recordings of the participants testing the AF'fective PWA.

Analysis

For the survey data, we calculated the mean and SD for each item in all surveys except for the UEQ, which has its own analysis tool in Microsoft Excel (Microsoft Corp) format. We compared our mean scores for the TAM and MARS against the theoretical average scores to determine whether physicians experienced any usability issues related to the interface design, functionality, information quality, or accessibility.

For the interview data, we reviewed and analyzed the transcripts following the thematic analysis framework proposed by Clarke et al [50]. The analysis was carried out by 3 researchers, 2 from the HCI field and 1 with a cardiology background. As the 2 HCI researchers were more familiar with the analysis method selected and had a long history of conducting thematic analysis, the initial formation of the themes was first conducted by them. The HCI researchers first read through all the transcripts to familiarize themselves with the content and highlighted interesting quotes. The quotes were then summarized and independently interpreted as "topics of interest" by the HCI researchers. The researchers then grouped the topics into several potential "themes" and involved the cardiologist to approve and edit the themes. The cardiologist researcher then joined the evaluation to come up with the final findings that were deemed meaningful in both the HCI and medical fields.

Results

Overview

In the final stage, we recruited 7 male cardiologists (aged 31 to 55 years) with 8 to 30 years of cardiology experience. After the interviews, they completed the surveys, and we calculated the mean scores to identify potential usability or design issues. The results suggested no significant usability problems, and the prototype showed strong potential to motivate physicians' intention to use it due to its ease of use, reliable information, and explainable functionality. The detailed survey results are reported in the following sections.

UEQ Results: Positive Perspicuity

The results from the UEQ showed that perspicuity received a positive evaluation (mean 1.21, SD 0.96), whereas attractiveness (mean 0.56, SD 0.71), efficiency (mean 0.625, SD 0.27), dependability (mean 0.33, SD 0.27), stimulation (mean 0.5, SD 0.3), and novelty (mean 0.58, SD 0.27) received neutral evaluations. Perspicuity stood out as the most positively perceived aspect of the UX, suggesting that ease of use and clarity are strong points of the AF'fective system. The neutral evaluations for the other aspects (attractiveness, efficiency, dependability, stimulation, and novelty) indicated that physicians had average or mixed perceptions of these factors.

TAM Results: Above-Average Technical Acceptance

In addition, the TAM measures showed that perceived usefulness (mean 4.22, SD 0.31), perceived ease of use (mean 5.13, SD 0.77), and behavioral intention to use (mean 4.77, SD 0.68) scores were all above the average (mean 3.5). The behavioral intention to use score indicated a strong intention to use the AF'fective system. These results suggest that the identified factors motivated users to engage with the system.

MARS Results: Perceived High Functionality and Information Reliability

Finally, the results of the MARS showed above-average scores for functionality (mean 4.25, SD 0.42), esthetics (mean 3.61, SD 0.68), information reliability (mean 3.38, SD 0.54), and perceived impact on practice (mean 3.33, SD 0.76). These results indicated that users perceived high functionality and reliable information from the AF'fective system, whereas they rated its esthetics and perceived impact on practice as somewhat mediocre. We were particularly interested in the physicians' high ratings for information reliability as these suggested that they felt confident in understanding and agreeing with the predictive model's decisions. Notably, this rating was achieved without physicians knowing the predictive model's performance. This serves as a strong indicator that insights derived from explainable models play a crucial role in physicians' adaptation to our technology. This was deemed acceptable for a system in its prototype phase.

Discussion

Principal Findings

Overview

Aligned with our positive survey results, cardiologists expressed strong acceptance of the explainable features and willingness to use the system during the in-depth interviews. They also praised the system's enhanced efficiency, comprehensibility, comparability, consistency, and trustworthiness:

> *I think it is useful to be able to express in a general, universal, numerical way what we used to say in the past, like, "This person is likely to have a recurrence," by using a risk score. I think it is useful.* [P04; male]

> *In clinical practice, we honestly don't have that much time to look at ECGs and scores in detail, so I think AI is a way to make it easier for us to get the numbers out.* [P07; male]

> *I think it is easy to pick up if you can tell from a quick glance at the list that a person in red is at higher risk of recurrence, or that a person in green has a low probability of recurrence.* [P06; male]

While most cardiologists in our study viewed the real data–backed explainable AI system positively, we identified potential concerns and (possibly) false expectations for its real-life implementation. During the interviews, cardiologists were asked to envision using the system in their daily routines, leading to a realistic discussion after 2 rounds of iterative design. This probing step was crucial for understanding the feasibility and challenges of implementing the system in clinical settings. Our findings are discussed in the following sections through 4 key themes.

Explaining the Symptoms Does Not Equal to Identifying the Causes

Perhaps due to our intentional mimicry of cardiologists' methods for identifying irregularities in ECG graphs, participants showed high acceptance of the predicted results after viewing our 7-item AF clinical explainable features. In fact, P04 gave a very positive endorsement of why the explainable items were necessary:

> *I am of course curious as to why the risk was higher, so the AI [predictive] model would be rather meaningless without a graph [with explainable AI items] that can explain it, or perhaps it would make me wonder why the model [makes such a decision].* [P04; male]

According to P04, the predictive model's results may fail to convince them without an explanation of why the model makes a particular decision. P04's reaction suggests that physicians find explanations based on the new clinical explainable features both agreeable and trustworthy. However, a concern emerged regarding the limitations of these features. A key request was, "Then what should I do?"—cardiologists wanted to understand the features influencing the risk score and actionable strategies to address them. This aligns with previous insights showing a preference for clear indicators and actionable steps. In one case, P05 even suggested using the system to nudge patients toward behavior change:

> *We are at a stage where only these numbers [of explainable items] are available. 40 or something like this is the only thing that comes out, so what should I do [with each of the items]?* [P04; male]
>
> *I feel that the numbers alone don't mean much, or don't seem to lead to a change in [patient's] behavior.* [P05; male]

It should be noted that physicians treated each explainable feature as a "treatable item," which was not possible with an ECG graph–based explainable model. This improvement suggests that converting graphical highlights into standardized feature explanations can foster the expectation that addressing each item will reduce the risk score. In our current phase, it is still too early to determine how to further link our features with treatment approaches; however, this does indicate an interesting and operationalizable future implementation for explainable models.

Hence, in our current system, while these features influence the predictive outcome, clinical causal insights should be interpreted with caution. Our 7-item explainable features are based on standard ECG wave interpretation, identifying AF symptoms but not directly indicating underlying causes such as excessive drinking or sleep apnea. As noted in the document by Shapley [51], estimating causal effects from explainable items can be misleading. Cardiologists should be cautioned about this limitation and guided to set appropriate expectations for decision-making.

A key lesson from our interviews was the need for better curation of explainable features in the model, especially in clinical contexts. While various approaches provide transparency in AI decision-making [31,39,52,53], it is crucial that the chosen features are relevant, operationalizable, and actionable for medical professionals. This focus ensures that AI predictions are both understandable and practically applicable, enhancing postablation patient care.

Window for Interpretation: When 0% and 100% Recurrence Risk Does Not Exist

While a predictive model can theoretically provide risk scores from 0% to 100%, in real life, extreme scores such as 0% or 100% are unattainable. Participants noted that the possibility of such extreme scores diminishes the perceived realism and reliability of the model's predictions:

> *Theoretically speaking, it has to be 0, so even if it's low, it's still bad. You can't say 30 is a good thing. There is still a chance for a recurrence...So there are cases where it comes out as 0? (Cardiologist interviewer: That would be considered extreme score. Well, some might be zero, but I think the smallest is probably 3 or 4 [in the natural clinical contexts].)* [P03; male]
>
> *I'm not quite sure what [the risk score] means. There are a lot of questions about what 12 means and what we should think about it. It's not 0 [even for a normal person], So are you saying that AF can happen to anyone? (Interviewer: I don't think we can lower that number any further.)* [P05; male]

In a similar manner, participants also questioned whether a predictive score of 100% was at all meaningful in clinical practice:

> *Are you saying that even if all of [the items] were full, it would not be 100?(Interviewer: Even if [all of the items were] full, I think it will probably be around 80-92, which is the highest risk score [in the natural clinical contexts].)* [P01; male]

It should be noted that it is uncommon for a predictive model to yield a full 100% score in clinical contexts, particularly in postsurgery contexts. The contributing factors would generally contain complex interactions and dependencies.

Cardiologists emphasized that recurrence risk scores should be viewed as reference points, not absolute indicators. Establishing a threshold, such as 50, is essential for guiding actions, but borderline scores (eg, 49 or 51) still warrant patient warnings or follow-ups. Similar "borderline windows" were noted in a grief-related study [52] where psychologists suggested taking the score as a reference for concerning cases. Although the width of the borderline window can also be highly subjective for each individual cardiologist and possibly for patients, this approach is common in clinical practice. Future studies should develop nuanced protocols for borderline cases to prevent misdiagnoses and patient stress, potentially standardizing risk level interpretation, as suggested by P05:

> *I think it would be better to indicate the risk of developing the disease on a 5-point scale, such as low, medium, and high, because I don't think there is such a difference between 40 and 41.* [P05; male]

In treatment decision-making, another notable implication from our findings was the patient's presumptive belief that the risk score should be 0%, particularly after undergoing ablation. It was apparently conflicting with what the predictive model would reveal:

> *However, if you think about it, after AF ablation, the number of people who think that AF recurrence is quite small. For example, more than 70% to 80% of the patients think it is zero.* [P03; male]

Even cardiologists familiar with the postablation risk might expect that addressing the explainable items (see the Methods section for more discussion on these items) could eliminate the recurrence risk:

> *Considering the importance of risk scoring...I am very interested in the explanatory factors or items involved, and which of them are [positively correlated to the risk score]. If the purpose of this system is to follow up the patient, it would be even better if we could get such risk factors and know what kind of intervention is being done here.* [P01; male]

It struck the research team that popular explainable AI approaches could lead to misinterpretations and unrealistic expectations, such as believing that a 0% recurrence risk is easily attainable. Our study highlights the need to set accurate expectations about what predictive results and explainable features truly imply in a clinical context and how much they can be influenced through intervention.

Offer a Holistic Risk Overview by Integrating Other Risk Factors and Temporal Data

In our study, we adopted the flow of cardiologists' diagnostic process by reviewing ECG graphs and assessing the presence of known risk factors one by one. Therefore, other known risk factors, such as high blood pressure, smoking, and drinking, were included as additional "risk factors" alongside the predicted risk score derived from the patient's ECG data. While we believed that this approach resembled a cardiologist's normal decision-making procedure and would increase their acceptance of the model's predicted results, our interviewees expressed concerns about the potential for the predictive model to yield biased risk estimates:

> *There are many known risks that are commonly associated with AF, such as high blood pressure, obesity, lack of exercise, etc... Inputting it would further make this risk [score], or perhaps, the evaluation, more correct.* [P03; male]

> *So we are predicting the risk score purely based on ECG...If you are going to make progress, I think it would be good to include obesity information, bmi, waist circumference, and so on.* [P06; male]

Furthermore, some of our participants also indicated that they would prefer a clear display and association with the medications or ongoing treatments that the patients are receiving. For instance, P02 requested us to explore whether the explainable model could reflect the effects of the patient's medications, and P01 indicated that it would be better to see which interventions were done to lead to the risk score:

> *If there was information on arrhythmia medications, it would be more useful. I think the doctor might be able to think about it more holistically, such as, "This ECG variation [highlighted by the explainable model] is caused by the medicine the patient is taking."* [P02; male]

> *If the purpose of this system is to follow up the patient, it would be even better if we could get such risk scores and know what kind of intervention is being done here.* [P01; male]

As the cardiologists pointed out, although our model provided an overview of the other risk factors, it would only be meaningful if they could establish a connection between the variation in risk scores and the specific risk factors. Our findings indicated that, for explainable elements to be truly useful in real-life practice, they need to relate to more holistic and treatment-related risk factors or medications. Otherwise, the contribution of such a predictive, even explainable, model to preventing disease recurrence would be quite limited.

In the end, perhaps the most important takeaway from the interviews was the need to provide a holistic overview and explanation of intrapatient temporal data and risk scores. Echoing the insights from previous interviews, the design strategy of comparing interpersonal ECGs (strategy G) was heavily criticized by the physicians as individual risk factors can vary significantly. However, comparing a patient's current and historical risk factors could provide valuable insights into the evolution of these factors and potential trends in recurrence risk. For instance, participants P04 and P06 described how they would like to plan their interventions by tracking variations in risk scores and identifying the underlying causal factors over different time points:

> *For a patient with a high estimated risk this time, but lower estimated risk in the previous times, why did it become so high? What factors contributed to it? [I would expect] this AI model to estimate and explain.* [P04; male]

> *I think it would be better to look at it...from a longitudinal point of view...to see what kind of intervention I should use, what's going wrong, and what the reason is for the increase [of the risk score].* [P06; male]

We were intrigued by the design opportunities revealed in our findings. As cardiologists reminded us, a significant and crucial aspect of their profession involves deciding on appropriate interventions. Although explainable AI models have shown promise in diagnosing and identifying patients at risk, they have yet to offer actionable insights for intervention planning. We believe that explainable AI tools should integrate comprehensive patient data, including temporal variations in risk factors, medications, and treatments, to enhance the model's relevance and utility in real-world settings. In addition, the insights generated should be clearly linked to potential intervention strategies that could influence risk scores. Without such integration, the potential of explainable AI tools to contribute meaningfully to patient care, particularly in preventing disease recurrence, may remain limited.

A Sense of Control and Learning From the Model

The findings of our interviews revealed that cardiologists valued the sense of control and the learning opportunities provided by these models, aligned with the findings in the previous rounds that suggested a self-actualizing and constant learning side of cardiologists.

One of the key insights that emerged from our study is the potential of explainable AI models to help cardiologists prioritize patients at higher risk. As P04 addressed, there was a potential for these models to become an integral part of daily practice:

> *If it becomes a habit, I will probably look at people with high estimated risk and wonder why they were at higher risk.* [P04; male]

Moreover, P02 also offered a similar thought regarding triaging patients based on the risk scores:

> *So the follow-up should be more thorough, and those who are more likely to be affected [by the recurrence risk] should be followed up in a shorter period of time.* [P02; male]

By discriminating the patients that need urgent attention, physicians gain a sense of control over who to allocate more time and treatment resources to. Cardiologists indicated that such a potential new routine would enhance their work efficiency and allow them to spare cognitive capacity for more critical treatment planning. Interestingly, our interview findings suggest that cardiologists may appreciate useful "hints" or "interpretations" from explainable models to help them narrow down potential problems:

> *I understand that the ECG is used as the reference, but I think it would be easier to understand if there was an explanation of what is of interest in this ECG, even though those who understand may [already] understand it.* [P01; male]

The power dynamic between cardiologists and the AI model is worth exploring. To what extent should an AI model's interpretations be considered, and to what extent should cardiologists accept its suggestions? These boundaries are critical to explore to ensure that the final AI models can be effectively integrated into the patient care routines.

Further enhancement of control over the prevention procedure might also occur as cardiologists begin to learn more from AI-augmented interpretation and actionability. Interestingly, the explainability of AI models appears to increase cardiologists' desire to validate their treatment approaches:

> *So, at the time of the ablation, if I burn the tricuspid valve, you know [the score will go down], or if I burn the superior vena cava, you know [the score will go down]...you can learn more and more from time to time.* [P03; male]
>
> *I would take another ECG before prescribing too much medication, and see if [the risk score] goes up or down on the next ECG...For those in yellow...I will adjust my [treatment plan] according to the risk level of the next ECG.* [P06; male]

P06 went further and emphasized that, while AI models are valuable for providing quantitative assessments, their true worth lies in delivering actionable insights that can guide clinical decision-making. This sentiment reflects a broader interest among cardiologists in understanding how AI models arrive at their conclusions, particularly in relation to identifying intervention points:

> *I wonder if you are highlighting these risk factors to tell us these are the areas for intervention. I wonder if there is a reason for this risk factor, such as if we treat these factors, it could lower the risk.* [P06; male]

In general, our findings indicate that cardiologists, particularly self-actualizers, are not only open to integrating AI suggestions into their decision-making processes but also eager to enhance their knowledge through interaction with the AI model provided that these suggestions are accompanied by clear rationales and practical recommendations.

Implications of Creating a Software as a Medical Device

In the development of AI algorithms for clinical applications, it is crucial to not only meet the user interface requirements but also ensure compliance with regulatory standards. Software as a medical device must adhere to international standards such as International Organization for Standardization (ISO) 13485 (medical device quality management systems), ISO 14971 (medical device risk management), and ISO 62304 (software life cycle processes). In addition, compliance with Food and Drug Administration approval and the European Medical Device Regulation is essential from the perspectives of patient safety, effectiveness, and legal requirements.

While the AF'fective study provides valuable foundational knowledge on user interface, it is still considered in the early stages of technology readiness level (1-3). However, with advancements in AI technology, the insights from this research could contribute to the revision of existing standards, such as the International Electrotechnical Commission 62366-1:2015 (usability engineering for medical devices). Specifically, the consideration of explainability in the AI result display methods proposed in this research—such as visually clarifying the rationale behind suggestions and intuitively conveying risk and uncertainty in interface design—will play a crucial role in helping health care professionals accurately understand AI-generated proposals and integrate them into clinical decision-making. Moreover, our study highlighted that health care professionals do not need to fully comprehend the technical background or mechanisms of AI. Instead, it is crucial to create a state in which users can reasonably understand "why this result was reached," which is effective in building trust in AI. Such efforts extend beyond display design and have the potential to be incorporated into new standards that facilitate smooth communication between AI and health care professionals.

Conclusions

This paper reports a 3-stage study involving 23 physicians to co-design, assess, and pilot an explainable AI system for AF postablation monitoring called AF'fective. Our co-design approach effectively identified 4 feasible explainable strategies.

Furthermore, while we actively used explainable AI to identify the features contributing to the predictive results, our explainable strategies enabled the design of a more holistic patient monitoring system that incorporates contextual factors such as patient history and established principles to support physicians' decision-making rather than merely explaining the features indicated by ECG graphs. In the third stage, the system prompted cardiologists to envision its use in their routines, leading to highly contextualized feedback. This study highlighted the need to curate actionable explainable features and set correct expectations for interpreting predictive scores. In addition, cardiologists were interested in understanding the AI's reasoning and identifying strategies to address recurrence risk factors.

Interestingly, although our focus was on AF recurrence prevention, many insights appear generalizable to other disease care contexts, such as temporal risk score monitoring and setting realistic expectations for scoring, particularly as extreme scores (0% and 100%) are practically unattainable. Further investigation is needed to determine whether these insights can be universally applied to enhance the feasibility of implementing explainable AI in clinical settings.

A future study will build on these findings and further evaluate the potential challenges and advantages when implementing the AF'fective system in near-live or live clinical care routines. We believe that AI possesses the potential to revolutionize medical practices and we can only realize it through putting the technology in actual use case scenarios.

Abstract

Background: Given the global burden of insufficient physical activity (PA) in children, effective behavioral interventions are needed to increase PA levels. Novel technologies can help expand the reach and accessibility of these programs. Despite the potential to use heart rate (HR) to target moderate- to vigorous-intensity PA (MVPA), most HR research to date has focused on the accuracy of HR devices or used HR for PA surveillance rather than as an intervention tool. Furthermore, most commercial HR sensors are designed for adults, and their suitability for children is unknown. Further research about the feasibility and usability of commercial HR devices is required to understand how children may use HR during PA.

Objective: This study aimed to explore the use of a chest-worn HR sensor paired with a real-time HR display as an intervention tool among preadolescent children and the usability of a custom-designed app (Connexx) for viewing real-time HR.

Methods: We developed Connexx, an HR information display app with an HR analytics portal to view HR tracking. Children were recruited via flyers distributed at local public schools, word of mouth, and social media posts. Eligible participants were children aged 9 to 12 years who did not have any medical contraindications to MVPA. Participants took part in a single in-person study session where they monitored their own HR using a commercial HR sensor, learned about HR, and engaged in a series of PAs while using the Connexx app to view their real-time HR. We took field note observations about participant interactions with the HR devices. Participants engaged in a semistructured interview about their experience using Connexx and HR during PA and completed the System Usability Scale (SUS) about the Connexx app. Study sessions were audio and video recorded and transcribed verbatim.

Results: A total of 11 participants (n=6, 55% male; n=9, 82%, non-Hispanic White) with an average age of 10.4 (SD 1.0) years were recruited for the study. Data from observations, interviews, and SUS indicated that preadolescent children can use real-time HR information during MVPA. Observational and interview data indicated that the participants were able to understand their HR after a basic lesson and demonstrated the ability to make use of their HR information during PA. Interview and SUS responses demonstrated that the Connexx app was highly usable, despite some accessibility challenges (eg, small display font). Feedback about usability issues has been incorporated into a redesign of the Connexx app, including larger, color-coded fonts for HR information.

Conclusions: The results of this study indicate that preadolescent children understood their HR data and were able to use it in real time during PA. The findings suggest that future interventions targeting MVPA in this population should test strategies to use HR and HR monitoring as direct program targets.

Introduction

Background

Physical activity (PA) levels are insufficient across most of the world's population [1], constituting a persistent problem in global health. PA engagement in the United States is reflective of global trends: only 25% of US children meet the minimum daily recommended amount of moderate- to vigorous- PA (MVPA) [2]. PA behaviors and insufficient PA developed during childhood often worsen during adolescence if not addressed through intervention [3]. Insufficient PA is also a risk factor for obesity, a condition related to various comorbidities [4] that can persist into adulthood [5,6]. Alarmingly, children who develop obesity at a young age are more likely to have obesity into adulthood [7]. Therefore, addressing obesogenic factors (eg, PA) during childhood has the potential to positively impact long-term overall health [8,9].

Effective behavioral interventions are essential to address insufficient PA, particularly before the significant decline that often occurs during adolescence, around the age of 13 years [10]. Novel technologies can help expand the reach and accessibility of PA promotion efforts. To date, most research leveraging commercial PA devices has focused on adult populations [11], although some studies focusing on children have examined step counts as a PA outcome [12]. Step count measures basic movement, but this metric insufficiently captures the intensity of movement and, therefore, may be inadequate for measuring or promoting MVPA.

In contrast to step count, heart rate (HR) holds great promise for measuring MVPA. Moreover, it is possible that novel technologies allowing children to view their HR in real time could foster PA awareness and engagement. However, this great potential is understudied; a recent systematic review found only two studies that examined the use of existing commercial sports-style HR sensors for use in preadolescent children [13]. The studies identified by the systematic review focused on whether children would wear an HR sensor on their chest paired with a wrist-worn HR display over a long time period [14] and the accuracy of commercial HR sensors on a preadolescent child's wrist against a medical-grade control [15]. Another recent study involved the use of chest-worn HR sensors paired with a wrist-worn HR display to monitor PA in adolescents and young adults. However, the study did not provide participants with education on HR or guidance on effectively using HR to achieve MVPA goals [16].

These studies demonstrate the accuracy of commercial HR sensors and displays for preadolescent children. The adoption of devices capable of displaying real-time HR information is growing in this age group, matching trends across the demographic spectrum. Recent statistics indicate wide adoption of smartphones: 97% of Americans own a smartphone [17], and ownership is equitable across racial and socioeconomic groups [18]. Statistics from a survey conducted in July 2019 reported that approximately 21% of the US population owned a smartwatch [19]. Smart device adoption is growing among preadolescent children in the United States; by their teenage years, 95% of children either have their own smartphone or have access to one through their family [20]. Despite the growing ubiquity of these devices, research has only focused on the technical ability of smart devices to surveille user HR [16]. Research should now be conducted to explore the use of real-time HR as an intervention tool to target specific MVPA goals.

Objectives

Pairing chest-worn HR sensors with existing smart devices in the form of smartphones and smartwatches is a novel opportunity that has not been sufficiently explored. However, providing real-time HR information without exploring preadolescent children's ability to understand and use HR in real time to effectively target MVPA would only replicate existing studies with new hardware [16]. Therefore, we provided participants with information about HR and how to target different HR zones during PA. This study primarily aimed to explore whether preadolescent children can use real-time HR information to target specific MVPA goals. A chest-worn HR sensor was paired to a smart device (eg, smartphone or smartwatch) that displayed real-time HR information. As the HR sensors used in this study were originally designed for adult use, a secondary objective of this study was to explore whether preadolescent children could feasibly use a chest-worn HR sensor paired with a smart device.

Another secondary objective of this study was to explore the usability of a custom app (Connexx) developed by the research team. As part of a broader program of research, the team is exploring the impact of collaboration on PA, and one facet of this research explores collaborative pairs in a family dyad consisting of a parent or guardian and child. Dyads collaborate by viewing each other's real-time HR information during PA. There are currently no commercial apps capable of transmitting and displaying real-time HR information between two users. We developed the Connexx app with this functionality. However, a key aim of this study was to explore the usability of Connexx for preadolescent children, who represent half of the intended pair in parent or guardian and child collaborative dyads. Thus, this study explored the usability of the Connexx app in solo mode to establish its feasibility in use with preadolescent children.

Methods

Study Setting

This feasibility study was conducted at the University of Florida, Gainesville, Florida. Data collection occurred between October 2023 and February 2024.

Ethical Considerations

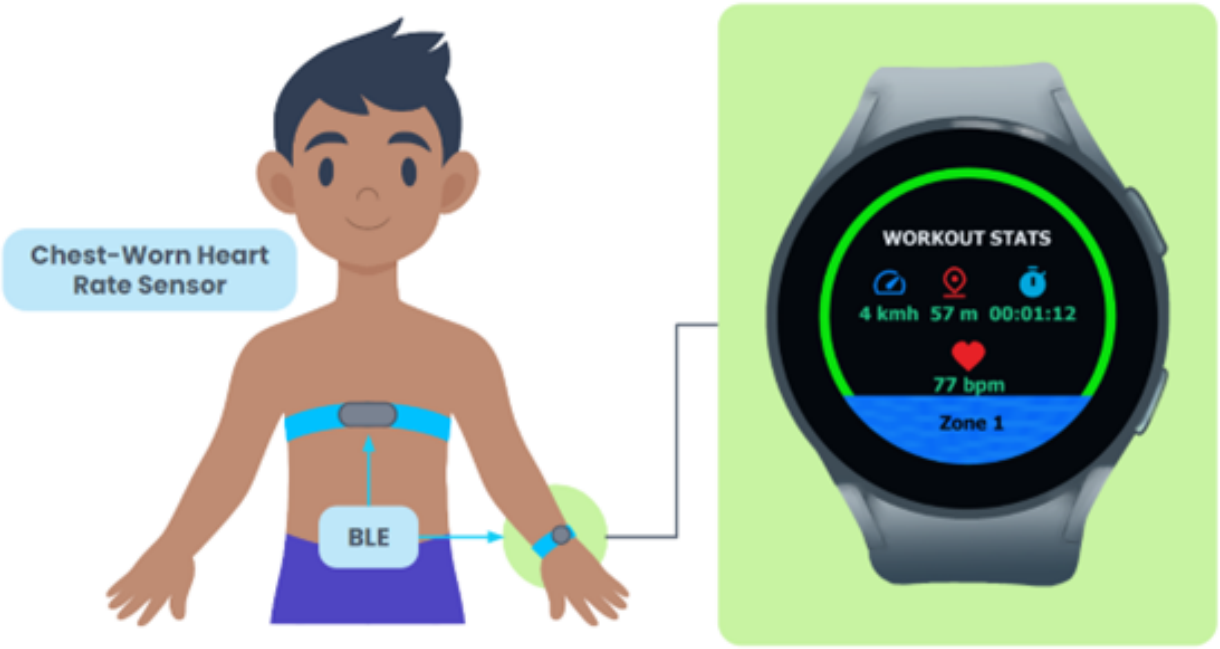
The study was approved by the University of Florida Institutional Review Board (IRB202301463) and complies with the ethical guidelines mandated therein. Informed consent was

obtained from a parent or guardian electronically, and written assent was obtained from the participants themselves at the start of each study session. Audio and video recordings from study sessions were stored on secured servers mandated as part of the University of Florida Institutional Review Board parameters. A US $25 Amazon e-gift card was provided to the participant's parent or guardian at the conclusion of the study session.

Study Equipment

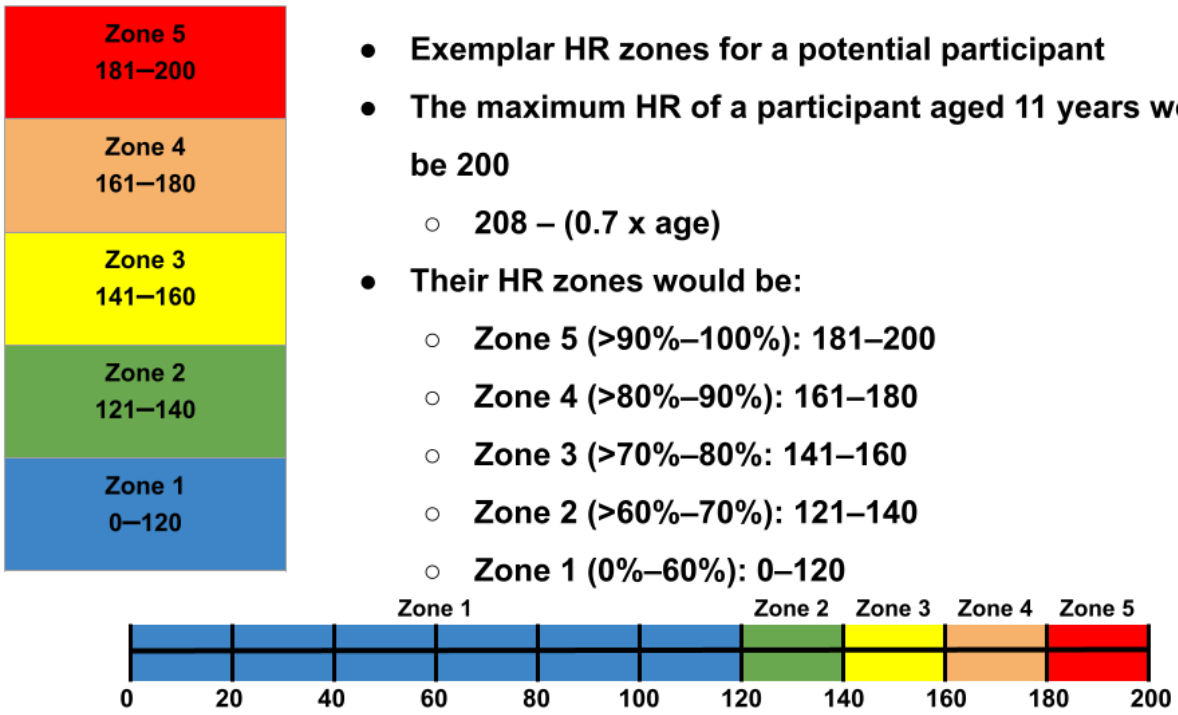
Several pieces of commercial technology were used to measure and display HR information (Figure 1). HR was measured using a sport-style chest-worn HR sensor (Garmin HRM-Pro Plus), and HR information was transmitted via Bluetooth Low Energy and displayed on either a smartphone or smartwatch. The smartphone used was a Google Pixel 4A, selected due to its low cost and the ability of Android phones to sideload apps, allowing us to install the Connexx app on the smartphone. The smartwatch used was a Samsung Galaxy Watch 4, selected for its Android-based operating system, which allows the Connexx app to be modified from the smartphone version to be compatible with the Galaxy Watch 4.

Figure 1. Smartwatch with solo workout screen connected to Bluetooth heart rate sensor. bpm: beats per minute; BLE: Bluetooth Low Energy.



This study used HR rather than accelerometry readings to measure MVPA. HR was chosen because it can be used to display effort in real time across various types of activities, which can contribute to a more accurate measure of the amount of time spent in MVPA [16]. We developed the Connexx app to display real-time HR information between two users. The Connexx app transmits real-time HR information between two devices via a traditional Bluetooth connection. However, Connexx is also capable of operating in solo mode, displaying the real-time HR of a single user, as we did in this study (Figure 1). Information on the user's current speed, distance covered during the workout, and workout duration was displayed along the top row of the Connexx solo workout screen. Speed and distance fields can be toggled between metric and imperial units by tapping on the display. The middle row of the workout screen displays the user's real-time HR. Connexx is able to display real-time HR information as either beats per minute (BPM) or as a percentage of maximum HR; users can toggle between these two display options by tapping on the HR display. A color-coded HR zone indicator is displayed below the HR field. This color coding matched the colors on HR exemplar cards used to explain HR information to participants (Figure 2). In this study, maximum HR was calculated using an established formula that is accurate for preadolescent children: 208 – (0.7 × age) [21]. The Connexx app automatically calculates HR zones using a straightforward 5-zone division based on the percentage of maximum HR, selected because there was no clear consensus or definitive definition of specific HR zones for preadolescent children [22-24] (zone 1: 0%-60%, zone 2: >60%-70%, zone 3: >70%-80%, zone 4: >80%-90%, and zone 5: >90%-100%). Furthermore, the Connexx app has an analytics portal; after the app records a workout, the information is sent to this portal, capable of displaying data from the workout on a graph.

Figure 2. Exemplar heart rate (HR) zone explanation card for a participant aged 11 years.



Participants, Eligibility, Recruitment, and Screening

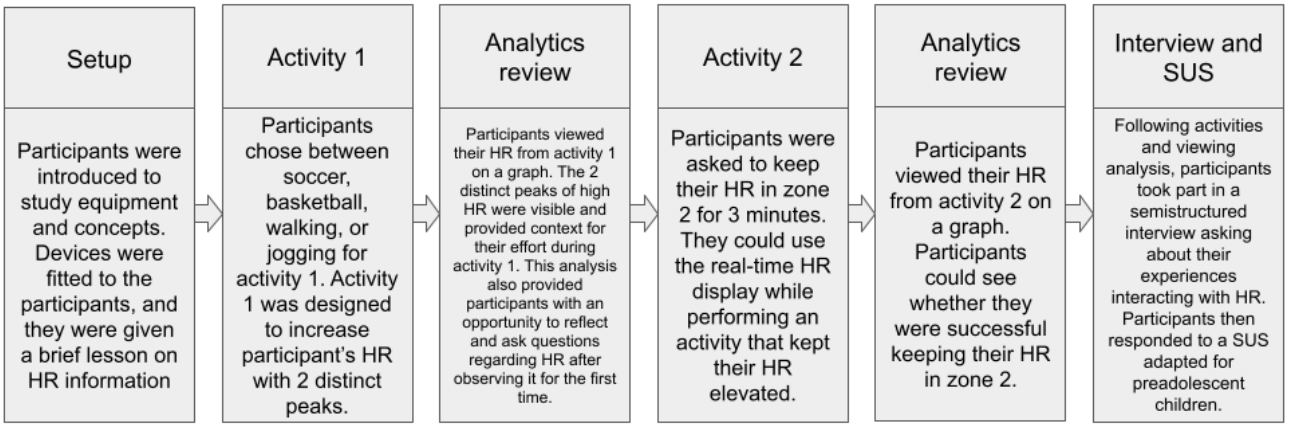
This study aimed to enroll a sample of 12 diverse preadolescent children to complete the full protocol. This sample size was chosen based on best practices in usability testing, showing that a sample of 10 to 12 participants is able to identify most major user issues [25]. Children were eligible to participate if they were aged 9 to 12 years and in good health with no physical conditions, injuries, or other conditions precluding them from engaging in MVPA for up to 30 minutes (assessed via a modified Physical Activity Readiness questionnaire for everyone [26]). We sought an equal number of male and female participants and equal distribution between Black, Hispanic, and non-Hispanic White participants (the three largest racial or ethnic groups in the local area).

Recruitment targeted parents of potentially eligible children using an electronic flyer distributed via local public elementary and middle schools, social media posts, and word of mouth. The flyer provided basic information regarding the study, eligibility criteria, compensation (US $25 Amazon e-gift card), and a link or QR code to a Qualtrics screening questionnaire. Parents or guardians completed the eligibility questionnaire, which included demographic information about their child. If the child was eligible, the parent or guardian was contacted via email to sign an electronic consent form through REDCap (Research Electronic Data Capture; Vanderbilt University). Once consent was obtained, a study team member (LL) scheduled the child for a study session.

Study Session

Study sessions were conducted at an indoor multiuse facility at the University of Florida. The space measures approximately 1021 square meters (27.7 meters by 36.9 meters) and can be used for a variety of uses, including basketball and volleyball; it has a maximum capacity of 1140 people. The study session began with obtaining assent for participation from the preadolescent child and followed the format outlined in Figure 3.

Figure 3. Study session activities flowchart. HR: heart rate; SUS: System Usability Scale.



Device Setup

Following assent, participants were fitted with Rode wireless lapel microphones. A researcher (LL) explained the study equipment and demonstrated the functionality of the chest-worn HR sensor. Parents aided participants in putting on the HR sensor. The session was recorded with a video camera. Next, participants chose between a smartphone and a smartwatch to view their real-time HR information. The Connexx app was available to all participants on either a smartphone or a smartwatch. However, all participants chose to use the smartwatch. The participants were guided through the process of entering their study information, such as their research identification number, age, and maximum HR, into the Connexx app. A workout was then initiated on the app, allowing participants to view their HR in real time, with more HR information provided to them.

HR Information

HR and HR zones were explained to the participants using a real-time HR display in Connexx (Figure 1) and an exemplar HR information card (Figure 2) based on their age (Table 1). Additional language used to explain HR and HR zones is provided in Multimedia Appendix 1. The goal of the brief explanation was to frame the upcoming activities in a way that participants could understand in relation to their HR zones. The researcher encouraged the participants to ask questions during the HR explanation.

Table 1. Example of the 5-zone heart rate (HR) categorization and description for participants aged 11 years.

HR zones	BPM[a]	Zone effort category	Example activities associated with the zone	Description of the zone
Zone 5	181 to 200	Maximum	Very high effort activities, which are often repeated (eg, sprinting in games such as tag multiple times in a row)	Extremely difficult to hold a conversation and most people must wait until after this effort to speak
Zone 4	161 to 180	Vigorous	Vigorous activities, such as playing a sport (eg, soccer or basketball), strenuous hiking, running, or climbing flights of stairs continually at a brisk pace	Difficult to hold conversation and often can only squeeze in short 1- or 2-word responses around breathing
Zone 3	141 to 160	Endurance	Shorter vigorous activities or long endurance activities (eg, climbing 2 to 3 flights of stairs or walking or hiking for an hour)	Slight difficulty to hold a normal conversation and speech is negotiated around breathing
Zone 2	121 to 140	Low endurance	Watching an exciting program and slow walk for short distances (eg, walking to the kitchen and walking around the block at a slow pace)	Can hold normal conversations without thinking about breathing
Zone 1	≤120	Rest	Sleeping, sitting and reading a book, or watching television	Can hold normal conversations without thinking about breathing

[a]BPM: beats per minute.

Activities

Next, we outlined the structure of the study to participants (Figure 3). The study consisted of 2 activity intervals; activity 1 lasted for 10 minutes and activity 2 lasted for 3 minutes, each followed by a brief rest period during which participants could view their HR information via an analytics portal on a laptop.

Activity 1

This study primarily aimed to explore whether preadolescent children can use real-time HR information to target specific MVPA goals. Activity 1 was designed to provide participants with an opportunity to observe their HR as it elevated through several different zones aligning with MVPA, providing practical, experiential use of HR information for participants. For activity 1, participants chose from playing basketball or soccer, or walking or jogging around the gym space. A researcher moderated participant effort during activity 1 by speeding up or slowing down the activity to take participants through a range of HR values. During this activity, the researcher asked participants to report their real-time HR at regular intervals. Querying for HR regularly was intended to help participants notice how their HR responded to various activity levels. Activity 1 was designed to increase participants' HR through multiple HR zones twice. Participants viewed their HR through the Connexx app while engaged in PA. After completing activity 1, the researcher guided participants through ending the workout on the Connexx app, and then, participants viewed a graphical representation of their HR in a Connexx analytics portal. We guided participants through the HR observation process, drawing attention to how HR can vary at rest, how HR responds to effort levels during PA, and how the body feels at various HRs.

Analytics Reflection

Once a workout ended on the Connexx app, workout data were uploaded to the analytics portal. The analytics portal displayed the participant's color-coded HR zones in the background of the graph, with HR in BPM on the vertical axis and duration on the horizontal axis (Figure 4). The researcher pointed to the connection between the HR graph and PA level: the more intense the PA level, the steeper the HR graph line became. Furthermore, the researcher pointed to how variable HR was: when at rest, HR did not stay at a consistent BPM; rather, it varied up and down slightly. In addition to the HR timeline graph, the analytics portal also presents an HR zone breakdown, which is a bar graph showing the total cumulative time the participants' HR spent in each zone (Figure 5). Participants were encouraged to ask questions throughout the process of viewing their HR graph.

Figure 4. Sample heart rate graph following activity 1. bpm: beats per minute.

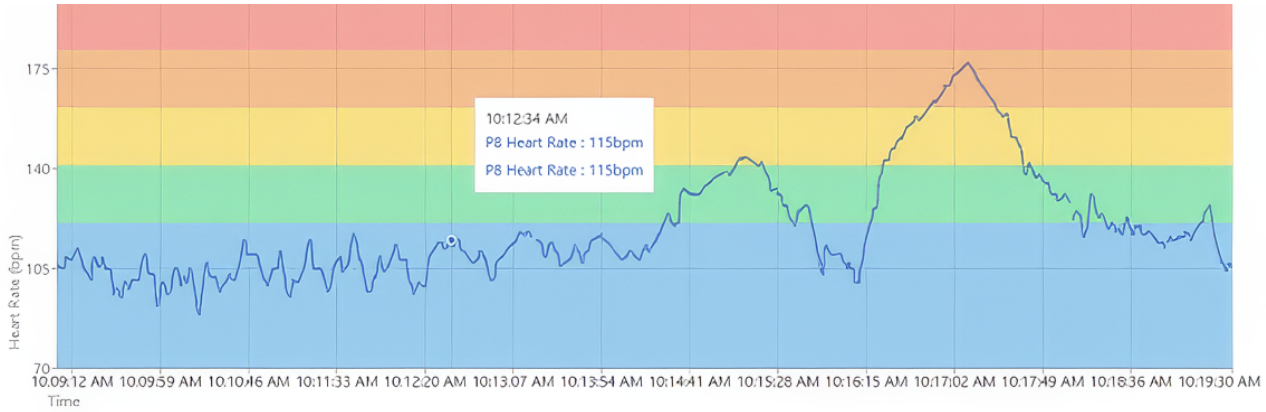


Figure 5. Sample heart rate zone cumulative time.

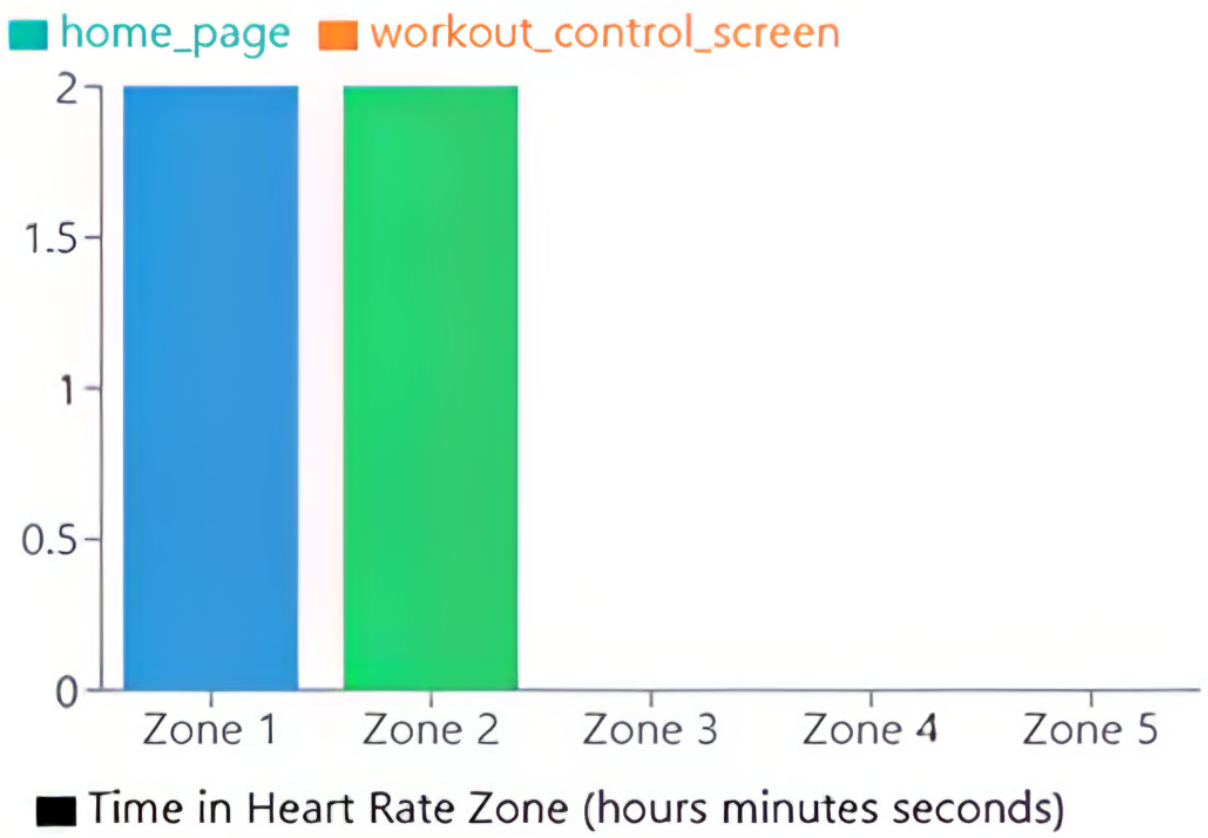


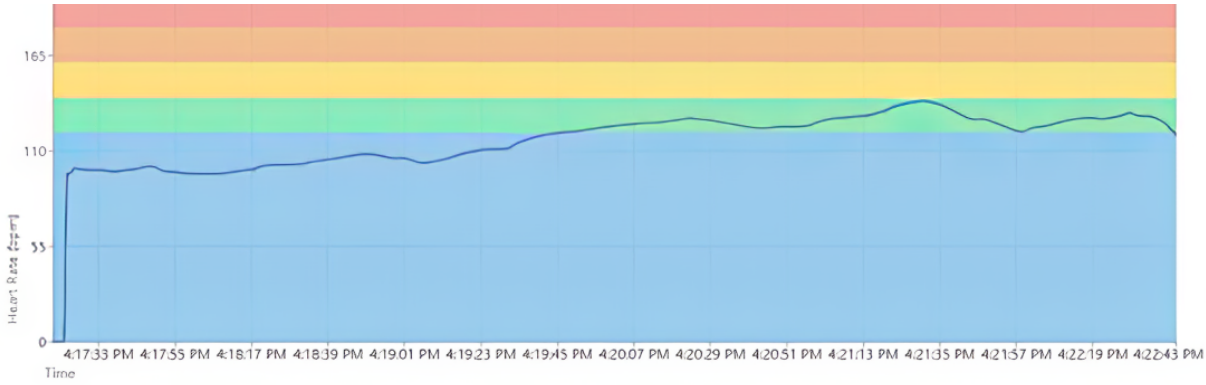
Activity 2

Activity 2 was designed to determine whether participants could make use of the tools provided to them so far (such as the information they have learned about HR, the HR sensor they were wearing, and the Connexx display, which provided a real-time display of their HR in BPM and HR zones) to maintain their HR in a targeted zone. Participants were asked to maintain their HR in zone 2 while engaged in the PA of their choice (basketball, soccer, walking, or jogging). Zone 2 was chosen because it was accessible to all participants, regardless of their fitness level, and they had to use the tools provided to maintain zone 2 HR, as they could easily exceed zone 2 HR by exercising too intensely. Participants could use the Connexx display to monitor their own HR and HR zone in real time to maintain zone 2 HR. The only prompts we provided were for timing (eg, when each minute elapsed). After 3 minutes, the participant was invited to save and end their workout on the Connexx app and view their HR graph for the second interval.

Analytics Review

The analytics portal displayed whether participants were successful in maintaining their HR in zone 2 (Figure 6). The HR zone breakdown also indicated the total time participants spent in each HR zone.

Figure 6. Sample heart rate graphical displays following activity 2. bpm: beats per minute.



Interview and System Usability Scale

After completing the 2 activities, participants engaged in a semistructured interview about their experiences. The interview explored participants' preference for smartwatch or smartphone, the comfort of commercial chest-worn HR sensors and smart devices, the participant's real-time actions to adjust their HR to meet a target goal, what HR zones mean to them, their preference for HR zones, whether they had previous experience with HR, and their enjoyment and potential future use of the Connexx app (refer to Multimedia Appendix 2 for the full interview script). During the interview, relevant objects and visual aids were presented to the participants as needed (eg, smartwatches and HR zone cards).

Finally, after the interview, participants filled out a modified version of the System Usability Scale (SUS) specifically modified and validated for use with preadolescent children [27]. This 10-item scale is used to calculate a usability score between 0 and 100. The commonly accepted threshold for a usable technology is a score of 68 [28].

Observational Data Collection Measures

We conducted observational data collection during each study session. In the event of recording capture device failure, a physical copy of the start and end times of each activity and a log of the participant's HR report and its corresponding value during the study session provide an overview of the participant's HR. Fortunately, this backup was not necessary during analysis.

The researcher who primarily interacted with the participants recorded field notes after each session. Notes focused on participant interaction with the instruments that might not be captured through the interview or SUS questionnaire, such as whether additional adjustments to the chest-worn HR sensor were required and how quickly participants adapted to the input methods for the Connexx app.

Analysis

Demographic data were summarized with descriptive statistics. Observational data were collated with the session transcripts to provide more depth and nuance to the thematic analysis. Additional observations that were not captured in the transcripts or SUS results are included as separate findings in the Observational Findings section.

Interviews were recorded and automatically transcribed via Microsoft OneDrive; we reviewed and revised autogenerated transcripts. Three researchers (LL, MA, and HAL) with qualitative research experience performed an inductive thematic analysis [29]. They followed the 6 steps of thematic analysis: data familiarization, initial code generation, searching for themes, theme review, defining and naming themes, and reporting [30,31]. While this study was designed with several objectives, we remained open to accepting any informative findings in the data. LL, MA, and HAL collaborated to familiarize themselves with the data and generate codes using a sample of the first 2 participant transcripts. The researchers worked together to search and identify themes, creating a codebook. The team then coded transcripts independently, meeting after completing the third and fourth participant transcripts to refine the codebook. Then, they coded the rest of the participant transcripts independently. Intercoder reliability was calculated using Krippendorff α [32] on a sample of 4 independently coded transcripts across 3 coders using the SPSS software (IBM Corp) extension developed by Hayes and Krippendorff [33]. Krippendorff α reliability estimate for the 3 coders was 0.907 (95% CI 0.8348-0.9621), corresponding to a high degree of agreement among them.

Results

Participant Demographics

A total of 11 preadolescent children with an average age of 10.5 (SD 1.0) years participated in this study, of whom 6 (55%) were male and 9 (82%) were non-Hispanic White. While the team sought to recruit a sample with equal numbers of male and female children and an even distribution of races and ethnicities, this diversity was not achieved in the final sample.

Observational Findings

Several observations demonstrated that preadolescent children can use real-time HR information to target specific MVPA goals. Participants shared a strong interest in their real-time HR information; some participants were quick to explore how their HR would respond to changes in PA. Participants looked at their HR information multiple times after initially starting a workout in the Connexx app and observed how controlling their breathing or fidgeting in their chairs may impact their HR. Their ability to use real-time HR information was further demonstrated by the actions of participants in activity 2. For activity 2,

participants were asked to maintain their HR in zone 2 for 3 minutes of PA. A total of 7 participants successfully used the Connexx display to hold their HR in zone 2. Of the remaining 4 participants, 1 (25%) initially ran at a high intensity that raised her HR above zone 2; however, throughout the rest of the 3-minute activity, she ran progressively slower to bring her HR back into zone 2. The 3 (75%) other participants took the opportunity to exert themselves as hard as possible in an attempt to achieve the highest HR reading instead of holding their HR in zone 2. These participants knew how to use the Connexx display to observe their HR in real time, as they looked at their smartwatch throughout activity 2. However, these 3 participants had a strong desire to see how high their HR could go. The parent of 1 of these 3 participants noted that she was highly competitive and always wanted to outcompete her older brother (who was also a participant in this study). One of the participants who successfully held his HR in zone 2 during the second activity demonstrated a similar desire to achieve a high HR value when he asked to be allowed to run around the gym space after completing the study so that he could see how fast his HR could read in the Connexx app.

Regarding hardware suitability for the children, all 11 participants chose to use a smartwatch to observe their HR in real time, and the watch straps successfully fit across a range of wrist sizes. However, there were some challenges with the chest-strap HR sensor. Two (18%) of the 11 participants needed the strap on the HR sensor to be shortened beyond its normal range to fit securely around their bodies. In both cases, the strap was shortened by <5 cm (by folding the excess fabric over and securing it with a safety pin) from the lower limit of the original strap range.

Furthermore, participants were able to quickly learn how to use the Connexx app. All participants were able to report their real-time HR and HR zone when prompted. Several participants (7/11, 64%) were also able to navigate the Connexx app themselves after the initial setup. They could swipe through the different screens in the app and start and end workouts themselves, and 2 (18%) out of 11 participants were able to navigate the text input interface with minimal guidance from the researcher. However, participants identified a substantial issue with the Connexx app in its current state. During the activities, participants noted that the font size of their HR display was too small. This was of particular concern during activity 1, as participants were moving vigorously at points to raise their HR through multiple HR zones. Participants had to adopt several different strategies to be able to see their HR values, including bringing the watch close to their face or slowing down their movement. The small font size of the Connexx app contributed to interruptions in the MVPA participants were engaged in.

Interview Findings

The interview provided rich data that generated themes related to using commercial devices to observe real-time HR to target specific MVPA goals. Three major themes emerged: one focused on real-time use of HR, one related to HR knowledge, and another on device and app use. Specific subthemes ranged from reports of real-time HR to preferences for the construction of HR zones. Themes, subthemes, definitions, and sample quotes are provided in Table 2. Major subthemes are described in the following sections in detail.

Table 2. Interview themes and sample quotes.

Theme and subtheme	Subtheme definition	Sample quotes
Real-time sensemaking of HR[a]		
Reporting HR and HR zones	Declarations of participant's real-time HR and HR zone	"Oh, I'm at Zone 4!... (which is) 160 (BPM)." [Participant 2]
Real-time HR use	How participants make use of real-time HR during activities	"I just looked at the watch a couple of times throughout the exercise and I saw Zone 2 and I'm like, OK, I'm, I was and I, you know, thought that I was doing good. So, I just kept it at that pace." [Participant 9]
HR and correlation to body sensations	How participant's body feels at different HR and HR zones	"I feel like I have to breathe more, but it mostly feels similar." [Participant 1]
HR-related knowledge		
Confusion regarding HR	Confusion about HR or HR zones	"I was just walking up and going over there to play soccer and it (HR) was (already) at 117." [Participant 4]
HR as an achievement	Desire for a high HR or HR zone displayed	"... with five, it's, I just like feel kind of accomplished." [Participant 8]
Previous knowledge of HR	Previous experience learning about HR	"In elementary school in PE class... count... how many beats we have in six seconds? And then he would tell us to, like, multiply it by 10 and that's beats per minute" [Participant 4]
HR zone preferences	Preference for HR zones, 3 larger or 5 smaller zones	"I personally like breaking stuff down to like smaller pieces and understanding it better." [Participant 9]
Device and app		
Device user experience	Comments on function and design of the device	"The smartwatch, you could just turn it over to look..." [Participant 7]
Device comfort or discomfort	How the devices felt for participants	"Wasn't too tight, too heavy... it feels comfortable." [Participant 3]
App usability	Like or dislike the app and willingness to use (or not use) the app in the future	"Probably just for like for fun, just to see (my HR)." [Participant 7]

[a]HR: heart rate.

Using Real-Time HR Information

During the interview, participants were asked about their strategies for adjusting their efforts to meet specific MVPA goals, including holding their HR in zone 2 for 3 minutes in activity 2. Participants who successfully held their HR in zone 2 discussed how they adjusted their effort based on the HR display (coded as "Real-time HR use" in Table 2):

> *I tried to keep the same speed when it was in Zone 2, because if I got faster, it [referring to his HR] will go higher, and if I went slower, it will go to Zone 1.* [Participant 3]

Often, this involved reducing their effort to not exceed the upper limit of zone 2 (coded as "HR and correlation to body sensations" in Table 2):

> *I tried using less power for [basketball] shots and like, try and walk or running across slower to conserve [energy].* [Participant 1]

The participants who were successful in keeping their HR steady in zone 2 used their smartwatch to adjust their effort much more often:

> *I just kept looking at the watch.* [Participant 2]

Some participants (2/11, 18%) noticed that their HR would change even when they did not think their actions should correspond to the change (coded as "Confusion regarding HR" in Table 2):

> *I was just walking up and going over there to play soccer and it [HR] was [already] at 117.* [Participant 4]

However, noting this unexpected result demonstrated that the participant was actively making connections between their PA and the displayed HR.

Not all participants were able to successfully keep their HR in zone 2 during activity 2. These participants acknowledged that they knew the goal was to maintain their HR in zone 2, but they wanted to achieve the highest HR possible. When asked what their HR was, participant 1 stated that "it just hit Zone 4, it is 161... I can go way faster than that!" (coded as "HR as achievement" in Table 2), and participant 8 expressed interest in his HR throughout the course of the study session. After finishing activity 1, he told the researcher that he "would like to see what it (his HR) looks like on a graph." Furthermore, after activity 2, where he was not successful in keeping his HR in zone 2, he told the researcher that he did "want to see how long I was in [zone] 5 for."

HR-Related Knowledge

In addition to findings on the specific research objectives, several themes emerged during the inductive thematic analysis process.

Previous Experience With HR

Four (36%) of the 11 participants had learned about HR in school before taking part in the study (coded as "Prior knowledge of HR" in Table 2); however, none of the participants had a complete understanding of HR. Learning about HR in school was summed up by a participant as follows:

> *[We would] do jumping jacks or jog in place for like 30 seconds, 20 seconds, and then... count our heart, how many beats we have in six seconds, and then he would tell us to, like multiply it by 10, and that's beats per minute.* [Participant 4]

None of the participants had used a chest-worn HR sensor before the study.

HR Zones

Participants were asked to describe what HR zones meant in their own words, and overall, they were able to provide a basic description of each zone. A participant explained the zones in a manner similar to how we had explained them before activity 1, as follows:

> *Zone 1, just calm, sitting down and not doing anything. Zone 2 I might be walking around, and I don't know. Zone 3 I would start to feel really hard to breathe and a little faster [breathing]. Zone 4, I might be breathing kind of heavier and having to slow down a little bit.* [Participant 4]

Other participants described the zones in relation to their own experiences during the study:

> *[Zone] 4 was like, I got to 4 when I was like shooting the ball and running.* [Participant 7]

Participants were asked whether they had a preference for the 5 HR zones used in this study or a more simplified 3 HR zones (coded as "HR zone preferences" in Table 2). Three (27%) of the 11 participants preferred the simplicity of having fewer zones:

> *It would be easier to look at if there was just easy, medium, hard. It would be easier to keep it in the easy-medium zone [referring to Zone 2].* [Participant 4]

The other participants (8/11, 73%) preferred 5 HR zones. Reasons for preferring 5 zones differed between participants; some preferred the greater granularity offered by more zones, and others preferred more HR zones as it provided a sense of achievement. A participant explained the meaning of having more HR zones as follows:

> *It would narrow it down and be easier just to keep it at that zone.* [Participant 6]

Another participant explained his preference for more HR zones as follows:

> *Oh, it's just like an achievement. It kind of feels like an achievement.* [Participant 7]
>
> *I just want to know if I'm in Zone 5, because, like, it's exciting.* [Participant 7]

Feasibility of Chest-Worn HR Sensors Paired to Smart Devices

Device Preference

To explore device preferences, participants were asked why they chose to use a smartwatch over a smartphone to observe their HR during PA (which all participants did). While only 2 (18%) of the 11 participants had consistently used a smartwatch before the study (one had their own, and another used their father's), all participants commented on the greater convenience they could foresee with a smartwatch, particularly while engaging in PA (coded as "Device user experience" in Table 2):

> *The smartwatch, you could just turn it over to look. But for a smartphone, you have to grab it, then you have to [mimes the action of pulling a phone out of their pocket to look at it]. If you're like working out, and you want to know [your HR] you could just look.* [Participant 7]

Device Comfort

When asked about the comfort or discomfort of the devices, all participants stated that the smartwatch felt comfortable (coded as "Device comfort or discomfort" in Table 2):

> *I'm used to wearing watches, so it's pretty normal for me to put one [smartwatch] on.* [Participant 1]

While there was some initial discomfort with the chest-worn HR sensor, it soon became unnoticeable:

> *When I first put it on, it kind of feels weird. But I got used to it when I used it for quite a while.* [Participant 3]

Only one participant reported continued discomfort and a desire to take off the HR sensor before the conclusion of the interview:

> *It was hot and kind of squeezing, so you get uncomfortable feeling.* [Participant 7]

Furthermore, one participant noted that using a softer fabric for the strap would increase the comfort of the instrument:

> *If like the material is different, so you didn't feel it as much. Like if it's like a smoother material or something maybe not as thick.* [Participant 6]

Usability of the Connexx App

Overall, participants were enthusiastic about the Connexx app and the ability to observe their own HR data (coded as "App usability" in Table 2). Participant 7 represented most participants when he declared that using Connexx "was kind of fun!" However, the small font size on the Connexx display made it challenging to view real-time HR while engaged in PA. For instance, participant 1 stated that what he "found frustrating was when we were running that when I wanted to check my HR, I couldn't see it straight because of it shaking." Many

participants (9/11, 82%) expressed interest in using the Connexx app in the future. The final response of participant 11 to a series of questions regarding the Connexx app and the ability to view her own HR was that she could "use it for playing games" with her friends. Similarly, participant 7 noted that he would like to use the Connexx app again in the future, "probably just for like for fun."

SUS Findings

The Connexx app can be considered highly usable in its current iteration; participants rated the Connexx app with an average score of 77.1 (SD 13.7), well above the threshold score of 68 [28]. However, feedback from this study will contribute to its future refinement to further increase usability.

Discussion

Principal Findings

While significant research has demonstrated the accuracy of commercially available HR devices for children [15], there has been insufficient research on how real-time HR information can be used to target MVPA goals. In this study, preadolescent children were provided with a basic lesson about their HR and HR zones, and then, they engaged in 2 PA sessions. Participants demonstrated an understanding of the HR display during PA by effectively using it to regulate their efforts. Therefore, real-time HR information can be used by children as a tool to meet PA guidelines more effectively; children can monitor their own HR information to ensure that they are engaged in MVPA. In addition, this study provides insight into the feasibility of HR sensors and smart devices, smart device preferences, the usability of a custom HR app, preadolescent children's previous HR experiences, and HR zone preferences.

Preadolescent Children Using Real-Time HR Information to Target Specific MVPA Goals

The findings of this study are unique in research on HR device use. Previous research often focused exclusively on accuracy [34], overlooked how users interact with commercial fitness trackers [35], or did not include HR information [36] in the design. In fact, preadolescent children in one study complained that the only real-time information they could see were step count and distance [36]. Participants in a study that paired chest-worn HR sensors with a wrist-worn display regulated their effort based on running speed; these participants did not use their available real-time HR information to adjust their effort [16]. Participants in this study demonstrated their ability to use real-time HR and HR zone information during PA by successfully keeping their HR in zone 2. We observed participants adjusting their effort while exercising (during activity 2) to keep their HR in zone 2. Participants confirmed in the interview that they adjusted their movement speed based on their real-time HR display, demonstrating an ability to use their real-time HR information to target specific MVPA goals during the study session.

Feasibility of Chest-Worn HR Sensors Paired to Smart Devices

Results of this study suggest that chest-worn HR sensors are feasible for use by preadolescent children. While some participants (2/11, 18%) mentioned slight discomfort when first putting on the chest-worn HR sensor, this did not seem to be an ongoing issue and was not brought up during activity 1 or 2. This study provides a more comprehensive investigation into the comfort and usability of these devices compared to previous research. One study that examined the use of a chest-strap HR sensor in conjunction with a wrist-worn device for preadolescent children focused on the accuracy of measurement rather than how preadolescent children felt about using these devices [14]. Another study focused on the accuracy of commercial devices for HR measurements, in this case, wrist-worn devices, without consideration for the comfort of the device [15]. Participants in this study were undergoing surgery, which may not be an appropriate situation to consider the comfort of an HR monitoring device. Furthermore, previous research that focused on the comfort of devices [16] examined an older population, whose more developed bodies may be better suited for devices typically designed for adults. However, the findings of this study indicate that chest-worn HR sensors and smartwatches were generally comfortable for preadolescent children.

Preference for Smartwatch

An interesting finding of this study on the feasibility of smart devices is the appeal of a smartwatch over a smartphone. Researchers did not anticipate all participants to choose a smartwatch over a smartphone for observing their HR information during the study. This is an issue that was not discussed in previous literature [37,38]. Upon reflection, this preference aligns with current commercial trends. Most preadolescent children (9/11, 82%) who participated in this study did not have previous experience with smartwatches or wristwatches in general, which may have contributed to a novelty effect. However, during the interview, they identified the convenience of using a wrist-worn device to view their HR in real time. Several participants (6/11, 54%) commented on perceived ease of use, where they would only have to move their wrists up to be able to view their HR rather than pulling a phone out of a pocket. Other participants (5/11, 45%) favored the security of a worn device, noting that they do not have to worry about dropping a watch compared to a phone. Furthermore, some participants (2/11, 18%) noted that watches may be more comfortable during PA, as a phone in their pocket would move undesirably.

Usability

Research on the design of mobile apps and the use of commercial wearable sensors has focused on the design process; technical limitations, such as loading speed; and efforts to ensure hardware capabilities and accuracy [39,40]. We developed the Connexx app following best practices based on industry standards and previous research [40,41]. Participants rated the Connexx app with a SUS score of 77, which is above the threshold score of 68 [28], indicating that the app has above-average usability. In addition, the Connexx app received a higher score than other digital health apps, more in line with

other PA apps [42]. The usability of the Connexx app was demonstrated by participants throughout the study.

For most participants (9/11, 82%), this was their first time using a smartwatch, and for all participants, this was their first time observing their real-time HR. We helped participants with the initial setup, such as inputting their age and other information in the Connexx app. However, many participants (7/11, 64%) quickly figured out how to operate the Connexx app themselves, and they could input text, navigate the menus, and begin and end workouts on their own without our intervention. This ability not only demonstrated the Connexx app's usability but also this population's familiarity with modern technology and its use, which was a concern for developing health-related apps for preadolescent children [43].

Despite the high SUS score, there were issues with the Connexx app. The Connexx app was initially developed for smartphones and then adapted to smartwatches, creating unanticipated usability challenges. The main PA screen for Connexx featured live tracking of several data fields, including HR, activity time, and speed. While this was easy to read on a smartphone display, on a smaller smartwatch display, the presence of multiple data fields resulted in each field being too small to be easily legible during PA. Thus, participants used multiple strategies to stabilize the smartwatch to be able to read what their HR was. The inclusion of a large color-coded portion at the bottom of the smartwatch display was helpful in informing participants of their HR zone at a glance. Despite difficulty reading portions of the app display, participants found it easy and fun to use. Furthermore, some participants (2/11, 18%) indicated that they not only wanted to use the app again in the future but also would like to share it with their friends.

Other HR Findings

Additional findings from this study indicated that an introductory lesson on HR helped provide participants with a basic understanding of their HR and demonstrated the feasibility of using HR during MVPA. Some participants (2/11, 18%) viewed high HR as an achievement, and the preferences for HR zones are linked to HR achievements for some participants.

Many participants (7/11, 64%) did not have previous experience with HR. An introductory lesson on HR and HR zones was provided for participants at the beginning of the study session, using a simple description of HR zones, including color-coded visual aids (Figure 2) and multiple descriptors that demonstrated how the participants' bodies might respond to various HR zones (Table 1). Participants subsequently demonstrated an understanding of their HR information while engaged in PA, responding to our queries about their HR with reports of both their HR and the corresponding HR zones. Furthermore, participants recalled the introductory lesson on HR well enough after engaging in PA to describe HR zones during the interview; some repeated the descriptors from the lesson, while others applied the descriptors to their own experiences. These findings suggest that participants were able to quickly grasp the HR concepts taught during the session and that using HR to target MVPA with preadolescent children is feasible.

This understanding of HR is even demonstrated by participants who were unable to keep their HR in zone 2 during activity 2. Participants who did not keep their HR in zone 2 demonstrated their understanding of HR by fully exerting themselves in an attempt to achieve a high HR reading. These participants were more interested in hitting the highest HR and HR zone possible; they viewed higher HR and HR zone as an accomplishment. While participants used the technology in a way not originally intended by the study's design, it still showed their understanding of HR and its application during PA.

Finally, many participants (8/11, 73%) preferred having a more granular HR zone division, favoring the 5-zone model over the 3-zone option. Some participants (2/11, 18%) equated zone 5 with a higher sense of accomplishment, mirroring the drive to achieve the highest HR possible. The drive for higher values is reflected in commercially available products for PA tracking. Platforms such as Strava [44] reward users by keeping track of their personal records. Furthermore, when a user's best performance is faster than any other user for a particular segment, the fastest user is rewarded with a crown icon and the title "King of the Mountain" or "Queen of the Mountain." The desire for high achievement of these participants is likely a reason why gamification and leaderboards are more effective in PA promotion than health benefits [45].

Limitations

Despite these findings, this study is not without its limitations. First, the participants had never encountered an app such as Connexx before; therefore, the novelty factor of a new measurement offered by the Connexx app may have offset potential shortcomings arising from font size or other use limitations [46]. As participants continue to use the Connexx app, the SUS score may decrease, as the novelty of displaying real-time HR information wears off. However, as participants indicated having little previous experience or education with HR, this highlights an educational opportunity missing from school curricula, as the participants were interested in learning about their HR.

In addition, the small sample size of this feasibility study limits the generalizability of the findings. While there were almost equal numbers of male and female participants, there was little racial or ethnic diversity (9/11, 82% non-Hispanic White). However, the sample size was still sufficient to demonstrate the usability of these HR monitoring technologies with preadolescent children [25]. Future research is needed to explore the technologies with a larger, more diverse sample.

Because this was a feasibility study to explore whether adolescent children could understand and use their HR information in real time as opposed to measuring HR change in response to PA, we did not control for other confounding variables (eg, the child's fitness level, diet, and resting HR). Rather, as a first step, this study simply examined whether HR use was possible. Moreover, due to the study design, this study did not take advantage of the full scope of capabilities developed as part of the Connexx app, including displaying a paired partner's HR information in real time. Future studies will further explore these capabilities of the Connexx app.

Conclusions

This study aimed to investigate the feasibility and usability of multiple technologies to measure and display HR information for preadolescent children. It examined whether preadolescent children could effectively use these devices to view their HR and make practical use of the information. The results indicate that preadolescent children understood and used their HR to regulate their MVPA and enjoyed using Connexx for real-time HR observation. Participant responses demonstrate the ability to use and the desire for access to real-time HR information during PA. Future research should build on these findings regarding the use of real-time HR as an intervention tool to target specific MVPA goals. This could involve testing strategies that use HR and real-time monitoring as direct targets in program designs. Preadolescent children's interest in using real-time HR should be leveraged by researchers, health professionals, and educators to promote MVPA in an engaging way for this population.

Acknowledgments

The authors would like to thank Sunny Dhama for assisting with software and investigation, Lidong Lin for assisting with the investigation, and Wesly Menard and Mollie Brewer for assisting with the conceptualization and methodology of the study. Abstract

Background: Maternal mortality remains a persistent public health concern in sub-Saharan African countries such as Ethiopia. Health information technology solutions are a flexible and low-cost method for improving health outcomes with proven benefits in low- to middle-income countries' health systems.

Objective: This study aimed to develop and assess the usability of an electronic dashboard to monitor facility-level readiness to manage basic emergency obstetric care (BEmOC) in Amhara, Ethiopia.

Methods: The study used three methods to iteratively refine the dashboard: (1) user-centered design sessions with individuals who interact with the BEmOC supply chain, (2) review and feedback from domain and information visualization subject matter experts (SMEs) to refine the dashboard, and (3) usability heuristic evaluation with human-computer interaction (HCI) SMEs.

Results: User-centered design sessions resulted in a preliminary version of the dashboard informed by end-user preferences and perceptions, with recommendations focusing on aesthetic design, filtering and sorting, and matching with the real world. An example of an end-user recommendation included increasing font sizes on the dashboard and using a red, yellow, and green color-coding scheme. Next, domain and visualization SMEs continued the dashboard's iterative refinement, focusing on aesthetic design and navigation, by confirming design choices incorporated from the user-centered design sessions and recommending changes to enhance user experience moving through the dashboard, such as adding more filtering options. HCI SMEs rated the dashboard as highly usable (0.82 on a scale of 0-4, with 0 being no usability concern and 4 being a catastrophic usability concern). The principle with the highest usability severity scores was a match between the system and the real world with a score of 1.4. The HCI SMEs also rated the information visualization aspects of the dashboard favorably with 2 usability principles, spatial organization and information coding, scoring 0.

Conclusions: Dashboards are a novel method for promoting and tracking facility capacity to manage BEmOC. By including targeted end users and SMEs in the design process, the team was able to tailor the dashboard to meet user needs, fit it into the existing government health systems, and ensure that the dashboard follows design best practices. Collectively, the novel, customized

BEmOC dashboard can be used to track and improve facility-level readiness in Amhara, Ethiopia, and similar global BEmOC facilities.

Introduction

Maternal mortality is a critical public health issue, particularly in low-resource settings like sub-Saharan Africa, which accounts for over three-fourths of global maternal deaths [1]. Despite progress in reducing adverse maternal outcomes in countries like Ethiopia, high maternal mortality ratios persist, largely due to gaps and stockouts of essential supplies for managing obstetric emergencies [2,3]. Inadequate supplies for basic emergency obstetric care (BEmOC) can lead to delayed or suboptimal care. A study on facility-level readiness to manage BEmOC in Amhara, Ethiopia, using the Clinical Cascades reported a 63.3% mean overall BEmOC readiness for managing the 6 most common emergencies, which underscores the need for improving facility-level BEmOC readiness in this region [4].

A promising approach to improve facility-level BEmOC readiness is the development and implementation of health information technology (HIT) to monitor critical supply availability. HIT involves the processing, storage, and exchange of health information in an electronic environment, and has been shown to improve health outcomes and strengthen health systems in low-resource settings [5,6]. Electronic dashboards are a form of HIT that can be used to track critical information, provide alerts, assess performance indicators, develop reports, and customize data views, which makes them a useful tool for monitoring inventory data and facility-level readiness [7,8]. For example, dashboards were used in Ethiopia to monitor the supply inventory of malaria medications and prevent stockouts from occurring, and a simple dashboard was merged into the existing Integrated Pharmaceutical Logistics System (IPLS) in the Amhara and Oromia regions of Ethiopia, resulting in improved facility-level readiness to treat tuberculosis by ensuring health care facilities had adequate supplies [7,8]. Beyond Ethiopia, HIT has been used to anticipate medical stockouts and improve maternal health outcomes in low-resource settings [9,10]. This evidence highlights the potential for HIT to improve facility-level BEmOC readiness in Amhara, ultimately contributing to improved maternal care quality and reduced maternal mortality ratios.

Previous studies, including those conducted in low-resource settings and Ethiopia, have demonstrated the benefits of HIT and dashboards in improving facility-level readiness [5-8]. Furthermore, the growing utilization of technology and cellular services across Africa further supports the feasibility of implementing successful electronic solutions, driven by the increasing adoption of HIT [11,12]. Finally, Ethiopia has recognized the value of HIT in strengthening health care systems and has been implementing electronic medical records in its health care facilities since 2013 [13].

However, while dashboards can be a powerful tool for improving health outcomes, their success depends on ensuring high usability, enabling end users to effectively accomplish their tasks. Usability is defined as “the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use” [14]. Despite the potential of HIT, many implementations have failed due to insufficient consideration of end users’ needs and the environment in which the technology is applied [15,16]. Similarly, while dashboards show promise for improving facility-level BEmOC readiness, their success relies on development that incorporates input from targeted end users, accounts for the context of use, and adheres to usability principles. This study aims to develop and assess the usability of an electronic dashboard for monitoring facility-level BEmOC readiness.

Methods

Overview

To create the initial version of the dashboard, the team incorporated findings from previous qualitative interviews with individuals who worked in Ethiopia’s obstetric emergency supply chain, used information and designs from the preexisting dashboards in Ethiopia’s IPLS, and followed best practices found in the current literature for dashboard development [17-20]. The initial dashboard and its components were developed in Microsoft PowerPoint (refer to Multimedia Appendix 1).

To ensure adequate fit between the dashboard, the required tasks, the current system, the environment, and intended users, the research team conducted participatory user-centered design sessions, performed informal evaluations with domain and information visualization subject matter experts (SMEs), and completed a heuristic usability evaluation with human-computer interaction (HCI) SMEs.

Ethics Considerations

The research team obtained ethics approval from Columbia University’s institutional review board (IRB) (IRB-AAAU2006), Emory University’s IRB (MOD005-STUDY00005335), and the Amhara Public Health Institute (NoH/RfftTlDlo7l44). Before collecting data, the research team provided participants with an information sheet and gave them time to ask questions about the study. Once all questions had been answered, the team obtained verbal informed consent from all participants before

collecting data. All ethics review boards waived the requirement for written documentation of informed consent because the study procedures met the criteria for minimal risk to participants. All data was de-identified and participants data was linked to a random identification number. Only KD had access to the list of participant names linked to the ID numbers. None of the targeted end-users, domain experts, or subject matter experts received compensation for their participation in the study. Human-computer interaction experts participating in the heuristic evaluation received a $50 amazon gift card for their participation.

Sample Selection

User-Centered Participatory Design Sample Selection

Consistent with existing literature in the field of participatory design, the team estimated that a sample size of 15 would be sufficient to reach design saturation, a state where the design sessions reveal no major revisions to the designs reviewed [21,22]. The research team purposively recruited individuals with firsthand experience working within the BEmOC supply chain in Amhara, Ethiopia, at both the regional and local or facility levels. Participants were required to be at least 18 years old. Study participants were Ethiopian citizens and full-time employees in one aspect of Amhara's BEmOC supply chain, such as hospital supply managers, regional hub employees, and pharmacists.

Informal Expert Review Sample Selection

The domain SME was a research team member with over 6 years of experience conducting research in Amhara, Ethiopia; evaluating the supply chain; and measuring facility-level readiness to manage BEmOC. The information visualization SMEs were individuals from Columbia University School of Nursing's Visualization Design Studio, where individuals with varying levels of expertise can learn and gain advice on their current projects. The discussions at this studio were led by 2 PhD-level faculty, a nurse scientist with expertise in visualization design and evaluation, and a human-factors engineer. Key contributions also came from other faculty members at the university who have training in the areas of nursing research and biomedical informatics. All information visualization SMEs have published in the areas of information visualization, HCI, and user experience.

Heuristic Evaluation Sample Selection

The study sample included 5 HCI SMEs who were recruited through the team's professional networks. Previous research has found that 5-8 SMEs can identify over 80% of HIT usability violations [23,24]. HCI SMEs were eligible for inclusion if they had conducted research or published in the field of user interfaces or information visualizations and had not previously evaluated the dashboard.

Procedures

User-Centered Design Procedures

Staff from Emory-Ethiopia Partnership and Amhara Regional Health Bureau identified BEmOC supply chain stakeholders and reached out to determine if they were interested in participating in this study. A member of the research team contacted interested individuals via phone call, email, and WhatsApp (Meta) messaging to explain the study in detail, answer any questions, and set a time to meet in person with the participant to obtain verbal consent and perform the research activities. We used multiple communication channels to reach potential participants; in particular, WhatsApp has been found to be a useful tool for recruiting participants, specifically in global settings [25,26]. Design sessions were conducted in English and Amharic, and data collection tools were available in both languages since Amharic is the national language and Ethiopia's health care professionals receive clinical training in English [27,28].

Design sessions lasted approximately 60 minutes and occurred in small groups of 2-4 people within the health care facility or health bureau offices. Participants were given printed copies of the initial dashboard and asked to verbalize their thought processes as they explored the visualizations and information in the preliminary dashboard [29-32]. Design sessions were audio recorded and transcribed into English for analysis by a team member who is bilingual in Amharic and English. The individual conducting the analysis is a native Amharic speaker with over a decade of experience translating Amharic to English for health care research. Given their extensive expertise and the time constraints of the study, the team opted not to perform back translations. The dashboard development followed an iterative process, consisting of 4 design sessions. After each session, the research team incorporated recommended changes into the dashboard, which were then presented in the subsequent sessions [30].

Informal Expert Review Procedures

The team presented the Microsoft PowerPoint dashboard to a domain expert and a group of information visualization SMEs. Team member (KD) used Zoom (Zoom Video Communications) screen-sharing capabilities to walk the domain expert through the dashboard and their various features. The domain expert then reviewed the dashboard and provided recommendations for improvement.

KD presented the same dashboard to information visualization SMEs at 2 sessions of the Visualization Design Studio [33]. KD walked the SMEs through the dashboard, answered questions about their intended use, and elicited feedback and recommendations. Collectively, both rounds of feedback were used to optimize and further develop a medium-fidelity version of the dashboard for use in the heuristic usability evaluation.

Heuristic Evaluation Procedures

The team used Figma to develop a medium-fidelity prototype, which allowed the simulation of the dashboard's workflow [34]. Using Zoom Pro, a Health and Insurance Portability Accountability Act (HIPAA)–compliant videoconference platform, and its screen-sharing technology, KD asked the HCI SMEs to complete several tasks using the dashboard and encouraged them to explore other components of the dashboard (Multimedia Appendix 2). During their exploration, participants completed a heuristic evaluation checklist to identify and rank the severity of the usability violations and had the opportunity

to explain the violations they encountered [23,24,32]. They were also asked to describe what they were thinking, feeling, and seeing while completing the various tasks. The sessions were video recorded, and KD took field notes. At the end of the sessions, the HCI SMEs and KD discussed potential solutions for the identified usability violations. Participants were asked to complete tasks during the heuristic usability evaluation mentioned in Textbox 1.

Textbox 1. List of tasks participants were asked to complete during the heuristic usability evaluation.

Heuristic usability evaluation tasks

- Filter the main screen to only view primary hospitals.
- Determine which health care facilities are not ready to manage retained placenta.
- Determine if [hospital name] is ready to manage hypertensive emergencies. If not, identify which items are missing.
- Determine if [hospital name] is ready to manage maternal sepsis or infection. If not, identify which items are missing.
- Determine what emergencies [hospital name] is ready to manage.
- For prolonged labor at [hospital name] filter the supplies table to see the items that are at the emergency order point.
- For prolonged labor at [hospital name] filter the supplies to see the items that are overstocked.
- Determine how many health care facilities are at risk for not being able to manage retained placentas.

The Heuristic Evaluation Checklist used in this study was guided by Nielsen's 10 usability heuristics (ie, best practices; Table 1) [24,35] and includes a 5-item scale where experts rate each usability heuristic on a scale of 0 (not a problem) to 4 (catastrophic violation; Table 2) [23,32,36]. The research team modified the original checklist to fit the needs of a medium-fidelity dashboard (Multimedia Appendix 2). For example, questions for heuristics related to error prevention, help users with errors, and help and documentation were excluded since those tasks could not be simulated with the medium-fidelity prototype. In addition, 3 usability heuristics specific to information visualizations in the dashboards were included: spatial organization, information coding, and orientation [19].

Table 1. Usability heuristics and their definitions used in the heuristic usability evaluation.

Usability heuristic	Type	Definition
Visibility of system status	HIT[a]	The system should always keep users informed about what is going on through appropriate feedback in a reasonable time.
System and real-world match	HIT	The system should speak the user's language, with words, phrases, and concepts familiar to the user. The system should follow real-world conventions and ensure the dashboard fits within the existing workflow and technology system.
User control and freedom	HIT	Users should be free to select and sequence tasks and make their own decisions regarding the cost of exiting current work. Users should have clearly marked "emergency exit" to leave the unwanted state.
Consistency and standards	HIT	Users should not have to wonder whether different words, situations, or actions mean the same thing. Systems should maintain interface design choices in similar contexts and differ in different contexts.
Recognition rather than recall	HIT	The user should not have to remember information from one part of the dialogue to another. Objects, actions, and options should be easily visible, and instructions should be visible or easily retrievable whenever appropriate.
Flexibility and efficiency of use	HIT	The system should offer users several options for finding content. Users should be able to customize their interface and achieve their goals in an efficient manner and have the capacity to adapt to users' needs.
Aesthetic and minimalist design	HIT	The main dashboard should not contain information that is irrelevant or rarely needed. The system should present the largest amount of data with the least amount of ink.
Spatial organization	Information visualization	The overall layout of a visual representation should make it easy for the user to locate an information element in the display.
Information coding	Information visualization	The symbols and numbers used in the visualization should aid perception. The numeracy and graph literacy of the visualization should match the intended users' ability.
Orientation and help	Information visualization	The system should provide support for the user and help to orient them in their visualization.

[a]HIT: health information technology.

Table 2. Severity ratings for usability violations in the heuristic evaluation.

Score	Usability problem	Explanation
0	Not a usability problem at all	No problem identified
1	Cosmetic problem	Need not be fixed unless extra time is available on the project
2	Minor problem	Fixing this should be a low priority
3	Major usability	Important to fix, so should be given high priority
4	Usability catastrophe	Imperative to fix this before the product can be released

Data Analysis

User-Centered Design Analysis

Analysis was concurrent with data collection with modifications of the dashboard occurring after the initial 2 design sessions and following the third and fourth sessions. Using the translated transcripts of audio-recorded sessions and field notes, KD extracted key preferences, identified poorly performing graphics and dashboard components, and improved the design based on participant feedback. The team maintained detailed notes on design decisions and the rationale for those decisions alongside the notes and transcripts, which functioned as an audit trail.

Heuristic Usability Evaluation Analysis

The responses on the Heuristic Evaluation Checklist were transferred into Microsoft Excel for analysis [19,20]. The research team used unique participant numbers to link the responses to a confidential participant list. The data were analyzed with descriptive statistics (frequencies and means) [37]. Both session field notes and qualitative responses reported in the free response comments section of the checklist were used to understand usability and enhance the dashboard's design. During the evaluations, KD documented key areas of concern that HCI SMEs verbalized during the sessions. Combing those notes with the free-response comments, KD used the frequency that those concerns were mentioned to understand their importance. The usability concerns and potential solutions reported from the free-response comments were also compiled into a single list of action items, with duplicates removed, and KD used this list to guide the refinement of the next version of the dashboard.

Results

User-Centered Design Sessions

Sample Characteristics

In total, 6 individuals, who work at the regional health bureau or regional hubs for supply distribution, participated in the first 2 design sessions and reviewed the initial version of the dashboard. Following the refinement of the dashboard by KD, 5 individuals who work at health care facilities in the region participated in the third and fourth design sessions and reviewed the updated version of the dashboard. Recruitment and data collection ended prematurely at 11 participants due to civil unrest and safety concerns in the region [38].

Evolution of the Dashboard Design

During design sessions 1 and 2, participants reviewed the initial version of the prototype, and during design sessions 3 and 4, they reviewed a revised version that incorporated feedback from study participants in design sessions 1 and 2. During design sessions 1 and 2, participants viewed the initial design of the dashboard and were able to easily grasp the idea the dashboard was trying to portray related to facility readiness to manage BEmOC. The users felt the dashboard, specifically, the regional view, helped them to understand which facilities would be ready to handle the emergencies. One regional respondent stated,

> *This image [dashboard] demonstrates how they [individual health care facilities] would be able to handle each health issue considering the level of the supplies that each hospital has for these health problems. In general, we can conclude from this image [regional dashboard] that some hospitals are in good condition for these health issues and others are not in good condition for these health issues.*

Generally, participants in the first two sessions focused on (1) individual graphical component preferences such as which type of charts they preferred to see the data presented and (2) how they would want the data to be filtered and sorted. The third and fourth sessions with the refined dashboard focused on (1) confirming the terminology in the dashboard, and that it matched terms used in the supply chain, and (2) affirming design changes that were incorporated from the earlier sessions. Respondents in the third and fourth sessions also provided feedback on which job roles should have access to the dashboard. A participant during the fourth design session stated,

> *This dashboard [emergency-specific view] is essential for the dispensary unit as well. The store and supply officer bears most of the workload or duty in this workplace, but if the pharmacists and hospital managers have access to the data, it would be very good.*

The changes that were incorporated during the design sessions, as well as the session number, iterations of the dashboard, and job level that provided the recommendations, can be found in Multimedia Appendix 3. In the following paragraphs, more details are provided on aesthetic design, filtering and sorting, and matching with real-world preferences.

Aesthetic Design

For colors used throughout the dashboard, participants wanted to use multiple colors that were consistent with those currently used in the existing dashboard. Furthermore, participants in the

first 2 design sessions identified pieces of information that they thought should be removed from the dashboard because they did not assist the end users with making decisions related to supply ordering or maintaining facility-level readiness. However, to ensure users could find information that was not included in the dashboard, the research team added a button that would allow users to view the comprehensive drug list, which is already embedded in the electronic components of the existing IPLS. Facility-level participants, during design sessions 3 and 4, explained that not all health posts will manage certain obstetric emergencies, such as sepsis, so they should not receive readiness classifications for those emergencies. In response to this, the research team grayed out the classifications for those facilities and their corresponding emergencies.

Another aesthetic preference in the early design sessions included requests to include keys in the dashboard that define the colors and terms. Participants in design sessions 3 and 4 agreed that the keys assisted in their comprehension of the dashboard. Participants in design sessions 3 and 4 affirmed the design choices of the previous sessions and provided only small recommendations for the overall look of the dashboard, such as increasing the font size. Related to aesthetic decisions, design saturation was met with the smaller sample size.

Filtering and Sorting

Participants in the early sessions wanted to ensure there were multiple ways to filter the data so they could view pieces of information that were most important to them. Preferred filtering and sorting options included viewing inventory alphabetically within preestablished categories from the Ethiopian Pharmaceutical Supply System (eg, medical equipment, pharmaceuticals, and supplies), filtering supplies based on quantity available at the facility, and filtering facility by health care facility tier (eg, primary, general, referral, and center) [17]. Participants during the third and fourth design sessions endorsed the filtering options identified in the earlier sessions.

The participants from design sessions 3 and 4 also wanted employees at individual facilities to be able to view inventory data at other facilities besides their own. They felt having access to these data could support transferring excess supplies from one facility to another when neighboring facilities faced stockouts or were at an emergency order point. Thus, the research team added the ability for facility-level users to select different facility readiness data, similar to the regional-level users. Since there was very little new information identified during the second 2 design sessions, the research team determined that the study achieved design saturation for filtering preferences even with the smaller respondent sample.

Match With the Real-World Preferences

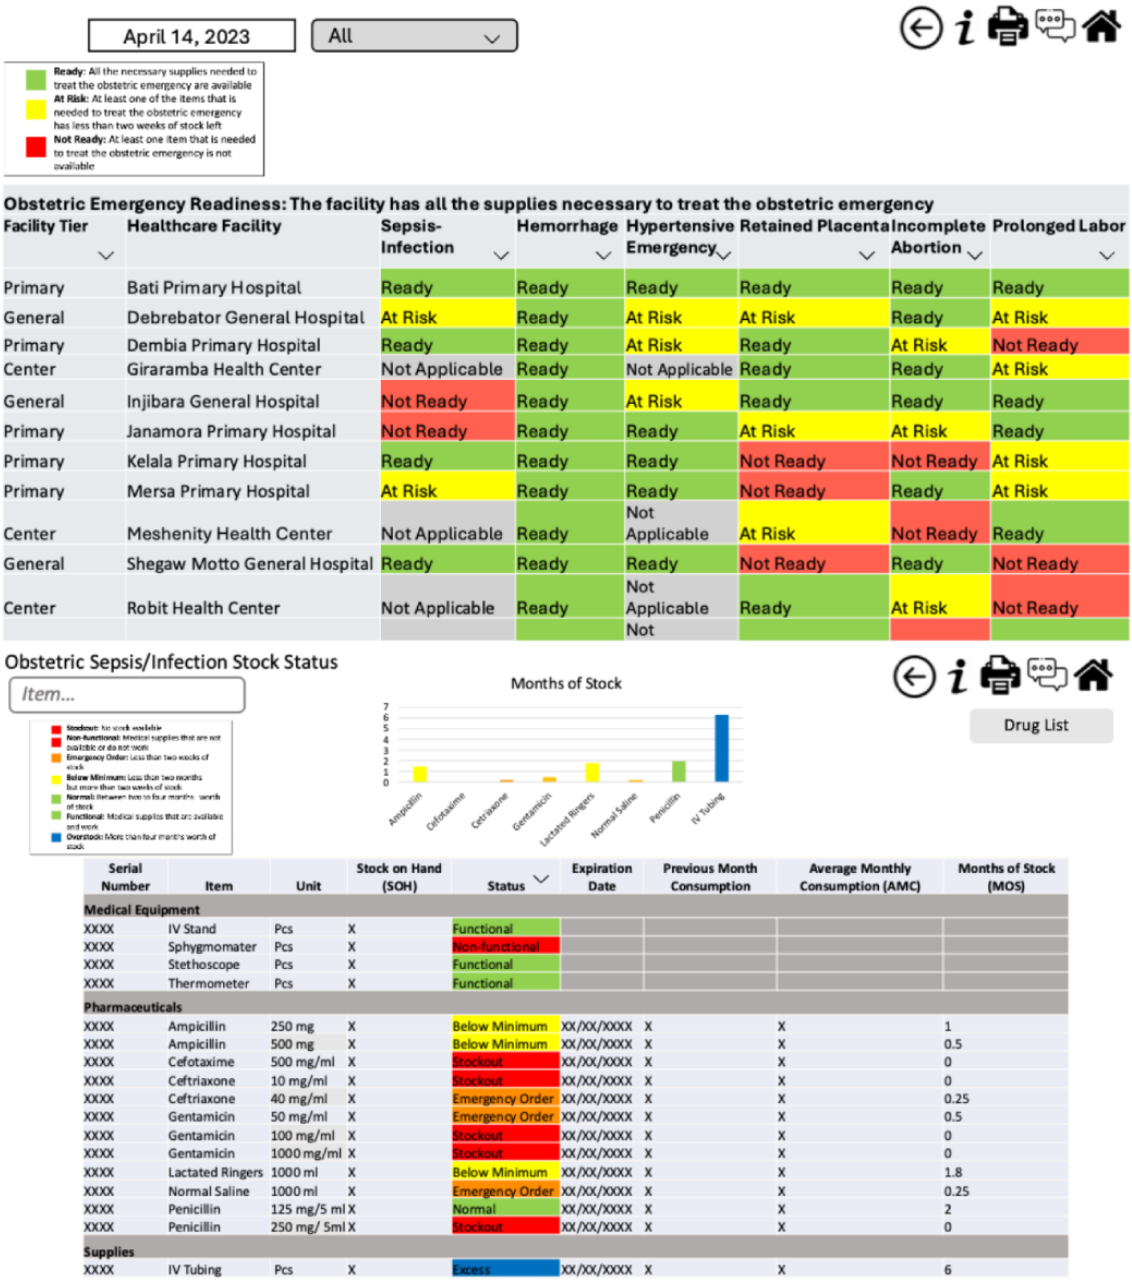
A feature that was a very important point of discussion in all the design sessions was using appropriate terminology that aligned with the participants' current workflow and job expectations. Participants wanted to ensure that all the terms used within the dashboard aligned with terms from the IPLS. For example, supply names and categories as well as terms for quantities available were updated (eg, overstock changed to excess, and normal changed to functional for the category medical supplies).

One important change to note is that during the third design session, participants recommended changing the terminology for BEmOC readiness from ready, at risk, and not ready to normal, emergency order, and stockout so they would be the same as the terms used with the emergency-specific dashboard view. Based on this recommendation, the research team created 3 different readiness terminology keys. The 3 options included the original terms; the newly recommended terms; and a third option of yes, no, and emergency order. Since the team could not confirm their preferred choice for readiness terminology due to the civil conflict in the region, the domain expert selected the final terms—yes, at risk, and no. Since the team was unable to obtain user preferences related to this final change, the study did not achieve design saturation in the "match with the real-world" domain.

Final Design

The final design comprised 2 different dashboard views for monitoring BEmOC readiness—one for the regional level and another for the facility level. The regional-level dashboard view provides a summary of readiness for the 6 obstetric emergencies for all health care facilities in the region. The facility-level dashboard view focuses on one facility and one obstetric emergency at a time. Overall study participants viewed the dashboard positively, with one respondent from design session 4 reporting "The hard copies [of the dashboard] you showed us today are beautiful and wonderful." Figure 1 shows the design of the dashboard following the integration of the findings from the third and fourth user-centered design sessions, and Multimedia Appendix 3 lists all the changes that were incorporated into the dashboard following the user-centered design sessions.

Figure 1. Regional basic emergency obstetric care (BEmOC) readiness dashboard and emergency-specific, facility-level dashboard following user-centered design sessions. Hospital names are real, but all readiness data are fictitious.



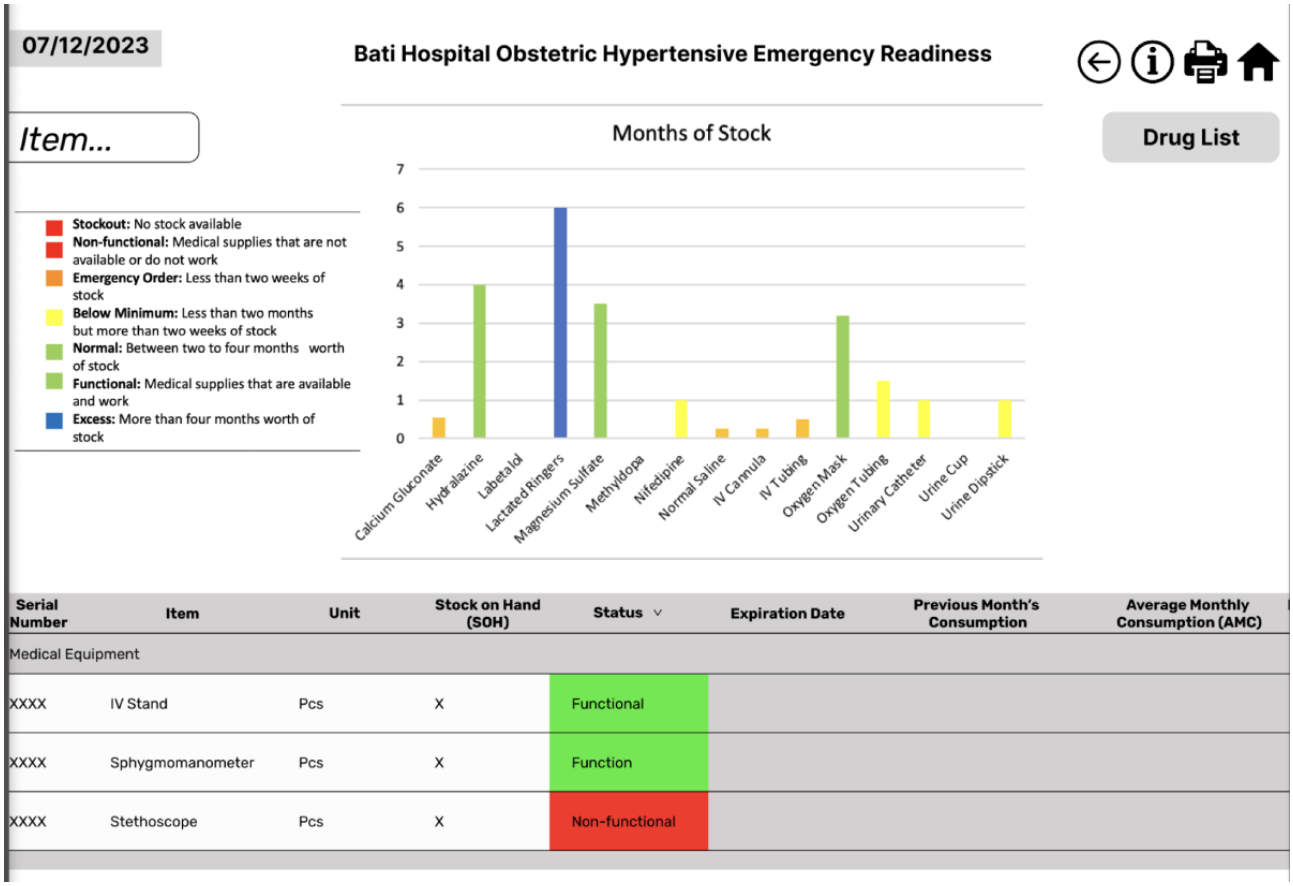
Informal Expert Review

The domain expert's largest contribution to the refinement of the dashboard was his input on which terms to use to define BEmOC readiness, specifically for the regional view dashboard. To make the final decision on readiness classification terms that were discussed in the final user-centered design session, KD presented the domain expert with 3 different options created following the fourth design session. After reviewing the options, the domain expert recommended KD use yes, emergency order, and no. The rationale for this decision was the yes and no choice was the simplest option, and he believed the end users would be able to readily act based on these classification terms. The domain expert also affirmed KD's decisions to group data at the regional and facility levels and felt that no critical information was missing from the dashboard.

During the review by information visualization SMEs, most recommendations aesthetics related to aesthetics and navigation. In terms of aesthetic design, the recommendations mainly focused on where to place different pieces of information or graphics to best grab the users' attention or prevent overcrowding on a screen, for example, moving several columns of data to the right in the emergency-specific dashboard view. This would allow users to scroll horizontally to see that information, but it would not be visible without scrolling so there would be less information crowding the page. To improve navigation between the various dashboard views, the SMEs during the design studio recommended adding additional filtering options, such as for emergency readiness categories. They also recommended adding an affordance feature to the dashboard so that users would be able to see which items on the screen are clickable or not. In addition, the experts

recommended adding several additional titles to different dashboard views to enhance clarity. These changes were incorporated when the dashboard was updated from PowerPoint to Figma (Figure 2).

Figure 2. Regional view dashboard following informal expert review. All inventory data in this dashboard are fictitious.



Heuristic Usability Evaluation With Human-Computer Interaction Experts

The heuristic evaluation took approximately 30 minutes per session. The years of experience for HCI SMEs ranged from 4 to 14 years, with a mean of 9. All HCI SMEs were female.

Overall, severity scores for heuristic evaluation ranged from 0 to 3 for the 10 usability principles. The mean usability score for all ten heuristics combined was 0.82 (SD 0.98), with a mode of zero. The principle with the highest severity rating was a match between the system and the real world, with a score of 1.4, which falls between a minor and cosmetic usability concern. For this principle, 4 HCI SMEs identified inappropriate color choices for both potential users with color blindness and using colors not congruent with common color-coding expectations as a common issue. Additional problems included the dashboard using concepts and phrases that were unfamiliar to the evaluators, and 3 evaluators felt the section headings were not ordered in the most logical fashion. HCI SMEs identified issues with usability principles visibility of system status, user control and freedom, consistency and standards, and recognition rather than recall (mean 1.2 for each, SD 0.84, 1.3, 0.84, and 1.3, respectively), which also falls between a cosmetic and minor usability concern. Concerns related to these principles included 2 of the HCI SMEs identifying the lack of clear exits for every dashboard and feeling that the current design hindered their ability to efficiently navigate the system. Table 3 shows the mean value, range, and mode for the 10 heuristic principles.

Table 3. Identified heuristic usability problems and their severity scores.

Heuristic category	Problems	Score, mean (SD)	Score, range	Score, mode
Visibility of system status	• Title font is too small • Color choices may be inappropriate for color-blind users • Vertical bar charts make reading supply labels more difficult • Need hyperlinks to improve navigation • Menu-naming terminology is not consistent with the user's task domain	1.2 (0.84)	2	1 and 2
Match between system and real-world	• Color choices may be inappropriate for color-blind users • Section headings and subheadings are not ordered in the most logical way • Not all words, concepts, and phrases were familiar to the human-computer interaction subject matter experts • Some of the colors used in the dashboard do not correspond to common expectations about color codes	1.4 (0.89)	2	1
User control and freedom	• Need hyperlinks to improve navigation • Not a clear exit on each dashboard screen • Not all screens are accessible across the system • Users could not easily move forward and backward between fields	1.2 (1.3)	3	0
Consistency and standards	• Titles on the regional view dashboard do not update when the user filters the data • Abbreviations not clearly explained • Some colors are too similar to distinguish from other categories • Not enough or inconsistent visual cues to identify active screens	1.2 (0.84)	2	1 and 2
Recognition rather than recall	• White space is not optimized within the emergency-specific dashboard view • Prompts, cues, and messages are not placed where the eye is likely to be looking on the screen	1.2 (1.3)	3	0
Flexibility and efficiency of use	• Need hyperlinks to improve navigation	0.6 (0.89)	2	0
Aesthetic and minimalist design	• Not all field labels are brief, familiar, or descriptive • Large objects, bold fonts, and simple areas have not been used to distinguish sections • There is not enough white space between color representation • Too much text is present in the keys which makes the screens look busy	0.8 (0.84)	2	0 and 1
Spatial organization	• Font size is too small throughout the dashboard • Information does not follow a logical flow	0 (0.0)	0	0
Information coding	• No problems identified	0 (0.0)	0	0
Orientation	• Measurement units are not displayed clearly • Users cannot control the level of detail they see in a representation	0.6 (1.3)	3	0

The experts provided several recommendations for how to remedy the problems identified during the heuristic evaluation. They believed adding hyperlink functions would improve users' ability to navigate between the dashboard views, thus increasing usability scores for visibility of system status, user control and freedom, and flexibility and efficiency of use. Aesthetically, the experts believed increasing the font size of titles and data within the dashboard, as well as moving different components of the dashboard around to maximize white space would improve scores for spatial organization, aesthetic and minimalist design, recognition rather than recall, and visibility of system status.

HCI SMEs also made recommendations that disagreed with user preferences identified during the design sessions. These differences included the experts preferring horizontal bar charts compared to vertical bar charts. An expert explained the rationale for this preference stating a horizontal bar chart allows for the labels in the table to be read horizontally, which can be easier for users. However, during the user-centered design sessions, the participants had a resounding preference for the vertical bar charts because they were more familiar with that format since some of their preexisting dashboards included vertical bar charts in the IPLS. Given the importance of the new dashboard to mimic the look of the existing ones, as well as the

fact that the users explicitly preferred the vertical presentation, KD chose to retain the vertical bar charts. The color of the tables and graphs was also a point of disagreement between experts and users. The experts did not think the red, yellow, and green color choices were appropriate because these colors can be difficult to distinguish if individuals are color blind [39]. However, the targeted end users of the dashboard preferred those colors because the colors reminded them of traffic lights, and the users could make assumptions related to the significance of the colors based on what those colors mean by a traffic light. The research team chose to keep the traffic light color scheme.

Beyond these recommendations, the reviewers cited several positive features of the dashboard. This includes things such as the belief that the icons used throughout the dashboard were clear and easy to associate with their function. In addition, the experts found the labels and keys to be clear and assisted with comprehension of the data. One respondent reported, "Your labels are quite clear. It's [the dashboard] very accessible and you have nice keys right here." The heuristic violation severity scores for information visualization-specific heuristics were low with scores of zero for spatial organization and information coding, and 0.6 for orientation. Table 4 summarizes the changes incorporated into the dashboard following the completion of the heuristic usability evaluation. The final dashboard is displayed in Figure 3.

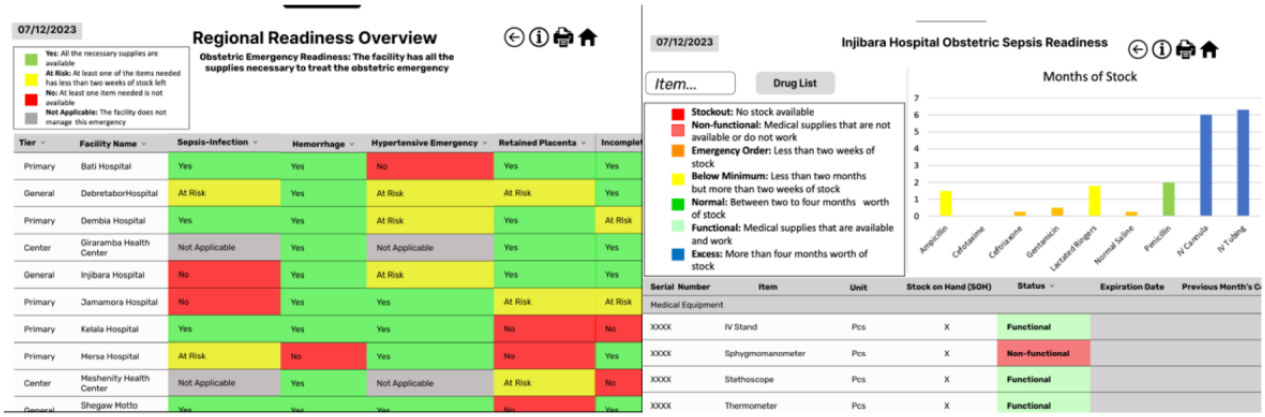
Table 4. Summary of changes incorporated into the dashboard following the heuristic evaluation

Heuristic category	Changes following heuristic evaluation
Visibility of system status	• Increased font size throughout the dashboard • Added hyperlinks to the dashboard
Match between system and real-world	• Updated section headings to reflect filtering capabilities • Updated the terminology defining BEmOCa readiness on the regional-level dashboard
User control and freedom	• Added hyperlinks to the dashboard • Ensured exit buttons on every screen are activated • Activated more functions within the dashboard to make it a higher-fidelity prototype
Consistency and standards	• Updated section headings to reflect filtering capabilities • Defined all abbreviations used in the dashboard • Changed the colors for functional and nonfunctional on the emergency-specific screen so that they are more easily distinguishable from the other colors used on the screen • Added additional visual cues to identify active screens
Recognition rather than recall	• Moved graphics at the top of the dashboard to optimize white space • Added additional visual cues to identify active screens
Flexibility and efficiency of use	• Added hyperlinks to the dashboard
Aesthetic and minimalist design	• Shortened information in the keys to make them one line of text • Shortened data within the tables to make it one line of text • Used bold fonts for all titles • Moved graphics at the top of the dashboard to optimize white space
Spatial organization	• Increased font size throughout the dashboard • Improved the navigation between dashboard views to make them a higher-fidelity prototype
Information coding	• N/Ab
Orientation	• Increased font size for measurement units • Activated more functions within the dashboard to make it a higher-fidelity prototype

[a]BEmOC: basic emergency obstetric care.

[b]N/A: not applicable.

Figure 3. Final regional view and emergency-specific view of the dashboard following the heuristic usability evaluation. Hospital names are real, but all readiness data are fictitious.



Discussion

Principal Findings

The dashboard underwent iterative refinement based on user input, domain expert feedback, information visualization evaluations, and heuristic usability assessments. Regional participants emphasized preferences for vertical bar charts, traffic-light color coding, and keys to define readiness levels, while facility-level users focused on aligning terminology with existing workflows and tailoring readiness classifications. The information domain expert provided critical input on readiness terminology, and information visualization experts suggested improvements in layout, navigation, and aesthetics, such as optimizing white space and increasing font sizes. Collectively, the central tendency of heuristic severity scores, combined with a mode of zero, indicated high overall usability of the dashboard. However, the HCI experts did highlight minor usability concerns, including navigation and accessibility improvements, which were addressed in the final design. While some expert recommendations, such as horizontal bar charts and alternative color schemes, differed from user preferences, the team prioritized end-user input to ensure practical usability. The final dashboard is intuitive, visually clear, and aligned with real-world needs, achieving high usability and user satisfaction.

This study highlights the importance of including participants from all targeted end-user groups. By including employees from both regional and facility levels, the team gathered diverse, relevant perspectives, ensuring the dashboard met the real-world needs of users across different supply chain roles and experiences. Feedback from both end users and experts enhanced the overall usability and functionality of the dashboard. This aligns with existing usability literature, which emphasizes the value of involving both end users and experts to identify distinct concerns and improve HIT design [40]. Participants' spontaneous interpretations of the dashboard underscore their understanding of the content, and obtaining these perceptions and insights can assist in preventing usability errors from occurring later in the piloting or implementation phase of HIT development. These refinements will likely maximize the ease of implementation and promote consistent uptake and utilization by future users [41,42].

There were 2 areas of disagreement between HCI SMEs' recommendations and end-user preferences: bar chart orientation and color schemes. The research team chose to keep the vertical bar charts for their familiarity with the end users and alignment with existing dashboards. In addition, lower color blindness prevalence among Black African and African American populations (4.2% compared to 6.6% and 1.4% compared to 5.6% respectively) compared to White populations (6.6% and 5.6%) [43,44] supported the decision to maintain the preferred color scheme, as most targeted end users were unlikely to face difficulties distinguishing the colors.

This study reinforces the notion that obtaining expert opinions and performing usability testing can be a low-cost, efficient method for exploring technology needs [45]. Performing the evaluations with the domain expert and the information visualization SMEs took less than an hour for both groups and provided critical information on how to improve upon the design of the dashboard. Performing usability evaluations can identify problems and usability concerns that may not have been noticed before HIT implementation, avoiding costly and time-consuming corrections [24].

Finally, this study contributes to the growing body of literature on the use of dashboards to support BEmOC in sub-Saharan Africa. Similar to findings by Banke-Thomas et al [46] and Wang et al [47], stakeholders expressed enthusiasm for dashboards and prioritized features like reporting facility characteristics on the dashboards. However, there remains a gap in the literature regarding the specific design preferences of end users. This study addresses that gap by highlighting key preferences, such as the use of stoplight color coding and IPLS-specific terminology, which enhance usability and are tailored specifically for dashboards intended for Ethiopia and BEmOC contexts.

Limitations

During data collection, there was unanticipated civil unrest in the Amhara region, which prevented the research team from recruiting participants outside of the regional capital of Bahir Dar and from completing participant recruitment from multiple facilities outside the regional capital. Despite this unforeseen barrier, design saturation was reached for 2 out of the 3 categories during the design sessions. There was also a lack of

gender diversity among our participants. Only one user-centered design participant from Ethiopia was female. However, this gender imbalance mirrored the existing gender imbalance in the existing health system for these roles. However, future research related to this dashboard and facility-level BEmOC readiness would benefit from an emphasis on opinions and participation from female participants with relevant expertise. Conversely, all HCI SMEs were female. While the incorporation of a female perspective is critical since the sample for user-centered design sessions was predominately male, the effect of having completely female HCI SMEs is unknown. Future research should incorporate technical and gender-balanced perspectives during both user and HCI SMEs' review of this dashboard.

Furthermore, the dashboard design was informed by responses from participants in qualitative interviews. However, due to time constraints, the initial prototype was developed by the research team rather than being cocreated with participants. While this approach allowed the team to efficiently move forward with development, it may have limited the incorporation of deeper, iterative feedback from participants during the initial design phase. This limitation could have influenced the alignment of the prototype with user needs and preferences, which may require further refinement in future iterations.

To prospectively limit social desirability bias, the research team created a low-stress, comfortable environment for data collection and emphasized our desire to obtain personal responses to the dashboard while reiterating that all opinions would be blinded so no one could identify specific feedback from specific participants. The team chose to have an Amharic-speaking Ethiopian team member conduct the user-centered design sessions rather than the principal investigator, who is from the United States and does not speak Amharic. The team took steps to ensure confidentiality and used indirect questioning techniques in an attempt to garner the participants' true opinions [48]. Furthermore, the dashboard reviewed in the heuristic usability evaluation was medium fidelity. This means the dashboard was not able to complete all required tasks and certain usability heuristics, such as *help and documentation* and *error prevention*, were excluded from this evaluation, since their tasks were not applicable at this stage in the design process. Future research will need to explore all usability heuristics before implementation to ensure no new concerns arise once the dashboard transitions from a medium- to high-fidelity model.

Conclusion

In conclusion, this study demonstrates the value of user-centered design and usability evaluations in developing HIT for low-resource settings. By integrating diverse perspectives from regional and facility-level participants, as well as domain and usability experts, the dashboard was refined to meet real-world needs and achieve high usability. This iterative approach not only addressed usability concerns but also incorporated end-user preferences, ensuring alignment with existing workflows. The study fills a gap in the literature by identifying design preferences tailored to Ethiopia's health care context, offering a model for future HIT development aimed at improving BEmOC readiness and maternal health outcomes. These findings emphasize the importance of engaging end users and experts early in the design process to create functional, user-friendly systems that support effective implementation and long-term adoption.

Acknowledgments

We would like to thank Emory-Ethiopia Partnership's Addis Ababa and Bahir Dar offices for their support and guidance in this research.

This work was supported by the National Institute of Nursing Research (F31NR020569), a Fulbright US Student research award to Ethiopia, and a research grant from Sigma Theta Tau Alpha Zeta chapter.

Authors' Contributions

YA performed data collection with support from MB and LA. HB supported the project administration and maintained ethics approvals throughout the study. KD analyzed the data and created the dashboard with assistance from SB and JNC. KD drafted the manuscript, and all other authors assisted in editing and refining the final manuscript. JNC conceptualized the nested study design and obtained parent funding for the Saving Little Lives study which this research was nested within. AG provided contextual expertise on Amhara and Ethiopian clinical care.

Abstract

Background: The Early Psychosis Intervention Network of California project, a learning health care network of California early psychosis intervention (EPI) programs, prioritized incorporation of community partner feedback while designing its eHealth app, Beehive. Though eHealth apps can support learning health care network data collection aims, low user acceptance or adoption can pose barriers to successful implementation. Adopting user-centered design (UCD) approaches, such as incorporation of user feedback, prototyping, iterative design, and continuous evaluation, can mitigate these potential barriers.

Objective: We aimed to use UCD during development of a data collection and data visualization web-based and tablet app, Beehive, to promote engagement with Beehive as part of standard EPI care across a diverse user-base.

Methods: Our UCD approach included incorporation of user feedback, prototyping, iterative design, and continuous evaluation. This started with user journey mapping to create storyboards, which were then presented in UCD workshops with service users, their support persons, and EPI providers. We incorporated feedback from these workshops into the alpha version of Beehive, which was also presented in a UCD workshop. Feedback was again incorporated into the beta version of Beehive. We provided Beehive training to 4 EPI programs who then piloted Beehive's beta version. During piloting, service users, their support persons, and EPI program providers completed Beehive surveys at enrollment and every 6 months after treatment initiation. To examine preliminary user acceptance and adoption during the piloting phase, we assessed rates of participant enrollment and survey completion, with a particular focus on completion of a prioritized survey: the Modified Colorado Symptom Index.

Results: UCD workshop feedback resulted in the creation of new workflows and interface changes in Beehive to improve the user experience. During piloting, 48 service users, 42 support persons, and 72 EPI program providers enrolled in Beehive. Data were available for 88% (n=42) of service users, including self-reported data for 79% (n=38), collateral-reported data for 42% (n=20), and clinician-entered data for 17% (n=8). The Modified Colorado Symptom Index was completed by 54% (n=26) of

service users (total score: mean 24.16, SD 16.81). In addition, 35 service users had a support person who could complete the Modified Colorado Symptom Index, and 56% (n=19) of support persons completed it (mean 26.71, SD 14.43).

Conclusions: Implementing UCD principles while developing the Beehive app resulted in early workflow changes and produced an app that was acceptable and feasible for collection of self-reported clinical outcomes data from service users. Additional support is needed to increase collateral-reported and clinician-entered data.

Introduction

Background

Research estimates that the lifetime prevalence of psychotic disorder diagnoses is approximately 1.5%, and the prevalence of psychotic symptoms is between 4.2% and 17.5% [1]. California, the most populous and second most diverse state in the United States [2], had a population of 39.11 million in 2023, according to the California Census Bureau. This indicates that 586,650 to 6.8 million Californians may experience psychosis symptoms in their lifetime. In response to this, many California counties have developed specialty early psychosis intervention (EPI) services, which vary widely in their implementation approach [3]. The Early Psychosis Intervention Network of California (EPI-CAL) [4] was developed to support the provision of quality EPI services and to create an infrastructure to conduct standardized measurement of the impact of early psychosis care delivery. To support this goal, the EPI-CAL team, in collaboration with several California counties, developed a learning health care network (LHCN) consisting of EPI programs across the state. The EPI-CAL LHCN later joined the national Early Psychosis Intervention Network [5], which allowed additional California EPI programs to participate. Members of the LHCN agreed to gather standardized information and outcomes from their clinics as part of measurement-based care (MBC). Collecting this information is critical to support quality early psychosis care provision within clinical programs as well as enhance statewide learning and development. For example, a narrative review of an MBC approach in behavioral health clinics found such benefits as significantly improving clinical outcomes, improving symptoms more quickly, and decreasing treatment costs [6].

To this end, the EPI-CAL team chose to design and implement a web-based and tablet app called Beehive. We chose the name Beehive to reflect the envisioned purpose for the app: to help LHCN programs learn and grow together for the betterment of the collective, just as bees work together to build a hive for the benefit of the colony. Beehive is a robust, stand-alone eHealth app for use by service users, their support persons, and EPI program providers. In this text, we use the term *service user* to refer to the individual with a psychosis diagnosis who is receiving mental health care from an early psychosis program. We use the term *support person* to refer to any person that the service user has chosen to involve in their care. This is typically the individual's parent but might be another family member, a friend, a partner, or some other close relative. Beehive's purpose is to promote MBC in EPI programs by standardizing data collection across a network of programs focusing on community partner priorities; supporting key components of care such as assessment, safety monitoring, and ongoing care delivery; supporting program-level management of care; and aggregating data across a large network to support evaluation and research at state and even national levels [4].

We chose an eHealth approach to implementing MBC due to its appropriateness for the EPI setting and its potential benefits. Despite the perceived challenges related to experiences of suspicion or paranoia, individuals experiencing mental health difficulties, such as schizophrenia and bipolar disorder, have widely found use of eHealth both feasible and acceptable [7-10]. Furthermore, the use of eHealth can support the advancement of MBC. For example, eHealth apps have been previously demonstrated to promote symptom and outcomes monitoring in both early psychosis care [11,12] and LHCNs [13]. Conducting MBC with eHealth enhances its benefits as it allows for data collection to be standardized across programs and instantly available. For example, MBC may promote collaboration across a care team [14-16], which is relevant for EPI programs for which the evidence-based treatment, coordinated specialty care, is inherently team based [17]. Use of eHealth to collect data in this setting allows data collected by one team member or entered by a service user to be instantly available for all team members. eHealth also enhances the benefits of MBC through data aggregation, which enables evaluation of program performance [16,18,19] or promotion of evidence-based treatments [16,20].

Though there are many potential benefits, there are also numerous barriers to implementation of both new eHealth technology and MBC. According to a systematic literature analysis, the top factors posing a barrier to eHealth app implementation include lack of digital health literacy, lack of devices, financing issues, service-user cognition, and security [21]. These barriers contribute to low adoption and user acceptance, which limit the success of implementation [22,23]. Barriers to implementation of MBC include training burden, concern that negative feedback causes harm to service users, and the time required for survey completion [24-26].

To pursue the benefits of using eHealth to implement MBC and mitigate the potential barriers, we developed Beehive with user-centered design (UCD) principles. UCD prioritizes the needs and expectations of the end user [27,28]. UCD approaches include dedicated design activities, active involvement of users

in the design process, incorporation of their feedback, prototyping, and continuous evaluation [29], which can address low user acceptance and low adoption [30]. Beehive's iterative development began with a collaborative process with service users, support persons, and EPI program providers to identify and prioritize which outcome measures should be collected in the app [31]. We also explored how service users, support persons, and EPI program providers wanted to be informed about data-sharing options in Beehive and built Beehive's end user license agreement (EULA) workflow to incorporate user perspectives [32]. With the survey content and EULA workflow finalized, we moved onto the development of the user-facing parts of Beehive.

Objectives

In this study, we aimed to (1) use UCD principles to create a co-designed web-based and tablet app, called Beehive, to support MBC in EPI programs, and (2) assess Beehive's initial feasibility in clinical settings by piloting it in 4 EPI programs.

Methods

Design

To promote Beehive engagement across multiple types of users and across multiple domains of engagement, we integrated UCD principles of incorporation of user feedback, prototyping, iterative design, and continuous evaluation. Service users, support persons, and EPI program providers had multiple opportunities to provide feedback, which was incorporated throughout Beehive development. Figure 1 shows the study design from conceptualization through data collection.

Figure 1. Study design for Beehive development.

The development process began with conceptualization of user journeys. User journey mapping envisions how specific types of users, such as a service user or a service provider, will interact with an app from access point through all required activities [33]. User journey mapping allowed us to identify which storyboards we should develop to present in UCD workshops and which user-types we needed to recruit for those workshops. Storyboards are a tool to visualize app workflows and the user interface [34]. We developed storyboards to present as prototypes in UCD workshops so that feedback could modify the app design before time was invested in coding the alpha version of the app. The alpha version of the app included core workflows and was both evaluated internally and presented in another UCD workshop to gather more feedback before coding the beta version of the app. The beta version of the app incorporated remaining feedback from storyboard workshops, new feedback from the alpha stage, and added the remaining core functionality that was not in-scope for the alpha version (eg, reports). The beta version of Beehive was piloted by 3 EPI programs over 6 months to further refine the app before launching it across all EPI-CAL programs. We used pilot data to assess initial use and uptake of Beehive's beta version.

This UCD approach allowed the EPI-CAL team to receive and incorporate feedback during conception, design, and testing phases of eHealth app development, and include multiple perspectives to facilitate user engagement in eHealth. Notably, UCD has also been demonstrated to increase eHealth adoption and user acceptance in research and clinical settings [30,35].

Participant Recruitment

UCD Workshops

For UCD workshops of the Beehive storyboard, we recruited participants from the following three EPI community partner

groups: (1) EPI service users, (2) their support persons, and (3) EPI providers. Eligible participants were (1) actively or formerly affiliated with an EPI-CAL EPI program, (2) English speaking, and (3) able to provide written informed consent and assent (minors or conserved adults). EPI program providers were recruited through contact with the team lead of the 12 active EPI-CAL EPI programs. Service users and support person participants were invited either through EPI program provider referral or by the research team directly contacting individuals who had previously consented to be contacted for future research opportunities.

One EPI-CAL clinic agreed to participate in a workshop for the alpha version of the app to support the refinement of Beehive before piloting.

Piloting

In total, 4 EPI-CAL clinics agreed to participate in 6 months of Beehive beta testing before Beehive's full launch across the entire EPI-CAL LHCN. During this period, programs integrated the Beehive app into standard clinical care. Pilot sites registered service users who were active in their program at the time of launching Beehive and new service users who started after the launch. Each participating program has different acceptance criteria for service users, and this has been described in a separate protocol paper for the EPI-CAL study (NCT04007510) [4]. Service users and support persons were excluded from piloting if they did not speak English because Beehive beta version was only available in English. At their first point of contact with Beehive, service users and primary support persons completed the Beehive EULA and were asked if they gave permission for their clinical data collected in Beehive to be used for research purposes [32]. We trained clinics to involve the legal guardians of service users aged <18 during EULA completion, and these service users were required to have a primary support person registered in Beehive. Individuals could update their data-sharing permissions at any time.

Methods

User Journey Mapping

The EPI-CAL research team worked collaboratively with the contracted app developer in the user journey mapping and storyboard design phases for the Beehive tablet and web apps. Three primary user groups with distinct roles were identified: (1) service users or support persons, (2) direct-service providers, and (3) program administrators. Beehive user journeys were developed for each group.

For all user groups, user journeys were designed to guide individuals smoothly through Beehive onboarding and account creation to the EULA explainer video detailing the types of information Beehive collects, who can access their data, and how to select their preferred permissions for who can view their data [32]. Users then choose their data-sharing permissions.

Beehive then presents service users and support persons with a series of one-time and longitudinal surveys to measure clinical outcomes at 6-month intervals. Specific survey items associated with risk, such as suicidal or homicidal ideation, send real-time alerts to EPI program providers if they are endorsed by service users. Beehive creates visualizations of this survey data. While service users and support persons cannot independently access survey visualizations, we considered this is as part of their user journey because it should be shown to them by EPI program staff as part of regular care.

EPI program provider user journeys were designed to facilitate easy management of service user records and smooth navigation to service user data. A dashboard presents the most important information to users, such as outstanding survey alerts or other action items. A client list presents all registered service user records in list format with the most relevant information displayed. EPI program provider users can click into service user records to view survey results, survey visualizations, and complete provider-entered surveys. Providers can display survey results and survey visualizations as part of ongoing care with service users and their support persons to facilitate understanding and coordinate treatment priorities.

Administrator user journeys were designed to promote clinic-level management tasks, such as Beehive implementation and quality assurance. Administrator dashboards present aggregate-level information of survey data and allow for the ability to compare clinic averages to the average of the EPI-CAL LHCN. Administrator dashboards also present summaries of Beehive activity across the clinic. Administrator users can also download reports, including survey data reports, to use their clinic data for quality assurance or reporting requirements.

UCD Workshops

Next, the development team created dynamic storyboards of the above user journeys. These storyboards were presented to community partners from early psychosis clinics in 90-minute UCD workshops. Figures 2 and 3 are images from the storyboards presented to community partners.

In the storyboard workshops, we presented major features of the app and asked for feedback on the app's look and feel, as well as functionality as it related to existing clinical workflow, and ease of use and acceptability for service users, their support persons, and EPI program providers. Because we determined 3 user-types during user journey mapping, we held 3 different types of storyboard workshops tailored to the journeys of these users: service users or support persons, direct-service providers, and program administrators. If EPI providers had roles in both direct-service provision and program administration, they could attend both groups. UCD workshops were conducted through videoconferencing to comply with the COVID-19 social distancing restrictions. Each session was audio recorded and included 2 facilitators (KEB, LMT, TAN, or SE) and a notetaker (VLT). There were no other individuals present other than researchers and participants. The notetaker took detailed notes, as close to verbatim as possible. Audio recordings were used as a reference to fix any portions of the notes which were not clear.

After storyboard workshops, we integrated feedback to make design changes to the alpha version of the app. During a 90-minute alpha testing workshop, we solicited feedback on the alpha app, with a special emphasis on how compatible it was with the existing clinical workflows. We created test

accounts for each participant and had them complete various core workflows in the app, such as registering a service user, completing surveys, and reviewing data visualizations. This workshop included one facilitator (KEB) and one notetaker (LS). After the conclusion of all workshops, we continued to integrate feedback to make design changes in the beta version of the app.

Figure 2. Survey item in storyboard.

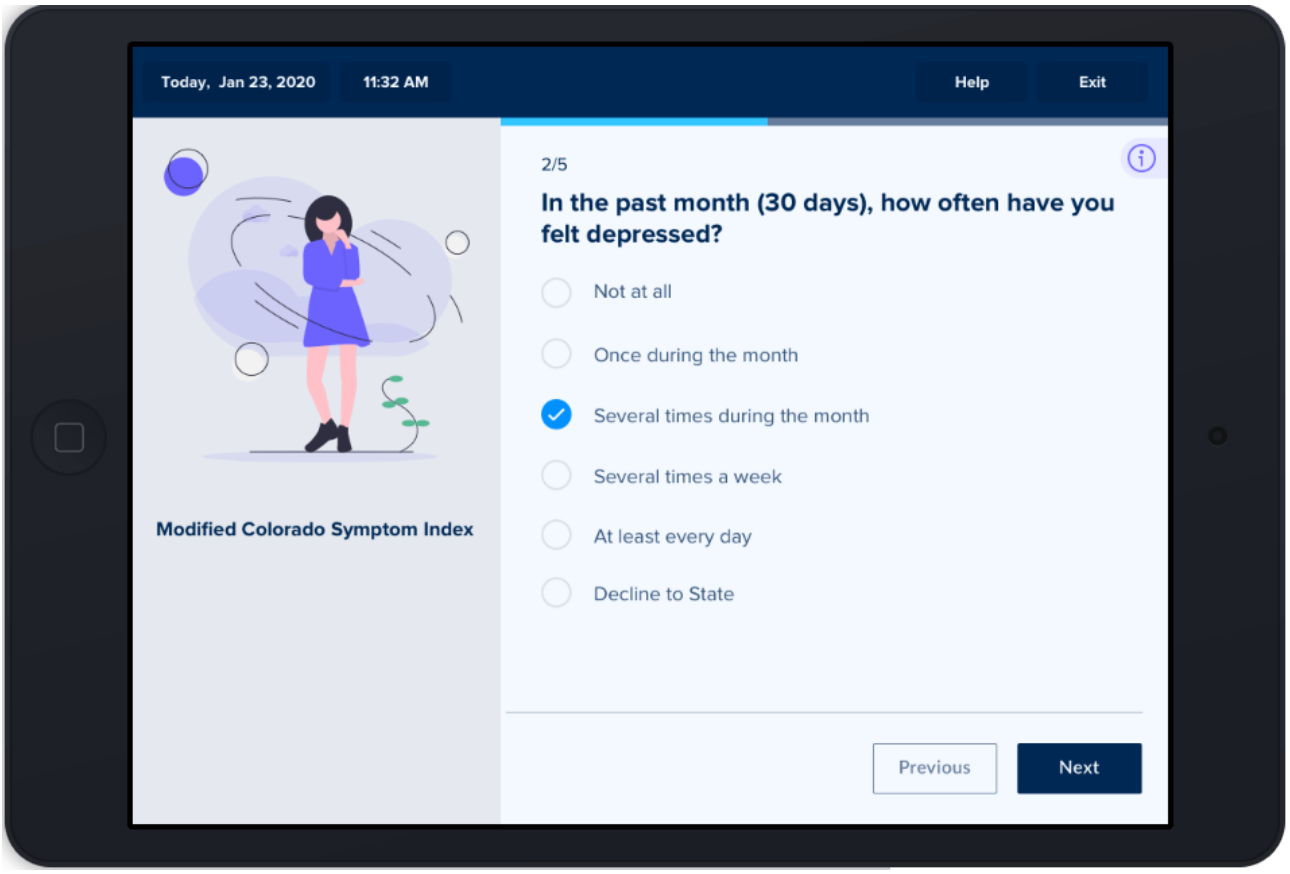

Figure 3. Clinical administrator dashboard in storyboard.

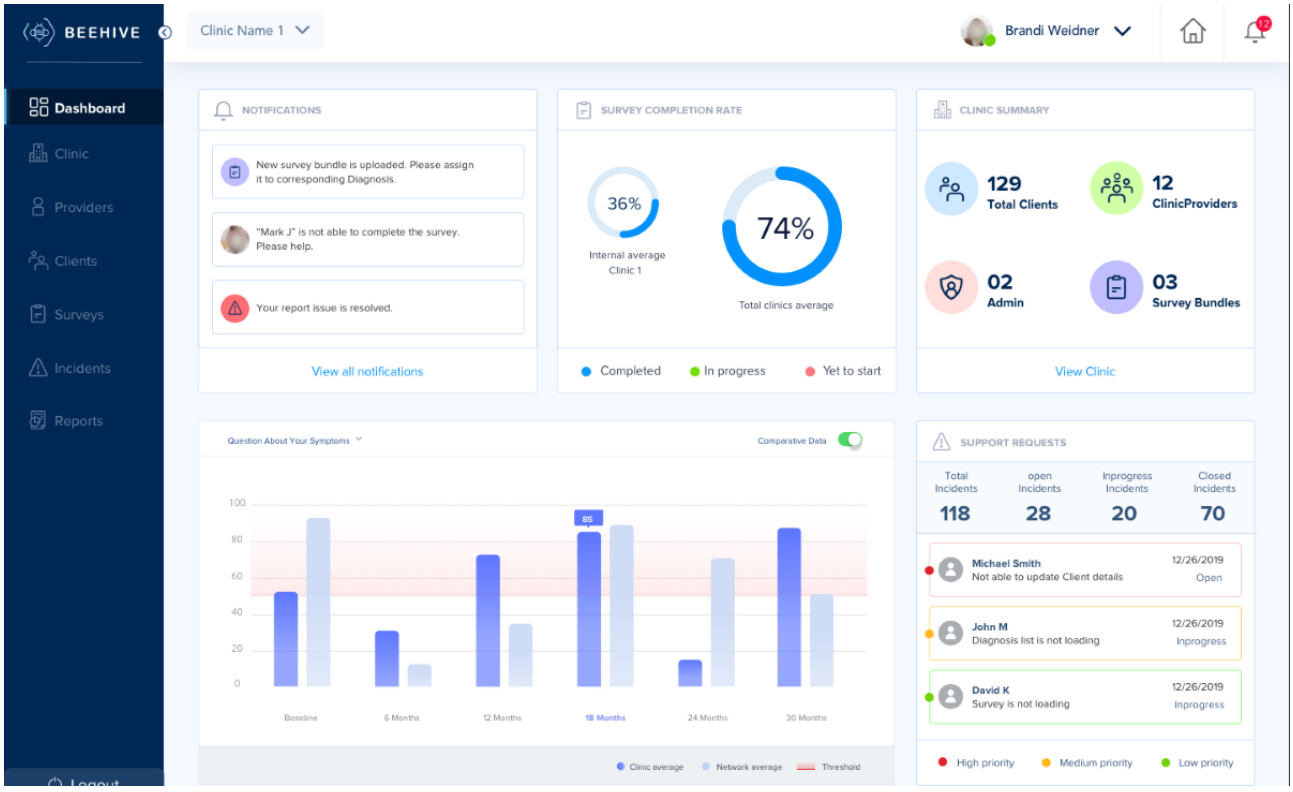
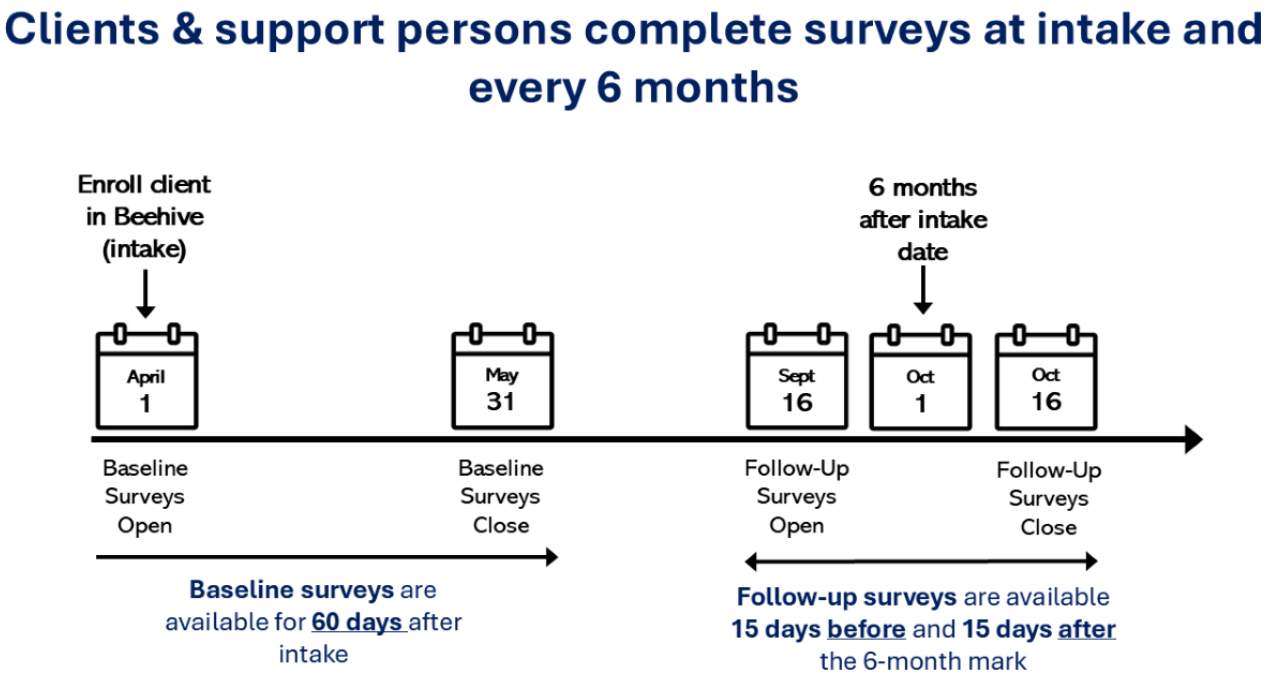


Piloting

Finally, piloting of the beta version of Beehive was conducted over a 6-month period with EPI-CAL LHCN programs that were identified as pilot sites. We provided training to each pilot site and assigned them a point person from our research team to provide regular support, troubleshoot implementation challenges, and escalate app bugs and implementation barriers. We trained all program staff, regardless of clinical role. The training series showed users how to complete key Beehive workflows, introduced the EPI-CAL core assessment battery, and included activities on how to interpret data visualizations. We also met with key staff at each program to support them to devise a plan to integrate Beehive into their existing clinical workflows, such as how to integrate service user registration during the clinical intake process. The full description of this training and support is described in a separate paper [4]. During this training and support process, we received informal feedback from program staff about implementation successes and challenges.

During piloting, programs integrated the Beehive app into standard clinical care for all service users. Service users and their support persons were registered in Beehive web app by staff at their EPI program. Program staff entered the service users' treatment start date which was considered the start of the service users' baseline window in Beehive. At enrollment, baseline, and every 6 months thereafter, surveys were assigned to service users, their support person, and their provider. One-time surveys assessing lifetime experiences were available for all respondents at enrollment. Service users had 3 enrollment surveys, support persons had 1, and clinicians had 1. Longitudinal surveys were assessed at treatment baseline and every 6 months thereafter. Service users had 17 longitudinal surveys, support persons had 6 surveys, and clinicians had 9 surveys. The duration of baseline survey window was 60 days; the duration of follow-up survey windows was 30 days (15 days before and after the target completion date). Figure 4 shows a Beehive training slide with a visualization of survey windows.

Figure 4. Beehive training slide showing survey windows during piloting.



Programs were instructed to enroll all service users, regardless of how long they had been affiliated with the EPI program. Therefore, some individuals may have been enrolled in Beehive after their baseline window had closed, and their first time point during piloting may have been a 6-month time point or a 12-month time point. Service users and support persons could access and complete surveys in-person at the clinic on the tablet app or they could complete them remotely via "web link." The "web link" was a unique link that was texted or emailed to them weekly during survey windows if surveys were not fully completed. Surveys accessed via web link could be completed on any personal device that had access to the internet and a web browser. Service providers completed surveys and could review data on the web app. Baseline surveys were intended to support the clinical intake process, including initial assessment and collaborative treatment planning. Follow-up surveys were intended to support ongoing assessment, adjustments to treatment planning, and monitoring of treatment goals.

The EPI-CAL core assessment battery, including how it was created and all included measures, is described in a separate paper [4]. Briefly, Beehive survey content includes both the Early Psychosis Intervention Network core assessment battery [36] and additional measures based on EPI community partner feedback determined in earlier qualitative work for the EPI-CAL study [4,31]. A table of measures is included in the Multimedia Appendix 1 [4]. One survey of particular interest is the Modified Colorado Symptom Index (MCSI) [37], a measure central to the aims of the broader EPI-CAL study and which we asked sites to prioritize [4]. The MCSI is a 14-item, self-report scale

which measures the frequency of psychiatric symptoms, including symptoms of mood, psychosis, cognition, forgetfulness, and risk to self and others. Respondents indicate frequency of symptoms over the past 30 days on a 0 to 4 scale of "not at all" to "at least every day." Total scores range between 0 and 56, with higher scores indicating higher frequency and number of psychiatric symptoms.

Data Analysis

In UCD workshops, we asked highly structured questions to solicit feedback on the storyboard and alpha version of Beehive. Subsequently, we organized our data categories relevant to the workflows and features we were evaluating. We then organized comments by whether they were supportive of the existing features or critical and asked for change so that we could focus on what features to move forward and what features to change as we created the alpha and beta versions of Beehive.

To investigate the initial feasibility of Beehive in EPI-CAL clinics, we reviewed descriptive statistics of pilot participants, including registration, enrollment, participant characteristics, and survey completion. Engagement with surveys and survey completion were examined in three ways as follows: (1) determine the proportion of service users for whom any data were entered, regardless of respondent type, (2) determine the rate of survey completion across all available surveys, and (3) evaluate whether participants completed all, partial, or no surveys across survey time points during piloting phase. Partial survey completion indicates that the respondent completed at least 1 survey, but did not complete all of their surveys in the specified time point. We also evaluated completion of MCSI because it is a measure that we asked programs to prioritize.

Ethical Considerations

The institutional review board of the University of California, Davis, approved the study (1403828-21, California Collaborative Network to Promote Data-Driven Care and Improve Outcomes in Early Psychosis). In addition, several of the counties and universities with a program participating in EPI-CAL required a separate review and approval of the project by their institutional review board. All study participants provided written informed consent and assent (as appropriate). Participants received US $30 compensation for each workshop they participated in. Participants in the piloting phase were not compensated because integration of Beehive was part of routine care in the EPI program. Audio recordings UCD workshops include voice print identifiers and are stored in compliance with University of California, Davis HIPAA (Health Insurance Portability and Accountability Act) policies and procedures. Data collected during piloting for research includes limited identifiers including zip code, dates of service, and month and year of birth. Only trained research staff with a need-to-access have access to identifiable data.

Results

UCD Workshops

We conducted 14 storyboard workshops with 77 total participants between April 3, 2020, and August 28, 2020. In total, 4 workshops were with service users (n=8, 10%) and their support persons (n=9, 12%). In addition, 10 workshops were with EPI program providers (n=60, 78%), including 6 for service providers, 3 for administrators, and 1 for both service providers and administrators. Demographics for workshop participants are provided in Table 1.

We completed an interim analysis of storyboard workshop data in May 2020. We completed the final analysis of workshop data in August 2020, after all groups were completed. After each analysis, we discussed and synthesized the feedback for the developers to support app development. We attempted to balance the needs of all types of participants. However, if there were needs or feedback in direct contrast with one another, we prioritized service-user feedback due to our value of centering service-user feedback in this app. This feedback and the action taken to address it are summarized in Table 2.

We conducted 1 alpha workshop in October 2020 with 4 EPI program provider participants. Feedback from this workshop was analyzed in October 2020. During this workshop, participants identified a few bugs in the app, but their feedback primarily focused on ideas for integrating Beehive into clinical workflows. For example, they suggested that Beehive training should include best practices for how providers can review the data, engage with the data, and make the most out of Beehive. They also shared concerns about using technology in telehealth settings. For example, switching to telehealth in response to the COVID-19 pandemic had been very difficult for some families, and they predicted those same families would find using Beehive challenging if the clinic could not meet with them in-person to teach them how to use it. They were less concerned about service users and support people using Beehive on a tablet in the clinic where they could provide in-person support. Finally, participants brought up the importance of shifting the culture of clinics to view data collection as an important part of treatment, not just an extra task where information is being extracted from service users. For example, surveys should be directly related to service-user recovery goals. Participants discussed how visualizations could be used to demonstrate the clinical utility of gathering these data. For example, 1 clinician said they would want to use the graphs to point out the way a service user is improving or doing better and that they would want to highlight their strengths. Another participant cautioned that some service users may not want to look at data visualizations and that this should be an optional part of their care. Figures 5 and 6 illustrate design changes present in the beta version of app after the conclusion of all workshops.

Table 1. Demographics of user-centered design workshops[a].

	Service users (n=8)	Support persons (n=9)	EPI[b] program providers (n=60)

Table 2. Implementation of feedback from user-centered design workshops.

Problem or need identified in workshop	Solution implemented in alpha version
The color scheme and layout seemed "overly clinical"	Brought in more color into the palette and added icons for visual information
Some important aspects of the user-interface were too subtle, such as the survey progress bar or the urgent clinical issues widget	Changed color and design to make it more prominent
Service-user and support person registration were only available as self-registration and could not be completed by EPI program providers	Added this workflow to the web app so that EPI program providers may complete it in advance of service users engaging with surveys
Clinic-level data for service-user demographics was not visualized	Added clinic-level visualizations for race, ethnicity, sex, gender identity, and other demographic metrics
Not all service users or support persons wanted to see score thresholds or comparative data on clinical measures, but some did	Added a toggle to individual-level visualizations so that users can turn on the threshold information or comparative data if they want to see it, or turn it off if they do not want to see it
Service users might have differed on which individual-level survey visualization they wanted to see by default on their data view page	Added feature that allows users to set which measure displays by default for each service user
Some language used in the app needed to be clarified for users to understand what data was being collected or how certain features worked	Changed "homeless" to "without a permanent address" when assessing housing status; changed "help" to "Ask for help" to make it clearer that selecting button will alert the EPI program provider; changed "Diagnosis" to "Primary diagnosis"
Different programs used different words to refer to service users, and individuals might have varied on their preference for what word to use regardless of what their program tended to use	Wherever possible, implemented dynamic text so the service user's preferred name shows throughout the app, rather than any specific word to denote "service user"
Program staff wanted to see overall progress on completion of all surveys at any given time point	Added in visual indicator to show survey completion across multiple surveys (not just while completing one individual survey)
When visualizing a survey, they wanted to have more than just the global score visualized. Also, they wanted a visualization that showed responses to individual items	Added in a visualization that shows individual items as well as the global score
Service users and support persons might not have preferred the official names for measures and might have preferred a more simplified title	Added the ability to enter a display name for surveys (eg, "Family Impact" instead of "Burden Assessment Scale")
Early psychosis intervention program providers needed a way to see both the official measure name as well as the display name	Added a hover modal on survey titles to show the display name for the survey
The provision of clinic services might have been fully remote for the foreseeable future, and the current design of Beehive only allowed service users and support persons to complete surveys on a tablet in-person at the clinic	Design a web link solution which allows service users and support persons to answer surveys remotely. A link to complete their surveys can be emailed or texted to them

Piloting

We conducted piloting of Beehive beta app between March 2021 and September 2021. Our training and ongoing support of pilot sites allowed us to gather informal feedback about both the training and the Beehive app. We used this feedback to make adjustments in real time, when possible, or to plan for future changes to Beehive.

We made real-time changes to the training approach in response to program needs based on our observations and their feedback. At the time of training pilot sites in early 2021, these EPI programs were navigating constant uncertainty related to the COVID-19 pandemic, including influx of service users, uncertainty about work location, reduced workforce, etc. In response to this environment, we found it necessary to ask sites to focus on small implementation steps even though we trained them on all available workflows. For example, we asked pilot sites to initially focus on engaging service users and their support persons to complete enrollment and complete surveys. When that was mastered, we asked them to focus on engaging new service users and support persons with Beehive during their clinical intake process. Finally, toward the end of the piloting period, we encouraged them to focus on entering EPI program provider-entered data. Even if pilot sites registered existing service users, they were asked to set the service user's survey baseline date to align with their start in the EPI program. Therefore, some service users may have never been assigned surveys during their baseline survey window.

During the piloting phase, 93 service users, 78 support persons, and 86 service providers were registered across 4 clinics. Of the 93 service users who were registered into Beehive by their program, 59 (63%) completed the Beehive EULA during piloting, including 48 (51%) individuals who gave permission to use their data for research. Of the 78 support persons registered to a service user in Beehive, 52 (66%) completed the Beehive EULA, including 42 (54%) individuals who gave permission to use their data for research. Of these 42 support persons, 5 were excluded from analysis because the service user they were registered with did not give permission to use data in research, and we prioritize the data-sharing decision of the service user regarding use of collateral data for research purposes.

While most users entered at least one survey window during the piloting phase, 3 were discharged from their program before longitudinal surveys were available. Of the 86 service providers registered, 78 (91%) completed the Beehive EULA, including 72 (84%) individuals who gave permission to use their data for research. This information is presented in Figure 7.

Participant demographics and EPI program provider professional background are provided for individuals who agreed to share their data for research purposes in Tables 3 and 4. Of note, age is missing for some EPI program providers and support persons. This data was collected during registration, and this field was not included in the first release of the beta version of the app. Therefore, some users were not able to complete this field during registration and did not return later to update it, yielding missing data for 15 (36%) support persons and 37 (51%) EPI program providers.

First, to examine engagement during piloting, we assessed the number of service users that had entered any data that could be used in care. During piloting, respondents entered survey data for 85% (n=41) of service users. This includes self-reported data for 75% (n=36), collateral-reported data for 42% (n=20), and EPI program provider–entered data for 17% (n=8).

Second, we evaluated survey completion across the total amount of available surveys. A total of 1517 surveys were assigned across all respondent types during piloting and 35.4% (n=537) of those surveys were completed across all time points. We also evaluated survey completion by respondent type. Across all time points, service users completed 396 (49.4%) of 802 assigned surveys. Support persons completed 113 (47.5%) of 238 assigned surveys. EPI program providers completed 28 (5.9%) of 477 assigned surveys.

Finally, we evaluated how many respondents completed all, partial, or no surveys at each time point. Because participants could be enrolled at any point in treatment, the first time point for a service user may not have been their "baseline" appointment. These data are presented in Table 5.

The MCSI was completed by 54% (26) of service users, and 7 were excluded for responses of "prefer not to say" (Total Score: mean 19.58, SD 16.81). Additionally, 35 service users had a support person who could complete the Modified Colorado Symptom Index, and 56% (n=19) of support persons completed it. From these 19, 5 were excluded for responses of "prefer not to say" (mean 26.71, SD 14.43).

Through piloting, we also gathered informal feedback about workflows that could be improved in Beehive and that we would address with future change orders to the app after the testing of the beta version of Beehive. For example, we received feedback that the survey windows, initially chosen to mirror the data collection windows of clinical trials, were far too narrow and restrictive for data collection in community mental health programs. Program staff users also indicated that they wanted a better way of seeing a summary of what surveys service users and support persons completed. Service user and support person feedback was relayed to our team via program staff. For example, service users and support persons wanted to customize the day and time they received the web link via SMS text messaging and email.

Discussion

Principal Findings

This study describes the EPI-CAL program's design and acceptability testing approach for a custom web-based and tablet app, Beehive, to support systematic data collection, care delivery, program evaluation, and research across a statewide network of EPI programs. Our goal was to develop an app that was clinically useful for, usable by, and acceptable to diverse EPI programs across the state of California.

To ensure the app best matched the needs of the EPI participants, we adopted a UCD approach to develop Beehive. Previous research in the mental health digital space supports that active involvement from the app's intended users during the development phase can improve the appropriateness of the end product for the users of interest [38]. Initial feedback across the 3 development phases was primarily collected in workshops (storyboard and alpha version) and during pilot implementation (beta version). In storyboard and alpha workshops, we presented prototypes to demonstrate major features of the app and asked for feedback on the app's "look and feel," compatibility with existing clinical workflow, and ease of use and acceptability for service users, their support persons, and EPI program providers. Consistent with other studies who have included end users during the design phase of their eHealth apps [38-41],

feedback from these workshops resulted in immediate changes to the alpha and beta apps that would not have otherwise been made.

During piloting, we continued to collect user feedback around Beehive features, as well as assess acceptability of the app by examining preliminary enrollment and survey completion. Our enrollment and survey completion rates are consistent with the acceptability of other mental health apps developed using a UCD approach [42,43], although there is wide variability depending on the implementation approach.

During the design and testing phase, we observed that different types of community partners expressed different, and at times conflicting, needs. For example, we asked participants about their preferences for seeing score thresholds or comparative data as part of the visualization for their clinical measures. Some service users said that, in times of relapse or increasing intensity of symptoms, additional information on the visualization would be demoralizing. In contrast, many participants could imagine scenarios where that information would be useful as a form of psychoeducation to normalize service-user experiences or understand the relative severity of symptoms. To address these diverse needs and promote engagement with Beehive we added a toggle to individual-level visualizations so that users can turn the threshold information or comparative data on or off. A flexible design approach that is tailored to an individual's needs has been shown to be more efficacious in a mobile health app setting [43,44]. Therefore, design changes incorporated flexibility where possible to enable our team to meet the various needs of individuals while maintaining consistent implementation to meet evaluation and research goals.

Similarly, user feedback informed our training approach. For example, some EPI program provider users expressed that they would use the graphs in the app in clinical care with service users to highlight strengths and progress. In contrast, another EPI program provider participant cautioned that some service users may not want to look at data visualizations and that this should be an optional part of their care. Thus, our training approach highlights how visualizations may be used in direct care but are not prescriptive. Feedback from workshop participants also highlighted the importance of shifting clinic culture to view data collection as a key part of care provision. Our team considers EPI program providers to be integral in promoting engagement for service users and their support persons as it is the EPI program providers who communicate why Beehive is being used in care. To begin addressing potential barriers of buy-in and engagement for all users, we designed our trainings to include the context of why Beehive and MBC were being implemented in their programs, including a presentation on the potential value of Beehive (designed and delivered by author LS) [45].

During piloting, we observed barriers to integration. For example, despite our designing the first training such that the programs could start registering service users immediately afterward, the programs failed to do so. When asked, programs informed us that they were nervous to receive questions about Beehive that they did not know how to answer. This resulted in our team creating materials to provide more structure for programs as they introduced Beehive to service users, such as an introduction script, Beehive infographics, and other handouts. Once programs started enrolling existing service users, many found it difficult to transition enrolling new service users, given that they already had numerous documentation requirements during their clinical intake process. In response, we added a "workflow meeting" to our training series where we asked program leadership and key staff involved in intakes to walk us through their existing procedures so that we could help brainstorm where the required Beehive workflow steps could be implemented and who from their program would be responsible for each step. We additionally observed that clinician-entered data were hard for sites to prioritize. For example, there was a lack of clarity within teams about who was responsible for entering these data and what training was required. Therefore, we chose to add another "workflow meeting" between key program staff and our team to help programs identify who was responsible for which surveys, who needed training, and how programs could monitor survey completion. We added these workflow meetings to our formal training protocol and made the support materials available to all sites who joined after the piloting phase.

Furthermore, our team worked with programs beyond the piloting phase to ensure that we continued to incorporate individual feedback and offer continuous support, which is key to successful adoption and can improve engagement [46]. After the piloting of the beta version of Beehive concluded, we continued to make development changes to meet users' needs, such as further design changes to the admin dashboard, widening survey completion windows, adjusting and eventually allowing customization of the frequency and timing of web link notifications, allowing the EULA to be completed before survey baseline date, simplifying registration fields, adding a survey status page, adding additional survey visualizations, adding a workflow for providers to enter data collected outside of Beehive, and prioritizing the order of additional languages in the app based on active need in the participating clinics. This iterative approach in response to user feedback is consistent with the development process of other eHealth apps [47].

This study highlights how critical it is for programs using a continuous improvement approach, such as UCD, to budget appropriately for ongoing development needs and staff time for ongoing support. As long as an app is in use and collecting data from real users, there should be a plan for ongoing project management and app development to address feedback from users, improve engagement and useability, and respond to changing needs. Implementing UCD from the outset allowed our team to be aware of and address user concerns before investing valuable time and resources in initial development and implementation. Focusing on workflow during the storyboard and alpha phases of app and continuing this collaborative relationship throughout the implementation phase resulted in an app that represents the interests and needs of users.

During the piloting, we observed that survey completion rates varied among different types of users. This variance may be partially explained by our training approach during piloting (see the Results section). As we continue to collect data after the piloting phase, we can evaluate if this trend continues beyond

the initial onboarding period throughout multiple years of data collection. These varied results may also reflect the challenges of implementing MBC, with or without an eHealth app, such as the training burden and limited time to conduct new duties associated with eHealth implementation [24-26,31]. When implementing outcomes data collection in these settings, it may be critical to gather only the minimum required data from EPI program providers (eg, diagnosis) and rely on service-user self-report measures whenever possible. Future analyses will examine the relationship between characteristics of EPI program providers (eg, degree and years licensed) and completion rates of clinician-entered data. Future work, including barriers and facilitators interviews with users after they gain more experience using Beehive, will be used to prioritize the needs and perspectives of our users in the ongoing development of Beehive and to better understand the reasons why users do or do not engage with the app [48].

Limitations

The COVID-19 pandemic introduced multiple challenges for our study, which may have reduced the breadth and diversity of participation in various phases of the project. We offered workshops over remote teleconferencing instead of in-person, which may have excluded individuals who are less comfortable with using technology. This may have disproportionately impacted on the recruitment of service users and support persons for participation in workgroups, as our participant numbers were lower than previous studies where we were conducting in-person research [31]. To reduce bias that may have resulted from this imbalance, we chose to prioritize the feedback of service users and support persons if there was conflicting feedback between these participants and EPI program provider participants. In addition, the beta and full versions of Beehive have been introduced to all service users in participating programs, regardless of their comfort with technology, and this has allowed us to incorporate informal feedback from these individuals as we have continued to make improvements to Beehive.

Much of our data in UCD workshops were gathered at the start of the COVID-19 pandemic, before anyone had experienced the long-term shift in daily practices brought on by the increased use of telehealth and remote working. We sought feedback on an app that was intended for in-person use and received feedback based on participants' experience of using in-person services. This highlights the importance of planning multiple opportunities for soliciting and incorporating feedback from sites so that apps can be responsive to changing environments.

Our workshops and piloting were only conducted in English. To serve the diverse population of California, Beehive needs to be both translated and adapted, a process known as localization [49], into at least 15 languages. Since Beehive's launch, we have localized into 7 additional languages. We continue to solicit feedback from users, including those whose primary language is not English, to inform the ongoing development of Beehive, and we will continue localize this app into additional languages.

While we used our prior knowledge of mental health development in the development of Beehive [11,12], we did not use a structured analysis approach for the feedback obtained during workshops due to time constraints imposed by project deliverables. To reduce the impact of subjective biases, the researchers who conducted each group debriefed afterward to review the notes, and recordings were referenced if notes were unclear or vague. In addition, all decisions about how to incorporate feedback from these notes into app development were made collaboratively by authors KEB, LMT, TAN, and VLT. Future work in this area will benefit from organized approaches to data collection and formal qualitative analysis [50,51].

Conclusions

Working with community partners to co-design an eHealth app for use in community EPI programs helped us to anticipate and resolve barriers earlier in the app development and implementation pipeline. On the basis of our observation and the data, there appeared to be high levels of engagement with Beehive. This resulted in feedback and continued design improvements which allowed our team to be better poised to launch Beehive across the EPI-CAL LHCN. Variance in survey completion rates among respondent types suggests that support persons and EPI program providers especially may need additional support.

Acknowledgments

The authors would like to thank all service users, support persons, and EPI program providers who participated in this study, Binda Mangat of Quorum Technologies, and its team of professionals for supporting the development of Beehive, and the Early Psychosis Intervention Network of California learning health care network.

This research made was supported by One Mind, the National Institute of Mental Health under award R01MH120555-01, and the following California counties: Los Angeles, Napa, Orange, San Diego, Solano, Stanislaus, Lake, Nevada, Mono, Colusa, and Sonoma. The content is solely the responsibility of the authors and does not necessarily represent the official views of any sponsors of the research.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

KEB conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, recruited participants, collected data, trained pilot sites, audited and cleaned data, analyzed data, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. VLT conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, trained pilot sites, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. KMP audited and cleaned data, drafted the manuscript, and reviewed and revised the manuscript for important intellectual content. LMT conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. SE conceptualized and designed the study, created the focus group guides, collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. MS, ABW, and AJP conceptualized and designed the study and reviewed the manuscript for important intellectual content. LS collected data, trained pilot sites, and reviewed and revised the manuscript for important intellectual content. CKH trained pilot sites, audited and cleaned data, and reviewed and revised the manuscript for important intellectual content. VEP, APM, and MK-W trained pilot sites and reviewed and revised the manuscript for important intellectual content. CM, MJM, NS, KLHN, and YZ cleaned data and reviewed and revised the manuscript for important intellectual content. TAN obtained funding, conceptualized and designed the study, created the focus group guides, conceptualized and designed storyboards, collected data, reviewed and revised the manuscript for important intellectual content.

Conflicts of Interest

KEB consulted with ChatOwl Inc after data collection and before submission. LMT was employed by ChatOwl Inc, a digital mental health company after data collection and before submission. LMT was a founder and owner of shares in Safari Health, Inc. during project implementation, data collection, and write up (no longer true at time of writing) and is an employee and shareholder at Kooth LLC at time of publication. TAN is a cofounder and shareholder in Safari Health, Inc.

Abstract

Background: The growth of aging populations globally has increased the demand for new models of care. At-home, computerized health care monitoring is a growing paradigm, which explores the possibility of reducing workloads, lowering the demand for resource-intensive secondary care, and providing more precise and personalized care. Despite the potential societal benefit of autonomous monitoring systems when implemented properly, uptake in health care institutions is slow, and a great volume of research across disciplines encounters similar common barriers to real-world implementation.

Objective: The goal of this systematic review was to construct an evaluation framework that can assess research in terms of how well it addresses already identified barriers to application and then use that framework to analyze the literature across disciplines and identify trends between multidisciplinarity and the likelihood of research being developed robustly.

Methods: This paper introduces a scoring framework for evaluating how well individual pieces of research address key development considerations using 10 identified common barriers to uptake found during meta-review from different disciplines across the domain of health care monitoring. A scoping review is then conducted using this framework to identify the impact that multidisciplinarity involvement has on the effective development of new monitoring technologies. Specifically, we use this framework to measure the relationship between the use of multidisciplinarity in research and the likelihood that a piece of research will be developed in a way that gives it genuine practical application.

Results: We show that viewpoints of multidisciplinarity; namely across computer science and medicine alongside public and patient involvement (PPI) have a significant positive impact in addressing commonly encountered barriers to application research and development according to the evaluation criteria. Using our evaluation metric, multidisciplinary teams score on average 54.3% compared with 35% for teams made up of medical experts and social scientists, and 2.68 for technical-based teams, encompassing computer science and engineering. Also identified is the significant effect that involving either caregivers or end users in the research in a co-design or PPI-based capacity has on the evaluation score (29.3% without any input and between 48.3% and 36.7% for end user or caregiver input respectively, on average).

Conclusions: This review recommends that, to limit the volume of novel research arbitrarily re-encountering the same issues in the limitations of their work and hence improve the efficiency and effectiveness of research, multidisciplinarity should be promoted as a priority to accelerate the rate of advancement in this field and encourage the development of more technology in this domain that can be of tangible societal benefit.

(JMIR Hum Factors 2025;12:e59458) doi:10.2196/59458

Introduction

Background

With the general increase in global life expectancy and the ever-increasing ratio of retirement-age to working-age people, research in the scope of health and social care for older people is greatly increasing. As people live longer and the aging population grows, governments and international organizations are recognizing the need for a paradigm shift in the way we care for our older populations [1]. Current methods of care typically include a social care system to look after the most vulnerable and frail older adults, but as the size of this population increases at a faster rate than the working population, these institutional

models of care at the country level become progressively less practical and more costly. In response to this growing crisis, one solution researchers have sought to apply is the use of novel health monitoring technologies to tackle the problem of labor shortages in health care systems and to improve productivity and efficiency in care [2-11]. This can be in direct terms, for example monitoring systems that assist care professionals carrying out their duties within care settings [12] and also indirectly with at-home monitoring devices designed to reduce the occurrence of injuries by, for example, assessing gait [13,14] and predicting fall events [3,15], with the goal of reducing the potential burden on secondary care and ultimately reducing the burden on the care-home sector and keeping people at home, healthy, and independent for longer [9,16,17].

Research Hypothesis and Goals

The goals of this work can be summarized by the following 2 research questions:

1. Can we construct an evaluation framework for at-home health monitoring research and justify that a positive score in said framework broadly correlates with a higher likelihood of the research being effective in real-world use?
2. Can we identify the trends if they exist, between the method of research (single-discipline, multidiscipline, and the use of PPI or co-design) and the increase or decrease in effectiveness of said research?

In the context of this paper, “effective research” can be defined as research that is more efficient by being less prone to making oversights already identified in the existing literature across disciplines. We assert that research that addresses the already existing issues in the literature (and thereby scoring highly on our proposed metric) leads to more effective research and ultimately leads to products and platforms more likely to be usable in real-life applications (refer to the Evaluation Framework Justification in the Methods section for evidence of this).

To answer the research questions, this work is split into 2 phases, a scoping phase and evaluation phase. In the scoping phase, an overview is provided of the various systematic reviews across disciplines in the field of at-home health care monitoring for older adults. In doing this, we synthesize an evaluation framework based on the consensus and concatenation of these studies to measure the degree to which individual pieces of research encounter similar common problems. By defining this framework, observations can be made about the degree to which these problems are acknowledged by different types of research teams operating with or without multidisciplinarity, which types of issues are likely to be identified by which types of research, and how stakeholder involvement can improve the likelihood of developing an effective product. To justify this evaluation criteria and to address the first research question, examples of existing technologies in commercial use are positively evaluated by this approach to assert the positive relationship between a high evaluation score and the generation of more effective research, considerate to existing identified issues with real-world use (refer to the Methods section). To our knowledge, there is currently no evaluation methodology designed to measure research application effectiveness, based on multidisciplinary metrics.

In the evaluation phase. a review of individual works in the application of computerized at-home health-monitoring systems is then presented, with these works evaluated against the metric developed in the scoping phase, and with the results analyzed to address the second research question (refer to the Results section). For this evaluation phase, a total of 350 papers were found from the IEEE Explore, PubMed, and ArXiv databases, of which 60 papers were ultimately used, with the inclusion constraints being that the papers had to be individual pieces of original research relating either to the development of technology associated with the various applications of at-home older adult health monitoring or a review into the effectiveness of existing at-home health monitoring applications. This is including, but not limited to, development and deployment of disease diagnosis and progression analysis, fall detection and prevention, lifestyle monitoring, vital-sign monitoring, and smart-home systems. Candidate papers must present methods that have the prospect of or are already actively being tested in an at-home environment in whole or in part.

For this evaluation phase, a total of 350 papers were found from the IEEE Explore, PubMed, and ArXiv databases, of which 60 papers were ultimately used, with the inclusion constraints being that the papers had to be individual pieces of original research relating either to the development of technology associated with the various applications of at-home older adult health monitoring or a review into the effectiveness of existing at-home health monitoring applications. This is including but not limited to the development and deployment of disease diagnosis and progression analysis, fall detection and prevention, lifestyle monitoring, vital-sign monitoring, and smart-home systems. Candidate papers must present methods that have the prospect of or are already actively being tested in an at-home environment in whole or in part.

The Methods section contains the scoping phase and provides an overview of the literature in health monitoring technologies, constructing from them a concise evaluation framework in the form of a 10-point checklist criteria for research application effectiveness, based on consensus drawn from these works. The Results section presents the evaluation phase, reviewing individual pieces of research across disciplines using this evaluation framework. The interaction between multidisciplinarity and stakeholder involvement through PPI and co-design and the effectiveness of research are also analyzed here. Finally, the Discussion section summarizes the findings of this research and makes recommendations for how future health monitoring research should be conducted in order to improve the effectiveness of research in this field.

Research Contributions

The contributions of this paper can be summarized as follows:
:

1. A review of the recent literature of at-home health care monitoring. This is achieved by providing a 2-stage review of the literature, with the first (scoping phase) being a meta-review of reviews in the relevant literature, and the

second (evaluation phase) being a review of individual works across multiple disciplines in the area of at-home health monitoring.

2. The introduction of a comprehensive evaluation framework for assessing the likely real-world effectiveness of health monitoring application research, based on 10 key issues consistently identified from analysis of 15 literature reviews in the field across disciplines.
3. The identification and demonstration of various links between the manner of research and the effectiveness of research. We find that multidisciplinarity has a consistently positive effect in this respect, reflected by higher scores on the evaluation framework. We also find a convincing increase in scores when PPI and co-design methods are used.

The goal of this research is to concretely illustrate the necessity of multidisciplinarity for the success of at-home medical technology development and deployment and provide a framework for future research to reference when assessing the usefulness of their own applications.

Methods

Scoping Phase: Overview of at-Home Health-Monitoring in Older Adults

To identify the most common barriers to uptake in this field, an overview of 12 systematic and other review papers from 2014 onwards was conducted to identify and collate the common issues within some of the common subdisciplines of at-home health care monitoring: encompassing any autonomous monitoring methods used in a domestic context such as camera-based applications, wearable sensors, remote sensors, and ensemble smart-home systems. Table 1 provides a concise summary of the main reviews investigated, and the presence of each of the commonly identified barriers among them. Broken down in Table 1 are the makeup of the teams involved in the research, multidisciplinary, technical, or application-based. In the context of this work, “Technical” concerns research conducted by engineering or computer science teams, with “Application” making up all other types of research team, but predominantly teams in the fields of medicine and social science. In total, 10 core barriers are identified across these reviews and synthesized to be inclusive of all the barriers identified in all the systematic reviews evaluated in this section. An exact breakdown of the presence or absence of the 10 points in each review is available in the supplementary materials (refer Table S1 in Multimedia Appendix 1).

Factors Determining the Success and Failure of eHealth Interventions [16]	Overview of smart home. Applications with a focus on discovering the key factors behind the success or failure of med-tech applications.	Multidisciplinary	70

[a]ML: machine learning.

[b]AI: artificial intelligence.

"Research Team" denotes whether the teams conducting the research were technical or medical-based. See further in this section for a breakdown of the 10 common identified points and refer to the supplementary material for a specific breakdown of which barriers are present in each. The score value was computed by aggregating which of the 10 features were addressed in each review. Beyond these key reviews from which the evaluation framework was constructed, there are numerous other reviews and surveys whose findings are inclusive of the framework outlined at the end of this section (refer to Table S2 in Multimedia Appendix 1 for a full breakdown of the 13 reviews). Only the core 12 are included here for brevity, with these 12 being selected as they encompass all of the core at-home health care methodologies, include examples of all 10

key points that make up the framework, and represent a roughly equal variety of research teams, namely multidisciplinary teams (n=3), computer science (n=3) engineering (n=2), medical (n=2), and social science (n=2).

Table . Scoring of 2 current at-home monitoring projects being developed with the intention of widespread use. The factors are numbered corresponding to the attribute list given in the attribute list above. Y or N indicates "yes" or "no" as to the presence of the factors.

Project Name	Description	Factors (Y or N)									
		1	2	3	4	5	6	7	8	9	10
SPHERE[a] [19-21]	Smart-home system for behavior monitoring, under development for several years and the feature of multiple research studies.	Y[b]	Y	Y	Y	Y	Y	Y	Y	N[c]	Y
HALLEY[d] [22]	Internet of things-based Smart-home development project currently in commercial development.	Y	Y	Y	N	Y	Y	Y	N	N	Y

[a] SPHERE is a multi-year smart-home development project based in England which has been involved both in commercial smart-home production as well as research.

[b] Y: yes.

[c] N: no.

[d] HALLEYASSIST is a company based in Australia involved in developing multiple healthcare monitoring devices for a smart home context.

The study by Ghorayeb et al [23] presents a number of insights in their review of the literature regarding older adults using smart-homes, such as identifying solutions to the problems in most research applications. For example, they assert that gradual introduction of smart-home technology combined with the ability to “pause” it at will to provide “emotional release” is highly desired in end users for a more pleasant experience. They also find that more tech-literate people tend to have less concerns with the technology due to an improved understanding of the data being collected and the privacy risks involved, if any. One other concern identified was transmission of data and the insecurities associated with this, leaning to a user-preference that data should be handled manually instead of through remote connection. These findings are all further reinforced by the findings in [24], which similarly conduct interview sessions with 20 older adults regarding which aspects of health-monitoring systems concern them. These findings inform points 4 and 5 in the evaluation metric, defined in Methods section.

Regarding data access, the study by Robinson et al [25] finds that older adults could in some cases want control of data access to withhold the data from certain parties, namely their family and friends, for fear of burdening them as well as the parallel desire some express that they do not want to be micromanaged by their loved ones or health care providers, informing points 6 and 8 of the framework. Cost was also an identified challenge (informing point 3), for example focus group attendees in [2] were concerned by the cost of long-term use of monitoring devices, with the implication being that they would have to buy them outright.

The study by Hawley-Hague et al [3] discovers that when surveyed, there is a broad perception that older people view new advancements in smart-home related technology as good but “unnecessary for them,” as they don’t perceive themselves as being “unhealthy enough” to merit using what they see as a drastic action toward greater care. Mann et al [26] found in their study of 661 older people that a slim majority (56.3%) perceived smart-home technology as not being of use to them specifically.

Ghorayeb et al [23] identify a series of factors through their investigation with older participants which are crucial to account for when considering the integration of new technology into real life. These factors range from societal stigma to technical reliability, covering points 1, 2, 3, and 6 in the evaluation framework. Research in studies by Boström et al and by Boström et al [2] and Liu et al [6] also point to the issues surrounding the implication of autonomous monitoring being a decline in human contact, addressed by point 7. In the systematic review conducted by Ghorayeb et al [23], observations were made regarding the progression of smart-home technologies. Regarding patient acceptability, they note that less than half of the papers reviewed take into consideration the acceptability of their technology where privacy is concerned: with the focus of the paper instead being explicitly about the functions of the novel technology. Some steps taken toward improving privacy in certain papers included encrypting collected data [27] and locking data access behind authorization [28].

Regarding health care professionals, their main concerns with smart-home technology and health care monitoring concern the feasibility of use. Unlike patient acceptability, acceptability by health care professionals is underresearched, where many papers will either focus on the technology being developed and not address it in application or they will focus only on the opinions of the end users and how they will use and accept the technology [29]. This finding is echoed in the lack of surveys found in the scoping review in the Results section, where the focus is on health care professionals rather than patients. Of the 60 papers in the scoping review, only 7 made any explicit use of external medical caregivers in their research development.

Evaluation Framework Criteria

Across the review papers both in Table 1 and the other reviews referenced in this section, the following list of 10 factors were collated to encompass all the common considerations identified when designing and implementing novel monitoring technology for use with older adults in a domestic environment. They are segmented by category of concern (technical, application, or multidisciplinary), where the technical are purely engineering or computer-science implementation concerns and application are concerns involving human interaction with the technology and any adjacent concerns important to medical and social science-based disciplines. The framework is as follows (Textbox 1).

Textbox 1. The evaluation framework

- Usability-technical: concerning the use of the technology and how feasible it is to be used by caregivers, health care professionals, and end users.
- Accessibility-technical: this concerns the ease of use by laypeople of the computer technology and the barriers for entry in terms of effectively using the technology.
- Reliability-technical: covers issues relating to the long-term viability of the application, for example, is it expensive, does it require upkeep, charging or maintenance.
- Control-multidisciplinary: concerns the level of access both patients and health care staff should have to the application and the data it records.
- Privacy-multidisciplinary: constitutes issues relating to the intrusiveness of the data being collected, and the manner in which it is collected.
- Stigma-application: anything relating to the societal pressures and negative connotations people may feel by using monitoring technologies for the purposes of personal health.
- Lack of human response-application: concerns the issue of the perception that increased autonomous monitoring would result in a decrease in person-to-person interaction as a result.
- Burden to others-application: regarding the perception of older adults that additional at-home monitoring is representative of applying additional pressure on their caregivers.
- Lack of perceived need-application: concerns a commonly identified phenomenon in the literature that people have a tendency to think a technology is useful but unnecessary for them personally.
- Affordability-application: this concerns the cost both on a personal and institutional level to implement solution applications in real life.

Evaluation Framework Justification

To demonstrate the descriptive power this evaluation system has to the likelihood of success in application, Table 2 provides an overview of papers concerning 2 technologies being developed for commercial use (Sphere [21] and HalleyAssist [22]), and the degree to which the prior research and development of these systems adhere to the criteria in the evaluation metric, with scores being calculated based on all existing literature regarding each technology, as opposed to individual articles. Both have demonstrated a commitment to addressing barriers relating to both technical and human elements, addressing 90% and 70% of the evaluation metrics respectively (the average score across the scoping review in the Results section is 36.2% for comparison). They also both were developed by a multidisciplinary research team from computer science and signal processing to nursing, geriatric medicine and social care, with both systems now being in varying stages of commercialization. The relationship between the absence of certain metrics such as multidisciplinarity and the lack of consideration for common barriers to uptake is further concretely illustrated during the analysis at the beginning of the Results section. While these are only 2 data points and cannot be said to constitute a trend on their own, it can be asserted that they provide a strong positive indication that successful applications are likely to score highly on the introduced metric.

Results

Evaluation Phase: Scoping Review and Parameters

Figure 1 illustrates the selection process for papers considered for the scoping review. From the 3 databases, the following search term was used:

((healthcare monitoring) AND (older adult)) AND ((home) OR (at-home) OR (domestic)) AND ((obtrusive) OR (unobtrusive) OR (intrusive)) AND ((machine learning) OR (AI) OR (artificial intelligence))

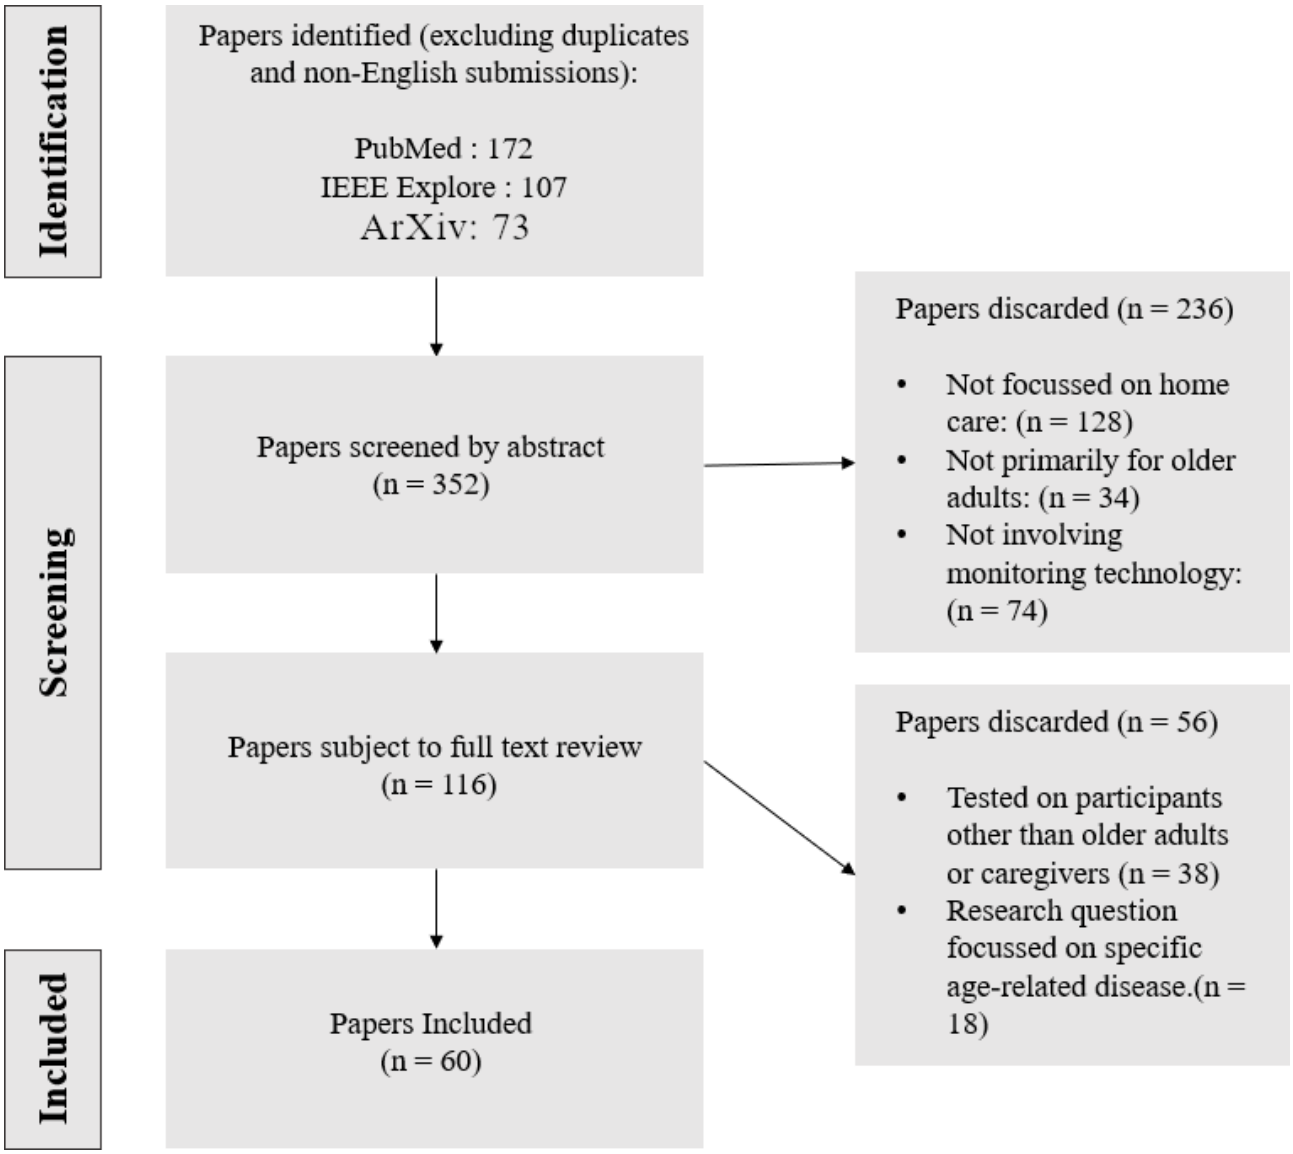
with the exception of the ArXiv database, where the

((obtrusive) OR (unobtrusive) OR (intrusive))

section was omitted for a larger range of initial texts. Language was restricted to English and the date was restricted to 2014 or later, with the search commencing on January 7-24, 2024. Excluded were papers that did not in whole or in part reference older adult monitoring as the purpose of their application or review, and papers where the application was specifically designed for care homes or hospitals. The initial search yielded a total of 352 papers. Paper title and abstract analysis excluded 236 papers, which resulted in 116 remaining, with the final count being 60 papers after a full-paper review resulting in 56 more deletions (Figure 1).

The following section is broken down by technical and application-based research, following the definitions for both established in the beginning of the Methods section. Papers defined as multidisciplinary are those in which the research team consist of at least 1 person from each category.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram: screening process illustration for the scoping review portion of this research.



Technical Research

The majority of research in this space relies either on traditional or neural network–based machine learning methods to make their systems effective and largely automatic. Researchers in [30] construct a machine learning model that can differentiate between regular, prefrail, and frail gait within a population of 50 older adults at an accuracy of 88.5% based on gait data

collected from wearable accelerometer signals. They rely mostly on “traditional” methods of machine learning: that is, machine learning methods that don’t use deep neural networks.

With vision-based applications, on the other hand, deep neural networks, especially convolutional networks designed specifically for processing image data, are frequently used. Researchers in the study by Lin et al [31] use a novel 3D convolutional neural network (CNN) to process gait silhouette images from the CASIA-B dataset [32] to achieve a person-identification accuracy of 97.6%. While the question of person identification through gait can be fairly trivially solved with modern CNN frameworks, the question of gait analysis, or assessing health requires a more nuanced approach and is still an active research area.

Researchers in [33] use a Spatiotemporal Graph Convolutional Network (ST-GCN) [34] framework to assess Parkinson disease severity as classified under the Unified Parkinson’s Disease Rating Scale [35]. The ST-GCN is an extension of the standard CNN model that works specifically on skeletal graph data as opposed to raw images, and works by processing input data with sequential attention to both the spatial and temporal dimensions of the input. As gait assessment is a far more complicated problem than simple person-identification or even traditional action recognition, they achieved 53% F_1-score using a dataset of 53 individuals with Parkinson disease.

Recently, in the study by Yin et al [36], the Spatio-temporal joint adjacency GCN (STJA-GCN) was developed that uses 3 input streams for joints, bones and velocities, a novel joint attention module to emphasize spatial data and a simplified skeletal graph input architecture to achieve state-of-the-art results (93.17% and 92.08%) on the domain of recognizing and classifying different types of abnormal gaits compared to other ST-GCN–based methodologies. This was tested on a pair of synthetic gait datasets introduced by the researchers, totalling 22 participants and 8600 instances of gait data collected from a total of 7 sensors across the 2 datasets.

Demonstrably, machine learning methods are extremely capable in multiple health care monitoring applications, necessitating the inclusion of highly technical fields in this type of research. The issue with the papers in this field, however, is that they score poorly on the proposed evaluation framework due to an overt focus on technical innovation at the expense of applicational concerns as well as scoring consistently lower than papers in the applicational and multidisciplinary categories on all but explicitly technical metrics (Figure 2). This analysis indicates a narrow focus almost purely on the effectiveness of the technology at the expense of an omission of application considerations, such as cost or perceived need by end users and medical stakeholders (refer to Figure 3 for a per-category breakdown). End users in this context refers both to patients and health care professionals who would be involved with the use of the technology (such as general practitioners, nurses, physiotherapists, occupational therapy and care workers). Stakeholders, on the other hand, refers to family members, friends or dependents of the patient using the technology. To take a more concrete example of this narrowed focus, research by Brunzini et al [13] is explicitly geared toward the development of a decision-support algorithm for health care professionals, complete with bespoke visual aids. However, there is no evidence of consideration of the requirements of health care professionals who would prospectively use such a system (in this case namely GPs, geriatricians, and nurses) being used in the design of the system itself. Similar issues were found in several studies where technical teams sought to develop assistive tools for caregivers or patients without direct involvement of prospective caregivers or end users, ranging from tools designed for doctors and nurses to carers, physiotherapists, and occupational therapists [37-41].

Figure 2. Illustration of evaluation performance per-evaluation category. Shown here is the impact that the use of multidisciplinarity has on the likelihood of each of the 10 metrics being taken into consideration.

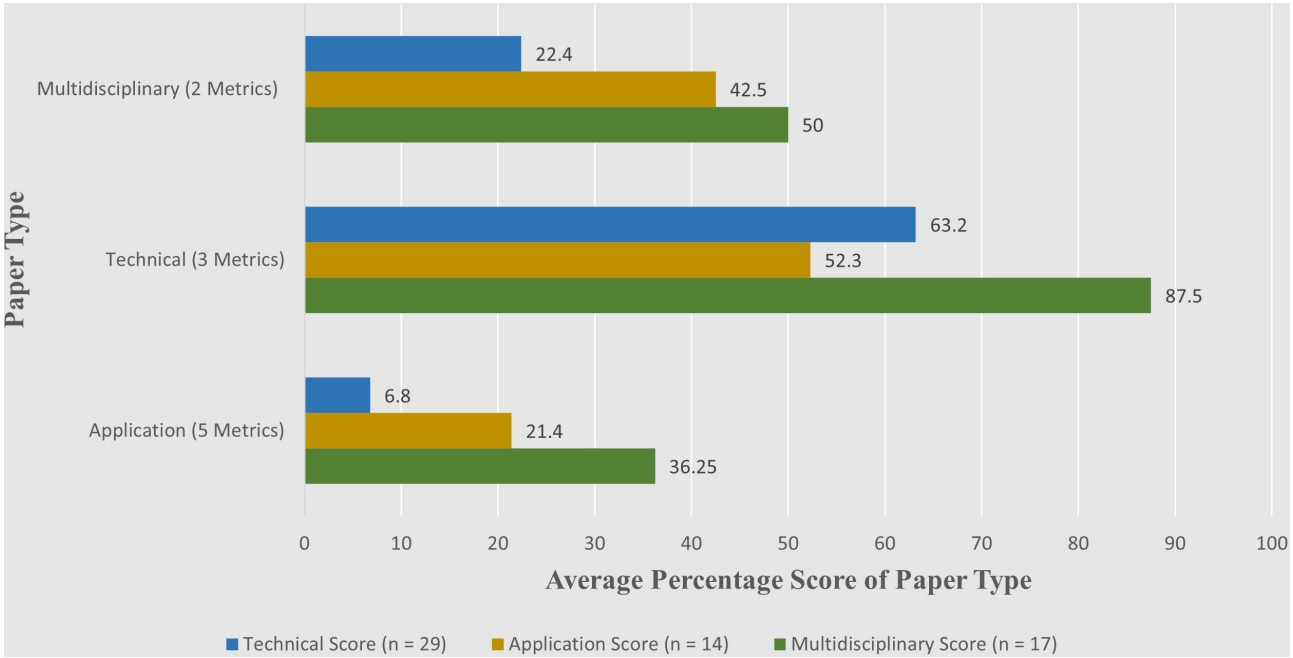


Figure 3. Breakdown of the average presence of each evaluation attribute by research team type.

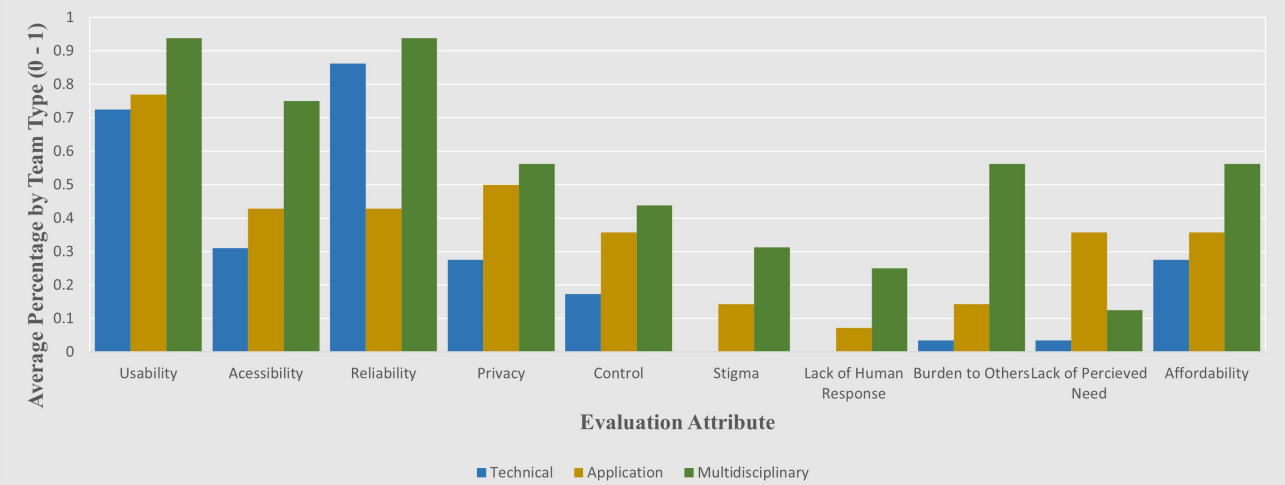

Application and Multidisciplinary Research

Of the surveyed technical papers (n=29), they scored an average 6.8% on the application-centered metrics in the proposed evaluation framework (Figure 2). In contrast, the application papers (n=14) mainly authored by health care researchers scored 21.4% on application-based metrics. While this indicates that application focused papers typically address more concerns with real-life deployment of research solutions, there is also a notable trend that this focus on application comes at a slightly increased tendency to neglect technical aspects of research (with both technical and multidisciplinary papers outperforming application-based papers on technical metrics). A clear trend can be seen in multidisciplinary papers consistently outperforming technical or application-based papers, even on the metrics specific to their own discipline (Figure 3).

As indicated in the second research question in the Introduction, we speculate that there exists a relationship between the inclusion of different stakeholders in PPI and co-design with the effectiveness of the resultant applications and research. As indicated by Table 1, this type of inclusion is usually implemented using focus groups. In this section, we highlight the typically moderate-to-high scores where this stakeholder input is prioritised, whilst also outlining other areas of shortcomings that follow from lack of multidisciplinarity in other, mainly technical domains.

In the study by Mireles et al [42], a total of 75 health care professionals (mostly nurses, n=47) are interviewed as a means of investigating the effectiveness of 3 different eHealth technologies for at-home monitoring of older adults with chronic conditions. Scoring 40%, this research focuses on the implications of e-health solutions as they affect end users, namely stakeholders, with less consideration for the technical implications of their recommendations. Research in the study by Bjornsdottir and Ceci [43] is similar, conducting qualitative interviews with both health care professionals and also patients. By including the patients and getting their insight, this research scores higher (60%) but suffers on the same technical metrics, highlighting the shortcomings in the systems they are evaluating without explicit consideration of the technical implications of their conclusions. In [44], 5 focus groups were conducted with both older adults and caregivers; namely family and care staff, to help synthesize a consensus on the design of future at-home sensor-based systems, with a focus on acceptability, respect for privacy and how to best provide control of care to the end users themselves. Scoring 50%, the authors neglect aspects such as system reliability at the expense of greater privacy, and other application-driven barriers such as societal stigma and the threat of greater isolation resulting in the deployment of remote monitoring technology. Expanding on this focus-group centered research [45], conduct a series of interviews with both formal and informal caregivers to identify the key parameters which need to be addressed to achieve effective at-home lifestyle monitoring systems. Scoring 60%, their strengths come from the inclusion of both medical and end user input, however they similarly lack extensive consideration for how the parameters being set by stakeholders would affect the performance of the monitoring systems themselves. Itoh et al [46] investigated issues of application from a medical perspective but score only 40%. Not only does their investigation consist only of testing an existing technology without the intention of developing said technology further, they also concern their research only with application concerns as far as the caregivers and medical stakeholders are concerned, with no involvement being afforded to the end users and patients. As a result, issues around stigma and even privacy are completely unaddressed.

As can be seen in Table 3, there is a clear lack of involvement in research and application design from the medical community and caregivers. Overall, 13.7% and 64.2% of single-discipline papers involve end user participation versus a mere 14.2% and 0% exhibiting caregiver or medical participation in the development of the research (for application and technical based papers. respectively). While the likelihood of involving both types of stakeholders (caregivers and end users) is more than double when multidisciplinary teams are involved (14.2% vs 37.5%), this is not conclusive due to the relatively small number of papers in each category when divided by the inclusion of different stakeholder types (end user and caregiver). Likewise, there is a definite trend across all research team types that exhibit lower evaluation scores when neither caregivers nor end users participate in the design or evaluation of research. However, discerning the differing impact between the 2 stakeholder types is difficult due to the small positive sample size (with only 2%

separating end user only and caregiver only scores for both research team types, refer to Table 4). The trend in the research, especially in survey-style research seems to be to focus on end users rather than caregivers or other medical stakeholders with only 7 of 60 papers involving medical stakeholders and 22 of 60 involving end user input.

Table . The presence or absence of caregivers and end users in the co-design of research across the review, split by research team type.

Team type	Caregivers (%)	End users (%)	Total (%)
Multidisciplinary[a]	37.5	56.25	*37.5*
Application[a]	38.4	64.2	14.2
Technical[a]	0	13.7	0

[a] Values are not mutually exclusive and some papers have both caregivers and end users involved. As a result, values may not necessarily add up to 100%.

Table . The average evaluation score by research team type when caregivers and end users are included or not in the research.

Team type	Neither (score %)	Caregivers (score %)	End users (score %)	Caregiver and End users (score %)
Multidisciplinary	35.7	70	68	70
Application	27.5	40	42	43
Technical	24.8	0	35	0

The strongest scores using the evaluation framework come from those where interdisciplinary teams are used (average score of 5.43 versus 3.5 and 2.68 for application-based and technical teams respectively), with a distinct trend shown in Table 4 indicating the presence of caregiver and end user involvement in a co-design or PPI capacity leads to a stronger evaluation score.

In general, as shown in Figure 3, different categories of research team tend to neglect certain aspects identified in the evaluation framework. Technical papers struggle with “Stigma” and “Human Response,” and application-based papers, mostly led by medical teams often omit factors such as “Accessibility“ and “Burden to Others” from their consideration. Both tend to struggle particularly with addressing societal stigma, possibly due to the varying levels and types of stigma for at-home monitoring from researcher’s home countries, or potentially due to considerations for more general issues not directly related to their specific research being deemed as outside of the scope of their work.

A common theme across all of these works is the tendency to make assumptions on the necessity of their application in the eyes of end users (Figure 3), as the lack of perceived need is seldom addressed regardless of the make-up of the research team. Technical issues are generally well addressed such as usability and reliability, however broader human issues such as societal stigma and feelings of end users becoming a burden, or the technology itself being a burden to use by caregivers are likewise rarely addressed. Across the entire evaluation phase, there is a consistent trend of greater representation of every attribute when multidisciplinary teams are involved in the research, with specifically technical teams being especially susceptible to a lack of focus on application-based concerns.

Discussion

Principal Findings

The research presented here concludes that a root problem underlying the issues affecting real-life uptake of research applications is the lack of multidisciplinarity in the research. We find that the developed evaluation metric is effective for quantifying the likelihood an application will transition into further development and effective deployment in real-world use. We also identified a series of common themes across the literature, namely the consistent underrepresentation of end users and other stakeholders in research, a distinct lack of multidisciplinarity in technical applications and the consistent underappreciation of societal factors such as stigma and human contact when developing at-home medical technologies.

Using a novel evaluation metric based on the 10 key barriers to uptake identified in the literature, a concrete trend can be observed that that multidisciplinarity between engineers, computer scientists, medical experts, and social scientists, alongside co-design or PPI-based inclusion of caregivers (such as family, friends, or dependants) and end users (health care professionals or patients) is highly beneficial to the effective development of technology that has direct practical application and tangible social benefit. The evaluation framework itself was also justified by the demonstration of a trend of extremely high evaluation scores on research projects that had reached the point of successful practical application, namely HalleyAssist and SPHERE. Using this evaluation metric, we find an increase of between 19.3% - 27.5% for multidisciplinary teams versus single discipline, and an increase of between 7.4% - 19% when research includes the use of caregivers or end users in a PPI or co-design capacity.

Limitations and Future Work

The main limitation of this study is that the results can only demonstrate the lack of multidisciplinarity is a root issue, not necessarily the root issue. For example, many extenuating factors not included in the research itself can explain why effective technology was researched but not developed, such as personal material conditions for the researchers, leading them to be uninterested or unable to develop effective research further. One other limitation is in the methodology of the framework itself. Ways to improve the descriptive power and nuance of the framework could be to introduce more criteria, break the criteria down into further subdisciplines or introduce criteria weighting so that criteria deemed more “vital” or less common are weighted higher when calculating the score. Had more resources been available, a broader review in both phases could have been conducted, using a greater number of papers from a greater number of databases, an especially important factor given the number of different disciplines relevant to this type of research.

In future, a larger study could be conducted on the literature to further verify the effectiveness of the evaluation framework, including the application of the framework to more smart-home technologies in commercial development. The framework itself could also benefit from being imbued with greater complexity for example, additional factors or a bespoke weighting of them to make certain factors more important to the success of a technology in application, and thus scoring a higher score. To our knowledge there is no comparable work in quantitatively assessing the effects of multidisciplinarity on research in at-home health monitoring, so in general, more research is needed to saturate the domain and allow for trends to be more concretely identified. As HalleyAssist and SPHERE are leading examples in the area of in-home monitoring of ageing singles, it would be good to follow up their development and experiences in the future, to see how well the assessment undertaken here was predictive of their successes.

Acknowledgments

This research was funded by the Legal and General Group (research grant to establish the independent Advanced Care Research Centre at University of Edinburgh).

Authors' Contributions

CL and RBF were both involved in the conception of the paper, with CL carrying out the literature reviews and being the primary drafter of the manuscript. RBF was also responsible for supervisory support and redrafting and revising the manuscript. Both authors have given final approval for the manuscript presented for publishing.

Conflicts of Interest

This research was funded by the Legal & General Group (research grant to establish the independent Advanced Care Research Centre at University of Edinburgh). The funder had no role in the conduct of the study, interpretation or the decision to submit for publication. The views expressed are those of the authors and not necessarily those of Legal & General. To the authors knowledge there are no conflicts of interest during the undertaking of this research.

Abstract

Background: Rehabilitation aims to restore and optimize the functioning of impaired systems for people with disabilities. It is an integral part of universal health coverage, and access to it is a human right.

Objective: We aimed to identify the key challenges to rehabilitation services in Sub-Saharan Africa from a user, health system, and service provider perspective.

Methods: This scoping review was conducted in accordance with the 5-stage framework proposed by Arksey and O'Malley. A comprehensive electronic search was run to identify published articles on rehabilitation services in Sub-Saharan Africa. Of the 131 articles retrieved, 83 articles were assessed for eligibility and 15 papers that met the inclusion criteria were considered.

Results: The results show that people with disabilities in Sub-Saharan Africa face multifactorial challenges to access rehabilitation services. Poor access to rehabilitation services is associated with less attention given to rehabilitation by governments, which leads to less funding, negative cultural and social beliefs, fewer rehabilitation centers, poorly equipped rehabilitation units, failure of health systems, lack of training to rehabilitation practitioners, and logistical and financial constraints. This review also reveals that digital rehabilitation reduces costs and improves access to services in hard-to-reach geographical areas. However, digital rehabilitation faces challenges as well, including connectivity issues, inaccessibility to technology, a lack of technical knowledge, a lack of privacy, and ethical concerns.

Conclusions: People with disabilities face multifactorial challenges to access rehabilitation services in Sub-Saharan Africa. It is therefore critical to address these challenges to optimize patients' health outcomes and offer better rehabilitation services.

Introduction

Rehabilitation refers to a set of therapeutic approaches that are structured to address physical, developmental, emotional, and mental challenges and improve patients' health outcomes and quality of life [1]. Rehabilitation is an integral part of universal health coverage and contributes greatly to the achievement of the United Nations' Sustainable Development Goal 3, which aims to ensure healthy lives and promote well-being for people of all ages [2]. Access to rehabilitation for people with disabilities is a human right, as stated in Article 26 of the United Nations Convention on the Rights of Persons with Disabilities [3]. Rehabilitation services can be either delivered through traditional face-to-face methods or, using remote approaches, facilitated by existing technologies [4,5]. Digital rehabilitation has reduced costs and improved access to rehabilitation services in hard-to-reach geographical areas [5].

Demographic changes that lead to chronic health conditions and accidents have gradually contributed to the increased need for rehabilitation services [6]. It is estimated that 2.4 billion people have a health condition that may benefit from rehabilitation services; however, these services are still

inaccessible due to a shortage of rehabilitation practitioners [1]. A World Health Organization (WHO) report disclosed that the ratio of skilled rehabilitation practitioners to patients is 10 to 1,000,000 in low- and middle-income countries. This leads to a persistent scarcity of health-related human resources and reduced access to rehabilitation services in low-resource regions [7].

Sub-Saharan Africa (SSA) has a shortage of health-related human resources, with the region accounting for only 3.5% of the world's health workers, despite it having a high disease burden that includes several kinds of disabilities [1]. In this low-resource region, there is a significant difference in the availability of and access to rehabilitation services, and this impedes individuals with disabilities from achieving their desired health outcomes [8,9]. The WHO reported that in SSA, 50% of people do not get the rehabilitation services they need, and a high proportion of people with disabilities with unmet needs are in low- and middle-income countries [10].

Demand for rehabilitation services in SSA is well established given the prevalence of unmet rehabilitation needs, the rising cases of noncommunicable diseases, and the significant incidence of road traffic accidents that result in disabilities. Additionally, lack of access to rehabilitation services for people with chronic conditions can lead to a need for assistance with activities of daily living and long-term hospital stays [11]. It is important to explore the rehabilitation challenges faced by users, health systems, and service providers. This scoping review aims to enhance our understanding of the complex demands imposed by these factors in SSA and examine the challenges associated with rehabilitation services from those 3 domains.

Methods

Study Design

This review follows the framework of conducting scoping reviews as proposed by Arksey and O'Malley [12]. This framework consists of 5 distinct stages: identifying the research question; identifying relevant studies; selecting studies; charting the data; and collating, summarizing, and reporting the results.

Identifying the Research Question

The research topic and its associated objectives helped to determine the scope of the review, appropriate literature, search strategy, and inclusion and exclusion criteria. To attain the main aim of this review, the scope of rehabilitation services in SSA was explored and key challenges that users, service providers, and health systems face on the availability of and access to rehabilitation services were identified.

Identifying Relevant Studies

Search Strategy

A comprehensive electronic search was conducted to retrieve published data on the availability of and access to rehabilitation services in SSA. Research studies published in reputable journals and databases such as PubMed, National Center for Biotechnology Information, Scopus, PLOS, BioMed Central, Taylor and Francis, Science Direct, Frontiers, Springer Nature, and Web of Science were chosen, as they yielded the most topic-relevant articles. A search strategy using the keywords "rehabilitation services," "availability," "access," and "Sub-Saharan Africa" was used. To increase the number of accessed literatures, "Sub-Saharan Africa" was replaced by the name of the country, and "rehabilitation services" was replaced by specific types of rehabilitation services such as physiotherapy, occupational therapy, speech and language therapy, and prosthetics services. To maximize the literature coverage and to provide additional evidence, reference lists of primary studies and review articles were screened to identify additional relevant literature.

Inclusion and Exclusion Criteria

Inclusion criteria were developed to ensure that all relevant publications focusing on availability of and access to rehabilitation services in SSA were included. Works written in English and published in the above-mentioned reputable journals and databases between 2018 and 2023 were considered. Articles not written in English, published before 2018, and that did not report on rehabilitation services in SSA countries were excluded.

Study Selection

One team member led the search and screened the titles and abstracts of all retrieved papers based on the inclusion and exclusion criteria. Articles retained for review were confirmed by the research team after discussion. Duplicates were removed and the articles that satisfied the inclusion criteria were selected for full-text review.

Charting the Data

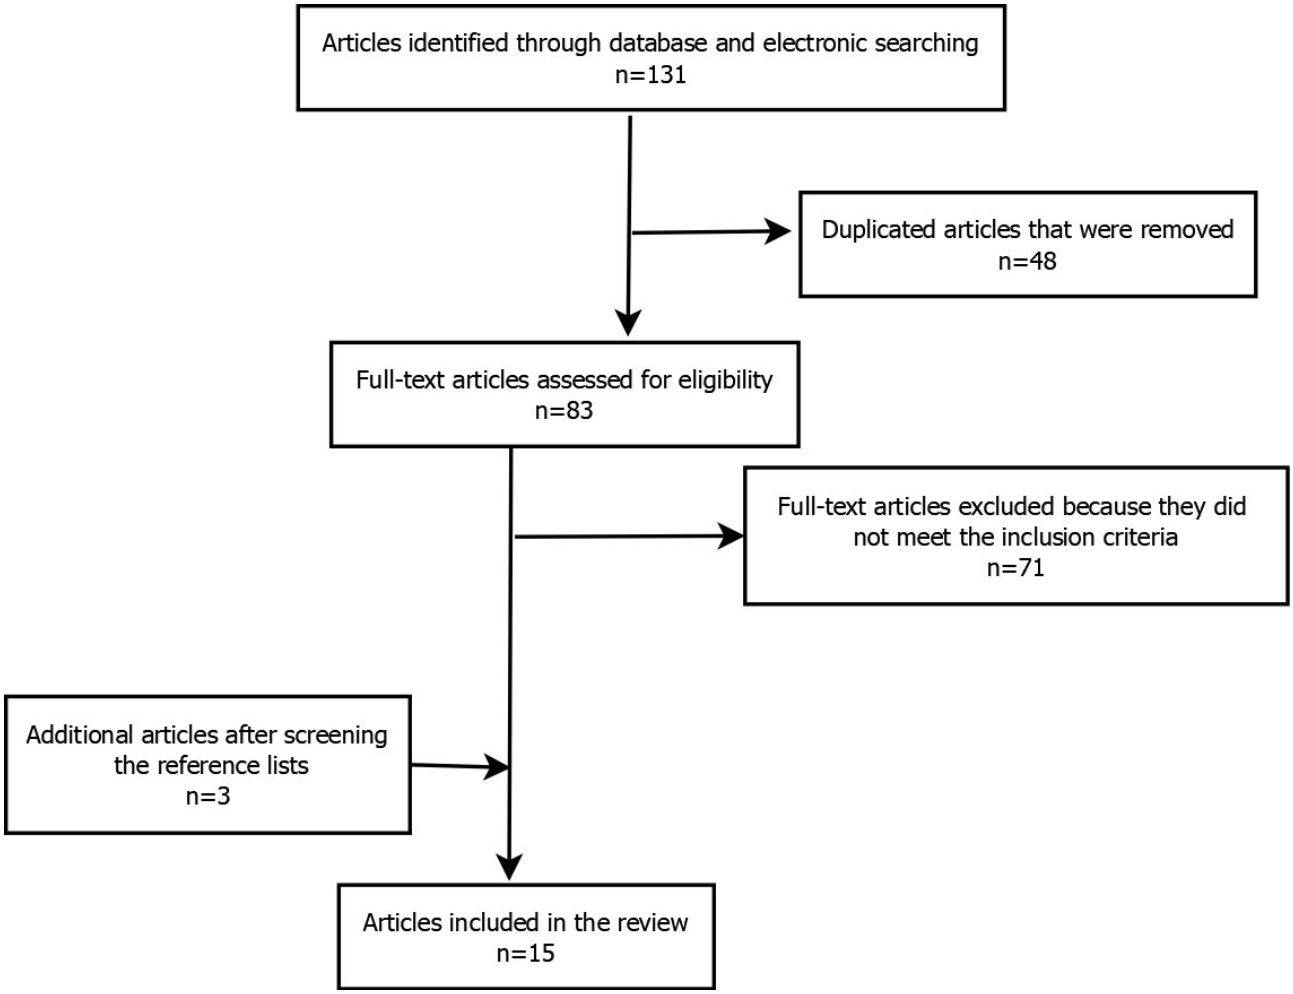
With the help of Microsoft Excel, data on availability of and access to rehabilitation services were extracted from the full texts. Challenges faced by users, service providers, and health systems were recorded. Information such as the title of the paper, names of authors, year of publication, study setting, study design, objectives of the paper, inclusion criteria, and study findings were extracted and recorded in the Excel table. Reference lists of included papers were also screened to optimize the search. The data extraction document is attached as a supplementary file (Multimedia Appendix 1).

Results

Overview

The search yielded 131 research and review articles overall. Forty-eight articles were duplicates and 71 articles did not satisfy the inclusion criteria. The full texts of the remaining 12 articles were screened, and 3 more articles were identified using the reference lists, resulting in a total of 15 articles eligible for analysis. Six of the 15 (40%) articles were original studies while 9 (60%) were scoping or systematic reviews covering other aspects of rehabilitation. Figure 1 illustrates how the articles were selected. All 15 considered articles indicated the existence of rehabilitation challenges; of these, 6 papers discussed the challenges faced by users, 5 discussed those faced by health systems, 3 discussed those faced by service providers, and 1 review article reported challenges for all.

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flowchart illustrating the article selection process.



Challenges to Rehabilitation Services in SSA

A synthesis of the literature revealed 2 categories of challenges to rehabilitation services from user, service provider, and health system perspectives (Table 1).

Table . Challenges to rehabilitation services reported in studies involving users, providers, and health systems.

	Category	
	Accessibility	Availability
Users	Overall challenges: • Unsuitable environment and buildings for people with disabilities • Inaccessibility to technology • Stigma, negative attitudes, and discrimination from therapists and other hospital staff • Long queues and waiting time • Financial constraints to purchasing medicines • Mindset that nothing can be done to help them • Lack of psychological support • Nonsupportive family members • Lack of trust in service providers • Pain during the rehabilitation process • Religious beliefs and socially accepted norms and traditions that claim that disability results from witchcraft or divine origins • Language barriers Digital rehabilitation–specific challenges: • Lack of secure platforms and privacy • Lack of technical knowledge or digital literacy • Connectivity issues • Inconsistency in power supply	• Do not know where to find the services • Long distance between users' homes and health facilities • Lack of reliable transport and logistical affordability • Distant health units
Service providers	Overall challenges: • Insufficient time for consultation • Inadequate follow-up • Inappropriate treatment procedures • Lack of patience • Ethical challenges Digital rehabilitation–specific challenges: • Lack of technical knowledge or digital literacy • Connectivity issues	• Lack of communication skills • Lack of professional training and necessary skills • Lack of maintenance for the assistive tools • Failure to schedule online appointments
Health systems	Overall challenges: • Consideration of rehabilitation as a less important health care strategy that is not well integrated into services • Fragmented health services • Lack of community awareness on rehabilitation services • Failure of the health system Digital rehabilitation–specific challenges: • Financial constraints	• Irregular referral to well-equipped health facilities • Lack of medicines and services • Shortage of health-related human resources • Low attention from governments and underfunding • Limited rehabilitation centers and poorly equipped rehabilitation units

Discussion

Principal Findings

This review revealed that people with disabilities in SSA have limited access to rehabilitation services. The limited access can be explained partly by user, service provider, and health system factors [8,13]. Studies included in this review [5,14] found that rehabilitation was given less priority by governments and not recognized as a crucial health care service. Consequently, the sector faced underfunding; experienced a deficiency in health-related human resources, particularly in therapists; encountered a scarcity of rehabilitation centers; and witnessed inadequately equipped rehabilitation units within health facilities. This contributed to the compromised access to high-quality rehabilitation services [5,14,15].

Another study reported that limited access to rehabilitation services in SSA is attributed to the financial inability to afford treatment, lack of insurance covering service expenses, long waiting times at the health facilities, and lack of drugs at health facilities [10]. Other studies have also found that some patients lack psychological support, are unaware of where to find

services, believe that nothing could be done to help them, and are not involved in making decisions on their health [8,16].

This review identified stigma as an impediment to accessing rehabilitation services. A study conducted in Rwanda [17] found that stigma around disability, coupled with negative attitudes and discrimination from therapists and other hospital staff, negatively impacted the uptake of rehabilitation services. Likewise, the role of family in accessing rehabilitation services is well documented. Patients with family members who do not perceive the need for rehabilitation services and who do not trust service providers may be demotivated to seek rehabilitation services [13,17,18]. Additionally, compromised access to health information, irregularities in referral to health facilities that are well equipped, inadequate policies and standards that govern the services, lack of adequate follow-up, insufficient time for consultations, and pain during the rehabilitation process are all hindrances to accessing rehabilitation services [9,15].

This review found that people with disabilities in SSA lack reliable, affordable, and accessible transportation means to reach health facilities. Furthermore, long distances to services and health units, unsuitable environments, and a lack of wheelchair-accessible buildings prevent users from accessing rehabilitation services. A review conducted in Brazil documented patients' determinants (residential location, economic resources, and social characteristics) and characteristics of services (cost, location, and status of the available facilities) as factors that limit access to rehabilitation services [8].

The results published by Bright et al [18] revealed that compromised health systems, lack of professional training and necessary skills for therapists, inappropriate treatment procedures, and lack of maintenance for the assistive tools reduce access to high-quality rehabilitation services. Health care providers who have not received enough training may lack the skills required to provide successful rehabilitation services. This lack of competence implies that misdiagnoses or outdated and inappropriate techniques could be used, causing harm to patients.

The study conducted by Jones et al [5] on telerehabilitation reported how digital rehabilitation services have addressed some logistical challenges; however, they come with additional challenges, including the absence of secure platforms and privacy, inaccessibility to technology, and lack of technical knowledge for both users and therapists [8]. Other challenges identified include a failure to schedule online appointments, connectivity issues, ethical challenges, and failure of the health systems. Patients and health care providers may struggle to use digital tools for rehabilitation, limiting the effectiveness of remote health services. Additionally, the inability to schedule and failure to maintain digital appointments may result in missed sessions, decreased patient participation, and care delays. Health systems face the challenge of poor policies that lead to a lack of financial capacity to afford digital technologies in health service delivery [19]. Digital technologies such as online medical records, wearable devices, and telemedicine can improve patient care and accessibility to health services, particularly in hard-to-reach areas. When financial limitations prevent the use of these technologies, patients may not receive the necessary high-quality care on time.

This review discerned that religious beliefs, cultural norms, and traditions that attribute disabilities to witchcraft or divinity serve as deterrents for individuals with disabilities seeking rehabilitation services at health facilities. A study conducted in Rwanda found that people with mental disorders believe that traditional and faith healers are more effective at treating mental problems than hospital specialists [20]. Such cultural beliefs dissuade people with disabilities from rehabilitation services, casting doubt on their quality and efficacy. Uncertainties regarding the precise origins of their conditions, which are often intertwined with mystical beliefs, add to this dissuasion [21].

Considering the rehabilitation challenges identified in this review, there is a need to bridge the gaps of infrastructure and social and cultural awareness regarding disability and rehabilitation services. This should be done by decentralizing services, providing continuous professional training to therapists, and promoting regular community awareness about rehabilitation services to inform service seekers and break the stigma around it. While this review has enumerated the challenges to rehabilitation services in SSA, it is worth noting that a majority of articles retained for consideration were scoping and systematic reviews that examined other aspects of rehabilitation. User and health system challenges were mostly highlighted in comparison to service provider challenges, which were limited in content.

Conclusion

This review reveals that rehabilitation services in SSA face multifactorial challenges that negatively impact timely access and quality of rehabilitation services for people with disabilities. As a consequence, those who require rehabilitation services experience longer periods of decreased mobility and functioning, inferior quality of life, and lower socioeconomic well-being. Future studies should examine the application of digital technologies to improve rehabilitation services' accessibility, especially in remote settings.

Abstract

Background: Health professionals face significant psychological burdens including burnout, anxiety, and depression. These can negatively impact their well-being and patient care. Traditional psychological health interventions often encounter limitations such as a lack of accessibility and privacy. Artificial intelligence (AI) chatbots are being explored as potential solutions to these challenges, offering available and immediate support. Therefore, it is necessary to systematically evaluate the characteristics and effectiveness of AI chatbots designed specifically for health professionals.

Objective: This scoping review aims to evaluate the existing literature on the use of AI chatbots for psychological health support among health professionals.

Methods: Following Arksey and O'Malley's framework, a comprehensive literature search was conducted across eight databases, covering studies published before 2024, including backward and forward citation tracking and manual searching from the included studies. Studies were screened for relevance based on inclusion and exclusion criteria, among 2465 studies retrieved, 10 studies met the criteria for review.

Results: Among the 10 studies, six chatbots were delivered via mobile platforms, and four via web-based platforms, all enabling one-on-one interactions. Natural language processing algorithms were used in six studies and cognitive behavioral therapy techniques were applied to psychological health in four studies. Usability was evaluated in six studies through participant feedback and engagement metrics. Improvements in anxiety, depression, and burnout were observed in four studies, although one reported an increase in depressive symptoms.

Conclusions: AI chatbots show potential tools to support the psychological health of health professionals by offering personalized and accessible interventions. Nonetheless, further research is required to establish standardized protocols and validate the effectiveness of these interventions. Future studies should focus on refining chatbot designs and assessing their impact on diverse health professionals.

artificial intelligence; AI chatbot; psychological health; health professionals; burnout; scoping review

Introduction

Health professionals are on the front line of patient care, enduring enormous responsibilities and constant pressure. Their work often occurs in an environment in which they must make life-and-death decisions, making them particularly vulnerable to psychological burnout [1]. According to recent studies, more than 50% of health professionals worldwide experience symptoms of burnout, such as fatigue, cynicism, and decreased effectiveness, leading to low job satisfaction [2], high turnover [3], and low-quality patient care [4]. This phenomenon not only causes an individual crisis but also has broader implications for health care systems [2,4]. Since the COVID-19 pandemic, psychological health issues such as anxiety, depression, and burnout among health professionals have become more prevalent because of long working hours, high-stress working environments, and exposure to traumatic events [5]. These issues directly affect health professionals' well-being and work performance and can ultimately negatively impact the quality of health care [6]. Therefore, supporting the psychological health of health professionals and preventing burnout are urgent challenges.

While traditional face-to-face counseling has been used to prevent psychological illness among health professionals, this

method presents various limitations including temporal and spatial constraints, limited availability of mental health professionals, accessibility barriers, and anonymity concerns [7-9]. Health professionals face significant challenges in accessing psychological care owing to demanding work schedules and high work intensity [10]. Additionally, they may feel psychologically burdened when seeking help in situations in which anonymity is not guaranteed [8]. To address these challenges, artificial intelligence (AI) chatbots have emerged as a potential solution, offering a new way to deliver psychological health interventions that can compensate for the limitations of traditional methods [7,8]. AI chatbots have the potential to be accessible anytime and anywhere while maintaining user anonymity, which may provide an alternative approach to psychological health support [7].

Recently, rapid advances in AI and natural language processing (NLP) have opened new possibilities for psychological health interventions, with AI chatbots gaining particular attention in the field of psychological health. Studies have demonstrated the potential of AI chatbots—AI-driven conversational agents—in providing mental health support [11] while emphasizing the importance of their safe and explainable implementation [12]. AI chatbots analyze users' conversation histories and data to provide advice and support tailored to their specific needs. This can help health professionals better manage psychological health issues, such as burnout, and enable timely interventions tailored to individual situations [13]. Previous research has shown that AI chatbots can improve coping skills through natural conversations with users [7], enhance the user experience, facilitate effective intervention delivery [13,14], and provide interventions tailored to specific needs [13,14]. This conversational approach enhances the effectiveness of interventions by fostering positive user engagement, as people are more likely to empathize with and respond to tools that feel engaging and relatable [6,7,14].

Despite the potential of AI chatbots for enhancing psychological health, there remains a lack of research on their effectiveness for health professionals. Much of the existing research has focused on using AI chatbots in patient care, whereas relatively little research exists on the use of AI chatbots to support health professionals. This research gap highlights the need to systematically investigate the characteristics and effectiveness of AI chatbots that target health professionals. Therefore, this study aimed to fill this gap and analyze the characteristics and effectiveness of AI chatbot interventions targeting health professionals to contribute to future research and practice.

Methods

Study Design

We conducted a scoping review to identify the available evidence regarding AI chatbot interventions for health professionals' psychological health. A scoping review maps the relevant literature in the field and is useful for identifying gaps in knowledge [15]. This review was conducted in accordance with the scoping review framework of Arksey and O'Malley. The study adopted the following five steps: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; and (5) collating, summarizing, and reporting the results. The five stages provided a structured approach to assist in understanding the current evidence by examining the literature. There was no rating of quality performed on the included studies, as scoping studies do not require a quality evaluation [16]. Therefore, a scoping review is suitable for providing a broader perspective on the current research and mapping the relevant literature on AI chatbot interventions for health professionals' psychological health.

Identifying the Research Question and Relevant Studies

The research question was, "What is the status of the current body of knowledge regarding AI chatbots for the psychological health of health professionals?" According to Arksey and O'Malley, the search strategy involves identifying relevant studies, including published and unpublished works, with an emphasis on being as comprehensive as possible [15]. A literature search was performed between May and August 2024 from the following eight databases: seven global search engines in English (Cochrane Library, CINAHL, Embase, ProQuest Dissertations & Theses Global, PsyclNFO, PubMed, and Web of Science) and one Korean search engine in Korean (Research Information Sharing Service). Various combinations of search terms (Textbox 1) were used to either broaden or narrow the search, depending on the results in a specific database. The reference lists of the retrieved studies were searched manually. Finally, gray literature, relevant letters, and editorials were searched.

Textbox 1. Query box

medical team OR medical staff* OR healthcare worker* OR healthcare provider* OR health personnel* OR health professional* OR doctor* OR surgeon* OR physician* OR nurse* OR midwife* OR Licensed Practical Nurse* OR licensed vocational nurse* OR physician assistant OR nurse practitioner OR clinical nurse specialist* OR nurse clinician* OR registered nurse* OR resident* OR therapist* OR pharmacist* OR nurse assistant* OR nurse aid* AND burnout OR burn-out* OR depress* OR depression OR stress* OR exhaust* OR depersonalization OR personal accomplishment OR anxiety* AND chatbot* OR artificial intelligence OR conversational agent* OR dialogue system* OR machine learning OR natural language process*

Study Selection

Overview

Studies published before May 2024 were selected for this review. The studies retrieved from the literature search were reviewed by three researchers using the following inclusion and exclusion criteria.

Inclusion Criteria

(1) The purposes of the studies included the development or implementation of AI chatbot interventions. (2) Participants of the studies included licensed health professionals such as

physicians or surgeons, dentists, medical doctors, registered nurses, licensed practice or vocational nurses, pharmacists, and allied health professionals such as respiratory and physical therapists. Studies that included nonhealth professionals in addition to health professionals as part of their participants were included if the main purpose of the AI chatbot was to alleviate the psychological distress of health professionals. (3) The intention of the AI chatbots was to improve the psychological health of health professionals, focusing on outcomes such as stress, burnout, depression, and anxiety. (4) The studies were written in English or Korean.

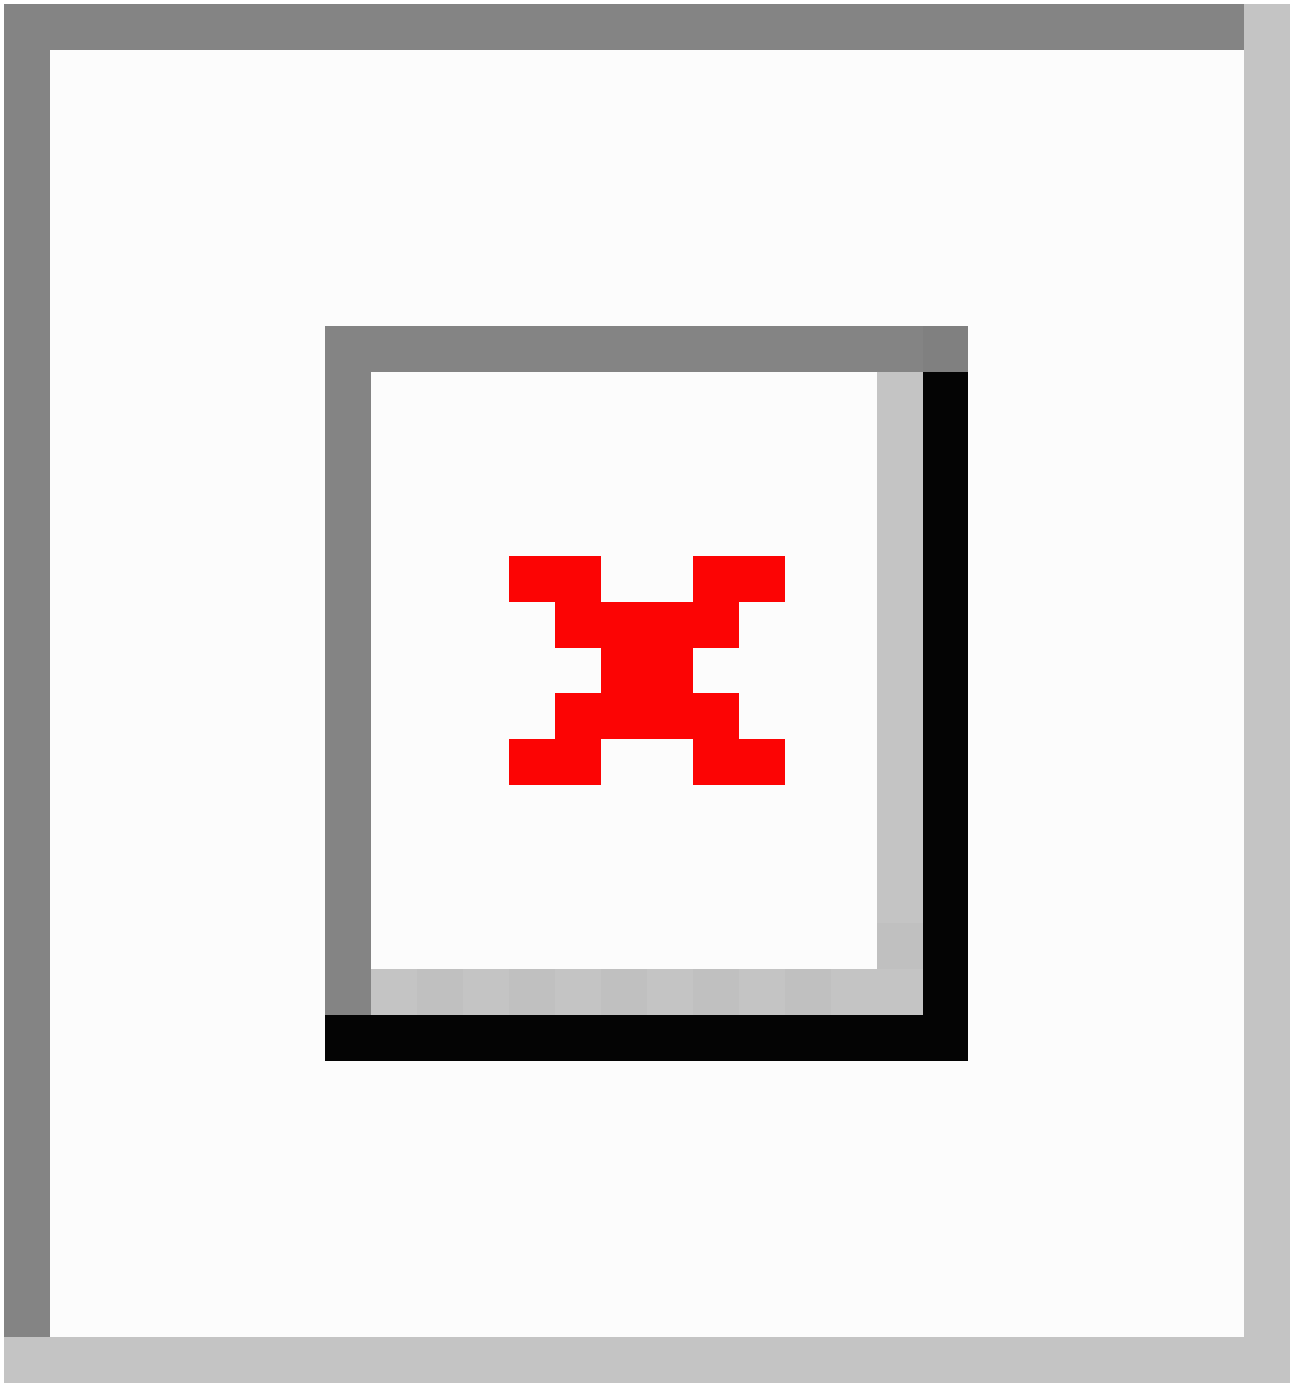
Exclusion Criteria

Studies in which we could not retrieve the full text were excluded.

A total of 2465 studies were retrieved from the initial database search (Figure 1). After removing duplicates, 1766 studies remained. The titles and abstracts were reviewed, and 1750 studies were excluded, leaving 16 studies for a full-text review. Six studies completely met the inclusion criteria after full-text review. Then, by reviewing the reference lists and manually searching, five additional studies were obtained, of which four studies met the criteria for the scoping review. Finally, 10 studies were included in this scoping review.

Throughout the review process, two researchers (GB and JH) took the lead in data extraction, and all researchers reviewed the content. Any uncertainties and disagreements were resolved through weekly meetings. The literature review software Covidence (Veritas Health Innovation Ltd), a study-managing tool for collaborating researchers [17], was used to manage the retrieved studies and to screen for redundant studies.

Figure 1. Flowchart. AI: artificial intelligence.



Charting the Data

The data are presented in tables, summarized, and synthesized qualitatively according to the purpose and research questions of the review.

Collating, Summarizing, and Reporting the Results

The final stage of a scoping review involves collating, summarizing, and reporting the results [15]. Data extraction was performed by two researchers (GB and JH) and checked for accuracy by all the researchers. Uncertainties and disagreements were resolved through discussions. The data were extracted using a common data extraction format.

Results

General Characteristics

Table 1 presents the characteristics of the analyzed studies. Ten studies published between 2018 and 2024 were retrieved. The studies were published worldwide: in Canada [7,18], Japan [19], Malawi [20], Netherlands [21], Singapore [13,22], Spain [23], and the United States [24,25]. Four studies examined diverse health professionals, including doctors, nurses, nurse assistants, clinical officers, pharmacists, lab technicians, and other allied health professionals [20,21,23,26]. Two studies specifically targeted doctors and nursing staff [13,27] such as nurse practitioners, registered nurses, licensed practical nurses, and nursing assistants, while one study exclusively covered chatbots

for nurses [19]. Three studies identified their participants as health professionals, without specifying the specific types [7,18,22]. Of the ten studies, eight studies focused solely on health professionals [13,19-23,26,27]. Two studies included both health professionals and their families [7,18].

The study designs were diverse. Of the 10 studies, three were development studies [18,23,27], one was a design verification study [26], one was a pilot study [22], one was a randomized controlled trial [20], one was a mixed-method feasibility study [21], one was an intervention study [19], one was a cross-sectional study protocol study [7], and one was a qualitative study [13]. Three studies evaluated the development and feasibility of AI chatbots for psychological health support [23,26,27].

Table . Study characteristics.

Author (year)/ country	Study design	Participants	Source of participants	Sample size (M:F[a] ratio)	Age (years), mean (SD)	Publication type
Anmella et al [27](2023)/Spain	Development study	Primary care and health care professionals; medical doctors (GPs[b] and specialists from diverse disciplines), nurses, and nurse assistants	• GP referrals to PCMHSP[c] • Hospital Clínic de Barcelona health professionals	• Simulation study: 17 (24:76) • Feasibility and effectiveness study: 34 (24:76)	• Simulation study: 36.5 (9.7) • Feasibility and effectiveness study: 35.3 (10.12)	Journal study
Chaudhry and Islam [26](2021)/United States	Design verification study	Health professionals in their workplaces during the COVID-19 pandemic; RNs[d], NPs[e], LPN[f], CNAs[g], PAs[h], RT[i], PTs[j], students or intern nurses	Local medical services departments and health professionals' mailing lists	22 (9.1:90.9)	34.98 (8.55)	Journal study
Chang et al [22] (2024)/Singapore	Pilot exercise (service evaluation study)	Health professionals (types unspecified)	National tertiary health care cluster	527 (N/A)[k]	N/A	Journal study
Jackson-Triche et al [23] (2023)/United States	Development and usability study	Health professionals including faculty, staff, and trainees across various disciplines within the health care system	UCSF[l]	Over 26,000 (N/A)	N/A	Journal study
Kleinau et al [20] (2024)/Malawi	Randomized controlled trial	Health professionals (doctors, nurses, clinical officers, medical assistants, pharmacists, lab technicians, physiotherapy technicians)	Public and private health care facilities within Blantyre and Lilongwe districts	1584 (N/A) Completed: 511 (E=296, C=215)	N/A	Journal study
Kroon [21](2018)/Netherlands	Mixed method feasibility study (one group pre-posttest design)	Health professionals (radiation expert, social worker, nurse in training, training officer, pedagogue, health professional disability care HRD[m] adviser	Email using personal and iThrive connections.	12 (8.3:91.7) (interview participant=9)	Half of the participants were aged 18 to 25 years	Master's thesis
Matsumoto et al [19](2021)/Japan	Intervention study	Nurses	Two hospitals in Tokyo	70 (N/A)	N/A	Journal study
Noble et al [7](2022)/Canada	Cross-sectional study protocol	Health professionals and their families	The Canadian provinces of Alberta and Nova Scotia	2200 (N/A)	N/A	Journal study
Yoon et al [13] (2021)/Singapore	Qualitative study	Frontline health professionals (doctors and nurses)	Singapore general hospital and community care facilities (large scale institutional isolation units)	42 (24:76)	29.6 (3.9)	Journal study
Zamani [18](2022)/Canada	Development study	Health professionals and their families	The Canadian provinces of Alberta and Nova Scotia	N/A	N/A	Master's thesis

AI Chatbot Characteristics

Table 2 shows the characteristics of the AI chatbots developed or implemented in the retrieved studies. The types of AI chatbot algorithms were diverse; NLP-based AI was the most commonly used algorithm, appearing in six studies [7,13,18,19,21,23]; rule-based AI, an algorithmic method that does not learn from data or create rules on its own, was used in two studies [20,22]; and learning-based AI that learns from data was adopted in two studies [26,27]. AI chatbots were delivered through mobile apps in six studies [13,19,20,22,26,27], and web-based platforms via web links in four studies [7,18,21,23]. The interaction type in all studies was 1:1 interaction: Among them, one study included 1:1 interaction alongside group chat functionality [26], and another study included 1:1 interaction with optional human coach support [22]. In seven studies, the chatbot actively initiated the conversation [7,13,18-20,23,27], while in three studies, the conversation was passively initiated [21,22,26].

Participant completion of the AI chatbot interventions was reported in four studies [20,21,23,27]; among these, three studies provided the percentage of participants who completed the intervention: 14.3% [21], 67.7% [20], and 73% [27] while one study reported the employee access rate of the intervention as 10.88% [27]. Of the 10 studies, six evaluated the AI chatbot's usability [13,20,22,23,26,27]. Four studies relied on participant feedback: 54.6% rated it as useful [26], the average satisfaction score was 4.07 out of five [22], more than 80% reported it as helpful [23], and 91% of the users found the chatbot easy to use [20]. One study used user engagement indicators to identify high subjective usability (acceptability, usability, and satisfaction) but low objective engagement (completion, adherence, compliance, and engagement) [27]. Another study assessed chatbot performance metrics, reporting an intent detection accuracy of 99.1% and an entity extraction accuracy of 95.4% for the Mira Chatbot [18]. Chatbot usability was not evaluated in the remaining four studies [7,13,19,21].

Table . AI[a] chatbot characteristics.

Author (year)/ Country	Chatbot name	Purposes of chatbot	AI chatbot type	AI algorithm	Mode of delivery	Interaction type	Initiates conversation	Completion related	Chatbot usability evaluation
Anmella et al [27] (2023)/Spain	Vickybot	To screen anxiety, depression, and burnout with interventions	Digital decision support platform (PRESTO[b])	• Machine-learning severity prediction model	Mobile app	1:1 interaction	Active	27% completed second self-assessment	• High subjective UEI[c] (acceptability, usability, and satisfaction). • Low objective UEI (completion, adherence, compliance, and engagement)
Chaudhry and Islam [26] (2021)/United States	iChatBot (AIO) PeerChat (AI X)	To provide stress management support during COVID-19	Intelligent chatbot	• iChatBot: machine learning model • PeerChat: immediate communication with expert peers	Mobile app	iChatBot: 1:1 PeerChat: group chat	Passive (on-demand queries)	Not reported	• 54.6% participants rated the app as either useful or very useful • 59.1% participants were willing to use it
Chang et al [22] (2024)/Singapore	Wysa	To evaluate Wysa for health professionals' support	Conversational chatbot	• Rule-based AI model	Mobile app	1:1 interaction with optional human coach support	Passive	Not reported	• High engagement rate with positive feedback (91-92%) • Mean feedback score of 4.07 (SD 0.95) out of 5

Author (year)/ Country	Chatbot name	Purposes of chatbot	AI chatbot type	AI algorithm	Mode of delivery	Interaction type	Initiates conversation	Completion related	Chatbot usability evaluation
Jackson-Triche et al [23]/United States	UCSF[d] Cope	To provide behavioral health support via chatbot	An algorithm-based, automated, web-based AI conversational tool	• Natural language model	Web-based interface	1:1 interaction	Active	10.88% of employees accessed the chatbot	• >80%of attendees reported the experience as helpful
Kleinau et al [20] (2024)/Malawi	Viki (Vitalk's virtual mental health care assistant)	To assess chatbot impact on mental health in Malawi	Automated conversational agent	• Rule-based AI model	Mobile app	1:1 interaction	Active	Of 1584 participants, 511 completed	• 91% found the app easy to use; 87% found the content relevant; 92% benefited from the app, and 83% felt more resilient • Common barriers: lack of time (45%), app duration (30%), and usability issues (13%)
Kroon [21] (2018)/Netherlands	iThrive	To help health professionals manage inner critics and enhance self-compassion	Preprogrammed conversations and interaction	• Natural language model	Web-based interface	1:1 interaction	Passive (users initiate interaction with the chatbot)	12 of 14 participants included in the final analysis	• N/A[e]
Matsumoto et al [19] (2021)/Japan	CB[f] app (a chatbot app)	To support mental health self-care for busy professionals, especially nurses	Digital decision support platform	• Natural language model	Mobile app, VR[g]	1:1 interaction	Active	Not reported	• N/A
Noble et al [7](2022)/Canada	MIRA[h]		Hybrid NLP[i] and decision tree AI chatbot	• Natural language model	Web-based platform	1:1 interaction	Active	Not reported	• N/A

Author (year)/ Country	Chatbot name	Purposes of chatbot	AI chatbot type	AI algorithm	Mode of delivery	Interaction type	Initiates conversation	Completion related	Chatbot usability evaluation
		To provide tailored mental health information and services for health professionals and their families							
Yoon et al [13](2021)/Singapore	mHealth[j] app	To support frontline health professionals's psychosocial well-being during COVID-19	N/A	• Natural language model	Mobile app	1:1 interaction	Active	Not reported	• N/A
Zamani [18] (2022)/Canada	MIRA	To offer strategic mental health resources for health professionals and their families	Hybrid NLP and decision tree AI chatbot	• Natural language model	Web-based platform	1:1 interaction	Active	Not reported	• Intent detection: 99.1% accuracy in identifying user needs • Entity extraction: 95.4% accuracy in recognizing key terms for resource recommendations.

[a]AI: artificial intelligence.

[b]PRESTO: primary care digital support tool in mental health.

[c]UEI: user engagement indicator.

[d]UCSF cope: University of California, San Francisco faculty, staff, and trainee coping and resiliency program.

[e]Not available.

[f]CB: cognitive behavioral.

[g]VR: virtual reality

[h]MIRA: mental health intelligent information resource assistant.

[i]NLP: natural language processing.

[j]mHealth: mobile health.

AI Chatbot Intervention Characteristics and Outcomes

Table 3 lists the contents and outcomes of the AI chatbot interventions. The primary component is the screening function for mental health conditions such as anxiety, depression, and stress, which was included in seven studies [19-23,26,27]. Four studies included cognitive behavioral therapy techniques [13,20,22,27]. Additionally, four studies implemented stress management techniques, such as breathing exercises and meditation [13,19,20,22]. Three studies incorporated problem-solving strategies [7,18,22] and psychoeducation [19,22,27]. Two studies used behavioral activation [20,22], cognitive restructuring [21,22], and gratitude training [20,22]. One study featured storytelling [21]. In addition, there was a

function to support portal sites connected to community resources in three studies [7,18,23].

Table . AI[a] chatbot intervention characteristics and outcomes.

Author (year)/ country	Chatbot contents	Additional features	Intervention doses	Main outcomes
Anmella et al [27](2023)/Spain	• Screening and monitoring for self-assessment tools • Personalized psychological modules: CBT[b], mindfulness, DBT[c], and ACT[d] • Psychoeducation and coping strategies for stress management • Chatbot-guided navigation	• Emergency alert for suicidal thoughts • Weekly objective reminders • Audio recording option for reflections after self-assessments	• 1 month (self-assessments conducted at baseline and biweekly)	• Anxiety (t_8=1.000; P=.34) and Depressive (t_8=0.40; P=.70) symptoms were not significant differences • Work-related burnout was moderately reduced (z=–2.07, P=.04, r=0.32)
Chaudhry and Islam [26] (2021)/United States	• iChatBot—provides real-time answers (self-monitoring and stress-tracking information related to patient care and workplace stress management) • PeerChat—enables peer-to-peer support	• AssignedTasks: records stress levels and task completion times • MyNotifications: Sends reminders for health activities like sleep, exercise, and meals • SmartMonitor: connects with devices to track vitals (eg, blood pressure, oxygen, pulse, and temperature) • InfectionCheck: Manual COVID-19 symptom checker via chatbot	• N/A[e]	• Usefulness and willingness: 54.6% found the app useful; 59.1% willing to use it. • Six feature feedback: MyNotifications: useful reminders; PeerChat: positive for peer support; AssignedTasks: good for tracking, but time-consuming; InfectionCheck: useful, potential redundancy; StressMonitor: very helpful for coping; iChatBot: concerns about emergency responsiveness
Chang et al [22](2024)/Singapore	• Mental health assessments: anxiety—GAD-7[f], depression—PHQ[g]-2 • Intervention modules: mindfulness, sleep meditation, guided visualization, thought recording, behavioral activation, psychoeducation, breathing exercises, cognitive restructuring, acceptance, grounding, social support, problem-solving, habit building, gratitude training	• Option to connect with a human coach • Weekly objective reminders and notifications • Gratitude challenge to boost engagement • Audio recording for self-reflection	• Varied among users (on average, users completed 10.9 sessions over 3.80 weeks)	• 495 completed at least one full session; 422 completed two or more sessions • The interventions most used were for sleep and anxiety, with a strong repeat-use rate • 46.2% reported symptoms of anxiety • 15.2% reported symptoms of depression
Jackson-Triche et al [23] (2023)/United States	• Mental health assessment screening: suicide or self-harm thoughts, substance use concerns, emotional distress, social withdrawal and work-related struggles, resource navigation • Web-based self-care resources • Behavioral health services: emergency support	• Telehealth assessments for crisis evaluation • Self-management website offering curated resources • In-person navigator for personalized support • Support groups with regular peer meetings	• Varied based on user interaction	• UCSF[h] cope reached all units • 10.88% (3785/34,790) of employees accessed the technology • 39.7% (708/1783) of employees with psychological distress requested in-person services • Positive feedback on all program elements. • Over 80% of attendees found the experience helpful

Author (year)/ country	Chatbot contents	Additional features	Intervention doses	Main outcomes
Kleinau et al [20](2024)/Malawi	• Mental health assessments: anxiety (GAD-7), depression (PHQ-9), burnout (OLBI[i]), loneliness (UCLA Loneliness Scale)[j], resilience (RS-14)[k] • Careline programs (thematic mental health conversation tracks) • Intervention: CBT techniques, positive psychology strategies, behavioral activation, gratitude exercises, breathing, relaxation, and meditation exercises,	• Mood tracking with emojis for human-like interaction • Gamification for engagement • Emergency support with local psychologist contact info for high-risk users	• 8 weeks -First 4 weeks: daily interactions • Second 4 weeks: interactions every other day	• GAD-7 showed a decrease (–0.44), but the result was not statistically significant. • OLBI showed a decrease (–0.58), with borderline significance. • PHQ-9 showed a significant decrease. • UCLA loneliness scale: no significant • RS-14 showed a significant increase.
Kroon [21](2018)/Netherlands	• Awareness of inner critics: storytelling, encouraging reflection • Identification of inner critics: assessment tool • Cognitive restructuring techniques • Self-compassion development	• Humor: adds humor for engaging interactions • Tokens: rewards for task completion • Compliments: encourages users with motivating feedback	• 2 weeks	• ProQOL[l] and SCS[m] no significant. • Quantitative results: no significant changes in self-compassion or compassion fatigue. • Qualitative results: Positive feedback on the iThrive intervention, with increased awareness of inner critics and changes in thinking patterns. • Chatbot interactions reportedly reduced stress and improved self-compassion.
Matsumoto et al [19](2021)/Japan	• Digital-SAT[n] method: self-guided stress management, techniques to convert stress-related physical discomfort into positive sensations, image-based therapeutic exercises • Mental health assessments: self-esteem, anxiety, emotional support, depression, problem-solving abilities • Stress management: guided stress relief sessions, emotional stabilization exercises, visualization techniques	• Automated daily messages with reminders and psychoeducational content • Gamification elements such as progress tracking • Immersive VR[o] experiences	• 4 weeks	• Self-esteem and family support significantly improved. • Self-repression showed a trend of improvement but was not significant. • SDS scores and counseling needs increased in the VR + CB[p] group. • Maximal blood pressure decreased significantly in the VR group and showed a decreasing trend in the VR + CB group. • Minimal blood pressure significantly decreased in the VR group.
Noble et al [7](2022)/Canada	• Mental health education and information: problem-solving • Personalized resource navigation • Self-help strategies and coping skills		• N/A	• The findings will be reported in follow-up research

Author (year)/ country	Chatbot contents	Additional features	Intervention doses	Main outcomes
		• Emergency contacts for urgent mental health support • Hybrid AI approach: free-text input and predefined options • Crisis support referrals for suicidal thoughts		
Yoon et al [13](2021)/Singapore	• Personalized goal setting: tailored goals for lifestyle improvements (eg, sleep, exercise), feedback on progress to encourage behavioral changes, reminders to support adherence to personal goals • Educational resources: mindfulness exercises and short wellness studies, stress management techniques	• In-app counseling and peer support • Reminders and notifications • Gamification elements: point-based rewards • Engaging features to promote continued app use • Mood tracking and progress monitoring	• N/A	• Mood-tracking reminders were helpful, but workers struggled with self-awareness. • Goal-setting and resources were valued; frequent notifications were distracting. • A built-in counselor chat was preferred for accessibility and privacy. • Gamification was not well-received. • Peer support was needed, but app-based interactions raised concerns. • Motivation, usability, and rewards were crucial for app use.
Zamani [18](2022)/Canada	• Information on mental health topics, including substance use and coping strategies: problem-solving • Delivers personalized recommendations • Facilitates access to local mental health services and programs through a resource portal	• Emergency contact option for users experiencing distress • Stores conversation logs • Feedback system	• N/A	• Intent detection: 99.1% accuracy in identifying user needs. • Entity extraction: 95.4% accuracy in recognizing key terms for resource recommendations.

[a]AI: artificial intelligence.

[b]CBT: cognitive behavior therapy.

[c]DBT: dialectical behavioral therapy.

[d]ACT: acceptance and commitment therapy.

[e]N/A: not available.

[f]GAD-7: general anxiety disorder-7.

[g]PHQ: patient health questionnaire.

[h]UCSF cope: University of California, San Francisco faculty, staff, and trainee coping and resiliency program

[i]OLBI: Oldenburg burnout inventory.

[j]UCLA: University of California, Los Angeles loneliness scale.

[k]RS-14: 14-item resilience scale.

[l]ProQOL: Professional Quality of Life Scale.

[m]SCS: Self-Compassion Scale

[n]SAT: structured association technique.

[o]VR: virtual reality.

[p]VR-CB: virtual reality-chatbot.

Across the studies, a variety of additional features were incorporated. Seven studies included AI chatbot functionalities for crisis management and support [7,13,18,20,22,27]. Specific features encompassed emergency contact information for crises [7,18,20,27], peer support groups and in-app forums for social support [13], expert support through in-app counseling, and options for connecting with human coaches [13,22,23]. Six studies incorporated reminders to encourage chatbot use [13,18,19,22,26,27]. Gamification elements, such as point-based rewards to encourage participation, were featured in four studies [13,19-21]. Peer support functionalities were available in three studies [13,23,26]. Two studies included mood-tracking features for health and lifestyle management [13,20], while another two studies provided an audio recording option [22,27]. Additionally, one study integrated devices for tracking vital signs [26] and provided an immersive virtual reality experience [19]. A total of 4 out of 10 studies explicitly stated the duration of chatbot use or intervention dose ([19]: 4 wk; [20]: 8 wk; [21]: 2 wk; [23]: 1 mo) while it was not specified in six studies. The dose varied among users in two studies [22,23].

The research in four studies evaluated psychological health outcomes [19-21,27], whereas, in six studies, the focus was primarily on the development and description of user perceptions of the AI chatbot without providing specific outcome measures [7,13,18,22,23,26]. The most commonly measured psychological health outcomes were anxiety and depression, which were examined in three studies [19,20,27]. Burnout was investigated in two studies [20,27]. Compassion fatigue [21], loneliness [20], resilience [20], and self-compassion [21] were also evaluated. Anxiety was measured in three studies: one reported a significant reduction of scores [20] while the other two reported no significant differences in anxiety scores [19,27]. Burnout was assessed in two studies, and each reported a significant decrease in its scores [20,27]. Depressive symptoms were measured in two studies: one reported a significant reduction of scores [20] while the other did not [27]. Other psychological variables were measured in one study each; of those, the variables that showed significant change in scores were health counseling needs [19] and resilience [20].

Discussion

Principal Results

The studies retrieved for this scoping review were published during the past seven years, between 2018 and 2024, and reflect the rapidly evolving trend of AI chatbot technology for supporting psychological health. The global distribution of studies across countries indicates a widespread interest in using AI for psychological health support and health professionals' psychological health.

Our review revealed that chatbots were used by a broad spectrum of health professionals, highlighting their diverse applications. This diversity underscores the potential for universally designed chatbots to effectively address psychological health needs across different professional settings. However, prior research has shown that nurses, who have direct and continuous patient contact, experience greater mental health distress compared to other health professionals [24]. Therefore, future studies should consider incorporating role-specific options into chatbot designs to create tailored interventions for diverse professional groups.

The diverse research methods used in the retrieved studies signify the nascent stage of research on AI chatbots for psychological health support, emphasizing technology refinement and user experience comprehension. Such a variety of research approaches is crucial for validating the efficacy and safety of AI chatbot technology, enabling iterative improvements and a deeper understanding of how health professionals interact with AI chatbots [25]. However, it is noteworthy that only 4 out of 10 studies measured psychological health outcomes. This limitation underscores the significant gap between technological developments and clinical validation. As the field matures, it becomes imperative to quantitatively assess the impact of AI chatbots on psychological health indicators. Further studies measuring outcome variables to demonstrate the clinical effectiveness of AI chatbots are needed.

The studies reviewed here demonstrate the variety of AI algorithms used in chatbot design, including NLP-based-, rule-, and learning-based approaches. NLP-based AI chatbots which provide personalized responses by analyzing user inputs [28] are the most commonly used AI algorithms. Evidence has shown that an NLP-based AI chatbot, which simulates natural conversations, is successful at delivering tailored interventions [29]. Rule-based AI algorithms, adopted in 2 studies out of the 10 retrieved studies, are effective in providing fixed and predetermined responses; however, they lack the adaptability required to provide more dynamic and engaging psychological interventions [30]. Previous research has shown that NLP technology, which interprets psychological health cues from user-generated texts, significantly improves the effectiveness of interventions [31,32], a finding consistent with our review [7,13,18,19,21,23]. Moreover, the development of deep learning techniques has led to the widespread use of general-purpose pretrained language models in various NLP applications [33]. This suggests that NLP-based algorithms are particularly suitable for delivering personalized psychological support in real-time interactions. Machine learning and deep learning algorithms show promise in enhancing AI chatbots' effectiveness by continuously learning through user interactions. These algorithms can provide accurate and personalized interventions over time [34]. Future studies should investigate how these advanced algorithms can be used to offer more precise psychological support tailored to individual user experiences.

User engagement is a critical factor in the success of mental health interventions; however, several studies did not report intervention completion rates [20,21,23,27]. These issues might become more pronounced in real-world settings, where factors such as interface complexity, the chatbot's ability to provide meaningful and personalized feedback, and technical issues impact the overall user satisfaction and perceived effectiveness of the intervention [35]. This underscores the need for further exploration of how chatbot interactions can be designed to maintain user engagement, possibly through improved user experiences and personalization techniques [36,37]. From a different perspective, unlike traditional interventions, which are typically designed to be completed from start to finish, chatbot

interactions often do not follow this linear structure. Users may terminate interactions once their immediate concerns are addressed, reflecting the unique flexibility of chatbots [38]. For instance, if a chatbot provides critical information for crisis management and the user responds affirmatively, the user is likely to exit the chat after their need is met. This immediate resolution highlights the efficiency of chatbot interventions in addressing user concerns promptly, even if the interaction appears incomplete. Recognizing this distinction is essential for accurately interpreting dropout rates and evaluating chatbot effectiveness.

The AI chatbots reviewed here comprised various therapeutic approaches. The incorporation of established psychological treatment techniques such as cognitive behavioral therapy, mindfulness, and dialectical behavior therapy into AI chatbots represents a novel approach to delivering psychological health interventions. This approach is considered novel because it uses AI to deliver evidence-based psychological techniques 24/7, serve multiple users simultaneously, tailor interventions based on individual responses, and combine various therapeutic modalities on a single platform.

This multidisciplinary therapeutic approach has the potential to address health professionals' diverse psychological needs [31]. AI chatbot interventions are characterized by a digital and responsive design, which allows for integrating practical tools such as stress management techniques, mood tracking, and personalized goal setting [39]. These features align with the immediate and personalized support often required by health professionals. However, while personalization is a key advantage of AI chatbots, a need also exists for some level of standardization to ensure the interventions' quality and effectiveness [40]. This standardization should focus on establishing evidence-based core components and assessment methods while still allowing for personalized delivery [31]. Future research should focus on identifying the most effective components of these chatbots and tailoring them to the specific psychological health needs of health professionals while maintaining a balance between standardization and personalization.

In this study, a temporary increase in depression scores was observed in one study [20], whereas previous research has reported AI chatbots' positive effects in reducing anxiety, depression, and work-related burnout among health professionals [41]. These contrasting findings may reflect the challenges faced by such professionals, who frequently experience high levels of stress and emotional demands [42]. This suggests the complexity of psychological interventions and highlights the importance of careful monitoring to determine the appropriate duration and intensity of chatbot use.

Some studies in our review demonstrated the potential of AI chatbots to act as first-line responders in identifying and managing mental health crises. Prior research has also shown the potential benefits of AI chatbots not only in improving mental and emotional well-being but also in promoting behavioral changes [43]. While these features may only benefit a subset of users, their impact on preventing escalation to severe mental health conditions or emergencies is invaluable. Future research should prioritize the integration and evaluation of these features to enhance the safety and efficacy of chatbot interventions.

Although AI chatbots address the unique time constraints and stress among health professionals, balancing automated responses with genuine therapeutic interactions remains a significant challenge. Personalization technologies that provide tailored features to AI chatbots have emerged as key factors in their effectiveness, with studies reporting increased user engagement and satisfaction through customized responses and immediate support [29]. Consequently, the development of tailored intervention strategies that consider the individual needs and preferences of health professionals is essential to maximize AI chatbots' effectiveness. These strategies should integrate ongoing user feedback and dynamically adapt interventions to maintain long-term user engagement and effectiveness. Future research should focus on larger sample sizes, extended follow-up periods, and diverse health care professional groups of health professionals. Such comprehensive studies will play a crucial role in developing evidence-based guidelines for implementing AI chatbots in psychological health and in advancing the sophistication of personalization algorithms.

Limitations

This scoping review has several limitations. First, the limited number of studies adopting diverse study designs and using various AI algorithms complicated making direct comparisons among the retrieved studies. Second, the findings' generalizability is restricted because many studies were published in specific regions, particularly high-income countries. Additionally, the short duration of many interventions and limited follow-up periods make it difficult to evaluate the long-term effectiveness and sustainability of AI chatbots. Future research should address these limitations by conducting more rigorous trials, standardizing the outcome measures, and exploring the long-term applications of AI chatbots across diverse populations and settings.

Conclusions

This scoping review explored the current state of AI chatbots aimed at supporting the psychological health of health professionals. Although the reviewed studies demonstrated AI chatbots' potential to reduce stress, anxiety, depression, and burnout, research in this area remains in its early stages. The diversity of study design, AI algorithms, therapeutic approaches, and outcome measures highlights this field's innovative but fragmented nature.

Despite promising results, particularly with NLP-based chatbots, a significant need exists for more rigorous and standardized studies to fully evaluate their clinical efficacy. Challenges such as usability issues and limited generalizability of the findings must be addressed to enhance the long-term application and effectiveness of AI chatbots in real-world settings. Future research should focus on refining chatbot designs, expanding the research to diverse populations, and conducting long-term studies to clarify the role of AI chatbots in supporting the psychological health of health professionals. Thus, AI chatbots could become a valuable solution for addressing the

psychological health challenges faced by health professionals worldwide.

Abstract

Background: Antimicrobial resistances pose significant challenges in health care systems. Clinical decision support systems (CDSSs) represent a potential strategy for promoting a more targeted and guideline-based use of antibiotics. The integration of artificial intelligence (AI) into these systems has the potential to support physicians in selecting the most effective drug therapy for a given patient.

Objective: This study aimed to analyze the feasibility of an AI-based CDSS pilot version for antibiotic therapy in sepsis patients and identify facilitating and inhibiting conditions for its implementation in intensive care medicine.

Methods: The evaluation was conducted in 2 steps, using a qualitative methodology. Initially, expert interviews were conducted, in which intensive care physicians were asked to assess the AI-based recommendations for antibiotic therapy in terms of plausibility, layout, and design. Subsequently, focus group interviews were conducted to examine the technology acceptance of the AI-based CDSS. The interviews were anonymized and evaluated using content analysis.

Results: In terms of the feasibility, barriers included variability in previous antibiotic administration practices, which affected the predictive ability of AI recommendations, and the increased effort required to justify deviations from these recommendations. Physicians' confidence in accepting or rejecting recommendations depended on their level of professional experience. The ability to re-evaluate CDSS recommendations and an intuitive, user-friendly system design were identified as factors that enhanced acceptance and usability. Overall, barriers included low levels of digitization in clinical practice, limited availability of cross-sectoral data, and negative previous experiences with CDSSs. Conversely, facilitators to CDSS implementation were potential time savings, physicians' openness to adopting new technologies, and positive previous experiences.

Conclusions: Early integration of users is beneficial for both the identification of relevant context factors and the further development of an effective CDSS. Overall, the potential of AI-based CDSSs is offset by inhibiting contextual conditions that impede its acceptance and implementation. The advancement of AI-based CDSSs and the mitigation of these inhibiting conditions are crucial for the realization of its full potential.

Introduction

Sepsis infections caused by pathogens with antimicrobial resistance (AMR) represent a significant global challenge in health care [1,2]. In 2017, there were 48.9 million new cases of sepsis and 11 million deaths related to sepsis, accounting for 19.7% of all global deaths [3]. In Germany, sepsis incidence increased by an average of 5.7% per year, from 280 cases in 2010 to 370 cases in 2015 per 100,000 individuals [4]. A recent meta-analysis indicated that the 30-day mortality rate for sepsis in Germany was estimated to be 26.5%, which is consistent with the observed rates in North America and Europe [5]. Furthermore, over 1.27 million deaths per year are attributed to AMR worldwide. In 2019, there were 9650 deaths attributable to AMR (mortality rate of 5 per 100,000) and 45,700 deaths associated with AMR (mortality rate of 22 per 100,000) in Germany [6]. Recent data from Germany show heterogeneous trends in AMR proportions of infected patients underscoring the urgent need for enhanced infection prevention measures to limit AMR spread [7]. Inappropriate antibiotic prescribing represents a significant contributing factor [8]. In particular, the prolonged or improper use of nonspecific, broad-spectrum antibiotics is highly problematic, as these antibiotics provide symptomatic relief but also facilitate the development of resistance in other bacteria [9,10].

Clinical decision support systems (CDSSs) provide a solution for promoting targeted and guideline-based antibiotic prescribing [11-13]. CDSSs adopt a variety of forms and are integrated into routine practice. Despite their diverse nature, they share a common objective: to assist medical professionals in identifying the most appropriate form of therapy for each patient, based on existing data and established guidelines, through the use of programmed algorithms or artificial intelligence (AI) [14,15]. In the context of CDSSs, previous studies have demonstrated a decrease in antibiotic prescription rates, more rapid initiation of appropriate antibiotic therapy for patients, and improved clinical outcomes, such as reduced mortality, increased antibiotic-free days, and fewer medical complications [16-19]. However, CDSSs do not always improve clinical practice [20]. For example, there is still insufficient evidence to conclusively show positive effects on therapy duration, dosage, or adherence to clinical guidelines [11,16,21].

Despite the growing body of research on AI-based CDSSs in intensive care units (ICUs) [22,23], there is a notable gap in the implementation of AI tools in routine care in general [24] and the availability of AI-based CDSSs for sepsis in the German health care system. The KINBIOTICS (translated as “AI-based decision support for antibiotic therapy”) project, funded by the German Federal Ministry of Health, aimed to train AI-based algorithms and improve the prediction of suitable antibiotics for sepsis infections on the basis of a comprehensive data set. In addition to the development of an AI-based CDSS, a cross-sectoral resistance observatory and a new rapid test for sequencing the antibiotic genome were developed [25].

Engaging clinicians in the design and development of CDSSs is often suggested as a strategy to enhance the alignment between the system and the needs of its users [26-28]. Interviews and expert groups are approaches used for preimplementation clinician involvement [29]. Insights into clinicians’ views provide valuable information on the barriers and facilitators that affect their willingness to adopt and use CDSSs in practice [30]. By examining clinicians’ perceptions, the study seeks to inform targeted strategies to improve the CDSS’s design, usability, and relevance, thereby promoting more effective and widespread adoption in clinical practice.

This study aimed to perform a use case analysis of a pilot version of the AI-based CDSS within an ICU setting. The objective was to analyze the clinical decision-making processes, and adopt a more comprehensive perspective on the factors that facilitate or hinder the future implementation of such a system.

Methods

Reporting is based on the Standards for Reporting Qualitative Research (SRQR) [31]. The SRQR checklist is provided in Multimedia Appendix 1.

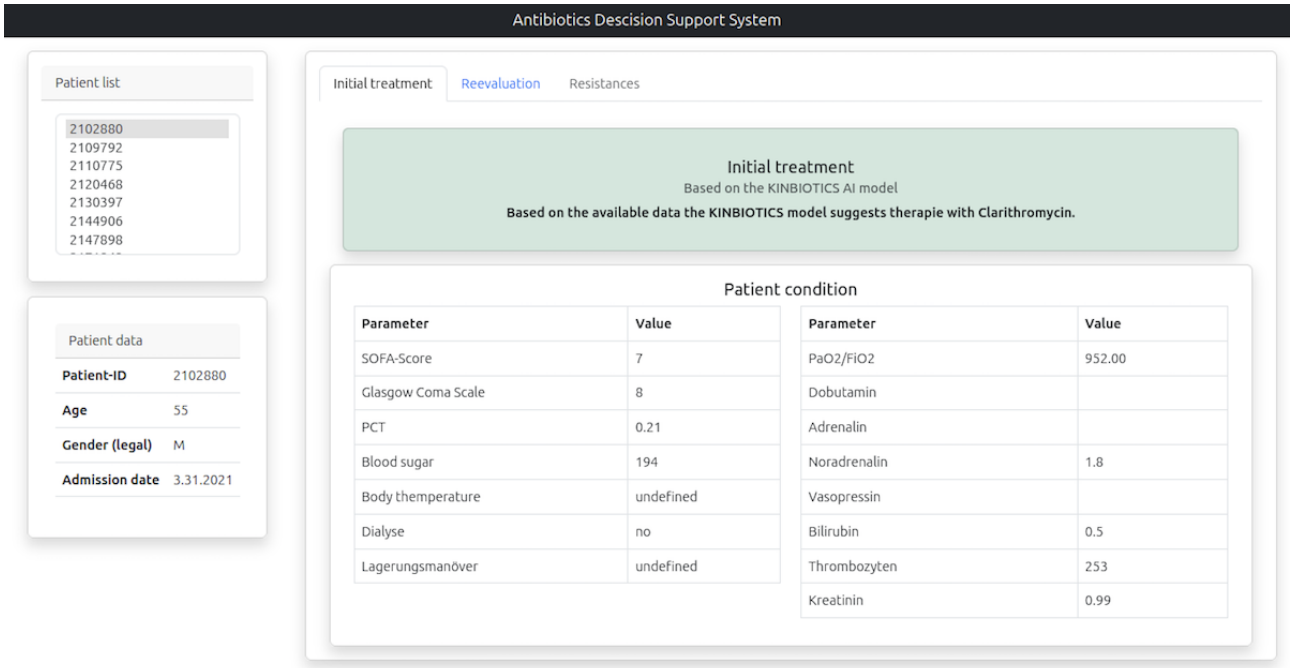
Study Design and Setting

A 2-stage base model (random forest at both stages) was developed for the initial therapy using patient data, laboratory data, and clinical data. Subsequently, the model was optimized using a variety of parameters, including the number of decision trees and tree depth (the model specifications and results will be published separately once the AI-based CDSS model has been finalized). The developed model was trained and tested on data from 1 of the 3 participating clinics and then evaluated for robustness using data from a second clinic. Although the performance of the underlying AI model was insufficient in terms of accuracy, specificity and sensitivity at the time of the evaluation, it was crucial at this time to gain insights into the decision-making mechanisms of the physicians. This was undertaken in order to scrutinize the variables included in the initial model and, where necessary, to supplement or adjust them. Accordingly, the preliminary prototype was not modified during the interview phase. However, subsequent to the interviews, the model underwent alterations and is still under development.

The pilot version of the AI-based CDSS was evaluated in a 2-stage semistructured qualitative process [32]. With regard to feasibility, physicians were each shown 5 exemplary sepsis patient cases in a desktop version of the CDSS. Cases were selected randomly from the evaluation dataset and were identical for each interviewee. In addition to basic patient information, this contained relevant vital parameters, and the treatment recommendation determined by the AI-based CDSS (Figure 1). This antibiotic therapy recommendation was presented to the physicians both for the admission situation to the ICU (initial treatment; the start of antibiotic therapy) and for a possible therapy correction at the time the microbiological findings were available (re-evaluation; usually 48-72 hours after start of antibiotic therapy). The physicians were informed during the individual interviews that the CDSS is still in a pilot status and that the recommendations are likely not yet reliable. The physicians were asked to assess and evaluate the intensive care situation at both time points as well as the AI-based model

recommendation for antibiotic therapy. In addition to the plausibility of the content of the therapy recommendations, the design and layout of the pilot version were evaluated.

Figure 1. Screenshot of the pilot version of the artificial intelligence–based clinical decision support system.



Following the individual interviews, physicians from each clinic were interviewed again as part of a focus group interview. The theoretical focus here was on technology acceptance of AI-based CDSSs and the identification of challenges and conductive conditions with regard to future implementation.

Expert Selection

Expert interviews were conducted with intensive care physicians from the 3 clinical centers involved in the project at the University Medical Center East Westphalia-Lippe. The interviews were conducted on a voluntary basis and the potential participants were selected by the respective project partners in the 3 clinical centers.

Data Collection

Between October and November 2023, the face-to-face expert interviews and focus groups were conducted. The interview guideline (Textbox 1) for the focus group interviews was developed on the basis of the extended Unified Theory of Acceptance and Use of Technology (UTAUT 2) [33,34]. The UTAUT has recently being used to explain technology adoption among health care practitioners' intention to use AI-based CDSSs [35].

Textbox 1. Interview guideline for the focus groups (based on the Unified Theory of Acceptance and Use of Technology 2).

- Opening question
- What were the objectives of today's meeting?
- Questions about the tool
- Please describe your impressions of the KINBIOTICS user interface.
- What information may have been lacking in your medical decision-making process that led to the prescription of antibiotics?
- Please indicate which aspects you consider to be beneficial for a potential application.
- What additional functions would be beneficial to include in the KINBIOTICS user interface to ensure effective utilization in routine clinical practice?
- Questions regarding the use of artificial intelligence (AI) in general
- To what extent do digital tools contribute to the processes undertaken in your day-to-day work?
- Please indicate which digital applications you currently use in your professional activities.
- Please indicate which digital health applications you use in your private life.
- Please indicate your opinion on the utilization of AI, and provide your expectations regarding the implementation of AI in healthcare, both in general and on your ward.
- Please describe your previous experience of contact with AI and clinical decision support systems.
- What is the prevailing attitude in your clinical setting, on the ward and among your professional colleagues with regard to the utilization of artificial intelligence in everyday medical procedures?
- In the hypothetical scenario of utilizing such a tool like KINBIOTICS in tomorrow's clinical decision-making process, what potential challenges might be identified?
- Questions about future utilization of a clinical decision support system
- Please describe the benefits you perceive in the utilization of AI and clinical decision support systems in your everyday professional practice.
- In order to apply such a system in medical decision-making, what prerequisites must be met?
- Please indicate whether you identify any additional aspects that should be addressed for use in everyday clinical practice.

The interviews were recorded by audio and subsequently transcribed. After complete transcription, the audio recordings were irrevocably deleted in accordance with the data protection policy.

Data Analysis

The data analysis of the transcribed interview material was conducted deductively and inductively based on categories according to Kuckartz (2018) [36]. The procedure for the individual interviews primarily followed evaluative content analysis, while the focus groups were analyzed in terms of content structure. To gain as much knowledge as possible, the transcripts of the individual interviews were also analyzed with regard to possible content-structuring findings. The transcripts were analyzed anonymously using the qualitative analysis software MAXQDA (version 2022, VERBI) [37]. The interview analyses and category assignment were carried out independently by 2 researchers (JAD and MK). In the case of discrepancies, a third researcher (DL) was consulted. Categories were adapted or reformulated by the interdisciplinary research team (JAD, MK, DL, SE, and WG).

Ethical Considerations

Informed consent was obtained before the interviews. A positive ethics vote (November 22, 2021) from the ethics committee of the Medical Association of Westphalia-Lippe and the Westphalian Wilhelms University of Münster was received for the entire project (No. 2021-699-f-S). The interview transcripts were anonymized. The interviewees did not receive any compensation; participation was on a voluntary basis.

Results

Sample

A total of 19 individual interviews and 3 focus group interviews were conducted. The distribution of respondents with regard to gender, age, and professional experience was relatively balanced, with 10 (53%) of the respondents identifying as male. In each case, 7 (37%) respondents were aged 30-40 years, and 40-50 years. In total, 5 (26%) respondents had less than 5 years or 11 - 20 years of professional experience, 4 (21%) had between 5 and 10 years, and 3 (16%) respondents indicated that they had more than 20 years of professional medical experience. The duration of the expert interviews ranged from 17 to 43

minutes, while the average duration of the focus group interviews was 1 hour.

Feasibility of the AI-Based Clinical Decision Support System

The approval or rejection of the AI-based antibiotic recommendations was heterogeneous and primarily dependent on 2 factors: first, the plausibility of the AI-based individual therapy (change) recommendations (refer to quotes 1 and 2). It should be noted that not every detailed recommendation was already plausible or medically advisable due to the pilot status of the CDSS respective example cases.

> ***Quote 1:****The system now suggests piperacillin/tazobactam. Of course, this is a very far-fetched suggestion for primary antibiotics when it comes to designing a calculated antibiotic therapy. For me, this would not be the first drug of choice for patients who arrive at the hospital as primary patients, who have been treatment-naïve so far and have not yet received antibiotic therapy [...].* [Expert 5, Clinical Center 3]

> ***Quote 2:****So, [piperacillin/tazobactam]. Well, difficult [...] with a completely normal PCT [Procalcitonin], I would find it difficult [...] to start directly with such a broad antibiotic.* [Expert 8, Clinical Center 2]

> ***Quote 3:****[...] So, [...] such a recommendation, I'm very sure, will be malpractice in the next three to five years [...]. This reflects the reality, but this is the worst thing that can happen, to treat a Staphylococcus aureus bacteremia with [piperacillin/tazobactam], that is an absolute no-go.* [Expert 4, Clinical Center 1]

Second, the evaluation of the recommendations is dependent upon the level of professional experience (quote 3). Accordingly, the more advanced the professional experience, the more confident a recommendation was to be approved or rejected. However, the data indicate that the majority of respondents expressed consensus regarding the CDSS recommendation in each case study (Table 1).

Table . Assessments of the experts surveyed on the feasibility of the pilot version of the artificial intelligence–based clinical decision support system (N=19).

	CDSS recommendation for initial treatment		CDSS recommendation for re-evaluation	
	Agreeing with the recommendation, n (%)	Rejecting the recommendation, n (%)	Agreeing with the recommendation, n (%)	Rejecting the recommendation, n (%)
Use case 1	14 (78)	4 (22)	12 (67)	6 (33)
Use case 2	11 (61)	7 (39)	1 (5)	18 (95)
Use case 3	3 (16)	16 (84)	2 (11)	16 (89)
Use case 4	15 (83)	3 (17)	14 (78)	4 (22)
Use case 5	13 (76)	4 (24)	12 (71)	5 (29)

A suggestion was made that the pilot CDSS should be expanded to include the integration of combination therapies. The vital parameters and patient information should be included as variables in the statistical model for predicting therapy to include the suspected focus of infection. In addition, it was noted that the data provided for the development of the model and the case studies in the pilot version were incomplete in many instances (Table 1). The physicians encountered significant challenges in evaluating the CDSS recommendation when the fields for data that could be viewed in the application were left empty (quote 4).

> ***Quote 4:****Here again the PCT [Procalcitonin] is missing, that would make it easier for us. We only have [...] indirect information that we have an infection here [...] measured by the thrombocytopenia, and then [...] I can get along with actually using piperacillin and tazobactam primarily here when it comes to the calculated antibiotic therapy [...].* [Expert 5, Clinical Center 3]

> ***Quote 5:****The [application] is more explanatory than my phone. So, everything is fine in that respect.* [Expert 3, Clinical Center 3]

From the physicians' perspective, the primary factor influencing the acceptance of the AI-based CDSS was the time required for completion of the process. If the system is able to produce an evident medication recommendation in a shorter time than the physicians can achieve, a high willingness to use it was reported. There was unanimous feedback that the design and layout of the CDSS are pleasant and easy to understand (quote 5). Furthermore, the majority of respondents indicated a preference for a mobile version of the system for use in everyday clinical practice. This preference was again justified by the availability of digital resources.

Facilitating and Inhibiting Factors for the Implementation of an AI-Based Clinical Decision Support Systems

The focus group interviews showed that while there is already strong foundational support for digital tools and applications in diagnostics and therapy as part of routine clinical practice, the use of more advanced applications, especially those based on AI, was limited to isolated cases and primarily on a project basis. Previous experiences with CDSSs had a significant impact on expectations regarding the quality of the CDSS, the effort required for integration into everyday medical practice, and the intention to potentially use such a system (quotes 6 and 7).

> ***Quote 6:****I'm thinking about the echocardiography, [...] where the AI has become so good that we let it*

take over. We do the examination ourselves. And yet the module helps us with that. That's how I imagine it [here] too. [Expert 2, focus group 2]

Quote 7:*Yes, for the colonoscopy [...] we once had [a CDSS]. But the human was faster than the AI. So in that respect [...] rather not.* [Expert 3, focus group 3]

Nevertheless, the majority of respondents indicated a high level of willingness to adopt AI-based CDSSs (quotes 8 and 9). The option of re-evaluation included in the application was considered to be particularly beneficial.

Quote 8:*I actually found the idea compelling. Because in the early days of my clinical work, even more so than now, the question always arises: am I doing it right now?* [Expert 1, focus group 2]

Quote 9:*[T]he field is so complex [...] that's why I think a support tool that works well is very helpful.* [Expert 3, focus group 1]

As previously noted, the acceptance and implementation of digital solutions is largely dependent on the amount of time available. In addition, the majority of respondents indicated that they are consistently seeking tools that facilitate efficient support in routine clinical practice. Consequently, the respondents exhibited an intrinsic motivation to use CDSSs, which was observed across all age groups and genders, but was particularly pronounced in the "30 - 40 years" and "40 - 50 years" age groups.

In contrast with the physician's technology openness as a beneficial factor, the level of digitization in the clinics was found to be heterogeneous. Furthermore, the physicians' assessment indicated that there was significant potential for improvement in all 3 hospitals (quote 10). The statements indicated that the level of digital infrastructure, including stable internet coverage, exhibited considerable variation not only between the clinics but also between individual wards within the clinics. Overall, there was a consensus that better equipment in terms of digital devices and applications was needed (quote 11). The lack of comprehensive digital and cross-sectoral availability of relevant patient health information was also identified as a barrier to the implementation of AI-based CDSSs and efficient medical treatment in general. This demonstrated that the degree of digitization in everyday clinical practice affects the perceived feasibility of implementing the CDSS and is the most significant barrier to the beneficial factors.

Quote 10:*So, it's really funny that you can still secure good pens. Because we do so much paper based.* [Expert 2, focus group 2]

Quote 11:*The problem is that there are far too many individual components that all [...] communicate with each other via interfaces. And in the process, values are lost or the data transfer doesn't work. And then you end up standing there and yes, the computer hangs.* [Expert 4, focus group 2]

Furthermore, the existing data basis for the AI-based CDSS model was identified as a significant challenge. The participants were aware that, in addition to the aforementioned lack of digitized patient information, the heterogeneous quality of previous antibiotic administration practice also had an influence on the predictive ability of the recommendation from the CDSS. Furthermore, an increased documentation and justification effort in the event of potential deviation from the CDSS recommendation was also seen as a barrier. However, all participants were aware that such a system would be implemented as a supportive and not a replacement measure, and this was not criticized.

Two relevant recommendations for improvement were derived from the interviews. First, the majority of respondents indicated that applicable guidelines on antibiotic therapy should be incorporated into the specification of the underlying statistical models. Second, there was a recurring suggestion that, alongside the further development of the presented system, the capability to diagnose sepsis infections should also be integrated into a CDSS. Once again, the time to correct diagnosis and subsequent appropriate treatment was identified as the main driver. Suggestions for adapting the tested CDSS comprised the inclusion of quantities and suggestions for the duration of antibiotic administration, in addition to the therapeutic agents themselves (quote 12).

Quote 12:*So, in an ideal world, [...] [AI] can be a huge step forward as a decision-making tool. But [A] the right information has to flow in. And [B] the decisive recommendation [...] is already anticipated here [...]. So, the first step: can this be sepsis? That is an important step. [...] In the second step, a recommendation for initial therapy is helpful [...], yes.* [Expert 4, focus group 1]

Discussion

Principal Findings

Overall, this use case analysis shows various barriers and facilitators for the implementation of AI-based CDSSs for antibiotic therapy in sepsis (Textbox 2). The findings of the expert and focus group interviews indicate that the potential of digitization and, in particular, AI-based tools is expected and viewed in a favorable light by the majority of the physicians. This finding is in line with other research which indicates that clinicians have a predominantly positive perception of AI systems [38-40]. Similarly, the willingness to use these tools is high [41]. In this context, the plausibility of the prediction and the potential time savings are of particular importance. It is evident that the existing contextual conditions represent the most significant obstacle to future implementation. In addition to the basic technical equipment in the clinics, other factors, such as a stable, comprehensive internet supply and the necessary digital availability of data, were also identified as potential barriers to future implementation. Accordingly, the question arises as to what extent clinics are equipped with the digital infrastructure to fully leverage the benefits of AI-based CDSSs. At this point it has to be noted that the digital maturity of German hospitals appears to be comparatively limited [42]. This can be attributed, at least in part, to a lack of financial resources [24,43]. It remains to be seen to what extent hospitals use the transformation fund provided by the German Hospital

Future Act and how this can enhance the conditions for the implementation of AI systems.

Textbox 2. Summary of barriers, facilitators, and recommendations for artificial intelligence–based clinical decision support systems' feasibility and implementation.

Barriers

- Overall
- Low degree of digitization in everyday clinical practice.
- Lack of comprehensive digital and cross-sectoral data availability.
- Negative previous experiences with clinical decision support systems.
- Use Cases
- Heterogeneous quality of previous antibiotic administration practice limits predictive ability of the artificial intelligence–based recommendations.
- Increased effort to document and justify potential deviations from the clinical decision support system's recommendation.
- The confidence to approve or reject artificial intelligence–based antibiotic recommendations depends on the level of professional experience.

Facilitators

- Overall
- Potential time savings.
- Physician's technology openness or intrinsic motivation.
- Positive previous experiences with clinical decision support systems.
- Use Cases
- Re-evaluation of clinical decision support system recommendations is considered to be particularly beneficial.
- Pleasant design and layout of the clinical decision support system (easy to understand).

Recommendations

- Incorporation of guidelines on antibiotic therapy into the specification of the statistical models.
- Clinical decision support systems should include the integration of combination therapies.
- Statistical model for predicting antibiotic recommendations should include vital parameters and further patient information to identify the suspected focus of infection.
- Besides sepsis treatment, the capability to diagnose sepsis infections should also be integrated into a clinical decision support system.
- Preference for a mobile version of the clinical decision support system.

The medication recommendations by the CDSS were not yet perceived as reliable due to the limited and biased data available for training the AI system. Often, a very broad standard therapy (piperacillin/tazobactam) was recommended. This was mainly due to the fact that this medication occurred considerably more frequently within the learning data set than all other antibiotics. According to the experts, this approach is not absolutely mandatory and sometimes maybe counterproductive in terms of calculated antibiotic therapy. Younger physicians in particular tended to agree with the recommendations. This is a sign that a CDSS for the most common "standard medication" might not be beneficial if not detrimental. This can be confirmed by the physicians' statements that they would like decision support primarily for medication combinations and for rare antibiotic agents or rare sources of infection. In view of the goal of avoiding the development of resistance by reducing the use of broad-spectrum antibiotics, the current pilot version of the AI system would possibly even promote this risk of further resistance. To avoid this, current guidelines should be incorporated into the model design in addition to retrospective primary data.

The respondents' call for the upstream integration of sepsis diagnostics in addition to the further development of the existing CDSS appears to be purposeful. A recent study has confirmed initial successes in this regard [44]. Although no clear correlations between sociodemographic characteristics and the willingness to use CDSSs were found in the present evaluation, differences in the approval or rejection of the AI-based CDSS recommendations depending on professional experience were identified. This finding is supported by Lambert et al [45]. It is recommended that future studies investigate the degree to which professional experience and other sociodemographic variables exert an influence on technology acceptance and the willingness to use CDSSs. In this regard, using the UTAUT would be appreciated [35].

Generally, the following challenges associated with the use of AI in health care should not be overlooked. For example, automation bias, in which health care providers may develop an overreliance on AI recommendations, potentially reducing their clinical vigilance and leading to oversights in patient care, needs to be considered [46]. Furthermore, AI-driven CDSSs may unintentionally propagate biases present in training datasets, resulting in discriminatory recommendations that may disadvantage certain demographic groups [47]. Another key concern is the ambiguity and complexity of liability; it remains unclear who is legally responsible if an AI-influenced decision contributes to a negative patient outcome [48]. Furthermore, previous research has highlighted the potential negative impact of a lack of user involvement in the development of CDSSs on the willingness to use them, even when the system quality is optimal [26]. One of the key strengths of the study is the early involvement of future users. The participatory approach highlights the need for involvement. Consequently, given the significant lack of engagement with CDSS interventions reported within the literature [49], future studies should consider the involvement of users from the earliest stages of development [26,28,50]. The findings of the present study confirm that in addition to personal factors, the plausibility of the recommendations is the most decisive factor determining the willingness to use the tool [51]. Further development of the pilot version or similar systems is therefore crucial for implementing and exploiting the potential benefits of AI. Furthermore, the feedback from the physicians participating in this study provided valuable insights into additional variables that were subsequently integrated into the further development of the CDSS, following the completion of the interviews.

Limitations

Several limitations must be acknowledged in the evaluation of the use case presented in this study. First, the efficacy of the CDSS was clearly limited due to the rather small amount of data used for training. The findings suggest that the CDSS may offer less benefit for physicians during the initial therapy phase compared with its use in the context of therapy re-evaluation. At this stage, it was not feasible to accurately predict the most appropriate antibiotic, one that would minimize treatment changes and side effects, based on the currently available data. The acceptance of AI-based interventions heavily depends on the plausibility and relevance of therapy recommendations, which ultimately impacts their efficacy. Therefore, further development and refinement of AI-based CDSSs are essential, along with an expansion of the digital data infrastructure.

In addition, it is important to consider that the evaluation was based on a qualitative interview study, which comes with inherent limitations. The voluntary nature of participation may introduce self-selection bias, potentially leading to an overestimation of the participants' openness to technology and their acceptance of AI-based CDSSs. This limitation suggests that the findings may not be fully generalizable to the broader population of health care professionals.

Conclusion

This pilot study of an AI-based CDSS indicates that further development is needed to achieve the original goals of minimizing switches in antibiotic prescriptions and reducing the reliance on broad-spectrum antibiotics. Relying solely on retrospective data from past care practices does not seem to be an effective strategy for meeting these objectives. In addition, it is essential to address the key challenges identified in this study to enable the successful integration of AI into clinical settings. While the respondents generally showed a positive attitude toward the use of AI-based CDSSs, a more comprehensive evaluation of technology acceptance among health care professionals can only be conducted when a version with realistic, guideline-compliant recommendations is available. Early engagement of users in the development process proves beneficial, not only for refining the CDSS but also for fostering acceptance among medical practitioners.

Acknowledgments

The authors would like to thank all members of the KINBIOTICS project and in particular the contact persons at the 3 hospitals (Evangelisches Klinikum Bethel, Klinikum Bielefeld Mitte, and Klinikum Lippe) for their support in conducting the interviews. Special thanks go to all the physicians who took part in the interviews and to Inga Heißenberg, who helped to prepare and conduct the interviews. Furthermore, we would like to thank Dr Timothy Mc Call for his support in translating the original quotations. The KINBIOTICS project was funded by the German Federal Ministry of Health (grant ZMVI1-2520DAT930). The funding organization was not involved in the data collection, evaluation, analysis, or writing of the manuscript.

Conflicts of Interest

Abstract

Background: The integration of collaborative robots (cobots) in industrial settings has the potential to enhance worker safety and efficiency by improving postural control and reducing biomechanical risk. Understanding the specific impacts of varying levels of human-robot collaboration on these factors is crucial for optimizing cobot use.

Objective: This study aims to investigate the biomechanical effects of different levels of human-robot collaboration on postural stability and control during simulated working tasks.

Methods: A total of 14 participants performed simulated cashier working activities under 4 different collaboration modalities, with increasing levels of cobot assistance: full (Fu), half robot touch (HRT), half robot (HRb), and full robot (FRb). Center of pressure trajectories were extracted from 2 force plates' data to calculate 4 posturography parameters—mean distance (MDIST), mean velocity (MVELO), 95% confidence ellipse area (AREA-CE), and sway area (AREA-SW)—which were analyzed to assess the impact of cobot intervention on postural control.

Results: Nonparametric tests showed significance in the effect of the collaboration modalities on the 4 analyzed parameters. Post hoc tests revealed that FRb modality led to the greatest enhancement in postural stability, with a reduction in MDIST (4.2, SD 1.3 cm in Fu vs 1.6, SD 0.5 cm in FRb) and MVELO (16.3, SD 5.2 cm/s in Fu vs 7.9, SD 1.1 cm/s in FRb). AREA-CE and AREA-SW also decreased significantly with higher levels of cobot assistance (AREA-CE: 134, SD 91 cm^2 in Fu vs 22, SD 12 cm^2 in FRb; AREA-SW: 16.2, SD 8.4 cm^2/s in Fu vs 4.0, SD 1.6 cm^2/s in FRb). Complete assistance of the cobot significantly reduced interindividual variability of all center of pressure parameters. In FRb modality, as compared with all other conditions, removing the weight of the object during loading or unloading phases caused a significant decrease in all parameter values.

Conclusions: Increased cobot assistance significantly enhances postural stability and reduces biomechanical load on workers during simulated tasks. Full assistance from cobots, in particular, minimizes postural displacements, indicating more consistent postural control improvements across individuals. However, high levels of cobot intervention also reduced the natural variation in how people balanced themselves. This could potentially lead to discomfort in the long run. Midlevel cobot assistance modalities can thus be considered as a good compromise in reducing biomechanical risks associated with postural stability at the same time granting a satisfactory level of user control.

KEYWORDS

human-robot collaboration; cobot assistance; postural control; biomechanical risk; ergonomics; collaborative robot

Introduction

Industrial manufacturing is transitioning from well-established production procedures toward more flexible and intelligent manufacturing systems (Industry 4.0, as initially described by Kagermann et al [1]). This evolution aims to develop innovative, sustainable solutions that create new business models, improve working conditions, increase plant productivity, and enhance product quality [2]. Robotics plays a crucial role in this context, with industrial robots being widely adopted due to their ability to relieve humans from repetitive, unhealthy, or dangerous tasks [3]. The field of robotics has evolved to not only allow humans to share the same workspace with robots but also use them as assistants, thereby enhancing human-robot collaboration (HRC) [4].

Collaborative robots (cobots) are at the forefront of this revolution, offering increased productivity, flexibility, versatility, and safety compared with traditional industrial robots. Cobots are designed to work alongside humans, sharing the same workspace without the need for safety cages and

providing greater mobility and flexibility [5]. The integration of cobots in industrial environments has been shown to significantly enhance operational efficiency [6] and worker satisfaction by enabling safer and more ergonomic working conditions [7,8]. However, the integration of cobots impacts various human factors, which include psychological aspects [9], emotions [10], and biomechanical effects [11]. Consequently, it is important to consider both cognitive ergonomics and biomechanical safety to optimize the overall effectiveness and well-being of human workers [12]. For instance, Gualtieri et al [13] have investigated the cognitive elements involved in human interaction with cobots, revealing significant insights into how mental workload and task complexity can affect worker performance and satisfaction [14]. Similarly, improper collaboration with cobots can expose workers to biomechanical risks, even though these robots are intended to alleviate heavy and tedious tasks. Previous research studies [15,16] emphasized the importance of ergonomic considerations in HRC to prevent musculoskeletal disorders (MSDs) among workers.

Thus, the right choice of cobot collaboration modality can reduce biomechanical overload on workers, ensuring their safety.

Recent advancements in sensor technology and data analytics have enabled detailed assessments of human biomechanics during HRC [17,18]. Studies have shown that real-time monitoring and analysis of physiological data can provide valuable insights into the physical strain experienced by workers and help in optimizing collaborative processes [19]. For example, the use of wearable sensors and motion capture systems could effectively measure and analyze the biomechanical load on workers during different collaborative tasks with robots [20]. Other recent studies investigated the effects of different HRC modalities on physiological human parameters such as trunk oscillations [21] and muscle coactivation [22,23]. Such studies can also be profitably taken into consideration for the optimization of workplace design and task allocation.

When work tasks are performed in quasi-static conditions, direct measures of posture could reveal insights into the stability and balance of workers and can thus be used to improve ergonomics during HRC, as they can help identify postural adjustments and biomechanical loads, providing a more comprehensive understanding of HRC ergonomic impact [24].

Following this principle, this study will evaluate and analyze posturography data to assess the biomechanical risks in HRC working contexts where cobots are used in different modalities. Through this evaluation, the study seeks to determine whether cobot assistance can effectively reduce biomechanical risks: by examining how different collaborative modalities influence workers' stability and balance, thus providing insights into the effects of cobot assistance on postural control, as this latter one indirectly reflects safety, efficiency, and ergonomic well-being of human workers in collaborative environments.

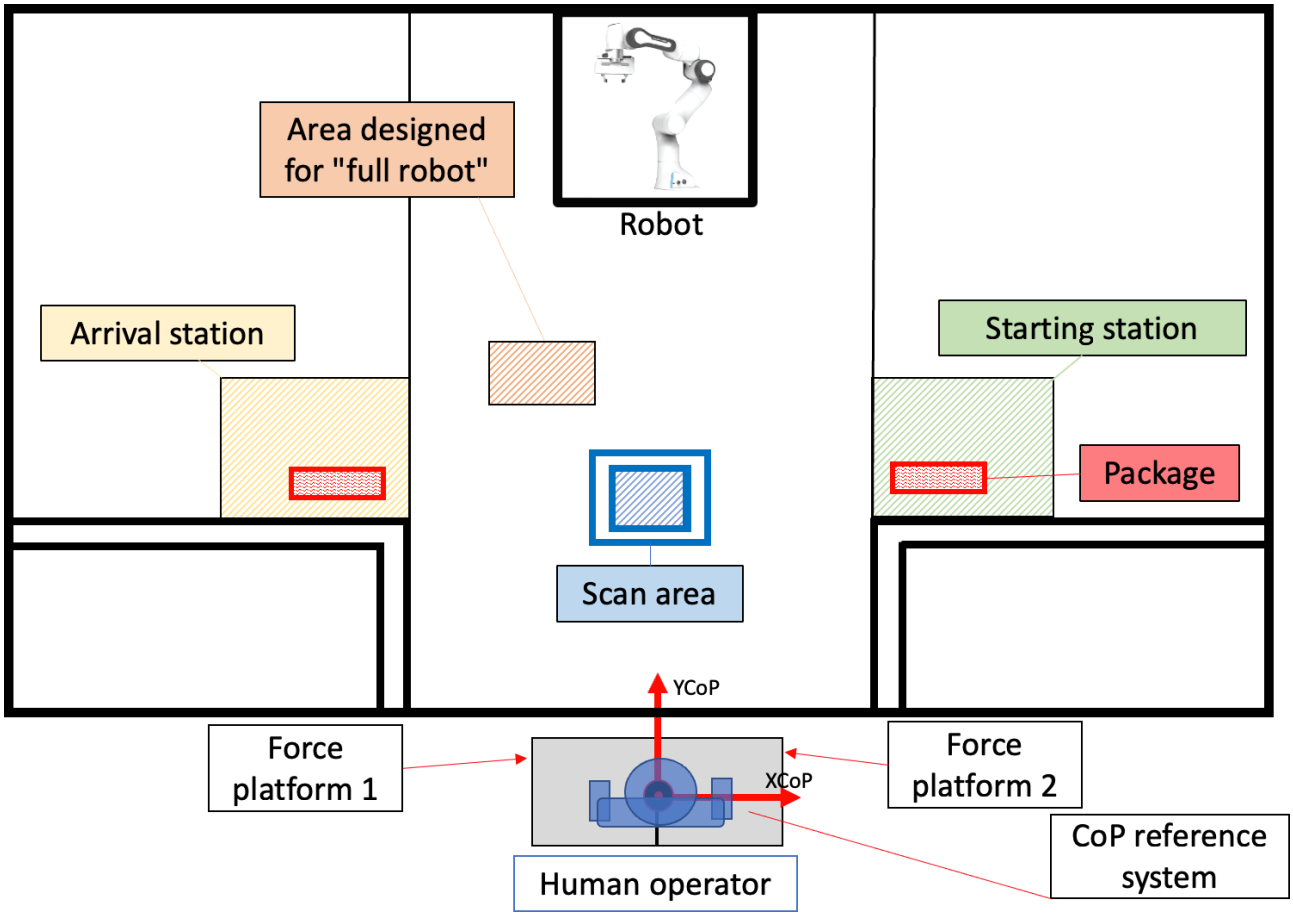
Methods

Experimental Setup

Overview

The setup was designed to compare a simulated work activity performed with and without cobot assistance. A specific workbench was created by positioning the cobot on one of the longer sides of a 2 × 1 m table, with the operator standing upright on the opposite side (Figure 1). The operator's standing position was fixed relative to the edge of the table, defined by the position of his or her feet and the projection onto the ground of the long side of the table. A starting station (ie, the initial position to the right of the operator) and an arrival station (ie, the final position to the left) were defined, each 1m apart from the other and 30 cm away from the operator in the direction of the cobot. A scanning area was defined in the center of the table in front of the operator. This workbench arrangement allowed the operator to perform all the activities (or part of them) independently, while the cobot could collaborate on some or none of the tasks without interfering with the operator's movements. This configuration was defined to minimize possible hindering of the operator's movements.

Figure 1. Experimental setup dimensioning for the simulation of load-moving activities on a workbench. CoP: center of pressure.



The activities involved the handling and relocating of rectangular packages, each measuring 14 × 12 × 5 cm and weighing 1 kg, bearing a QR code on one side.

The tests were conducted with a group of 14 male volunteers aged between 25 and 48 years (weight: 79, SD 7 kg; height: 180, SD 5 cm). All volunteers were healthy and had no evident or declared mobility issues. Moreover, given the design of the setup, only right-handed subjects have been involved in the tests. Participants were instructed to (1) grasp the packages from the starting station, (2) identify the QR code and scan it (ie, facing the QR code to the scan area) in the central area, and then (3) place the package in the arrival station. Different levels of collaboration were implemented by removing the first part of these activities (ie, grasping the package and bringing it to the center of the table) when in partial assistance, and removing also the last part (ie, bringing the package to the arrival station) when in full cobot assistance. Each participant was asked to perform the task as naturally as possible. This task was designed to simulate the work activity of a cashier in a supermarket, a highly relevant example in terms of strenuous activity [25], where an increase in the level of cobot assistance is hypothesized to reduce the associated biomechanical risk.

In the test, each participant performed consecutive repetitions of the same task, for a 5-minute duration, with different levels of cobot assistance.

The frequency of processing (packages per minute [PPM]) to be handled was not defined a priori, and participants were allowed to choose their own pace in performing all the activities. When collaborating with the cobot, the PPM frequency was however influenced by the cobot's package handling activity, as described below.

Each participant was asked to perform the described activity under 4 different collaboration modalities, performed in random order, with a 5-minute break between each test.

Full (Fu)

In this baseline scenario, the operator performs the tasks independently, without cobot collaboration. The operator picks up the package from the starting station with the right hand, examines it with both hands to locate the QR code, brings it close to the scanner simulation area, and finally places the package in the arrival station with the left hand. The processing rate was freely self-selected by each participant.

Half Robot Touch (HRT)

In this condition, the cobot task is to pick up the package from the starting station and wait for the operator to extend their right arm toward the same area, and to touch it to start. When touched, the cobot moves bringing the package in front of the operator who grabs and examines it with both hands to locate the QR code. The operator then brings it close to the scanner simulation area and finally places the package in the arrival station with the left hand. The task is kinematically like the "Full" case, but there is no lifting of the package from the starting station toward the scanning area. Moreover, the operator drives the activation of the cobot with a touch, and therefore the number of PPM is decided by everyone, taking into account the cobot speed.

Half Robot (HRb)

In this modality, the cobot's task is to pick up the package from the starting station and autonomously transport it in front of the operator, who grabs and examines it with both hands to locate the QR code. The operator then brings it close to the scanner simulation area and finally places the package in the arrival station with the left hand. The operator is not required to initially reach the right arm toward the starting station to ask the cobot for help, so the task is different in terms of kinematic features compared with the previous cases. Packages are moved continuously by the cobot while the operator is performing the required tasks, therefore, the cobot determines the number of PPM.

Full Robot (FRb)

In this condition, the cobot's task is to pick up the package from the starting station and autonomously transport it continuously in front of the operator, who grabs and examines it with both hands to locate the QR code. The operator then brings it close to the scanner simulation area and finally places the package in a closer area with respect to the arrival station (Figure 1). Meanwhile, the cobot picks up the package left by the operator and takes it to the arrival station. The cobot intervenes significantly, fully collaborating in the activity. However, the time taken by the cobot to move the packages always exceeds the time that the operator needs to perform the activity. Therefore, the operator must wait for the cobot, and the motor activity is discontinuous, with the number of PPM defined by the cobot kinematics.

Ethical Considerations

The experimental protocol was approved by the Commissione Etica dell'Università degli Studi Roma Tre (BRIC2019-BRISK approval r.01-10/06/2021). Informed consent was obtained from all participants prior to their inclusion in the study, and they were informed of their right to withdraw at any time without consequences. All data collected were anonymized to protect participants' privacy and confidentiality. No personally identifiable information was retained, and strict security measures were implemented to safeguard the data. Participants did not receive any financial or material compensation for their involvement in this study.

Data Acquisition and Processing

To assess the dynamic interaction of the operator with the ground, two 6-component force platforms (BTS P-6000) were positioned under the participants' feet. These platforms allow for measuring the ground reaction of each participant's lower limbs (force and moment components), from which the center of pressure (CoP) position of each foot is extracted during the execution of performed tasks. Data were acquired from force platforms using a sampling frequency of 500Hz (fixed by the HW system). An optoelectronic system (SMART DX 6000, 8 infrared cameras, 2 Mpixel@300 Hz) was employed to segment and identify each task repetition, and each phase of the repetition. Data from the optoelectronic system were acquired using a sampling frequency of 250Hz. Force platforms data were undersampled at 250 Hz to synchronize those with the optoelectronic system ones.

Dynamic Parameters Extraction

Trajectories of the CoP for each of the lower limbs (ie, CoP-right and CoP-left) during the execution of each task were extracted from the force plates data [26]. The total CoP is obtained as the weighted average between CoP-right and CoP-left and its displacement is defined by both the medial-lateral and the anterior-posterior coordinates with respect to a reference system centered between the 2 force plates (Figure 1).

Four CoP-derived parameters were calculated to evaluate the postural stability of the operator and quantify alterations in balance: for each of the collaboration modalities, the mean distance (MDIST), mean velocity (MVELO), 95% confidence ellipse area (AREA-CE), and sway area (AREA-SW) were calculated, according to the definitions reported in [27], for each cycle of the task repetition. For each parameter, mean values (as a measure of central tendency) and SD across repetitions (as a measure of intraindividual variability) were also calculated and underwent inferential statistics.

Cycles were identified using data extracted from motion capture data, which were synchronized with force plate data: in particular, the time location of the maximum excursion to the left in the medio-lateral direction of the marker placed on the right wrist was used to segment each cycle, as it corresponds to the instant when each repetition finishes.

Statistical Analysis

For each CoP-derived parameter thus obtained, the normality of the data, using the Shapiro-Wilk test, was assessed. When all distributions were normal, the homogeneity of the variances was checked with the Leneve test. If these conditions were not satisfied, the Kruskal-Wallis nonparametric test was applied to examine the effect of the collaboration modality. When significant, a post hoc test with a Bonferroni correction was conducted to investigate the differences among the 4 examined collaboration modalities. The α level was set to .05 and .01 (denoted by * and **, respectively).

Results

Rate of Package Processing

The average rate of package processing chosen by the operators in the absence of cobot assistance (Fu) was 15 (IQR 14-16) PPM. The different cobot collaboration modalities yielded median rates of 8 (IQR 7-8.5) for PPM for half robot touch (HRT), 12 (IQR 11.5-13) PPM for half robot (HRb), and 4 (IQR 3.9-4.1) PPM for full robot (FRb).

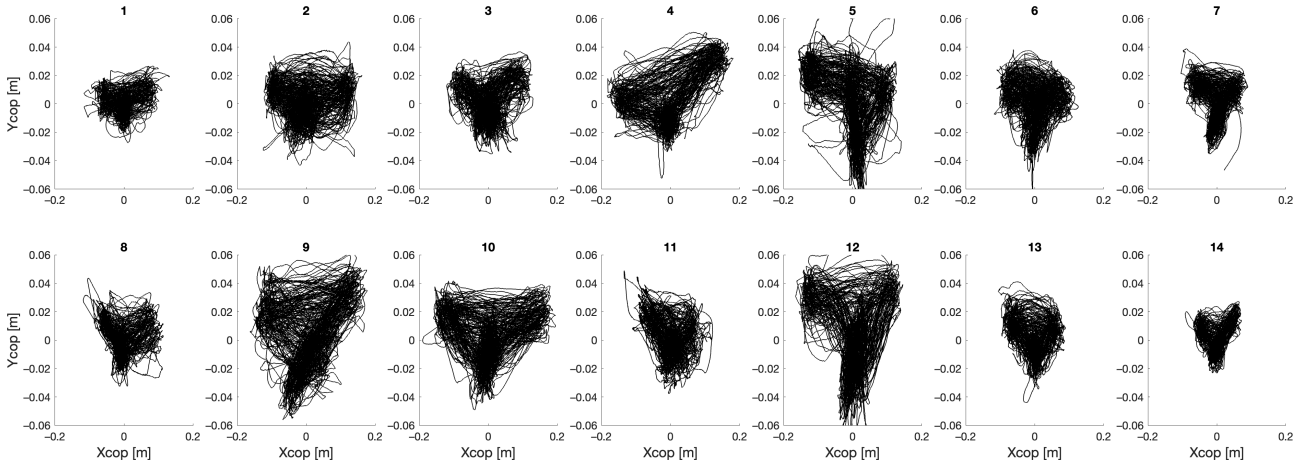
CoP Trajectories

In the following, the different trajectories of the CoP, for all 14 participants and for the 4 different collaboration modalities (ie, full [Fu], HRB, HRb, and FRb) are shown, with Xcop and Ycop denoting respectively the medium-lateral and the antero-posterior coordinate.

Considering the Fu modality (Figure 2), observed CoP paths can be classified into 2 main groups: participants (1,2,3,6,7,8,11,13,14) displayed a compact size of the CoP path, spread in both anterior-posterior (AP) and medial-lateral (ML)

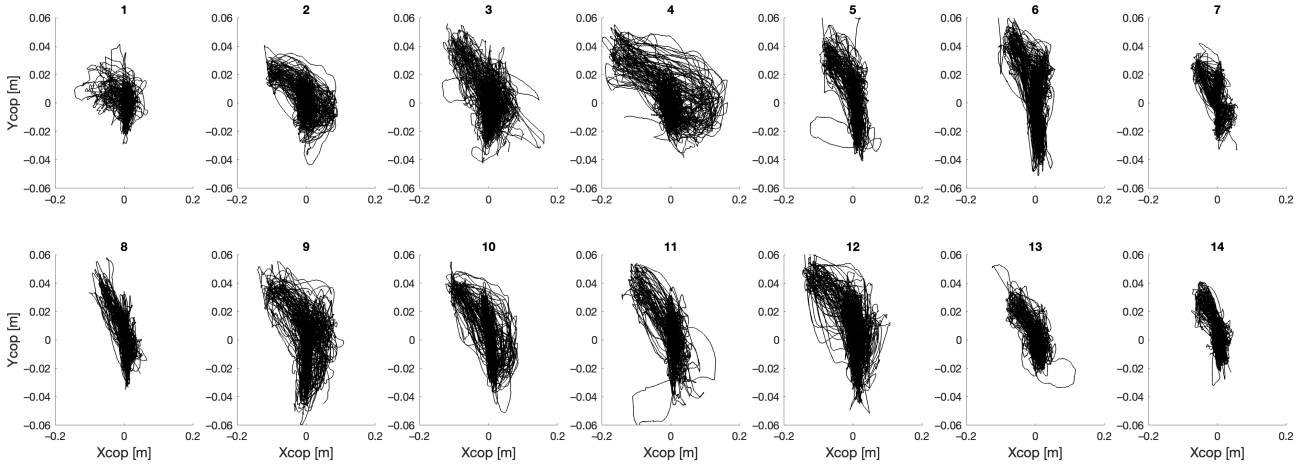
directions, while participants (4,5,9,10,12) drew wider areas, with a remarkable trajectory from the central backward position to the right forward position. However, all the CoP paths present quite diverse behavior, with no visible common aspects. Negative values for Ycop denote backward displacements.

Figure 2. Center of pressure (cop) trajectories for each participant during the full collaboration modality.



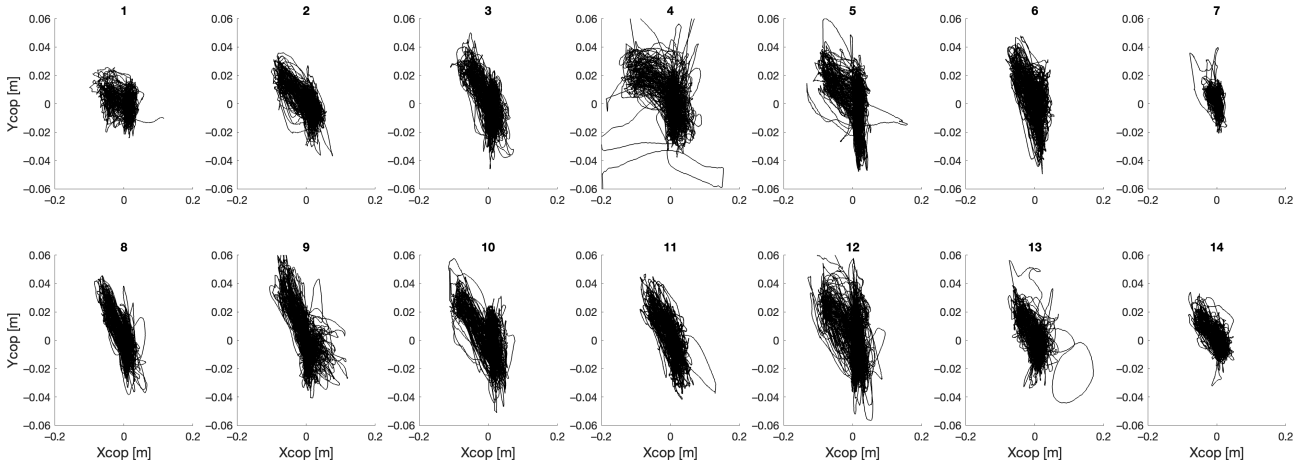
Considering the HRT collaboration modality (Figure 3), CoP path can be classified into 2 main groups also in this case: participants (1,2,7,8,13,14) maintained a compact size of the CoP path, more spread along the AP direction, while participants (3,4,5,6,9,10,11,12) drew a wider area of the CoP path. In this case, all CoP trajectories denoted a bias from the central backward position to the left forward position. Displayed CoP paths still exhibit rather diverse behavior, but with more commonalities as compared with Fu modality.

Figure 3. Center of pressure (cop) trajectories for each participant during the half robot touch collaboration modality.



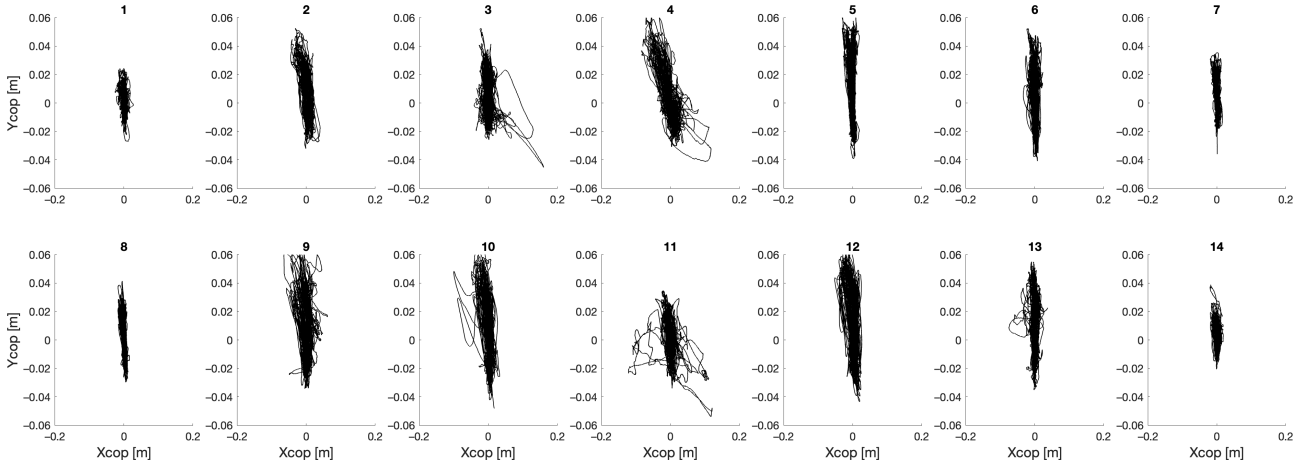
For the HRb collaboration modality (Figure 4), also in this case CoP path can be classified into 2 main groups: for participants (1,2,7,13,14) CoP path was maintained compact, differently from participants (3,4,5,6,8,9,10,11,12), especially considering the AP coordinate. Common behavior of CoP excursion across subjects was instead present along the ML coordinate, while the CoP bias from the central backward position to the left forward position observed in the HRT case is less evident.

Figure 4. Center of pressure (cop) trajectories for each participant under the half robot collaboration modality.



In the FRb collaboration modality (Figure 5), commonalities of CoP behavior are more relevant. While some participants still display lower excursions along the AP direction, the characteristics of CoP trajectories are mostly similar, with no bias both in the right and left forward positions. The amount of excursion in the ML direction is similar across participants.

Figure 5. Center of pressure (cop) trajectories for each participant during the full robot collaboration modality.



Normality Tests

The Shapiro-Wilk test indicated that some conditions of the parameters did not follow a normal distribution. For the MDIST values, a *P* value <.05, indicating rejection of the null hypothesis of normal distribution, was observed for the Fu condition (*P*=.048). In contrast, a normal distribution (*P* value >.05) was found for all the other conditions (HRT: *P*=.44; HRb: *P*=.57; FRb: *P*=.60).

Similar results were obtained for both the AREA-CE and AREA-SW parameters. The Fu condition showed a nonnormal distribution (*P*=.02 for AREA-CE and *P*=.04 for AREA-SW), while all other conditions were normally distributed (for AREA-CE: HRT, *P*=.18; HRb, *P*=.25; FRb, *P*=.33; for AREA-SW: HRT, *P*=.08; HRb, *P*=.86; FRb, *P*=.25).

Since at least 1 of the distributions for each parameter was not normal, nonparametric statistical analyses were applied.

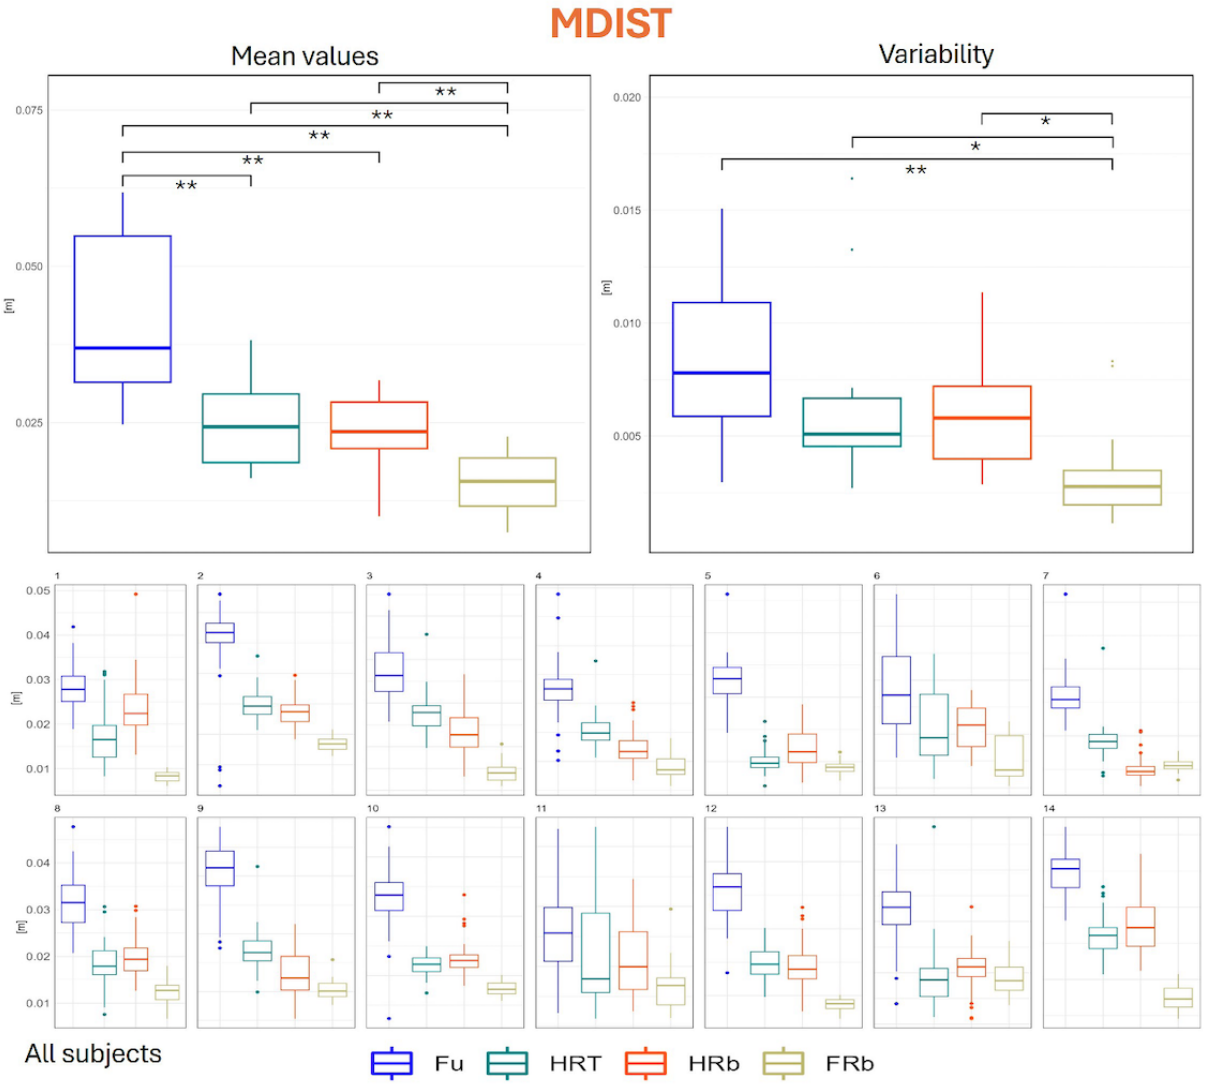
For the MVELO parameter, data were normally distributed across all conditions. However, Levene test revealed that the variances among the different conditions were not homogeneous (*P* value <.05). Consequently, a nonparametric test was also used for this parameter.

CoP-Derived Parameters

Descriptive statistics at the individual level, and descriptive and inferential statistics at the group level for MDIST, MVELO, AREA-CE, and AREA-SW, as obtained across the 4 collaboration modalities, are given in the following figures.

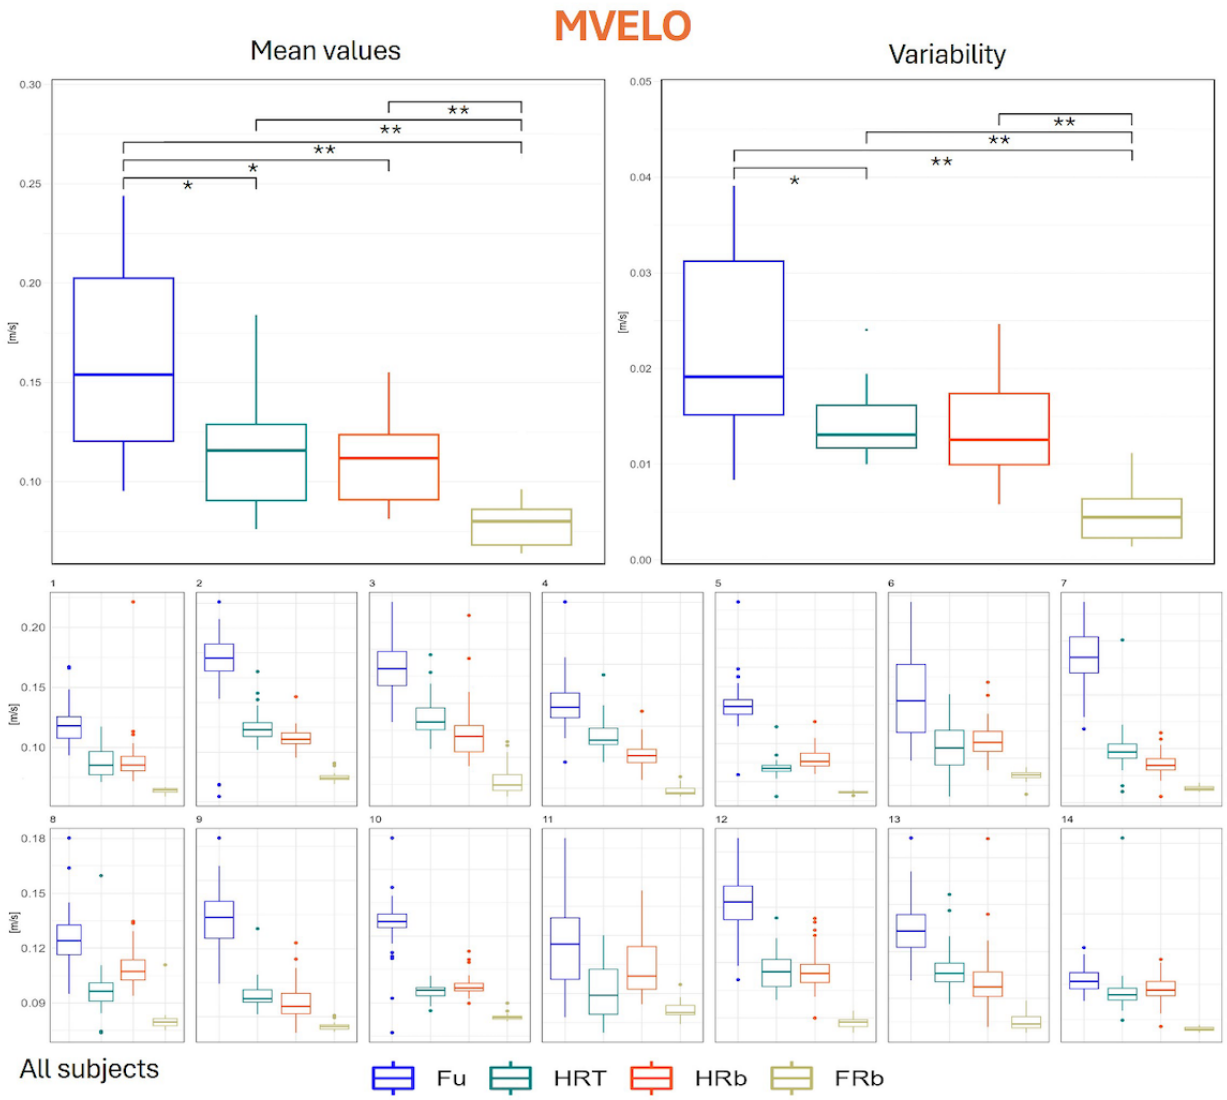
MDIST, an overall measure of excursion of the CoP from its equilibrium position, was clearly and significantly higher in Fu condition (4.21, SD 1.30 cm) than in all other conditions, and this was confirmed also at the individual level for almost every participant. In addition, as shown in Figure 6, FRb condition caused significantly lower values (1.55, SD 0.50 cm) than both HRT (2.50, SD 0.67 cm) and HRb (2.38, SD 0.59 cm), and this appeared also in all individuals but 2. No significant difference was observed between HRT and HRb conditions, as the result of different behavior across participants. Regarding intraindividual variability, we observed a reduced variability of MDIST across most participants in FRb condition (0.34, SD 0.22 cm) as compared with HRb (0.59, SD 0.23 cm), HRT (0.65, SD 0.37 cm), and Fu (0.85, SD 0.36 cm).

Figure 6. Distribution of MDIST values. Upper panel, left: group mean values across the 4 collaboration modalities; upper panel, right: distribution of intraindividual variability (SD across repetitions); lower panels: distribution of values for each participant. * denotes $P<.05$ as obtained from inferential statistics; ** denotes $P<.01$ as obtained from inferential statistics. FRb: full robot; Fu: full; HRb: half robot; HRT: half robot touch; MDIST: mean distance.



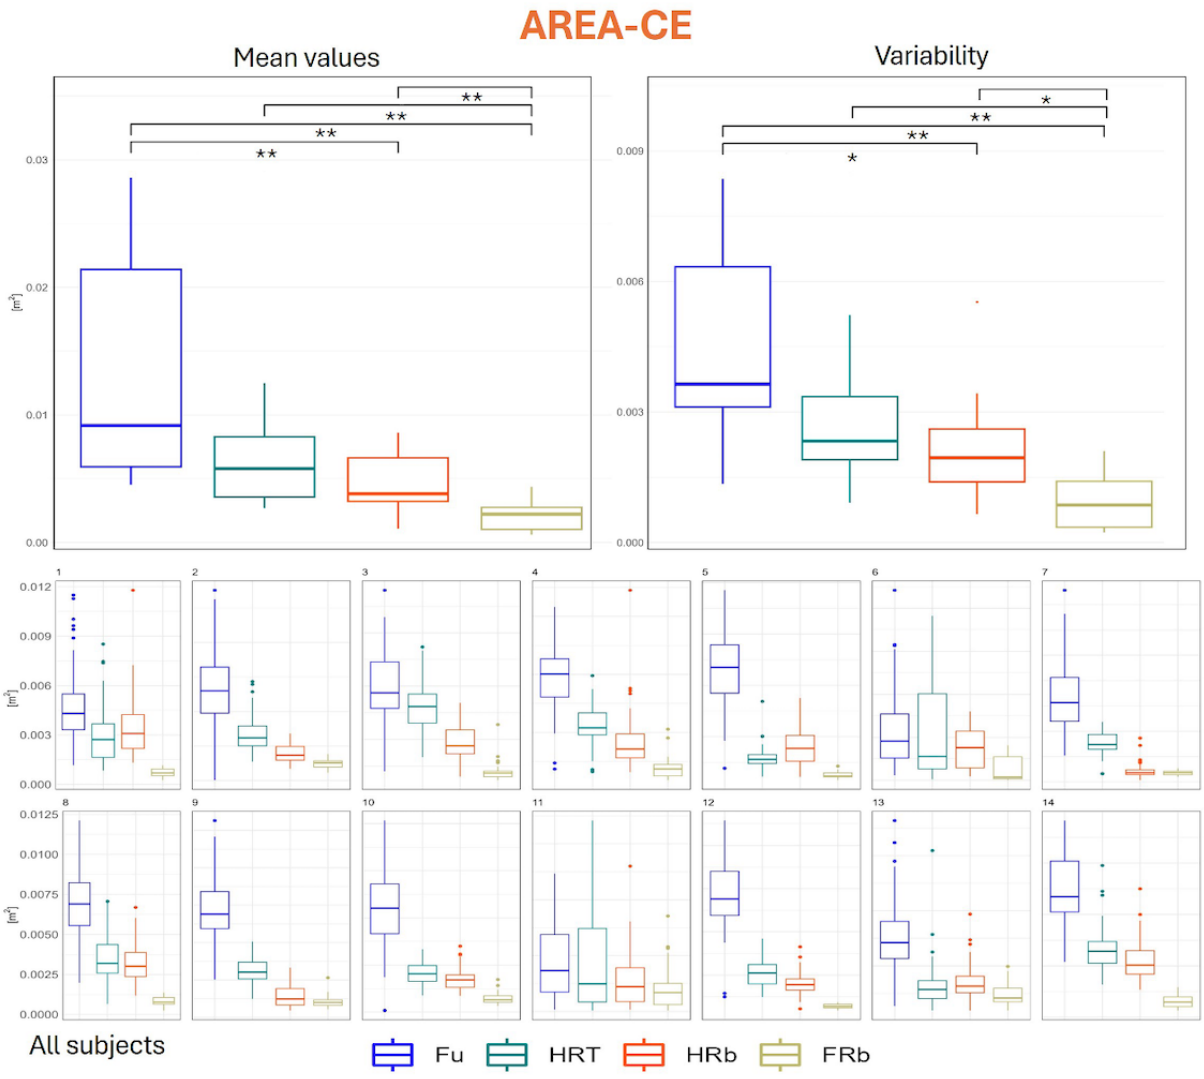
MVELO, an indicator of the amount of movement described by the CoP trajectory, in general confirms what already reported for MDIST: Fu condition determined higher values (16.3, SD 5.2 cm/s) than all other collaboration conditions, and in FRb, MVELO was significantly lower (7.9, SD 1.1 cm/s) than in all other conditions (11.1, SD 2.2 cm/s for HRb; 11.3, SD 2.9 cm/s for HRT). As depicted in Figure 7, these figures were confirmed also at the individual level for all but 2 participants. In terms of variability, while we observed that it was mostly reduced in the FRb condition (0.5, SD 0.3 cm/s) as compared with all the other conditions (2.3, SD 1.0 cm/s for Fu; 1.4, SD 0.5 cm/s for HRb), a significant decrease of the variability was present also when moving from Fu to HRT (1.4, SD 0.4 cm/s). Other variations were not significant at the group level.

Figure 7. Distribution of MVELO values. Upper panel, left: group mean values across the 4 collaboration modalities; upper panel, right: distribution of intraindividual variability (SD across repetitions); lower panels: distribution of values for each participant. * denotes *P*<.05 as obtained from inferential statistics; ** denotes *P*<.01 as obtained from inferential statistics. FRb: full robot; Fu: full; HRb: half robot; HRT: half robot touch; MVELO: mean velocity.



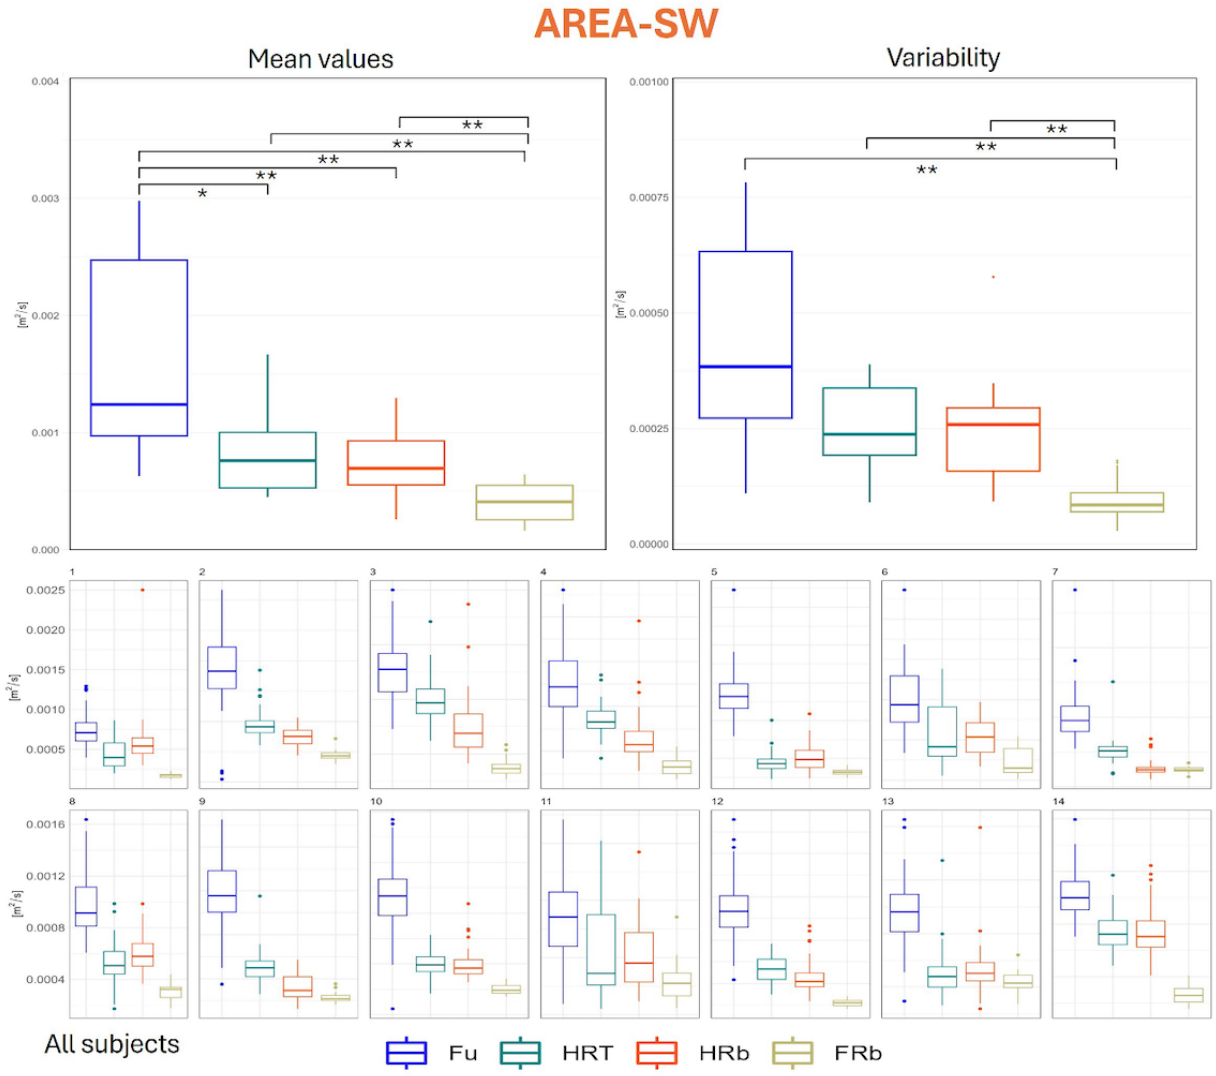
AREA-CE, which quantifies the planar extent of coverage of the CoP, displayed a behavior similar to what was seen for MVELO: values resulted significantly higher in Fu (134, SD 91 cm²), and lower in FRb (22, SD 12 cm²) than in all the other conditions (64, SD 32 cm² for HRT; 47, SD 24 cm² for HRb), respectively (Figure 8). Again, FRb intraindividual variability was lower in FRb (10, SD 7 cm²) than in all other conditions, and we saw a reduced variability when passing from Fu (45, SD 23 cm²) to HRb (21, SD 12 cm²).

Figure 8. Distribution of AREA-CE values. Upper panel, left: group mean values across the 4 collaboration modalities; upper panel, right: distribution of intraindividual variability (SD across repetitions); lower panels: distribution of values for each participant. * denotes *P*<.05 as obtained from inferential statistics; ** denotes *P*<.01 as obtained from inferential statistics. AREA-CE: confidence ellipse area; FRb: full robot; Fu: full; HRb: half robot; HRT: half robot touch.



Finally, AREA-SW, a planar measure that combines CoP extension and velocity, displayed behavior similar to what obtained with MDIST: Fu caused significantly higher AREA-SW values (16.2, SD 8.4 cm²/s) than all the other conditions (8.4, SD 3.7 cm²/s and 7.3, SD 2.8 cm²/s for HRT and HRb, respectively), and again FRb brought to values lower (4.0, SD 1.6 cm²/s) than all the other collaboration modalities (Figure 9). Both these results were reflected at the individual level for all participants but one. Intraindividual variability of AREA-SW was significantly lower in FRb (0.9, SD 0.4 cm²/s) than in all other conditions (4.4, SD 2.2 cm²/s; 2.5, SD 0.8 cm²/s; and 2.5, SD 1.2 cm²/s for Fu, HRT, and HRb, respectively).

Figure 9. Distribution of AREA-SW values. Upper panel, left: group mean values across the 4 collaboration modalities; upper panel, right: distribution of intraindividual variability (SD across repetitions); lower panels: distribution of values for each participant. * denotes *P*<.05 as obtained from inferential statistics; ** denotes *P*<.01 as obtained from inferential statistics. AREA-SW: sway area; FRb: full robot; Fu: full; HRb: half robot; HRT: half robot touch.



Discussion

Principal Findings

The analysis of the CoP trajectories shows that considering data obtained in tests going from the absence of cobot intervention (Fu) to the ones with maximum cobot assistance (FRb), the area of the CoP trajectory significantly decreases, thus possibly indicating a lower amount of oscillations of the body when the cobot intervenes.

As a general consideration, CoP trajectories, when no action of the cobot is present, tend to show greater intensity toward the loading area, indicating a higher amount of sway. This suggests that lifting affects balance control strategies. On the other hand, in both tests involving partial cooperation with the cobot, the CoP draws trajectories mainly toward the arrival station, even in the HRT modality, where the participant's arm moves toward the starting station direction to ask the cobot for help. This aspect suggests that the movement of the arm while carrying the load notably influences the CoP trajectory, while the arm movement, required to ask the cobot for help occurring in the HRT condition, does not produce a significant influence on the CoP trajectory, as compared with the modality where the cobot independently carries the load to the scanning zone (ie, HRb collaboration modality).

Regarding the detailed analysis of the specific CoP trajectories of all subjects and for all test types, results show that during tasks performed alone, CoP paths can be classified into two types: (1) concentrated with symmetrical movements toward both the starting and arrival stations (right and left), and (2) more scattered with a tendency to oscillate between the central rest zone and the arrival station (left). The variability of CoP trajectories across individuals may confirm the adoption of different independent control strategies, as also identified by the 2 types listed before. When instead maximum assistance by the cobot is present, areas drawn by CoP are smaller, and with a reduced interindividual variability. This homogenization effect can be explained by the fact that the cobot sets the activity's pace, causing the subject to adopt a more uniform behavior and timing. This is both apparent at the individual level (ie, each

subject tends to maintain a more uniform CoP trajectory across repetitions), and at the group level.

Results coming from the qualitative description of CoP trajectories were also confirmed by statistical analysis of CoP-derived parameters: specifically, CoP tends to travel more (MVELO and, to a certain extent, AREA-SW) and further (MDIST and AREA-CE) if the level of intervention from the cobot increases. In general, smaller excursions can be associated with improved balance: this means a higher tendency to remain in a smaller (and generally more stable) area during task repetitions. A possible interpretation is that while the cobot influences task execution, it also makes the operator move less with reduced postural oscillation. This aspect is relevant as an increased excursion from the equilibrium position and increased movement of the CoP are associated with an increased risk of falling [28], and incorrect postures in the working scenario are agreed to lead to the development of MSDs [29]. As seen from this perspective only, the modality of full assistance by the cobot brings to the lowest risk, as it clearly leads to minimal excursions and movements of the body.

However, we also observed a marked reduction of intraindividual variability of these parameters when full assistance from the cobot is present: one hypothesis for this evidence is that the presence of the cobot reduces autonomy in task execution and may thus impose a control strategy which is not necessarily beneficial (or chosen) by the operator. If a reduction of variability of such parameters from the baseline condition may be seen as an indicator of long-term discomfort, this needs to be appropriately considered when designing the most beneficial collaboration modalities. In this regard, intermediate collaboration modalities seem to incorporate a tradeoff between the advantages in the carrying task compensation given by the cobot on the load and the possibility of granting autonomy to the operator during the task execution.

Regarding the 2 collaboration modalities that maintain a material operator intervention, statistical analysis at the group level was rather inconclusive: in excursion-based CoP parameters, no difference was found, and this is counterintuitive, considering that one of the modalities required participants to raise the arm and kinematically reach out to ask for assistance. This was not reflected in most CoP-derived parameters, and the possible explanation for this absence of differences may be ascribed to the inherent nature of the CoP variable: it is only indirectly associated with whole body movement: coming from the ground reaction forces, it is a measure of where the foot pressure is concentrated [30]. In static conditions, CoP basically tracks the body barycenter projection to the ground (and dynamically overtakes it in specific conditions) to counteract balance disequilibrium. According to the inverted pendulum hypothesis, the body barycenter projection is thus a filtered version of the CoP trajectory. However, with self-initiated body part movements, the central nervous system is able to predict future whole-body excursions [31], and the position of the CoP may not necessarily reflect the excursions of the body barycenter. If this were the case, activation of the relevant muscles (typically, tibialis anterior) would appear in anticipation of the upper limb movement.

Regarding the inconclusive results appearing between the 2 modalities where collaboration was midlevel (ie, HRb and HRT), we tend to ascribe this process to a rather diverse behavior observed at the individual level: decreases of measures of CoP excursion and movement were in some individuals clear when decreasing the amount of user intervention (ie, passing from HRT to HRb), however this effect disappears in a nonnegligible share of individuals; as it was apparent from the qualitative description of CoP trajectories, 2 different group behaviors seemed to emerge: in one group, CoP is maintained compact despite the lesser level of cobot intervention as compared with FRb, while the second group displays higher amounts of excursion and movement. We were not able to ascribe this phenomenon to specific individual characteristics; whole body kinematics and electromyography activity analysis may help shed light on this, in particular, to check if this evidence might be associated with task role-taking, which may be a key factor in HRC activities [32].

Reduced postural variability, as evidenced by the decreased CoP trajectory area and reduced inter and intraindividual differences under maximum cobot assistance, can have significant long-term implications for musculoskeletal health. A prolonged state of limited variability in posture and movement, while potentially stabilizing in the short term, may contribute to the development of MSDs over time. This is because variability in postural strategies allows the redistribution of mechanical loads across different tissues and joints, reducing the risk of overuse injuries or chronic strain on specific musculoskeletal structures. Conversely, homogenized and repetitive postures imposed by external systems, such as cobots, may lead to localized fatigue, reduced muscular engagement, and impaired adaptability of the neuromuscular system. Consequently, these factors can heighten the susceptibility to cumulative trauma disorders, particularly in dynamic occupational scenarios. These findings highlight the importance of designing collaborative robotic systems that balance task support with opportunities for natural and varied movement patterns to mitigate potential long-term health risks for operators.

The implications of these findings for industrial settings may be interesting. The integration of cobots can significantly enhance worker safety and productivity by reducing physical strain and improving postural control. By enabling safer and more ergonomic working conditions, cobots can play a crucial role in creating healthier work environments, reducing the incidence of work-related MSDs, and improving worker satisfaction.

In general, referring to the obtained results, it must be remarked that the tasks analyzed were simulated rather than conducted in real-world contexts, so further analysis could be conducted to generalize the findings. However, the tests conducted in this study, even if simulating a cashier task, represent real work tasks themselves, and this supports the hypothesis that similar results can be obtained in the real world. Additionally, the sample consisted exclusively of young male participants, so a direct validation on female subjects and older ones was not conducted. Rather than a limit, this might be seen as a validation for the examined population, although it can be extended to other worker categories.

Conclusions

This study investigated the biomechanical impact of various levels of HRC on postural control during working tasks while standing, providing substantial insights into the benefits of cobot assistance for workers' safety and ergonomics. Through an analysis of CoP trajectories and related parameters, it was found that higher levels of cobot collaboration, particularly in the HRT, HRb, and FRb modalities, significantly improved postural stability and reduced biomechanical load on workers. These findings suggest a decreased risk of MSDs, as evidenced by lower values in CoP-derived parameters when cobot assistance increases. The study also highlighted that the intraindividual variability of CoP parameters diminished when levels of cobot involvement were increased: this indicates on one side that cobot integration promotes more uniform ergonomic benefits across different individuals, but at the same time it may tend to impose a similar behavior in balance control which can lead subjects to adopt less ecological strategies.

Moreover, while participants can set autonomously their repetition pace, HRC activities will determine an increased homogenization of repetition rhythm (or parts of it) across workers, and this may potentially lead to decrease ergonomics, as subjects can feel forced to perform the required tasks based on timings dictated by HRC. Intermediate collaboration modalities, such as HRT, can provide both advantages in terms of reduction of CoP-derived parameters—that can be indirectly associated with a reduced biomechanical risk—with the possibility of selecting a more comfortable rhythm in executing tasks.

However, further research is needed to explore the long-term effects of cobot assistance on worker health and productivity. In particular, future studies should include other sensing technologies, able to capture the neuromechanics of HRC. In addition, application to diverse populations and real-world industrial settings to generalize the results and provide a more comprehensive understanding of the benefits and potential challenges of cobot integration. Additionally, exploring the psychological and social impacts of working with cobots on employees would provide a holistic view of the implications of collaborating scenarios in industrial environments: if properly integrated into working environments cobots can potentially revolutionize industrial work by enhancing safety, efficiency, and ergonomic well-being, facilitating the development of more intelligent and flexible workrooms and working conditions.

Acknowledgments

Abstract

Background: During the COVID-19 pandemic, in-person visitation within hospitals was restricted and sometimes eliminated to reduce the risk of transmission of SARS-CoV-2. Many health care professionals created novel strategies that were deployed to maintain a patient-centered approach. Although pandemic-related restrictions have eased, these systems, including videoconferencing or web-based bedside visits, remain relevant for visitors who cannot be present due to other reasons (lack of access to transport, socioeconomic restraints, geographical distance, etc).

Objective: The aims of this study were (1) to report the experience of intensive care nursing staff using a bespoke videoconferencing system called ICU FamilyLink; (2) to examine the scenarios in which the nursing staff used the system; and (3) to assess the future use of videoconferencing systems to enhance communication with families.

Methods: A modified Telehealth Usability questionnaire was administered to the nursing staff (N=22) of an intensive care unit in a model 4 tertiary hospital in Ireland 1 year after implementing the bespoke videoconferencing system.

Results: In total, 22 nurses working in the intensive care department at University Hospital Galway, Ireland, responded to the survey. A total of 23% (n=5) of participants were between the ages of 25 and 34 years, 54% (n=12) were between 35 and 44 years, and 23% (n=5) were between 45 and 54 years. Most (n=15, 68%) of the participants reported never using videoconferencing in the intensive care setting to communicate with family members before March 2020. The modified Telehealth Usability Questionnaire showed overall satisfaction scores for each subcategory of ease of use and learnability, interface quality, interaction quality, reliability, satisfaction and future use, and usefulness. In total, 21 (95%) participants agreed or strongly agreed with the statement, “I would use the ICU FamilyLink system in future circumstances in which family members cannot be physically present (ie, pandemics, abroad, inability to travel, etc),” and 1 participant responded neutrally. One participant highlighted a common scenario in intensive care settings in which a videoconferencing system can be used “Even without COVID, web-based communication is important when patients become unexpectedly ill and when families are abroad.”

Conclusions: This study provides valuable insights into health care professionals’ experience using a videoconferencing system to facilitate web-based visits for families. We conclude that videoconferencing systems when appropriately tailored to the environment with the users in mind can be an acceptable solution to maintain communication with family members who cannot be physically present at the bedside. The bespoke videoconferencing system had an overall positive response from 22 nursing staff who interacted with the system at varying frequency levels.

Introduction

Background

In recent years, many intensive care departments have adopted a patient- and family-centered care approach. This includes having close family members physically present at the bedside during day-to-day activities and attending care meetings. Previous studies have highlighted the psychological and physical benefits of this approach for patients and their families during an individual's inpatient stay in intensive care [1-3]. However, having family members physically present at the patient's bedside can be difficult or even impossible due to geographical distance, financial challenges, and other family obligations. A significant barrier to bedside visits in the recent past was the COVID-19 pandemic.

The pandemic imposed severe and often complete restrictions on visits and forced health care professionals to change their traditional way of delivering patient care [4]. Prior to COVID-19, critical care nursing staff had been striving toward involving relatives in the intensive care unit (ICU) setting. However, many ICUs suspended these practices with the imposition of visitor restrictions [5]. These restrictive policies were introduced to decrease the risk of transmission of COVID-19 in health care settings [4]. These policies have been shown to be extremely isolating for patients, distressing for family members, and even hampering clinical care provided by health care professionals [1,6]. In particular, patients who are critically ill or vulnerable are often reliant on family for support, and at times, families are surrogate decision makers for patients. Health care professionals quickly realized the impact of visitor restrictions on family-centered care in intensive care settings. They called urgently for ways to maintain communication with family members who were no longer allowed to be physically present at the bedside [7]. At the beginning of the pandemic, hospitals quickly adopted technological solutions, including videoconferencing systems, to maintain or reopen communication channels. Previous studies have shown that adopting telemedicine solutions has numerous barriers, including the user's acceptance and experience with the technology [8-10]. Other studies have shown positive patient experiences using videoconferencing systems for web-based family support during patient rounds. However, other studies identify challenges for health care professionals, including additional workload and difficulty learning and integrating new technology into clinical practice [11,12].

Prior to the pandemic, videoconferencing in the intensive care department was limited to tele-ICU and rarely used for remote family communication. At the start of the COVID-19 pandemic, ICUs worldwide adopted various modes of maintaining communication with family members who were not allowed to be physically present at the bedside due to the risk of transmission of COVID-19. Intensive care units often serve wide geographical areas, so videoconferencing systems have the potential to improve communication with patients' families and reduce the psychological effects of intensive care admission on both patients and families. Videoconferencing systems can enable family members who cannot be physically present to be more involved during a patient's intensive care journey.

Aim of the Study

The aims of this study were (1) to report the experience of intensive care nursing staff using a bespoke videoconferencing system designed for patients and staff to communicate with patients' families remotely during hospitalization in an intensive care department of a tertiary referral hospital that had no prior video-calling system in place; (2) to examine the scenarios that nursing staff used the videoconferencing system; and (3) to assess the future use of videoconferencing systems to enhance family communication in intensive care settings using a modified version of the validated Telehealth Usability Questionnaire (mTUQ) [13].

Methods

Overview of ICU FamilyLink

A bespoke videoconferencing system called "ICU FamilyLink" was developed for the intensive care environment to allow for ad hoc web-based bedside visits available 24/7 with 1 or more close family members who may be in separate households [14]. The system was designed to be easy to use and to allow health care professionals to maintain appropriate control to maintain the security and privacy required for a hospital setting. The technology was chosen to deliver a reliable connection with high-quality audio and video. Several key requirements were previously identified during the iterative process of development [14]. This system used a 23-inch touch-screen video end point mounted on a mobile unit stand with a commercial cloud videoconferencing platform (Figure 1).

Figure 1. Video end point mounted on a mobile unit stand at an intensive care unit bedside.

A simple menu was designed for ease of use and maximum video-call security. Functions such as recording, chat, and screen sharing were disabled for security and privacy. The home screen mirrored the department's naming scheme for patient bed spaces and had the minimum number of clicks to connect. Three mobile video units were available for bedside web-based visits, and a stationary unit was available in a quiet room for medical staff to meet with families digitally.

A suite of documents, email templates, and multimedia was also created to support staff training, use, and troubleshooting. In addition, volunteer IT professionals operated a helpline for family members to ensure clinical staff were not burdened by technical queries outside their clinical training scope. A Data Protection Impact Assessment was completed, and the system was in keeping with hospital protocol and General Data Protection Regulation compliant.

The system was developed and rapidly introduced, with the first call within 2 weeks and the complete system rollout in under 3 weeks. Despite this rapid rollout, significant emphasis was placed on staff training, completion of relevant hospital risk assessments, and adherence to hospital policies. Focus on these areas was essential to ensure that staff, who were the main facilitators of the system, would find the system acceptable.

Survey Development

The validated Telehealth Usability questionnaire (TUQ) was used with minor modifications to capture relevant information to the specific use case [13]. The modified questionnaire (mTUQ) was developed with input from clinicians, engineers, a medical physicist, and a senior intensive care nurse.

The survey consisted of 40 questions in total. It included 22 questions from the TUQ, using a 7-point Likert scale, to assess the ease of use and learnability, interface quality, interaction quality, reliability, satisfaction and future use, and usefulness. The remaining questions ascertained participants' demographics and details on the respondent's use of the videoconferencing system in the ICU. Free-text comment boxes were available to gather additional qualitative data.

Recruitment

The mTUQ was distributed in paper form and via a web-based survey 1 year after the ICU FamilyLink was deployed. This allowed the system to become established in the department and minimized any bias that may have been created at the peak of the pandemic. All ICU nursing staff were eligible to participate in this study. Nursing staff were the primary users and facilitators of the ICU FamilyLink system. The system was mainly used for web-based bedside visits, rather than formal medical updates from the ICU medical team, although it was available if needed. The survey was open to any ICU staff member. Staff were recruited via emails, verbal reminders at nursing handover, and paper copies of surveys left in break rooms and main staff areas.

Data Analysis

Data were exported from the web-based survey and manually inputted from the paper surveys into a Microsoft Excel spreadsheet for analysis.

Ethical Considerations

Ethics approval for this study was obtained from the Galway Hospital Clinical Research Ethics Committee (ref C.A. 2674), and written informed consent, including web-based signatures for web-based participants was obtained from all respondents. All respondents participated voluntarily, could opt out at any point, and did not receive financial compensation. All data were anonymized.

Results

A total of 22 nurses who had been working in the intensive care unit at University Hospital Galway responded to the survey. All the respondents had used the ICU FamilyLink system at least once, although prior usage was not a requirement for participation in this study.

Characteristics of Participants

All participants were nursing staff, of these, 18% (n=4) were nurse managers. In total, 23% (n=5) of participants were between the ages of 25 and 34 years, 54% (n=12) were between 35 and 44, and 23% (n=5) were between 45 and 54 years. A total of 68% (n=15) of participants reported that they had never used videoconferencing in the intensive care setting to communicate with family members prior to March 2020 (Table 1).

During the initial introduction of the system, short training sessions were held, “superusers” were trained, and an instruction manual and video training were created. The survey showed that 36% (n=8) of participants watched a colleague before independent use and 77% (n=17) asked a colleague to teach them.

Table . Baseline characteristics of respondents.

	Respondents (N=22), n (%)
Age categories (years)	
25-34	5 (23)
35-44	12 (54)
45-55	5 (23)
Role	
Staff nurse	18 (82)
Nurse manager	4 (18)
Prior experience with any videoconferencing software in the critical care setting to communicate with patient’s family members	
Yes	7 (32)
No	15 (68)
Frequency of use (number of video calls)	
1-2	6 (27)
3-5	3 (14)
6-10	4 (18)
10-20	4 (18)
>20	5 (23)

Participants’ Use of ICU FamilyLink

The system’s usage was examined based on the frequency of video calls made (Table 1) and various scenarios (Table 2). In total, 27% (n=6) of participants used the system only 1-2 times, while 23% (n=5) of participants used the system over 20 times. Participants most commonly used the system for family time with patients while the staff were present (n=19, 86%), family time with the patient without clinical staff present (n=15, 68%), and providing daily progress updates (n=10, 45%). In total, 27% (n=6) used the system for remote family support while 1 family member was physically present at the bedside. While 9% (n=2) of respondents used the system to deliver bad news, 14% (n=3) used the system for an end-of-life scenario; 1 respondent

reported using the system for a formal care team meeting with the family. In addition, respondents were asked what purposes they felt the system was not suitable for (Table 3). A total of 45% (n=10) of respondents felt that delivering bad news and end of life were not suitable scenarios for using the videoconferencing system (Table 3). One respondent commented that, "Ideally, you would give bad news in person, but it could be used if not possible."

Table . Use of the ICU FamilyLink system.

Scenarios that the respondent has used the ICU FamilyLink system	Respondents (N=22), n (%)
Family time with the patient (while clinical staff carry out routine care)	19 (86)
Family time with the patient (without clinical staff present)	15 (68)
Daily progress updates	10 (45)
Remote family support for a designated in-person family member	6 (27)
End of life	3 (14)
Giving bad news	2 (9)
Formal care team meeting or family meeting	1 (4)
Education session for family	0 (0)

Table . Scenarios that participants felt were not suitable for the ICU FamilyLink system.

Clinical scenarios	Respondents (N=22), n (%)
Giving bad news	10 (45)
End of life	10 (45)
All are suitable	7 (32)
Formal care team meeting or family meeting	3 (14)
Education session for family	2 (9)
Daily progress updates	1 (4)
Other	1 (4)
Family time with the patient (without clinical staff present)	1 (4)
Family time with the patient (while clinical staff carry out routine care)	1 (4)
Remote family support for a designated in-person family member	0 (0)

Usability Attributes of the Videoconferencing System Using the mTUQ

The mTUQ showed an overall positive satisfaction score for all subcategories, including ease of use and learnability, interface quality, interaction quality, reliability, satisfaction and future use, and usefulness (Table 4).

Table . Responses to the modified Telehealth Usability questionnaire (N=22).

	Strongly disagree, n (%)	Disagree, n (%)	Somewhat disagree, n (%)	Neutral, n (%)	Somewhat agree, n (%)	Agree, n (%)	Strongly agree, n (%)
Ease of use and learnability							
1. It was easy to learn how to set up and use the system.	0 (0)	0 (0)	2 (9)	3 (14)	6 (27)	3 (14)	8 (36)
2. It was simple to use the system.	0 (0)	0 (0)	3 (14)	2 (9)	8 (36)	2 (9)	7 (32)
3. Compared to facilitating and managing in-person visits, the FamilyLink system was a more time-efficient way to engage with families.	0 (0)	2 (9)	1 (4)	4 (18)	7 (32)	6 (27)	2 (9)
Interface quality							
4. I am able to navigate setup, initiate, and complete calls without difficulty.	0 (0)	1 (4)	2 (9)	4 (18)	4 (18)	3 (14)	8 (36)
5. The onscreen menu for FamilyLink was intuitive to navigate.	0 (0)	1 (4)	0 (0)	2 (9)	5 (23)	6 (27)	8 (36)
6. The ICU FamilyLink system could do everything I wanted it to do.	0 (0)	0 (0)	1 (4)	2 (9)	4 (18)	5 (23)	10 (45)
Interaction quality							
7. The video quality was good and provided a clear 2-way conversation between me (and the patient, when able) and the family members.	0 (0)	1 (4)	0 (0)	0 (0)	3 (14)	4 (18)	14 (64)
8. The audio quality was good and provided clear 2-way conversation between me (and the patient, if able) and their family members.	0 (0)	0 (0)	1 (4)	1 (4)	1 (4)	5 (23)	14 (64)
9. I prefer the ICU FamilyLink monitor on a stand rather than a handheld device or smaller tablet.	0 (0)	0 (0)	0 (0)	6 (27)	1 (4)	5 (23)	10 (45)

	Strongly disagree, n (%)	Disagree, n (%)	Somewhat disagree, n (%)	Neutral, n (%)	Somewhat agree, n (%)	Agree, n (%)	Strongly agree, n (%)
10. I was able to express myself effectively using the FamilyLink system.	0 (0)	0 (0)	0 (0)	1 (4)	6 (27)	5 (23)	10 (45)
11. Compared to telephone conversations, the ICU FamilyLink was better to communicate and expressing important messages.	0 (0)	1 (4)	2 (9)	2 (9)	3 (14)	6 (27)	8 (36)
Reliability							
12. The system was reliable and consistently facilitated video calls.	0 (0)	0 (0)	1 (4)	2 (9)	4 (18)	4 (18)	11 (50)
13. I feel the FamilyLink system facilitates private and secure communication.	2 (9)	2 (9)	0 (0)	3 (14)	3 (14)	8 (36)	4 (18)
14. Whenever I made a mistake using the ICU FamilyLink system, I could quickly recover.	0 (0)	0 (0)	0 (0)	4 (18)	4 (18)	10 (45)	4 (18)
15. Family members were able to follow the emailed instructions and connect to a web-based visit call without additional technical assistance from me or other health care staff.	0 (0)	1 (4)	0 (0)	2 (9)	7 (32)	6 (27)	6 (27)
Satisfaction and future use							
16. I feel comfortable communicating with my patient's family members using the FamilyLink system.	0 (0)	0 (0)	0 (0)	1 (4)	5 (23)	8 (36)	8 (36)
17. The ICU FamilyLink system is an acceptable way to communicate while visitors are restricted.	0 (0)	0 (0)	0 (0)	0 (0)	2 (9)	9 (41)	11 (50)

	Strongly disagree, n (%)	Disagree, n (%)	Somewhat disagree, n (%)	Neutral, n (%)	Somewhat agree, n (%)	Agree, n (%)	Strongly agree, n (%)
18. I would use the ICU FamilyLink system in future circumstances in which family members cannot be physically present (ie, pandemics abroad and inability to travel).	0 (0)	0 (0)	0 (0)	1 (4)	0 (0)	6 (27)	15 (68)
19. I will use the ICU FamilyLink system in addition to in-person visits in the future.	0 (0)	0 (0)	1 (4)	2 (9)	2 (9)	7 (32)	10 (45)
20. I would recommend the ICU FamilyLink system in other health care settings.	0 (0)	0 (0)	0 (0)	1 (4)	1 (4)	4 (18)	16 (73)
Usefulness							
21. The ICU FamilyLink system provides for continuity of communication while visiting is limited.	0 (0)	0 (0)	0 (0)	0 (0)	2 (9)	5 (23)	15 (68)
22. The ICU FamilyLink system has positively impacted the overall care of patients in critical care during the visitor restrictions.	0 (0)	0 (0)	0 (0)	1 (4)	3 (14)	5 (23)	13 (59)

Ease of Use and Learnability

The majority of nursing staff responded positively to ease of use and learnability questions. Interestingly, when specifically asked to compare the time efficiency of organizing in-person visits versus web-based visits (question 3), 18% (n=4) of participants responded neutrally, 14% (n=3) provided negative responses, and 68% (n=15) gave positive responses (Table 4, questions 1-3).

Two comments were made about the process of sending the videoconferencing link to family members, indicating the need to improve the process.

The equipment itself was very easy to use, it can be a pain to log out of the computer and relog in, an app on the computer at the nurses station would be better.

[Respondent who used the system 10-20 times]

I think it would be beneficial if the email sent to the families to download the software could be sent to every computer in the unit.

[Respondent who used the system more than 20 times]

These comments indicate an area for improvement to reduce the burden of work for staff members and highlight the frustration staff commonly feel when newly introduced technology adds extra tasks. There are limitations to fully integrating technology; however, decreasing the administration time for the clinical staff could lead to better technology uptake. Despite this feedback, the 2 participants reported frequent use of the system.

Interface Quality

Nursing staff most frequently responded with “strongly agree” to the interface quality questions, question 4 (n=8; 36%), question 5 (n=8; 36%), and question 6 (n=10; 45%), respectively (Table 4).

Free text comments from 2 participants included “very simple and easy to use” and “good quality.”

Interaction Quality

A total of 64% (n=14) participants strongly agreed that the video and audio quality was good and provided clear 2-way conversation. When asked about their preference for the ICU FamilyLink monitor on a stand rather than a handheld device or smaller tablet, the majority of participants (n=16, 73%) responded in the positive, only 6 (27%) participants were neutral, and none responded in the negative. Most of the respondents (n=17, 77%) felt that compared to telephone conversations, the ICU FamilyLink was better for communicating and expressing important messages (Table 4, questions 7-11).

One participant highlighted the importance of network coverage for family members, though beyond the hospital’s control, was an important factor: “Very dependent on internet coverage for the family.” Another participant indicated that the visual aspect of the system was better than phone communication: “It helped build a connection with families that isn’t possible via phone.”

Reliability

Overall, respondents more frequently responded positively to reliability (Table 4, questions 12-15). However, 4 (18%) respondents disagreed or strongly disagreed with the statement, “I felt the ICU FamilyLink system facilitates private and secure communication.”

Satisfaction and Future Use

All participants responded positively to the statement, “The ICU FamilyLink system is an acceptable way to communicate while visitors are restricted.” In total, 21 (95%) participants agreed or strongly agreed with the statement, “I would use the ICU FamilyLink system in the future circumstances in which family members cannot be physically present (i.e., pandemics, abroad, inability to travel, etc),” and 1 participant responded neutrally (Table 4, questions 16-20).

Qualitative data also indicate health care professionals’ positive feedback and wish to use the system in the future:

Even without COVID, online communication is important when patients become unexpectedly ill, and families are abroad.

Extremely valued by family members, I have had limited exposure to its use due to working mostly night shifts.

Familylink has been a lifesaver during the pandemic; in my opinion, it is very easy to use and great for patients to be able to see their relatives onscreen while visiting is restricted. I will use it at any opportunity.

Usefulness

In total, 21 (95%) participants responded positively to questions about usefulness (Table 4, questions 21 and 22), except 1 neutral response to question 22: “The ICU FamilyLink system has positively impacted the overall care of patients in intensive care during the visitor restrictions.”

Discussion

Overview

With an overall shift toward a patient- and family-centered approach, health care professionals can harness technology to enable and optimize this approach. However, with the introduction of any technology into a new environment, particularly one as complex as health care delivery, careful design, assessment, and research should be completed to ensure acceptability, usability, and impact on all users. While health care professionals are trained to a high degree in health and medicine, their training, understanding, and use of technology vary widely.

Strengths, Limitations, and Future Directions

This study included participants who had only interacted with the ICU FamilyLink system a handful of times and also very frequent users. It also was inclusive for all age ranges and had both staff grade and senior nurses. In usability studies, it is vital to capture input from all spectrums of technical users.

One limitation of this study was that it did not interview or survey patients or their families. While this was considered, due to limited staff and stressful circumstances for patients and families, it was not included as a component of the study. There have been studies recently published examining family and patient experiences in using both phone and video for web-based visits [15-17]. Staff acceptance is critical for implementing systems like the ICU FamilyLink into regular practice. ICU staff are usually required to facilitate these calls due to the dependency needs of the ICU patients.

This study, like many similar studies, was conducted under pandemic conditions. The TUQ was modified to account for these conditions. It is encouraging that responses to questions on usefulness and future use are overall positive, with 68% (n=15) of respondents “strongly agreeing” that they would use the ICU FamilyLink system in future circumstances in which family members cannot be physically present (question 18). While there are positive indications for postpandemic use and its potential value is noted by the staff members, confirming these results outside of pandemic conditions would be important.

Conclusions

The findings of this study provide valuable insights into health care professionals’ experiences using a videoconferencing system to facilitate web-based bedside visits for family members. We conclude that when appropriately tailored to the environment and with the users in mind, videoconferencing systems can be an acceptable solution for maintaining communication with family members who cannot be physically present at the bedside. Further studies are needed to better understand usability factors for technology in order to enhance and augment communication with ICU patients, staff, and patients’ family members.

Acknowledgments

The authors would like to thank all the staff and volunteers who supported the development and deployment of the ICU FamilyLink system in Galway University Intensive Care Unit as well as the participants of this study for their valuable insight and feedback about the system. This publication has resulted from research supported in part by a grant from Science Foundation Ireland and the European Regional Development Fund (grants 13/RC/2073_P2 to AM and DTOK and 13/RC/2094_P2 to DTOK).

Abstract

Background: Mobile health (mHealth) apps provide easy and quick access for end users to monitor their health-related activities. Features such as medication reminders help end users adhere to their medication schedules and automatically record these actions, thereby helping manage their overall health. Due to insufficient mHealth tools tailored for HIV preventive care in young men who have sex with men (MSM), our study evaluated the usability of the mChoice app, a tool designed to enhance preexposure prophylaxis (PrEP) adherence and promote sexual health (eg, encouraging the use of condoms and being aware of the partner's HIV status and PrEP use).

Objective: This study aimed to apply systematic usability evaluations to test the mChoice app and to refine the visualizations to better capture and display patient-reported health information.

Methods: Usability testing involved heuristic evaluations conducted with 5 experts in informatics and user testing with 20 young MSM who were taking or were eligible to take PrEP.

Results: End users demonstrated satisfaction with the appearance of the mChoice app, reporting that the app has an intuitive interface to track PrEP adherence. However, participants highlighted areas needing improvement, including chart titles and the inclusion of "undo" and "edit" buttons to improve user control when recording PrEP use.

Conclusions: Usability evaluations involving heuristic experts and end users provided valuable insights into the mChoice app's design. Areas for improvement were identified, such as enhancing chart readability and providing additional user controls. These findings will guide iterative refinements, ensuring that future versions of the app better address the needs of its target audience and effectively support HIV prevention.

Introduction

The incidence of HIV, although having declined modestly overall in the United States, remains a significant public health problem for men who have sex with men (MSM) [1,2]. Notably, young MSM aged 13 to 34 years represent 58% of the estimated HIV infections in 2021, indicating a pressing need for targeted intervention in this group [2]. Preexposure prophylaxis (PrEP) is a highly effective biomedical prevention strategy to reduce HIV incidence and curb the HIV epidemic [3-10]. When taken as prescribed (daily or at least 4 times per week), PrEP reduces HIV transmission by up to 99% among MSM [7-9,11-13]. While awareness of PrEP has increased among MSM [14,15], those who are most disproportionately affected have been found to be less aware of PrEP [15], and overall, widespread uptake among those with the greatest indications for PrEP remains low [14-17].

To overcome this clinical and public health challenge, technological interventions, such as mobile health (mHealth) apps, have emerged to support public health care initiatives [18]. However, despite the potential of mHealth for delivering sexual health and HIV prevention awareness, mHealth is underutilized for supporting PrEP adherence [19,20]. In response, our study team developed mChoice, an innovative PrEP adherence monitoring app, which combines the CleverCap smart pill bottle with WiseApp, allowing end users to

self-monitor and manage their medication adherence. The CleverCap pill bottle dispenses the prescribed medication and interfaces with WiseApp for real-time tracking. The app was created by Compliance Meds Technology and has been used in prior studies among persons living with HIV [10,21-25]. It was adapted for the mChoice study. The app's key functionalities include monitoring PrEP adherence, visualizing data trends, and documenting sexual behavior, particularly among young MSM from diverse backgrounds.

A notable issue in the proliferation of mHealth apps is the development of this technology with minimal input from end users, leading to poor design, inadequate consideration of user needs, and ultimately, poor usability [26]. Poorly designed apps, lacking in usability, are prone to misuse, underutilization, and failure to achieve their intended objectives.

To ensure the best utilization of mHealth apps, it is essential to understand their usability, keeping in mind target end users (eg, young MSM), tasks (eg, PrEP adherence management and sexual health tracking), and cultural contexts (eg, language and beliefs). Adherence to PrEP is crucial for its effectiveness in preventing HIV, yet many young MSM face challenges such as inconsistent medication schedules and limited access to tailored support tools. The mChoice app was designed to address these barriers by providing intuitive features, including medication reminders, adherence tracking, and functions to support sexual health decision-making. In this study, we sought to apply systematic usability evaluations to test the mChoice app and to refine the functions to better capture and display patient-reported health information.

Methods

Ethical Considerations

The Columbia University Institutional Review Board reviewed and approved all study activities (approval number AAAT8812). Participants signed informed consent forms prior to participating in usability testing. In our dataset, each participant was assigned an identifier, and information was deidentified at the point of analysis.

Heuristic Evaluation

Sample

Usability testing of the mChoice app included heuristic evaluation conducted with experts in informatics and end-user testing conducted with young MSM. Five experts were recruited as evaluators in accordance with Nielsen's recommendation to include 3 to 5 experts in usability testing [27]. Of the 5 experts, 4 had a PhD in Nursing with expertise in human-computer interaction, interface design, and usability testing. The experience of the experts varied between 7 and 23 years, with several impactful publications in the field of informatics.

Procedure

The experts were provided with the mChoice app and asked to complete a session in the app through case scenarios that represented the main functions of the system and think-aloud methodology [28]. The mChoice app required a password, and all study data were encrypted and stored on secure HIPAA-compliant servers at Columbia University. The experts were asked to describe what they were thinking, seeing, and doing as they completed the following 10 scenarios: (1) log in to the CleverCap app; (2) complete a sexual activity log; (3) mark your PrEP dose for today as "Taken"; (4) view tomorrow's pending PrEP dose; (5) edit your sexual activity log; (6) delete your sexual activity log; (7) view information on PrEP dosing over the past month; (8) send a chat to the study team; (9) watch a video about an HIV story; and (10) find PrEP information (see Figures 1 and 2 illustrating app functions and Figure 3 demonstrating the CleverCap smart pill bottle). Following their use of the app, the experts completed an online Heuristic Evaluation Checklist to assess how the system adhered to Nielsen's 10 usability principles [27] using Qualtrics XM, an online survey software. Each question ranged from 0 (not a usability problem) to 4 (usability catastrophe). A member of the research team analyzed the experts' comments regarding usability problems to identify areas of usability concern that could be targeted for improvement. The mean usability problem severity scores were calculated for each of the 10 usability heuristics.

Figure 1. Sexual activity log. A confidential and secure feature for users to record their sexual activities, such as gender of partner, whether a condom was used, and the HIV status of their partner. Users of the on-demand/intermittent (2-1-1) preexposure prophylaxis (PrEP) regimen can use this feature to trigger subsequent PrEP dose reminders following sexual activity (ie, one pill 24 hours and one pill 48 hours after sexual activity).

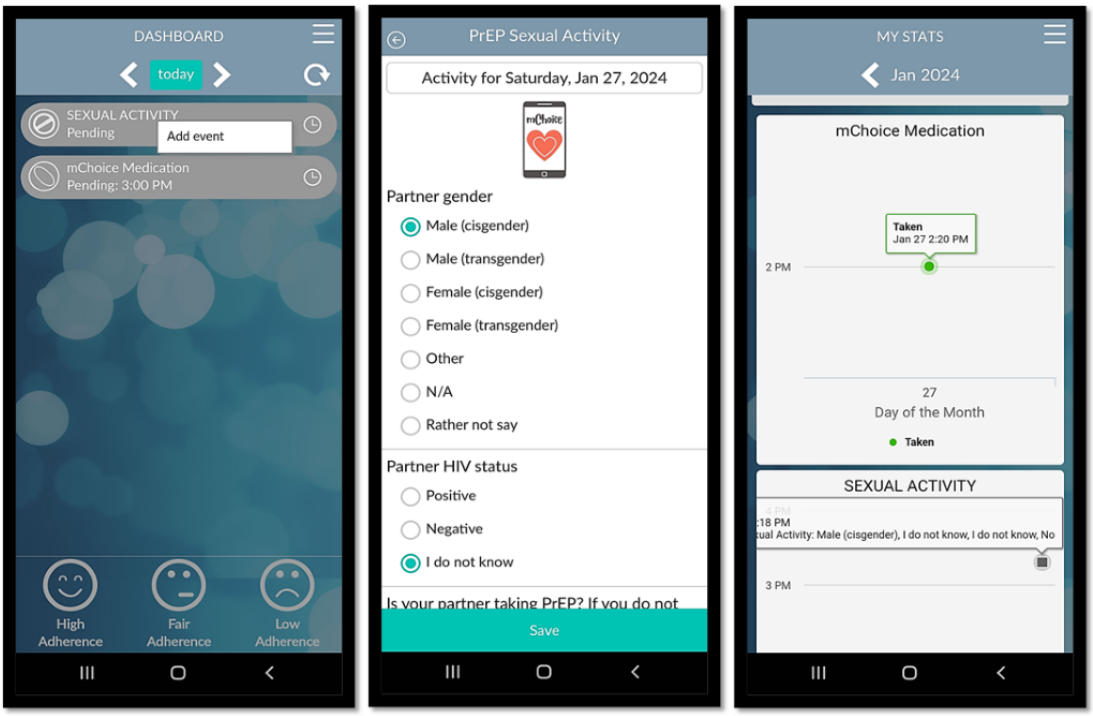

Figure 2. Preexposure prophylaxis (PrEP) adherence tracking. A simple interface for users to track PrEP intake, facilitating adherence monitoring over time. This feature is linked with the CleverCap device, a smart pill bottle that tracks when users take their medication. PrEP tracking is also customizable for users on different PrEP regimens (ie, 2-1-1, injectable, or daily oral dose) to ensure the timely intake of PrEP medication. For instance, users on injectable PrEP will be alerted of their upcoming appointment or need for their PrEP injection.

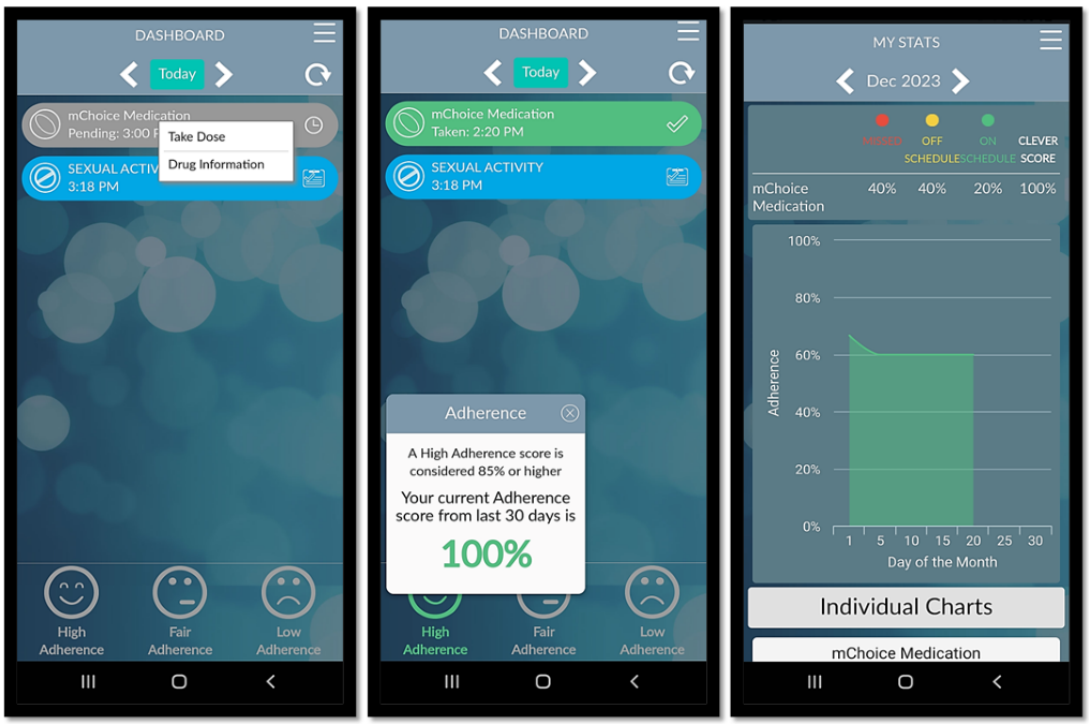

Figure 3. CleverCap device. A smart pill bottle linked with the mChoice app to track preexposure prophylaxis (PrEP) medication.

End-User Testing

Sample

Twenty end users were recruited for the usability testing. The eligibility criteria were young MSM between 18 and 39 years old, English speaking, living in New York or Alabama, and taking or eligible to take PrEP. The inclusion criteria were designed to ensure the mChoice app was evaluated by its intended target audience, ensuring a diverse usability evaluation. Potential end users were contacted using a research database and invited to participate in the study.

Procedure

During usability testing, the end users were provided with a brief explanation of the mChoice app and its functions. The end users were directed to complete the same 10 scenarios completed by the experts in the heuristic evaluation. Sessions took place remotely via Zoom meetings (Zoom Communications, Inc), and a member of the team was present during sessions to provide guidance when an end user was unable to move through a task independently and to take notes. Following their use of the app, the end users completed a survey using the Qualtrics XM software.

The survey included demographics and two validated measures of usability. The first usability measure was the self-reported ease of use measured by using the Health Information Technology Usability Evaluation Scale (Health-ITUES) [29,30]. This 20-item tool is designed to support customization at the item level to match the health information technology while retaining standardization at the construct level. It has been demonstrated to be useful for evaluating the usability of mHealth [31]. It is scored on a 5-point Likert scale ranging from 5 (strongly agree) to 1 (strongly disagree), where higher scores indicate a system that is easier to use. The second measure was the short version of the Post-Study System Usability Questionnaire (PSSUQ), a 16-item survey that assesses users' perceived satisfaction with a system [32]. Scoring is based on a 7-point Likert scale ranging from 1 (strongly agree) to 7 (strongly disagree). Lower scores indicate satisfaction with the system. Through validated measures, the end users contributed feedback on the app's functionality and user experience.

Data analysis was performed using R statistical software (version 4.1.2; R Foundation for Statistical Computing) to analyze the usability measures. The mean scores were calculated for each survey.

Results

Heuristic Evaluation

Overall, the severity scores ranged from 0.8 to 2.2 for the 10 items on the heuristic checklist, where scores closest to 0 indicate a more usable system. The mean severity scores for each heuristic item are presented in Table 1. The area identified as the most in need of improvement was "user control and freedom," where the experts identified that the app did not have an "undo" button or "edit" button for the PrEP medication entry.

The next most identified area for improvement was the "visibility of the system status," for which experts identified the lack of one "add" button to add a new sexual event. To improve the "visibility of the system status," the experts suggested we provide one "edit" button for modifying recorded sexual encounters and incorporate a separate "add" button for logging new encounters, especially in instances of multiple events. Additionally, "consistency and standards" was an area of concern with difficult terminology in charts. "Error prevention" was another concern, and experts highlighted the importance of one "edit" button to edit medication time as an issue that might impede system usability. Experts provided favorable feedback on the app's user experience. One expert (Expert 2) reported, "the app is very simple and intuitive interface…and it's nice that the button changes color with pleasant colors."

The rating score ranged from 0 (ie, best) to 4 (ie, worst), with a score of 0 indicating no usability problem, 1 indicating a cosmetic problem only, 2 indicating a minor usability problem, 3 indicating a major usability problem, and 4 indicating a usability catastrophe.

Table . Mean severity scores for items on the heuristic evaluation.

Heuristic principles	Mean (SD) severity score	Experts' comments to identify the areas of usability concerns
User control and freedom	2.2 (1.3)	• "No undo or edit for the medication entry. This is a big problem." (Expert 5)
Visibility of the system status	1.6 (1.1)	• "…When adding a sexual encounter record, it is not clear whether it edits or adds a new one, so there should be two buttons, one for edit and one to add a new one. The screen when you use edit also shows the old entry, which implies you are editing it, not starting a new one, but actually it is starting a new one. That is confusing." (Expert 3)
Consistency and standards	1.6 (1.1)	• "Not clear if the clever score is just adherence or if it means something else." (Expert 4) • "…I think in the menu it says stats. Rather than stats, it'd be adherence stats or adherence tracking over time. You know something that makes it really clear what people are clicking on." (Expert 2)
Error prevention	1.6 (1.1)	• "When entering the time of a medication, it might be easy to miss the AM/PM change. I don't think there's any design change to be made for this, but rather the user needs to be able to edit their entry if they forget to adjust this." (Expert 4)
Match between the system and the real world	1.4 (1.3)	• "Would like to see one section specific to PrEP information." (Expert 5)
Recognition rather than recall	1.4 (0.9)	• "Some of the main features can be moved to more obvious places." (Expert 1) • "Organization for videos could be improved, especially if you plan to add more content." (Expert 4)
Help and documentation	1.4 (1.3)	• "Information buttons and an introduction to the app would be helpful." (Expert 1)
Help users recognize, diagnose, and recover from errors	1.2 (1.1)	• "When the dose was missed, no way to edit if it was a mistype." (Expert 5)
Aesthetic and minimalist design	1.2 (1.1)	• "Graphs need clearer tiles and more labels." (Expert 1) • "Need more medication information or guidance if adherence is low." (Expert 5)
Flexibility and efficiency of use	0.8 (1.1)	• "…Search function for videos. Tags for topics would be good, too." (Expert 4)

End-User Testing

The end-user group for evaluating the mChoice app's usability consisted entirely of men, with the majority identifying as homosexual (14/20, 70%). The mean (SD) age was 28 (3.4) years. Half of the end users were White, and 75% (15/20) were non-Hispanic or Latino. Considering education, 50% (10/20) had a college degree. Two specific measures were employed for the usability assessment: the Health-ITUES and the PSSUQ, as detailed in Table 2.

The Health-ITUES scale, where a higher score indicates better usability, showed that "perceived ease of use" scored the highest with a mean (SD) score of 4.6 (0.5), suggesting a favorable user assessment. However, "user control" received the lowest score in this category, with a mean (SD) score of 3.8 (0.9), corroborating the heuristic evaluator's ratings.

Conversely, the PSSUQ, where a lower score indicates better usability, reflected different aspects of the mChoice performance. "System quality" scored the lowest with a mean

(SD) of 1.7 (1.2), while "interface quality" had the highest score with a mean (SD) score of 3.0 (1.8). These results suggested a positive user experience with notable ease of use and system quality strengths. However, there were areas for improvement, particularly in enhancing user control and interface quality.

Table . Usability measures.

Measures	Mean (SD) score
Health-ITUES[a]	
Perceived ease of use	4.6 (0.5)
Impact	4.1 (0.8)
Perceived usefulness	4.0 (0.8)
User control	3.8 (0.9)
Overall Health-ITUES score	4.2 (0.4)
PSSUQ[b]	
System quality	1.7 (1.2)
Information quality	2.4 (1.3)
Interface quality	3.0 (1.8)
Overall PSSUQ score	2.3 (0.6)

[a]Health-ITUES: Health Information Technology Usability Evaluation Scale (rating the score from 5 being the best score to 1 being the worst score).

[b]PSSUQ: Post-Study System Usability Questionnaire (rating the score from 1 being the best score to 7 being the worst score).

Discussion

Principal Results

Our study evaluated the mChoice app's usability in enhancing PrEP adherence for young MSM. Overall, heuristic experts and end users demonstrated satisfaction with the mChoice app, reporting that it is a simple and intuitive interface for tracking PrEP adherence. Graphs, charts, and icons are the main features of mHealth apps that help end users track their goals, habits, and achievements [33,34]. The mChoice app combines iconography (eg, emoticons) and color-coded charts to provide clear and immediate feedback on PrEP adherence. These diverse visualizations allow end users to interpret their data in several formats. The app includes emoticons in different colors (green for high adherence, red for missed doses, and yellow for off-schedule doses) to represent adherence status. For instance, a sad emoticon in red for low adherence might highlight medication adherence challenges and prompt self-reflection on areas needing improvement. Such immediate visual feedback can motivate end users to improve their medication routine. In addition, graphs showed the trend of PrEP medication adherence over time, including evidence-based information on the percentage of missed, off-schedule, and on-time doses.

While prior research has indicated that varied data visualization options help match different end users' preferences [33] and color-coded visual cues can aid in quick decision-making and interpretation of health data [35-38], our study did not directly assess end-user interpretations of these visual elements. The mChoice app incorporates these evidence-based design principles, but further research would be needed to evaluate their impact on user comprehension and medication adherence behaviors.

Our findings suggest that the visual elements available in the mChoice app offer a positive end-user experience and function accessibility that could assist in timely medication intake and monitor adherence. However, our heuristic evaluation highlighted areas needing improvement, particularly in the need for clearer chart titles and more labels to exemplify each component (eg, Clever score), underscoring the importance of refinement of the mChoice design for optimized end-user experiences.

The accuracy of the information collected through the mChoice app was another area of attention that heuristic experts raised concerns, particularly highlighting the absence of "undo," "edit," and "add" buttons. These limitations restricted user control, potentially affecting the accuracy of patients' health information input. For instance, the absence of "undo" and "edit" buttons could lead to inaccuracies if end users mistakenly enter the time of their PrEP dose intake. Additionally, the lack of an "add" button for recording multiple sexual events was seen as an important barrier, restricting end users from documenting their sexual event entries accurately. These findings underscore the need for enhanced app capabilities to ensure accurate and comprehensive user input and customizations. Similarly, other studies [39,40] reported concerns about user experiences and data accuracy in mobile apps, reinforcing the findings of our study.

The actionable finding from this study is to reevaluate the functions of the mChoice app after integrating end-user feedback and addressing heuristic violations. Iterative usability evaluations should be considered as a best practice in the app development process to ensure the effectiveness of the app's future iterations.

Limitations

A limitation of our study was the convenience sample, recruited from a database that included participants who had participated in past research and expressed interest in future studies. Additionally, while our sample targeted young MSM, English-speaking men, and those living in New York or Alabama, this demographic representation might limit our ability to understand how the app might perform for medication adherence across diverse populations. Given that PrEP users come from varied cultural, linguistic, and socioeconomic backgrounds, our findings may not be generalizable to groups whose cultural beliefs, language preferences, and health care engagement patterns differ from those of our study population. While end users were central for evaluating the usability of the mChoice app through validated quantitative measures, qualitative data were collected only from experts during heuristic evaluations. In this study, we did not evaluate the artificial intelligence or algorithmic components that could enhance personalization and medication adherence predictions. Despite these limitations, we identified areas of improvement to refine the mChoice app. In addition, this study enriched the body of research on evaluating the mHealth usability for HIV prevention. This was achieved by employing end users and heuristic experts to assess this innovative app designed for PrEP adherence and HIV prevention.

Conclusions

Our usability study of the mChoice app involved rigorous evaluations through interactive heuristic evaluations and end-user testing. The results demonstrated the app's simplicity and user-friendly interface, showcasing its potential in monitoring health-related activities such as PrEP adherence. Further research could explore how these usability enhancements might influence user engagement and behavior change to support HIV prevention efforts.

Abstract

Background: Wearable transdermal alcohol sensor (TAS) devices generate continuous data on alcohol consumption through the indiscernible sweat vapors on the skin. This continuous alcohol monitoring capability could provide a new method for alcohol services to monitor service users at various stages of their alcohol treatment.

Objective: We aimed to assess the feasibility of using a TAS as part of alcohol treatment with alcohol service users using the device with or without contingency management (CM).

Methods: A feasibility study was conducted of a convenience sample of 29 current service users from 3 South London alcohol services. Participants were randomized into either a control (treatment as usual) or CM group (treatment as usual+CM). We assessed the feasibility of enrollment, participation, device tampering and return, and device wearability and the accuracy of data capture. These data were reported descriptively where appropriate, the groups were compared, and alcohol self-report data were compared to the transdermal alcohol concentration to assess accuracy.

Results: A total of 34 individuals were approached, and 32 (94%) were enrolled and randomized (n=17, 53% to the control group and n=15, 47% to the CM group) over 5 months. In total, 3 participants withdrew (n=2, 67% from the control group and n=1, 33% from the CM group). There was a total of 203 meetings arranged (29 participants × 7 meetings), and 185 (91.1%) were attended. Only 1 of the 29 participants (3%) admitted to turning the TAS off to avoid monitoring. There were some issues with the TAS not functioning properly and not being able to be cleaned. Removals were recorded, but the definition of TAS removal may need to be improved for future trials. There was a high TAS return rate (28/29, 97% of the participants returned the TAS). Secondary outcomes suggest that the BACtrack Skyn remains an accurate tool to monitor alcohol consumption compared to self-report data and that it is acceptable to wearers over 2 weeks, with many participants (27/28, 96%) answering that they would wear it again and for longer but that the CM procedure could be made clearer.

Conclusions: The delivery of CM via a TAS was feasible in this study, but recommendations for a future larger trial include that the study design should be changed to provide an operationalized rather than manual method of checking whether TAS data meet CM criteria. This would reduce researcher burden and researcher and participant time. Current recruitment and research meeting design seem suitable for a future larger trial.

Introduction

Background

Various wearable transdermal alcohol sensor (TAS) devices have been developed. These devices measure alcohol consumption from alcohol vapors in the skin via sweat, known as transdermal alcohol concentration (TAC), and can record at automated regular intervals. One potential use of TASs is as a tool for objective alcohol measurement in clinical alcohol treatment.

TASs could be used in specialist community alcohol services for monitoring alcohol consumption before detoxification to determine drinking levels and patterns, during detoxification, or after detoxification to be combined with sessions with key workers and other psychosocial or medication treatment. The recorded alcohol data could be used to consider triggers and provide evidence of abstinence or alcohol reduction and proof of engagement, which may be useful as evidence for funded treatment, or TASs could be used to implement contingency management (CM) for alcohol reduction. However, before TASs can be implemented into treatment, their accuracy, acceptability, and feasibility in this setting must be validated.

There have been several studies that have investigated the various TAS device brands on TAC data accuracy compared to self-report, blood alcohol concentration, and breath alcohol content data [1-17]. Most of this previous research was conducted with healthy adult volunteers [18,19]. Various brands of TASs have been developed and are in differing stages of validation and research. There have only been a few studies conducted with a specific focus on exploring TAS acceptability and feasibility measures [12,20-26] and even fewer specifically on TAS implementation of CM rewards [1,2,26-31]. While most of the TAS research reports on the SCRAM monitor, there is a growing number of individuals using a newer generation of TASs, the BACtrack Skyn [7,12-14,32-42].

CM has been evidenced as an effective treatment for substance use. It is an established treatment recommended by the National Institute for Health and Care Excellence [43] and has proven to be effective for a range of substance use treatments [44-47]. Although initially developed to be used with alcohol use disorder (AUD) treatment, it has had limited use in this area [48,49]. This is due to the nature of alcohol metabolism and its short detectability within the body [50,51].

Currently used methods for alcohol measurement include breath, blood, and urine tests, which have a relatively short time frame to detect alcohol [52]. Thus, to accurately implement CM in alcohol treatment, the individual would require frequent, multiple breath, blood, or urine tests daily to prove abstinence or alcohol reduction and accurately achieve CM rewards [47,49,53,54]. This is not always feasible with staff time and resources and increases the burden on both service users and staff. The portable mobile phone–linked breathalyzer has also tried to address this limitation and appears to work well in tracking alcohol treatment progress [55-58]. However, it still requires repeated daily compliance from the individual completing each breathalyzer test.

The development of TASs has the potential to address CM implementation with alcohol use and can provide a low-burden, low-intensity solution [1,2,26-31]. Previous literature has started to explore how TASs can implement CM [1,2,26-31]. These studies have found the SCRAM monitor successful in implementing the CM procedure and found that the CM intervention was able to significantly reduce alcohol consumption [1,2,27,29]. Of these 8 studies, none recruited alcohol-dependent participants. In total, 2 involved recent driving while intoxicated offenders with differing criteria on alcohol consumption, 1 with an Alcohol Use Disorders Identification Test score of ≥4 [28] and the other with an Alcohol Use Disorders Identification Test score of ≥8 [30]; 2 recruited HIV-diagnosed individuals with higher levels of alcohol consumption [26,31]; and the other 4 classified participants as risky or heavy drinkers with varying ways to define this [1,2,27,29]. The length of TAS wear periods and CM length ranged from 1 to 4 months, and all studies were conducted in the United States and used the SCRAM monitor.

This study followed a previous study that used the Skyn with individuals in alcohol treatment wearing the device for 1 week and interviewed staff on their thoughts [36,59,60]. From this previous study, we found that most of the individuals were willing to wear the device for longer and that staff want patients wearing the device for longer than a week for it to be used in alcohol treatment. Therefore, for this study, we extended the wear time for 2 weeks and added the CM component. The findings of this study will contribute to the knowledge on TAS feasibility in alcohol research and providing CM in alcohol services in South London.

Objectives

This study aimed to explore the feasibility, strengths, and limitations of using a TAS to monitor alcohol consumption in individuals in treatment for AUD with or without CM to promote abstinence or low-level alcohol consumption.

Methods

This was a randomized controlled trial with a 1:1 allocation ratio to the control and CM groups.

Patient and Public Involvement and Staff Consultation

To ensure that the recruitment, study design, and outcomes were appropriate, when designing this study, we conducted monthly patient and public involvement groups and staff consultation for 6 months. Service users and staff from 3 South London alcohol services were invited to attend. There were 2 meetings held each month, one for service users (in person) and one for

staff (on Microsoft Teams). In these groups, we discussed study aspects and the participants' thoughts on potential challenges.

Setting

In total, 3 drug and alcohol services were recruited from South London and Maudsley National Health Service Foundation Trust. The 3 services were the Pier Road Project (Erith), Wandsworth Community Drug and Alcohol Service (Wandsworth and Richmond), and the Assertive Alcohol Outreach Team (Camberwell). All services were willing to be involved in this study and had recruitment occur at their facilities. At each service, after referral, patients typically completed a community detoxification, were prescribed any medication if appropriate, and started to attend group meetings and regular one-to-one meetings with their key worker. All participants that were recruited for this study were currently attending groups and one-to-one sessions.

Participants and Sample Size

Participants were referred by service staff and by the researcher attending patient groups to discuss the study. One of the aims of this trial was to investigate the feasibility of conducting a larger trial. Therefore, this study conducted no formal statistical sample size calculation but aimed to recruit 30 participants (15 in each arm).

The inclusion criteria were (1) reception of alcohol treatment for an AUD in one of the participating South London alcohol services, (2) age of ≥18 years, (3) ability to speak English competently, (4) ability to meet throughout the study period, (5) no current participation in any other research trials, and (6) willingness to provide informed consent to participate. Exclusion criteria were (1) current use of any illegal or addictive substances (excluding cannabis), (2) age of <18 years, and (3) inability to speak English without a translator.

The study inclusion criteria were intentionally kept broad, enabling individuals receiving any treatment for an AUD (provided that they met the other criteria) to participate.

Randomization

Participants were randomized via dedicated software and sealed envelopes by an independent statistician. The team member recruiting participants (EB) was not aware of the randomization allocation sequence until the sealed numbered envelope was opened at each participant's first research meeting. EB enrolled all participants and assigned participants to their allocated group. The researcher and participants were not blind to the allocation; both were aware of whether they were receiving CM rewards.

Procedure

At enrollment, participants were randomized into one of two groups: (1) treatment as usual+wearing a TAS (control group) or (2) treatment as usual+wearing a TAS+CM for low or no alcohol consumption as measured using the TAS (CM group).

Each participant had 7 research meetings arranged across 15 days. At the first meeting, the participant was trained in using the TAS and provided with a quick leaflet guide to take home with them, had the study protocol explained, and was randomized into a group. Meetings 2 to 6 were for TAS data download and timeline followback (TLFB) completion. At the final meeting, meeting 7, participants also had TAS data downloaded and completed the TLFB as well as a postwear survey. This procedure is shown in Table 1.

Table 1. Study procedure—an example of the research meetings if the first meeting happened on a Monday.

	Meeting description
Week 1	
Monday	Meeting 1—talk participants through the study and train them in using the TAS[a]
Wednesday	Meeting 2—TAS data download and TLFB[b] (+CM[c])
Friday	Meeting 3—TAS data download and TLFB (+CM)
Week 2	
Monday	Meeting 4—TAS data download and TLFB (+CM)
Wednesday	Meeting 5—TAS data download and TLFB (+CM)
Friday	Meeting 6—TAS data download and TLFB (+CM)
Week 3	
Monday	Meeting 7—TAS data download, TLFB (+CM), and postwear survey

[a]TAS: transdermal alcohol sensor.

[b]TLFB: timeline followback.

[c]CM: contingency management.

If the participant was randomized into the CM group, in addition to the aforementioned steps, at each meeting (meetings 2-7), the TAS data were checked to confirm whether the participant had been abstinent or consumed an amount of alcohol below our set threshold and whether they had been wearing the TAS. If they met these 2 criteria, they were then rewarded with the corresponding amount for the days of abstinence or low level of drinking.

The reason for the research meeting design was for regular TAS data download to ensure that the TAS did not start overwriting data. At the time of this study, the Skyn could store up to 72 hours before overwriting data. Participants also completed a

TLFB with the researcher at every meeting, so they only had to recall alcohol consumption for the previous 2 to 3 days [61].

CM Intervention

Participants who were randomized to the CM group could also earn rewards by being abstinent or for low drinking as measured using the TAS and wearing the TAS consistently (we specified that removal of no more than 60 minutes per day was allowed for a shower or bath). The CM reward was a £5 (US $6.25) voucher for each day that the target behavior occurred. There were also bonuses for consecutive days of the target behavior occurring. At each meeting (meetings 2-7), the researcher checked their TAC data and provided any earned CM rewards since the previous meeting. If the participant met the target behavior every single day for the study period, there was an additional bonus given at the end (£35 [US $43.75]). Therefore, a total of £180 (US $225.02) over the study period could be given in CM vouchers. If there was a day in which this behavior did not occur, then participants received no CM for that day and were not eligible for that bonus. The CM plan is shown in Table 2.

Table 2. Contingency management (CM) plan—an example of the CM plan for a Monday start. Participants were ineligible for CM if the device was removed (skin temperature of <30 °C for >1 hour). A 1-time 1-hour removal was allowed per day.

Day number	Day	CM for 1-day abstinence (£5 [US $6.25] per day)[a]	CM bonus for consecutive-day abstinence (£5 [US $6.25] per day)[b]	CM bonus for 14 consecutive days of abstinence (£35 [US $43.75] for 14 days)[c]
1	Monday	£5 (US $6.25)	—[d]	—
2	Tuesday	£5 (US $6.25)	—	—
3	Wednesday	£5 (US $6.25)	£10 (US $12.50; second meeting)	—
4	Thursday	£5 (US $6.25)	—	—
5	Friday	£5 (US $6.25)	£10 (US $12.50; third meeting)	—
6	Saturday	£5 (US $6.25)	—	—
7	Sunday	£5 (US $6.25)	—	—
8	Monday	£5 (US $6.25)	£15 (US $18.75; fourth meeting)	—
9	Tuesday	£5 (US $6.25)	—	—
10	Wednesday	£5 (US $6.25)	£10 (US $12.50; fifth meeting)	—
11	Thursday	£5 (US $6.25)	—	—
12	Friday	£5 (US $6.25)	£10 (US $12.50; sixth meeting)	—
13	Saturday	£5 (US $6.25)	—	—
14	Sunday	£5 (US $6.25)	—	—
15	Monday	£5 (US $6.25)	£15 (US $18.75; seventh meeting)	£35 (US $43.75; seventh meeting)

[a]Total of £75 (US $93.76).

[b]Total of £70 (US $87.51).

[c]Total of £35 (US $43.75).

[d]Not applicable.

Measures

BACtrack Skyn

The TAS used in this study was the BACtrack Skyn (model T15). It was worn on the participants' preferred wrist, but they could change which wrist they wore it on during the study period if that was comfortable for them. The Skyn continuously measured the participant's TAC while being worn, as well as skin temperature (°C). Output was analyzed at 1-minute intervals. The participants could remove the TAS at any time if they did not wish to wear it and were required to remove it for bathing as it is not waterproof. The CM group were told that they could remove it once a day for up to 60 consecutive minutes to bathe and still be eligible for their CM reward. If it was removed for longer than an hour, they would no longer be able to receive the CM reward. If they wore the TAS according to this and the TAC did not increase above our set threshold of 115.660 µg/L, they were eligible for the CM reward for that day. Our set threshold was based on previous work by the research team [35].

TLFB Method

A TLFB was completed at meetings 2 to 7 to assess self-reported alcohol consumption and compare it against TAC. The TLFB is a calendar-based measure to record self-reported substance use. A day was considered from midnight to 11:59 PM.

Postwear Surveys

Participants completed a postwear survey on their experience of wearing the Skyn at their last meeting. This survey was adapted from the work by Alessi et al [20]. If participants were randomized to the CM group, they also completed a survey on their CM experience. This survey was adapted from the work by Miguel et al [62].

Outcomes

Feasibility of the Trial

This primary outcome was the feasibility of this study design. Feasibility was defined by enrollment, participation, device tampering, removals, adjustments, malfunction rates, and the number of TASs returned.

Enrollment

Participants who were identified, approached, eligible, and enrolled were recorded. Participants who were approached but did not wish to participate were asked about their main reason for this. Participant safety was recorded via adverse events for each participant. The number of participants enrolled on each service was also recorded.

Participation

The number of attended meetings by enrolled participants, withdrawal rate, compliance with wearing the TAS, and reasons for incomplete participant data (nonattendance, TAS data overwriting, and TAS technical faults) were recorded. Participants were asked what their main reason was for nonattendance or for not complying with TAS wear.

Removals

TAS removals were defined as a skin temperature of <30 °C for >2 minutes. Removals were recorded for each participant.

Tampering

Participants were asked about tampering with the TAS if there was no clear reason for missing TAC data in the output.

Malfunction

TAS errors, missing data due to a technical fault, and charging or syncing issues were recorded, as well as how much data were missing for these reasons.

TAS Return

The number of Skyn devices that were returned to the research team at the end of each participant's study period was recorded.

CM Delivery

The feasibility of TASs to measure CM target behavior was a combination of the factors mentioned previously, including compliance, removals, TAS tampering, malfunction, and accuracy.

Secondary Outcomes

Acceptability

This was measured using the postwear survey.

Accuracy

Accuracy outcomes were measured using the TLFB and TAC data. The TLFB was self-reported [63] and was used to determine alcohol-drinking days and how many units were consumed (in the United Kingdom, 8 g or 10 mL of pure ethanol=1 unit). The TAS (BACtrack Skyn) continuously measured TAC and skin temperature (°C), and from this, Skyn removal and then reported drinking days based on the TAC (µg/L) were determined. The TLFB and TAC data were analyzed to determine TAS accuracy compared to self-report data.

To note, the alcohol-drinking day defined using TAC is different to the CM intervention criteria, which allowed for a low amount of drinking and had a higher TAC criterion of 115.660 µg/L.

Data Handling

There is currently no guidance from BACtrack to determine drinking event criteria. Courtney et al [34] described their procedure for processing Skyn output to identify drinking episodes, and we used these guidelines when processing participant data. We replaced any negative values recorded with 0 in the data output. Missing data were classified as any minutes not reported. Removed data were those reporting a temperature of <30 °C for >2 minutes.

An alcohol event was based on TAC greater than a specific value (µg/L) for more than a set number of minutes. These criteria were chosen due to previous work carried out by this research team [35,59].

Analysis

Descriptive statistics were reported for baseline and demographic variables. All statistical analyses were conducted using SPSS (version 28; IBM Corp).

The feasibility outcomes reported included enrollment and recruitment rate, participant attendance, response and compliance, removals, TAS tampering and error, and TAS return. Appropriate summary statistics were reported, and independent-sample 2-tailed *t* tests were used to compare means between the control and CM groups when appropriate.

Summary statistics were reported for the secondary outcomes to be explored for a possible future larger trial. The postwear survey answers were reported. TAS accuracy was determined by analyzing the TAS data compared to self-report TLFB. The analysis focused on the sensitivity, specificity, positive predictive value, negative predictive value, and percentage accuracy in classification of TAC compared to TLFB as the gold standard. Recorded drinking and abstinent days were assessed using Spearman rank correlations. Sensitivity in detecting alcohol events and specificity in classifying an alcohol-drinking day versus a non–alcohol-drinking day were assessed using different TAC criteria: TAS 15 (TAC>15 µg/L for >15 min), TAS 60 (TAC>15 µg/L for >60 min), and TAS 90 (TAC>15 µg/L for >90 min).

Ethical Considerations

This study was approved by the Cornwall and Plymouth Research Ethics Committee (reference: 23/SW/0066) and registered on the Open Science Framework and International Standard Randomised Controlled Trial Number (reference: ISRCTN46845361). Informed written consent was obtained from all participants and their data were anonymized. All participants received a £5 (US $6.25) voucher at every meeting they attended (total for all 7 meetings=£35 [US $43.75]), a voucher for the return of the TAS on the last meeting (£10 [US $12.50]), and reimbursement for travel costs to each meeting.

Therefore, each participant could have received up to £45 (US $56.25) for their participation plus travel costs.

Results

Participants

A total of 32 healthy adult participants (n=10, 31% female and n=22, 69% male) enrolled, and a total of 29 (91%) completed the study. In total, 3 participants withdrew (n=2, 67% from the control group and n=1, 33% from the CM group). Of these 3 withdrawals, 2 (67%) happened during the study period (P8 [control group] on day 3 and P28 [CM group] on day 12), and 1 (33%) occurred at the end of the first meeting (control group) due to the specific type of voucher, which could not be used at the participant's local supermarket. P8 and P28 withdrew because of personal circumstances changing. Therefore, a total of 29 participants were included in the analysis (n=10, 34% female and n=19, 66% male; Figure 1). Table 3 shows the characteristics of the 29 participants included in the analysis split by group (control vs CM).

Figure 1. Flowchart of participant recruitment and retention. CM: contingency management.

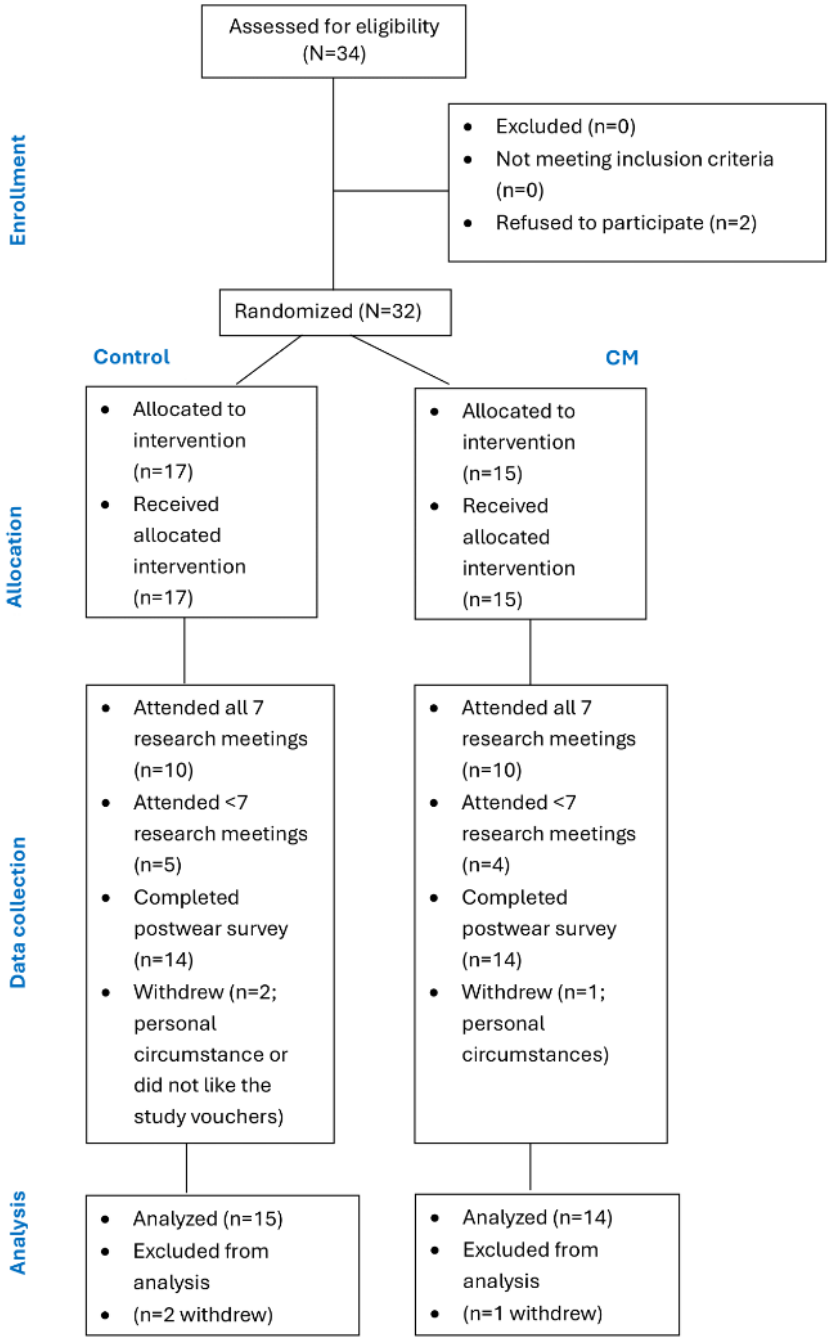

Table 3. Differences in group characteristics.

Characteristic	Control group (n=15)	CM[a] group (n=14)	Group intervention difference
Sex[b], n (%)			χ^2_1=0.4; *P*=.52
Female	6 (40)	4 (28.6)	
Male	9 (60)	10 (71.4)	
Age (y), mean (SD; range)	44.4 (13.78; 30-75)	51.5 (9.77; 35-60)	*P*=.12
BMI (kg/m^2), mean (SD; range)[c]	27.3 (6.24; 20.8-42.3)	28.7 (6.35; 22.2-42.5)	*P*=.58
Height (cm), mean (SD; range)	168.17 (6.40; 162-177)	171.29 (7.49; 162-185)	*P*=.24
Weight (kg), mean (SD; range)	77.2 (17.16; 53-112.5)	84.63 (19.75; 59-126.33)	*P*=.31
Ethnicity[b], n (%)			χ^2_{16}=43.3; *P*<.001
Black African	3 (20)	0 (0)

[n]n=98.

Feasibility of the Trial

Enrollment

A total of 34 potentially eligible participants were approached. Only 6% (2/34) who were identified by staff declined to participate after discussing the study with the researcher. Their reasons were (1) that they did not like wearing a watch so did not think that they would like to wear a TAS and (2) that they were very busy and could not commit to the regular meetings. No adverse events occurred. The services involved were also willing to help with recruitment, and all recruited at least 4 participants over the 5-month recruitment period.

Participation

It was feasible to enroll more than our target sample size (30 participants) within 5 months. The first participant was enrolled on July 5, 2023, and the final participant (N=32) was enrolled on December 6, 2023. These data could be used to inform the sample size power calculation for a future larger trial.

Among the 29 participants who completed the study period and did not withdraw, a total of 203 meetings were arranged (29 × 7 visits). Of these 203 meetings, 185 (91.1%) were attended. Reasons for nonattendance included illness, their partner being ill, being double booked with another health appointment, a broken phone so the researcher could not be contacted, and hospitalization. The research team decided to book research meetings one at a time, so at meeting 1, meeting 2 was agreed upon, and so on. The day before each meeting, a reminder SMS text message was sent out with the time and date and asking the participants to let the research team know whether this needed to be changed. This design seems feasible to maintain a high attendance rate.

Only 1 of the 29 participants (3%) spoke to the research team about removing their TAS early and removed it at the sixth meeting (2 days early) because they did not want to wear it anymore as they felt that “it is messing with my head” (P22).

Among the 3 services involved, the Assertive Alcohol Outreach Team recruited 53% (17/32) of the participants, the Pier Road Project recruited 34% (11/32) of the participants, and Wandsworth Community Drug and Alcohol Service recruited 12% (4/32) of the participants.

Removals

We defined TAS removal as >2 minutes during which the skin temperature was of <30 °C. We reminded participants to wear the TAS as much as possible, including while asleep. However, the TAS is removable by the wearer, and they could choose not to wear it if they wanted to and must remove it for water activities (bathing and swimming). Of the total minutes collected from the 29 participants (464,324 minutes of data, approximately 322 days), there was a total of 19.59% (90,982/464,324) of minutes of removals (approximately 63 days).

The control group had a total of 20.21% (60,879/301,179) of minutes of removals. The CM group had a total of 10.79% (30,103/278,862) of minutes of removals (t_{27}=1.843; P=.08; d=0.685).

Tampering

One participant (P1) admitted to turning the Skyn off while wearing it when they did not want to be monitored. No other evidence or reports of tampering from any other participant was recorded. This participant had 65.65% (13,173/20,067) of minutes of their participation time successfully recorded and 34.35% (6893/20,067) of missing data. Of these missing data, approximately half could be due to not attending meetings and data being overwritten (3386/6893, 49.12%). However, all other meetings were attended, so the 50.88% (3507/6893) of minutes of missing data could be due to the TAS being turned off or technology error and additional data overwriting (approximately 2.5 days’ worth of data).

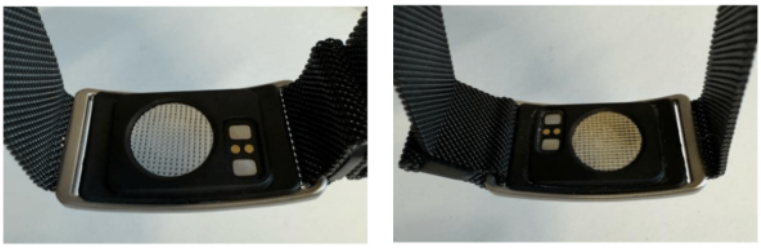
Malfunction

A total of 16 Skyns were ordered in phases during the study period. The first order of 6 Skyns had 2 issues: one Skyn had trouble pairing for the first 2 weeks, and another would not charge or pair with any research iPhone. BACtrack sent 3 Skyn replacements, and 2 of these would not pair with a research iPhone at first (they did 1 month later). We ordered a second batch of 7 Skyns halfway through data collection, and there were no issues with any devices from this order. BACtrack were unsure about the reasons for the issue with pairing and charging. Other issues experienced included syncing taking >40 minutes on occasions (the usual time is approximately 5 minutes). This was most likely due to poor connection or Wi-Fi.

Apart from 1 Skyn that arrived and could not be charged, there were no charging issues. The Skyn website states that the battery lasts for approximately 10 days; however, we found that it lasted for >2 weeks. Participants were provided with a fully charged Skyn at the first meeting. There were 2 participants whose battery decreased to a low level within their 2-week study period, so the warning red light started flashing. As the TASs were typically able to retain the charge for the entire study period, we did not provide the charging cable to participants. If the TASs will be used for >2 weeks in a future study, either the charging cable will need to be provided or there will need to be planned charging time with the researchers.

There was evidence of Skyn degradation after 2 months, which is partly why it was decided to order another batch of Skyns halfway through data collection [33]. Another reason for this order was their state of cleanliness (Figure 2). BACtrack do provide guidelines on how to clean the sensor; however, after following these instructions, the sensor could not be cleaned well.

Figure 2. These 2 photos of the BACtrack Skyn sensor show a brand-new, unworn Skyn (left) and a worn Skyn (right).



TAS Return

All but 1 Skyn were returned. This was due to the participant disengaging from the service and not being contactable by the researcher or key worker. One other participant did not attend their last research meeting, but they arranged an additional meeting to return the TAS.

CM and Intervention Delivery

CM rewards were delivered if 2 criteria were met: (1) the TAC for the day (midnight-11:59 PM) had a peak of <115.660 µg/L and (2) there were no removals lasting >60 minutes (temperature of <30 °C).

The TAS data were downloaded at each meeting (meetings 2 to 7) and checked, and any CM vouchers were provided for the previous 2 to 3 days. This was considered the best way to implement CM as close to those days in which the behavior occurred as possible. Table 4 details the amount of CM rewards earned by each participant and any reason why CM rewards were not earned.

Table 4. Contingency management (CM) rewards earned by participants in the CM group.

Participant ID	Days in which CM rewards were earned[a]	Total amount earned[b]	Days in which CM rewards were not earned[c]	Reason why CM rewards were not earned[d]
P4	0	£0	15	15 days=TAC[e] over the limit
P5	13	£105 (US $131.26)	2	1 day=TAC over the limit; 1 day=removal for >60 min
P6	12	£95 (US $118.76)	3	1 day=TAC over the limit; 2 days=removal for >60 min
P7	10	£85 (US $106.26)	5	1 day=TAC over the limit; 4 days=removal for >60 min
P10	12	£90 (US $112.51)	3	1 day=TAC over the limit; 2 days=removal for >60 min
P11	0	£0	15	15 days=TAC over the limit
P16	2	£10 (US $12.50)	13	6 days=removal for >60 min; 7 days=DNA[f] appointment and data overwritten
P17	5	£25 (US $31.25)	10	6 days=TAC over the limit; 2 days=removal for >60 min; 2 days=DNA appointment and data overwritten
P18	9	£55 (US $68.75)	6	6 days=removal for >60 min
P19	9	£75 (US $93.76)	6	3 days=removal for >60 min; 3 days=DNA appointment and data overwritten
P21	13	£110 (US $137.51)	2	2 days=removal for >60 min
P22	1	£5 (US $6.25)	11	9 days=TAC over the limit; 2 days=removal for >60 min; handed TAS[g] back 2 days early
P25	3	£15 (US $18.75)	12	2 days=TAC over the limit; 10 days=removal for >60 min
P29	11	£85 (US $106.26)	4	4 days=removal for >60 min

[a]Total: 48.3% (100/207) of days.

[b]Total: £755 (US $943.82).

[c]Total: 51.7% (107/207) of days.

[d]Total: 24.6% (51/207) of days with transdermal alcohol concentration over the limit, 21.3% (44/207) of days of removals, and 5.8% (12/207) of days of data overwritten.

[e]TAC: transdermal alcohol concentration.

[f]DNA: did not attend.

[g]TAS: transdermal alcohol sensor.

Control group participants attended 89.5% (94/105) of the meetings, and the CM group participants attended 92.9% (91/98) of the meetings (t_{27}=−0.573; *P*=.57; *d*=−0.213). The control group self-reported 48.6% (107/220) of abstinent days, and the CM group self-reported 70% (147/210) of abstinent days (t_{27}=−1.403; *P*=.17; *d*=−0.522). The proportion of days in which the Skyn data reported <1 hour of removals was 15.9% (35/220) for the control group and 24.8% (52/210) for the CM group (t_{27}=−1.326; *P*=.20; *d*=−0.493). The difference in the amount of units consumed between groups was not statistically significant (control: mean 109.33, SD 27.47; CM: mean 53.33, SD 24.91; t_{27}=1.503; *P*=.14; *d*=0.559).

Acceptability and Postwear Survey

A total of 97% (28/29) of the participants completed the postwear survey. One participant did not complete it because they did not attend their final research meeting and became unreachable. When asked about physical comfort, most participants (11/28, 39%) rated it to be quite to very comfortable, with the average score being 8.57/10 (SD 0.71; 10=very comfortable). Social comfort (how they felt wearing it in public) was also rated highly, with an average score of 9.63/10 (SD 0.00; 10=very socially comfortable). When asked how often they noticed the Skyn on their wrist, only 11% (3/28) of the participants said that they never noticed it when wearing it. Most (18/28, 64%) noticed it once or twice a day to every hour, but 25% (7/28) did report noticing it several times per hour. When asked to rate its interference with various activities

(exercise, mood, normal work, enjoyment of life, ability to concentrate, social life, and clothing choices), these were all rated with an average score of <2 (1=no interference at all; general activity: 1.75, SD 0.00; exercise: 1.07, SD 0.00; mood: 1.11 SD 0.00; work: 1.07, SD 0.00; enjoyment of life: 1.21, SD 0.00, ability to concentrate: 1.43, SD 0.00; social life: 1, SD 0.00; choice of clothing: 1.24, SD 0.00). The only activity that ranked higher was sleeping, with an average score of 2.71 (SD 2.83; 1=no interference at all).

A total of 32% (9/28) of the participants reported experiencing a mark on their skin from the TAS, with the other 68% (19/28) reporting never experiencing a mark or side effect. These side effects included itching (mean 1.95, SD 0.00), sweating (mean 1.88, SD 0.00), soreness (mean 1.07, SD 0.00), and irritation (mean 1.50, SD 0.00), with the scale being from 1=not noticeable to 10=unbearable. Participants were asked whether they would continue to wear the TAS for longer than the 2-week study period, and 96% (27/28) reported *yes*, and only 4% (1/28) reported *no*.

The following statements—"the device is too uncomfortable to wear for any longer," "I wouldn't want to wear it any longer because I am embarrassed," and "I want to wear short sleeves but won't while wearing the device"—were answered by all participants with "not true." Statements asking about changing their clothing choices, wanting to remove the TAS, and not liking the regular download visits all had an average score of 0.25 (SD 0.00 for all these statements) (on a scale of 0-4 where 0=*not true* and 4=*very true*). Only 4% (1/28) of the participants stated that they were tired of explaining the device to people. In total, 4% (1/28) stated that they were "ready to stop wearing the device because I am just ready to be done," and another participant (1/28, 4%) said that the "financial compensation for wearing the device any longer than this would not be worth it." A total of 7% (2/28) of the participants said that it was true that "I would not continue wearing the device because I do not like having to do the downloads at a specific time."

When asked about their drinking, 11% (3/28) self-reported that they were able to completely reduce their drinking, 25% (7/28) reported that they reduced it quite a bit, 14% (4/28) reported that they reduced it somewhat, 7% (2/28) reported that they tried but did not reduce it, and 11% (3/28) reported that they did not reduce or try to reduce it. In total, 32% (9/28) of the participants were abstinent throughout their study period.

Many participants (12/28, 43%) liked the in-person vouchers that were given at each meeting; however, 7% (2/28) would have preferred an e-voucher, 21% (6/28) would have preferred a bank transfer, and 18% (5/28) would be happy with any of these options (in-person voucher, e-voucher, or bank transfer). In total, 7% (2/28) reported preferring only an e-voucher or bank transfer, and 4% (1/28) preferred an in-person voucher or a bank transfer. Finally, participants were asked about the ease of meeting the researcher for the meetings, and 89% (25/28) reported that it was *not at all difficult*, whereas the other 11% (3/28) reported that it was *a little bit difficult*.

CM Survey

The 48% (14/29) of participants who were allocated the CM group completed another survey specifically on their experience of the CM rewards. All participants in the CM group (14/14, 100%) completed this survey. When asked about how easy it was to understand the CM reward procedure, most (9/14, 64%) said that it was very easy, but 21% (3/14) rated it as very difficult. When asked whether the CM had any effect on their response to treatment, half (7/14, 50%) said that it helped them either a lot or a little, 43% (6/14) said that it did not make a difference, and 7% (1/14) said that it had a negative impact. When asked whether they liked the CM rewards, all (14/14, 100%) said that they liked them either a lot or a little. When asked when CM rewards would help other people who seek substance treatment for alcohol dependence, 86% (12/14) said that it would help them a lot or a little, and 14% (2/14) said that it would depend on the person.

Accuracy

Participants wore the TAS for a cumulative total of 580,040 minutes. A total of 80.05% (464,324/580,040) of minutes of this participation was successfully recorded by the TAS. Of these 464,324 minutes of recorded data, there was a total of 90,982 (19.59%) minutes that suggested removal, a total of 56,858 (12.25%) minutes that were missing for unknown reasons, and a total of 58,986 (12.7%) minutes that were missing due to being overwritten as a result of not attending appointments. The Skyn is not waterproof, so participants were required to remove it for showering, baths, and any other water activities (eg, swimming). No fit adjustments were required.

The TAS recorded data for a total of 388 days. Of these 388 days, 337 (86.9%) had >60 minutes of removals or missing data. There was a total of 68.6% (266/388) of days in which there were >300 minutes of removed or missing data (not necessarily a consecutive 5-hour period).

TLFB Versus Skyn TAC

Overview

TLFB drinking days were recorded via the participant reporting any alcohol consumed. TAS drinking days were recorded according to the TAC criteria. We considered 3 different criteria for detecting alcohol-drinking days: TAC of >15 µg/L for >15 minutes, TAC of >15 µg/L for >60 minutes, and TAC of >15 µg/L for >90 minutes. The agreement between the TLFB and these criteria is reported in Table 5.

Table 5. Timeline followback (TLFB)– and transdermal alcohol sensor (TAS)–reported alcohol-drinking and nondrinking days.

Criteria	Alcohol-drinking days detected	Alcohol-drinking days in agreement (n=388), n (%)	Non–alcohol-drinking days in agreement (n=388), n (%)	Days reported by the TAS but not by TLFB as alcohol-drinking days (n=388), n (%)	Days reported by TLFB but not by the TAS as alcohol-drinking days (n=388), n (%)
TAC[a] >15 µg/L for >15 min		164 (42.3)	145 (37.4)	65 (16.8)	14 (3.6)
TLFB	185				
TAS	227				
TAC>15 µg/L for >60 min		146 (37.6)	171 (44.1)	39 (10.1)	32 (8.2)
TAS	185				
TLFB	185				
TAC>15 µg/L for >90 min		139 (35.8)	179 (46.1)	31 (8)	39 (10.1)
TAS	185				
TLFB	170				

[a]TAC: transdermal alcohol concentration.

Criteria for a Drinking Event of TAC>15 µg/L for >15 Minutes

The TLFB and TAS agreed on 42.3% (164/388) of days as alcohol-drinking days and on 37.4% (145/388) of days as abstinent days. There were 3.6% (14/388) of days in which the TLFB reported an alcohol-drinking day and the TAS did not and 16.8% (65/388) of days in which the TAS reported an alcohol-drinking day and the TLFB did not.

When splitting the groups and conducting a correlation between TAS- and TLFB-reported drinking days, both were positively significantly correlated, but the CM group had a stronger correlation effect (control group: r_{15}=0.625 and P=.01; CM group: r_{14}=0.836 and P<.001).

Criteria for a Drinking Event of TAC>15 µg/L for >60 Minutes

The TLFB and TAS agreed on 37.6% (146/388) of days as alcohol-drinking days and on 44.1% (171/388) of days as abstinent days. There were 8.2% (32/388) of days in which the TLFB reported an alcohol-drinking day and the TAS did not and 10.1% (39/388) of days in which the TAS reported an alcohol-drinking day and the TLFB did not.

When splitting the groups and conducting a correlation between TAS- and TLFB-reported drinking days, both were positively significantly correlated, but the CM group had a stronger correlation effect (control group: r_{15}=0.764 and P<.001; CM group: r_{14}=0.895 and P<.001).

Criteria for a Drinking Event of TAC>15 µg/L for >90 Minutes

The TLFB and TAS agreed on 35.8% (139/388) of days as alcohol-drinking days and on 46.1% (179/388) of days as abstinent days. There were 10.1% (39/388) of days in which the TLFB reported an alcohol-drinking day and the TAS did not and 8% (31/388) of days in which the TAS reported an alcohol-drinking day and the TLFB did not.

When splitting the groups and conducting a correlation between TAS- and TLFB-reported drinking days, both were positively significantly correlated, but the CM group had a stronger correlation effect (control group: r_{15}=0.805 and P<.001; CM group: r_{14}=0.913 and P<.001).

Skyn TAC

Reasons why the TAS did not detect an alcohol event but it was reported in the TLFB could include a large amount of missing data; TAS removal; a low amount of alcohol self-reported; or it being the last day of participation, which may mean that there was not enough time for alcohol to appear in the TAC output. There were other days in which there was no obvious reason why the TAS did not detect alcohol consumption.

Reasons why the TAS reported an alcohol-drinking day but the participant did not self-report alcohol consumption could include a sudden TAC spike, which suggests contact with an alcohol-containing product (eg, aftershave, deodorant, or hand sanitizer); the skin temperature suggesting that the TAS was not being worn at the time of TAC event detection, so the TAS may have been on a table near an alcohol spill or alcohol-containing product; and the TAS appearing to detect an alcohol event, so the self-report was inaccurate. There were other days in which there was no obvious reason why the participant did not self-report alcohol consumption.

In Figure 3, a visual presentation of the data for each TAC criteria is provided. It shows TLFB and the TAS criteria of TAS 15 (TAC>15 µg/L for >15 min), TAS 60 (TAC>15 µg/L for >60 min), and TAS 90 (TAC>15 µg/L for >90 min). The presence of the color corresponding to each of these TAC criteria indicates that an alcohol-drinking day was detected.

Figure 3. Visual representation of participants' Timeline Followback (TLFB)– and transdermal alcohol sensor (TAS)–detected alcohol-drinking days for (A) the control group and (B) the contingency management (CM) group. The figure includes 3 different TAS criteria for detecting a drinking day: TAS 15 (transdermal alcohol concentration [TAC]>15 µg/L for >15 min), TAS 60 (TAC>15 µg/L for >60 min), and TAS 90 (TAC>15 µg/L for >90 min).

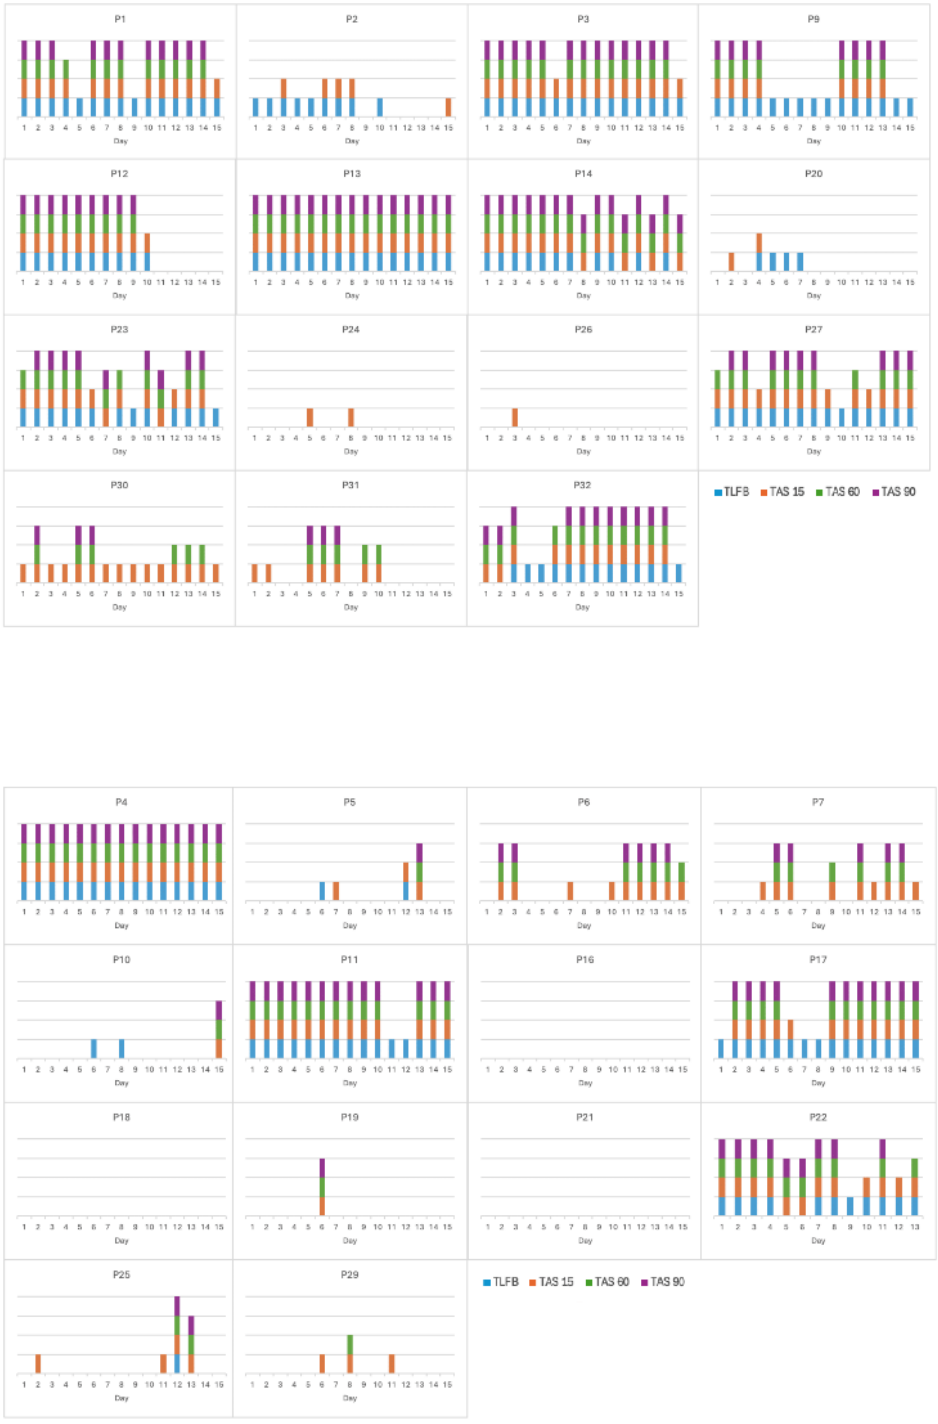


Figure 4 shows the data for TAC and the skin temperature of all participants who wore the TAS for the entire study period. There were participants whose TAC (blue line) peaked on separate occasions, suggesting multiple alcohol events, for example, P5 or P17. In contrast, other participant data suggest more frequent alcohol consumption, for example, P9 and P13. The orange lines depict the skin temperature recorded; the skin temperature for P1 and P20 suggests regular, long TAS removal.

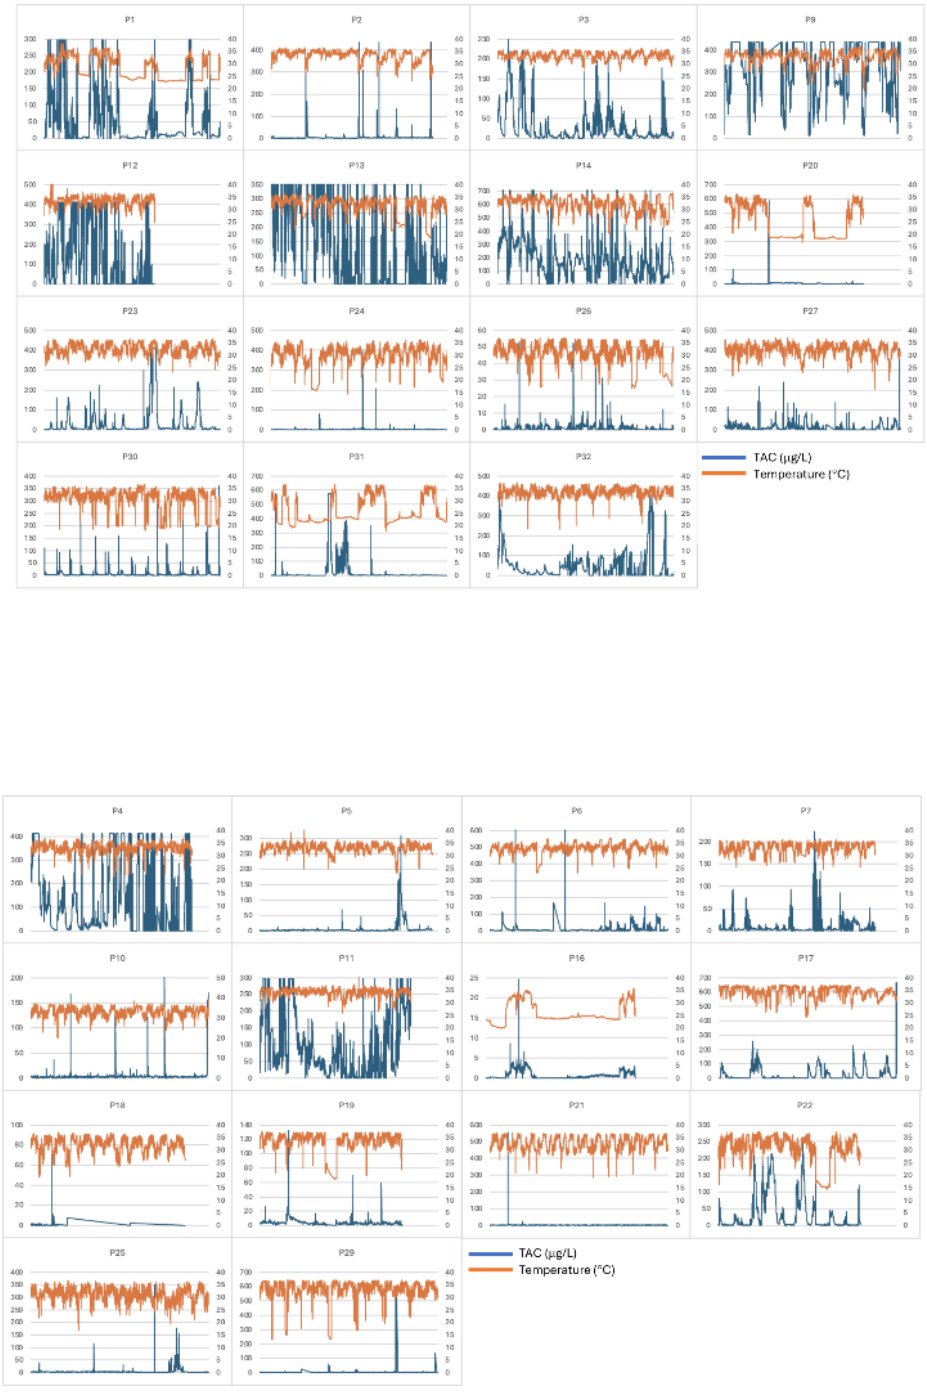
Figure 4. Individual participant Skyn data (excluding withdrawn participants). The primary axis shows the transdermal alcohol concentration (TAC; µg/L) data (blue line), and the secondary axis shows the skin temperature (°C) data (orange line).



Sensitivity, Specificity, and Correlations

We calculated the sensitivity, specificity, positive predictive value, negative predictive value, and percentage accuracy in classification for 3 drinking event thresholds: TAS 15 (TAC>15 µg/L for >15 min), TAS 60 (TAC>15 µg/L for >60 min), and TAS 90 (TAC>15 µg/L for >90 min), shown in Table 6.

Table 6. Transdermal alcohol concentration (TAC) criteria—sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and percentage accuracy classification (PAC).

Criteria	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	PAC
TAC>15 µg/L for 15 min	92.7	68.29	71.74	91.5	0.80
TAC>15 µg/L for 60 min	82.49	80.5	78.92	83.85	0.81
TAC>15 µg/L for 90 min	78.09	85.31	81.76	82.19	0.82

A Spearman correlation found a significant relationship between TLFB- and Skyn-measured alcohol-drinking days at the TAC>15 µg/L for >15 minutes threshold (r_s=0.695, bias–corrected and accelerated [BCa] 95% CI 0.417-0.883; *P*<.001) [29]. A Spearman correlation between the number of standard alcohol units self-reported and the average TAC values was also found to be significant (r_s=0.770, BCa 95% CI 0.632-0.852; *P*<.001) [29].

A Spearman correlation found a significant relationship between TLFB- and Skyn-measured alcohol-drinking days at the TAC>15 µg/L for >60 minutes threshold (r_s=0.773, BCa 95% CI 0.599-0.861; *P*<.001) [29]. A Spearman correlation between the total number of standard alcohol units self-reported and the TAS-reported drinking days at the TAC>15 µg/L for >60 minutes threshold was also found to be significant (r_s=0.740, BCa 95% CI 0.439-0.891; *P*<.001) [29].

A Spearman correlation found a significant relationship between TLFB- and Skyn-measured alcohol-drinking days at the TAC>15 µg/L for >90 minutes threshold (r_s=0.784, BCa 95% CI 0.625-0.868; *P*<.001) [29]. A Spearman correlation between the total number of standard alcohol units self-reported and the TAS-reported drinking days at the TAC>15 µg/L for >90 minutes threshold was also found to be significant (r_s=0.745, BCa 95% CI 0.460-0.892; *P*<.001) [29].

Discussion

Principal Findings

This study aimed to explore the feasibility, strengths, and limitations of using a TAS to monitor alcohol consumption in individuals in treatment for AUD with or without CM to promote abstinence or low-level alcohol consumption. The findings suggest that TAS-delivered CM to encourage alcohol reduction was feasible and acceptable to participants. There was a high correlation between TAS-recorded alcohol-drinking days and self-reported alcohol units, suggesting that the TAS was accurate in measuring the desired behavior. There was also high recruitment, attendance, and compliance of participants. Good rates of meeting attendance and data completeness were achieved. It was feasible to deliver CM using the TAS; however, key features of this process were identified for improvement. This is the first study of TAS-delivered CM in the United Kingdom and the first targeted at alcohol service users for alcohol treatment and reduction.

Participants found the wear of the TAS acceptable and comfortable even for social occasions. They found that it did not interfere with daily activities, and most (19/28, 68%) did not experience any side effects (such as a rash or skin irritation) from the strap. There was a high attendance rate and willingness to participate from those approached. Participants liked the reminder SMS text messages about each meeting, and there were few issues when arranging meetings. Only 3% (1/29) of the participants lost contact with the researcher during participation and did not return the TAS.

However, the answers to the CM survey suggest that this process may need to be improved. Some participants (3/28, 11%) reported it as difficult to understand, and half (7/14, 50%) said that it made no difference or did not help their treatment. These findings suggest that there should be more consideration on how the CM procedure is described and presented to participants at the start. Most (12/14, 86%) said that they did think that CM rewards would help other people who seek treatment for alcohol dependence a little to a lot, with the other 14% (2/14) of the participants saying that it would probably help but only if the patient was motivated.

To deliver the CM, TAS data were downloaded and reviewed at meetings 2 to 7. This was feasible; however, there were issues that arose that would need to be dealt with before scaling up the study size. Considering other options for automated TAC data interpretation will reduce the time-consuming manual data checking, which would only increase the researchers' time burden if conducted on a larger trial. In addition, creating an automated system could increase consistency and avoid human error.

The recruitment and follow-up rates from this study were the same as or higher than the recruitment and follow-up rates of other TAS feasibility or pilot studies. Previous studies using TASs had sample sizes for analysis of 5 to 13 participants [2,12,34,64]. In total, 2 of these studies used the SCRAM monitor [2,64], and 2 used the BACtrack Skyn [12,34], but 3 [2,34,64] mentioned discomfort with the TAS as key feedback, with Courtney et al [34], who used the BACtrack, having one participant drop out due to discomfort.

Overall, the findings support the feasibility of implementing and delivering CM using a TAS over a 2-week wear period with alcohol service users currently receiving alcohol treatment. The TAS used, BACtrack Skyn, was well liked and rated as comfortable by participants, with little daily interference. The recruitment rates were high and are encouraging for a larger trial. TAS delivery of CM has been shown to be effective in the United States using the SCRAM monitor [1,2,26-31,65], but this pilot shows promise for translation to other TAS brands delivering CM in the United Kingdom, with these findings highlighting aspects to address and improve before scaling to a larger study design. On the basis of these results, future work could explore the possibility of solutions to these challenges and a cost-effectiveness assessment.

In the future, we would also recommend collecting initial data from the participants to determine each participant's baseline skin temperature. This could be done with the researcher present to ensure correct TAS wear. Some participants were observed by the researcher to be wearing the Skyn during the meeting but the Skyn temperature was reported as <30 °C. Therefore, it may be better to establish a baseline for each participant to then use for their Skyn data for better accuracy at determining wear and removals.

Strengths and Limitations

The strengths of this study are that it was able to demonstrate the feasible use of the BACtrack Skyn over 2 weeks with individuals currently diagnosed with alcohol dependence and receiving alcohol treatment. Participants wore the TAS in their natural settings and unsupervised, consistent with how it should be worn. While the objective of this study was to assess the feasibility of a larger trial, the data collected as part of this study were able to provide more evidence of how this population wears, uses, and experiences a TAS. There was a high meeting attendance and TAS return rate for this study and no issues with participants being unsure or needing additional training for using the TAS after the baseline training. This study continues to support the use of TASs among the population.

The limitations of this study are similar to those of the design of all the studies conducted as part of this PhD—participants were only recruited if they were willing to wear the TAS from the start of the study period. This means that no participants were recruited who were not willing to attempt wearing the TAS. While this is not a limitation in some considerations as the TAS would be a voluntary treatment option to service users if implemented in services, it does mean that the postwear survey findings may be skewed more positively. Only those who were interested in and willing to wear the TAS had the chance to complete the postwear survey at the end of the 2 weeks. However, participants being willing to wear the TAS for the study does not necessarily mean that they were positive about the technology or that they had a good experience of wearing it; therefore, while we note that the study design does exclude those who are not initially willing to attempt wearing a TAS, this may reflect a truer view of service users who would try wearing the TAS as part of alcohol treatment if TASs were to be implemented in clinical settings.

Conclusions

To conclude, if planning a future larger trial for TAS delivery of CM, the proposed design changes from this study are (1) changes to how TAC data are checked for CM rewards from a manual to an automatic process, (2) a clearer explanation of the CM procedure, (3) consideration of the times available for participant meetings to improve participant availability and reduce missed appointments, (4) consideration of other TAS brands that have longer data storage, (5) consideration of whether participants should be provided with an iOS device and trained to sync their data or whether participants should have this option with their personal iOS device if using the BACtrack Skyn (which has been deemed feasible by wearers), and (6) consideration of the assessment of each participant's baseline skin temperature. These points could be assessed via an internal pilot study.

Acknowledgments

This is a summary of independent research funded by the National Institute for Health and Care Research (NIHR) Applied Research Collaboration South London. The views expressed are those of the authors and not necessarily those of the National Health Service (NHS), the NIHR, or the Department of Health and Social Care. CD and PD were supported by the NIHR Maudsley Biomedical Research Centre at the South London and Maudsley NHS Foundation Trust and King's College London. They were also supported by the NIHR Collaboration for Leadership in Applied Health Research and Care at King's College Hospital NHS Foundation Trust and the NIHR Applied Research Collaboration South London at King's College Hospital NHS Foundation Trust. CD was supported by an NIHR Senior Investigator Award. SP has been partly funded by income from research grants obtained from Mundipharma Research Ltd and Camurus AB. SP was a Research Fellow at King's College London at the time of writing. The authors would also like to acknowledge Andrea Solar-Reyes and Noel Kehoe for their data collection work alongside EB for this study and Simon Coulton for his help in participant randomization.

Authors' Contributions

EB led on the conceptualization, methodology, analysis, investigation, resources, data curation, project administration, visualization, and drafting and revision of the manuscript. CD supported the conceptualization, methodology, analysis, supervision, and revision of the manuscript. SP supported the supervision and revision of the manuscript. PD supported the conceptualization, methodology, analysis, supervision, and revision of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The Dutch acute health care system faces challenges with limited resources and increasing patient numbers. To reduce outpatient follow-up, direct discharge (DD) has been implemented in over 30 out of 80 Dutch hospitals. With DD, no routine follow-up appointments are scheduled after the emergency department (ED) visit for low-complex, isolated, and stable musculoskeletal injuries. This policy is supported by information leaflets, a smartphone app, and a telephone helpline with human support. Growing evidence shows that DD is satisfactory, safe, and effective in reducing secondary health care use, but thorough patient experiences are lacking.

Objective: The aim of this study was to explore the experiences of patients with DD to ensure durable adoption and to improve the treatment protocol.

Methods: A mixed method study was conducted parallel to the implementation of DD in 3 hospitals. Data were collected through a survey directly after the ED visit, a survey 3 months post injury, and semistructured interviews. Quantitative data were reported descriptively, and qualitative data used thematic analysis. Outcomes included the Bowen feasibility parameters: implementation, acceptance, preliminary efficacy, and demand. All patients who consented to the study face-to-face with one of the 12 low-complex musculoskeletal injuries were included in the study during the implementation period.

Results: Of the 429 patients who started the primary survey, 138 patients completed both surveys. A total of 18 semistructured interviews were conducted and analyzed. Patients reported a median treatment satisfaction score of 7.8 (IQR 6.6-8.8) on a 10-point scale of DD at the ED. Information quality was experienced as good (106/138, 77%), and most preferred DD over face-to-face follow-up (79/138, 59%). Patient information demands and app use varied among patients, with a median frequency of use of 4 times (ranging from 1 to 30).

Conclusions: This study shows that patients consider DD a feasible and safe alternative to traditional treatment, with a favorable perception of its acceptability, efficacy, applicability, and demand. Nevertheless, response rates were relatively low, and personal nuances and preferences must be considered when implementing DD. Clinicians and policy makers can use the insights to improve DD and work towards the integration of DD into clinical practice and future guidelines.

Introduction

The Dutch acute health care system faces substantial challenges due to limited resources and a rising number of patients requiring in-hospital care [1,2]. To alleviate this pressure, virtual fracture clinics have been introduced for Orthopedic and Trauma surgery patients [3]. Direct discharge (DD) is the most basic part of a virtual fracture clinic, concerning solely low-complex, isolated, stable musculoskeletal injuries. With DD, patients with these injuries are discharged directly from the emergency department (ED) without routine outpatient follow-up. Patients receive a removable orthosis or sling and are given information summarized in a mobile self-care app, the Virtual Fracture Care (VFC) app.

Growing evidence shows that DD is a safe and effective alternative to "traditional" care with routine follow-up [4,5]. DD reduces secondary health care use without causing a shift to primary health care use, while patient-reported outcomes (eg, functional outcome and satisfaction scores) and adverse outcomes (eg, complications and persistent complaints) are comparable [3,4]. These results and the usefulness of this method during COVID-19 social distancing measurements have led to a rapid uptake of DD in the Netherlands for 12 frequent injuries at the ED [6]. Since the first introduction in 2019, over 25 out of the 80 Dutch hospitals have implemented DD as the standard of care, adding to over 100 virtual fracture clinics and DDs worldwide [7]. While this reorganization of care has yielded beneficial outcomes in terms of reducing resources with comparable patient outcomes, there is a lack of research on the experiences of patients and their relatives with DD.

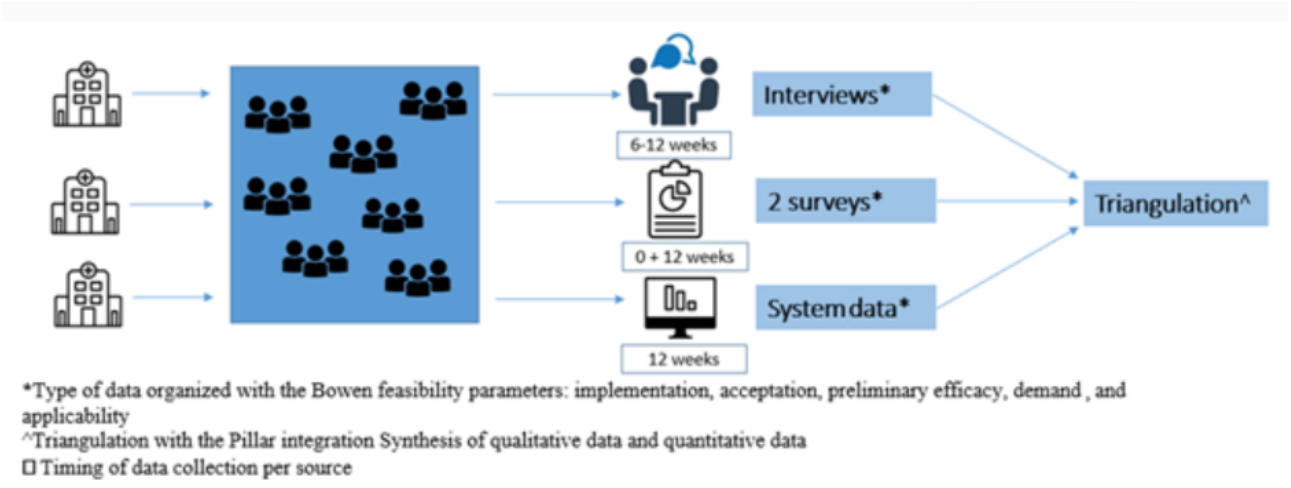
Performing an in-depth evaluation from an end user perspective deepens the insight into the quality of care by gaining a deeper understanding of user experiences and exploring reasons for nonadoption or abandonment, ensuring sustainable adoption of DD (inter)nationally. The aim of this study was therefore to explore the experiences of patients with DD to ensure durable adoption and to improve the protocol.

Methods

Design

An observational mixed method study was conducted among patients and parents of patients younger than 12 years who sustained low-complex, isolated, stable musculoskeletal injuries parallel to the implementation of DD in 3 Dutch level-2 trauma centers from September 2021 to July 2022 with an inclusion period of 3 months per hospital (Figure 1). Quantitative data and qualitative data were collected and analyzed separately by a quantitative team (GW and JS) and a qualitative team (WL and E Mathijsen). The Bowen feasibility framework was used to organize the data within the following parameters: implementation, acceptation, preliminary efficacy, and demand [8]. After separate analyses, quantitative data and qualitative data were triangulated with the Pillar Integration Process [9]. This study was reported according to the Good Reporting on a Mixed Methods Study (GRAMMS) criteria (Multimedia Appendix 1) [10], and according to the "Improving and Standardizing Evaluation Reports of Web-based and Mobile Health Interventions from the CONSORT-EHEALTH" [11].

Figure 1. Summary of study procedures and models used to evaluate the direct discharge protocol among patients.



Context

All participating centers were urban, level-2 trauma centers and teaching hospitals with up to 3 locations per hospital. All locations per hospital have an ED and implemented DD at the same time. Each hospital treats between 1200 and 1800 patients with low-complex, stable, isolated musculoskeletal injuries annually.

Traditional Treatment

Before DD was implemented, patients were treated according to local trauma protocols. These protocols consisted of immobilization or support with either a cast, sling, bandage, or splint and brief information about the injury at the ED. At least 1 outpatient follow-up appointment was scheduled at the plaster room or in the outpatient clinic within 2 weeks after the injury for review, extensive information, and definitive management planning.

Direct Discharge Protocol

This protocol was derived from the British model of a virtual fracture clinic and adapted to the Dutch health care setting in 2018. In its Dutch adaptation, DD includes 12 treatment protocols for low-complex, stable traumatic orthopedic injuries with additional injury-related criteria (Multimedia Appendix 2) [6]. Patients who met the injury-related inclusion criteria in Multimedia Appendix 2 and spoke Dutch or English fluently were included. No further predefined restrictions (eg, age or comorbidity) were used. Patients were excluded from the protocol if they had initial treatment in another hospital, follow-up in another hospital (eg, closer to home), multiple injuries, the reason for follow-up other than the injury (eg, social-care reasons), Eye/Motor/Verbal-score<15 at presentation, or intoxication. With DD, patients were discharged directly from the ED without routine outpatient follow-up. They receive a removable orthosis or a sling (eg, brace instead of a cast), and extensive information at the ED, summarized in a mobile self-care app, the VFC app. Apart from the criteria in Multimedia Appendix 2 and Dutch or English language skills (level B1), the protocols did not contain any predefined restrictions (eg, age or comorbidity). If, however, the ED staff believed physical follow-up was the most suitable treatment, outpatient follow-up was scheduled accordingly.

Patient eligibility for the protocol was re-evaluated on the next workday (within 24 h) by a team consisting of an (orthopedic) trauma surgeon and a radiologist. Patients who were incorrectly discharged directly were contacted by phone and scheduled for a face-to-face appointment.

VFC App

The VFC app provides self-care assistance through information, videos, and a helpline and can be downloaded for free at the Google Play Store and iOS App Store (Figure 2). Injury-specific leaflets with recovery information, treatment rules, and red flags were included. Furthermore, frequently asked questions, audiovisual exercise-, immobilization-, and analgesic instructions were included to assist patients. If patients required human contact in addition to the information, a helpline operated by an employee (eg, plaster technician) was available during working hours. The VFC app aimed to increase self-management and self-care during recovery and to substitute face-to-face follow-up. No reminders were sent, and use was voluntary. The app was developed by OLVG to reduce health care use and built by medical doctors with IT experience, usability testing was performed with peers. Due to its success, it was implemented in other hospitals. No major changes occurred during the study period.

Figure 2. English and Dutch in-app screenshots of the Virtual Fracture Care app used in the direct discharge protocol.

Study Population

Patients who met inclusion criteria and consented to participate in the surveys in the VFC app were included. Based on the annual number of patients (1200 - 1800 per hospital), and the inclusion time of 3 months per hospital, the estimated number of eligible patients was between 900 and 1350. Parents were asked to fill out the surveys if patients were 12 years or younger. If patients were between 13 and 16 years of age, patients and parents were allowed to complete the surveys. Patients older than 16 years could fill out the surveys alone. The exclusion criteria for this study were the same as the previously mentioned exclusion criteria for DD.

Sampling and Recruitment

Before discharge from the ED, in a face-to-face setting, eligible patients were asked to download and open the VFC app. An in-app pop-up asked for informed consent to participate in 2 surveys and an interview. After informed consent, patients were redirected to a Research Electronic Data Capture (REDCap) environment, a web-based survey system, to fill out the primary survey and were given an opt-out form by the treating physician, [12]. Additional information was given about the study and withdrawal methods. In the REDCap environment, all participants who started the survey were invited to participate in the interview by clicking a button and providing their email addresses. Age, sex, type of injury, and hospital were used to select a purposive sample among the quantitative population for interview patients. Eligible patients were contacted a

minimum of 6 weeks after injury to schedule a semistructured interview. During data collection, authors WDL and E Mathijsen considered whether the qualitative data had gained sufficient depth to perform a thorough analysis. Patients were reminded by email to complete the survey, and the second survey was sent 3 months post injury. Additional patient data were collected from electronic patient records.

Data Collection

Data were collected from surveys, semistructured interviews, and system data.

Surveys

Two surveys, 1 directly after the ED visit and one 3 months after the ED visit, with 63 questions, including close-ended questions, multiple-choice questions, 5-point Likert Scales, visual analog scales, and free-text questions, measured 5 Bowen feasibility parameters (Multimedia Appendix 3) [8]. As no golden standard for the evaluation of innovations exists, the surveys and topic list were developed by 4 researchers (JS, GW, BT, and THG) and checked by 2 experts on relevance: a professor in trauma surgery (JC Goslings) and an associate professor in-process evaluations of health care innovations (JCA Trappenburg). We pretested the survey with 5 patients to improve clarity.

Semistructured Interviews

Two independent researchers specialized in qualitative research, not involved in daily clinical practice or the VFC research team, conducted digital semistructured interviews to minimize social-desirability bias. The interviews were held within 6 and 10 weeks post injury to warrant an optimal recall. The interviews were guided by a topic list based on literature, including previously mentioned Bowen feasibility parameters (Multimedia Appendix 4) [8]. The research team piloted the topic list for clarity and completeness and modified it during data collection.

System Data

Quantitative data were extracted from the electronic patient record after 3 months of follow-up. The patient characteristics included compliance to therapy, complications (yes/no), type of complications, follow-up (yes/no), type of follow-up, and imaging. Downtime from the app was extracted from the log record of the VFC app.

Data Analysis

Quantitative data were analyzed using the SPSS (version 27; IBM Corporation) [13]. Baseline characteristics were reported descriptively using numbers and proportions for categorical variables and mean with SD or median with IQR as appropriate. The normal distribution of continuous data was assessed with visual analysis. Discrete variables were reported as numbers (percentages of the total population). The paired *t* test or the Mann-Whitney *U* test was used to determine the statistical significance of parametric variables for normally and nonnormally distributed data.

Qualitative data were analyzed according to the principles of the 6 phases of thematic analysis by Braun and Clark [14]. We have used an inductive, categorical approach because the triangulation process started after 4 phases. Data analysis started after the first 5 interviews. Interviews were audiotaped, transcribed verbatim, and analyzed using the software program NVivo (QSR International) [14]. One researcher (WL) independently analyzed the data, and another researcher (E Mathijsen) reviewed the analysis. Two researchers (WL and E Mathijsen) used several methods to ensure reliability and validity [15-17]. Discrepancies and remarks were discussed until they reached a consensus about data interpretations. Memos were made to track research decisions during analysis. Code saturation was reached when no new categories or themes emerged from the new raw data [15,16]. Instead of steps 5 and 6 according to Braun and Clark [14], we organized the data per theme during the triangulation session. The final themes were used to describe the value and feasibility of DD from the perspective of patients.

Triangulation

After the separate quantitative and partly qualitative analyses, findings were triangulated with a simplified approach of the Pillar Integration Process technique [9]. This approach uses a transparent and rigorous 4-stage technique for integrating and presenting qualitative and quantitative findings in a joint display Microsoft Excel, 2018 [18]. One of the researchers presented the quantitative findings (JS) per study parameter, and another the qualitative findings (WDL). (Dis)similarities and self-contained themes were objectified. One of the researchers (E Mathijsen) merged these themes into a meaningful narrative (the pillar), reviewed by researchers JS and WDL.

Ethical Considerations

This study, including the process analysis, was reviewed and approved by the Medical Ethical Committee of Utrecht, Netherlands (W21.261). Patients provided consent for participation in the research and could opt out at any time after request by email. The original consent and institutional review board approval covers secondary analysis without additional consent. A data key is stored at the local hospitals in a secured map and coded file. This is only accessible to JS and GW. The accessible data have been deidentified as far as possible (eg, age in years instead of the date of birth). Patients received no compensation to participate in this research.

Results

Demographics

Of the 429 patients who started the primary survey, 203 did not provide any data or contact details and did not complete the first survey and 88 did not complete both surveys (Figure 3). Of the 138 patients that completed both surveys (response rate: 138/429, 32%), 83 out of 138 (60%) were female, and the median age was 50 years (IQR 12 to 61) (Table 1). Patients who provided contact details at baseline varied significantly from responders regarding age (P=.01) but not sex (P=.14). Most patients were native Dutch speakers, who had attended primary school in the Netherlands (136/198, 98%), and over half had a minimum of a bachelor's degree (82/198, 59%) (Table 1). In addition, 18 patients sampled from the quantitative source participated in a web-based semistructured interview, of which

15 (83%) patients were female and 6 (33%) patients were parents of children (Table 2).

[a]Fx: fracture.

Implementation

Both data sources indicated that most patients were satisfied with their ED visit and the introduction of the app, despite some mentioning the hectic ED environment and difficulty downloading the app due to poor Wi-Fi connection. The physiological distress, and the hectic ED environment, resulted in an inability to recollect all the information provided by the ED physician. Several patients pointed out that the information in the VFC app was a valuable supplement to their ED visit (quote 1). Mobile app stability was excellent, with only 1 patient reporting issues accessing the app. The helpline could not be reached in 4 cases, resulting in 2 patients contacting the ED directly. The app was available 99.6% of the time, with the only downtime (5 hours in 3 months) caused by a software problem that was fixed by the app builder.

> *Because… it always goes quickly. It is always busy. But still, you know, this was completely clear; what I could expect and that I could download the app.* [quote 1; ID #10]

Acceptation

The median satisfaction with treatment was 7.8 (IQR 6.6-8.8) on a 10-point scale. Qualitative data complemented quantitative data, as most patients mentioned that they were satisfied with DD (quotes 2 and 3).

> *I would give DD a 7 or 8. Yeah, let's say 7, because I do feel that it might be difficult for older people. Especially because they don't always understand technology, you know.* [quote 2; ID #15]

> *To be honest, I think it's better. You know, often it's like, you go to a hospital, and it takes half a day just to get there, and come back, and all those things, and then it's just like: "O, it looks fine."* [quote 3; ID #5]

VFC App Acceptation

Most patients (106/138, 77%) reported that the quality of the information in the app was good and reported that the information answered the questions they had during their recovery (82/138, 58%). Additionally, 59% (79/138) would prefer the app over face-to-face follow-up if they were to have a similar injury. However, in qualitative data, some patients expressed concerns that the app may not be suitable for people with limited digital skills. Even though none of the patients identified themselves as "vulnerable," many reported that the app may not be appropriate for vulnerable individuals. Patients expressed that DD should not be mandatory for all in order to protect potentially vulnerable patients for whom DD would not be suitable.

Brace Acceptation

A total of 122 patients out of 138 (89%) used the brace for the prescribed period. Most patients (116/138, 84%) removed the brace or the sling during showering, at night (118/138, 86%), and (72/138, 52%) during non–weight bearing exercises. Most patients (97/138, 71%) found the brace comfortable, and 94 out of 138 patients (68%) found the brace convenient for these types of injuries (Multimedia Appendix 5). These findings were

complementary to the qualitative data. Patients preferred the brace to a cast as it allowed for better mobility because it was less bulky and less rigid compared with a cast (quote 4). However, the increased mobility made it tempting to overexert oneself, resulting in increased pain and insecurity for some patients (quote 5). The smaller size of the braces made some injuries seem less serious and burdensome, reportedly leading to social pressure to return to work earlier than advised by the doctor or app. Additionally, the less rigid nature of the brace resulted in increased skin friction, causing a superficial ulcer in 1 patient in the qualitative data.

> *I really like the brace because it allowed me to move. So, I was not stuck with a bulky cast on my leg, but rather, I had a lot of flexibility. I could actually determine what I wanted to do or not. So, I found that very enjoyable.* [quote 4; ID #2]

> *The brace was sometimes the reason I went over my limit. I could move more and was in the process of moving to a new home. But then the pain came back. I found it very difficult to 'guard' my limits.* [quote 5; ID #18]

Helpline and Perceived Safety

Most patients found the helpline important (116/138, 84%) and that the helpline offered them a sense of security (86/138, 62%). For some patients, the helpline was a way of checking if their recovery was still on track (quote 6). Most patients (94/138, 68%) in both data sources expressed that treatment with a brace and a helpline is safe for these types of injuries. However, some expected that if injuries were more severe, they would need more assistance than a brace and a smartphone app (quote 7).

Self-Empowerment

An increase in perceived self-empowerment was reported in 67 out of 138 (49%) of all patients, 51 (37%) patients reported neutral results, and 20 (14%) patients reported no increase. Enhanced treatment engagement was reported in 58 (42%) patients, while 50 (36%) patients reported neutral results, and 31 out of 138 (23%) patients reported no enhanced engagement (Multimedia Appendix 6). In the qualitative data, some of the interviewed patients stated that this type of treatment provided more self-empowerment and therefore, more control in their recovery (quote 8).

> *After about a week or three, I had a setback. I couldn't find this in the app, so I decided to call the helpline. The pain came back, and I was afraid I had broken something or something like that. They reassured me that it could not happen so quickly and that I just needed to rest for 24 hours h. They were right! It was nice to be able to check this.* [quote 6; ID #11]

> *Yes, I believe it is safe, given the circumstances. Because it wasn't that serious. Yes. I do have the confidence that if it is something serious I won't receive this type of treatment.* [quote 7; ID #17]

> *It was nice that I could read what I was allowed to do and what I was not. I think that gave me more control over my recovery. I knew what I could do myself in terms of exercises, and that was very helpful.* [quote 8; ID #2]

Preliminary Efficacy

Secondary Health Care Use

A total of 10 out of 138 (7%) patients had a face-to-face follow-up, and 9 (7%) patients by phone. Two patients attended the ED again after discharge due to anxiety and pain at the fracture site and were scheduled for outpatient follow-up. Two patients received follow-up for a wound check and 2 received follow-up as decided by the medical specialist due to severe pain complaints at the ED.

Functional Outcome

More than half of the patients had fully recovered 3 months after injury in terms of daily activities, sports, and work (84/138, 61%). Between 31% and 40% of patients were limited in functional outcomes once or twice a week. Approximately one in 10 patients were limited in physical activities more than 3 times a week. (Multimedia Appendix 7).

Pain

Most (92/138, 67%) patients have used painkillers in the first 3 weeks of recovery. Of these patients, 70 out of 92 (76%) patients have used acetaminophen, 17 (12%) patients have used nonsteroidal anti-inflammatory drugs, and 5 (4%) patients have used other undefined analgesics. Few patients (7/92, 5%) used cooling of the injury site to reduce pain. Analgesic use in the second week was lower (35/92, 38%) and further declined in the third week (9/92, 10%) and in the fourth week or after (9/92, 10%). Qualitative data showed limited pain complaints after immobilization of the initial trauma. Pain complaints in the first weeks were treated with analgesics. After the immobilization, a few patients had persistent pain symptoms. Most of these patients sustained a Weber A ankle fracture or ankle distortion. Those patients were most limited in their daily activities, specifically during more intense physical activities (eg, labor and sports) (quote 9).

> *The eight weeks of recovery are over, I believe. So now I should be able to start exercising again, well I do karate but I'll wait a little longer for that.* [quote 9; ID #4]

Demand

Almost all patients used the app during recovery (133/138, 95%) with a median of 4 times (IQR 2-6.5, range 0 - 30). Reasons to use the app included checking recovery exercises (91/138, 68%), treatment rules (69/133, 51%), the phase of recovery (68/133, 51%), seeking helpline information (57/133, 42%), and analgesics (10/133, 8%). Qualitative data supported the quantitative data. App use was focused on the first weeks post injury, and parents consulted the app more than children. They occasionally showed it to their child, predominantly if the information contained photos and videos (quote 10). Among the interviewed patients, almost all patients reported not requiring face-to-face follow-up for these types of injuries. The biggest advantage of DD is that it is time-saving on a personal level. Nevertheless, a few patients expressed a preference for outpatient follow-up. Especially if they had persistent complaints

or when the recovery was slower than expected. Patients expressed that this led to insecurity, which was also expressed by patients who used the app more frequently or later in the recovery phase (quote 11).

A minority of patients reported a lack of human contact and the physicians' reassurance of adequate recovery. Subsequently, as a minimal substitute, these patients suggested a feedback system (eg, pain scores or communication tools) to assist them further.

> *As for the app, he did see it, but you know, whatever! The only thing they find really interesting are pictures. What I liked that in the app is that they actually showed what was going on and what it looks like.* [quote 10; ID #17]

> *I was constantly looking for confirmation in the app, online, or at the fracture helpline.* [quote 11; ID #11]

Discussion

Principal Findings

This study shows that patients consider DD a feasible and safe alternative to traditional treatment, with a favorable perception of its acceptability, efficacy, applicability, and demand. Nevertheless, response rates were relatively low, and personal nuances and preferences must be considered when implementing DD.

Comparison With Literature

Patient satisfaction and perceived safety with DD aligned with previous studies [3,19,20]. Most patients responded positively to the introduction of DD at the ED, brace treatment, and assistance with the VFC app and helpline. The VFC app proved valuable in overcoming low recall of verbal information due to the chaotic ED environment and psychological distress. This finding is consistent with a systematic review highlighting the benefits of additional visual and written information in enhancing recall and injury knowledge [21]. Adequate understanding of the injury is crucial for properly following self-care protocols and monitoring red flags, this aligns with the finding that almost all patients used the app at least once. The braces used with DD were well-received, offering advantages such as easy removal (eg, during or at night), and improved daily living activities due to the early weight bearing. Braces seem to affect patients positively, as the lack of these advantages has been reported as most burdensome during cast immobilization [22]. However, the perceived decreased severity of the injury may pose a risk of overexertion and require further research.

Preliminary efficacy results align with previous research, demonstrating low complication rates, secondary health care use, comparable functional outcomes, and patient satisfaction with treatment [4,5,23]. Most patients preferred the VFC app over face-to-face follow-up for these injuries. While using apps in orthopedic and trauma surgery is not new, adding a self-care app to DD and virtual fracture clinics is a novel approach [24-26]. Patients found the information quality good and appreciated the time-saving component (eg, reducing work absenteeism). However, in the case of more severe injuries with wounds or complex fractures, some patients would prefer face-to-face interaction for additional reassurance. As previously suggested, digital self-care could be combined with face-to-face follow-up or used for preappointment education in patients with more severe injuries [27,28].

Although a good fit for most, some (young) patients noted that the app might not be suitable for older individuals or those with limited digital skills, potentially increasing health inequities in an already digitally oriented world [29,30]. However, it is important to note that DD targets relatively young patients, who are considered capable by the treating physician.

While previous studies have highlighted the potential for increased self-empowerment and patient engagement with eHealth, this study did not explicitly confirm it [31-33]. Despite positive study results, individual nuances in patients and injury types require a continuous assessment to ensure personalized patient care.

Information demand and app use varied among patients, implying different levels of demand among users. A minority of patients expressed a desire for more human contact and reassurance. A possible suggested solution was developing an in-app numerical feedback system, such as a questionnaire or communication tool.

Strengths and Limitations

This study has several strengths. To our knowledge, it is the first to provide in-depth interviews with patients treated using DD, providing valuable insights. Second, the research team's multidisciplinary involvement ensured a comprehensive evaluation and analysis of the data from multiple perspectives. Thirdly, the mixed method approach, including the separate collection of both data sources until data saturation, combined with the triangulation, increased the likelihood of realistic and rigorous results. Additionally, using a validated framework provided a structured insight into each feasibility parameter.

However, limitations include potential responder and selection bias due to a younger sample of patients with higher education levels and Dutch literacy rates than the general Dutch population. This age difference could be caused by the 12 selected injuries, of which half only occur in pediatric patients. Furthermore, the response rate of this study was 32%. Response rate, literacy, and education may limit the generalizability of the findings to a broader Dutch population, especially those with lower health literacy or digital skills. Furthermore, the timing to measure functional outcomes might have been suboptimal in these patients, as for some injuries (eg, mallet finger injuries), the immobilization period had just ended, resulting in limitations in daily activities.

Implications for Clinicians and Policy Makers, and Future Perspectives

DD has emerged as a promising approach to reduce outpatient follow-up while maintaining positive effects on primary health care use, patient satisfaction, complications, and functional outcomes [4,5]. By delivering follow-up care close to home, associated health care costs and societal costs decrease [34]. In addition, it limits unnecessary patient travel to the hospital thereby reducing the environmental impact of health care.

Including patients' perspectives in evaluating new care pathways, whether digitally assisted or not, is crucial for sustainable adoption and quality of care. Clinicians, researchers, and policy makers should prioritize patient involvement throughout the design, prototype, pilot, and evaluation phases. "Design thinking," a validated approach widely recognized in user experience and implementation literature, can be used to design these pathways. For example, replacing hospital care with DD involves changes in location and care deliverers, which presents new needs, challenges, and opportunities suitable to solve with design thinking. This study has identified areas for improvement of DD in terms of functions and features, and adjusted language to lower literacy. Future studies should focus on co-designing in-app feedback systems that address patient and health care professional needs for reassurance and monitoring like communication tools or questionnaires.

Conclusion

Patients consider DD a feasible and safe alternative to traditional treatment, with a favorable perception of its acceptability, efficacy, applicability, and demand. Nevertheless, response rates were relatively low, and personal nuances and preferences must be considered when implementing DD. Clinicians and policy makers can use the insights to improve DD and work towards the integration of DD into clinical practice and future guidelines.

Acknowledgments

The authors wish to thank Dr JCA Trappenburg, associate professor at the Julius Center from the University Medical Center of Utrecht, and Drs WL and E Mathijsen from the Healthcare Innovation Center (THINC) for the assistance in the development of the surveys and collecting and analyzing of the qualitative data. Abstract

Background: Ward rounds are an essential component of inpatient care. Patient participation in rounds is increasingly encouraged, despite the occasional complicated circumstances, especially in acute care settings.

Objective: This study aimed to evaluate the effect of real-time ward round notifications using SMS text messaging on the satisfaction of inpatients in an acute medical ward.

Methods: Since January 2021, a service implementing real-time ward round notifications via text messaging (WR-SMS) has been operational at a tertiary-care medical center in Korea. To assess its impact, we conducted a retrospective cohort study of patients admitted to the acute medical unit who participated in a patient experience survey. Patient satisfaction was compared between patients admitted in 2020 (pre–WR-SMS group) and 2021 (post–WR-SMS group).

Results: From January 2020 to December 2021, a total of 100 patients were enrolled (53 patients in the pre–WR-SMS group and 47 patients in the post–WR-SMS group). Compared with the pre–WR-SMS group, the post–WR-SMS group showed significantly greater satisfaction about being informed about round schedules (mean 3.43, SD 0.910 vs mean 3.89, SD 0.375; $P<.001$) and felt more emotionally supported during admission (mean 3.49, SD 0.800 vs mean 3.87, SD 0.397; $P<.001$). Regarding other questionnaire scores, the post–WR-SMS group showed an overall, although statistically insignificant, improvement compared with the pre–WR-SMS group.

Conclusions: Real-time round notifications using a user-friendly SMS may improve inpatient satisfaction effectively.

Introduction

Inpatient ward rounds constitute a salient core activity of the daily care of hospitalized patients and present a critical opportunity to deliver patient-centered care [1,2]. Ward rounds are a complex process that involves organizing the clinical care of inpatients, including diagnostic assessment and therapeutic planning by the care team [3]. For the patient, inpatient ward rounds provide an opportunity for direct patient-clinician communication, sharing of information, and participation in their own care planning [3,4]. Despite the widely recognized importance of ward rounds, an environment conducive to conducting such rounds and effectively communicating with patients is not always achievable, resulting in ineffective communication with and dissatisfaction of patients [5]. Especially in acute care settings, the participation of patients in ward rounds is likely to be limited not only due to their acute illness and fatigue [6] but also by the acute care context itself and time constraints of the ward staff [7,8].

With the emphasis on patient-centeredness, the Korean Ministry of Health and Welfare (MOHW) and the Health Insurance Review and Assessment Service (HIRA) developed the Korean Patient Experience Survey, to gain insight into the needs of inpatients and improve inpatient care quality. This survey has

been conducted biennially by telephone since 2017 among patients discharged from hospitals, and the results have repeatedly revealed that patients remain least satisfied with inpatient ward rounds [9,10]. In line with global trends, studies from the United States and the United Kingdom highlight the importance of improving patient communication and providing clear, predictable information to enhance patient satisfaction [11-13]. Furthermore, evidence suggests that interventions focusing on real-time communication [14], such as the use of SMS text messaging, can help alleviate patient dissatisfaction by improving the timeliness and transparency of ward rounds.

As part of the efforts to improve patients' satisfaction, Seoul National University Bundang Hospital (SNUBH), a 1300-bed tertiary referral hospital in the Republic of Korea, has implemented the real-time ward round notifications via text messaging (WR-SMS) service since January 2021 to inform the patients and their carers about the start of daily ward rounds, and thereby alleviating arbitrary waiting for rounds.

In 2015, a hospitalist-run acute medical unit (AMU) was established to enhance patient safety and care efficiency for patients with acute medical conditions. Although the AMU improved patient outcomes and efficiency of care [15,16], patients' perceptions of inpatient care were found to be inconsistent, which could be attributed to the acuteness and complexity of clinical conditions, the hectic hospital environment, and heightened levels of anxiety.

As mobile devices continue to advance, SMS text messaging has been suggested to enhance clear and efficient communication in various clinical contexts [14,17]. However, there remains a gap in research regarding the potential impact of informing patients about round times via SMS text messages on communication effectiveness and patient satisfaction. This study aimed to determine the effect of real-time WR-SMS service on the satisfaction of AMU inpatients.

Methods

Study Design and Clinical Setting

This retrospective cohort study was conducted at the AMU of SNUBH, a hospitalist-run 46-bed ward caring for patients with acute medical conditions, who were admitted from the emergency or outpatient departments for active acute medical care, unless being hemodynamically unstable requiring invasive monitoring and critical care or terminally ill with cancer requiring only palliative care. After receiving active acute care, patients were either discharged or transferred to a specialty ward for further treatment. The AMU was operated 24 hours a day and 7 days a week by 10 board-certified medical hospitalists on a weekly rotation basis.

The SNUBH patient-experience survey has been routinely performed by telephone since 2006. Patients eligible for the survey were randomly selected within 2 to 56 days (8 wk) after discharge. Patients unable to communicate effectively due to conditions resulting in severe cognitive or communication impairments were excluded from the survey. Following the introduction of the official Korean Patient Experience Survey developed by the Korean MOHW/HIRA in 2017, the SNUBH patient-experience survey used the very same questionnaire to assess patients' hospital experiences.

Study Participants

Adult patients ≥19 years of age who were admitted to the AMU of SNUBH between January 2020 and December 2021 for ≥1 day and who participated in the SNUBH patient-experience survey after discharge were included. Their demographic data were retrospectively collected from the electronic medical record system, and their satisfaction was assessed based on the SNUBH patient-experience survey results. To determine whether patient satisfaction improved, we compared the scores from 2020 (before the implementation of the WR-SMS, pre–WR-SMS group) with those of 2021 (after the implementation of the WR-SMS post–WR-SMS group).

Real-Time Ward Round Notification Service With Text Messaging

The WR-SMS service was first developed in September 2020. It was actively implemented in January 2021, after an introductory period of 3 months (October to December 2020) during which the staff was educated about and encouraged to use the service via campaigns and email or SMS notifications.

The WR-SMS service was embedded into the SNUBH electronic health record system, enabling the doctors to send short text messages (80 to 160 bytes; ie, SMS) to their inpatients directly from the electronic health record system with a few clicks. From their patient list, doctors were able to select or deselect the patients who would receive the SMS text message. The default content of the SMS text message read, "Ward rounds by Dr. OOO will begin shortly. Visiting times may vary depending on the room." Further adjustments to the content of the message could be made as needed by the doctor. The notification could also be sent simultaneously to other relevant medical staff. The doctors were encouraged to send this WR-SMS to their patients just before starting their ward rounds, usually right after reviewing the patients' records.

Patient-Experience Survey

The SNUBH patient-experience survey questionnaire, which uses the same questions as the official Korean Patient Experience Survey developed by the Korean MOHW/HIRA, comprises 19 questions organized into 5 domains about the patients' hospital experience (4 questions pertaining to "Services from nurses," 4 pertaining to "Services from physicians," 5 pertaining to "Medication and treatment processes," 2 pertaining to "Hospital environment," 4 pertaining to "Ensuring patients' rights", and 4 assessing patients' demographic characteristics) (detailed questionnaire is presented in Multimedia Appendix 1). Each question was scored on a 4-point Likert scale (1=very dissatisfied, 2=dissatisfied, 3=satisfied, and 4=very satisfied) to assess patients' subjective satisfaction with the quality of inpatient services. Except for the question about providing information about plans after discharge, answers were either "Yes" or "No." For this study, the responses to the "Services from physicians" and "Medication and treatment processes" domain, which are closely related to inpatient ward rounds, were considered.

Statistical Analysis

Data reflecting patients' baseline characteristics were expressed as a median with ranges for continuous variables and as frequencies and percentages for categorical variables. Data from Likert scales were expressed as means and SDs, as well as median with ranges (IQRs). Comparisons were performed using the Mann-Whitney *U* test, Student *t* test, and χ^2 test. All tests were 2-sided and performed at a significance level of .05. Statistical analyses were performed using IBM SPSS v. 21.0 (IBM Corp).

Ethical Considerations

The study was conducted in accordance with the Declaration of Helsinki, revised in 2013. The SNUBH institutional review board approved this study design and waived the need for obtaining informed consent from the participants due to the retrospective design (B-2203-746-101). Participant confidentiality and anonymity were strictly maintained throughout the research process, and data were handled in a secure manner to protect their privacy. In addition, the study ensured that no undue harm or burden was placed on participants and that their rights, safety, and well-being were prioritized at all times.

Results

Baseline Characteristics of the Participants

A total of 100 patients were enrolled from January 2020 to December 2021 (53 in the pre–WR-SMS group before WR-SMS implementation and 47 in the post–WR-SMS group after WR-SMS implementation). The median age of the patients was 59.5 (range 25 - 81) years, and of the total, 59 were female. A total of 74 patients were hospitalized because of malignancy and 26 patients were admitted for non-cancer illnesses. A total of 44 and 56 patients were admitted from the emergency and outpatient departments, respectively. The median length of hospital stay was 7 (range 3 - 30) days. No statistically significant difference of patients' baseline characteristics between the pre- and post–WR-SMS groups was observed (Table 1).

Table . Baseline demographic and clinical characteristics of study participants.

Characteristics		Pre–WR-SMS group[a] (n=53)	Post–WR-SMS group[b] (n=47)	*P* value
Age (year), median (range)		58 (25-81)	60 (38-76)	.90
Sex, n (%)				.36
	Male	19 (36)	22 (47)	
	Female	34 (64)	25 (53)	
Disease, n (%)				.43

[a]Pre–WR-SMS group: patients hospitalized at the acute medical unit in 2020, before the implementation of ward round notifications via text messaging service.

[b]Post–WR-SMS group: patients hospitalized at the acute medical unit in 2021, after the implementation of ward round notifications via text messaging.

Effects of Real-Time Round Notification on Satisfaction of Hospitalized Patients

After the WR-SMS implementation in 2021, the score for the question pertaining to whether the patient had received information about round schedules improved significantly compared with 2020. Differences in the Likert scale for this question are illustrated in Figure 1. The proportion of patients who assigned a rating of 4 points (very satisfied) increased from 66% (35/53) in the pre–WR-SMS group to 92% (43/47) in the post–WR-SMS group, while the proportion of those who assigned a rating of 1 point (very dissatisfied) decreased from 6% (3/53) in the pre–WR-SMS group to 0% in in the post–WR-SMS group.

Figure 1. Changes in Likert scale scores regarding the provision of patient information on round schedules before and after the implementation of ward round notifications via text messaging. Pre–WR-SMS group: patients hospitalized at the acute medical unit in 2020, before the implementation of ward round notifications via text messaging service; Post–WR-SMS group: patients hospitalized at the acute medical unit in 2021, after the implementation of ward round notifications via text messaging service.

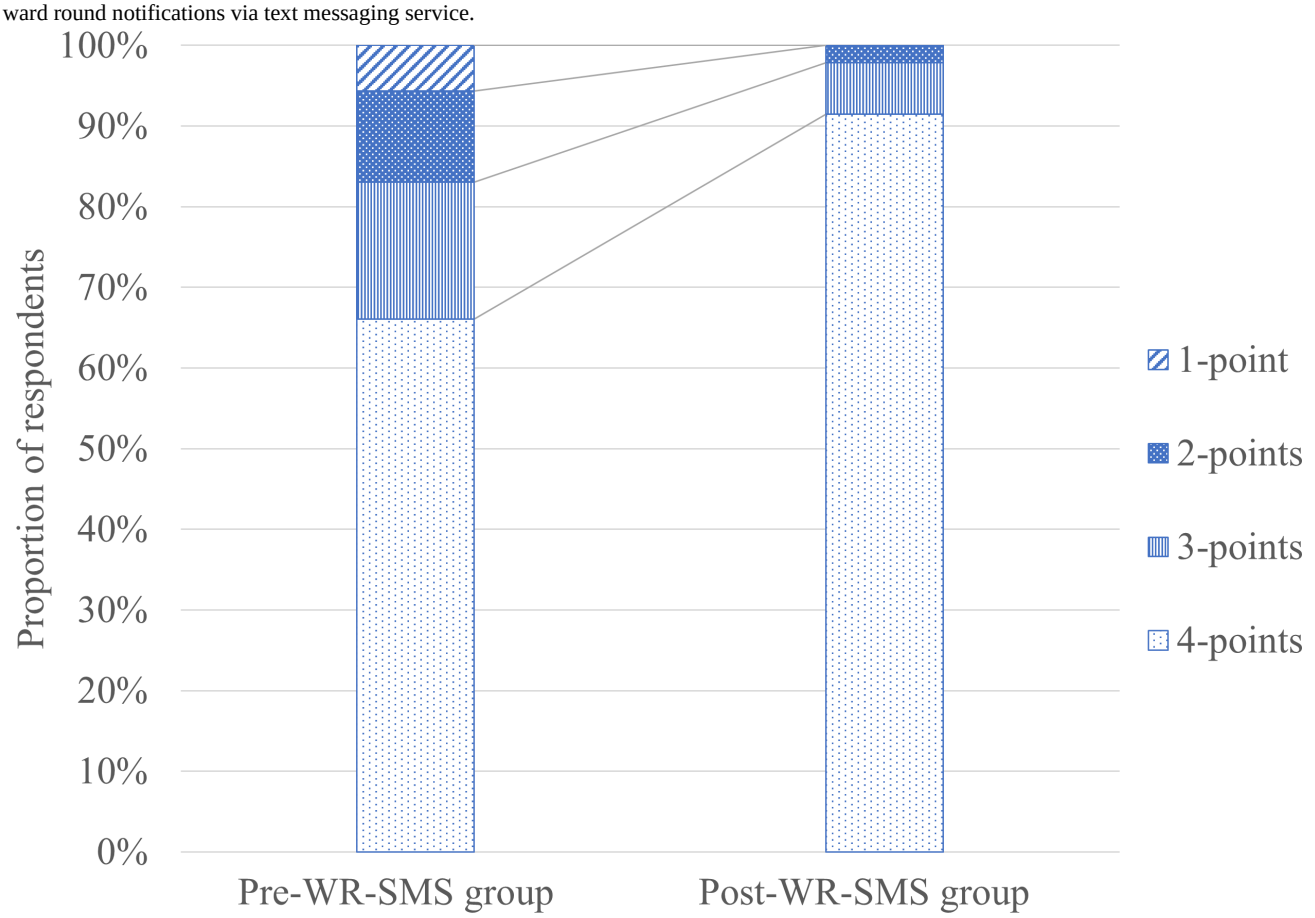

Table 2 summarizes the responses for the "Services from physicians" and "Medication and treatment processes" domains. Naturally, patients in the post–WR-SMS group showed significantly higher satisfaction about being informed about round schedules (mean 3.43, SD 0.910 vs mean 3.89, SD 0.375; *P*<.001) compared with patients in the pre–WR-SMS group. Interestingly, patients in the post–WR-SMS group also demonstrated significantly higher satisfaction with the emotional support (comfort and empathy) they received during admission (mean 3.49, SD 0.800 vs mean 3.87, SD 0.397; *P*<.001). Although not statistically significant, they were also satisfied with the description of the treatment processes (mean 3.62, SD 0.713 vs mean 3.83, SD 0.481; *P*=.09) and the explanations of possible side effects during treatment (mean 3.60, SD 0.743 vs mean 3.85, SD 0.465; *P*=.05). For all other questions in the "Services from physicians" and "Medication and treatment processes" domain, the post–WR-SMS group recorded a higher overall score compared to the pre–WR-SMS group, although it was not statistically significant (Multimedia Appendix 2).

Table . Survey results on patient satisfaction before and after the implementation of ward round notification using SMS text messaging service[a].

Parameter		Pre–WR-SMS group[b] (n=53)	Post–WR-SMS group[c] (n=47)	*t* test (df)	*P* value
Services from physicians					
	Courtesy and respect for patients			–0.93 (83.47)	
	Median (IQR)	4 (4-4)	4 (4-4)		.65
	Mean (SD)	3.81 (0.557)	3.89 (0.312)		.36
	Careful listening to patients			–0.47 (88.02)	
	Median (IQR)	4 (4-4)	4 (4-4)		.88
	Mean (SD)	3.83 (0.545)	3.87 (0.337)		.64
	Opportunities for patients to meet their doctors			–1.58 (94.08)	
	Median (IQR)	4 (3-4)	4 (4-4)		.15
	Mean (SD)	3.58 (0.663)	3.77 (0.476)		.12
	Receipt of information about round schedules			–3.37 (70.90)	
	Median (IQR)	4 (3-4)	4 (4-4)		.002

Discussion

Principal Findings

The WR-SMS implementation resulted in significant improvement of inpatient satisfaction among patients hospitalized in the AMU. Besides the direct improvement in scores pertaining to the receipt of round schedule information (mean 3.43, SD 0.910 vs mean 3.89, SD 0.375; *P*<.001), patients felt more emotionally supported and involved in the care process (mean 3.49, SD 0.800 vs mean 3.87, SD 0.397; *P*<.001), and also expressed higher satisfaction with the explanations provided

about treatment side effects (mean 3.60, SD 0.743 vs mean 3.85, SD 0.465; *P*=.047). These significant findings emphasize the value of real-time communication on both procedural and emotional aspects of care. Our results indicate that by enabling patients to participate more actively in routine ward rounds, WR-SMS fosters a greater sense of involvement and satisfaction, reaffirming the critical role of patient-centered communication in inpatient care.

Patient-centeredness is an essential component of high-quality health care, contributing to improved experience and clinical outcomes [18]. It is defined by the Institute of Medicine as the establishment of a partnership between the patient and health care providers to ensure that the wishes, needs, and preferences of the former are respected in the shared decision-making process [19]. Since the early 2000s, many countries have implemented patient-reported experience measures (such as standardized surveys) at the national level. The data are publicly reported, in order to assess and monitor patients' health care experiences and improve the quality of care [11,12]. For example, the United States Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey, first implemented in 2006, measures patients' perspectives on the quality of care they receive during their hospital stay, with its scores influencing hospital payment [13]. The United Kingdom and the Netherlands also conduct national-level surveys to assess patient satisfaction, which are used for various purposes related to improving health care services [20,21]. Previous studies revealed that quality improvement activities were initiated after patient care performance data were publicly released [22], with even hospitals that exhibited high levels of patient satisfaction delivering higher-quality clinical care [13].

In South Korea, the Korean Patient Experience Survey has been regularly conducted by HIRA biennially since 2017 by telephone among patients discharged from hospitals. It was developed based on the American HCAHPS, but further modified to suit the Korean context and to promote improvement of current Korean health care service quality [23]. A 2015 survey by the Korea Institute for Health and Social Affairs revealed that 30.5% of hospitalized patients claimed not to have been adequately informed about ward rounds and 20.4% reported not being included in the care process [24]. Furthermore, qualitative research during the Korean Patient Experience Survey development process revealed that inpatients were frequently unsatisfied with the communication with their doctors, especially regarding the lack of advance notice and unpredictability of ward round times [23]. To gauge these concerns, a direct question about whether the patient has been informed about the ward round time was included in the official Korean Patient Experience Survey.

Despite the increasing emphasis on patient-centeredness, patients are often still excluded from their own care process [5,6]. The results of the previous Korean Patient Experience Surveys (first to third, conducted from 2017 to 2021) reveal that the scores for the "Ensuring patients' rights" and "Services from physicians" domains remain lowest [9,10,25], suggesting that communication between patients and doctors remains unsatisfactory and patients do not feel sufficiently involved in the care process. Among several factors influencing patient participation and communication, such as the ward staff's attitude, time constraints [7], and health literacy [26], the care environment context itself has been identified as critical [8]. Previous Korean patient surveys revealed that patients felt dissatisfied and even frustrated by the medical staff's impolite, indifferent, or authoritarian attitudes and faced difficulties in communicating with their doctors who always appeared busy, and took issue with unpredictable and irregular round times [23]. Particularly in acute care environments, the patients' ability to participate is further diminished by their vulnerability, illness, and anxiety; furthermore, even the ward atmosphere is often disorderly and far from suitable for effective communication. In such situations, patient involvement is notably infrequent [6].

Patients in our AMU were mostly afflicted with complex, acute illness and frequently in need of interventional procedures, imaging studies, and even surgical procedures. Therefore, these patients and their carers often missed routine ward rounds during planned procedures or did not notice that ward rounds were taking place. Furthermore, the acuteness of the patients' conditions and lack of awareness about ward rounds likely led to frustration, anxiety, and dissatisfaction of patients and their carers toward their care. Real-time notifications provided through the WR-SMS addressed these issues by increasing awareness and predictability of ward rounds, which may help mitigate the emotional burden associated with the uncertainty of acute care. This aligns with studies suggesting that structured and predictable communication mechanisms, such as SMS notifications, create a more conducive environment for patient participation in care processes. A study conducted by Redley et al [6] at an acute inpatient ward indicated that only 18% (20/52) of rounds involved patient participation in clinical decisions, although even the patients who participated in rounds indicated low preferences for participation upon arrival at the hospital. The authors suggest that the patients' preferences for participation could change during the course of their hospital stay and it is also likely that passive participation may have been driven by limited opportunities to participate [6]. Similarly, Walton et al [27] revealed that familiarity with the hospital environment tended to positively affect participation in ward rounds, with several participants highlighting the uncertainty regarding the timing of rounds as a source of difficulty and anxiety.

With the development of communication devices such as cellular phones and smartphones, text messaging via SMS is increasingly used to enhance effective communication with patients and carers [14,17]. In our institution, the WR-SMS was developed and introduced to inform inpatients about the start of ward rounds in real time to improve their opportunities to participate in them. As physicians typically review their patients' medical records right before they begin ward rounds, the WR-SMS was embedded into our electronic health record system to enhance its use instead of using a separate platform. Following its implementation in January 2021, its utilization rate rapidly increased with long-term promotional activities, reaching an average of 65% in 2021. With its use, although only a statistically insignificant increase in patients' perceptions of opportunities to meet their doctors was noted (possibly owing

to the small sample size and the nature of the ward, which is staffed by hospitalists who are primarily based within the unit), inpatient satisfaction significantly improved with regard to "providing information about round-time" and the "Medication and treatment processes" domain. However, scores for other aspects in the "Services from physicians" domain did not improve significantly, suggesting that while real-time SMS notifications enhance patients' involvement and satisfaction with specific aspects of care, they may need to be supplemented with other interventions to address broader communication gaps.

Limitations

To our knowledge, this is the first study to investigate the effect of real-time round notification via SMS on inpatients' satisfaction. Nevertheless, it has some limitations. First, it was conducted at a single referral center in South Korea. As of 2019, the penetration rate of mobile phones in South Korea was 100%, with smartphones accounting for 95%. Therefore, our results may not be reproduced in other countries with lower mobile phone penetration rates. Second, as we used information from subjects who participated in the SNUBH patient-experience survey, instead of conducting a new survey, the number of patients included in this study is relatively small, precluding further adjustments and analyses based on clinical characteristics or comorbidities. However, the clinical setting remained constant throughout the study period and the subjects for the SNUBH patient-experience survey were randomly selected, which should minimize bias. Third, since this study included only patients capable of communication as survey respondents, it was not possible to assess the impact of WR-SMS on caregiver satisfaction.

Conclusion

Effective communication between physicians and patients, particularly during inpatient ward rounds, is a crucial aspect of inpatient care. This study proposes that real-time round notifications delivered through a user-friendly SMS service could improve inpatient satisfaction, likely by providing predictability and fostering an improved perception of emotional support. In the contemporary landscape, with personal communication devices becoming increasingly ubiquitous, the strategic utilization of such devices is anticipated to significantly influence patient satisfaction.

Abstract

Background: Rhinolaryngoscopes are one of the most widely used tools by otolaryngologists and speech-language pathologists in current clinical practice. However, there is limited data on adverse events associated with or caused by the use of rhinolaryngoscopes.

Objective: In this study, we used the Manufacturer and User Facility Device Experience (MAUDE) database with the aim of providing insights that may assist otolaryngologists in better understanding the limitations of these devices and selecting appropriate procedures for their specific clinical setting.

Methods: We characterized complications associated with the postmarket use of rhinolaryngoscope devices from the US Food and Drug Administration MAUDE database from 2016 through 2023.

Results: A total of 2591 reports were identified, including 2534 device malfunctions, 56 injuries, and 1 death, from 2016 through 2023. The most common device problem with rhinolaryngoscopes was breakage (n=1058 reports, 40.8%), followed by fluid leaks (n=632 reports, 24.4%). The third most common problem was poor image quality (n=467 reports, 18%). Other device issues included contamination or device reprocessing problems (n=127 reports, 4.9%), material deformation or wear (n=125 reports, 4.8%), and device detachment (n=73 reports, 2.8%). Of the 63 reported adverse events, the most common patient-related adverse event was hemorrhage or bleeding, accounting for 18 reports, with the root causes including material deformation or wear, breakage, wrinkled rubber, or improper operation.

Conclusions: Our study offers valuable insights for endoscopists and manufacturers to recognize potential issues and adverse events associated with the use of rhinolaryngoscopes. It emphasizes the need for improving device reliability, training, and procedural protocols to enhance patient safety during diagnostic procedures.

(JMIR Hum Factors 2025;12:e67036) doi:10.2196/67036

Introduction

Rhinolaryngoscopes are currently available in various forms, including rigid, flexible, and video versions. They are essential tools routinely used by otolaryngologists and speech-language pathologists [1,2]. Given the substantial proportion of patients who require a rhinolaryngoscopic procedure as part of a head and neck examination, rhinolaryngoscopy has become an indispensable diagnostic procedure in otolaryngological practice [3]. Modern rhinolaryngoscopes can have a distal diameter as small as 2 mm, are equipped with lighting, are flexible, and have photo and video capabilities, enabling direct visualization of the nose, throat, and airway in diverse clinical settings, including emergency, inpatient, and outpatient scenarios. The range of indications for rhinolaryngoscopy includes visualizing polyps, tumors, and sources of epistaxis in the nasal cavity and aiding in the identification of suspected tumors or adenoidal hypertrophy [4]. In the oropharynx or laryngopharynx,

rhinolaryngoscopy can be instrumental in evaluating foreign bodies and potential airway obstructions from etiologies such as neoplasm and epiglottitis, obstructive sleep apnea, dysphagia, dysphonia, tonsillar hypertrophy, glossoptosis, laryngomalacia, and vocal fold lesions [5,6]. Rhinolaryngoscopy may also assist in assessing the severity of angioedema. An alternative visualization tool is the flexible fiber-optic laryngoscope [7]. While laryngoscopes may be less expensive and simpler to use than rhinolaryngoscopes, fiber-optic rhinolaryngoscopy provides clearer visualization and better access to the larynx anatomy. In general, imaging quality, including illumination, color fidelity, resolution, and accurate length representation, plays a pivotal role in visualizing abnormalities. Therefore, the choice of instrument is often determined by clinician preference or equipment capabilities [8].

Rhinolaryngoscopes are classified as a moderate-risk medical device and require a 510(k) submission for premarket review by the US Food and Drug Administration (FDA; regulation number 21 CFR 874.4760). Although rhinolaryngoscopy is considered a generally safe procedure with rare serious adverse events, complications such as mucosal tearing, damage to anatomic structures (particularly with rigid scopes), bleeding, and laryngospasm have been reported [9]. However, there is limited data regarding device failures for both rigid and flexible rhinolaryngoscopes, incidence rates, and adverse events associated with these devices. The FDA's Manufacturer and User Facility Device Experience (MAUDE) database serves as a repository for adverse events and malfunction reports related to medical devices, and it has been used as a data source to study device-related adverse events [10,11]. In addition, capturing user experiences and integrating them into the design during medical device development has become an essential component for ensuring patient safety and device effectiveness. In this study, we used the MAUDE database to characterize postmarket complications associated with the use of rhinolaryngoscope devices from 2016 through 2023, with the aim of providing insights that may assist otolaryngologists in better understanding the limitations of these devices and selecting appropriate procedures for their specific clinical setting.

Methods

Search and Selection

MAUDE, a comprehensive postmarket surveillance database from the FDA, was chosen because of its extensive collection of medical device reports (MDRs) from both mandatory and voluntary reporters related to FDA-cleared medical devices [11]. Mandatory reporters comprise manufacturers or device user facilities, whereas voluntary reporters include physicians, patients, or other device consumers. The MDRs from MAUDE include device malfunctions and potential patient harms associated with device failures during procedures. Therefore, the event classifications used in this analysis include device malfunctions and adverse events among patients.

The MAUDE database was queried by searching for the product category "rhinolaryngoscope (Flexible or Rigid)," which included MDRs from January 2016 through December 2023. This search encompassed terms such as "rhino-laryngo videoscope," "rhino-laryngo fiberscope," "telescope," and "single use endoscope." Each MDR was then logged in a Microsoft Excel spreadsheet. Among the reports, items that may have been incorrectly classified, such as cystoscopes and arthroscopes, were manually removed. These misclassifications accounted for only a small portion of the reports and resulted from errors made by the reporters. The MDRs underwent manual review, including assessment of the date of the event, event type (device malfunction, injury, or death), and the root causes of the adverse event. Device failures were defined as reported instances of rhinolaryngoscopes not functioning as expected during a procedure.

Data Extraction

The device failure problems were classified as (1) breakage, (2) fluid leakage, (3) poor image quality, (4) contamination, (5) material deformation, (6) device detachment, (7) unintended movement, (8) mechanical problems, (9) unidentified device or use problems, (10) device overheating, (11) improper or incorrect procedures, (12) moisture damage, (13) packing problems, and (14) electrical shorting. To minimize potential bias and ensure consistency in categorization, 2 reviewers (SHC and DC) independently screened and categorized the reported events. Adverse events among patients included all reported complications resulting in injury, harm, or death during procedures associated with rhinolaryngoscopes. Following the categorization of the failure problems and adverse events, statistical analysis was conducted. The frequency of each failure type and adverse event was calculated, and the results were expressed as the number and percentage of occurrences within each category.

Additionally, to assess the context of these device failures in clinical practice, we analyzed the US Medicare population using *Current Procedural Terminology* (*CPT*) codes associated with rhinolaryngoscope diagnostic procedures (excluding surgeries). Specifically, we selected *CPT* codes 31231 (nasal endoscopy, diagnostic; unilateral or bilateral), 31575 (laryngoscopy, flexible; diagnostic), and 92511 (nasopharyngoscopy with endoscope), which may correspond to diagnostic procedures involving rhinolaryngoscopes. The data were accessed under the "Research, Statistics, Data & Systems" section. The Centers for Medicare and Medicaid Services Part B National Summary Data File was used to obtain annual procedure data based on *CPT* codes 31231, 31575, and 92511. These codes were used to compare the number of procedure claims with the number of device failure reports, allowing us to explore the relationship between the frequency of rhinolaryngoscope use (as indicated by procedure billing) and the reported failure incidents. This comparison provide a picture of the relative incidence of device failures in clinical practice compared to the frequency of procedures conducted, shedding light on potential areas for improvement in device performance or clinical training.

Ethical Considerations

This study involved querying the FDA MAUDE database and US *CPT* codes. These activities did not involve direct interaction with human subjects, nor did they involve the collection or analysis of personal health data. Therefore, such data queries typically do not require approval from an institutional review

board. Publicly available databases like the FDA MAUDE and *CPT* codes generally do not raise ethical concerns. We analyzed publicly available data and did not collect personal data or perform clinical trials, so institutional review board approval was not required.

Results

Device-Related Problems

A total of 2591 reports were identified, including 2534 device malfunctions, 56 injuries, and 1 death among patients from 2016 through 2023. The number of reports submitted significantly increased in 2021, 2022, and 2023 (n=347, n=1147, and n=918 reports, respectively), constituting greater than 90% of all reports submitted during the study period. Device malfunctions and their incidence rates are presented in Table 1. The most common device problem with rhinolaryngoscopes was breakage (n=1058 reports, 40.8%), followed by fluid leakage (n=632 reports, 24.4%). The third most common problem was poor image quality (n=467 reports, 18%). Other device issues included contamination or device reprocessing (n=127 reports, 4.9%), material deformation or wear (n=125 reports, 4.8%), device detachment (n=73 reports, 2.8%), and unintended movement (n=55 reports, 2.2%), with the remaining issues each accounting for less than 1%. Mechanical problems, device overheating, packaging issues, and electrical shorting were relatively infrequent problems, as summarized in Table 2.

Table . Event types reported to the US Food and Drug Administration Manufacturer and User Facility Device Experience (MAUDE) database for rhinolaryngoscopes per year.

Year	Deaths (n=1), n (%)	Injuries (n=56), n (%)	Malfunctions (n=2534), n (%)
2023	0 (0)	14 (25)	918 (36.2)
2022	1 (100)	7 (12.5)	1147 (45.3)
2021	0 (0)	2 (3.6)	347 (13.7)
2020	0 (0)	10 (17.8)	37 (1.5)
2019	0 (0)	14 (25)	38 (1.5)
2018	0 (0)	2 (3.6)	21 (0.8)
2017	0 (0)	5 (8.9)	13 (0.5)
2016	0 (0)	2 (3.6)	13 (0.5)

Table . Device problems reported for rhinolaryngoscopes.

Device problems	Reports (n=2591), n (%)
Breakage	1058 (40.8)
Fluid leakage	632 (24.4)
Poor image quality; optical distortion	467 (18)
Contamination; device reprocessing problem	127 (4.9)
Material deformation; wear	125 (4.8)
Detachment of device	73 (2.8)
Unintended movement	55 (2.2)
Mechanical problem	12 (0.5)
Unidentified device or use problem	11 (0.4)
Overheating of device	10 (0.4)
Improper or incorrect procedure	6 (0.2)
Moisture damage	6 (0.2)
Packaging problem	5 (0.2)
Electrical shorting; flare or flash	4 (0.2)

We conducted a comprehensive analysis of device failures, examining variations across specific manufacturers, including Olympus, Storz, Pentax, and Gyrus. A high incidence of breakage and fluid leakage reports was associated with Pentax. In comparison, Olympus devices showed a breakage rate of 4.8% (50/1028). However, Olympus devices were also associated with the highest frequency of contamination reports, followed by Pentax. These higher failure rates could be linked to the relatively larger market share of these manufacturers. Additionally, we scrutinized the frequency of nasal endoscopies performed in the US Medicare population using *CPT* codes 31231, 31575, and 92511. In 2022, a total of 1,196,520

procedures were performed. Meanwhile, the MAUDE database reported 1155 device failures. This results in an estimated failure rate of approximately 1 per 1000 procedures.

Patient-Related Adverse Events

Adverse events or complications associated with device problems were evaluated based on the MAUDE database. Adverse events in patients in reports included all instances of complications resulting in injury, harm, or death associated with the use of rhinolaryngoscopes. Adverse events in patients were categorized as (1) hemorrhage/bleeding, (2) a foreign body in the patient, (3) burns or thermal burns, (4) discomfort or pain, (5) anaphylactic shock, (6) edema, (7) laryngospasm and dyspnea, (8) unspecified tissue injury, (9) allergic reaction, and (10) death. The specified root cause of the adverse event included material and mechanical problems, device chemical contamination, improper operation, fluid leakage, overheating, and display issues, among others.

The adverse events in patients and their specified root causes are presented in Table 3. A total of 63 reported adverse events were identified, including hemorrhage/bleeding (n=18 reports, 28%), a foreign body in the patient (n=12 reports, 19%), discomfort/pain (n=10 reports, 16%), thermal burns (n=9 reports, 14%), anaphylactic shock (n=4 reports, 6%), edema (n=3 reports, 5%), laryngospasm and dyspnea (n=3 reports, 5%), unspecified tissue injury (n=2 reports, 3%), allergic reaction (n=1 report, 2%) and death (n=1 report, 2%). The most common patient-related adverse event was hemorrhage/bleeding, accounting for 18 reports, with the root causes including material deformation or wear, breakage, wrinkled rubber, or improper operation. One death was reported, with an unspecified cause. Material breakage, material wear, and improper operation were identified as the major root causes for the reported adverse events. In 2019, 1 case of edema was attributed to improper reprocessing and device contamination with chemicals. The manufacturer's investigation determined that the customer had insufficiently wiped phthalaldehyde-based disinfectants off the endoscope during reprocessing, resulting in the possibility of anaphylactic shock. Table 4 displays the numbers of adverse events from 2016 through 2023, including thermal burns, foreign bodies in patients, and discomfort, reported in 2023.

Table . Adverse events in patients from rhinolaryngoscope device problems.

Adverse event	Root cause	Events (n=63), n (%)
Hemorrhage/bleeding	Material deformation or wear; breakage; rubber wrinkling; improper operation	18 (28)
Foreign body in patient	Detachment of device or device component; breakage; material fragmentation; wear; improper operation	12 (19)
Discomfort/pain	Material wear; breakage; material invagination; mechanical problems	10 (16)
Burns/thermal burns	Scratched material; cut or torn material; burst battery; device overheating; use of device problem	9 (14)
Anaphylactic shock	Material perforation; material cracks or holes	4 (6)
Edema	Unidentified device or use problem; allergic reaction due to improper reprocessing and device chemical contamination	3 (5)
Laryngospasm and dyspnea	Display problem/poor image; unspecified issue	3 (5)
Unspecified tissue injury	Fluid/blood leakage; material wear	2 (3)
Allergic reaction	Reprocessing agent	1 (2)
Death	Unspecified issue	1 (2)

Table . Number of adverse events based on year and type.

	Events, n							
	2023	2022	2021	2020	2019	2018	2017	2016
Hemorrhage/bleeding	0	0	0	2	12	0	3	1
Foreign body in patient	4	0	0	0	2	0	5	1
Discomfort/pain	5	2	0	1	2	0	0	0
Burns/thermal burns	3	1	1	1	0	1	1	1
Anaphylactic shock	0	0	0	4	0	0	0	0
Edema	0	0	0	0	1	0	2	0
Laryngospasm and dyspnea	0	0	0	0	3	0	0	0
Unspecified tissue injury	0	2	0	0	0	0	0	0
Allergic reaction	0	0	1	0	0	0	0	0
Death	0	1	0	0	0	0	0	0

Discussion

Principal Findings

This study examined adverse events associated with the use of rhinolaryngoscopes based on the MAUDE database, analyzing 2591 common device issues and 63 patient-related adverse events from January 2016 through June 2023. Breakage (40.83%) was the most common device issue, whereas hemorrhage (28.57%) was the most common patient-related adverse event, primarily attributed to material deformation or breakage. These findings underscore the overall low occurrence of adverse events associated with the use of rhinolaryngoscopes. Previous studies have highlighted mucosal tearing and bleeding as the most common complications, with laryngospasm occurring in less than 1% of procedures [12-14]. To prevent these complications, adequate nasal decongestion and limited force are recommended. However, our results show that improper operation or use problems frequently contributed as the root cause of adverse events, including hemorrhages, foreign bodies in patients, thermal burns, pain, and edema. Operator experience with the device may also influence the occurrence of adverse events. One customer reported a broken eyepiece on a rigid scope (report number 9610773-2023-03626). Following investigation, the manufacturer attributed the issue to wear and tear coupled with excessive force. Similarly, another report detailed a damaged lens at the distal end of a scope (report number 9610773-2023-02419). Upon examination, the manufacturer concluded that this damage stemmed from user error, improper handling, and the application of excessive force. Therefore, considerations of usability and ergonomics are imperative to enhance patient care [15-17].

Despite gathering 125 reports of material wear from the MAUDE database, which accounted for one-ninth of the total breakage reports, it is noteworthy that the majority of the reported failures were not attributed to routine wear and tear, as determined by the manufacturer's investigation. This observation underscores the importance of scrutinizing reported failures to distinguish between typical wear-related issues and potentially more serious underlying concerns. It is evident that device failures may arise from various root causes beyond routine wear and tear, which manufacturers may not consistently highlight in their manuals. For instance, in the manual for the TJF-Q180V (Olympus) endoscope, there is an acknowledgment that repeated use and reprocessing of the endoscope and its accessories can lead to gradual wear and tear. This underscores the importance of thorough understanding of and adherence to manufacturer instructions, as well as recognizing potential factors contributing to device failures, beyond typical wear-related issues.

Moreover, it was observed that many cases of device failure could be linked to improper reprocessing practices. In this study, 127 device failures caused by rhinolaryngoscope contamination were reported. Although manufacturers provide recommendations for product use and reprocessing, Biadsee et al [18] reported that less than 20% of physicians adhere to the recommended decontamination process outlined by manufacturers. Another study, from Jiang et al [19], of rhinolaryngoscope device failure due to contamination using the MAUDE database from 2013 to 2019 revealed associations with laryngeal edema, rather than infection, highlighting 1 injury resulting from improper reprocessing procedures (insufficient disinfectant removal from the endoscope). Anaphylaxis resulting from the use of phthalaldehyde-based disinfectants has been reported in cases involving the cleaning of rhinolaryngoscopes and cystoscopes [20,21]. In this case (report number 9610877-2019-00238), the risk of injury from microbial

infection may be less than the potential harm caused by the disinfectant solution itself. In response to this incident, 5 members of the otolaryngology department were identified and retrained as the personnel at the hospital did not properly reprocess the endoscope. Regarding the compatibility of disinfectants, the manufacturer of the endoscope recommends that facilities adhere strictly to the instructions provided by the disinfectant manufacturer, including specific parameters such as concentration, temperature, and exposure time. Furthermore, it is crucial to ensure thorough rinsing of internal channels, external endoscope surfaces, and components with clean water to remove any residual detergent solution, thereby minimizing the risk of adverse reactions or complications associated with disinfectant use. Our results identified 1 allergic adverse event associated with a reprocessing agent, and 3 cases of edema due to improper reprocessing or device use, confirming previous literature regarding rhinolaryngoscope contamination [22,23]. Compared to other endoscope types, such as bronchoscopes and duodenoscopes, the contamination rate of rhinolaryngoscopes is less commonly associated with patient harm or death [18]. This indicates a comparatively lower risk associated with rhinolaryngoscopes in contrast to other endoscopic examinations.

This study reviewed the MAUDE database and identified 9 cases of thermal burns in patients who underwent rhinolaryngoscope examinations over 8 years. Scope overheating was reported as a root cause, likely because of prolonged procedure times with the light source on or the brightness setting of the lamp. Several studies assessed the heat effects of endoscopes in otorhinolaryngology and recommended keeping light sources at the lowest effective intensity [24-26]. MacKeith et al [27] evaluated the amount of heat produced by endoscopes and showed that larger-diameter endoscopes attain a higher temperature. Chitnavis [28] demonstrated that even momentary proximity could cause a thermal burn to a patient's skin, without generating smoke or fire. The risk of thermal injury may be associated with the light source, endoscope caliber, and angulation [25,27,29,30]. Consequently, available cameras are often equipped with a regulation system capable of automatic gain control in poor lighting situations [31].

Furthermore, it is noteworthy that the number of MDRs underwent a significant surge in 2021, 2022, and 2023, with 347, 1147, and 918 reports, respectively. This notable increase underscores the importance of continued vigilance and thorough investigation into the factors driving these trends to ensure the safety and efficacy of medical devices. The growth in frequency can be attributed to several major factors, including the increased prevalence of laryngeal diseases, heightened use of laryngoscopes in airway management, guideline recommendations, elevated demand for respiratory products, and the impact of the COVID-19 pandemic. However, there was no significant rise in the number of nasal endoscopies performed in the US Medicare population with *CPT* codes 31231, 31575, and 92511 from 2016 to 2022. Another plausible explanation for the increased MDRs could stem from new product launches and strategic activities by manufacturers, which have had a moderate impact on the laryngoscope market, influencing the growth in the frequency of MDRs.

The statistical analysis conducted using the FDA's MAUDE database carries significant implications for clinical practice. These data not only help identify trends and patterns in device failures but also provide critical safety information for clinical health care. By analyzing the MAUDE data, we can identify failure types and frequencies associated with specific devices, such as rhinolaryngoscopes, thereby understanding their potential impact on patient safety. The data reveal the sources of device failures, including variations across manufacturers and models, which can aid clinical decision-makers in selecting devices based on more informed criteria. Furthermore, by examining the time trends of device failures in the MAUDE database, we can correlate these trends with medical policies or other external factors. This trend analysis can assist health care institutions in adjusting operational processes and training programs to address the growing issue of device failures, especially during times of infectious disease outbreaks or when new devices are introduced. The data derived provide empirical evidence that can help in developing more effective clinical guidelines and training plans, ultimately contributing to improved quality of health care services [32]. These findings highlight the importance of timely adjustments to clinical operational processes and training programs to address the growing issue of device failures and provide guidance for future device improvements and clinical recommendations.

Limitations

A major limitation of this study is its reliance on reports from the FDA's MAUDE database, which may not account for comorbidities involved in reported device failures. Furthermore, the information may be incomplete or limited because MDRs can be submitted by health care professionals, patients, or manufacturers. Reporting variations between private-practice clinics and large academic medical centers may also affect data accuracy and which brands are used. Therefore, establishing causative associations for some reported adverse events is challenging. However, it is important to note that manufacturers are required to investigate reported adverse events and device failures, and their findings or follow-up reports are included in the MAUDE database. The manufacturer reports help to mitigate potential bias arising from self-reported data. Since the MAUDE database primarily focuses on device-related issues, we recognize the possibility of underreporting or inconsistent reporting practices. Nonetheless, the inclusion of both user-reported and manufacturer-investigated information adds a level of rigor to the analysis, allowing for a more nuanced understanding of the issues related to device failures. Despite these limitations, our study provides important insights for endoscopists and manufacturers to recognize potential issues and adverse events associated with the use of rhinolaryngoscopes, emphasizing the importance of patient safety.

Conclusions

Although our findings underscore the overall low occurrence of adverse events associated with the use of rhinolaryngoscopes, the results indicate that improper operation frequently contributed to adverse events, including hemorrhage, foreign bodies in patients, thermal burns, pain, and edema. Operator

experience with the device may also influence the occurrence of adverse events. Results from this study will be important for endoscopists and manufacturers to have a thorough understanding of the equipment and its limitations. Future research should assess the broader organizational impact, including otolaryngology teams, documentation practices, clinician training, and patient perspectives.

Abstract

Background: The Swedish health care system is undergoing a transformation. eHealth technologies are increasingly being used. The System Usability Scale is a widely used tool, offering a standardized and reliable measure for assessing the usability of digital health solutions. However, despite the existence of several translations of the System Usability Scale into Swedish, none have undergone psychometric validation. This highlights the urgent need for a validated and standardized Swedish version of the System Usability Scale to ensure accurate and reliable usability evaluations.

Objective: The aim of the study was to translate and psychometrically evaluate a Swedish version of the System Usability Scale.

Methods: The study utilized a 2-phase design. The first phase translated the System Usability Scale into Swedish and the second phase tested the scale's psychometric properties. A total of 62 participants generated a total of 82 measurements. Descriptive statistics were used to visualize participants' characteristics. The psychometric evaluation consisted of data quality, scaling assumptions, and acceptability. Construct validity was evaluated by convergent validity, and reliability was evaluated by internal consistency.

Results: The Swedish version of the System Usability Scale demonstrated high conformity with the original version. The scale showed high internal consistency with a Cronbach α of .852 and corrected item-total correlations ranging from 0.454 to 0.731. The construct validity was supported by a significant positive correlation between the System Usability Scale and domain 5 of the eHealth Literacy Questionnaire (P=.001).

Conclusions: The Swedish version of the System Usability Scale demonstrated satisfactory psychometric properties. It can be recommended for use in a Swedish context. The positive correlation with domain 5 of the eHealth Literacy Questionnaire further supports the construct validity of the Swedish version of the System Usability Scale, affirming its suitability for evaluating digital health solutions. Additional tests of the Swedish version of the System Usability Scale, for example, in the evaluation of more complex eHealth technology, would further validate the scale.

Introduction

In the rapidly evolving landscape of global health care, the advent of eHealth technologies has emerged as a transformative force that promises innovative solutions to the multifaceted challenges faced by health care systems worldwide [1,2]. The Swedish health care system is currently transforming along these lines. The use of digital applications and other digital contact methods, collectively described under the term eHealth, is increasing. The World Health Organization (WHO) defines eHealth as "the use of information and communication technologies (ICT) for health." These technologies include a wide range of systems interventions, applications, and devices such as mobile health and telehealth [3]. There is compelling evidence for the increasing influence of eHealth on the provision of health care globally today and how it is enhancing the efficiency and responsiveness of health systems to meet people's needs and expectations [3]. It is essential to ensure that health technologies are designed appropriately to meet the needs of end users before deploying them as health interventions [4].

Employing robust evaluation methods to ensure high-level usability has been recognized as a crucial component of good practice for achieving this goal [5].

Usability is defined as "the extent to which a product can be used by specified users to achieve specified goals with effectiveness, efficiency, and satisfaction in a specified context of use" [6]. To determine the potential usability of a digital solution, the System Usability Scale (SUS) has been widely adopted as a standardized evaluative device. In 1996, Brooke [7] published the SUS as an instrument that could easily measure usability. Since then, it has been used to evaluate computer systems, applications, and other digital solutions in a wide range of areas [8-10]. The SUS is a questionnaire, consisting of 10 items each scored on a 5-point Likert scale from "strongly disagree" to "strongly agree." It is easy to administer and has been shown to generate results with good reliability and validity [7,8,11]. The instrument is free, and no fees are required to use it [7]. With an international reach, it is the most widely used standardized questionnaire for the assessment of perceived usability today [10]. The SUS can be used to evaluate a wide range of usability in products, including digital applications, mobile devices, and web pages [8-10].

However, as psychometric properties are sample dependent, it is essential to evaluate the psychometric properties when using patient-reported outcome measure in new settings or populations [12]. The SUS has been translated into numerous languages such as Chinese [13], Finnish [14], French [15], Hindi [15], Indonesian [16], and Polish [17]. It has undergone psychometric validation [18], including in Arabic [19], Danish [20], Dutch [21], German [22], Italian [23], Malay [24], Persian [25], Portuguese [26], Slovene [27], and Spanish [28]. The psychometric properties that have resulted from these studies show that adapted versions of the SUS are a reliable tool for usability assessments. However, a number of these studies adopted a general focus and examined only the total sum in the test. Only a small number of studies have tested the instrument at an item level [19-28], with none of them in Swedish. This emphasizes the need for a comprehensive testing of a Swedish version of the SUS on an item level. Determining the robustness is critical for ensuring that the measurement instrument has sufficient validity in the proposed context.

Lewis [10] outlines the essential requirements for translating the SUS into multiple languages and conducting validations across diverse countries. In Sweden, one translation of the SUS has been published in a scientific journal [29], although several unpublished versions exist [9]. However, the linguistic discrepancies between these translations give room for ambiguities, and a united translation with a rigorous psychometric testing in a Swedish context is warranted.

In 2016, an initial vision was for Sweden to be "the best in the world" in eHealth by 2025. However, a more realistic view today is that Sweden has made significant progress in this area. Within the European context, Sweden demonstrates a distinct approach to digitalization in health care, emphasizing collaboration and innovation to address specific challenges and opportunities [30].

With this in mind, there is a great need for a nationally united SUS that has been rigorously tested and proven effective. A robust process of evaluating the psychometric properties of a Swedish SUS will foster participatory usability research and ultimately improve the quality of health care services on a broader scale. Although there are different Swedish translations of the SUS, there is still a lack of psychometric testing showing their robustness. Before any Swedish SUS can be recommended for use, both translation and psychometric evaluation of the instrument are necessary. Therefore, the aim of this study was to translate and psychometrically evaluate a Swedish version of the SUS.

Methods

Overview

This study consists of 2 steps. In step 1, the SUS was translated and adapted into Swedish. In step 2, the psychometric properties of the Swedish version were tested: data quality, scaling assumptions, acceptability, convergent validity, and internal consistency. The translation, adaptation process, and psychometric evaluation adhered to the COSMIN (Consensus-Based Standards for the Selection of Health Status Measurement Instruments) checklist [31].

The SUS Instrument

The SUS instrument consists of 10 items (statements). The items are divided equally into positively and negatively worded statements. Requests for a response are graded on a scale of agreement ranging from strongly disagree (1) to strongly agree (5). The score is calculated as follows: for positively worded items (1, 3, 5, 7, and 9), the score is the position on the scale (1-5) minus 1, and for negatively worded items (2, 4, 6, 8, and 10), the score is the position on the scale minus 5. Individual item scores, therefore, can range from 0 - 4. The sum of all 10 scores is then multiplied by 2.5, resulting in a total score ranging from 0 - 100, with higher numbers representing greater usability [7,8].

To date, factor analysis has not been able to show conclusively whether the SUS consists of one factor (usability) or two (usability and learnability) [11]. Efforts to replicate these findings have led to the conclusion that addressing the instrument as 2 dimensional has no practical or theoretical interest. This study, therefore, treats the SUS as a unidimensional instrument of perceived usability [32].

Translation and Adaption

According to Brooke's [7] original formulation of the SUS, no formal permission is needed for translation, and it can be used free of charge. Further, Brooke [7] allows for the possibility to, in any version, exchange the wording of the scale to a word or expression suitable for the situation. The translation process adopted in this study was inspired by Beaton et al [33]. First, the original instrument was translated from English to Swedish by one of the researchers (CC), proceeding from the versions presented by Bangor et al [34] and Lewis [10]. During the process, perceived difficulties and uncertainties were noted. This first version was then reviewed and discussed by the group, consisting of researchers familiar with eHealth, until consensus

was reached. Second, an authorized translator, naive to the research field, carried out a back translation on the instrument and the notes taken during the research process. Finally, the research group reviewed all versions of the translation, with all notes attached, and finalized a second version of a Swedish SUS. This version was then compared to other SUS translations within the Scandinavian countries for content validity and the original version for expressions and conceptions that could have been culturally influenced. Following this last step, the group then decided upon a final version by consensus. The response options were structured in the same way as the original questionnaire, although the phrases “strongly disagree” and “strongly agree” were exchanged for the Swedish equivalents of “totally disagree” and “totally agree.”

Psychometric Evaluation

Sample

The evaluation of the psychometric properties was carried out in conjunction with a larger intervention study evaluating eHealth, the eChildHealth tablet study [35]. Parents of children with a range of illnesses and health conditions who were patients in the pediatric department of a level-3 hospital in the south of Sweden were invited to take part. A total of 66 parents to 52 unique children gave informed consent and were included in the eChildHealth tablet study. Of these parents, 62 provided information on the SUS, resulting in a total of 82 measurements.

Data Collection

Parents were introduced to an app on a tablet computer through which they could communicate with health care staff after their child had been discharged from hospital. The app made it possible to continue to communicate with hospital staff whom the parents knew well, through chat messages, sending photos, video calls, and predesigned questionnaires. Using a questionnaire, data on various aspects of eHealth were collected for each parent. The SUS was one aspect, and the eHealth Literacy Questionnaire (eHLQ) [36] was another. A study-specific questionnaire was used to collect demographic data such as age and level of education. Between October 2022 and October 2023, the 66 parents were included in study. Data were collected after 1 - 2 weeks of use and at a second time point for those participants who used a tablet for more than 1 month. These parents constitute the eligible participants for this study. A sufficient adequate sample size of approximately 80 measurements was based on recommendations from COSMIN [31] and Beaton et al [33].

Data Analysis

The psychometric properties of the SUS were analyzed with IBM SPSS Statistics for Windows (version 28.0, IBM Corp). Descriptive statistics (mean, SD, and percentage) were used to visualize participants’ characteristics along with data quality, scaling assumptions, and acceptability. Construct validity was evaluated by convergent validity, and reliability was evaluated by internal consistency.

For data quality, use within the clinical setting was determined by item nonresponse and missing scale scores, as they reflect the acceptance and understanding of a measure [37]. Data quality was determined as high if the percentage of missing data per item was low (<10% acceptable). In this study, there were missing data in 5 items (ranging from 1/81, 1% to 3/81, 4%), representing high data quality. Participants with more than 3 unanswered questions were excluded (n=1), while mean imputation was carried out for those with 1 or 2 missing items (n=6, all missing 1 item) [38]. This resulted in a total of 81 measurements being included in the final analysis.

Regarding scaling assumptions, the dimensionality of the SUS has been evaluated previously [32]. In accordance with these studies, this study assumes that the SUS is to be treated as unidimensional (all items measure the same construct). Instruments composed of Likert-scale items can be summarized if they have similar means and SDs. Furthermore, item-total correlations (the correlation between each individual item score and the total score) would indicate if all items contribute equally to the total score. In line with Hobart et al [37], item-total correlations with values of $r \geq 0.3$ were regarded as sufficient for summing up the items to a total sum score.

To evaluate the acceptability of score distributions, ceiling and floor effects along with skewness were calculated. Ceiling and floor effects were regarded as present if they exceeded 90%, that is, the percentage of responses for the lowest and highest scores. Skewness statistics should preferably be within the range of −1 to +1 [37].

Construct validity was explored through convergent validity. It was evaluated with the correlation between the high total sum of the SUS and one of the domains of the eHLQ [36], with the hypothesis that it would correlate with the total score of the SUS. Both instruments were distributed to the parents at the same time points. The eHLQ has already been translated, adapted, and validated within a Swedish context [39]. The eHLQ consists of 7 domains across 35 items, with each domain being extractable and treatable as a separate scale. Responses to each domain on the eHLQ are recorded on a Likert scale from 1 (strongly disagree) to 4 (strongly agree). The eHLQ was designed to be used to understand and evaluate people’s interaction with digital health services [36,39]. The research group independently reviewed the eHLQ and, after discussion, decided to use domain 5, measuring the motivation to engage with digital services. The correlation between the instruments was assessed using the nonparametric correlation coefficient of Kendall Tau-b. With regard to the comparative instrument not being used in total (only 1 domain), the correlation was regarded as acceptable if it was moderate or greater (>0.3) [40] and with the level of significance being $P<.05$.

Internal consistency—how items are related to each other—was explored according to the indicators recommended by Hobart et al [37]: corrected item-total correlations and Cronbach α. The cutoffs were >.04 for acceptable corrected item-total correlations and >.8 for Cronbach α [37,41]. The internal consistency was completed with an SEM to analyze the measurement error of the instrument. The SEM represents the smallest difference in scores and indicates a change on a group level. SEM was analyzed with $SD_{baseline} \times \sqrt{1}$ – reliability and complemented with a CI 95% [12].

Ethical Considerations

This study was conducted in accordance with the Declaration of Helsinki [42] and approved by the Swedish Ethical Review Authority (2021 - 05077). The invited parents were recruited through gatekeepers at the pediatric department. Information regarding the study was initially provided orally and then followed up by written information, before written informed consent was obtained by a study nurse. Data were handled confidentially, and participating parents were able to quit without any explanation or impact on the care their children received. Participation in the study was voluntary, and no financial or other form of compensation was provided to the participants.

Results

Translation and Adaption

Both translations (forward and backward) were similar and did not differ substantially. Overall, the conformity of phrasing was high, with some discrepancy for phrasing in statements 2 (I found the system unnecessarily complex) and 8 (I found the system very cumbersome to use). In statement 2, the word “complicated” was suggested in the back translation from the Swedish word “komplex.” In statement 8, the word “awkward” was suggested instead of the original word “cumbersome.”

All such discrepancies were discussed within the research group and a consensus was reached for the final version. The final step, comparing the Swedish version to other Scandinavian versions, generated no further changes. Table 1 shows the original English version and the final Swedish version of the SUS.

Table . Original English version [7] and the proposed Swedish version of the System Usability Scale, including (1) response alternatives and (2) statements.

Component	English version	Swedish version
Response alternatives	• 1 - Strongly disagree • 2 • 3 • 4 • 5 - Strongly agree	• 1 - Instämmer inte alls • 2 • 3 • 4 • 5 - Instämmer helt
Statements	1. I think that I would like to use this system frequently 2. I found the system unnecessarily complex 3. I thought the system was easy to use 4. I think that I would need the support of a technical person to be able to use this system 5. I found the various functions in this system were well integrated 6. I thought that there was too much inconsistency in this system 7. I would imagine that most people would learn to use this system very quickly 8. I found the system very cumbersome to use 9. I felt very confident using the system 10. I needed to learn a lot of things before I could get going with this system	1. Jag tror att jag skulle vilja använda denna applikation ofta 2. Jag uppfattar denna applikation som onödigt komplex 3. Jag tycker att denna applikation är enkel att använda 4. Jag tror att jag skulle behöva stöd för att kunna använda denna applikation 5. Jag upplever att de olika funktionerna i denna applikation var väl integrerade 6. Jag tycker att applikationen är inkonsekvent 7. Jag föreställer mig att de flesta personer skulle lära sig att använda denna applikation väldigt snabbt 8. Jag upplever denna applikation som krånglig 9. Jag känner mig trygg med att använda denna applikation 10. Jag behövde lära mig många saker innan jag kunde komma igång med denna applikation

[a]In this study, the Swedish instruction was as follows: "Markera det alternativ som bäst beskriver din reaktion för applikation i surfplatta idag," meaning “Please indicate your agreement with the following statements, one at a time.”

Psychometric Evaluation of the Swedish Translation

A total of 62 individuals were included in this study. Of these, 20 answered the questionnaire, including the SUS, twice. This resulted in a total of 81 measurements included in the analysis. Demographic data for the participants are shown in Table 2.

Table . Demographic data of participants included in the study (N=62).

Demographic data	Values
Age (years), median (range)	33 (22 - 52)
Gender, n (%)	
Female	41 (66)
Male	20 (32)
Unknown	1 (2)
Marital status, n (%)	
Married	33 (53)
Living together	28 (45)
Divorced or separated	1 (2)
Education level, n (%)	
High school	18 (29)
College or university	42 (68)
Other	2 (3)
Born in Sweden, n (%)	
Yes	52 (84)
No	6 (10)
Unknown	4 (6)
First language	
Swedish	56 (90)
Other	6 (10)

Data Quality

The percentage of missing data per item was low (ranging from 0/81, 0% to 3/81, 4%) across all items. A tendency could be seen for a higher percentage within the 3 highest steps of the scale, resulting in 5 items having 0% in the lowest points of the 5-point scale (Table 3).

Table . Missing data (n and %) and item frequency distribution (%) of answers per response alternative in each question of the Swedish System Usability Scale (n=81). The item “0” equals the response of “1” on the scale, etc.

Item	Missing data, n (%)	Item frequency distribution, n (%)				
		0	1	2	3	4
1	0 (0)	1 (1)	5 (6)	21 (26)	36 (44)	19 (23)
2	1 (1)	0 (0)	4 (5)	16 (20)	9 (11)	52 (63)
3	0 (0)	1 (1)	0 (0)	10 (12)	24 (29)	47 (58)
4	2 (2)	0 (0)	0 (0)	6 (7)	16 (20)	58 (71)
5	0 (0)	2 (2)	2 (2)	21(26)	32 (39)	25 (31)
6	3 (4)	2 (2)	3 (4)	21 (25)	13 (16)	40 (49)
7	1 (1)	0 (0)	1 (1)	4 (5)	34 (42)	42 (51)
8	2 (2)	1 (1)	1(1)	5 (6)	10 (13)	63 (77)
9	0 (0)	0 (0)	0 (0)	6 (7)	28 (34)	48 (59)
10	0 (0)	0 (0)	1 (1)	4 (5)	14 (17)	63 (77)

Scaling Assumptions

Item means ranged from 2.82 to 3.70 (Table 4). The item-total correlations showed that each item contributed substantially to the total score with correlations ranging from 0.454 to 0.731 (Table 5), thus indicating that the scale can be summarized. The total sum for the SUS in the data ranged between 50 and 100 (mean 84, SD 13).

Table . Item descriptive statistics for the Swedish version of the System Usability Scale (n=81).

Item	Score, mean (SD)	Skewness
1	2.82 (0.904)	−.550
2	3.35 (0.964)	−1.094
3	3.41 (0.800)	−1.490
4	3.65 (0.618)	−1.585
5	2.93 (0.940)	−.766
6	3.09 (1.076)	−.876
7	3.44 (0.652)	−1.038
8	3.66 (0.762)	−2.682
9	3.51 (0.633)	−.943
10	3.70 (0.622)	−2.203

Table . Item-total statistics for the Swedish version of the System Usability Scale (n=81).

Item	Scale mean if item deleted	Corrected item-total correlations	Cronbach α if item deleted
1	30.80	0.463	.847
2	30.30	0.731	.820
3	30.22	0.534	.840
4	30.00	0.657	.833
5	30.72	0.479	.847
6	30.57	0.463	.852
7	30.21	0.454	.846
8	29.99	0.687	.827
9	30.12	0.675	.831
10	29.96	0.585	.837

Acceptability

As indicated by the item mean score (range 2.82-3.70; Table 4) and item-frequency distribution (Table 3), the instrument showed acceptability. For 3 items (4, 8, and 10), the item frequency was above 70%, which is still within the acceptable range for the absence of a ceiling effect. Skewness statistics were below or near the acceptable range of −1 for a total of 7 items, thus indicating that the distribution was excessively skewed (Table 4).

Convergent Validity

Convergent validity was evaluated with the correlation between the total sum of the SUS and the total sum of domain 5 in the eHLQ. As expected, there was a positive correlation between the total score of the instruments (correlation coefficient 0.305), which was significant (*P*=.001) and supported the construct validity of the Swedish version of the SUS.

Internal Consistency and Measurement Error

Cronbach α for the scale was .852. Corrected item-total correlations were between 0.454 and 0.731, as shown in Table 5, indicating internal consistency for the different items. For all items except item 6 (I thought there was too much inconsistency in this system), the α value if the item deleted was lower than the Cronbach α for the scale. The SEM was 5.05 (95% CI –4.84 to 14.954) points for the Swedish version of the SUS.

Discussion

Principal Findings

This study presents a new Swedish version of the SUS that is psychometrically tested. This study seeks to establish the new Swedish version of the SUS as a reliable and valid instrument for assessing system usability. Overall, the psychometric testing showed high data quality, good scaling assumptions, high internal consistency, and fair convergent validity. Together, these analyses support the validity and reliability of the new Swedish version of the SUS.

The translation process of the new Swedish version of the SUS was executed incrementally, both within and outside the research team, involving an authorized translator who conducted a back translation. This method facilitated thorough scrutiny and comparison of the translation from multiple perspectives. The approach also helped reduce the risk of bias and improved the scale's validity by incorporating multiple viewpoints [43].

The psychometric testing regarding internal consistency showed that the Cronbach α values were satisfactory and that all items

contributed to the instrument's total score. This indicates that the Swedish translation of the SUS is a stable instrument to use in a Swedish context.

Convergent validity showed fair correlation between the SUS and domain 5 of the eHLQ, which measured the motivation to engage with digital services (I find that digital technology support me in taking care of my health). This supported our hypothesis that a generally positive attitude toward digital solutions would correlate with a high usability score. This hypothesis is also in line with previous research, which shows that positive expectations directed toward a product generate positive subjective usability ratings [14].

There was an indication of a ceiling effect for 3 items on the Swedish version of the SUS (items 4, 8, and 10). They presented above 70% in item frequency distribution and a high mean total score, which is in line with studies indicating a generally high score for the SUS [10]. Previous studies have also shown ceiling effects of the SUS but only for the total score [15,44], thus the responses on the different items can not be justly compared between studies. This study, however, explores the SUS in much more detail and in line with recommended psychometric evaluations, as it explores the psychometric properties for each item separately [12,37]. Further, the distribution was excessively skewed. This could be an expected result of the nonnormal distribution, since negatively skewed variables are assumed to have a ceiling effect [37,45]. Also, the robustness of skewed distribution as the sole indicator of ceiling effect has been questioned [45].

However, based on the skewness result of the items, the question arises as to whether the range of the response options is wide enough (5-point scale) and if the wording in the response options ("strongly disagree" to "strongly agree") is a sufficient description. It could be interesting to expand the number of response options but, arguably, there could be obstacles with revising such a widely used and widespread instrument.

Regarding the high mean scores for both the total sum and the items of the SUS, it should be noted that the population had a mean age of 33 years and are, therefore, used to digital solutions. This could have influenced their experience of the app. Therefore, the high item scores of the SUS could also indicate a product that is perceived to have usability for this group. A recommendation for future studies would be to test the instrument in other contexts and with different age groups. This app was designed to support users who were in exactly the same situation as the participants in this study: parents in a specific situation. Going home with a child after hospitalization can be stressful; the parents in this study reported this eHealth solution as supportive [46]. The SUS has previously been tested for its sensitivity in different digital solutions and has shown a high scoring (ceiling effect) within the best-of-class products [44].

The Swedish government has envisioned Sweden as a leading country of eHealth in the near future. It has declared the need for individual users to act as the cocreators of such solutions [30]. Within eHealth, there has already been a call for a participatory design to increase the equality of access to digital solutions [47]. Even though digital technology and eHealth are intended to enhance access to health care, for example, despite geographical distances. It may also result in the opposite, as people have different knowledge in using digital solutions. For example, younger people tend to use and access digital solutions differently than older people, which is why solutions should be adapted to the intended end users [48]. In this study, the population was younger, as previously discussed, which could have influenced the result. To have a project design of cocreation often means that end users are involved from the start of the project as collaborators. Coproduction, on the other hand, often involves the end users during the implementation phase [49]. Arguably, the end users are invaluable in all steps of the process, and the usability of products needs to be evaluated where instruments such as the SUS can be useful [50]. This study could therefore be regarded as enhancing the possible participation of end users in the future development of digital solutions and eHealth in a Swedish context.

In conclusion, this study indicates that this developed and psychometrically tested Swedish version of the SUS can be recommended for use within the Swedish adult context.

Limitations

There are some methodological challenges in this study. First, the sample could be regarded as small (N=62), although it was sufficient according to the recommendations [31,33]. A larger sample might enable different methods of analysis, such as Rasch analysis, which might offer deeper psychometric insights.

Second, the 1-year interval for data collection could be considered long in a rapidly changing world. This length of time could influence how the app was perceived. That said, the digital product was not changed to any great extent during this period, so the perception of usability should not have been influenced to any great extent. Additional data collection was carried out after COVID-19 restrictions were essentially withdrawn in Sweden. There is, however, always the possibility of perceptions fluctuating, as the product could be used in various ways according to the circumstances of the parents.

Third, there was an intention to pursue a data quality test for reproducibility as some of the participants answered the SUS twice. Regrettably, the test-retest sample (n=20) was regarded as too small in this study, and such analyses need to be considered in future studies. In addition, the use of imputation can be discussed. There was a low number of missing data, with a noncomplete frequency of only 9 responses in total. The percentage of missing data per item was also low across all items. This resulted in only 6 imputed scores across the items, and based on mean score for the item, this was regarded as not influencing the result noticeably.

Conclusions

This study presents a new Swedish version of the SUS. It is the first study to carry out a psychometric evaluation of a Swedish SUS, to establish the Swedish version of the SUS as a reliable and valid instrument for assessing system usability. Overall, the psychometric testing showed high data quality, good scaling assumptions, high internal consistency, and fair convergent validity, all of which support the validity and reliability of the new Swedish version. The results from this study are promising. They raise the possibility that the Swedish version of the SUS

could be used to evaluate digital health solutions. To further strengthen the usability of the scale, we suggest additional analysis on data that evaluate more complex eHealth technology and include a wider participant age group, both younger and older.

Acknowledgments

We would like to express our sincere gratitude to the participants in the study. We would like to acknowledge Inger Kristensson Hallström, who passed away in 2024, for her extensive work, deep commitment to the field of pediatric nursing, and expertise dedicated to the eChildHealth program. Additionally, we wish to express our appreciation to Magnus C. Persson, for the design of the questionnaires in REDCap (Research Electronic Data Capture) and assisting in data transfer, as well as Desirée Lemmen and other gatekeepers for their assistance with participant inclusion and the distribution of questionnaires to the study participants. This study was funded by the Swedish Research Council for Health, Working Life and Welfare, Sweden (grant 2018-01399).

Authors' Contributions

All authors have made substantial contributions to all of the following: (1) the conception and design of the study, the acquisition of data, or the analysis and interpretation of data; (2) the drafting of this paper or its critical revision for important intellectual content; and (3) final approval of the manuscript version to be submitted.

Abstract

Background: Evaluating digital health service delivery in primary health care requires a validated questionnaire to comprehensively assess users' ability to implement tasks customized to the program's needs.

Objective: This study aimed to develop, test the reliability of, and validate the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire for evaluating the implementation of maternal and child digital health information systems.

Methods: A cross-sectional study was conducted in 2 phases. The first phase focused on content item development and was validated by a group of 10 experts using the content validity index. The second phase was to assess its psychometric testing for reliability and validity.

Results: A structured questionnaire of 65 items was constructed to assess the TPC-OHCIS delivery for primary health care use based on literature and has been validated by 10 experts, and 319 respondents answered the 65-item TPC-OHCIS questionnaire, with mean item scores ranging from 1.99 (SD 0.67) to 2.85 (SD 1.019). The content validity, reliability, and face validity showed a scale-level content validity index of 0.90, scale-level content validation ratio of 0.90, and item-level face validity index of 0.76, respectively. The internal reliability was calculated as a Cronbach α value of 0.90, with an intraclass correlation coefficient of 0.91. Scales were determined by the scree plot with eigenvalues >1, and 13 subscales were identified based on principal component analysis. The Kaiser-Meyer-Olkin value was 0.90 (P<.049). The total variance explained was 76.07%, and factor loading scores for all variables were >0.7. The Bartlett test of sphericity, determining construct validity, was found to be significant (P<.049).

Conclusions: The TPC-OHCIS questionnaire is valid to be used at the primary health care level to evaluate the TPC-OHCIS implementation. It can assess health care workers' work performance and job acceptance and improve the quality of care.

telehealth; electronic health; eHealth; public health information system; psychometric analysis

Introduction

Background

Digital health is mostly used interchangeably with eHealth, telehealth, or mobile health in the literature [1,2]. It requires integrated and interdisciplinary sector involvement to use knowledge information and communication technology in health (eg, medicine, public health, pharmaceutical, dentistry, and health management) [1-8]. It enables the national health system to ensure population access to health services and the ability to monitor and evaluate health system delivery performance [1,2,9]. Electronic health records are created from digital health systems for case management monitoring and can be shared

across health care settings [9]. The data sharing platform allows access to integration interfaces that include electronic medical records, appointments, electronic prescriptions, e-commerce, public health surveillance, system monitoring such as vaccination, environmental health, institutional health management, and an online platform for teaching and learning among health care workers (HCWs) [10-16].

Malaysian Digital Health

Malaysia began integrating digital health into its health care system in 1998 [4,5]. The Telemedicine Act 1997 (Act 564) was enacted to regulate telemedicine practices in the country [4,5,17-25]. Later, the telemedicine blueprint was created to outline the government's vision for digital health implementation and align it with the 7 National Multimedia Super Corridor flagship applications [19-22]. The initiative was referred to as telemedicine and later restated as telehealth. The telehealth system serves as a platform for digital health services in Malaysia [20]. The National Telehealth Policy was launched to support the Vision 2020 agenda, focusing on four key components: (1) lifetime health plan, (2) mass customized health information and education, (3) continuous medical education, and (4) teleconsultation application [1]. The policy was formulated during the Eighth Malaysia Plan and managed by the National Health Informatics Centre Division [4,17,19-22]. The lifetime health plan covers health services from womb to tomb [19]. The telehealth system also includes the clinical support system and health information management and support services, and it encompasses the hospital information system and the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) [18-24]. The TPC-OHCIS is a comprehensive electronic medical record system for primary health care [22-24]. It was initially developed for outpatient services at primary health care clinics (PHCs), and later, it incorporated maternal and child health (MCH), oral health, and other life stage health services to ensure continuity of care [21,22]. The development of TPC-OHCIS was a collaborative effort between the Ministry of Science, Technology, and Innovation; the Ministry of Health, Malaysia; and the Malaysian Institute of Microelectronic Systems, Berhad [21-24]. The system was first tested in the PHCs of Seremban District, Negeri Sembilan, and later expanded to 34 PHCs across 3 states (ie, Perlis, Sarawak, and Selangor) [17,21]. To date, the TPC-OHCIS has been implemented in 108 PHCs across 7 additional states [22,25]. The TPC-OHCIS is a web-based platform that allows HCWs to enter data during clinic services or home visits, automatically updating when connected to the internet [23,24].

Role of Digital Health in Service Quality Performance

The recent COVID-19 pandemic revealed a significant public health issue in health care system delivery to provide comprehensive quality care [2,26-28]. Malaysia has experienced various health service delivery disruptions at PHCs during the critical phase of the COVID-19 pandemic [29]. MCH services include a wide range of services covering school health programs that experienced substantial disruptions due to closing and movement control orders, thus preventing mothers and children from receiving adequate health care services [22]. During the COVID-19 pandemic, many countries have improved health care delivery through digital technology, enhanced resource coordination, and facilitated universal health coverage [29,30].

The HCWs at the PHCs worked on the frontlines, assessing risks, monitoring care treatment, and promoting health empowerment in the community [17]. Most of the administration work related to patient care is recorded manually. Even with the implementation of TPC-OHCIS, many facilities still need to record data manually and enter it into the system because of internet instability at some PHCs [22]. At present, there is no specific policy published by the Ministry of Health to completely replace manual recording of patient information monitoring with digital health. The HCWs monitor patients during home visits and conduct outreach activities to cover areas inaccessible to health facilities [17,22]. Therefore, it is important to continue patient using manual data recording when services are provided offline. The TPC-OHCIS is an electronic medical record system used as a daily operating system and in "real time" at PHCs [22-24]. However, the TPC-OHCIS implemented in selected facilities in Malaysian PHCs is used mostly to record data and monitor patient care only [22-24].

Specific Study Measurement Tool

The conceptualization of this study diverges from earlier studies primarily in its integration of advanced technological modalities and emphasis on patient-centered care delivery, unlike traditional telehealth frameworks, which often focus on providing remote consultations or basic medical services [1,3,18,25]. The TPC-OHCIS incorporates elements of comprehensive primary care delivery, leveraging telehealth technologies to facilitate longitudinal patient-provider relationships, care coordination, and proactive health management. Moreover, this study's conceptualization places a heightened emphasis on the integration of patient health data, wearable devices, and digital health platforms to enhance care delivery and patient engagement. The TPC-OHCIS can remotely monitor patient health metrics, deliver personalized interventions, and empower individuals to take an active role in their health management [24]. The importance of interdisciplinary collaboration and team-based care is crucial in the implementation of the TPC-OHCIS at PHCs. Hence, it is important to assess the implementation of TPC-OHCIS by focusing on technology, organization, environment, or human resource components, as suggested in the literature [3-5,9]. Earlier studies were conducted to evaluate the effectiveness of the TPC-OHCIS in improving health care quality; however, there is limited evidence on assessing HCWs' perceived usefulness and ease of use [9,18,25]. A comprehensive study of HCWs' perspectives is important to provide a shred of extensive knowledge and evidence on the TPC-OHCIS implementation in PHCs.

Therefore, this study aimed at developing, testing reliability, and validating the TPC-OHCIS questionnaire, which was designed as a survey instrument to collect data on the implementation of the TPC-OHCIS at the PHC setting among HCWs related to various aspects of primary care services, including MCH services. It aims to ensure that the TPC-OHCIS questionnaire is a robust and effective tool for assessing the

implementation of MCH services, which are the core services for PHCs. The research question formulated was as follows: "Is a customized questionnaire on digital health information system (TPC-OHCIS) able to assess the HCWs' perception of its implementation process in the delivery of MCH services at the primary care level?" A thorough design of the TPC-OHCIS questionnaire validation helps increase the questionnaire's relevance and usefulness for decision-making purposes, as it is designed to facilitate monitoring and evaluating the TPC-OHCIS operability among the HCWs working at PHCs. To the best of our knowledge, there is no valid questionnaire available to measure the implementation evaluation of any digital health information system for the primary care level that focuses on MCH services, which is a priority service component of PHC and which was monitored regularly for sustainable development goals performance achievement [17].

Methods

Study Design

This study involved several steps for questionnaire development (phase 1), reliability, and validation (phase 2).

Phase 1: Questionnaire Development

The questionnaire is adapted from literature and document review [4,5,9,17-25,31-36]. The TPC-OHCIS questionnaire was developed based on various theoretical models, which may address multiple aspects of remote primary care and patient information systems. The questionnaire was created based on a combination of the technology-organization-environment (TOE) theory [31], the technology acceptance model (TAM) theory [32,33], the human organization technology-fit (HOT-fit) model [34,35], and the diffusion of innovation (DOI) theory [36]. There was a 65-item questionnaire with a 4-point Likert scale (1=highly disagree, 2=disagree, 3=agree, and 4=highly agree) developed based on the aforementioned theories [31-36]. The score scale is created according to the Likert scale that indicates the following: 1=strongly agree, 2=agree, 3=disagree, and 4=strongly disagree. In this study, the researcher did not put a neutral on a scale of 3 to avoid respondent bias [37]. The 4-point Likert scale does not impact the reliability and validity of the questionnaire [2,37].

The development of the questionnaire items was partly adapted from various questionnaires available from previous studies conducted in Malaysia, based on selected theoretical models, using a 4-point scale questionnaire: (1) technology, (2) organization, (3) environment, and (4) human [31-36] (Multimedia Appendix 1 [4,5,9,17-25,31-36]). Therefore, we classified the 65-item TPC-OHCIS questionnaire into 4 scales (Multimedia Appendix 2), described below.

- Domain A, technology: this comprised 17 items and four subscales that include (1) relative advantage (items 1-5), (2) compatibility (items 6-9), (3) complexity (items 10-13), and (4) security concern (items 14-17).
- Domain B, organization: this contained 18 items and four subscales that include (1) the presence of a specified liaison officer (BCHAMP: items 18-22), (2) infrastructure (BINFRA: items 23-26), (3) top management support (BTP: items 27-31), and (4) financial resources (BFIN: items 32-35).
- Domain C, environment: this focuses on vendor support (CVEN: items 36-39).
- Domain D, human: this contained 26 items and six subscales that include (1) staff competency in information systems (DPT: items 40-44), (2) knowledge of the TPC-OHCIS system (DEISK: items 45-50), (3) clinical information technology competency (DCIT: items 51-54), (4) perceived innovativeness of the IT officer (DCIO: items 55-57), (5) perceived ease use (DPEU: 58-61), and (6) perceived usefulness (DPU: items 62-65).

The 65-item TPC-OHCIS questionnaire was developed based on the requirement of the TPC-OHCIS implementation plan for the PHCs in Malaysia. A total of 15 items (item numbers 10, 11, 12, 13, 33, 40, 41, 42, 48, 49, 50, 53, 54, 58, and 39) were written as negative items. The Likert scale score of negative items was reversed for scoring analysis before data were entered into the SPSS software (version 26.0; IBM Corp).

Phase 2: Questionnaire Validation

On the basis of the steps suggested by Boateng et al [38], the second phase involved scale development, which consists of pretesting questions, sampling and survey administration, item reduction, and extraction of latent factors. The scale evaluation requires tests of dimensionality, reliability, and validity. A cross-sectional study was conducted to assess the psychometric properties of the questionnaire.

Study Sample

The sample for each step was calculated and listed in Table 1.

The sample-to-item ratio was decided based on the number of items in the questionnaire. The ratio per item was determined using 5 to 20 samples per item [39,40]. In this study, the survey included 65 items. Therefore, the total calculated sample size required was 325 respondents.

Table 1. Calculated sample size for each validation step.

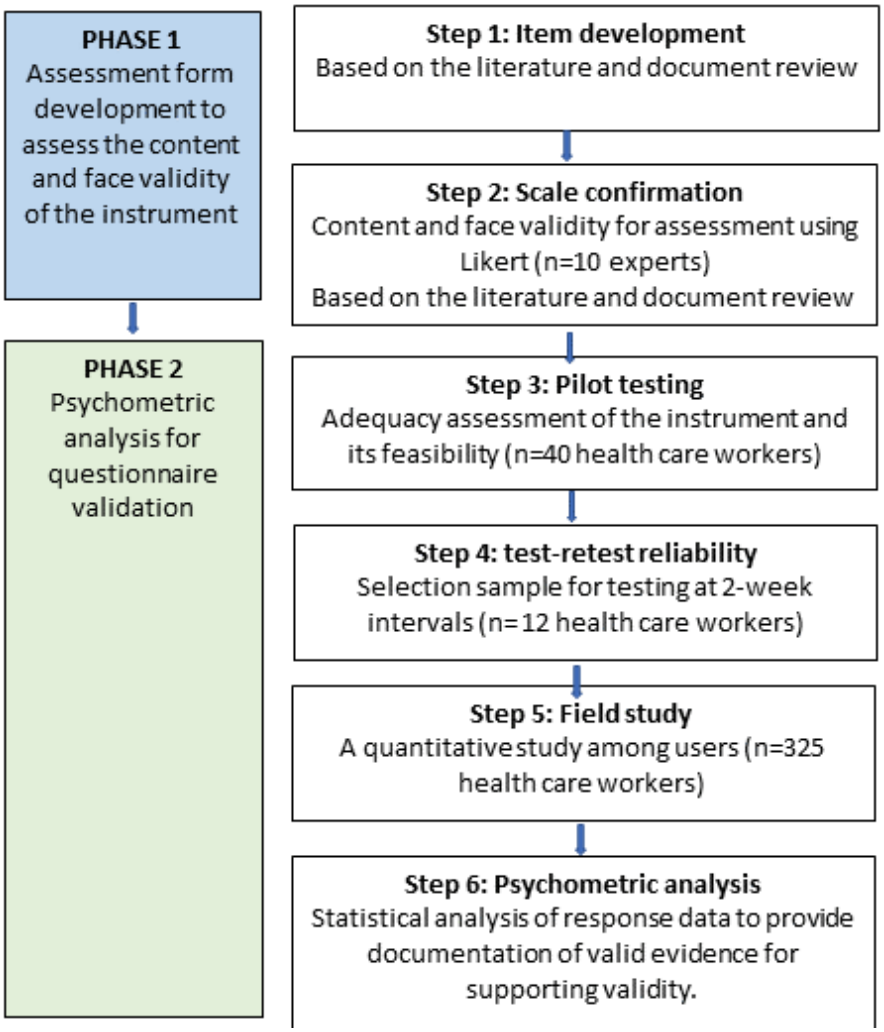
Steps and aims	Sample size required, n	Reference
Pilot study and face validity: to test the adequacy of instrumentation in which the outcome is in the form of a scale	40	[3]
Test-retest reliability: to test the degree of consistency exhibited when a measurement is repeated under identical conditions	12	[4]
Field survey: to test the psychometric analysis of the questionnaire based on tests of dimensionality, reliability, and validity	325	[5]

Content Validity Index

The flow process of questionnaire validation was conducted based on Figure 1.

On the basis of Figure 1, a total of 6 steps were taken to perform content validity for the questionnaire.

Figure 1. Flow process for questionnaire validation.



Step 1: Assessment Form Development for Content and Face Validity

In our literature review search [37,39-41], we listed items to determine the content and face validity. We used the clarity scale of 1 to 3 to indicate the relevance of each item (1=not clear, 2=revision needed, and 3=very clear). The essentiality of the questionnaire was identified using a 1 to 3 scale (1=not essential, 2=useful but not essential, and 3=essential). A similar form was used to assess face validity in evaluating the language, feasibility, readability, and style formatting consistency [37,41].

Step 2: Content and Face Validity (Expert Review)

Face validity was conducted among the experts who were involved in designing and using the system at the primary care level. Ten experts were invited to review the 65-item Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire. All experts have extensive experience and knowledge related to the TPC-OHCIS. Of the 10 experts, 3 (30%) were from the TPC-OHCIS division, 3 (30%) were public health researchers, 2 (20%) were from the maternal and child health unit services in the Selangor State Health Department, and finally, 2 (20%) were individuals who worked directly with the TPC-OHCIS system and also served as system liaison officers at health clinics. The adaptation of questionnaires from earlier studies [41-43] was checked for content suitability and appropriateness before forward translation was performed. Scale evaluation was performed by experts using a developed form. Owing to time constraints and lockdown because of the COVID-19 pandemic, a face-to-face method for collecting data from the experts was impossible. A Google form (Google LLC) link was created and sent via WhatsApp (Meta Platforms, Inc) to assess the face and content validity. The selected 10 experts were asked to evaluate the scale for content and face validation. All 10 experts' comments were used to improve the questionnaire. Experts were encouraged to provide both verbal and written comments regarding the questionnaire items. Verbal comments were collected via phone call, and written comments were collected via the Google form.

Step 3: Pilot Study

A pilot study was conducted to assess the adequacy of the instrumentation, which measured outcomes to ensure that the instruments used were appropriate and effective for the intended purpose. Through the pilot study, face validity was evaluated to confirm that the 65-item TPC-OHCIS questionnaire developed was constructed accurately and comprehensively. We purposively invited health care workers (HCWs) who were involved in the initial pilot-tested version of the TPC-OHCIS in Seremban District, Negeri Sembilan [17]. The questionnaire was sent after a thorough face and content validity assessment by the experts. Correction and fine-tuning were conducted by the researchers based on their feedback.

Step 4: Test-Retest Reliability

We selected 12 HCWs who were familiar with the TPC-OHCIS involved in the pilot study mentioned above to test the degree of consistency exhibited when a measurement is repeated under identical conditions. The same questionnaire was sent to the same respondents 2 weeks after the first time the survey was conducted.

Step 5: Field Study

A cross-sectional study was performed to assess the item reduction and extraction factors among the HCWs of the TPC-OHCIS public health care clinics (PHCs) in selected states in Malaysia. The TPC-OHCIS is a system used in the PHCs. The PHC is headed by a family medicine specialist who supervises staff from various disciplines (eg, physicians, nurses, medical assistants, pharmacists, laboratory technicians, and record officers).

Step 6: Performing an Analysis for Content Validity, Face Validity, and Test-Retest Reliability

The item-level content validity index (I-CVI) and scale-level content validity index (S-CVI) were used. I-CVI is defined as the proportion of content experts giving items a relevance rating of 3 and 4. S-CVI was calculated by the proportion of understanding by experts (universal agreement [UA] of S-CVI), which gave ratings of 3 and 4, or by average scores given (average of S-CVI). The average of S-CVI is defined as the average of the I-CVI scores for all items on the scale or the average of proportion relevance judged by all experts. The UA of S-CVI is the proportion of items on the scale that achieve a relevance scale of 3 or 4 by all experts. UA score is given as 1 when the item achieved 100% agreement by all experts; otherwise, the UA score is given as 0 [39]. First, we calculated the experts in agreement. Second, a score of 1 was given to items that achieved 100% agreement by all experts, while a score of 0 was given to items that did not achieve 100% agreement. Third, experts in the agreement were divided by the total number of experts (calculated for I-CVI). The fourth step was to divide the results obtained in the third step by 65, which was the total number of items in the questionnaire (calculated for average of S-CVI). Finally, we divided the UA result from step 2 by 65 items (calculated for UA of S-CVI). The face validity index was used to evaluate the form of clarity and comprehensibility of language and instructions used in the questionnaire [41]. The respondents were requested to rate the comprehensibility of each item using a scale of 1 to 4 (1=not understandable, 2=somewhat understandable, 3=understandable, and 4=very understandable). The item-level face validity index was computed for each item by dichotomizing the 4-point scale, where items scoring either 1 or 2 were recorded as 0 and items scoring 3 and 4 were recorded as 1. The values later were added up according to each item, and the total values were divided by the total number of respondents. Test-retest reliability was used to define whether the questionnaire was answered by respondents due to chance. The internal reliability of questionnaires was assessed using the Cronbach α coefficient. The Pearson correlation and intraclass correlation coefficients of the scores of the 2 tests were calculated. The test-retest reliability is achieved when the value of intraclass correlations is 0.6 to 0.8 (good reliability), and values >0.8 indicate excellent reliability, which means the higher the correlation, the higher the test-retest reliability, with values close to 0 indicating low reliability [38].

Forward-Backward Translation

The questionnaire was translated from English to the Malay language, then underwent content assessment, and its cross-cultural validity was evaluated by 3 experts representing Malaysia's diverse ethnic backgrounds (Malay, Chinese, and Indian), proficient in both English and Malay. After the questionnaire had been reviewed, the forward-backward translation was sent to Proofreaders United company for translation and proofreading.

Ethical Considerations

Ethics approval was granted by the National University of Malaysia (FF-2021-124) and the Ministry of Health Malaysia National Medical Research Registry (NMRR-21-599-58521, investigatory initiated research). Meanwhile, the researcher also needed to obtain verbal permission and a signed consent letter from the respondent as evidence of consent to participate in the study. Respondents were informed that their participation was voluntary and they would not receive any payment. All research information collected was treated as confidential. The data are displayed anonymously without the name, address, or any identity that describes the respondent when presented as the study output.

Statistical Analysis

The internal reliability was assessed using Cronbach α. The validity index was calculated based on the content validity index (CVI). The Bartlett test of sphericity was used to determine the construct validity. The Kaiser-Meyer-Olkin measure and total variance explained (TVE) were evaluated. Factor analysis was performed using varimax rotation in principal component analysis (PCA) to verify construct validity (ie, discriminant and convergent validity). Items loading >0.60 were considered for further analysis [38].

Results

CVI Evaluation

Out of 10 experts evaluating the 65-item TPC-OHCIS questionnaire (TPC-OHCIS questionnaire in Multimedia

Appendix 2), the scale-level CVI (S-CVI) average for item 1 of domain A, relative advantage, to item 65 of domain D, perceived usefulness, was 0.9. The average of S-CVI (based on item-level CVI) was 7.415, the average of S-CVI (based on proportion) was 0.742, and the universal agreement of S-CVI was 0.045. The universal agreement of S-CVI was calculated based on the proportion of items on the scale that obtained a relevance value of 3 or 4 from all the experts (Multimedia Appendix 3).

Face Validation

The face validity index was assessed for clarity, language comprehensibility, and instructions used in the questionnaire. The calculated item face validity index was 0.785 and fulfilled the face validity criteria, which was >0.6 [41].

Test-Retest Reliability

The 65-item survey's internal reliability score for Cronbach α was 0.90 for the whole instrument and exceeded the suggested minimum value of Cronbach α=0.70 [38]. Pearson correlation coefficient was 0.90, and the intraclass correlation coefficient was 0.91.

Descriptive Analysis

There were 319 respondents (Table 2) who answered the 65-item TPC-OHCIS questionnaire, with mean item scores ranging from 1.99 to 2.85 (Table 3). Our study found that a high mean score was achieved in all subscales except for the item 17 in domain A, security concerns (*how much can I trust the vendor)*. The subscale mean scores were lowest at 1.93 (SD 0.751) and 1.99 (SD 0.832) for item 63 in domain D, perceived usefulness (*TPC-OHCIS application improved the quality of my work, respectively).* The mean score for communication was the highest for item 38 in domain C, vendor, with a mean score of 3.45 (SD 0.819), and item 39 in domain C, vendor, with a mean score of 3.39 (SD 0.805).

Table 2. Respondent profile for field study (N=319).

Variables and category	Frequency, n (%)
Occupation	
Family medicine specialist	5 (1.6)
Medical officer	69 (21.6)
Matron	2 (0.6)
Head nurse	17 (5.3)
Nurse	138 (43.3)
Community nurse	88 (27.6)
Sex	
Male	6 (1.9)
Female	313 (98.1)
Race	
Chinese	7 (2.2)
Indian	21 (6.6)
Malay	285 (89)
Others	6 (1.9)

Table 3. Descriptive statistics for item mean score of the Tele-Primary Care Oral Health Clinical Information System (TPC-OHCIS) questionnaire.

Item question	Question statement	Scores, mean (SD)
ARA[a] 1	Using the TPC-OHCIS application enables me to do my work quickly.	2.05 (0.865)
ARA 2	Using the TPC-OHCIS application improves the quality of my work.	1.99 (0.832)
ARA 3	Using the TPC-OHCIS application enhances my effectiveness on the job.	2.01 (0.864)
ARA 4	Using the TPC-OHCIS application increases my productivity.	2.04 (0.825)
ARA 5	Using the TPC-OHCIS application makes my job easier.	2.02 (0.795)
ACOM[b] 6	TPC-OHCIS application can be easily accessed across multiple platforms (laboratory results, x-ray, and other related patient data).	2.53 (0.941)
ACOM 7	TPC-OHCIS user interfaces provide transparent access to all platforms (e-notification and VEKPRO[c]).	2.62 (0.931)
ACOM 8	Data received from other devices (tablet/laptop/ smartphone) outside health facilities in the TPC-OHCIS application can be easily merged into the database for analysis.	2.74 (0.932)
ACOM 9	Information is shared seamlessly across our organization regardless of location.	2.74 (0.839)
ACOMPLEX[d] 10	I do not know enough about the TPC-OHCIS application to handle my job satisfactorily.	2.86 (0.870)
ACOMPLEX 11	I need a long time to understand and get familiar with the TPC-OHCIS application.	2.82 (0.961)
ACOMPLEX 12	I do not find enough time to study and upgrade my technology skills before using the TPC-OHCIS system.	2.71 (0.870)
ACOMPLEX 13	I often find it too complex for me to understand and use the TPC-OHCIS application.	2.99 (1.019)
ASEC[e] 14	I feel secure in using the TPC-OHCIS application, keying in patients' data, and sharing it across my organization.	2.05 (0.855)
ASEC 15	I would feel safe using the TPC-OHCIS application to retrieve patient data.	2.80 (0.754)
ASEC 16	I am concerned about data patient leakage.	2.07 (0.785)
ASEC 17	I am concerned about how much I can trust the vendor.	1.93 (0.751)
BCHAMP[f] 18	A specified liaison officer will provide useful information to top managers and vendors about the TPC-OHCIS application faulty.	2.02 (0.736)
BCHAMP 19	A specified liaison officer plays a role in upgrading the TPC-OHCIS application for users' needs.	2.01 (0.760)
BCHAMP 20	A specified liaison officer has a good relationship with both vendors and top managers.	2.22 (0.851)
BCHAMP 21	A specified liaison officer can bring staff to use the TPC-OHCIS application well.	2.41 (0.972)
BCHAMP 22	A specified liaison officer provides training/courses for the users a few times a year.	2.54 (0.895)
BINFRA[g] 23	We have enough computers for the TPC-OHCIS application use.	2.27 (0.743)
BINFRA 24	We have a reliable computer network in our use.	2.11 (0.767)
BINFRA 25	Appropriate hardware, software, and network infrastructure were in place before TPC-OHCIS implementation.	1.90 (0.749)
BINFRA 26	We have integrated IS[h] applications encompassing different functional areas (laboratory and pharmacy).	2.05 (0.775)
BTP[i] 27	Top management always supports and encourages the use of the TPC-OHCIS application for job-related tasks.	2.15 (0.785)
BTP 28	Top management provides most of the necessary help and resources to enable people to use the TPC-OHCIS system.	2.17 (0.746)
BTP 29	Top management provides good access to hardware when staff need it.	2.15 (0.732)
BTP 30	Top management gives feedback to vendors on every dismayed or unsatisfactory comment from staff.	2.44 (0.822)

Item question	Question statement	Scores, mean (SD)
BTP 31	Top management provides good access to the TPC-OHCIS application when staff need it.	2.55 (0.842)
BFIN[j] 32	There is enough financial aid from the organization for the coordination of the system implementation.	2.44 (0.901)
BFIN 33	I find difficulties in using the TPC-OHCIS application because it cannot be upgraded due to not having enough budget.	2.75 (0.814)
BFIN 34	Enough computers are available to access the TPC-OHCIS application.	2.29 (0.743)
BFIN 35	We easily obtain obsolete computer replacements.	2.28 (0.729)
CVEN[k] 36	Vendors entertain each of our complaints dutifully.	2.41 (0.704)
CVEN 37	The vendor can upgrade the TPC-OHCIS according to our needs.	2.41 (0.771)
CVEN 38	The system vendor attends technical meetings quite frequently.	3.45 (0.819)
CVEN 39	I have a platform to voice out problems regarding the TPC-OHCIS application directly to the vendor.	3.39 (0.805)
DPTC[l] 40	I do not know how to use computers.	3.19 (0.874)
DPTC 41	I never used to work online.	2.11 (0.849)
DPTC 42	I need people's help to use a computer.	2.15 (0.859)
DPTC 43	I like to work using the online system.	2.29 (0.836)
DPTC 44	The TPC-OHCIS application is easy to operate.	2.33 (0.794)
DEISK[m] 45	I have enough training before working with the TPC-OHCIS application.	2.25 (0.836)
DEISK 46	It took me only a few days before I could master the TPC-OHCIS application well.	2.85 (0.920)
DEISK 47	The TPC-OHCIS facilitates task management.	2.63 (0.912)
DEISK 48	The TPC-OHCIS application is hard to use.	2.61 (0.900)
DEISK 49	I have to open many interfaces just to key in 1 patient's data.	2.05 (0.730)
DEISK 50	The TPC-OHCIS application takes much time because I have to open so many interfaces.	2.50 (0.715)
DCIT[n] 51	I have confidence in my ability to operate the TPC-OHCIS application.	2.60 (0.725)
DCIT 52	I have the expertise regarding Information technology to provide valuable knowledge to the organization.	2.23 (0.737)
DCIT 53	It does not make any difference whether I add/share knowledge with others related to the use of the TPC-OHCIS application.	2.22 (0.688)
DCIT 54	I feel that other employees can provide more valuable knowledge about the system's use.	2.22 (0.688)
DCIO[o] 55	The ITO[p] is actively considering the introduction of new technology to solve to organization's problem.	2.34 (0.672)
DCIO 56	The ITO tries to keep a technological leading edge by adopting new technology early.	2.84 (0.823)
DCIO 57	The ITO tends to take risks in the decision-making of new technology introduction.	2.80 (0.847)
DPEU[q] 58	I often become confused every time I use the TPC-OHCIS application.	2.11 (0.810)
DPEU 59	Interacting with the TPC-OHCIS application is frequently frustrating.	2.18 (0.768)
DPEU 60	I find that the TPC-OHCIS application makes my job easier.	2.28 (0.846)
DPEU 61	The TPC-OHCIS application provides useful guidance in performing tasks.	2.06 (0.764)
DPU[r] 62	My job would be hard to perform without the TPC-OHCIS application.	2.13 (0.835)
DPU 63	Using the TPC-OHCIS application improves my job performance.	2.18 (0.767)
DPU 64	Using the TPC-OHCIS application saves me time.	2.13 (0.851)

Item question	Question statement	Scores, mean (SD)
DPU 65	Using the TPC-OHCIS application supports critical aspects of my job (e.g, retrieving patients with missed treatment).	2.17 (0.782)

Statistical Analysis

The 65-item TPC-OHCIS questionnaire was created based on a mix of items adapted from various sources in the development of the questionnaire. It was adapted by a combination of the TOE theory [31], the HOT-fit model [34,35], the DOI theory [36], and the TAM theory [32,33]. The content validity was assessed by experts according to the 4 scales (ie, technology, organization, environment, and human), as highlighted in the previous studies [33-35]. In this study, we explored the constructs generated from this initial group of 65 items, which were developed based on their multidimensional nature. An exploration of the subdimensions based on the 65-item TPC-OHCIS questionnaire at the initial phase found that there were 13 factors, without being restricted to 4 domains. Exploratory factor analysis (EFA) determined the quantity of components (or themes) that emerged for the questionnaire items. The process involved grouping the measurements of comparable themes. The scree plot reveals that there were 13 components in a 65-item questionnaire (Figure 2).

A PCA with varimax rotation yielded 13 components with an eigenvalue of >1. The eigenvalue for the first component was 17.71 and accounted for 27% of the variance. The difference between the first and second components was 11.98, while the subsequent eigenvalues were small (4.91, 4.64, and 3.40). The Kaiser-Meyer-Olkin value was 0.908, which showed sample adequacy. The Bartlett test of sphericity value for the approximate chi-square was χ^2_{2080}=18,219.9; this was significant (P=.001).

Table 4 shows that the eigenvalues from 1.01 to 17.71, corresponding to the extraction sums of squared loadings of 13 subscales of the questionnaire. The highest eigenvalue accounted for 17.71% of the total variance, while the lowest eigenvalue explained 1.01%. The result also shows that the extraction eigenvalue does not vary much from the rotation eigenvalue. Therefore, 65 items loaded strongly on 13 factors at the extraction level.

Table S1 in Multimedia Appendix 4 provides the scale construct and its item. All 13 components had acceptable internal reliability (Cronbach α>0.7). All construct eigenvalues were >1. The deleted items were 14 and 15 of domain A, relative advantage, and 56 and 57 of domain D, chief information officer innovativeness, and the deletions were done because their factor loadings were <0.6. After discussing with the experts, questions for items 56 and 57 of domain D, chief information officer innovativeness, were rephrased for clarity. Question for item 15 of domain A, relative advantage, was omitted, and question for item 14 of the same domain remained as it was.

Table S1 in Multimedia Appendix 4 provides a detailed breakdown of various items and their corresponding domain scores, reflecting their relative contribution to each domain. The items are identified by numbers and grouped under distinct domains. For instance, items 18, 19, 22, 20, 21, 16, 17, and 14 display scores ranging from 0.493 to 0.854, indicating their relevance within a particular domain. Similarly, items 63, 65, 62, 64, 61, 60, 59, and 58 exhibit scores from 0.636 to 0.807 and, therefore, were grouped in another domain. The third domain was categorized based on items 40, 42, 44, 43, 41, 38, and 39, with scores ranging from 0.701 to 0.927. The fourth domain includes items 48, 46, 49, 47, 45, and 50, with scores between 0.0715 and 0.829, and the last domain covers items 27, 31, 30, 29, and 28, with scores ranging from 0.773 to 0.822.

Figure 2. Scree plot revealing the 13-factor components extracted from principal component analysis with varimax rotation.

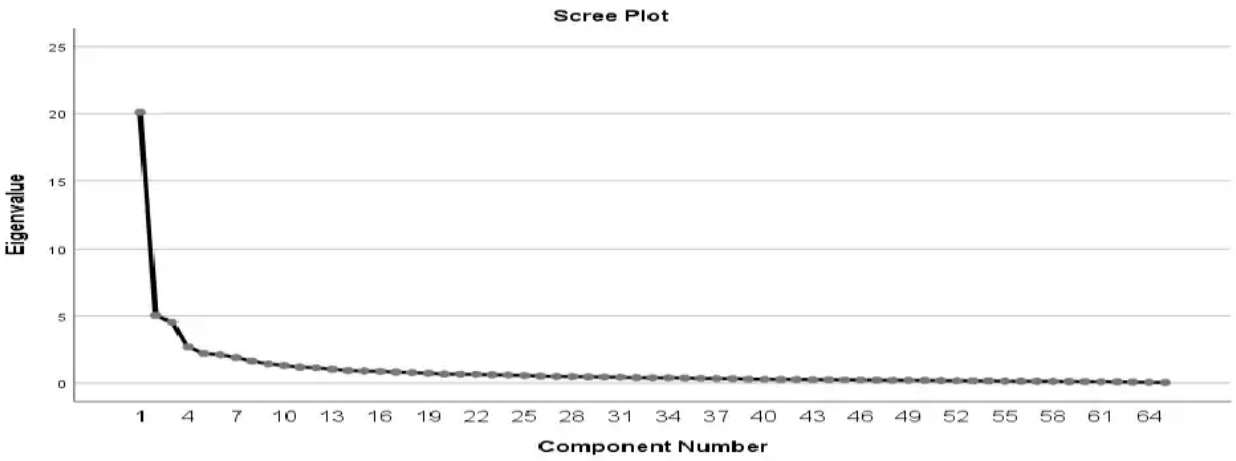

Table 4. The total variance explained.

Factor	Initial eigenvalues			Extraction sums of squared loadings		
	Total, n	Variance (%)	Cumulative (%)	Total, n	Variance (%)	Cumulative (%)
1	18	27.2	27.2	18	27.2	27.2
2	6	8.8	36.1	6	8.8	36.1
3	5	7.6	43.6	5	7.6	43.6
4	5	7.1	50.7	5	7.1	50.7
5	3	5.2	55.9	3	5.2	55.9
6	3	4.3	60.3	3	4.3	60.3
7	2	2.9	63.2	2	2.9	63.2
8	2	2.7	65.9	2	2.7	65.9
9	2	2.6	68.6	2	2.6	68.6
10	1	2.2	70.7	1	2.2	70.7
11	1	2.1	72.8	1	2.1	72.8
12	1	1.7	74.5	1	1.7	74.5
13	1	1.6	76.1	1	1.6	76.1

Discussion

Principal Findings

This study aimed to validate a specific tool used in health care delivery in Malaysia's health care system, a new technology telehealth application called TPC-OHCIS, making this evaluation timely. The 65-item TPC-OHCIS questionnaire demonstrated a comprehensive and reliable tool ready to be used for the assessment of the implementation of the digital application system for monitoring the health service program at the PHCs. Monitoring any health care service performance requires a periodic and ongoing operation to ensure that it can be delivered as planned and with good tracking of progress. Evaluation of how the program should be implemented needs to have a valid tool that can give relevant and appropriate results. A validated tool can be used to replicate similar studies in the future for evaluation and comparison.

Developing and validating a locally customized questionnaire for specific program service delivery is important. Therefore, this study used 4 theories, including the HOT-fit model, DOI theory, TOE theory, and TAM theory. The TPC-OHCIS questionnaire was proven valid based on content, face, and construct validities, as well as good psychometric analysis reliability. A total of 4 scales created using PCA did not align with a local study [17] that assessed the hospital information system implementation in Malaysian hospitals. Measuring implementation of technology in different service set-ups and levels of care, at either hospitals or PHCs, should use a customized tool. No similar research paper is available to check for disagreement or benchmarks on other tools, to compare them with the TPC-OHCIS questionnaire validation. Our findings showed that the 13 scales were validated based on the local population working in the PHC with the TPC-OHCIS. In comparison, an earlier study conducted local testing on the hospital information system and identified 4 scales [18]. Our

analysis focuses on the MCH services, which are the routine and regularly monitoring health services delivered at PHCs.

A CVI score of 0.90 is generally considered very high and indicative of strong content validity for a measurement tool, particularly in the academic context. Content validity refers to the extent to which the items in a measurement instrument represent the entire range of content that the instrument is intended to measure [39]. A CVI of 0.90 provides strong evidence that the measurement tool has undergone rigorous development and validation processes.

Face validity has been widely used not only in questionnaire development but also in questionnaires that were adopted from other researchers' tools, which required local forward-backward translation [37-41]. Experts in the field who were recruited to determine face and content validity in our study gave feedback regarding content relevance, wording, quantity of items, the amount of information, and other related issues. The analysis results for the CVI from 10 experts indicated good quality (>0.9), which complies with the recommendations in the literature [41].

Internal reliability assessment using Cronbach α revealed how close the selected items are to one another when measuring the construct [39]. The Cronbach α value of the 65-item TPC-OHCIS questionnaire was 0.90, which exceeded the suggested minimum value of 0.70 [39]. By measuring Cronbach α, the tool's accuracy and reliability have been verified. Our findings demonstrated that the variables are correlated with the components as constructed through PCA, and it proved that they are internally consistent.

The EFA also determined the TVE for the construct. The TVE illustrated the precision with which the measuring objects and their constituent parts estimate the construct. This study found that the TVE was 76.08%, which exceeded the required minimum of 60%, indicating that the overall variance explained was satisfactory [39]. PCA is the most common EFA method for dimension reduction. The EFA results using varimax rotation with maximum likelihood showed that the TPC-OHCIS questionnaire has 13 subscales.

The study may provide evidence-based recommendations for policy makers and health care stakeholders regarding the implementation and optimization of the TPC-OHCIS in the MCH service delivery monitoring. By identifying key factors influencing the TPC-OHCIS implementation and effectiveness, the study offers actionable insights into policy development, resource allocation, and quality improvement efforts aimed at strengthening MCH care systems. The study may contribute methodological innovations to the field of TPC-OHCIS evaluation, such as novel approaches to questionnaire development, validation, and implementation. By documenting the methodological processes and challenges encountered in assessing the TPC-OHCIS questionnaire validation, the study adds to the methodological toolkit available to researchers and practitioners working in the field of digital health.

Overall, the TPC-OHCIS study offers novel insights into the evaluation of the TPC-OHCIS, which focuses on the MCH services, highlighting the importance of tailored assessment tools, cross-cultural adaptation, policy considerations, and methodological innovations. These insights contribute to a deeper understanding of the complexities and opportunities associated with the integration of digital health technologies into health care delivery and provide a foundation for future research and practice in this area. The TPC-OHCIS questionnaire is validated for evaluating other health information systems, as it takes into account the outcome aspects of health services, technology, organizations, vendors, and human resources. Future researchers can replicate studies to validate the findings of the TPC-OHCIS questionnaire in different populations, settings, and contexts. By replicating studies using a valid and reliable tool with diverse samples, researchers can assess the generalizability and robustness of the questionnaire across various demographic, cultural, and organizational contexts.

Suggestions to Stakeholders

There is a need to integrate machine learning and artificial intelligence into the TPC-OHCIS so that data can be extracted faster and can be used in line with precision medicine. The validated TPC-OHCIS questionnaire can help stakeholders make effective evidence-based decisions in managing patient-centered care. The system needs to be more stable, easier to use, and faster in terms of data collection, without the need for complicated training, and easy to download from the system itself. Awareness related to the importance of complete and accurate data from an organizational perspective needs to be understood at the level of clinic users and data administrators because they will then enter, process, and ensure that the data entered are complete and accurate. These crucial issues were addressed in our study during the content and face validity assessment of the tool.

The COVID-19 pandemic made us see the need for the TPC-OHCIS to be rolled out to wider PHCs in Malaysia. With <10% of the TPC-OHCIS currently implemented, the vision to having a digital health system in Malaysia by the year 2030 needs to be facilitated. The TPC-OHCIS should be developed as a comprehensive package that includes embedded training and health education to facilitate its delivery. The issue of data security can be compared to the concept of banking system apps in Malaysia, where users only need to download the app on their mobile phones to share information with other health care providers, unlike the TPC-OHCIS, which ensures continuity of care. Otherwise, printing a duplicate report is sufficient for the time being while the country works on transitioning all clinics into a digital system.

Study Strength

The study demonstrates the development of a tailored questionnaire specifically designed to assess the implementation process and the effectiveness of the TPC-OHCIS in the context of MCH health services at the primary care level. This tailored approach acknowledges the unique challenges and complexities of MCH service delivery and highlights the importance of designing measurement tools that are sensitive to the needs of this population. The study determined comprehensive items to measure the integration implementation of the TPC-OHCIS, which is one of the digital health technologies focusing on

priority services, such as MCH service delivery at the primary care level. The study sheds light on the practical considerations, barriers, and facilitators associated with the adoption and use of digital health solutions in MCH care settings. The study offers insights into the cross-cultural adaptability assessment tools, particularly in diverse multiethnicity population settings. By evaluating the linguistic and cultural appropriateness of the TPC-OHCIS questionnaire, the study highlights the importance of considering cultural context and language preferences in developing and validating measurement instruments for MCH services.

Limitations of This Study

This study was conducted in 2021 when movement control orders were implemented in Malaysia. The study was conducted entirely online, and all surveys were distributed to the respondents' superiors without proper briefing about the survey and the overall idea of the research except for study information highlighted at the beginning of the online survey questionnaire form. Therefore, each respondent answered as they saw fit, without recognizing the true meaning of the survey. In addition, the deployment of staff during the COVID-19 pandemic could have caused fatigue among them, which was likely to cause them to answer the questions lightly without focus. Meanwhile, the distribution of questionnaires through Google Forms contributed to the risk of bias among respondents when there was no supervision or explanation that could be given as a guide to answering the questionnaire.

Conclusions

The psychometric validation process of the questionnaire was done comprehensively for all iterative stages, including initial reliability tests, potential modifications based on these tests, and integration with existing digital health assessment frameworks. The novelty of the study lies in its unique approach to conceptualizing the implementation of the TPC-OHCIS. This may offer new insights into the integration of life stage records, with a focus on priority services at PHCs, such as MCH services, for its development. Cross-cultural adaptability was considered to ensure wider applicability, and the rigor of the process was demonstrated in part by high CVI scores, which is important in an academic research setting. Likert scale points were carefully chosen to capture nuanced responses, and while the TPC-OHCIS has certain academic limitations, its robustness paves the way for future research on policy implications and telehealth. Comparison with existing literature establishes its validity and reliability, showing its potential impact on policy development.

Acknowledgments

The authors would like to especially thank the Selangor Health State Department, Kuala Lumpur and Putrajaya Health State Department, and Pahang Health State Department for their support in the study. The authors would also like to thank the Director General of Health Malaysia for his permission to conduct the study and publish this paper. This work was supported by a research grant from the Ministry of Higher Education (FRGS/1/2021/SKK04/UKM/02/1) and by the Medical Faculty of Universiti Kebangsaan Malaysia, which contributed to the publication costs of this paper.

Authors' Contributions

SI, RS, and RI conceived the scope of the review to meet the study objectives. Literature search, data collection, analysis, and interpretation were conducted by SI and verified by RS. SI drafted the first iteration of the manuscript, which was revised and improvised by RS. All authors made substantial contributions to the critical review, editing, and revision of the manuscript. All authors approved the final version of the manuscript.

Abstract

Background: Patient-reported outcome (PRO) data refer to information systematically reported by patients, or on behalf of patients, without the influence of health care professionals. It is a focal point of the health care system's ambition toward becoming more involving and personalized. It is recognized that PROs provide valuable data. However, despite this recognition, there are challenges related to both patients' and clinicians' accurate interpretations of the quantitative data. To overcome these challenges, this study explores text vignettes as a representation of PROs.

Objective: This study aimed to develop data-informed text vignettes based on data from the Readiness and Enablement Index for Health Technology (READHY) instrument as another way of representing PRO data and to examine how these are perceived as understandable and relevant for both patients and clinicians.

Methods: The text vignettes were created from participant responses to the READHY instrument, which encompasses health literacy, health education, and eHealth literacy. The text vignettes were created from 13 individual text strings, each corresponding to a scale in the READHY instrument. This study consisted of 3 sequential parts. In part 1, individuals with chronic obstructive pulmonary disease completed the READHY instrument, providing data to be used to create vignettes based on cluster profiles from the READHY instrument. Part 2 focused on the development of scale-based strings representing all READHY dimensions, which were evaluated through iterative cognitive interviews. In part 3, clinicians and patients assessed the understanding and relevance of the text vignettes.

Results: Clinicians and patients both understood and related to the text vignettes. Patients viewed the text vignettes as an accurate reflection of their PRO responses, and clinicians perceived the text vignettes as aligned with their understanding of patients' experiences.

Conclusions: Text vignettes can be developed using PRO instruments, with individual scales as input strings. This provides an opportunity to present numeric values in a text format that is understandable and recognizable to most patients and clinicians. Challenges with the vignette's language and layout require customization and clinician training to ensure meaningful interpretation. Findings also support the need to expand the study and enhance clinical relevance with alternative or contextually relevant text vignettes.

Introduction

Background

Patient-reported outcome (PRO) data represent patients' self-assessed health status in terms of physical and mental health and do not involve health professionals [1]. PRO data can be used as a screening tool before outpatient visits as a supplement to in-person or virtual consultations, serving as a stratification tool to reduce the number of visits needed. PRO data can also be used during consultations to screen for symptoms or serve as a dialogue and decision tool. The use of PRO data during consultations may increase the patient's self-awareness and health literacy, facilitate joint decision-making, enable self-management, and lead to better health outcomes [1,2].

Health Literacy

Competence in health literacy and digital knowledge is fundamental for an accurate understanding of PRO data as well as knowledge about health behavior and health practices and how patients understand and interpret health information [3]. Challenges arise when data accessibility does not consider differences in health literacy. While aggregate-level understanding may tolerate some variations, individual patient pathways require a common understanding to capture nuances [4,5]. Therefore, it is crucial to account for patients' health literacy and cognition in the clinical use of PROs.

Interpretation of PRO Data

When incorporating PROs into individual patient pathways, it becomes crucial to ensure that patients fully understand the questions, fostering a shared understanding. In working with PRO data, an assumption is often made that people have the same needs, preferences, perceptions, and experiences and will attach similar importance to items in the questionnaire, thus leaving no room to capture different additions of value or uncover nuances [4]. The quantitative part of PRO data operates within a set of assumptions about the world, which states that the standardized numerical score is the objective representation of the respondents' health status and health-related quality of life, independent of an individual's unique life story [4].

For both clinicians and patients, it may be difficult to understand the meaning of PRO data when they are presented as values. Patients often prefer visual representations, such as bar charts and line charts, which prove useful for quick comprehension and comparisons over time [6]. However, the accuracy of interpretation is closely tied to the individuals' prior knowledge of these graphical representations [6].

Graphical presentations may be a challenge. Grossman et al [7] highlighted that individuals lacking prior knowledge of bar charts struggled to interpret them accurately. Furthermore, health literacy plays a crucial role in correct interpretation, with studies suggesting that patients with lower health literacy may find it challenging to grasp the longitudinal nature of PRO data [8]. There is a notable correlation between educational level and accurate interpretation, along with age-related difficulties in correctly interpreting graphic representations of PRO data [6,9]. Patients generally, regardless of educational level, prefer less-complex presentations of PRO data, but a correlation has been demonstrated between age and accurate interpretation, where patients aged >65 years had substantially more difficulty interpreting graphic representations of PRO data correctly [6,9]. In Denmark, 1 in 5 individuals is aged >65 years [10], which means that a relatively large proportion of all individuals will potentially have difficulty interpreting PRO data.

The use of traffic light colors, that is, green, yellow, and red, in representing PRO data adds another layer of complexity. While this method increases accuracy in interpretation across various graphical representations [6,11], it is not foolproof and 93% of patients in a study population were able to correctly interpret the meaning of traffic light colors [6]. Despite this visual aid, there remains a need for additional descriptive explanations to enhance understanding [9].

Patients' and health care professionals' perceived understanding of graphically presented PRO data often exceeds their actual comprehension [9]. In addition, studies indicate that there may be a discrepancy between patients' preferred form of visualization and the form of visualization they can interpret with the highest accuracy [9].

Patients may also view the use of PRO data in treatment as impersonal and nonbeneficial for the relationship between themselves and their clinicians because they experience that the focus shifts from their own perspective to quantitative goals [12]. This perspective highlights the significance of maintaining a patient-centered approach.

A Common Understanding of PROs

When patients and clinicians collaborate on data interpretation, potential errors may arise due to questionnaire misinterpretation. This divergence in understanding creates a need for a common language or understanding of the representations of colors, figures, or text. A challenge is that patients and clinicians possess distinct cognitive frameworks influencing their actions and comprehension [13]. Data interpretation involves understanding available data, extracting information, and supplementing it for comprehensive comprehension [13]. Clinicians are shaped by a positivist background and may differ from patients in cognitive approaches, impacting data interpretation. When PRO data are translated into quantitative targets, it may be unclear what data have been made available and what information can be extracted. Patients provide a wide range of data, but data visualization often only includes part of these data.

Despite psychometric validation, there is a need to address discordance in individual interpretations of PRO data. Discordance reasons include word interpretation mismatches, evolving patient circumstances, and differing expectations [14]. Awareness of these differences is crucial in interpreting PRO data [14]. PRO tools vary in complexity, leading to further potential errors if patients lack an accurate understanding. A study found that only 11% of 59 PRO questionnaires are readable by the average UK adult [15], emphasizing the need for a patient-clinician dialogue to enhance understanding and decision-making [5]. Numerical scores derived from PROs can represent a person's health status or health-related quality of life to a limited extent because some of the narrative is lost

along the way. In the representation of PRO data, there is a need to be able to give meaning to individual experiences [4]. Positivism argues that knowledge should be based on the objective world via empirically verified causal explanations based on "positive" facts and not on abstract inferences; however, according to Meadow [4], we cannot understand the patient if we do not also try to understand subjective and emotional meaning.

PROs as Text Vignettes

One approach to a more understandable and personalized representation of data about a group of patients or individuals is vignettes created based on a combination of clustered data, which are enriched with sociodemographic characteristics and interviews with individuals representing these clusters. An example of this is the Optimizing Health Literacy and Access (OPHELIA) process, where issues related to health care access and engagement are identified and addressed [16,17]. This way of creating data-informed text vignettes is a powerful tool to provide clinicians and policy makers with insights into a more detailed description of archetypes of patients [18]. In this way, text vignettes play a pivotal role in providing a nuanced understanding of the perceived status of various subgroups of patients in a specific context or area. The primary aim is to bring to life the "person behind the numbers," referring to PRO scores, addressing the challenge of visualizing the individuals behind the statistical data. To the best of our knowledge, this has not yet been done at the level of individuals by creating person-specific text vignettes.

In this study, inspired by the OPHELIA process, we will explore whether text vignettes can be developed from more structured text inputs and how this work can be advanced to create text vignettes that can be used at the individual level, rather than at the group level, to present personalized texts that reflect each patient's perception of their condition. The study uses the Readiness and Enablement Index for Health Technology (READHY) [19], which covers 3 key themes—self-management, social capital, and digital health literacy. This instrument was selected because, as its developers, we have extensive experience with its performance, and its design makes it well suited as a PRO tool for telehealth services. The study demonstrates the process of converting psychometric instrument scales into data-informed text vignettes, highlighting the challenges and implications to consider for ensuring understanding and relevance for both patients and clinicians.

Objectives

This study aimed to develop data-informed text vignettes based on data from the READHY instrument as another way of representing PRO data and to examine how these are perceived as understandable and relevant for both patients and clinicians.

Part 1 Introduction: Generating Vignettes Based on READHY Clusters Enriched With Sociodemographic Data

This part is a proof of concept, where cluster-based profiles were created to help develop representatives of characteristics of a patient population divided into subgroups. This enabled us to work with materials based on real-life data varying with respect to the 13 scale scores. This has provided insights into how dimension names can be phrased for text vignettes without a systematic approach, while also helping us establish a shared understanding of the OPHELIA [16] principles. These principles were operationalized in a data-informed manner, bridging the previously reported qualitative approach with a more quantitative-based methodology.

Part 2 Introduction: Creation of Text Strings and Testing of Meaning in Vignettes

In part 2, scale-based text strings describing the different dimensions measured in READHY were developed through a series of iterations. These were then combined into comprehensive text vignettes profiling the participants. For this process, the upper threshold was adjusted from 2.50 to 2.70 based on data from the study by Kayser et al [20]. The vignettes were continuously refined through cognitive interviews to evaluate and improve the participants' understanding and ability to comprehend the content.

Part 3 Introduction: Applicability of Text Vignettes in a Clinical Setting

The text strings iteratively created and validated in part 2 served as the foundation for the work in part 3. In part 3, the focus shifted to testing the applicability of individual text vignettes within a clinical setting. The emphasis was on how meaningful and relevant these text vignettes were in a setting involving both patients and clinicians within a telehealth service, where the READHY instrument was suitable as a PRO instrument. The clinical setting included here was the same as the one used to gather data for part 1.

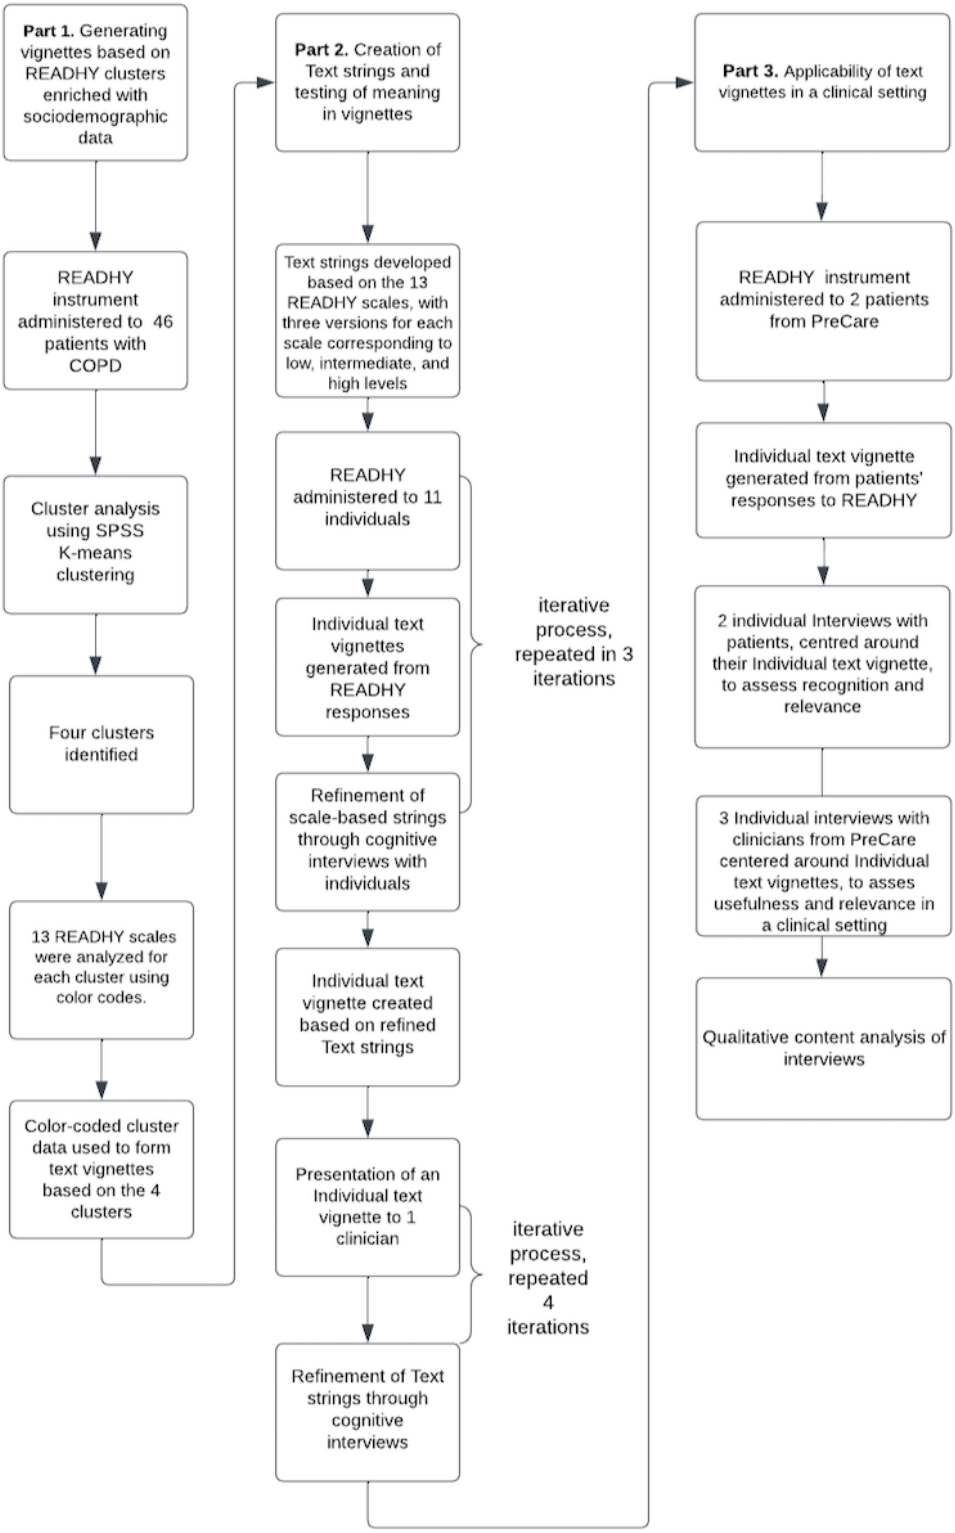
Methods

Overview

The study comprises 3 parts, each building upon the previous one. In part 1, which was inspired by the OPHELIA process [16], the READHY instrument was administered to individuals living with chronic obstructive pulmonary disease (COPD). Data gathered from this group of participants served as the foundation for generating 4 clusters, which were characterized by high, intermediate, and low levels of the 13 READHY scales, which together with another Health Literacy Questionnaire (HLQ) scale, "actively managing my health and sociodemographics", were used to develop a proof of concept of how data-informed text vignettes could be used to illustrate the quantitative data qualitatively to better understand profiles of user groups. The text vignettes in part 2 were crafted as narratives, emphasizing the group's high or low scores. This approach created profiles that highlighted their resources and barriers. In part 2, we expanded on the idea by constructing scale-specific strings for each of the 3 levels for each scale in READHY. The text strings were created to constitute a list of variables, which in a later process could be combined based on an algorithm to form the text vignettes. This computer-based combination of the text strings is beyond the scope of this study that only addresses the development of our concept up to a technology readiness level of 3 [21]. Text vignettes are consequently created by manually combining the text strings.

In this process, the text strings were evaluated for clarity and understanding through multiple iterations of cognitive interviews with a diverse set of participants. In part 3, the refined scale-based strings were combined manually, informed by the 2 patients' READHY scores, into individual text vignettes, which were presented to clinicians and patients for assessment of their understanding, relevance, and recognizability (Figure 1).

Figure 1. Flowchart: the 3-part process for examining the use of text vignettes. COPD: chronic obstructive pulmonary disease; READHY: Readiness and Enablement Index for Health Technology.



Setting and Population

The setting for the reported activities was in part 1 and part 3 of a telehealth service, PreCare [22], which provides 24-7 access to a response and coordination center manned with registered nurses and backed up by an e-doctor. PreCare is organized based on the Epital care model [22,23]. The participants in part 2 were

recruited broadly among individuals in the eastern part of Denmark and clinicians not currently working in telehealth.

Participants

Part 1

The participants were 46 adults living with COPD, with a mean age of 74.4 (SD 6.8; range 59-91) years. They were patients recruited by convenience sampling from the European Commission funded project Smart Inclusive Living Environments, were enrolled in the PreCare project in Region Zealand, and were diagnosed with different severity levels of COPD [24]. The inclusion criteria were a COPD diagnosis and being active in the PreCare project. The patients should be able to understand and communicate in Danish.

Part 2

Individuals

A total of 11 individuals were recruited using a snowball technique in the Capital Region of Denmark and Region Zealand. Initially, 3 members of interest were identified and approached within their local areas. These individuals were then asked to refer others in their community who might be willing to participate. With their consent, we received the necessary contact information and subsequently reached out to the referred participants by phone to arrange their involvement in the study. The inclusion criteria for individuals' participation was that they had to be aged >18 years, able to understand Danish, capable of giving informed consent, and able to complete the READHY instrument, with assistance if needed (ie, the ability to read and write independently was not a criterion). The first 3 recruited individuals resided in the metropolitan area, had medium-length higher education (International Standard Classification of Education level 6-7) [25], and had an average age of 53 (SD 12.36) years. This group was expanded to include 8 participants, aged between 36 and 86 years, from the capital region, Lolland, and Jutland with educational backgrounds ranging from International Standard Classification of Education level 4 to 6 [25] to attain a more diverse and comprehensive perspective.

Clinicians

A total of 4 clinicians were also recruited using a snowballing technique. Initially, 3 clinicians were approached, but not all expressed interest in participating. These contacts referred to others, and with their consent, we obtained their contact information and contacted them. The clinicians who participated in the interviews were 1 registered nurse, 2 physicians, and 1 professional with a master's and PhD degree in biomedicine. Of the 4 physicians, 2 (50%) had prior knowledge of READHY as active researchers using the instrument. All physicians were involved in professional settings related to digital health in patient care, and they were all familiar with PROs.

Part 3

A total of 3 registered nurses and 2 patients from the PreCare clinic were interviewed about the understanding, recognizability, and relevance of individual text vignettes in a clinical setting.

The 2 patients, a woman aged 75 years and a man aged 80 years, lived in the region where the PreCare project is based. They were selected by PreCare staff based on the following inclusion criteria: a COPD diagnosis, active participation in PreCare, the ability to understand and communicate in Danish, clinic enrollment at the time of data collection, and prior consent through PreCare as well as informed consent specifically for this study. A total of 3 (75%) of the 4 nurses in PreCare were available for interviews.

Application of the READHY Instrument

READHY is a validated PRO instrument that combines several aspects of PROs to illuminate experienced support, digital health literacy, and coping with everyday life in relation to one's health [19]. The tool focuses on aspects of knowledge and skills related to health; self-care, disease, and health-related mindset; experiences with health technology and the individual understanding of these; as well as the extent to which users feel supported by relatives and health care professionals [19].

READHY has been used to identify different health technology readiness profiles within different patient groups, such as patients living with type 2 diabetes and patients with cancer [26,27].

READHY consists of 65 items comprising 13 dimensions or scales. The 13 scales are selected from 3 PRO instruments. Four scales are from the Health Education Impact Questionnaire (heiQ), which evaluates the effect of health education interventions on self-care [28]. These address aspects of self-management with relevance for a digital health context, such as insights and attitudes. Two scales from the HLQ, which assesses health literacy, including support from relatives, peers, and health professionals [29], and all 7 scales from the eHealth Literacy Questionnaire (eHLQ), which address patients' digital health literacy, were included [30]. The eHLQ informs about knowledge, skills, motivation, perceptions, and experiences in relation to digital health. The 13 dimensions of READHY, which correspond to its 13 scales, are presented in Textbox 1.

Textbox 1. The 13 dimensions of the Readiness and Enablement Index for Health Technology framework.

- Health Education Impact Questionnaire (heiQ) 3: self-monitoring and insight
- heiQ4: constructive attitudes and approaches
- heiQ5: skill and technique acquisition
- heiQ8: emotional distress
- Health Literacy Questionnaire (HLQ) 1: feel understood and supported by health care providers
- HLQ4: social support for health
- eHealth Literacy Questionnaire (eHLQ) 1: using technology to process health information
- eHLQ2: understanding of health concepts and language
- eHLQ3: ability to actively engage with digital services
- eHLQ4: feel safe and in control
- eHLQ5: motivated to engage with digital services
- eHLQ6: access to digital services that work
- eHLQ7: digital services that suit individual needs

The READHY instrument uses a 4-point response scale for all items in the instrument [19], where 1 represents strongly disagree, 2 represents disagree, 3 represents agree, and 4 represents strongly agree. The results are 13 scale scores. For the scale heiQ8 (emotional distress), which includes 6 items, the scale is reversed by subtracting the scored value from 5. This adjustment simplifies interpretation, as higher scores now correspond to less impact.

Ethical Considerations

Written informed consent was obtained from all participants after providing information in accordance with the Helsinki II Declaration, including their right to opt out. Participants did not receive any salary or reimbursement of costs. Health science questionnaire surveys and interview studies that do not involve human biological material (section 14(2) of the Danish Act on Committees) do not require reporting or approval from the Danish National Center for Ethics [31].

Part 1 Methods

Data Sampling

The READHY instrument was handed out and collected with a combination of mail using prestamped envelopes by EKW and a researcher in PreCare in May 2021. A total number of 120 surveys including the READHY instrument were distributed.

Cluster Analysis

In managing the READHY data from the 46 patients, clusters were created using the K-means clustering function in IBM's software package SPSS Statistics (version 24) [32]. Three models were created with 3, 4, and 5 clusters. On the basis of an evaluation of which cluster model would be most meaningful from a clinical perspective, a 4-cluster model was selected. The final cluster constituted 41 valid cases and 5 missing cases out of the 46 responses. The number of cases in each cluster was as follows: 16 in cluster 1, 5 in cluster 2, 11 in cluster 3, and 9 in cluster 4.

The cluster data were then used to form the group-based text vignettes. For each cluster, the 13 scales were initially labeled with a color indicating whether the level was low, intermediate, or high. We used arbitrary thresholds informed by a regional survey, Sundhedsprofilen 2021 [33], which is the region where the PreCare project is based. All values <2.00 were assigned red, all values between 2.01 and 2.50 were assigned yellow, and values >2.50 were given green. This helped us create text strings that were specific for each of the colors indicating high or low average scores for each scale and assigning them to the cluster text vignette. The text strings were created from the dimension name and informed by the items in the scale. Additional data from an additional HLQ scale, "actively managing my health," and sociodemographic variables, such as educational level, experience living with, and number of chronic conditions, were added to the profiles to enrich them and create personas that were recognizable to the clinicians.

Part 2 Methods

Overview

The overall process for constructing the text vignettes involved several steps. First, text strings were developed based on the 13 READHY scales, with 3 versions for each scale corresponding to low, intermediate, and high levels. Next, participants completed the instrument. The average score for each scale was then manually calculated from their responses, and this average score was matched with the corresponding text string for that scale score. Finally, the 13 text strings were combined into an individual text vignette. The text strings were combined in a coherent order, prioritizing readability and clarity, rather than strictly following the numerical order of the scales. In part 2, the focus was only on the READHY scales and text vignettes; therefore, part 2 did not include sociodemographic information, as these are anticipated to be retrieved from other data sources such as electronic health records as they are specific at the individual level.

Constructing Data-Informed Text Vignettes

The text vignettes were created by combining 13 text strings into a cohesive PRO profile. Each sentence in the text vignette corresponds to a specific scale in READHY, describing the knowledge, skills, and attitudes that the scale items aim to capture.

Initially, 39 text strings were constructed—3 for each of the 13 READHY scales, representing different levels of knowledge, skills, or attitudes within each scale. These initial text strings were closely aligned with the scale names, as the scale names summarized the experiences the items were designed to encompass. For example, the scale "self-monitoring and insight" (heiQ3) assesses an individual's ability to monitor their health and their insight into their health [19]. An initial sentence for this scale might read as follows: "Has good insight into and control over his/her health and has a constructive attitude and approach to it."

The levels are determined based on the average score for each scale, with 3 categories: level 1 indicates problematic knowledge, skills, and attitudes; level 2 corresponds to limited or insufficient knowledge, skills, and attitudes; and level 3 signifies adequate knowledge, skills, and attitudes. To be classified as level 3, the average score must be >2.7, indicating agreement or strong agreement with the statement (Table 1). The cutoffs are estimates defined by the authors and have not been validated by other parties. However, they have been used and found relevant in other studies using HLQ and eHLQ scores [20,33].

Table 1. Breakdown of knowledge, skills, and attitude into levels based on average scores.

Average scale score[a]	Level of knowledge, skills, and attitudes
<2.00	Level 1
2 to 2.7	Level 2
>2.7	Level 3

[a]The cutoffs are author-defined estimates, unvalidated by others but found relevant in studies using the Health Literacy Questionnaire and eHealth Literacy Questionnaire [20,33].

These 39 text strings are organized in Table 2 with the 13 scales as rows and the 3 levels as columns. To construct a text vignette, the appropriate text strings were selected from the table based on the participant's average scale score for each scale. The 13 selected text strings were then manually combined into a coherent text vignette. The initial text strings were revised throughout part 2 of the study in an iterative process using cognitive interviews for accuracy and relevance.

Table 2. Refined text strings based on scores.

Scale	Scores <2.00	Scores between 2.00 and 2.70	Scores >2.70
heiQ3[a]: self-monitoring and insight	He/she experiences having insufficient insight into his/her state of health, with insufficient knowledge of how to deal with health problems when they arise.	He/she experiences having limited insight into his/her state of health, with limited knowledge of how to deal with health problems when they arise.	He/she experiences having good insight into his/her state of health, with sufficient knowledge of how to deal with health problems when they arise.
heiQ4: constructive attitudes and approaches	He/she finds that his/her health problems limit him/her from enjoying life.	He/she finds that his/her health problems limit him/her from enjoying life to some extent.	He/she does not find that his/her health problems limit him/her from enjoying life.
heiQ5: skill and technique acquisition	He/she experiences having insufficient skills and techniques to deal with health problems when they arise.	He/she experiences having limited skills and techniques to deal with health problems as they arise.	He/she experiences having sufficient skills and techniques to deal with health problems as they arise.
heiQ8: emotional distress	He/she generally experiences a high degree of emotional distress due to his/her health.	He/she generally experiences a bit of emotional distress due to his/her health.	He/she generally experiences no emotional distress due to his/her health.
HLQ4[b]: social support for health	He/she does not feel understood or supported by his/her social network.	He/she feels only partially understood and supported by his/her social network.	He/she feels adequately understood and supported by his/her social network.
HLQ1: feel understood and supported by health care providers	He/she experiences a lack of understanding and support from the health care professionals he/she has contact with and access to.	He/she experiences limited understanding and support from the health care professionals he/she has contact with and access to.	He/she experiences adequate understanding and support from the health care professionals she/he has contact with and access to.
eHLQ2[c]: understanding of health concepts and language	He/she experiences having trouble understanding information about health and illness and may experience insufficient knowledge to have conversations with others about this.	He/she may experience problems understanding information about health and illness and may experience having limited knowledge to have conversations with others about this.	He/she does not experience having problems understanding information about health and illness and has enough knowledge to have conversations with others about this.
eHLQ1: using technology to process health information	He/she finds that he/she has have insufficient knowledge about how he/she can use technology to take care of his/her health.	He/she finds that he/she has limited knowledge about how he/she can use technology to take care of his/her health.	He/she has sufficient knowledge about how he/she can use technology to take care of his/her health.
eHLQ3: ability to actively engage with digital services	He/she has insufficient knowledge of how to use technology to navigate health care systems.	He/she has limited knowledge of how to use technology to navigate health systems.	He/she has good knowledge of how to use technology and can navigate health systems easily.
eHLQ6: access to digital services that work	He/she experiences insufficient access to digital health systems that work and can be accessed by himself/herself and others who need it.	He/she experiences having limited access to digital health systems that work and can be accessed by himself/herself and others who need it.	He/she experiences having sufficient access to digital health systems that work and can be accessed by himself/herself and others who need it.
eHLQ7: digital services that suit individual needs	He/she believes that digital services are insufficiently able to adapt to his/her needs.	He/she believes that digital services can adapt to his/her needs to a limited extent.	He/she believes that digital services can adequately adapt to his/her needs.
eHLQ5: motivated to engage with digital services	He/she finds that technology is insufficiently helpful and helps him/her keep up with and take care of his/her health.	He/she finds that technology is helpful to a limited extent and helps him/her keep up with and take care of his/her health.	He/she finds that technology is sufficiently useful and helps them keep up with and take care of his/her health.
eHLQ4: feel safe and in control	He/she feels uneasy about how his/her health data are used by others.	He/she feels partly uncomfortable with how his/her health data are used by others.	He/she feels comfortable with how his/her health data are used by others.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

Data Sampling and Analysis

Data collection involved conducting cognitive interviews with each participant to validate the individual text vignettes developed from the individuals' READHY responses. These interviews allowed for iterative feedback and refinement of the text string to ensure their coherence and relevance. The analysis focused on identifying and addressing any issues in understanding and meaningfulness of the text strings and vignettes.

Iterative Validation of Data-Informed Text Vignettes

The text strings were validated through cognitive interviews with individuals and clinicians in an iterative process. Cognitive

interviews, often used for validating questionnaires, involve participants "thinking out loud" by verbally reporting their mental activity while engaging with an item in a questionnaire [34,35]. These interviews are conducted using a semistructured approach, with in-depth sessions where participants read a text vignette aloud and provide feedback by sharing their thoughts and insights throughout the process.

The interviews were conducted in 2 stages: first with individuals and then with clinicians. Before each individual's interview, they completed READHY, which was then used to create individual text vignettes. Each individual was presented with a full vignette, created based on their previous responses, to gather feedback on both individual text strings and the vignette as a coherent whole, evaluating its clarity and personal relevance.

After each interview, the data were analyzed individually to identify issues in the understanding and meaningfulness of the text vignettes. These individual findings were then aggregated across interviews to identify recurring problems, leading to adjustments of the text vignettes.

The iterative process included multiple stages of feedback incorporation. The first iteration considered feedback from 3 participants, with subsequent iterations incorporating feedback from additional participants—3 in the second and third iterations and 2 in the fourth.

Identified problems were categorized informally into 4 groups: scale-specific wording changes, need for further specification, issues with text vignette setup, and difficulties in answering the instrument [34].

Once all individual interviews were completed and the text vignettes and algorithm were adjusted, clinicians were introduced to the revised vignettes. The assignment of vignettes to clinicians was random, as they had no prior knowledge of or relationship with the individuals. Clinicians provided feedback on these vignettes, which led to further refinements. Each revised version was then presented to subsequent clinicians for additional input, ensuring that the final text was coherent and well understood.

Part 3 Methods

Data Sampling

First, 2 patients completed the instrument. From their responses, 2 individual text vignettes were constructed using the same method as applied in part 2. The average scale scores were calculated for each scale, and the scale score was then matched with the final adjusted corresponding sentence (Table 2). Afterward, the 13 text strings were combined to create an individual text vignette. These text vignettes were then presented to the 3 clinicians in 3 individual semistructured interviews designed to explore the text vignettes within an actual clinical environment and gain the clinicians' perspective. Each clinician was presented with 1 text vignette. Because all clinicians were somewhat familiar with booth patients, the specific vignette used in the interviews was randomly chosen based on which vignette was completed at the time of the interview.

Patients were also interviewed individually to assess their recognition of themselves in their text vignettes and whether it made sense for them in a clinical environment. However, the primary focus in part 3 was on the clinicians. Patient interviews were conducted via phone at the request of both patients. The interviews were recorded with consent and later transcribed.

The unique aspect lies in its exploration of text vignettes within clinical contexts, focusing on clinicians who interact with the patients described, and incorporating insights from their practical experience.

Analysis

Two interview guides were prepared, 1 for patient interviews and 1 for clinician interviews (Multimedia Appendix 1). These questions were grounded in the central inquiry: How can text vignettes generated by PRO data, as an alternative or supplement to traditional quantitative representations, improve dialogue and understanding between clinicians and patients regarding PROs?

All interviews were analyzed using qualitative content analysis using inductive coding to identify and describe patterns, categories, and meanings within the data [36]. The analysis was conducted using NVivo software (version 12.4.0; Lumivero) [37]. From the coding process, 4 main categories emerged: "recognition and confirmation," "challenges with context and conceptual understanding," "one size does not fit all," and "reflections on using text vignettes."

An example of a text vignette, as presented to both clinicians and patients, is shown in Textbox 2 (translated by the authors). This vignette is based on one of the patient's responses to the READHY instrument.

Textbox 2. Text vignette based on Readiness and Enablement Index for Health Technology.

She experiences having limited insight into her state of health, with limited knowledge of how to deal with health problems when they arise.

She finds that her health issues to some extent limit her from enjoying life.

She experiences having sufficient skills and techniques to deal with health problems as they arise and generally, experiences no emotional distress due to her health.

She feels adequately understood and supported by her social network and experiences adequate understanding and support from the healthcare professionals she has contact and access to.

She experiences having trouble understanding information about health and illness and may experience insufficient knowledge to have a conversation with others about this.

She finds that she has insufficient knowledge about how she can use technology to take care of her health and has insufficient knowledge of how to use technology to navigate healthcare systems.

She experiences having sufficient access to digital health systems that work and can be accessed by herself and others who need it, and that digital services can adequately adapt to her needs.

She finds that technology is helpful to a limited extent and helps her keep up with and take care of her health.

She feels comfortable with how her health data is used by others.

Results

Part 1

Four clusters with various levels of high, intermediate, and low average scores of scales within self-management, social capital, and digital health literacy were created (Table 3).

The mean value for each scale was presented for each of the 4 clusters that were informed. Values considered to represent a problematic level were indicated in red (<2.00), values considered to be below a sufficient level were indicated in yellow (2.00-2.50), and values considered to represent a sufficient level were represented in green (>2.50).

Table 3. Stratification using the Readiness and Enablement Index for Health Technology.

Metric (mean values)	Cluster 1 (n=16)	Cluster 2 (n=5)	Cluster 3 (n=11)	Cluster 4 (n=9)
heiQ3[a]: self-monitoring and insight	2.98	3.66	3.13	3.11
heiQ4: constructive attitudes and approaches	2.81	3.28	2.76	3.46
heiQ5: skill and technique acquisition	2.65	3.15	2.84	3.11
heiQ8: emotional distress	2.50	2.76	2.13	3.12
HLQ1[b]: feel understood and supported by health care providers	2.78	3.70	3.40	3.44
HLQ3: actively managing my health	2.68	3.40	2.92	2.68
HLQ4: social support for health	2.83	3.59	2.90	3.33
eHLQ1[c]: using technology to process health information	2.78	3.92	1.89	2.03
eHLQ2: understanding of health concepts and language	2.85	3.96	2.82	2.77
eHLQ3: ability to actively engage with digital services	2.95	3.96	1.99	2.65
eHLQ4: feel safe and in control	2.97	4.00	2.95	3.18
eHLQ5: motivated to engage with digital services	2.85	3.92	2.11	2.60
eHLQ6: access to digital services that work	2.86	3.96	2.42	2.97
eHLQ7: digital services that suit individual needs	2.78	3.80	2.04	2.68

[a]heiQ: Health Education Impact Questionnaire.

[b]HLQ: Health Literacy Questionnaire.

[c]eHLQ: eHealth Literacy Questionnaire.

On the basis of the thresholds, a focused text vignette was constructed almost as a narrative for each cluster together with key sociodemographic characteristics to create 4 text vignettes, wherein each represented an archetype of the profile—termed a "persona" (Multimedia Appendix 2). To simplify the information in this initial phase, only scales with high (initial green color) or low (initial red) average scores (>2.50 or <2.0) were included in the text vignettes, thereby creating focused text vignettes highlighting potential areas of barriers and resources.

EKW and LK then presented these text vignettes to colleagues in the Smart Inclusive Living Environments project. On the basis of the insights gained from the proof of concept with text vignettes at group or personal level, it was decided to proceed to part 2, focusing on the development of structured text strings that encompass high, intermediate, and low average score levels.

Part 2

A total of 39 initial text strings were created, with 3 strings for each of the 13 READHY scales, reflecting different levels of knowledge, skills, or attitudes within each scale. These text strings were designed to align with the scale names, which summarize the relevant experiences. The initial text strings are included in Multimedia Appendix 3.

Immediate feedback from the first 3 participants indicated that they could easily recognize themselves in the text vignettes, found them meaningful, and saw how their responses were reflected in them.

In the first iteration of text vignette validation, participants largely recognized themselves but identified issues related to the structure of the text vignettes and the completion of the instrument. Feedback included suggestions to revise lengthy sentences and reduce academic language, with specific terms

such as “health professionals” and “health-related concepts” being difficult to understand. Participants also struggled with the term “technology” used in the text vignette, such as in the description of scale eHLQ3.

On the basis of cognitive interviews, “healthcare providers” was changed to “healthcare professionals” and “health-related concepts” was simplified to “information of health and illness.” The order in which the scales were presented was also slightly changed. The order of HLQ4 and HLQ1 was adjusted to create a more natural flow when reading through the vignette. Similarly, the eHLQ items were reordered to enhance the coherence of the vignette.

In subsequent validation iterations, feedback was generally positive, with individuals finding the text vignettes understandable and recognizable. However, they struggled more with areas where they rated themselves as limited or insufficient. Some participants mentioned difficulties with the questionnaire due to the lack of a “don’t know” option and noted that terms such as “insufficient” felt too academic and unrepresentative of their self-view. The term “digital services” was also revised to “digital health services” to clarify its meaning. Participants suggested that discrepancies in text vignette descriptions might stem from specific episodes rather than their general experiences, and some participants requested more precise wording to better reflect their experiences. During iterations and refinement based on feedback, the understandability and recognizability of the vignettes improved, with individuals having an overall positive view of the text vignettes after final refinement.

The clinicians had a generally positive view about the generated READHY text vignettes. Feedback emphasized the need for clarity in highlighting that the text vignettes were based on a PRO instrument. The length of the text vignettes had mixed reviews. Feedback suggested categorizing content into taxonomic groups. The language was too academic, and adjustments had to be made to align with the instrument.

Clinicians see the value of using the text vignettes at the population level, allowing for generalization and description of specific populations based on competencies and characteristics. However, the current format may not be suitable for individual-level use, as it offers a simplified representation for personalized interaction. On the basis of input received from all participants, the strings were refined. The refined text strings are presented in Table 3 (translated from Danish to English by the authors). In the context of this study, we have used gender pronouns, but they should be adjusted to ensure relevance and significance within the context and setting.

Part 3

There was a positive attitude among the clinicians and patients toward the text vignette format and this way of presenting and communicating PROs. The clinicians experienced being able to recognize patients in the text vignettes, and patients experienced being able to recognize themselves in their text vignettes. Although the text vignette format does not necessarily meet the specific needs, the textual presentation makes the information from PROs more accessible in an understandable way for both clinicians and patients.

There are different preferences for how dynamic the tool should be. Some prefer to select only specific dimensions, while others believe that the strength of the text vignettes comes from them providing the full picture insights and exposing possibly overlooked aspects. Clinicians who favor the text vignette suggest that color coding as a supplement to the text vignette would be helpful and that a schematic summary would help with readability, indicating that flexibility in the profile presentation is needed to accommodate different preferences. Some prefer text-based representations, while others find visual presentations more intuitive.

Clinicians may face language and comprehension challenges due to ambiguity in words and abstract concepts within the text vignettes. Ambiguity in words and concepts, such as “to some extent,” leaves clinicians uncertain about the severity of the patient’s problems. Abstract concepts such as “health” and “technology” also pose challenges in interpretation. The text vignettes highlight new angles in patients’ self-perception, health, motivation, and emotional distress, which clinicians find crucial.

Opinions differ on whether to highlight strengths or weaknesses. Some prefer insights into both aspects, while others prefer focusing solely on the weaknesses that are most likely to be approved. Clinicians acknowledge the value of using text vignettes at a population or group level for generalization but point out some limitations for individual-level use due to simplified representations. Emphasis on personal dialogue with patients remains crucial for addressing unresolved questions and determining personalized interactions.

From the patient’s viewpoint, there is self-recognition and understanding; however, engaging in discussions about text vignette representation proves challenging. It is essential to note that clinicians report based on their experience of interacting with patients, highlighting the dynamic nature of this interaction in understanding and interpreting the text vignettes. The clinician’s insights provide a valuable perspective for understanding the broader implications of text vignettes in a clinical setting.

Discussion

Principal Findings

This study presents a process for developing text vignettes based on PRO data, resulting in the creation of individual vignettes that incorporate all 13 scales of the READHY framework. The motivation for the development of these text vignettes was the challenges associated with presenting PRO data as numeric values or graphical representations, aiming to provide a clearer and more engaging way to present and communicate PRO information.

This findings of this study suggest an overall positive attitude toward the PRO data–informed text vignette format and this way of presenting and communicating PROs. Clinicians experienced being able to recognize patients in the text vignettes,

and the patient's experienced being able to recognize themselves in and understand the text vignettes describing themselves.

Considering the background emphasizing the challenges associated with graphical representations of PRO data, the findings suggest that PRO-informed text vignettes are understandable for clinicians and patients. While the text format may not perfectly align with all the needs and interests of clinicians and patients, it presents PRO data in a comprehendible manner, with the text vignettes presenting a recognizable description.

Patients' Perspective

Patients found elements of self-recognition in the text vignettes, although discussing their representation could be challenging. It is important to note that text vignettes also face challenges related to health literacy and differences in understanding, as highlighted in part 3. These challenges can pose significant barriers for individuals with low health literacy or those who cannot read. In such cases, regardless of the presentation format, additional support, such as reading the vignettes aloud, may be necessary. However, the written format generally makes the data more accessible and less complex.

Another potential challenge is that the threshold values used to select appropriate text strings may result in choices that are not recognized by the informants. For example, individuals scoring between 2.00 and 2.70 might not feel limited, or they may perceive issues in areas not fully captured by the items in a scale. This issue requires further exploration in future studies to determine whether scales can be used effectively or whether a focus on single items is more appropriate, particularly for those scoring at the extremes. This may be necessary as we work in the intersection of presenting data from psychometric valid scales reporting on latent variables and presenting numeric values as an interpretation of experiences. The patients' experiences and feelings may sometimes be undermined or misinterpreted in this process.

Clinicians' Perspective

The data-informed text vignettes add a candid dimension to the information, making it directly engaging and allowing for the capture of new perspectives on patients that clinicians would not otherwise have focused on, although not all perspectives are equally relevant. It is especially the aspects of experienced support and patients' own knowledge about health and illness that are important for clinicians to understand and gain perspective on. There are different preferences among clinicians regarding the format of the text vignettes; some prefer text-based representations, while others prefer visual presentations. Likewise, there are different preferences regarding how dynamic the text-based tool should be. Some experience a need to be able to select only specific dimensions, while others believe it is part of the strength of the vignettes that it presents the full picture and thus insight into possibly overlooked aspects. This indicates that there is a need for flexibility in the text vignette presentation to accommodate different preferences.

Clinical Relevance

Clinicians using text vignettes stress the importance of technology that effectively addresses practical and treatment-specific needs. It remains imperative that the information within text vignettes aligns with the treatment being offered.

Clinicians emphasize that the central focus should be on understanding the condition and enabling patients to lead fulfilling lives. Reading the text vignettes prompts clinicians to reflect on aspects that may have been previously overlooked, serving as a reminder of the critical need for clinical relevance in any work involving PROs. It underlines that for PROs, and indeed text vignettes, to realize its full potential in creating value, it must align with the clinical context and be relevant to clinical practice.

A More Straightforward Representation of PROs

In addressing some of the challenges with the quantitative representation of PROs, the use of text vignettes allows for a deeper understanding of PROs. Text vignettes recognize the complexities of patients' experiences and provide a broader perspective. This approach prevents reducing patients to just numerical data, offering instead a more comprehensive view of an individual's health. The text vignettes are presented in an understandable and consistent format, with transparency about how the collected information is applied. This transparency is crucial for patients' effective use of PROs [38]. By transforming complicated numerical data into a clearer and more coherent text format, text vignettes offer a direct representation that ensures patients and clinicians can grasp details without relying on prior knowledge of graphical presentations. This textual format encourages conversation, minimizes ambiguity, and fosters dialogue for a better understanding of individual experiences.

Promoting Dialogue for Mutual Understanding

A data-informed text vignette is not a universal solution, but rather an approach with both advantages and disadvantages that must be weighted and adapted to individual preferences and needs and that requires a more dynamic approach to meet needs. Recognizing these challenges suggests a need for meaningful conversations between patients and clinicians about aligning their understanding at a conceptual level. Such discussions offer a chance to clarify word meanings and ensure a common understanding of the patient's experiences. This approach is essential for accurate and meaningful communication between patients and clinicians, ultimately improving the quality of care and treatment. Clinicians and patients may have different perspectives on what the patient reports in the PRO instrument. An example is how HLQ scores were not perceived in the same way by patients and their physicians, with a disconcordance ranging between 20% and 44% in the 9 HLQ scales [14]. Translating the data into text vignettes may ease the conversation and help identify these disconcordances for other PRO data also, ease the alignment of expectations, and provide a common understanding of the patient perspective.

Bias Concern

Clinicians are generally receptive to text vignettes and the insights they provide. Many clinicians feel that the text vignettes offer a strong sense of the patients before any direct contact is made. However, clinicians also express concerns that the text vignette may make them biased in their encounter with the patient, which may affect their ability to understand and treat the patient objectively. It emphasizes the necessity of acquiring proficiency in tool use, particularly when presenting information in a text format. Being mindful of potential biases becomes central, especially in a context where the text vignette format might intensify the impact. This highlights the importance of a nuanced and skillful application of the tool, recognizing that biases are not exclusive to text vignette representation but should be carefully navigated, especially when conveyed in a confrontational textual manner.

Strengths and Limitations

A strength of this study lies in the stepwise process of creating a dataset using a validated instrument, followed by data triangulation. This process is based on iteratively developed text lines that can be combined into cohesive text vignettes, forming complete paragraphs. The cocreation with individuals, people living with a chronic condition, municipalities, hospital-based clinicians, and 1 general practitioner helps ensure the validity and meaningfulness of the proposed solution.

The number of participants in each of the 3 parts may be considered a limitation. In part 1, convenience sampling was used among participants active in a telehealth service and was limited by availability. We do not find this to be a problem for the presented results, as we were able to create 4 profiles and personas that are meaningful and can serve to illustrate the principles used as background for parts 2 and 3. The number of participants in part 2 was determined through concurrent evaluation during data sampling. When the inclusion of additional informants no longer contributed new information, the sampling process was considered complete. By including data from 2 distinct sociodemographic areas, we aimed to capture a range of perspectives. On the basis of these arguments, we found the number to have sufficient information power for a proof-of-concept study [39]. This is also supported by most of the participants finding the text vignettes understandable and recognizable.

In particular, in part 3, the number of patients is likely to be too small, but we have included this part to illustrate how clinicians who are familiar with the patients respond to the text vignettes describing them. The findings need to be assessed in this light. Moreover, the results may differ from those that will be obtained using PRO data instruments that are developed for clinical purposes, such as European Organisation For Research And Treatment Of Cancer [40], The World Health Organization-Five Well-Being Index [41], or European Quality of life–5 Dimensions [42].

Perspective

The study has used the READHY instrument to demonstrate how data-based text vignettes can help to understand patients and align expectations about what the data tell. During the field studies and in discussions afterward, we have received expressions of interest in setting up algorithms to convert other established PRO data results into text vignettes. This calls for abundant work in this field in collaboration with several PRO instrument owners and distributors, and we welcome collaboration in this field. It also calls for atomization programming interfaces that build on the proposed structures with filters based on cutoff values combined with generative artificial intelligence to refine the created text vignettes.

Conclusions

The study demonstrates how text vignettes can be developed using PRO instruments, with individual scales as input strings. This provides an opportunity to present numeric values in a text format that is understandable and recognizable to most patients and clinicians. Some clinicians prefer text vignettes to other forms of presentations and find them especially useful in establishing a better understanding of a patient before initial contact. However, language and the arrangement of text vignettes can present challenges, underscoring the need for adaptation to specific needs and clinician training to ensure accurate interpretation of the text vignettes. Different preferences for text vignette formats highlight the need for a more dynamic and adaptable tool that can cater to individual needs and preferences.

Acknowledgments

The authors would like to thank all participants for their contribution. The authors would like to specially thank Torsten Risør, Sine Rossen, Rikke Terp, Thyge Lynghøj Nielsen, and the PreCareKlinikken for providing feedback throughout the process and Mette Krog Andreasen and Morten Brandrup for facilitating access to informants.

The authors thank the European Union (EU) Horizon 2020 and all partners in Smart Inclusive Living Environments (SMILE) for making this work possible. This research was funded by the EU Horizon 2020 Research and Innovation Program under grant 101016848.

Abstract

Background: Health care institutions face high systemic risk due to the inherent uncertainty and complexity of their operations. This often leads to stressful incidents impacting the well-being of health care professionals, which can compromise the effectiveness of health care systems. Enhancing resilience among health care professionals is essential for maintaining high-quality care and ensuring patient safety. The role of middle managers is essential to ensure the response capacity of individuals and teams.

Objective: This study aims to develop a web-based intervention aimed at middle management to enhance individual, team, and organizational resilience.

Methods: An observational study was conducted in 3 phases: design, validation, and pilot study. The study was initiated in February 2022 and concluded in June 2023. Phase 1 involved designing the content for the web-based tool based on a comprehensive review of critical elements around resilience. Phase 2 included validation by an international panel of experts who reviewed the tool and rated it according to a structured grid. They were also encouraged to highlight strengths and areas for improvement. Phase 3 involved piloting the tool with health care professionals in Ecuador to refine the platform and assess its effectiveness. A total of 458 people were invited to participate through the Institutional Course on Continuous Improvement in Health Care Quality and Safety offered by the Ministry of Public Health of Ecuador.

Results: The tool, eResiliencia, was structured into 2 main blocks: individual and team resilience and organizational resilience. It included videos, images, PDFs, and links to dynamic graphics and additional texts. Furthermore, 13 (65%) of the 20 experts validated the tool, rating content clarity at an average of 4.5 (SD 0.7) and utility at an average of 4.7 (SD 0.5) out of 5. The average overall satisfaction was 9.3 (SD 0.6) out of 10 points, and feedback on improvements was implemented. A total of 362 health care professionals began the intervention, of which 218 (60.2%) completed preintervention and postintervention questionnaires, with significant knowledge increases (P<.001). Of the 362 health care professionals, 146 (40.3%) completed the satisfaction questionnaire, where overall satisfaction was rated at an average of 9.4 (SD 1.1) out of 10 points.

Conclusions: The eResiliencia web-based platform provides middle managers with resources to enhance resilience among their teams and their components, promoting better well-being and performance, even under highly stressful events. Future research should focus on long-term impacts and practical applications in diverse clinical settings.

(JMIR Hum Factors 2025;12:e67263) doi:10.2196/67263

KEYWORDS

resilience; health care professionals; web-based intervention; middle management; well-being; patient safety

Introduction

Systemic Risk

Health care institutions are considered high-reliability organizations due to the inherent systemic risk associated with the activities they conduct [1]. Uncertainty and complexity, inherent in health care delivery along with other factors, contribute to the occurrence of higher stressful incidents that sometimes result in harm (adverse events) [2]. Health care professionals are exposed almost daily to stressful situations that can deteriorate their occupational well-being, thus compromising the effectiveness of health care systems [3]. In addition, the impact and demands stemming from unexpected health outcomes and health care crises further exacerbate this situation. Ultimately, the post–COVID-19 pandemic period has underscored a reality that has always existed but has not been adequately addressed until now: the well-being of health care professionals is a necessary condition to ensure the effectiveness of health care systems and the quality of care [4].

Professional Well-Being

In clinical contexts, situations with the potential to deteriorate the well-being of professionals are varied. These situations can range from those related to patient safety, such as near-misses, poor prognoses, unexpected health outcomes, a patient's deteriorating condition, preventable and unavoidable adverse events, and the unexpected death of a patient, to those more associated with working conditions or structural factors. These include a lack of resources, high care pressure, elevated staff turnover, increased demand, violence against professionals, and moral injury. They can have an emotional impact on professionals, which affects their habits, practices, or clinical decisions [5]. When this behavior change occurs in the undesired direction, we may encounter defensive practices, burnout, or detachment that often entail assuming unnecessary risks for the patient and additional costs for the system [6,7].

Vicious Cycle

Even in the absence of behavioral change, the loss of professional well-being is accompanied by an exponential increase in the risk of human error in patient care, leading to lower performance and a deterioration in the quality of care provided to patients [8]. This worsening of outcomes can, in turn, contribute to the occurrence of new errors and safety incidents. Thus, we find workers in a vicious cycle where the loss of well-being, the inability to regain balance and face stressful situations, and the quality of care are intimately related [5,9]. Hence, preserving and enhancing the resilience of professionals is a key element in ensuring the proper functioning of health care systems, the quality of care, patient safety, and achieving better health outcomes [10].

Resilience

Resilience refers to the ability of individuals, teams, and organizations to adapt, recover, and grow in the face of stress, adversity, and challenging circumstances [11]. In the context of health care, it enables professionals to maintain their well-being and continue to provide high-quality care despite the inevitable challenges they encounter. This not only benefits the individuals themselves but also enhances the safety and effectiveness of care provided by health care teams [12].

Individual Differences

In addition to the inherent risk in health care activities, other cultural aspects can also be a source of distress for health care professionals and may even constitute a barrier to the process of recovering well-being once it has been compromised and are also directly related to values. From an individual perspective, health care professionals share a set of ideals focused on doing good and prioritizing the well-being of others. While these ideals are desirable for good performance, their rigid application in critical situations can intensify distress or hinder constructive coping and professional recovery [13].

Organizational Culture

At the organizational level, the institution's culture plays a key role in determining how professionals feel, interpret, and cope with stressful situations. The prevailing professional culture in the health care sector is characterized by strong ideals of perfection that often lead to a negative and unconstructive view of human response, considering someone weak for asking for help or being unable to cope with a stressful situation. Understanding these causes allows for designing and implementing barriers that prevent or reduce the likelihood of succumbing to stressful situations occurring in the future.

Challenge

The World Health Organization has incorporated resilience in health care systems into the Global Patient Safety Action Plan 2021-2030 through strategy 2.4: providing a strong human factor and ergonomics-based perspective and contributing to strengthening the resilience of health care organizations and clinical practices [14]. This initiative aims to address a basic need for the proper functioning of health care systems, which is to take care of those who care.

We intend to address this need not only from a reactive approach when things go wrong but also by creating resilient teams and providing middle managers with tools to reinforce the resilience of professionals, teams, and the health care organization to ensure their ability to respond to critical situations. We believe that middle managers, due to their strategic position in the institution's structure, are key agents for the development of resilience at all levels; therefore, the materials of this project are specifically aimed at this group.

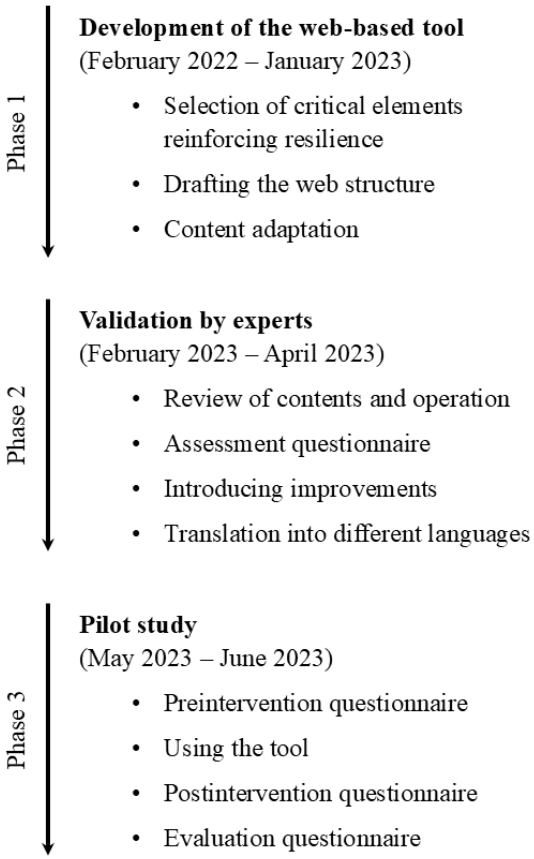
Methods

Study Design

An observational study was developed in 3 phases: development of the web-based tool (phase 1), validation by experts (phase 2), and piloting with professionals (phase 3; Figure 1). Primary care and hospital were defined as usual settings for the new tool

named eResiliencia. The established 8 principles for learning tools that aim to support the translation of resilience into practice by Haraldseid-Driftland et al [15] were used. In this study, resilience in health care was defined as the capacity to adapt to challenges and changes at different system levels to maintain high-quality care [12].

Figure 1. Flowchart of project phases and steps.



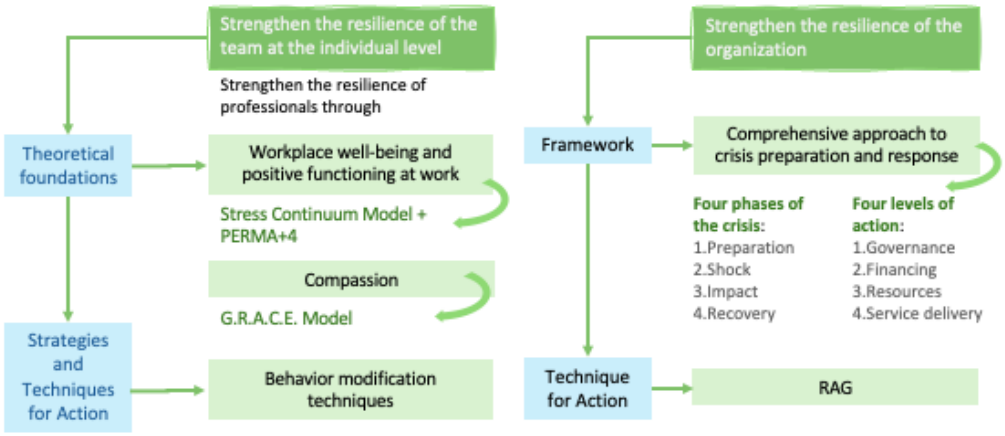
The study was developed by a core group involving a multidisciplinary team supported by a panel of international experts in health administration, occupational safety, and patient safety. It was initiated in February 2022 and concluded in June 2023.

Phase 1: Development of the Web-Based Tool

To design the content for the web-based tool (phase 1), a comprehensive search of critical elements reinforcing resilience was conducted, culminating in a preliminary selection from among the most frequently cited elements. This included the revision of reviews and systematic reviews (after 2019) on the concept of resilience, experimental studies measuring the effectiveness of recent programs designed to enhance the resilience of health care professionals, and the content of different scales for measuring resilience. In particular, this search was aimed at identifying experiences and successful strategies [16].

The eResiliencia intervention is built on a robust theoretical framework that integrates principles of resilience, human behavior, and organizational adaptability to address the complex challenges faced by health care systems (Figure 2). This approach emphasizes strengthening resilience through the development of 5 essential traits: self-control, which involves regulating emotions and behavior under pressure; adaptability or the flexibility to adjust to changes and demands; optimism, characterized by a positive outlook and confidence in overcoming challenges; self-sufficiency, reflecting the ability to independently manage difficulties; and persistence, the sustained effort to persevere in the face of adversity.

Figure 2. eResiliencia theoretical framework. PERMA+4: PERMA+4 Well-Being model; RAG: Resilience Analysis Grid.



The intervention draws from the 5-tier model proposed by Seys et al [17], which combines preventive and supportive measures to build resilience. Levels 1 and 2 focus on proactive strategies such as prevention and self-care, while levels 3 to 5 offer structured peer and clinical support to address resilience at both individual and organizational levels. This multilevel approach ensures that resilience-building efforts are comprehensive and adaptable to the diverse contexts within health care settings.

eResiliencia operates across 3 interconnected levels: individual, team, and organizational. It uses both proactive and reactive strategies to enhance resilience. Proactive measures aim to build capacity before crises occur, using tools such as stress management models and workplace well-being frameworks. Reactive strategies focus on recovery and learning following critical events, ensuring that individuals and organizations can adapt effectively to challenges.

The intervention is informed by several evidence-based models, including the stress continuum model [18], which helps monitor and manage stress; the PERMA+4 Well-Being model [19], which promotes workplace well-being through its multidimensional framework; the G.R.A.C.E. model [20], which supports health care workers in cultivating compassion and managing burnout; and the Resilience Analysis Grid [21], which was applied to assess and enhance team response capacity in unexpected events. In addition, eResiliencia incorporates a set of behavior change techniques [22] designed to equip middle managers with targeted strategies for promoting workplace well-being. These techniques are tailored to the unique cultural and organizational contexts of health care systems, ensuring their relevance and practicality.

Following this, a second step involved drafting the web structure to accommodate the intended contents effectively. Subsequently, a process of content adaptation to the health care context ensued, wherein various support materials for the tool were developed. These materials underwent 2 rounds of internal review before arriving at version 1.0, ensuring their alignment with the intended objectives. The first version of the web platform was developed in Spanish and hosted on the Miguel Hernández University of Elche (Spain) servers, which comply with security requirements and regulations. A total of 11 months were spent to complete this phase, commencing in February 2022.

Phase 2: Validation by Experts

Version 1.0 underwent a review and validation process by an international panel of experts between February and April 2023. A total of 20 professionals integrated this panel, comprising 14 (70%) from Spain, 2 (10%) from Colombia, 1 (5%) from Argentina, 1 (5%) from Ecuador, 1 (5%) from Brazil, and 1 (5%) from Chile. The experts' identification was made using the snowball approach. All experts were informed of the pursued objective and the approximate time commitment and were requested voluntary, unpaid participation. Of the 20 professionals, 11 (55%) were women and 9 (45%) were men, and all met the criterion of a minimum of 10 years of professional experience. It was ensured that no personal evaluation would be disclosed, and communications with them were conducted via telephone or email.

Following a comprehensive examination of all contents and their structural organization, experts engaged were required to respond to a rubric designed to evaluate various aspects. This rubric used a scale ranging from 1 to 5 to assess the clarity of the content and its utility and applicability, grading from completely disagree to completely agree on whether the materials facilitated learning strategies to foster the resilience of professionals or teams under their purview, their likelihood to recommend the tool to other colleagues, and their intention to apply learned tools or strategies. In addition, experts were encouraged to identify strengths and areas for improvement and to rate their overall satisfaction with the web-based intervention and its contents on a scale from 1 to 10, where the higher the score, the greater the satisfaction. The level of agreement among evaluators was assessed to inform decisions regarding aspects requiring changes. All feedback and suggested improvements were meticulously implemented to enhance the quality of the content. Subsequently, the refined version of the tool was translated into English, Portuguese, and Valencian. Careful attention was given to ensuring equivalence across all versions through a process of back translation. Necessary adjustments were made to ensure the adequacy and coherence of the system across languages. An adaptation was also made to the idioms

and expressions commonly used in Latin American Spanish. This procedure also ensured that social and cultural aspects specific to each country were considered.

Phase 3: Pilot Study

From May 1 to June 30, 2023, a pilot study was conducted in a real setting in Ecuador. The participants' feedback served to refine the platform and the tool. A broader cohort of 458 health care professionals from Ecuador was invited to participate. They served as executives or managers in one of the country's public health care networks. This invitation was extended through the Institutional Course on Continuous Improvement in Health Care Quality and Safety offered by the Ministry of Public Health of Ecuador with the support of the Miguel Hernández University, Spain. The invitation was formally extended to all professionals from the management teams of public health care institutions in the country, including physicians, nurses, and other professional profiles. They assessed whether they wished to participate in this training, ensuring their data and performance were completely anonymized. Participants were required to complete a preintervention questionnaire at the moment of registration to access the contents of the web-based tool. This questionnaire comprised 20 questions assessing the knowledge areas to be addressed. In Multimedia Appendix 1, the topics addressed by each question can be consulted. After 7 days, a postintervention questionnaire containing the same questions was made available to assess content assimilation. Participants had the option to retake this postintervention questionnaire up to a maximum of 10 times, with a minimum score of 8 out of 10 required to qualify for a proficiency certificate. Following the completion of the postintervention questionnaire, participants were presented with an evaluation questionnaire consisting of the same questions posed to the experts during phase 2.

Data Analysis

In this study, both quantitative and qualitative analyses were conducted. The profile of participants who completed all phases of the iteration was compared with those who dropped out and did not finish to identify potential differences. For phase 2, descriptive analyses were performed on the rubric scores, and content analyses were conducted for open-ended responses. Fleiss κ was used to analyze the level of agreement among evaluators. The response options were recoded into 2 categories: "agree" (values 4 and 5) and "disagree" (values 1, 2, and 3), evaluating the overall agreement among experts across the 5 variables (clarity, utility, intention to recommend, intention to apply, and eResiliencia).

Similarly, in phase 3, the same analyses as in phase 2 were performed for the evaluation questionnaire. Descriptive statistics were conducted for both the preintervention and postintervention questionnaires. To assess differences between the means of such questionnaires, the Wilcoxon signed rank test was used. In addition, the McNemar statistic was calculated to compare the number of correct responses before and after the use of the web-based tool for each question. Qualitative analysis also considered the frequency of positive comments and improvement suggestions made by participants at the end of the structured survey. These comments, expressed in natural language, were categorized by 2 researchers (EG-H and IC) to facilitate their documentation. Finally, sociodemographic data were analyzed using descriptive statistics.

Ethical Considerations

In accordance with the Ecuadorian Ministerial Agreement AM00005-2022 and the Spanish Law on Biomedical Research (14/2007), studies conducted through anonymous surveys that do not collect health-related data are exempt from ethical review. This study was fully compliant with all regulatory standards for personal data protection. Ethical principles for medical research involving human participants included in the guidelines set by the Helsinki Declaration were followed. Informed consent for study participation was obtained at the time of registration on the platform, whereby individuals were required to select the corresponding checkbox, with instructions provided regarding the process for revoking their participation. No form of financial compensation was provided for participation.

Results

Phase 1: Development of the Web-Based Tool

A total of 42 documents were deemed relevant and were analyzed in depth to extract lessons learned and proposals for the design of eResiliencia (Table 1).

Table 1. Documents considered when designing the content of eResiliencia.

Name	Study

The working team outlined a presentation structure for eResiliencia and chose the most suitable appearance from several options. With the information gathered and the ideas from the working group itself, the first draft of the content was structured in the beta version of the website that hosts eResiliencia [59].

The content was divided into 2 main blocks (Figure 3), one aimed at building resilience at the individual and team levels, and another at the organizational level, preceded by a conceptual framework. Platform navigation was conducted through both the menu bar and the side panel (Figure 4). Within each block, there were subdivisions as shown in Table 2. In the tab dedicated to the conceptual framework, an explanation of the course context, an introduction to resilience, several examples of situations where it is crucial, and a section with definitions of the most relevant concepts of the course were provided. The first block, tools to strengthen resilience at the individual and team levels, offered the necessary strategies to enhance the resilience of team members at an individual level, placing particular emphasis on the importance of workplace well-being. Finally, the block on tools to reinforce resilience at the organizational level provided strategies to assess and achieve resilient institutions in the face of crises and unexpected events. In addition, a road map was included at the end of the course to aid in selecting the most useful strategies based on the objectives.

Figure 3. The home screen of the eResiliencia web-based platform.

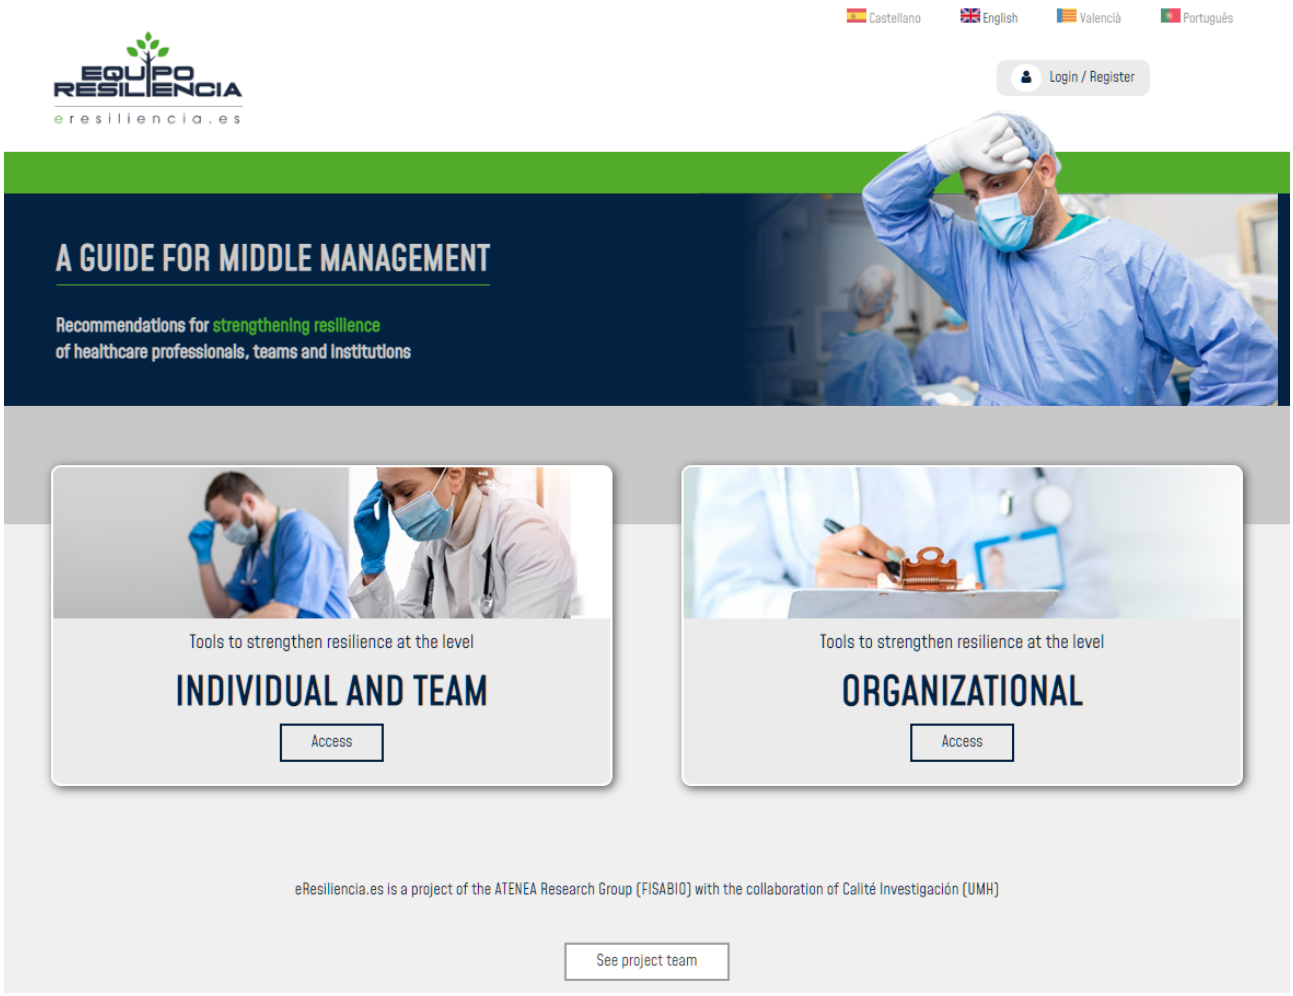

Figure 4. Navigation panel of the eResiliencia web-based platform.

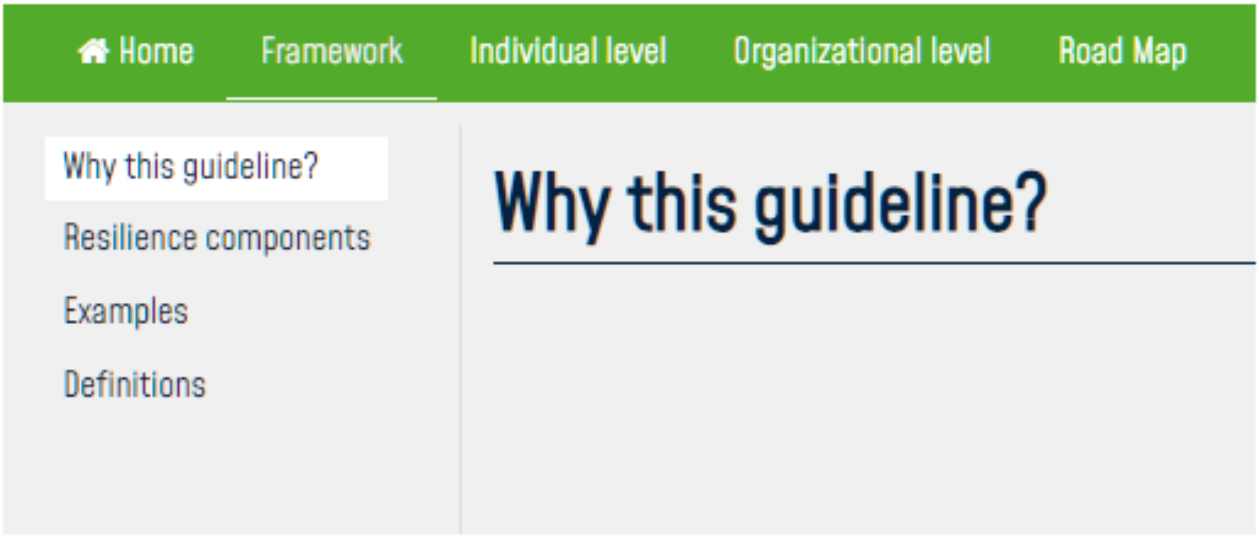

Table 2. Structure of the eResiliencia web-based platform.

Structure	Items
Framework	• Why this guideline? • Resilience components • Examples • Definitions
Individual level	• Stress Continuum Model • Enhancing resilience at the individual level • G.R.A.C.E. model • PERMA+4 Well-Being model for occupational wellness • Behavior change technique for building work-related well-being
Organizational level	• Enhancing resilience at the organizational level • Resilience Analysis Grid

In total, it comprised 17 videos, 11 figures and images, 4 PDF files, and references for further information expansion, among which downloadable materials or video, graph, and text links were also available. Upon accessing their personal account, users were provided with a section containing pertinent information regarding the platform's functionality, along with a video elucidating navigation and content. In addition, users had access to a support resource and the option to change their password.

Phase 2: Validation by Experts

Of the 20 experts, 13 (65%) assessed the tool and provided feedback. They rated the clarity of the content at an average of 4.5 (SD 0.7) and the utility and applicability at an average of 4.7 (SD 0.5), out of 5 in both cases. Regarding whether the materials facilitated learning strategies to foster the resilience of professionals or teams under their purview, 62% (8/13) of the experts indicated they *completely agree*, 31% (4/13) of the experts indicated they *agree*, and 8% (1/13) of the experts indicated they *completely disagree*. Regarding their likelihood to recommend the tool to other colleagues, 92% (12/13) of the experts responded *definitely yes*, and 8% (1/13) of the experts responded *probably yes*. The same results were obtained for their intention to apply learned tools or strategies. The level of agreement among experts for the combined set of the 5 evaluative variables of eResiliencia was 0.79 (95% CI 0.65-0.92).

Overall satisfaction was rated with an average of 9.3 (SD 0.6) out of 10 points. Some of the strengths highlighted were the chosen content and the ease of navigation and presentation of the web-based platform. In contrast, areas for improvement included making the videos more engaging and the possibility of incorporating practical exercises or a forum for participant interaction. As a suggestion, an introductory video of the content and the functionality of the web-based platform was included (Multimedia Appendix 2) [60]. The full list of comments made by experts is presented in Multimedia Appendix 3.

Phase 3: Pilot Study

Of the 458 professionals invited to participate, 362 (79%) registered on the platform. The preintervention and postintervention questionnaires of the pilot study were completed by 218 (60.2%) of these 362 health care professionals exercising leadership roles who began the intervention. Moreover, 146 (40.3%) health care professionals responded to the experience evaluation questionnaire.

Most of them were physicians (90/218, 41.3%) and nurses (59/218, 27.1%), with a mean experience of 10.3 (SD 8.8) years. Their primary work setting was primary care (113/218, 51.8%), hospital (79/218, 36.2%), quality area (9/218, 4.1%), or other management positions (7/218, 3.2%). The profile of those who did not complete the entire educational intervention was similar to those who did, with 42.4% (61/144 being physicians, 24.3% (35/144) being nurses, and 45.1% (65/144) working in primary care. Those who did not complete the intervention had slightly average experience, with 11.4 years compared with 10 years.

The scores obtained in the preintervention questionnaire averaged 42.0 (SD 16.6) of 100, while for the postintervention questionnaire, they averaged 74.7 (SD 22.7), with significant differences between them (P<.001; Z=–11.728). The increase in the percentage of correct answers for each question is represented in Table 3.

Table 3. Increase in percentage of correct answers for each question (n=218).

Questions[a]	Correct responses on the preintervention questionnaire, n (%)	Correct responses on the postintervention questionnaire, n (%)	Increase of correct answers (%)	McNemar test	*P* value
1	148 (67.9)	192 (88.1)	20.2	25.681	<.001
2	73 (33.5)	148 (67.9)	34.4	53.165	<.001
3	102 (46.8)	155 (71.1)	24.3	27.876	<.001
4	32 (14.7)	134 (61.5)	46.8	87.940	<.001
5	103 (47.2)	165 (75.7)	28.4	37.969	<.001
6	66 (30.3)	176 (80.7)	50.5	99.008	<.001
7	92 (42.2)	162 (74.3)	32.1	52.900	<.001
8	110 (50.5)	180 (82.6)	32.1	48.582	<.001
9	94 (43.1)	153 (70.2)	27.1	30.862	<.001
10	82 (37.6)	159 (72.9)	35.3	55.010	<.001
11	139 (63.8)	189 (86.7)	22.9	29.280	<.001
12	117 (53.7)	169 (77.5)	23.8	28.900	<.001
13	44 (20.2)	165 (75.7)	55.5	111.628	<.001
14	110 (50.5)	181 (83)	32.5	49.495	<.001
15	29 (13.3)	111 (50.9)	37.6	64.324	<.001
16	86 (39.4)	145 (66.5)	27.1	33.307	<.001
17	138 (63.3)	194 (89)	25.7	34.375	<.001
18	114 (52.3)	154 (70.6)	18.3	20.554	<.001
19	84 (38.5)	162 (74.3)	35.8	55.934	<.001
20	68 (31.2)	163 (74.8)	43.6	73.025	<.001

[a]Because this is active training, the questions have been masked to avoid spoilers. They are available upon reasonable request.

Moreover, 58.3% (127/218) of the health care professionals passed the postintervention questionnaire without requiring any retries. However, 14.2% (31/218) of the health care professionals needed 1 retry, 8.3% (18/218) needed 2 retries, 6% (13/218) needed 3 retries, and 3.7% (8/218) needed between 4 and 7 retries. Furthermore, 9.6% (21/218) of the health care professionals exhausted all 10 retry attempts without achieving the required score.

Regarding the perception of the 146 people who completed the evaluation questionnaire, the clarity of the content received an average score of 4.7 (SD 0.6) on a 1 to 5 scale, while the utility or applicability scored 4.8 (SD 0.5). The results of their opinion are depicted in Table 4.

Global satisfaction was rated 9.4 (SD 1.1) out of 10 points on average. Among the strengths underscored were the comprehensiveness of the content and the interesting techniques explained. Conversely, identified improvement areas consisted of incorporating more illustrative examples and providing downloadable materials.

Table 4. Results of the nonnumerical scale questions from the assessment questionnaire (n=146).

Question	Completely disagree, n (%)	Disagree, n (%)	Neither agree nor disagree, n (%)	Agree, n (%)	Completely agree, n (%)	Definitely not, n (%)	Probably not, n (%)	Not sure, n (%)	Probably yes, n (%)	Definitely yes, n (%)
The course content has enabled me to learn strategies for reinforcing the resilience of the professionals or teams under my supervision.	7 (4.8)	1 (0.7)	6 (4.1)	54 (37)	78 (53.4)	—[a]	—	—	—	—

[a]Not applicable.

Qualitative Analysis of Open-Ended Comments

Strengths

The most repeated topics among the strengths were the learning of new techniques or specific models (34/146, 23.3%), the web-based methodology that allowed access at any time (14/146, 9.6%), the organizational approach (10/146, 6.8%), the clarity of the content (9/146, 6.1%), stress management (6/146, 4.1%), and the examples provided (4/146, 2.7%).

Opportunities for Improvement

In terms of aspects to be improved, the incorporation of more examples (14/146, 9.6%) and the expansion of the content (14/146, 9.6%) were generally highlighted. In addition, improving the quality of the videos (12/146, 8.2%), including the possibility of interacting with other students in a more practical way (9/146, 6.2%), enabling downloadable content (9/146, 6.2%), reducing the length of the questionnaires (6/146, 4.1%), including web-based tutorials for resolving doubts with the teachers (5/146, 3.4%), and adding a progress bar to visualize the course as a whole (4/146, 2.7%) were emphasized.

Discussion

Principal Findings

Our developed web-based approach operates as a comprehensive tool designed primarily for middle managers, aiming to foster resilience at both individual and organizational levels within the staff at their charge. By using multimedia resources, this approach has been shown to enhance the knowledge about resilience of health care professionals across diverse fields and backgrounds.

eResiliencia was highly rated by the panel of experts regarding clarity and usefulness, indicating that the tool is perceived as comprehensible and relevant for application in professional contexts. High ratings were also obtained for the willingness to recommend the tool to colleagues and the intention to apply the learned strategies, demonstrating strong acceptance and confidence in the resource. For most (12/13, 92%) participants, the materials were potentially effective in strengthening team resilience, except for 1 (8%) expert who expressed complete disagreement. This highlights the need to consider diverse perspectives and possible improvements in adapting the content to various contexts. Nonetheless, overall satisfaction was high, with more than 9 points out of 10.

Implementing eResiliencia in Real-World Settings

The eResiliencia platform features a user-friendly interface, and in most cases, managerial staff possesses the necessary skills to use such digital tools effectively. However, some systemic limitations may impact its implementation. First, the increasing measures to prevent cyberattacks and data ransom incidents in health care institutions have led to stricter internet access controls, even in areas where connectivity was previously unrestricted. This decision may hinder access to eResiliencia within some organizations. In addition, in certain health care networks, managers lack the resources to access the platform outside their offices. Incorporating offline functionality could address these limitations and facilitate broader access to the platform.

Second, resistance from health care organizations, often rooted in established workflows or skepticism about the benefits of new interventions, represents a traditional barrier. In this case, the integration of eResiliencia was facilitated by embedding it within a national patient safety and quality training program aimed at launching a global institutional strengthening plan. A similar strategy could help overcome organizational resistance in other settings.

Third, ensuring flexibility and accessibility is essential to meet the diverse needs of users. The use of asynchronous learning options was key in this instance, allowing participants to decide when and how to engage with the platform. This flexibility significantly increases accessibility and is particularly relevant in environments with high workloads. However, allocating dedicated time during work hours could further enhance participation rates by reducing competing demands on participants' schedules.

Comparison With Prior Studies

It is known that health care professionals face stressful situations in their professional work. The frequency of burnout or the existence of defensive practices is also not uncommon. It is no surprise that the role of team leaders influences the team's ability to respond and recover after experiencing adverse situations [61]. The COVID-19 pandemic brought to the attention of managers, executives, and society in general concerns about the resilience capacity of these collectives, both at an individual and collective level, to face what has undoubtedly been the greatest global challenge for health care professionals. This study originates from that period and delves into both aspects, offering an easily accessible training format for those responsible for clinical teams. In this regard, it is based on the observation that most programs designed to increase resilience were developed to operate at the individual level and that it was necessary to create interventions focused on the work group [30].

eResiliencia incorporates agreed-upon resilience attributes [37] and skills that leaders must possess to strengthen their teams' resilience, which include self-efficacy, self-control, the ability to provide support and help, and learning from difficulties [62].

Uncertainty, resource shortages, constant protocol variations, the risk of infection and transmission, and critical decision-making with ethical implications, among other factors, were prevalent during the COVID-19 pandemic and contributed to fear, anxiety, stress, moral injury, or compassion fatigue among health care professionals [63,64]. These situations have highlighted the need to reconsider the role of middle management, as they must address the needs of their teams to face challenges. Therefore, their resilience is a crucial competence required for their work.

The scores obtained in this study by the professionals who underwent the training show that after the use of the tool, the results were better both overall and for each individual question. However, the preintervention questionnaire also revealed that participants' previous knowledge was relatively low in many areas, with correct response rates ranging from 13.3% (question 15; behavior change technique) to 67.9% (question 1; definition of resilience). This underscores the necessity and effectiveness of the educational intervention implemented. The greatest increases were in questions with initially low correct response rates (question 4, question 6, and question 13), suggesting the acquisition of new concepts. In contrast, questions such as question 1 and question 18, which initially had a higher percentage of correct responses, showed a less pronounced increase compared to those with lower initial performance. The increase in scores on the final questionnaire compared to the initial questionnaire is consistent with the findings of other studies, which show that both in-person [52,65-67] and on the web [50,68] interventions increase resilience capacity. In addition, it has been observed that they also protect the mental health of professionals [69].

Solutions to assist professionals were implemented in different countries and were similar, including the availability of psychological services, support hotlines, and websites with resource materials [70]. Focusing on tools available for Spanish speakers, an example is the digital platform and mobile app, Be+Against COVID, which was used in Argentina, Brazil, Colombia, Chile, Ecuador, and Spain [71].

Although middle managers have usually received training in occupational risk prevention and conflict management, many times there is a lack of specific and detailed training in fundamental aspects of team management and resilience. Traditionally, team management has focused on organizational and clinical aspects to ensure that patients' needs are adequately met. Nowadays, middle managers are expected to efficiently manage the resources of the professional teams they lead, particularly human talent, to adequately respond to health challenges.

Implications of Findings

In the postpandemic era, there is a growing consensus that among the functions of executives and middle managers (such as the organization of responses to care demands, task allocation, conflict management within teams, and the strengthening of teams to meet care demands effectively), there should be an emphasis on maintaining and strengthening the resilience capacity of their teams of professionals, because their ability to cope with highly stressful situations determines the quality of care provided and the outcomes for patients. This eResiliencia program follows this trend and takes a proactive approach by offering a framework for executives and middle managers to use some or all the resources to achieve this objective and prepare their team for everyday challenges and future crises.

Although most (197/218, 90.4%) of the participants were able to pass the training without any difficulties, some (21/218, 9.6%) individuals exhausted all reattempts without achieving the minimum required score. While these data suggest that the material and teaching methods are effective for most, it would be beneficial to delve into the reasons behind the difficulties faced by this small percentage to address and mitigate the problem.

Resilience training is presented as a crucial element in the professional development of middle managers in the health care sector. Promoting and reinforcing resilience is not only essential for the individual well-being of professionals but also strengthens the cohesion and effectiveness of the team as a whole. However, for this to be feasible, it is essential that clinical management evolves and provides effective tools to middle managers, facilitating resource management, including resilience training.

In this era, there is a growing consensus that the existing "find and fix" solutions should be replaced by those that are more forward-thinking [15]. Moreover, the organizational culture is

critical to ensuring patients receive adequate care and workers' resilience when things go wrong [72]. Health care organizations are evolving toward the principles of Safety II framework here [73], which involves recognizing the challenge of complexity and uncertainty in clinical practice to anticipate errors. Promoting the resilience of workers at both individual and team levels contributes to realizing the implementation of Safety II [74].

Fragmentation in the assignment of professionals poses a significant challenge to teamwork. Thus, cohesion among middle medical and nursing managers is essential to overcoming the barriers created by this fragmentation and fostering a more collaborative and efficient work environment. The training of middle managers in the health care organization must be a top-down strategy, driven by leadership. Health care executives must communicate these priorities to middle managers and provide the necessary support for implementation. Only through strong and consistent leadership from the upper echelons can we ensure that middle managers are equipped with the competencies required to effectively manage their teams and promote a resilient work environment.

The response rate indicates that 4 (40%) of the 10 professionals who registered on the platform were eventually not interested in the training on how to foster resilience in their teams and collaborators. This could be because they already possess the personal resources to tackle the task or because eResiliencia did not meet their expectations or failed to motivate them sufficiently. This aspect could be addressed, for example, with a more practical approach through group dynamics and cooperative tasks to generate greater interest and engagement, so participants can see a more direct application of the training tools.

Strengths

This study addresses the 5 key questions of a resilience study in the health care sector [75]. It proposes an alternative approach to individual-focused training by emphasizing the role of clinical team leaders and how to strengthen the resilience of their teams and team members.

Limitations

Although international experts share a common cultural background, they represent a group of Spanish-speaking countries. The generalization of content to other countries should not be done directly. Participants in the pilot study phase worked in various public health networks in Ecuador and took part in this experience as part of a quality and patient safety management course, which emphasized the need to move away from a blame culture. This aspect may have influenced their engagement with the eResiliencia content. Participants had a set amount of time to complete the training on the eResiliencia web-based platform. In a different self-directed learning context without this limitation, trainee behavior might be different. Because this is a study without a control group, the changes observed in participants' knowledge may not be exclusively attributable to eResiliencia. Finally, it should be noted that although the participants were enrolled in training organized by the Ministry of Public Health of Ecuador, it was emphasized that they could freely choose whether to complete the eResiliencia training and respond to the satisfaction survey. Answering the questionnaire did not provide any advantage and the responses were not disclosed, ensuring anonymity at all times, which was clearly communicated to the participants. This approach was taken to avoid a reporting bias.

Cultural Factors Influencing Resilience-Building Capacity

Ecuador's health care system is characterized by hierarchical structures and centralized decision-making, typical of high-power distance cultures. eResiliencia capitalizes on the influential role of middle managers, who act as intermediaries between upper management and frontline workers. By equipping middle managers with resilience-building tools, the intervention empowers them to cascade these strategies throughout their teams, reinforcing resilience at all levels of the organization. The networks engaged in this study operate with limited resources, requiring flexibility and improvisation to address challenges. eResiliencia provides structured yet adaptable strategies, offering tools for middle managers to tailor resilience-building efforts according to the specific needs and constraints of their teams. Although Ecuador faces challenges in long-term health care planning, eResiliencia introduces structured frameworks that emphasize proactive resilience building. These frameworks align with preventive measures to prepare health care professionals for crises, fostering a shift from reactive to proactive management.

Many of these aspects are common to countries in this region. However, the outcomes of eResiliencia in Asia, Europe, or North America are likely to differ significantly due to the cultural factors influencing resilience-building capacity. Cultural dimensions such as collectivism, power distance, and approaches to uncertainty, among others, play a crucial role in shaping how resilience strategies are developed and applied across different contexts.

Future Research

It is necessary to delve into a common definition of what is meant by resilience [11,75] and, by extension, the role of managers in the resilience of their team members. A critical aspect for future development involves the incorporation of mechanisms to monitor the utility and long-term impact of the knowledge acquired through the web-based tool, particularly considering the less optimistic data provided by some studies on nursing students [76]. In later phases, this intervention will be complemented by the development of improvement and action plans based on the application of the eResiliencia tools by health care teams and middle management interested in their centers. This will allow a more effective monitoring of the tool, its usefulness, and applicability. These approaches could also be extended to companies that provide home care, to train those who coordinate the work of informal caregivers in the home [77], in light of the growing caregiving economy. Finally, as these are preliminary data, this educational intervention should be tested in the context of other organizational models and diverse cultural settings to validate its effectiveness, acceptability, and utility.

Conclusions

The proposal to evaluate each professional, identify signs of stress, take appropriate measures, and manage team cohesion represents a training initiative that could be implemented clearly and explicitly. However, it is essential to first analyze the organizational context where the intervention will be applied and identify potential adjustments to improve its acceptability based on national and local organizational factors. This tailored approach ensures that the intervention aligns with the specific needs and characteristics of each setting, enhancing its effectiveness and relevance. This training would enable middle managers not only to manage conflicts but also to prevent them and foster a healthy and productive work environment. The developed tool proved to be well received by both the experts and the health care professionals who participated in this pilot phase.

Acknowledgments

The authors would like to acknowledge the experts who participated in the evaluation and validation of the web-based platform as well as all the participants from Ecuador who took part in the pilot study, thereby contributing to an improved experience with the platform. The authors also extend their gratitude to the National Directorate of Quality, Patient Safety, and Health Control of the Ministry of Public Health of Ecuador for their support and dissemination efforts in the initial recruitment process. Clara Pérez contributed to the statistical analyses.

The project was funded by Conselleria de Sanitat Universal i Salut Pública (Generalitat Valenciana, Spain) and the EU Operational Program of the European Regional Development Fund for the Valencian Community 2014-2020, within the framework of the Recovery Assistance for Cohesion and the Territories of Europe program, as the European Union’s response to the COVID-19 pandemic; Ser+ Contra COVID (UGP-21-408). The maintenance of the web-based platform is made possible by the funds allocated to the preparatory action in the UniSalut Program 2023 (subprogram ILISABIO, reference ILISABIO22_AP09). Throughout the execution of this study and composition of this manuscript, JJM benefited from an augmented research activity contract granted by the Carlos III Health Institute (reference INT22/00012).

Data Availability

The datasets generated analyzed during this study are available from the corresponding author on reasonable request. Topics addressed in each question are displayed in Multimedia Appendix 1.

Authors' Contributions

All the authors meet the International Committee of Medical Journal Editors criteria for authorship. JJM was responsible for the design of the study. JJM and IC conducted the search and the preliminary selection of contents related to resilience. IC and EGH drafted the web-based platform and developed the materials. JMD was responsible for the enrollment of people and the acquisition of data. DGT performed the statistical analysis and interpretation of the results. EGH developed the first version of the manuscript. All authors revised the paper critically for important intellectual content and read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Colonoscopies are vital for initial screening, follow-ups, surveillance of neoplasia, and assessing symptoms such as rectal bleeding. Successful colonoscopies require thorough colon preparation, but up to 25% fail due to poor preparation. This can lead to longer procedures, repeat colonoscopies, inconvenience, poorer health outcomes, and higher costs. eHealth tools can enhance bowel preparation and potentially reduce the need for repeat procedures.

Objective: This usability study aimed to identify strengths and weaknesses in a prototype companion app for colonoscopy examinations. The objective was to obtain in-depth insights into the app's usability, ease of use, and content comprehension, with the aim of refining the tool to effectively fulfill its intended purpose, guided by feedback from potential users.

Methods: From February to August 2024, we conducted a qualitative study using the think-aloud procedure. Each session involved 6 tasks and a semistructured interview to delve deeper into participants' task experiences. All think-aloud sessions and interviews were recorded. Quantitative usability questions were analyzed using Microsoft Excel, while qualitative data underwent coding and analysis based on thematic analysis principles.

Results: In total, 17 individuals, all smartphone users, participated in this study. Participants were recruited from 1 hospital, 1 private clinic, and 1 patient organization in Switzerland. The study found that participants rated the app's usability metrics positively, with an overall mean rating of ease of use at 4.29 (SD 0.59), usefulness at 4.53 (SD 0.72), and comprehensibility at 4.29 (SD 0.92). For the individual features, the mean ratings for ease of use were between 4 and 4.65, usefulness ranged from 4.35 to 4.82, and comprehensibility received ratings between 4.29 and 4.53, all measured on a 5-point scale, where 1 represented low agreement and 5 indicated high agreement. Additionally, 100% of participants indicated they will or may use the app if they require a colonoscopy examination. Participants highlighted the need for reminders and alerts in the week leading up to the colonoscopy, along with tailored content, simplified language, and visual aids.

Conclusions: The app prototype demonstrated favorable results with the majority of participants, and the testing process enabled the prompt identification and resolution of usability issues. The next phase will prioritize and assess potential improvements based on urgency and feasibility to guide a focused development plan. Usability testing highlighted features such as push notifications and personalized content as top priorities for participants, making them key areas for immediate attention. Moving forward, the app has the potential to function effectively as a companion app for colonoscopy examinations. To achieve this, further studies with a larger sample in real-world settings will be crucial.

Introduction

Background

Colonoscopies are widely recognized as the most reliable method for detecting colorectal issues; their effectiveness and safety hinge on the thoroughness of bowel preparation beforehand [1,2]. Ensuring adequate bowel preparation is crucial for achieving clear visualization of the colon's inner lining during the procedure. Poor bowel preparation is linked to risks such as missed significant lesions, procedural challenges, longer operation times, higher rates of interval colorectal cancers, and increased health care expenses [3]. However, a colonoscopy is an invasive procedure that demands extensive preparation. This includes taking a laxative, restricting food and liquid intake, and stopping certain medications in the week before the appointment.

Research indicates that up to 11% of individuals miss their colonoscopy appointments [4,5], and among those who do attend, many have insufficient bowel preparation, hindering clear colonic visualization [6-12]. A recent study investigated the efficacy of various bowel preparation regimens (4L, 2L, and ≤1L) for colorectal cancer screening, focusing on key quality indicators such as bowel cleanliness, cecal intubation rate, adenoma detection rate, and polyp detection rate, all aligned with the performance standards set by the European Society of Gastrointestinal Endoscopy (ESGE) [13]. While all regimens met the ESGE's minimum quality thresholds, the adequacy of bowel preparation varied significantly between volumes [13]. Ultralow-volume preparations achieved an adequacy rate of 79%, notably lower than the 86.4% seen with high-volume preparations [13]. In particular, bowel preparation with sodium picosulfate and magnesium citrate (SPMC) and 1L polyethylene glycol with ascorbic acid (1L-PEGA) was adequate in only 75.2% and 82.9% of cases, respectively, highlighting the need for careful consideration when selecting a preparation method based on patient needs and procedural goals [13].

Misunderstanding dietary guidelines and cleansing instructions, along with noncompliance, significantly contributes to inadequate bowel preparation [14]. Ineffective bowel preparation can lead to several adverse outcomes, including reduced adenoma detection rates, extended procedure times, lower cecal intubation rates, increased electrocautery risks, and more frequent examination intervals [15,16]. To enhance patient adherence to colonoscopy procedures, various educational strategies have been used. Tools such as booklets, cartoons, and SMS text messaging have proven effective in increasing follow-up rates compared to standard care [17]. Furthermore, smartphone-based strategies have been developed to assist patients in preparing for colonoscopy [18-24]. Research indicates that these smartphone interventions generally lead to better outcomes, such as higher bowel cleansing quality scores, compared to usual care control groups [18-20,25,26]. However, there is limited evidence that these tools were designed with input from their intended users [27], which may reduce their effectiveness. Engaging potential users in the app development process is likely to enhance usability by ensuring the app's content and features match user needs and preferences [28-30].

Objectives

Considering that user research can significantly enhance a tool's adoption and adherence rates post launch [28], this usability study was conducted to pinpoint strengths and weaknesses in the prototype of a companion app for colonoscopy examinations and to provide detailed insights into its quality regarding usefulness, ease of use, and content comprehension. The goal is to refine the product based on evidence gathered from potential users, ensuring it meets its intended purpose effectively.

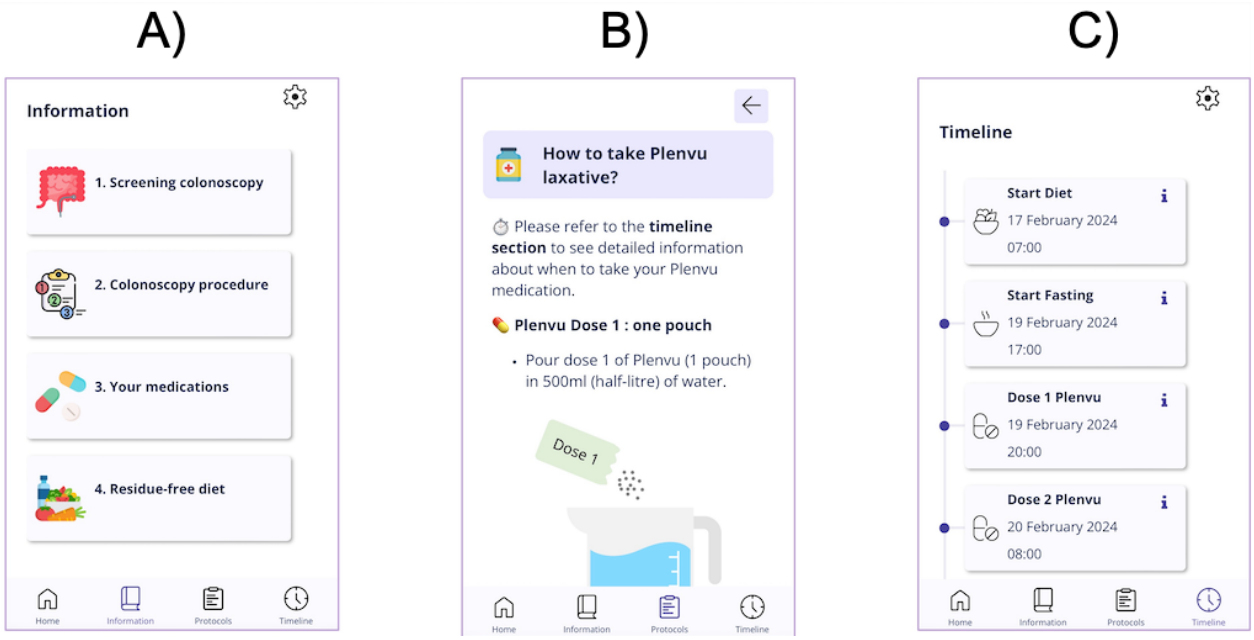
Methods

App Prototype

The health care technology company Gimini Biosciences SàRL is developing digital health solutions to empower patients undergoing complex medical interventions. Their mission is to ensure every patient has access to the necessary information for a successful medical examination.

The companion app for colonoscopy examinations, their first use case, features three main sections: (1) educational content about colonoscopy examinations; (2) digital protocols detailing diet, fasting, and laxative instructions; and (3) a personalized timeline based on the user's examination date and time to guide them on diet, fasting, and laxative schedules. Figure 1 illustrates the design of the prototype, showcasing these sections.

Figure 1. App prototype overview, including (A) patient information, (B) digital protocols, and (C) timeline and schedule.



Study Design

The study involved conducting a qualitative interview with each participant using the standardized think-aloud method [31], which is described in detail below. Participants were guided using a semistructured test script to articulate their cognitive process in real time while completing a list of predefined tasks. Similar to many qualitative studies, this research used purposive sampling to gather in-depth insights [32]. Participants were selected based on their capacity to offer detailed and firsthand insights into the research topic, ensuring they could effectively articulate their real-life experiences [32,33].

Participant Recruitment

The inclusion criteria covered individuals aged 40 - 65 years who use a smartphone, have undergone a colonoscopy examination, have access to Wi-Fi and email, are comfortable using teleconferencing tools (eg, Microsoft Teams), and are capable of screen-sharing during the testing session. Three institutions played a key role in recruiting participants: Clarunis (the University Digestive Health Care Center of St. Clara Hospital and University Hospital Basel), GGHA (Geneva Gastroenterology & Hepatology Associates SA), and EUPATI Switzerland (European Patients' Academy on Therapeutic Innovation).

Participants were directly approached and recruited by the collaborating institutions. Once a participant agreed to participate and signed the consent form, the respective institution forwarded the signed consent form along with the participant's contact details to the core research team at the University of Applied Sciences and Arts Northwest Switzerland (FHNW). From that point, the research team took over the coordination and management of the participant's involvement in the study.

Participants had the option to conduct the testing session in English, French, or German. The English version of the participant information sheet and consent form can be found in Multimedia Appendix 1. The information was also provided in both German and French, giving participants the freedom to select the language they felt most comfortable using, and the recruitment process spanned from February to July 2024. The researchers aimed to recruit a sufficient number of participants to achieve saturation, indicating that enough data had been collected when new information no longer provided additional insights [32,33].

Think-Aloud Procedure

The think-aloud method is extensively used in app development as a popular tool for assessing usability [34]. In a think-aloud test, participants are asked to use the system and verbalize their thoughts continuously as they navigate through the user interface. This technique allows researchers to gain deeper insights into user misconceptions, which often lead to practical recommendations for redesign: when users misunderstand design elements, those elements may require modification. It also sheds light on why users make incorrect assumptions about certain aspects of the design and why they find other parts intuitive. The method is used to make cognitive processes, which would otherwise remain implicit and unspoken, more visible. By having participants verbalize their thoughts while performing a task, researchers can gain insights into thought processes, decision-making strategies, and individual patterns of interpretation.

Participants evaluated a web-based prototype of the app. They were instructed to explore the prototype while vocalizing their actions and observations, and to offer feedback on features, navigation, and perceived usefulness as they interacted with it. Researchers reminded participants to maintain a continuous stream of thoughts when needed and observed their behavior throughout the test tasks. All sessions were recorded, capturing participants' screen interactions with the prototype. Detailed notes were taken during feedback sessions and stored using the research platform Tivian.

During each test session, participants were asked to complete 6 tasks, during which we observed their behavior and

interactions with the tool. Additionally, they provided subjective assessments for each task, evaluating its usefulness, ease of use, and comprehensibility of the content. Textbox 1 displays the list of tasks participants were required to complete during the test sessions. The English version of the complete test script can be found in Multimedia Appendix 2.

Textbox 1. The list of tasks participants were required to complete during the test sessions.

Task 1: Customization and language choice
Task 2: First screen tour
Task 3: Accessing and navigating the background information section
Task 4: Accessing and navigating the fasting and food instructions
Task 5: Accessing and navigating the laxative instructions
Task 6: Accessing and navigating the meal and exercise recommendations

The think-aloud test was designed to encompass every possible task a user might perform within the app, covering all available functions and interactions. By including all tasks, we ensured a thorough capture of user feedback across the app's entire functionality, providing a comprehensive assessment of the user experience. Below is a high-level summary of what each task involved:

- Task 1: Customization and language selection—In this task, participants were prompted to select their preferred language and adjust settings such as font size or content complexity, allowing them to personalize the app to their needs.
- Task 2: First screen tour—This task aimed to assess the intuitiveness of the app's initial screen, encouraging participants to reflect on the clarity of the navigation and their understanding of the content available in each section.
- Task 3: Exploring background information—Here, participants were guided to access and navigate the section on background information about the colonoscopy examination, supporting their understanding of the procedure as they prepared for their appointment.
- Task 4: Reviewing fasting and dietary instructions—This task directed participants to find and review guidelines on what they can and cannot eat before the examination, including details on when to begin the special diet and the required fasting period.
- Task 5: Reviewing laxative instructions—Participants were asked to locate and understand instructions on taking the laxative, including information on dosage timing for effective preparation.
- Task 6: Reviewing meal and exercise recommendations—This task involved participants exploring the app's suggestions for meals and exercises that could help them prepare optimally for the examination.

Analysis

After compiling all notes from the testing sessions, CJ, RM, and SS collectively reviewed and synthesized the findings. These were then presented to the app development team for discussion, focusing on identifying features and functions requiring modification. The data encompassed audio recordings of the think-aloud sessions, observations noted by CJ, RM, and SS, and responses to usability questions.

Quantitative usability data, such as user ratings of ease of use and usefulness of the different features, were aggregated and analyzed using Microsoft Excel for Mac 2021 (version 16.86) to compute totals, percentages, means, and standard deviations. Qualitative participant comments were translated into English as needed for coding purposes. NVivo version 1.7.2 (QSR International), a qualitative data analysis software, was used for coding and categorizing the qualitative data. The data underwent thematic analysis to capture the depth and the unique interpretative contributions of individual researchers [35]. To ensure coding reliability, the first 3 authors, who conducted testing sessions in 3 different languages, engaged in collaborative discussions. The initial codebook was organized around core eHealth app development components: user interface (including navigation and visual design), user experience design (such as personalization), functionality (including notifications and reminders), and patient engagement and support (such as educational content). Initial coding was carried out by the first author (CJ), followed by a review from RM. Any coding discrepancies were addressed through discussions with SS until a consensus was reached.

Ethical Considerations

The ethics committee of Northwest and Central Switzerland determined that ethics approval was not needed for this study, according to the Federal Act on Research Involving Human Beings, article 2, paragraph 1 (reference number Req-2023 - 01506). All participants were briefed about the research background and signed a consent form agreeing to participate. Participants did not receive payment but were offered the opportunity for early and free access to the app upon its launch.

Results

Sample Characteristics

In total, 17 participants from 4 institutions tested the app prototype (3 of them were pilot tests, 1 in each of the 3 test languages). Participants were mostly male (13/17, 76%) and aged 40 - 50 (8/17, 47%) years. The gender discrepancy among participants is largely due to recruitment challenges and the voluntary nature of the study. Since participation was optional, it may have led to a self-selection bias, where individuals more comfortable with technology or who have a specific interest in health applications were more likely to take part, resulting in a less balanced gender distribution among participants. Tests were conducted in German (6/17, 35%), French (6/17, 35%), and

English (5/17, 29%). Table 1 presents the demographics and characteristics of the sample.

Table . Sample characteristics (N=17).

Characteristic		Values, n (%)
Gender		
	Male	13 (76)
	Female	4 (24)
Age (years)		
	<40	1 (6)[a]
	40 - 50	8 (47)
	51 - 60	5 (29)
	>60	3 (18)
Language		
	German	6 (35)
	French	6 (35)
	English	5 (29)

Usability Metrics

Usability metrics are specific measurements used to evaluate a digital product's usability. These metrics typically assess how quickly users complete tasks, how often they make mistakes, and their overall satisfaction with the tool. By analyzing various usability metrics, we can gain a comprehensive understanding of the user's experience and the tool's overall usability.

During the testing sessions, we incorporated satisfaction metrics, which are subjective measures based on users' self-assessments. These metrics evaluated the ease of use, usefulness, and content comprehensibility of different sections of the app, as well as their overall impression of the app. Responses were rated on a Likert scale from 1 (low agreement) to 5 (high agreement). Table 2 provides an overview of these subjective measures for the various tasks and the app as a whole. Some measures were not applicable for certain tasks. For example, in task 1 (customization and language selection), there was no text content to assess for comprehensibility, so this measure is marked as N/A (not applicable) for that task. In task 2 (first screen tour), participants were only asked to reflect on whether the initial screen was intuitive, rather than completing an action. Therefore, measures such as ease of use, usefulness, and comprehensibility were not rated for this task.

Table . Subjective usability measures (N=17).

Task	Ease of use[a], mean (SD)	Usefulness[a], mean (SD)	Comprehensibility[a], mean (SD)
Task 1: Customization and language choice	4.41 (0.71)	4.35 (1.11)	N/A[b]
Task 2: First screen tour	N/A	N/A	N/A
Task 3: Accessing and navigating the background information section	4.41 (0.94)	4.76 (0.44)	4.53 (0.87)
Task 4: Accessing and navigating the fasting and food instructions	4 (1)	4.41 (0.87)	4.29 (0.99)
Task 5: Accessing and navigating the laxative instructions	4.53 (0.62)	4.82 (0.39)	4.35 (0.93)
Task 6: Accessing and navigating the meal and exercise recommendations	4.65 (0.7)	4.59 (0.62)	4.53 (0.8)
Overall satisfaction with the app as a whole	4.29 (0.59)	4.53 (0.72)	4.29 (0.92)

[a]User satisfaction of usability attributes was rated on a scale of 1 (low agreement) to 5 (high agreement).

[b]N/A: not applicable.

To provide a comprehensive assessment, test moderators also recorded observations on three additional usability metrics: (1) completion metrics (these measure whether users can successfully complete or partially complete tasks, indicating the tool's effectiveness); (2) duration metrics (these track the average time users take to perform a task, reflecting the design's complexity and the efficiency of user navigation); and (3) error metrics (these refer to actions users take that do not lead to the expected outcome, highlighting areas of confusion in the user interface or challenges with functionality). Table 3 presents an overview of these observed measures. Certain measures in this table were not applicable for task 2 (first screen tour), as participants were only asked to assess the intuitiveness of the initial screen rather than perform any specific action. As a result, metrics such as completion rate and error rate were not relevant for this task, since there was no actionable step for participants to complete or errors to quantify.

Table . Observed usability measures (N=17).

Task	Completion, n (%)	Error rate, n (%)	Duration (seconds), mean (SD)
Task 1: Customization and language choice	16 (94)	1 (6)	44.47 (32.39)
Task 2: First screen tour	N/A[a]	N/A	57.41 (45.94)
Task 3: Accessing and navigating the background information section	15 (88)	7 (41)	66.53 (46.32)
Task 4: Accessing and navigating the fasting and food instructions	16 (94)	7 (41)	75.41 (46.07)
Task 5: Accessing and navigating the laxative instructions	15 (88)	3 (18)	54.88 (47.89)
Task 6: Accessing and navigating the meal and exercise recommendations	17 (100)	3 (18)	56.76 (50.49)

[a]N/A: not applicable.

When asked if they would use the app for a colonoscopy examination once it becomes available, out of 17 participants, 14 (82%) said yes, 3 (18%) said maybe, and 0 (0%) said no.

Qualitative Feedback

Participants provided comments and qualitative feedback on the 6 tasks they performed during the test sessions. While their feedback concerning the comprehensibility of the content, the user-friendliness, and the general user benefits of the application was mostly positive, they also expressed some confusion about certain content or features. Additionally, they offered suggestions for improvements in areas such as design and visualization as well as user guidance to address the gaps or issues they identified in the prototype. Overall, participants stressed the importance of receiving reminders and alerts in the week leading up to their colonoscopy. They also preferred tailored content, simplified language, and visual aids to enhance their understanding. Table 4 summarizes their qualitative feedback, organized into 4 key themes: app content, design, guidance, and features. These themes collectively illustrate the

participants' preferences and priorities, providing valuable insights for the development and improvement of the application.

Table . Key themes that emerged from the thematic analysis of the qualitative feedback.

Themes and subthemes		Qualitative feedback
Content		
	Content accuracy	Participants expressed a need for greater accuracy in the app's content. Specifically, they suggested: • Allowing the selection of examination times down to the minute, rather than in 15-minute intervals. • Clearly stating that tea and hot drinks should not contain milk, as specified in the paper-based guidance. • Ensuring the app accurately reflects the strict fasting phase, as some participants experienced longer fasting periods than indicated.
	Content clarity	Some content has been found to be unclear or confusing. For instance: • The term "residue-free diet" may be difficult for laypeople to understand; "bowel cleansing" is suggested as a more straightforward alternative. • The term "protocols" is ambiguous, and "preparation" is recommended as a clearer option. • Instead of using the word "option" for meal examples, provide explicit examples to avoid misleading users into thinking these are the only choices available. • For dosage instructions, emphasize that the liquid should be consumed in sips rather than all at once. • The timeline entry "pickup medication" is unclear and potentially misleading; a more descriptive label is needed. • More information on physical exercise should be included, such as its effects and importance in the preparation process.
	Content completeness	It has been noted that certain content is currently lacking in the app, namely: • Expanded details on the colonoscopy procedure should be provided, with careful attention to wording. Starting the information section with cancer detection details can be perceived as alarming. It is essential to introduce the procedure in a reassuring manner, highlighting its benefits and emphasizing preventive care. • Information on the effects of laxatives. • Vegetarian menu options. • Post-colonoscopy care and potential adverse events. • Any assistance with laxative consumption would be greatly appreciated, as it can be quite unpleasant. For example, mixing the laxative with clear syrup to improve taste. Another tip is to sip water alternately with the laxative instead of consuming them sequentially, which can make the experience less difficult. Additional advice on making the process more manageable could include using a straw to drink the laxative or drinking tea beforehand to mitigate the salty taste.

Themes and subthemes		Qualitative feedback
	FAQs[a]	Participants have suggested including a section with FAQs to provide clear and concise answers to common concerns. Suggested questions include: • Why is a colonoscopy performed? Include an explanation of its purpose and benefits, and note any differences in the procedure or considerations for men and women. • Can I drive after taking the medication? • When can I resume a normal diet? • What are the advantages and disadvantages of various examination methods? Offer a comparison of different diagnostic options, such as stool examinations, to help users understand their relative benefits and limitations.
	Translation accuracy	A few minor translation inaccuracies have been identified: • “Dose 1” was incorrectly translated into German; the correct term is “Dosis.” • Under “fasting time,” “Untersuchung” is a more appropriate translation than “Prüfung.”
Design		

Themes and subthemes		Qualitative feedback
	Navigation clarity	Participants have proposed several improvements to enhance the clarity of the app's navigation. Suggested enhancements include: • Adjust the color scheme of the language selection navigation to make it more prominent. • The button for confirming language selection should be available in multiple languages. • Change the name of the navigation section labeled "Information" to better reflect that it pertains to the procedure rather than app-related information. • The back arrow should be made more prominent by increasing its size and repositioning it centrally for better visibility and ease of use. • There is uncertainty about the type of information the sections labeled "Protocols" and "Timeline" contain.
	Navigation structure	There were several suggestions to improve the app's navigation structure: • Increase the size of the customization icon and consider positioning it at the same level as the other main navigation icons to attract more attention. • Keep content concise and allow users to click for more detailed information when needed. • Display the timeline immediately after scheduling an appointment, as it is highly relevant. Ideally, place the timeline in the same section where laxative information is provided. • Clearly mark the section for taking the laxative in the protocol and integrate the "how" with the "when" to provide a comprehensive guide. • Distinguish and prioritize personalized content related to individual preparation for the colonoscopy from general informational content about the procedure, such as examination details and menu suggestions.
Guidance		

Themes and subthemes		Qualitative feedback
	Step-by-step guidance	Participants have reported some confusion and expressed a need for clearer guidance on navigating the app and understanding required actions. Specific recommendations include: • Add a note indicating that users can change the language and the date of their intervention, as this option is not immediately apparent. • Clearly explain why users need to enter their appointment details. • Provide a clear explanation of the next steps immediately after entering appointment information, as some users were unsure where to click. • Indicate that some content is customized based on the user's appointment time to clarify how the app personalizes information. • Include preliminary information about the general procedure at the start of the app, such as an overview page, to give users a better understanding of what to expect.
Features		
	Personalized notifications	Nearly all participants emphasized the critical need for personalized reminders and alerts, tailored to each patient based on the specific date and time of their colonoscopy appointment.
	Sharing and printing info	The importance of having the ability to print or share information directly from the app was emphasized.
	Tailored content	Participants noted that the app's capability to customize content for individual users makes it more favorable compared to other methods of information delivery, such as paper. Specific suggestions include: • Set the app to automatically select the language based on the user's browser settings. • Allow direct integration with the user's calendar for streamlined timeline management. • Ensure that the link directs users to the correct hospital right from the start. • Add the medical center's phone number or provide a direct link for users to easily contact the center.
	Visual aids	Participants recommended integrating visual aids to improve the clarity and comprehension of the information. Suggestions include: • Add illustrations to assist in understanding the content more easily. • Use visual cues to highlight the fasting time more prominently. • Present information about meal preparation and dishes in a more visual format, including photos of menu items. • Integrate photos and potentially a video to visually explain the procedure.

[a]FAQs: frequently asked questions.

Discussion

Principal Findings and Implications for App Improvement

Our findings indicate that participants were generally willing to use the companion app for colonoscopy examinations and found it mostly useful and easy to navigate. Usability is crucial for implementation, as technologies that are user-friendly are more likely to be consistently used over time. This is why leading technology acceptance frameworks such as the Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) emphasize ease of use and usefulness as key predictors for adopting new technologies [36,37]. The inclusion of subjective measures in assessments has been debated in the literature due to potential variability introduced by users' subjective views. Despite this challenge, many scholars advocate for the inclusion of subjective criteria, such as ease of use and visual appeal, because they are fundamental drivers of adoption [38-41]. Therefore, incorporating subjective criteria, such as perceived ease of use, into the testing process could enhance tool adherence and improve health outcomes [42]. However, it is important to recognize that moderating factors such as a person's age, education, and digital skills can influence their assessment of a technology's perceived ease of use and overall usefulness [38].

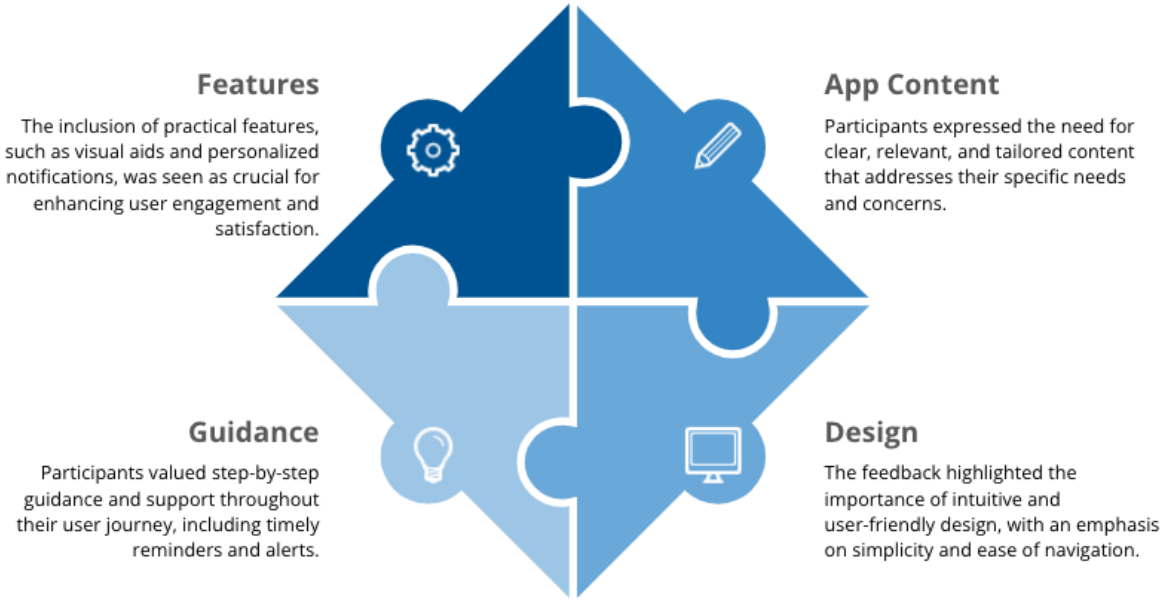
Although participants rated the app highly for both ease of use and usefulness, they also offered several suggestions for improvement. For instance, they recognized that preparing for a colonoscopy involves multiple complex steps during the week leading up to the appointment. They expressed a desire for the app to send timely reminders to guide users throughout the process, aligning with findings from previous similar research [27]. Reminders are likely crucial for the effectiveness of the app. In fact, a randomized controlled trial found that without reminders the app group had the same quality of bowel cleanliness as the control group [21]. Previous studies have demonstrated that personalized reminders and alerts enhance the adoption of electronic health technologies, effectively modifying various health behaviors [43].

The app content was generally well received for its clarity and ease of understanding. However, there were a few requests for improved clarity or accuracy in certain areas, as detailed in the Results section. Additionally, users identified some content gaps in the tested prototype. Specifically, they requested more comprehensive guidance on how to take the laxative and minimize the unpleasantness of the experience. Furthermore, there was a need for information addressing post-colonoscopy issues. This latter finding aligns with similar research; for instance, Sewitch et al [27] also highlighted the perceived importance of post-colonoscopy information among potential users. Their study similarly underscored the need for detailed guidance on what to expect and how to manage any subsequent issues after the procedure. This is especially pertinent considering that statistics reveal approximately 25% of patients experience a minor adverse event within 48 hours of a colonoscopy, and 0.5% encounter a serious adverse event within 30 days [44].

Participants indicated a need for more detailed, step-by-step guidance on using the app. They sought clear instructions on the use of entering specific information, such as their procedure date and time, and how to effectively use the app to prepare for their examination. This feedback aligns with the extensive literature emphasizing the importance of user training and guidance to enhance adoption rates [38]. Introducing an app tour with guided notes detailing each section, coupled with clear instructions on features such as adjusting font size, could greatly enhance the overall user experience. This initial guidance would make it easier for users to understand how to navigate the app and maximize its use right from the start. Research suggests that users' perception of ease of use can be significantly improved with high-quality training materials that guide them on how to effectively optimize these technologies [38,45,46].

Participants expressed a strong preference for more visual and interactive content, as well as a navigation design that prioritizes personalized information, such as the preparation timeline. They expressed a desire for information to be presented clearly at every stage of the colonoscopy preparation process. This feedback is consistent with previous research, which underscores the critical role of design elements and personalization in achieving successful patient adoption of digital health tools [38]. Several studies have specifically highlighted the importance of personalization. For example, a lack of customization options to meet individual needs can result in lower adoption rates or even abandonment of the tool [38,47]. Figure 2 provides a summary of our findings regarding user preferences for app design, content, features, and guidance. These insights will help boost the app's usability and functionality, ultimately improving user adoption.

Figure 2. Key areas for app improvement.



The next step will involve a thorough prioritization and impact assessment, where improvements according to urgency and feasibility will be ranked to guide a targeted development plan. For example, the usability testing results indicate that features such as push notifications and personalized content are top priorities for the participants. These will be addressed at the start of the next development cycle to ensure they are optimized before moving into real-world testing.

Limitations and Future Research

While the practical insights from participants regarding the app prototype were valuable and guided us in making important modifications, it is important to acknowledge several limitations. Using the think-aloud methodology, there is a potential for reporting bias where participants may shape their responses to align with perceived researcher expectations; additionally, participants might selectively verbalize thoughts that align with what they believe interviewers want to hear, known as social desirability bias [48]. To address these potential biases, moderators were trained to actively encourage participants to provide verbal feedback and to collect observational data. These observations were used alongside participants' subjective feedback during data analysis.

While the sample size of this study may appear small, previous research indicates that 80% - 90% of usability issues in websites and apps can be identified with 5 to 9 participants [49,50]. During the individual think-aloud sessions, recurring themes emerged, suggesting data saturation was achieved [32]. However, it is possible that additional participants could have uncovered different usability issues and provided diverse perspectives. Looking ahead, the app has promising potential as a companion for colonoscopy examinations. However, conducting larger-scale studies in real-world environments will be essential to validate and optimize its value and effectiveness.

Conclusions

Overall, participants expressed satisfaction with the app's usability. The think-aloud sessions provided real-time insights into the app's appeal, relevance, and use. Minor adjustments to the prototype's functionality were identified as necessary to enhance usability. Feedback and suggestions from participants have been integrated into the final app design. The initial findings from this usability study indicate that the app holds promising potential as a companion for colonoscopy examinations. This work establishes the foundation for further research to evaluate usability and feasibility among a larger, real-world population.

Acknowledgments

This study was sponsored by Innosuisse (Swiss Innovation Agency, grant 70325.1 INNO-ICT). The role of Innosuisse is to promote science-based innovation in the interests of industry and society in Switzerland. We extend our gratitude to the 3 institutions that were instrumental in recruiting the study participants: Clarunis (the University Digestive Health Care Center of St. Clara Hospital and University Hospital Basel), GGHA (Geneva Gastroenterology & Hepatology Associates SA), and EUPATI Switzerland (European Patients' Academy on Therapeutic Innovation).

Data Availability

The data that support the findings of this study are available from the corresponding author upon reasonable request. Restrictions may apply to the availability of some of these data due to, for example, privacy and ethical reasons.

Conflicts of Interest

AR and GR are cofounders of Gimini Biosciences SàRL, the technology provider developing the application being studied. CJ is an editorial board member of *JMIR Human Factors* at the time of this publication. The other authors have no conflicts of interest to declare.

Abstract

Background: Emergency and acute medicine doctors require easily accessible evidence-based information to safely manage a wide range of clinical presentations. The inability to find evidence-based local guidelines on the trust's intranet leads to information retrieval from the World Wide Web. Artificial intelligence (AI) has the potential to make evidence-based information retrieval faster and easier.

Objective: The aim of the study is to conduct a time-motion analysis, comparing cohorts of junior doctors using (1) an AI-supported search engine versus (2) the traditional hospital intranet. The study also aims to examine the impact of the AI-supported search engine on the duration of searches and workflow when seeking answers to clinical queries at the point of care.

Methods: This pre- and postobservational study was conducted in 2 phases. In the first phase, clinical information searches by 10 doctors caring for acutely unwell patients in acute medicine were observed during 10 working days. Based on these findings and input from a focus group of 14 clinicians, an AI-supported, context-sensitive search engine was implemented. In the second phase, clinical practice was observed for 10 doctors for an additional 10 working days using the new search engine.

Results: The hospital intranet group (n=10) had a median of 23 months of clinical experience, while the AI-supported search engine group (n=10) had a median of 54 months. Participants using the AI-supported engine conducted fewer searches. User satisfaction and query resolution rates were similar between the 2 phases. Searches with the AI-supported engine took 43 seconds longer on average. Clinicians rated the new app with a favorable Net Promoter Score of 20.

Conclusions: We report a successful feasibility pilot of an AI-driven search engine for clinical guidelines. Further development of the engine including the incorporation of large language models might improve accuracy and speed. More research is required to establish clinical impact in different user groups. Focusing on new staff at beginning of their post might be the most suitable study design.

Introduction

In making decisions about patient care, clinicians frequently are faced with queries and are often unable to retrieve answers to them in a timely fashion. A systematic review [1] estimates that the per-patient frequency of queries raised by clinicians ranges from 0.4 to 0.8 per patient and that about two-thirds of these queries are left unanswered. This picture has been fairly stable over time despite the broad availability of web-based evidence resources that can answer these questions. Unanswered

questions may lead to suboptimal patient care decisions and are missed opportunities for timely learning and practice improvement.

Medwise.ai is a solution codeveloped with Betsi Cadwaladr University Health Board), which helps clinicians find answers quickly from local guidelines and provide seamless and just-in-time access to high-quality evidence in the context of patient care decision-making in the clinical environment. A previous study [2] has demonstrated that smartphone apps can increase the speed to access guidelines when compared to using desktop computers. However, access to guidelines does not equate to finding answers to clinical questions quickly and effectively at the point of care. The Medwise.ai platform can collate local clinical guidelines and break them down into chunks of content that can be retrieved using natural language processing and information retrieval technologies as bite-sized answers for clinician's questions. We conducted a time-motion analysis, comparing cohorts of junior doctors using an artificial intelligence (AI)–supported search engine and the traditional hospital intranet, to examine the impact of the AI-supported search engine on participant time and workflow when seeking answers to clinical queries at the point of care. The secondary end points of our study were to assess whether effective question answering could lead to a better quality of work life and improve confidence in decision-making for the end user.

This study aimed (1) to gain user feedback for a novel context-specific proof-of-concept search engine and (2) to measure the time required to retrieve clinically relevant information with a novel engine compared to other search engines in the setting of hospital emergency care.

Methods

Study Design

We conducted a prospective direct pre- and postobservational pilot study in teams caring for medical emergency admissions examining the impact of access to Medwise.ai, a clinical query answering platform, versus information retrieval from guidelines saved on the hospital intranet using time-motion study methodology [3].

Study Setting

The study took place at the Ysbyty Gwynedd, Bangor. The Ysbyty Gwynedd is a district general hospital in North Wales with 550 beds covering all major specialties, including a dialysis unit and a 13-bedded critical care unit. Clinicians from 2 units in the hospital were recruited; the acute medical unit has 23 beds and is complemented by a same day emergency care unit for low-risk admissions.

Both units receive direct admissions from primary care and work closely with the emergency department (ED) to manage acute medical presentations. It is important to note that the traditional boundaries between emergency care and acute medicine have become less distinct in recent years due to increasing hospital overcrowding in the United Kingdom. While historically, patients were first seen in the ED by emergency physicians and then referred to the Acute Medical Unit for care by acute and general physicians, many acute and general medical teams now also work within the ED to manage the flow of acute medical patients.

During the day shift (8 AM to 8:30 PM), the on-call team consists of 4 doctors in training (a newly qualified foundation year 1 doctor, 2 core medical trainees with 1‐4 years of experience, and 1 medical registrar with 4 or more years of clinical experience and membership of the Royal College of Physicians) and an on-call consultant with a full specialist qualification. The sole task of the on-call team is the care of emergency admissions and emergencies of inpatients. Patients seen by doctors in training are subsequently reviewed by a consultant as part of the posttake ward round.

Intervention

Medwise.ai is a proof-of-concept search engine combining well-established information retrieval techniques with textual question answering and trained models that determine the best answer within a document. The search platform is available to the participating clinicians over a web app accessible via mobile web browser on both Android and iOS devices. Research staff trained the onboard clinicians and helped to install the Medwise.ai search on the participating clinicians' mobile devices ahead of observations.

Content development for Medwise.ai was informed by informal interviews (Multimedia Appendix 1) with staff and a single focus group, consisting of 14 participants, to identify relevant local guidelines and standard operating procedure documents to be included in the Medwise.ai platform, thus ensuring user buy-in and optimal functionality of the Medwise.ai platform. The local documents shared with Medwise.ai were in PDF or Microsoft Word format. It is important to note that searches using Medwise.ai were limited by the content available in the local repository; if the content did not exist within this repository, the AI would not be able to provide answers to queries. It should be noted that the underlying AI model's technical performance was not the focus of this study.

Research Procedure

A dedicated and trained member of the research team shadowed trainee doctors for 20 complete working days: observation days included 10 days without and 10 days with access to Medwise.ai. The 2 groups of participants were not matched for the hospital intranet versus AI-supported search engine using groups.

Doctors reviewed new admissions and conducted unscheduled reviews of previously admitted patients: the doctors were aware that they were observed, and written consent was taken prior to commencing the direct observation. The observed activity of doctors was entered into a work diary. For practical reasons, all observations were undertaken during office hours.

Sampling and Recruitment

The sample size was chosen pragmatically based on experience with previous time-motion studies [4]. Doctors working as part of the acute medical take throughout Ysbyty Gwynedd were recruited. To be included, participants had to be willing and able to give informed consent for participation in the study, be in possession of a smartphone to access web-based content, be permanent or locum staff, and be qualified as a doctor of any

grade. Participants had the right to withdraw from the study at any time. Participants received vouchers with a value of US $50 for participation in the study. Doctors who were only part of the clinical team for 4 hours or less were excluded from recruitment.

Candidates were approached by the principal investigator (CPS) or the dedicated research team member. Notification of the study was undertaken through existing WhatsApp groups and a Junior Doctors' Forum. Inclusion and exclusion criteria were identified during the initial screening.

Assessments

Participants' gender, specialty, grade, duration of work in their current post, and duration of clinical practice were recorded. Participants were shadowed for the duration of a shift but for a minimum of 6 hours per study day. Shadowing did not include times when doctors were consulting or examining patients.

Task duration for clinical queries was measured in minutes. Tasks were classified using a standardized list. Observed searches for information were classified by clinical content (diagnostic category, diagnostic pathway, treatment protocols, prognostication, scoring systems, normal values, and accessed data source). Confidence in decision-making was assessed at the end of each working day using a validated scale for self-assessment [5]. Confidence in decision-making and user satisfaction were measured using the Likert scale (How satisfied are you with the Medwise.ai product? On a Likert scale of 1-10) and the Net Promoter Score (NPS) [6] (How likely are you to recommend Medwise.ai to a friend or colleague?). NPS is a validated score that is used to measure user satisfaction. It is widely used in industry as a benchmark for comparing products within different industries. A positive NPS is considered as good, a score above 20 as favorable, and above 50 as excellent. Participants were also asked for suggestions for improvements of the platform.

Data Management and Statistics

Statistical analysis was primarily descriptive including key data items related to the frequency of clinical searches, the subject of such searches, the time taken for the searches, and graded feedback in relation to the app. Data were recorded on paper case report forms and subsequently transcribed into a Microsoft Excel database for further analysis. Data were anonymized through the removal of name, case report number, and age.

The comparison was made between the events during 10 observed shifts without the app and 10 observed shifts with the app. Diary data and data from questionnaires were analyzed using SPSS (IBM Corp). Kernel density plots were used to visualize the differences in observed task duration; Welch *t* test (2-tailed) was used to determine whether the apparent differences in distribution were likely to have occurred due to random chance or were due to a real difference in the mean task duration.

Given the sample size and the unknown baseline distribution of the variables in question, statistical comparison data from this study might inform subsequent power calculations for related research or a definitive trial.

Ethical Considerations

National Health Service (NHS) Research Ethics Review was not required as the study involved staff only as participants. The study was approved through Health and Care Research Wales and the Health Research Authority. No adverse events were anticipated. However, monitoring was in place in line with the sponsor safety reporting standard operating procedure. Data from focus group meetings were anonymized and deidentified. Written informed consent was given by all members of staff who were observed during the assessments. Participants were reimbursed with £50 (US $61.92) retail vouchers according to local regulations.

Results

Demographics and Baseline Characteristics

All assessments were undertaken between November 17, 2022, and February 8, 2023 (hospital intranet period) and July 6 and 27, 2023 (AI-supported search engine period).

The hospital intranet and AI-supported search engine groups both comprised 10 doctors each with 5 and 7 female doctors, respectively. The hospital intranet group had a median clinical experience of 23 months. Of these, 6.1 months were in their current specialty. The AI-supported search engine group had a median of 54 months of experience. Of these, 9.6 months were in their current specialty. No statistically significant differences between mean time in current specialty were observed between the groups (t=−1.01; 95% CI −11.4679 to 4.0179; P>.05).

Focus Group

The focus group was held on April 5, 2023, after the completion of the hospital intranet period. In total, 14 clinicians participated including foundation year 1 and 2 doctors, registrars, physician associates, and 3 consultant physicians. Participants were asked a list of prepared questions in relation to search habits, preferred information sources, and views about search engines (Multimedia Appendix 1).

Contributors discussed sources of information that they use for their clinical practice and recommended examples of web resources from other NHS organizations. Pros and cons of alternative models of information provision including share point sites were debated. Clinicians commented on the difficulties to find the right locally authorized resources in locations of the internet and intranet. On the other hand, they valued that Medwise.ai guidance is relevant for the organization in which the search is undertaken. Participants discussed their experience of using resources from other UK and international organizations if there is no identifiable local guidance for a topic. Doctors were concerned that Google searches might identify sources that contain misinformation. The challenge of identifying the right information in real time was described as crucial during the time pressures of acute and emergency care.

Descriptives

Overall, 67 searches were observed in the hospital intranet and 39 searches in the AI-supported search engine period. The mean number of clinical searches performed per shift was 6.7 (SD 3.43) in the hospital intranet group and 3.9 (SD 3.00) in the

AI-supported search engine group. Mobile phones were used for 40 of 67 (60%) searches in the hospital intranet group and 34 of 39 (85%) in the AI-supported search engine group. In the hospital intranet group, 11 searches were via Google. Other sources included apps, the British National Formulary, National Institute for Health and Care Excellence guidelines, and local guidelines. In the AI-supported search engine group, no search required Google.

Searches covered a large number of topics (Multimedia Appendices 2 and 3). The most commonly searched topics in both groups were medication-related (n=18 and n=10, respectively).

Participants in the AI-supported search engine group commented on the impact of Medwise.ai on workflow using free-text responses (Textbox 1).

Textbox 1. Free-text feedback provided by users collected at the end of observation.

"With more training [training of the AI system] this could be very helpful in speeding up carrying out jobs. Bit unfortunate study was carried out in final weeks of rotation, when doctors are the most comfortable with systems and need to search things very rarely" [Participant 1].

"Can see it has the potential to increase speed of doing jobs, thus means we see patients quicker" [Participant 2].

"May expediate time available for patient care if brings up more precise answers. When I know where to find the answers it is easier to go straight to the source" [Participant 3].

"As you get your answers under one second from hospital protocol, it saves time and helps you see more patients. also can provide more time for patient care rather than looking for protocol and guidelines in each app, it will be all in one. Highly recommended" [Participant 4].

"Probably not much difference. Perhaps better used in GP. I think it would be more useful in GP. In hospital it is okay but not majorly useful. I think over all it would be a good idea. But I think I search for stuff more in GP. I think overall ED staff would use it most in hospital" [Participant 5].

"Easy availability of resources saves up time and causes less disruption to the flow of clerking. Easy access to BCU/local guidelines is very helpful as some of these are difficult to find on the intranet. Great idea; would be really helpful" [Participant 6].

"Will reduce search time for searching guidelines resulting in more time for patient care. And all in one place makes it easy to find [information]. I am surprised that I have not needed to access my phone/ the app as yet today as this is unusual. Would usually look at betsinet multiple times during a shift for electrolyte levels. I anticipate that this app would be useful" [Participant 7].

"Makes it easier to search for relevant guidelines/policies/pathways etc. Easy and quick to use. User friendly. Appears to work well for searches during work time. Quickly found everything I searched for" [Participant 8].

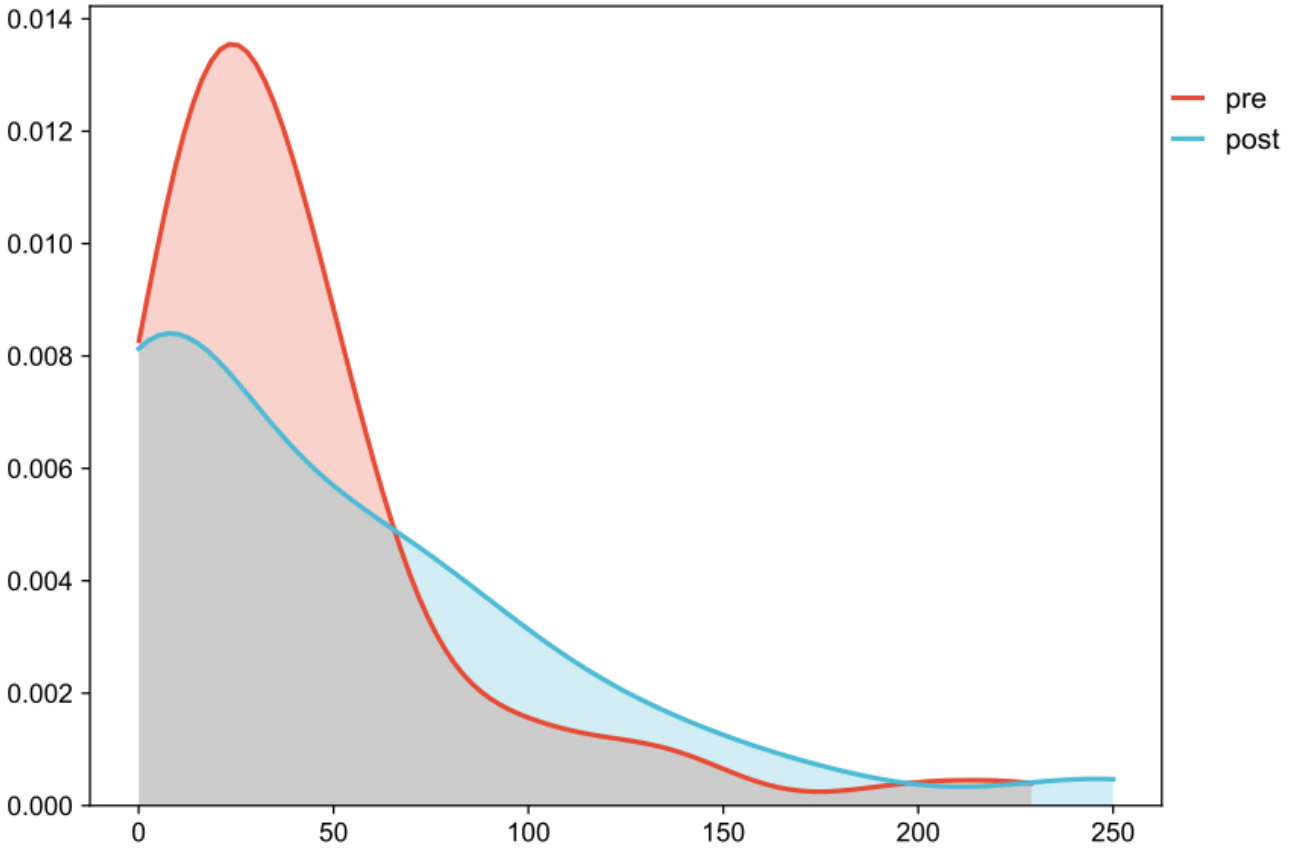
"Will help find relevant guidelines much more quickly, which will make work more efficient" [Participant 9].

"Directed me to mdcalc which I already use as an app. No impact on above criteria (workflow, number of patients seen and time for each patient). Would be more useful to have easy access to trust guidelines such as electrolyte imbalances and chest pain etc." [Participant 10].

Comparison of Groups

Comparison of the 2 groups revealed that searches in the hospital intranet group had shorter search times than in the AI-supported search engine group (41.4 vs 88.1 seconds, respectively; Welch t=4.06; 95% CI 20.30-59.09; P<0.05). The differences in the observed task duration are presented as Kernel density plots in Figure 1. There were no statistically significant differences between the groups with regard to user satisfaction (Welch t=0.75; 95% CI −1.2607 to 2.6607; P>.05) and likelihood of a search result solving the query (χ^2=2.2; 95% CI −3.24% to 27.45%; P>.05). Participants of the AI-supported search engine group were likely to recommend Medwise.ai to a friend or colleague as reflected in their NPS of 20 (40% promoters and 20% detractors).

Figure 1. Kernel plot of the duration of searches pre (hospital intranet) and post (artificial intelligence–supported search engine) phase.



Overall, the group using Medwise.ai spent longer searching for information, and their searches were not more likely to be successful compared to the usual information retrieval methods.

Discussion

What We Have Shown

To the best of our knowledge, this is the first study to evaluate the impact of an AI-based information retrieval system on clinical workflow in acute hospital care. The design and implementation of a clinical information search engine integrating intranet- and internet-based information resources using machine learning was feasible and well-received by participants.

Searches in this small sample were not faster, and there was no higher likelihood of a successful search result. Despite this, doctors believe Medwise.ai has the potential to improve efficiency and workflow in the future and hence highly recommended the digital tool to their colleagues.

Strength and Weaknesses

One of the strengths of our study is that it uses objective measures of efficiency including search times and search outcomes rather than relying on self-reported questionnaire data from users. This mitigates recall bias. Additionally, the free-text feedback from users provided useful insights in that it shows that despite Medwise.ai's limitations, the users were optimistic about its potential in the future and expressed views in favor of its implementation in clinical workflow, as evident in quotes in Textbox 1.

It is worth noting that no specific training in evidence searching was provided to the participants beyond what they would have received as part of their usual medical education. This lack of additional training could be seen as both a strength and a limitation of our study. On one hand, it reflects the real-world scenario where clinicians often rely on their existing search skills when using new tools. This approach allows for a more authentic assessment of the AI-supported search engine's usability and effectiveness in a clinical setting. On the other hand, it raises questions about whether targeted training in evidence searching or in using the new platform might have improved search efficiency and outcomes. The ideal search engine should require minimal introduction or training, but understanding its functionality could potentially enhance search yields. Future studies might consider comparing the performance of users with and without specific search training to better understand the impact of such preparation on the effectiveness of AI-supported search tools in clinical practice.

The initially unfamiliar user interface could have been a significant contributor to the longer search time. Additionally, the introduction of the AI-supported search engine occurred toward the end of the rotation when doctors were most confident about the processes and management of patients. Participants had spent an average of 8 months in their current specialty, throughout which they would have regularly used traditional information retrieval sources.

Our observations and user feedback highlighted several areas for potential improvement in future iterations of the AI-supported search engine. First, we recognized that the platform was initially developed for desktop use, but mobile

access emerged as the preferred method in the acute care setting. In response, the platform's developers are working on a mobile-first version, including dedicated iOS and Android apps, as well as access via a chatbot interface on WhatsApp. This adaptation aims to improve user experience and reduce search times. Additionally, we noted that the more experienced intervention group might have been less accustomed to new digital formats, potentially impacting their interaction with the novel interface. To address this, future iterations could incorporate more intuitive design elements and provide brief, targeted training to familiarize users with the system's capabilities.

In our pilot, Medwise.ai was neither more nor less efficient, successful, or satisfying to users than traditional information retrieval sources. Searches using Medwise.ai were limited by the content available: if content did not exist within the local repository, then the AI will not be able to provide answers to queries. Finally, the local documents that were shared with Medwise.ai were in PDF or Microsoft Word format. Further development to transform these documents into more machine-readable formats with seamless integration with the search could further improve the performance of the Medwise.ai search engine. Like all AI-based tools, Medwise.ai's performance is contingent upon the quality and quantity of data used to train the tool. As the bank of searches builds up over time, Medwise.ai would be able to offer easier and faster access to reliable local guidelines.

The effectiveness of the search engine is dependent on the underlying AI models' performance. Although not a focus of this study, it is an area for future attention, particularly with the growing use of large language models.

What Others Have Shown

The NHS Long Term Workforce Plan [7] emphasizes the need to leverage the power of AI to improve efficiency and workflow. This case study is an example of a technological innovation to improve work efficiency with the end goal of improving patient care. It contributes to the literature focusing on evaluating the potential of AI-based technologies to improve service provision in the NHS [8-10].

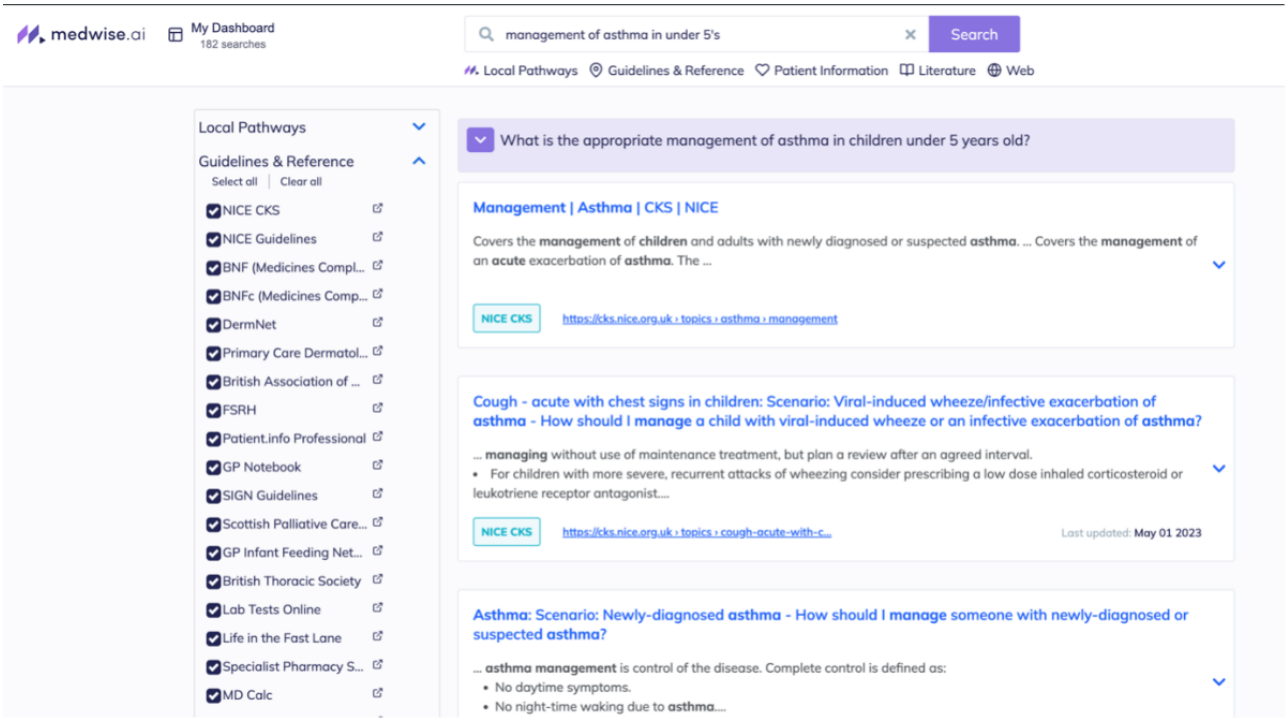
Clinical Implications

The search engine was implemented successfully during this trial. With the clear hierarchy of information sources, Medwise.ai might represent a source that has higher utility for clinicians at the bedside than public search engines such as Google or Safari. While it has been hypothesized that AI could aid to bring clinical guidelines to routine consultations [11], clinical apps remain scarce [12]. Moreover, evidence suggesting a significant reliance on colleagues and internet websites for information retrieval during shifts makes a strong case for the need for easy-to-access evidence-based local guidelines [13].

Research Recommendations

Given the small sample size and the unknown baseline distribution of the variables in question, statistical comparison is expected to be of limited value. A larger study with randomization of doctors at the beginning of rotational posts might provide a more robust assessment. The authors believe that less experienced clinicians (foundation year 1 trainees or advanced nurse practitioners in their first year of practice) would rely heavily on digital information sources and would be equally unfamiliar with other information retrieval methods and might hence be the most suitable group to evaluate effects on decision-making, safety, and possible clinical impact. More recent developments in AI such as large language models have shown the ability to encode clinical knowledge and answer medical questions [14]. Integrating these into the Medwise.ai engine might improve accuracy and speed. In the proof-of-concept platform, a full-text, query-augmented, retrieval engine configured and tuned for medical searches was used (Figure 2). No large language models were used. Further research is needed to evaluate how the accuracy and performance of the proof-of-concept search engine could be improved by incorporating large language models into the engine.

Figure 2. An image of the platform's search reply.



Conclusions

Implementation of Medwise.ai was feasible. In this small pilot study of an AI-supported search engine, we did not demonstrate increased workflow efficiency, search success, or satisfaction when compared with searches using the traditional hospital intranet. However, doctors in training believed the solution has the potential to do so in the future and hence recommend its implementation in clinical workflow. With added source content and integration of the Medwise.ai search with the next generation of AI large language models, it is likely that more benefits will be realized.

Acknowledgments

Marie Latham-Jones and Lynne Grundy were instrumental in establishing the connection between Betsi Cadwaladr University Health Board and Medwise.ai. Laura Longshaw was the driving force behind the progress of this grant. Without her encyclopedic knowledge of research frameworks, forensic attention to detail, unmeasurable patience, and immense commitment, the authors would not have succeeded. Without Gareth Jones' contribution to the recruitment of participants in the artificial intelligence–supported search engine group, the study would not have been completed on time. A big thank you! The study was funded through an Innovate UK grant administered through Medwise with Betsi Cadwaladr University Health Board as a coapplicant (Innovate UK grant application 10023176).

Conflicts of Interest

HLKT, LRUP, and MP are employees of Medwise AI Limited. The authors have no other conflict of interest.

Multimedia Appendix 2
Clustered column chart showing the distribution of search categories in the hospital intranet period (control) and artificial intelligence–supported search engine period (intervention). "General calc" comprised of calculating medication doses and converting units of measurements. "Interpreting invx" meant finding information about the significance of specific findings on investigations including plain films, electrocardiographs, and blood results. "Medication" meant medication-related information, that is, dose, route of administration, and interactions. "Scoring systems" meant users calculating prognostic scores including Well score. "Staff contact" meant looking up bleep numbers for other members of the health care workforce. "Term" meant looking up specific definitions. "Treatment protocol" meant treatment pathways for conditions and presenting complaints.

Abstract

Background: Colonoscopy is the standard diagnostic method for colorectal cancer. Patients usually receive written and verbal instructions for bowel preparation (BP) before the procedure. Failure to understand the importance of BP can lead to inadequate BP in 25%-30% of patients. The quality of BP impacts the success of colonoscopy in diagnostic yield and adenoma detection. We developed the "ColonClean" mobile health (mHealth) app for Android devices. It incorporates visual representations of dietary guidelines, steps for using bowel cleansing agents, and observations of the last bowel movement. We used the Technology Acceptance Model to investigate whether the use of the ColonClean mHealth app can improve users' attitudes and behaviors toward BP.

Objective: This study aims to validate the effectiveness of the ColonClean app in enhancing user behavior and improving BP, providing safe and cost-effective outpatient colonoscopy guidance.

Methods: This study uses a structured questionnaire to assess perceived usefulness, perceived ease of use, and users' attitudes and behaviors toward BP regarding the ColonClean mHealth app. A total of 40 outpatients who were physically and mentally healthy and proficient in Chinese were randomly chosen for this study. The data were analyzed using SPSS 25.0, and we used Pearson product-moment correlation and simple regression analysis to predict the perception of ColonClean.

Results: The results showed that 75% (30/40) of participants achieved an "excellent" or "good" level of BP according to the Aronchick Bowel Preparation Scale. Perceived usefulness and perceived ease of use of the ColonClean mHealth app were positively correlated with users' attitudes and behaviors (P<.05).

Conclusions: The ColonClean mHealth app serves as an educational reference and enhances the effectiveness of BP. Users expressed their willingness to use the app again in the future and recommend it to family and friends, highlighting its effectiveness as an educational guide for BP.

mobile health app; bowel preparation; nursing guidance; technology acceptance model; mHealth; mobile health

Introduction

Colorectal cancer (CRC) is the third most prevalent cancer and the second leading cause of cancer-related deaths worldwide [1-3]. Colonoscopy is the standard diagnostic method for colorectal cancer, and adequate bowel preparation (BP) is a necessary and crucial step to effectively examine the entire intestinal mucosa [4,5]. Currently, BP before colonoscopy is primarily provided by nurses through paper-based nursing instructions and oral explanations of relevant precautions [6,7]. This involves dietary restrictions and the use of bowel cleansing agents to remove feces from the colon and facilitate visual examination by physicians [8,9].

The explanations for BP are often lengthy, complex, and difficult to understand and remember. As a result, the proportion of inadequate BP ranges from 25% to 30% [10]. Poor BP could lead to 42% of adenomas and 27% of advanced adenomas not being diagnosed [11,12]. Inadequate BP also leads to a missed detection of 10.55% for sessile polyps [13], which can develop into CRC and are particularly difficult to identify as they lie flat on the mucosal layer of the colon [9]. Incomplete

colonoscopy increases the risk of cancer and requires repreparation, adding to health care resource costs [14-16].

The European Society of Gastrointestinal Endoscopy guidelines emphasize that good BP is essential for the diagnosis, treatment, and removal of tumors and precancerous lesions, as well as for the reduction of CRC incidence and its mortality rate. It ensures the quality, safety, and effectiveness of colonoscopy in the clinical examination environment. Adequate BP provides optimal visualization for physicians during the examination, facilitating the detection of polyps or other lesions [10,17].

During the COVID-19 pandemic in 2020, the need for a mobile health (mHealth) app became evident [18,19]. Currently, nursing instructions for BP mainly rely on paper-based materials accompanied by oral explanations, multimedia instruction CDs, or telephone interviews [20]. Using mobile apps can enhance patient education for bowel cleansing [21,22]. Therefore, our research team conducted a literature review and assessed current needs to design and build the "ColonClean" mHealth app for the Android operating system. The purpose of this study is to validate the effectiveness of the ColonClean mHealth app in enhancing users' attitudes and behaviors toward BP through the Technology Acceptance Model (TAM) by examining the correlations among perceived usefulness, perceived ease of use, usage attitudes, and actual usage behaviors. We aim for the ColonClean mHealth app to serve as a comprehensive and effective outpatient colonoscopy guidance tool, ultimately improving the effectiveness of BP.

Methods

Ethical Considerations

This study is an interventional investigation conducted in accordance with research ethics regulations. Approval from the Institutional Review Board of Taipei Veterans General Hospital was obtained prior to the commencement of the study (approval number 2021-10-007AC). The study was conducted from October 27, 2021, to December 31, 2022. Before enrolling participants, the purpose and details of the study were explained to them, and they provided informed consent by signing a consent form. Throughout the research process, all participants' privacy rights were strictly protected, and the collected data were used solely for research purposes. Participants were not compensated for their participation in this study.

Study Participants

G*Power 3.1.9.7 for Windows was used to analyze the questionnaire data, considering a power (1-β) of 0.8, α value of .05, a medium effect size of 0.3, and an estimated dropout rate of 20%. As a result, a sample size of 40 participants was determined. A total of 40 outpatients from the gastroenterology and endoscopy center of the medical center were recruited. The inclusion criteria were patients aged 20 years or older, recommended by physicians to undergo colonoscopy, without visual or hearing impairments, and without mental illnesses. After explaining the purpose and content of the study and obtaining written informed consent, paper-based nursing instructions were provided along with verbal explanations of ColonClean, and the BP was conducted. For easy access to ColonClean, the participants downloaded the ColonClean mHealth app on their mobile devices after scanning a QR code. The nursing instruction process involved 1-on-1 teaching, with an explanation lasting approximately 20 minutes in the independent waiting area outside the outpatient visit room. Each research participant was asked to submit feedback on their experience with ColonClean within 3 days of their colonoscopy.

mHealth App (ColonClean)

Individuals aged ≥50 years are the target group for CRC screening, making them the primary users of the ColonClean mHealth app. Considering the physiological and cognitive decline in older adults, it is crucial to design a user-friendly interface to avoid difficulties in usage. The interface design for older adults incorporates intuitive elements, clear and concise text, and straightforward operational steps [23]. Contrast colors were used for interface color schemes. The operational methods are simple and clear, with functions executed through clicks or straight-line swiping gestures [24,25]. All features were designed to operate within a single page, avoiding menu structures with more than 2 layers of information. This design reduces the psychological pressure on older adults, who may be afraid of making mistakes due to an unfamiliarity with technology; this allows them to focus and read the important information comfortably. Handwritten or voice inputs were preferred for filling in the forms. Clear return or cancel buttons were placed at the top or bottom of the screen. Considering the characteristics of the users, the emphasis was on interaction and feedback rather than simple page browsing to enhance the impression of BP.

The ColonClean mHealth app was developed using the Android 11 operating system due to its low development cost and popularity among the general public [26]. The user interface and content were designed using the Android app package, the Java programming language, and a built-in database.

The screen display of ColonClean is divided into 3 sections: top, middle, and bottom in a single-page layout for the main screen. The top section displays the "Examination Date and Time." The middle section features 6 key topics arranged in a zigzag pattern based on their importance. From left to right, these topics include "Dietary Guidelines," explaining the necessary dietary education starting 3 days before the examination as shown in Figure 1, and "Laxative Use," explaining the use of bowel cleansing medication. The "Fluid Intake" screen is for recording the amount of fluid consumed (Figure 2), while the "Stool Image Recognition" screen is for providing images to identify the type of the last bowel movement (Figure 3).

Figure 1. Representative images of “Dietary Options” in ColonClean.

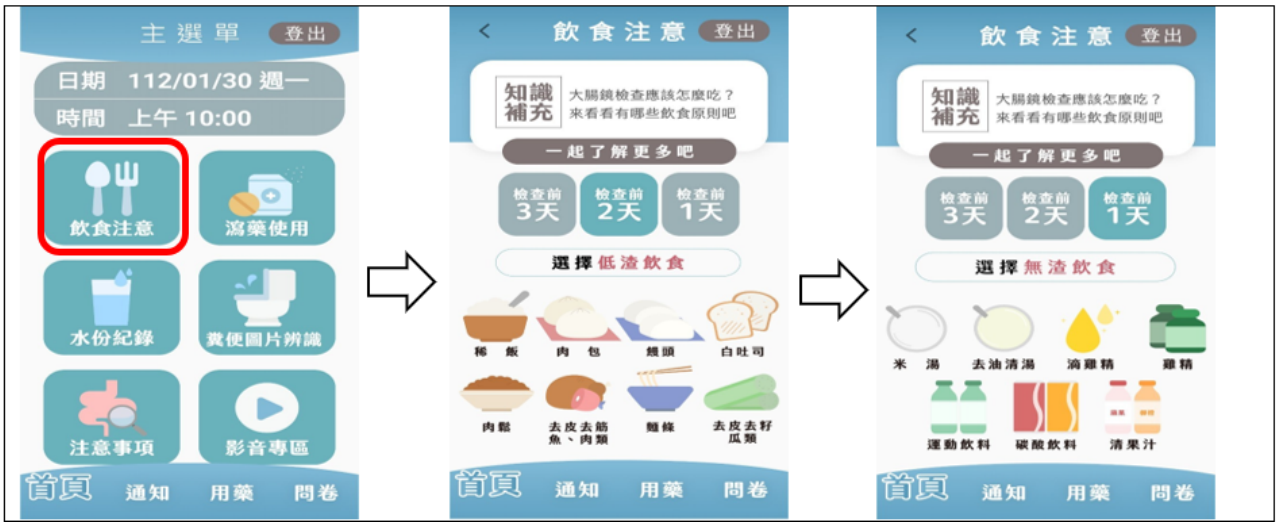

Figure 2. The “Hydration Intake Record” in ColonClean. Bowel preparation requires plenty of fluid intake to facilitate the passage of feces from the bowel.

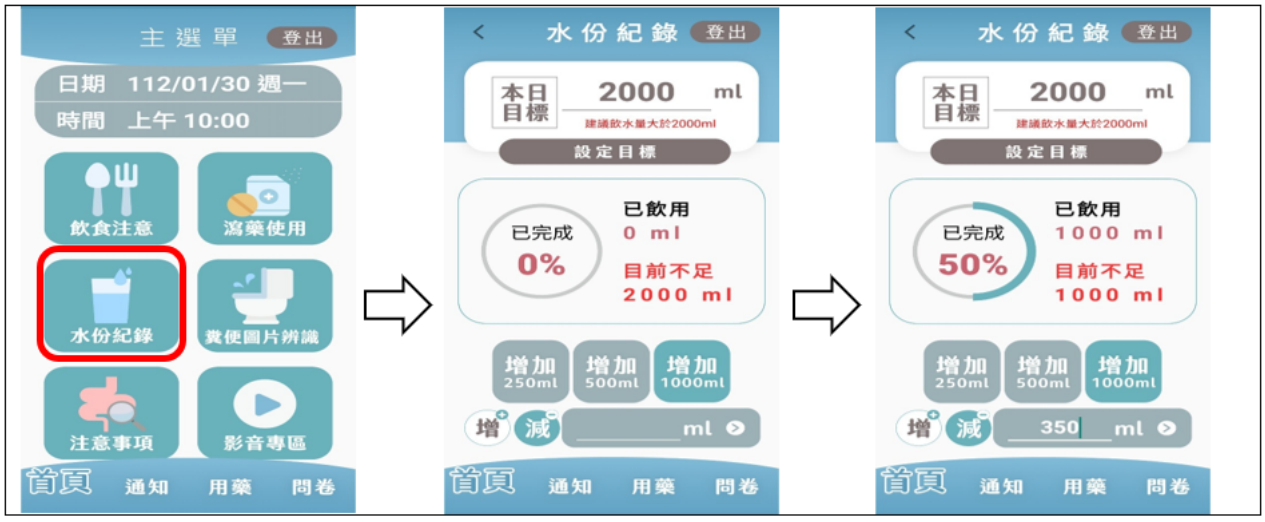

Figure 3. Images of the “Last Bowel Movement Type” section of ColonClean.

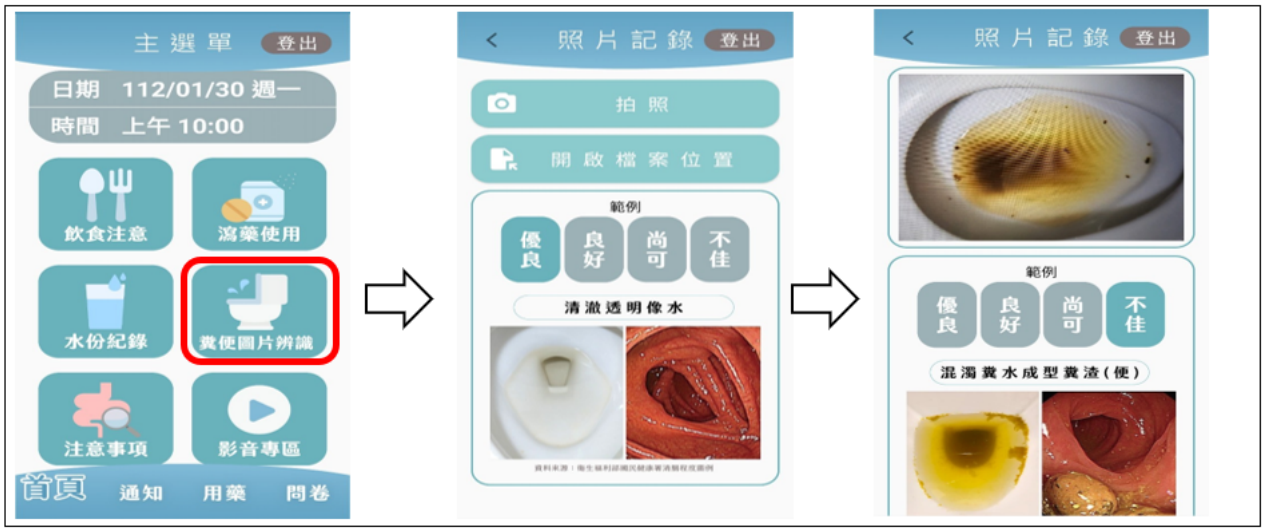

“Precautions” explains important points to keep in mind. The bottom section of the screen, from left to right, includes the “Home” button to return to the main screen; “Notifications,” which displays text messages; “Medication,” which provides

settings and modifications for regular medication or bowel cleansing agents; and "Questionnaire," which allows users to provide feedback on their experience using the ColonClean mHealth app.

The ColonClean app sent reminders and notifications to participants in the experimental group starting 3 days before their procedure. These notifications advised participants to begin dietary restrictions, such as avoiding high-fiber fruits and vegetables. Two days before the procedure, the app reminded users to switch to a low-residue diet, focusing on foods like congee or plain white noodles. The day before the procedure, the app prompted users to follow a clear liquid diet, including oil-free broth and sports drinks, and provided instructions on taking BP medications.

The app utilizes tap and swipe gestures for navigation; for user registration, it supports built-in Chinese phonetic input or handwriting recognition on mobile devices. The interface features a fresh color palette, primarily a warm lake green. Key information is highlighted in red, and unnecessary content is removed to offer concise summaries. Unique icons are designed as entry pointers to access relevant content. Tapping on an icon triggers entry into the main menu, which includes dietary guidance, instructions on using bowel cleansing agents (via images and videos), precautions for a colonoscopy, and fluid intake records, and provides references to the type of last bowel movement for understanding the differences compared to that during endoscopy. The design allows users to navigate intuitively, freely scrolling, tapping, and browsing related content between pages [27,28]. Push notifications are recommended to include instructions or prompts. Therefore, through push notifications, users are informed about relevant BP information to avoid any execution errors. Considering the user groups are middle-aged and older adults, complex actions are avoided. Instead, the key content is displayed directly in the push notification message. When a notification is received, users can click on the pushed message, which leads them to the relevant page with clear instructions or recommendations to view more detailed content. This approach reduces the chance of users misunderstanding the message. The user-centered push notification feature for BP steps enhances user engagement [29,30].

Aronchick Bowel Preparation Scale

After completing a colonoscopy, the physician submits a rating of the BP level using the Aronchick Bowel Preparation Scale (ABPS) in the endoscopy report system [1,31,32]. The ABPS is one of the most comprehensive and commonly used scales to describe the visualization of the colon and assess the percentage of stool covering the entire colon mucosa to explain the state of BP [33]. Based on this assessment, the adequacy of bowel cleansing is graded as excellent, good, fair, poor, or inadequate [11,33-35]. In Taiwan, domestic quality indicators for colonoscopy align with ABPS standards, targeting a 90% or above rating for both "excellent" and "good" categories. This ensures a high standard of care in colorectal screening, enhancing procedural accuracy and improving patient outcomes [36,37].

TAM

The TAM explains the behavior of users accepting new information technology in the field of computer technology [38]. Perceived usefulness and perceived ease of use affect users' attitudes toward adopting new technology, thereby influencing willingness and usage behavior. The perceived ease of use, perceived usefulness, attitudes, and behavior of outpatient endoscopy patients toward the ColonClean mHealth app were evaluated to assess their acceptance of using it. The questionnaire adopted a 5-point Likert scale. The 4 dimensions assessed by outpatient endoscopy patients after using ColonClean were perceived ease of use, perceived usefulness, attitudes, and usage behavior. The response options ranged from 1="strongly disagree," 2="disagree," 3="neutral," 4="agree," to 5="strongly agree." Higher scores indicated a higher level of agreement, while lower scores indicated a lower level of agreement. The questionnaire was initially developed based on literature references [39]. Three nursing informatics experts and scholars were then invited to evaluate the applicability and clarity of each question and to provide suggestions for improvement.

The Cronbach α coefficient was used to assess the internal consistency of the questionnaire items in this study. For the perceived usefulness dimension, consisting of 6 items, Cronbach α was 0.971. For the perceived ease of use dimension, consisting of 6 items, Cronbach α was 0.950. For the attitude dimension, consisting of 5 items, Cronbach α was 0.930. For the usage behavior dimension, consisting of 6 items, Cronbach α was 0.976. The questionnaire comprised a total of 23 items, and the Cronbach α coefficient for the scale was 0.986, indicating high internal consistency, meeting the requirement of a Cronbach α coefficient exceeding 0.7.

The structured questionnaire was designed and validated for reliability and validity by 3 nursing informatics experts. Participants accessed the questionnaire through a built-in link within the app, with the collected data stored in the backend management center for subsequent analysis.

Analysis

The data were analyzed using SPSS 25.0 (IBM Corp), with the utilization of the Pearson product-moment correlation and simple regression analysis to predict the perception of ColonClean.

Results

Demographic Characteristics

The demographic characteristics of the participants were as follows: 17 males (43%) and 23 females (58%); 27 participants aged ≥50 years (68%); and 35 participants with a high school/vocational education or above (88%).

ColonClean

After completing their colonoscopy, each research participant provided feedback on their experience with the ColonClean app within 3 days.. The feedback highlighted several key aspects of the app's design that contributed to user satisfaction and engagement:

- User-centered design: Participants appreciated the intuitive user interface, which maintained consistency in themes and main menu content. The clear and simple instructions, presented through a combination of text and visuals, facilitated user-friendly navigation. This consistency helped users feel more confident using the app.
- Examination date reminder: The feature displaying the examination date at the top of the main menu was well-received, as users felt it helped them stay organized and aware of the timing, potentially increasing compliance with preparation protocols.
- Graphic representations: Users found the unique graphic representations of dietary restrictions particularly helpful, as they enhanced understanding compared to traditional text descriptions. This visual approach was seen as effective in clarifying preexamination dietary options.
- Medication instructions: The clear, red-highlighted instructions for using bowel cleansing agents, along with drug images, dosage information, and timing, received positive feedback. Users appreciated the visual cues that simplified the medication process.
- Hydration tracking: Participants valued the hydration tracking feature, which encouraged them to monitor their water intake. Reminders to increase consumption when below recommended levels and positive feedback for meeting goals were highlighted as motivational elements that enhanced their commitment to the BP process.
- Bowel movement comparison: The option to take a photo of their last bowel movement and compare it with reference images was particularly beneficial. Users reported that this feature provided clarity on the required level of bowel cleanliness, enhancing their understanding of preparation requirements.
- Medication reminders and push notifications: The integration of medication reminders, particularly for chronic medications and anticoagulant discontinuation, was praised for preventing potential issues during the colonoscopy process. Users appreciated the timely push notifications that kept them informed about important tasks related to their preparation.

Overall, the research results indicated that users found the design of the ColonClean app effective in enhancing their understanding of and compliance with BP instructions. The app's focus on intuitive navigation, visual aids, and timely reminders contributed to a positive user experience, ultimately improving the effectiveness of BP for colonoscopy.

ABPS

After completing the colonoscopy, the BP level is reported by the endoscopist using the ABPS: 10 individuals (25%) achieved a "fair" level, 26 individuals (65%) achieved a "good" level, and 4 individuals (10%) achieved an "excellent" level. There were no cases of "poor" or insufficient preparation leading to interruption or inability to perform the examination.

TAM

Perceived Usefulness

The details of perceived usefulness are shown in Table 1.

Table . Perceived usefulness of the ColonClean app.

Perceived usefulness of the ColonClean app	Mean (SD)
Using ColonClean helps me quickly understand the tasks required for bowel preparation.	4.60 (0.59)
Using ColonClean provides easy access to relevant information about bowel preparation.	4.55 (0.68)
I believe that using ColonClean can improve the accuracy of my bowel preparation.	4.65 (0.53)
Using ColonClean enables me to effectively complete the required bowel preparation tasks.	4.65 (0.48)
ColonClean provides clear reminders about bowel preparation tasks, such as dietary restrictions and monitoring the type of my last bowel movement.	4.60 (0.59)
I find the educational information provided by ColonClean sufficient for completing my bowel preparation tasks.	4.65 (0.53)

The table presents users' perceptions of the usefulness of the ColonClean app in managing BP tasks. The mean scores, averaging around 4.62 of 5, suggest that users generally find the app very helpful. Below is an interpretation of the key findings:

- Understanding tasks (mean 4.60, SD 0.59): Users feel that the ColonClean app helps them quickly understand the requirements for BP, indicating clear and effective communication of instructions.
- Access to relevant information (mean 4.55, SD 0.68): The app is seen as a convenient tool for accessing important information about the preparation process. However, this metric has a slightly lower score, suggesting minor room for improvement in delivering information.
- Increased accuracy (mean 4.65, SD 0.53): Users believe that the app enhances the accuracy of their BP, reflecting a high level of trust in the app's guidance to meet medical standards.
- Effective completion of tasks (mean 4.65, SD 0.48): The app is viewed as highly effective in helping users complete BP tasks correctly, suggesting that it provides practical support throughout the process.

- Clear reminders (mean 4.60, SD 0.59): The app is viewed as highly effective in helping users complete BP tasks correctly, suggesting that it provides practical support throughout the process.
- Sufficient educational information (mean 4.65, SD 0.53): The app provides enough educational material for users to feel confident about completing their preparation, further supporting its educational role.

In summary, the ColonClean app was perceived as highly useful across various aspects of the BP process, with particularly strong scores for accuracy, task completion, and educational sufficiency. These results highlight the app's effectiveness in improving the user experience and promoting adherence to BP protocols.

Perceived Ease of Use

The details of perceived ease of use are shown in Table 2.

Table . Perceived ease of use of the ColonClean app.

Perceived ease of use of the ColonClean app	Mean (SD)
I think the interface design of ColonClean is clear and easy to understand.	4.63 (0.54)
I find the process of using ColonClean to be smooth.	4.63 (0.54)
It is easy to navigate and locate the desired functions in ColonClean.	4.63 (0.54)
I think the data presentation in ColonClean is quick and stable.	4.65 (0.58)
I find the font size in the ColonClean interface appropriate and easy to read.	4.53 (0.75)
The information provided by ColonClean makes it easier to understand the bowel preparation tasks.	4.68 (0.53)

Table 2 presents users' perceptions of the ease of use of the ColonClean app, highlighting their experiences with various interface features. The mean scores indicate a generally high level of satisfaction, with most ratings above 4.62 of 5, suggesting that users find the app intuitive and user-friendly. Below is an interpretation of the key findings:

- Clear interface (mean 4.63, SD 0.54): Users feel that the interface design is intuitive and user-friendly. This clarity in design is crucial for users' initial engagement with the app, suggesting that the developers prioritized usability.
- Smooth user experience (mean 4.63, SD 0.54): The app operates smoothly, without lag or issues, which is essential for encouraging continued use and satisfaction with digital health tools.
- Easy navigation (mean 4.63, SD 0.54): The ease of navigation suggests that users can quickly find the features they need, reducing frustration and enhancing overall satisfaction.
- Quick and stable data presentation (mean 4.65, SD 0.58): Users appreciate the app's rapid and reliable presentation of information. This reliability enhances user trust, which is particularly important in health care applications where accuracy is critical.
- Appropriate font size (mean 4.53, SD 0.75): Although the font size received a slightly lower rating, it still indicates that most users find it suitable. The slightly lower score suggests that some users might prefer larger text or different font styles, which could be an area for improvement.
- Enhanced understanding of BP (mean 4.68, SD 0.53): Users find that the information provided by ColonClean significantly aids their understanding of BP tasks, which is essential for ensuring compliance with medical procedures.

In summary, the high average scores across these metrics indicate that users generally find ColonClean to be an easy-to-use app that effectively supports BP. The highlighted areas demonstrate strengths in design, functionality, and educational support, with only minor adjustments needed in font size to further enhance the user experience. These findings suggest that ColonClean is a valuable tool for improving patient preparation and potentially contributing to better clinical outcomes.

Attitudes Toward Usage

The details of attitudes toward usage are shown in Table 3.

Table . Attitudes toward usage of the ColonClean app.

Attitudes toward usage of the ColonClean app	Mean (SD)
I believe ColonClean is an excellent choice for assisting with bowel preparation before an examination.	4.63 (0.54)
I am currently satisfied with the benefits provided by using ColonClean.	4.65 (0.53)
I would be willing to use ColonClean again in the future if I need to undergo bowel preparation.	4.63 (0.59)
I find the information provided by ColonClean to be very useful.	4.60 (0.59)
I prefer using ColonClean over paper-based nursing instructions (single sheets).	4.35 (0.77)

Table 3 summarizes users' attitudes toward the use of the ColonClean app, reflecting generally positive perceptions of its utility and effectiveness in assisting with BP tasks. The mean scores indicated a high level of satisfaction, with most ratings above 4.57 of 5, suggesting a strong endorsement of the app's features and benefits. Below is an interpretation of the key findings:

- Good choice for assistance (mean 4.63, SD 0.54): This high mean score reflects a strong consensus among users that ColonClean is an effective tool for supporting BP. The low SD suggests consistent agreement on its usefulness in this context.
- Satisfaction with benefits (mean 4.65, SD 0.53): Users' satisfaction indicates that the app meets their expectations and provides meaningful benefits during BP. The relatively low SD further shows that most users feel positively about the app's contributions.
- Willingness to use again (mean 4.63, SD 0.59): Users expressed a strong intention to use ColonClean for future BPs, suggesting that their initial positive experiences built trust in the app and that they see it as reliable.
- Usefulness of information (mean 4.60, SD 0.59): The perception that ColonClean provides highly useful information reinforces its role as a valuable educational resource, effectively aiding users in understanding the preparation process.
- Preference over paper instructions (mean 4.35, SD 0.77): Although users generally prefer ColonClean over traditional paper-based instructions, the slightly lower score and higher SD suggest that some users may still value printed materials or have mixed feelings about fully transitioning to digital formats. This variability presents an opportunity for further enhancements in the app's usability and content delivery.

In summary, the high mean scores (above 4.57) suggested that users had a positive attitude toward ColonClean, seeing it as an effective and beneficial tool for BP. The consistent responses (low SDs) indicated broad agreement among users on its usefulness. Meanwhile, the variation in preference over paper instructions may highlight areas for potential improvement. This feedback can guide future updates and enhancements to maximize user satisfaction and efficacy.

Usage Behavior

The details of usage behavior are shown in Table 4.

Table . Usage behavior of the ColonClean app.

Usage behavior of the ColonClean app	Mean (SD)
I am willing to use ColonClean as an aid for bowel preparation.	4.73 (0.45)
I am highly satisfied with the ability to access knowledge through ColonClean during bowel preparation.	4.70 (0.52)
I would recommend ColonClean to friends and family in the future.	4.63 (0.63)
I would use ColonClean to improve the effectiveness of bowel preparation.	4.70 (0.52)
I believe ColonClean provides useful information during the bowel preparation period.	4.68 (0.53)
Overall, I find using ColonClean to be satisfactory.	4.73 (0.51)

Table 4 summarizes the usage behavior of the ColonClean app and reveals overwhelmingly positive user sentiment. The overall mean score of 4.69 indicates high satisfaction with the experience of using ColonClean. This average score, combined with a relatively low SD (0.50), suggests a strong consensus among users regarding the app's effectiveness and utility. Below is an analysis of the meaning behind the scores:

- Willingness to use (mean 4.73, SD 0.45): The high mean score indicates that users are very inclined to use ColonClean as a supportive tool for BP. The low SD signifies that this sentiment is widely shared, suggesting strong confidence in the app's benefits.
- Satisfaction with knowledge access (mean 4.70, SD 0.52): Users expressed a high level of satisfaction with the knowledge accessible through the app during BP. This indicates that ColonClean effectively meets their informational needs, enhancing their preparation experience.
- Recommendation to others (mean 4.63, SD 0.63): The willingness to recommend ColonClean to friends and family reflects users' trust in the app's efficacy. Although this score remained positive, the slightly higher SD suggests some variability in users' willingness to recommend it, possibly due to differing experiences or expectations.
- Improvement of effectiveness (mean 4.70, SD 0.52): Users believed that ColonClean enhanced the effectiveness of their BP, reinforcing the app's perceived value as a helpful resource in the preparation process.
- Useful information obtained (mean 4.68, SD 0.53): The belief that the app provides useful information further underscores its utility as an educational tool. Users recognized that the app offers relevant guidance throughout the preparation period.
- Overall satisfaction (mean 4.73, SD 0.51): The high overall satisfaction score indicates that users felt positively about their experience with ColonClean. The consistency of this sentiment, reflected by the low SD, suggests that many users share a similar level of satisfaction.

In summary, the high mean scores across all categories reflect users' positive attitudes and satisfaction, underscoring ColonClean as a valuable tool for assisting with BP. The low SDs across most items indicate consistency in user experiences, suggesting that ColonClean effectively meets users' needs and

expectations. This feedback is critical for developers, as it reinforces the app's strengths and highlights areas where further enhancements could be beneficial.

Analysis

Pearson Correlation Coefficients

Pearson correlation coefficients were used to analyze the relationships among users' attitudes, perceived usefulness, perceived ease of use, and usage behavior of the ColonClean mHealth app (Table 5). The results indicated a significant positive correlation between users' attitudes and perceived usefulness (r_{38}=.907, P<.001), users' attitudes and perceived ease of use (r_{38}=.825, P<.001), users' attitudes and usage behavior (r_{38}=.835, P<.001), perceived usefulness and perceived ease of use (r_{38}=.894, P<.001), perceived usefulness and usage behavior (r_{38}=.933, P<.001), and perceived ease of use and usage behavior (r_{38}=.958, P<.001). Positive correlations were demonstrated between perceived usefulness and perceived ease of use, usage attitude, and usage behavior.

Table . Correlations among perceived usefulness, perceived ease of use, usage attitude, and usage behavior.

		Perceived usefulness	Perceived ease of use	Usage attitude	Usage behavior
Perceived usefulness					
	Pearson correlation analysis	1			
	Significance level (2-tailed)				
	Number	40			
Perceived ease of use					
	Pearson correlation analysis	0.894	1		
	Significance level (2-tailed)	<.001			
	Number	40	40		
Usage attitude					
	Pearson correlation analysis	0.907	0.825	1	
	Significance level (2-tailed)	<.001	<.001		
	Number	40	40	40	
Usage behavior					
	Pearson correlation analysis	0.933	0.958	0.835	1
	Significance level (2-tailed)	<.001	<.001	<.001	
	Number	40	40	40	40

Simple Regression Analysis

We used simple regression analysis to predict the correlation among the perceived usefulness, perceived ease of use, usage attitude, and usage behavior in the context of ColonClean. The correlation between perceived usefulness and usage attitude, with usage attitude as the criterion variable and perceived usefulness as the predictor variable, yielded B=0.907, t_{38}=13.3. This model explained 82.3% of the variance in usage attitude (R^2=0.823), and the test result with P<.001 indicated that perceived usefulness was a significant predictor variable for usage attitude. This suggests that when users perceive the app as providing substantial assistance, their attitude toward using it improves significantly. This highlights the importance of enhancing the app's practical functionality to foster a positive user experience. Similarly, the correlation between perceived usefulness and usage behavior, with usage behavior as the criterion variable and perceived usefulness as the predictor variable, resulted in B=0.933, t_{38}=16.0. This model explained 87.1% of the usage behavior (R^2=0.871), and the test result with P<.001 demonstrated that perceived usefulness significantly predicted usage behavior. When users believe that the app helps improve their preparation process, they are more likely to engage actively with it. The correlation between perceived ease of use and usage attitude, with usage attitude as the criterion variable and perceived ease of use as the predictor variable, resulted in B=0.825, t_{38}=9.0. This explained 68% of the variance in attitude toward use (R^2=0.68), with P<.001, indicating perceived ease of use as a significant predictor of attitude toward use. When users find the app easy to use, their attitude becomes more positive. This reflects their comfort and satisfaction during use, which in turn influences their willingness to engage with the

app. When determining the correlation between perceived ease of use and usage behavior, with usage behavior as the criterion variable and perceived ease of use as the predictor variable, the result was B=.958, t_{38}=20.5. This model explained 91.7% of the variance in usage behavior (R^2=.917), with P<.001, indicating that perceived ease of use significantly predicted usage behavior. When users perceive the app as easy to operate, they are more likely to engage actively. This underscores the importance of simplifying the app's interface and functionality to enhance user engagement and satisfaction.

In summary, the results indicate that both perceived usefulness and perceived ease of use have a significant positive impact on user attitudes and behaviors. This suggests that enhancing the perceived usefulness and ease of use of the ColonClean app during its design may encourage more positive user attitudes and behaviors, thereby improving health management outcomes. These findings not only validate the app's usability but also provide empirical support for future improvements.

Discussion

Principal Findings

Mobile health apps are increasingly used for illness prevention, education, and promoting healthy lifestyles [40]. However, the requirements for BP are often complex and challenging for patients to navigate and remember. To help outpatient colonoscopy patients adhere to dietary guidelines, manage bowel cleansing agents, and maintain regular medication schedules, push notifications were incorporated into the app's design. The app, protected under the patent titled "ColonClean Mobile Management System" (patent number M639094, Republic of China), features a user-centric interface that is both intuitive and visually appealing. The well-designed interface, content, push notifications, and multimedia section of the ColonClean mHealth app provide users with a convenient and helpful experience when using their mobile devices for health management. Users expressed their willingness to use the app again in the future and recommend it to family and friends, highlighting its effectiveness as an educational guide for BP.

User Attitudes and Preference for Paper-Based Instructions

Despite the overall positive reception of the ColonClean app, some users indicated a preference for paper-based instructions, as reflected in the lower mean score (mean 4.350.77) on this aspect. This finding aligns with existing literature suggesting that certain users may find physical formats more reliable or easier to reference than digital alternatives [41]. Factors contributing to this preference may include concerns about technology accessibility, device compatibility, or personal comfort with digital apps for health management.

Additionally, the preference for paper-based instructions may arise from a desire for tangible resources that can be easily annotated or highlighted [42]. Some users may feel that printed materials provide a more straightforward and immediate reference during the preparation process, particularly in situations where mobile devices are not accessible or convenient [43]. Therefore, while the digital format of the ColonClean app offers numerous advantages, such as interactivity and real-time updates, it is essential to recognize the value that traditional paper-based resources continue to hold for certain individuals.

Limitations and Recommendations

The ColonClean app operates on the Android system and functions as an mHealth app for mobile devices. However, it is important to note that during the acceptance process, instances may arise where individuals with non-Android operating systems or outdated device models are unable to be included in this study. Those unable to download ColonClean by scanning the QR code were excluded. It is advisable to consider optimizing future mHealth apps so that they can be integrated into mobile devices of various operating systems. This enhancement would contribute to more inclusive nursing guidance for BP, ensuring accessibility across platforms.

In the current era of smart health care, it is recommended to incorporate artificial intelligence recognition capabilities into the ColonClean app. Specifically, for the section where users capture images of their last bowel movement, artificial intelligence can automatically analyze and determine the quality of the stool, categorizing it as "excellent," "good," "fair," or "poor." This improvement would facilitate a more accurate assessment of the final bowel movement status. Furthermore, optimizing the ColonClean mHealth app for other individuals who require BP, such as those undergoing colorectal surgery or hospitalized patients preparing for colonoscopy, would ensure the successful completion of bowel cleansing.

Additionally, in light of the COVID-19 pandemic, when individuals undergoing screening needed to reschedule their appointments due to a positive diagnosis or being a close contact, or when they encountered issues like poor bowel movements, a consultation chat window was recommended as a future addition to address user inquiries and provide real-time solutions, thus maintaining user engagement and satisfaction. To ensure the continuity of examinations and achieve the objectives of examination, diagnosis, and treatment, it is crucial to minimize ineffective examinations or schedule cancellations that may impact individuals in need of these examinations. This approach aims to maintain a steady number of examinations and fulfill the purpose of providing necessary medical assessments and subsequent care.

Conclusions

In summary, while the ColonClean app shows promise in supporting BP, it is essential to recognize user attitudes toward traditional paper-based instructions. Enhancing the app with broader accessibility, artificial intelligence capabilities, and additional user support features could significantly improve its effectiveness and reach, ultimately contributing to better health outcomes for patients requiring BP.

Acknowledgments

We would like to express our heartfelt gratitude to the patients from the outpatient department of the gastroenterology and endoscopy center for their valuable participation in this study.

Data Availability

Data from this study are available from the corresponding author upon reasonable request.

Authors' Contributions

HYC conceptualized the study, participated in data curation and formal analysis, completed the methodology, validated the data, and drafted the manuscript. MHT supervised the study and reviewed the manuscript. MYC reviewed the manuscript. All authors have read and agreed to the published version of the manuscript.

Abstract

Background: Repeated applications of short-term dietary assessment instruments are recommended for estimating usual dietary intake. For this purpose, NutriDiary, a smartphone app for collecting weighed dietary records (WDRs) in the German population, was developed.

Objective: We aim to describe NutriDiary and evaluate its usability and acceptability.

Methods: NutriDiary was developed as a WDR, allowing users to enter food items via text search, barcode scanning, or free text entry. The sample for the evaluation study included 74 participants (n=51, 69% female, aged 18 - 64 years), including 27 (37.5%) experts and 47 (63.5%) laypersons (including n=22, 30%, nutrition students). Participants completed a 1-day WDR and entered a predefined sample meal (n=17 foods) the following day by using NutriDiary. An evaluation questionnaire was answered from which the system usability scale (SUS) score (0 - 100) was calculated. A backward selection procedure (PROC REG in SAS; SAS Institute) was used to identify potential predictors for the SUS score (age, sex, status [expert or laypersons], and operating system [iOS or Android]).

Results: The median SUS score of 75 (IQR 63 - 88) indicated good usability. Age was the only characteristic identified as a potential predictor for a lower SUS score (P<.001). The median completion time for an individual WDR was 35 (IQR 19 - 52) minutes. Older participants took longer to enter the data than younger ones (18 - 30 y: median 1.5, IQR 1.1 - 2.0 min/item vs 45 - 64 y: median 1.8, IQR 1.3 - 2.3 min/item). Most participants expressed a preference for NutriDiary over the traditional paper-based method.

Conclusions: Good usability and acceptability make NutriDiary promising for use in epidemiological studies.

Introduction

Usual dietary intake, the long-term average daily intake of a nutrient or food**,** is the relevant exposure when studying diet-health relationships in nutritional epidemiology. To estimate usual dietary intake, repeated applications of short-term dietary assessment instruments are recommended [1]. Self-reported dietary intake is the most commonly used method in large-scale studies through its rapid and cost-effective use. Mostly, instruments such as 24-hour dietary recalls, food frequency questionnaires or dietary records (DRs) are used, with each of these methods having individual limitations and strengths [2]. Repeated use of these traditional dietary assessment instruments is costly and burdensome for both participants and researchers [3,4]. Innovative technologies such as web- or smartphone-based tools have the potential to facilitate self-reported dietary assessment by reducing the costs and time effort of data collection and postprocessing while achieving higher acceptance in study participants [5-7]. Smartphone technology seems particularly promising among those innovative approaches. First, smartphones are widely available to a large proportion of the population. According to a survey conducted in 2021, over 95% of people aged older than 13 years in Germany already use a smartphone [8]. Second, due to the advantage of portability and the fact that most people always carry their smartphone with them, smartphone-based tools are well suited for real-time recording of food intake [1]. Third, smartphone apps can facilitate food entry through the supplementary use of an

integrated barcode scanner or by using the camera function, which reduces the need to look up every food item in a database or enter it manually [9]. Nowadays, a large number of commercial nutrition apps for self-tracking or nutritional advice are freely available [10,11]. However, because of their limited scope and questionable quality of nutrient information, those apps tend to be unsuitable for dietary assessment in epidemiological studies [12,13]. Thus, several DR apps have been developed specifically for use in epidemiological studies. In a systematic review by König et al [14], 5 core assessment features to collect data on dietary intake in scientific studies by smartphone apps were identified: photo-based assessment, assessment of serving or portion sizes, free-text description of food intake, selection from a food database, and classification systems. These features are used either alone or in combination. Thereby, the combination of photo-based recording with free-text descriptions of the consumed foods or the joint use of a food database and the assessment of serving or portion sizes were the most popular methods [14].

To provide a digital alternative for paper-based dietary assessment in epidemiological studies, we developed NutriDiary, an app for conducting weighed dietary records (WDRs) with an integrated barcode scanner. This paper aims to describe the current version of NutriDiary and to report on its usability and acceptability in laypersons and experts.

Methods

NutriDiary and the NutriDiary Database

Development and Functions of NutriDiary

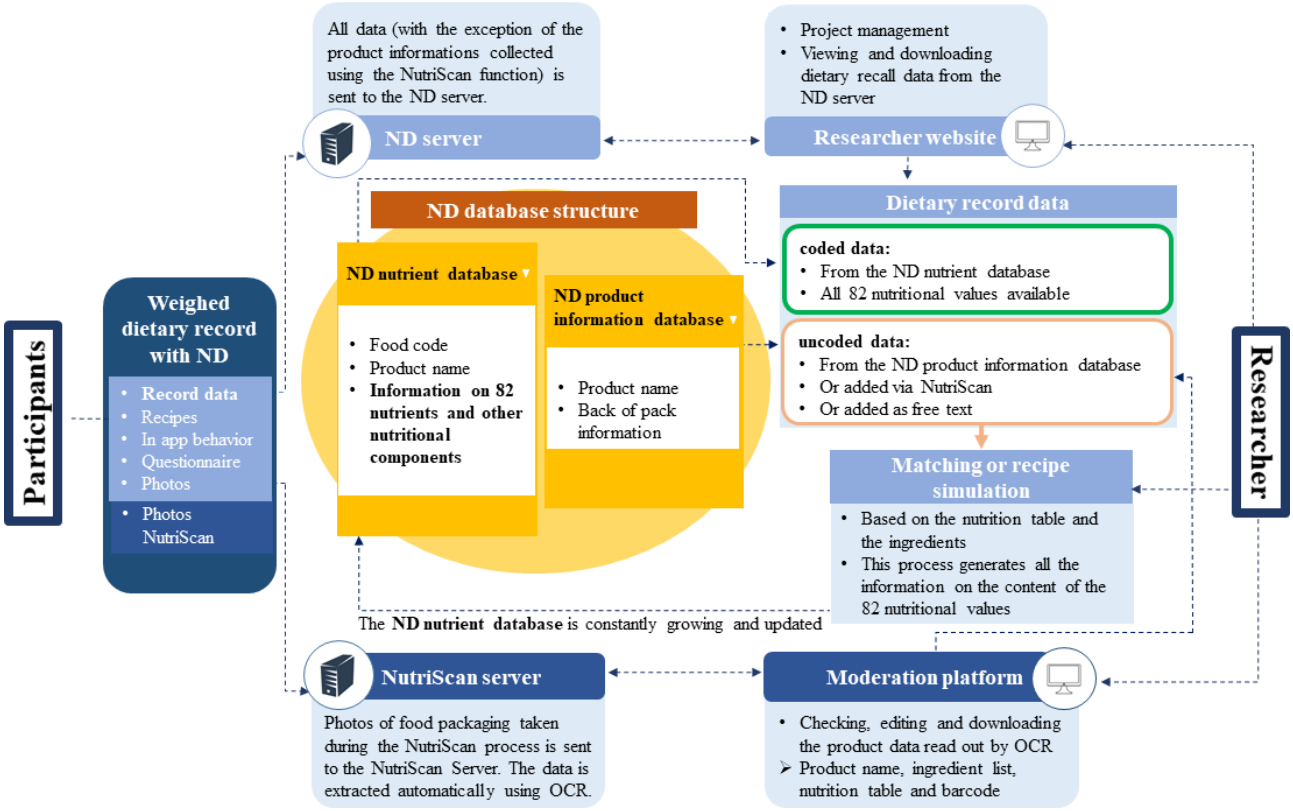
NutriDiary was developed as a smartphone app to conduct WDRs within nutritional epidemiological studies. The app is available in common app stores and study participants (hereafter referred to as users) can use the app on their smartphones with personal login data (Figure 1A). Users can start their WDR after agreeing to the data protection regulations (Figure 1B). When entering a new eating occasion, users are initially asked to enter the date, time, and place of consumption (Figure 1C). Then, the app offers three ways to enter food, beverages, and supplements: (1) a text search and subsequent selection from the underlying database, (2) barcode scanning in the underlying database, or (3) free text entry.

Figure 1. The NutriDiary app (android version): (A) screen for entering access data, (B) welcome screen, and (C) food entry.

If a food item cannot be identified via barcode scanning, the user is guided through a standardized process for collecting all relevant product information (hereinafter referred to as the NutriScan process). Thereby, the user is asked to take photos of the brand and product name, the barcode, the ingredient list and the nutrient table following step-by-step instructions (Multimedia Appendix 1). This data is then sent to the NutriScan server and automatically read out using optical character reading. Researchers can access, edit, and download this data via a moderation platform. Based on the packaging information, dieticians can match detailed nutrient data from a similar product in the database or estimate detailed nutrient values by recipe simulation in order to continuously update and expand the underlying database (Figure 2). The recipe simulation is carried out manually using the list of ingredients and the nutritional table and is described in detail elsewhere [15]. Finally, users enter the weighed amount consumed, preparation method, and quantity of potential leftovers (Figure 1C). If weighing is not possible, users are provided with a range of specified options in the drop-down menu to select an estimated portion size, such

as teaspoon or slice. After all foods and beverages have been entered, users are redirected to the main screen, where all entered eating occasions are displayed for final review. To further ease the process of recording, NutriDiary offers some usability features. A recipe editor allows entry of custom recipes, which will be added to the user's personal databases. An integrated help mode provides immediate and problem-specific assistance to users by simply touching the screen element they need help with. In addition, the app includes a photo function for collecting information, for example, on meals consumed out-of-home and entered via free text. After finishing the WDR, data are submitted to a server of the University of Bonn (NutriDiary server, Figure 2). This server also provides an administration tool to researchers (researcher website) where scientific personnel can select project-specific settings, for example, study name, study duration or the number of recording days. The app also offers the option to integrate an individual questionnaire at the end of the recording period.

Figure 2. Overview of the data structure and data flow of the NutriDiary app; ND: NutriDiary; OCR: optical character reading.



Description of the NutriDiary Database

The complex database structure of NutriDiary is shown in Figure 2. It currently contains more than 150,000 items (approximately 25% are duplicates due to different packaging sizes and different barcodes) which come from various sources. The core database is divided into the NutriDiary nutrient database and the NutriDiary product information database. The basis of the NutriDiary nutrient database is an adaptation of the in-house food and nutrient database of the DONALD (Dortmund Nutritional and Anthropometric Longitudinally Designed) study named LEBTAB (LEBensmittelTABelle, food table) [15-17]. LEBTAB currently contains around 19,000 generic and branded food items (as of June 2023) with corresponding contents of energy, 82 nutrients, and other nutritional components. Data entries for generic foods are based predominantly on the German national standard food database "Bundeslebensmittelschlüssel" (version 3.02 [18]; Federal Ministry of Food and Agriculture). The energy and nutrient contents of branded foods are predominantly estimated by recipe simulation using labeled ingredients and declared nutrient contents [15,17]. When the participant enters a food item from the NutriDiary nutrient database, this item is automatically coded and the corresponding values for energy and 82 nutrients are available. To enhance user-friendliness and allow barcode scanning, additional branded food products and barcode information were added to the NutriDiary database structure by:

- requesting product information (product name, barcode, ingredient list, and nutrition table) from food manufacturers and others (Atrify [19], a subsidiary of GS1 Germany [1WorldSync] and DATA NatuRe eG [20], a cooperative to create a central data pool for organically produced foods) to set up the NutriDiary product information database, and
- adding barcode information of already included branded products to the NutriDiary nutrient database by searching in open databases such as Open Food Facts [21], codecheck [22] (Producto Check GmbH), and Open EAN/GTIN Database (European Article Number [EAN]/Global Trade Item Number [GTIN]) [23].

For the branded products obtained through step 1 (NutriDiary product information database), information only on the nutritional values indicated on the packaging (big 7) and the ingredient list are available (Figure 2). When a participant reports one of these products in a WDR, the trained dieticians

match extended nutrient values of an equivalent food from the NutriDiary nutrient database or carry out a recipe simulation as already mentioned above [15]. This step generates all 82 nutrients for these products and they are then transferred to the NutriDiary nutrient database, which is constantly growing.

The NutriDiary Evaluation Study

Study Design

A layperson and expert evaluation was conducted. Participants were asked to keep an individual WDR with NutriDiary for 1 day and to enter a predefined sample meal on the following day. The sample meal was identical for all participants and included 4 meals (breakfast, snack, lunch, and dinner) and was provided as a digital presentation sent to study participants via email. The sample meal comprised both, generic (n=15, presented as text) and branded food items (n=3, presented as pictures of the packaging including barcode), all labeled with a hypothetical quantity of consumption, preparation method, and type of entry (text entry vs barcode scanning). Participants were generally instructed to enter branded products via scanning the barcode. Further, 1 product was intentionally not available in both NutriDiary databases, requiring participants to complete the NutriScan process in order to add the food item to the record. Furthermore, participants were tasked to correct a logged entry and to enter a hypothetical leftover without further instructions but with reference to the NutriDiary website [24] to test whether the aids provided there (frequently asked questions and help videos) fulfill their purpose (ie, helping users to help themselves). After participants completed their WDR and entered the sample meal, they were asked to answer an app-integrated evaluation questionnaire on usability and acceptability of NutriDiary on day 3. As the WDRs were not analyzed at the nutrient level, no scales were handed out for weighing the food on day 1. The participants were asked to use scales from their households.

All participants were provided with a short video giving key instructions on how to use NutriDiary before starting the WDR. The video gave a brief overview of how to use the help mode, enter foods (via text search, barcode scanning, or free text entry) and navigate the recipe book. Furthermore, participants were informed about the NutriDiary website [24], where frequently asked questions and help videos for both, iOS and Android can be found. Beyond this, participants did not undergo any additional training in using the app.

Recruitment of This Study's Population

We aimed to recruit a minimum of 51 participants, based on the assumptions outlined by Lewis and Sauro [25]. This recommendation takes into account an SD of 17.7, which is typical for system usability scale (SUS) scores [25], and ensures sufficient precision to achieve a 95% CI with a margin of error of ±5 points. This study recruited both laypersons and experts. Experts (trained nutritionists with experience in the field of dietary assessment) were recruited via direct invitations (n=28). Laypersons (n=52) were recruited via oral advertisement in lectures, mailing, and personal contact by students studying nutrition and food science at the University of Bonn, and as part of a student project. The latter mainly targeted participants between 30 and 60 years of age (in the personal environment of the students and in 2 gyms) in order to increase the number of participants in middle age and older in the group of laypersons. All participants had to be fluent in the German language, have a functioning smartphone and a valid email address. Written informed consent from all participants was obtained before enrollment.

Usability and Acceptability Assessment

The questionnaire on usability and acceptability included 14 questions on 3 different categories (usability, acceptance, and technical issues). The usability of NutriDiary was assessed by using the SUS by Brooke [26,27], which allows for comparison between similar systems or products. In short, the SUS is a Likert scale consisting of 5 positive statements (odd-numbered) and 5 negative statements (even-numbered) to which respondents indicate their degree of agreement on a scale from 1 (strong disagreement) to 5 (strong agreement). For odd items, 1 is subtracted from the user response, and for even-numbered items, 5 is subtracted from the user response, added up and multiplied by 2.5 to convert the score ranging from 0 to 100, whereas higher scores indicate better usability. According to Bangor et al [28], an SUS score below 50 is considered as "not acceptable," a score between 50 - 70 years as "marginal," and a score above 70 as "acceptable" [28,29]. In our study, an appropriate German translation of the SUS developed by SAP usability professionals of a German software corporation (SAP SE; Systems, Applications & Products in Data Processing Societas Europaea) was used and integrated into the usability questionnaire [30].

Age and sex of the participants were assessed within the evaluation questionnaire. Status (expert or layperson) was already categorized during the recruitment process. Information on the operating system was automatically recorded when NutriDiary was used and sent to the server together with the questionnaire data. To find out whether participants would prefer the app to a traditional paper-based WDR, 2 additional questions in the same structure of the SUS were added. In order to assess technical problems participants were asked whether technical errors occurred (yes or no) and, if yes, to describe the error in more detail (free text entry).

Furthermore, in-app behavior of users was recorded and evaluated. The completion time for a WDR with NutriDiary was determined by using the activity protocol of the app, in which all actions were recorded and time-stamped. For this, the time of all input activities was summed up. Interruptions of more than 5 minutes were counted as breaks and excluded from summation. As the time effort of a WDR depends on the complexity of the meals and the number of foods eaten, the relative completion time (completion time divided by the number of items) was additionally calculated. Furthermore, the percentage of estimated household measurements was of interest as well as the percentage of automatically coded WDR entries.

Statistical Analyses

Results and participants' characteristics are presented as median with their lower IQRs for continuous variables or as relative frequencies (%) for categorical variables. A backward selection

procedure (PROC REG in SAS) was used to identify characteristics of participants that were potential predictors for the SUS score. The following variables were tested: sex (male or female), age (years), status (expert or layperson), and operating system (iOS or Android). All statistical analyses were conducted using SAS (version 9.4). The significance level was set at $P<.05$.

Ethical Considerations

All examinations were carried out with written informed consent from study participants. The NutriDiary evaluation study was approved by the Ethics Committee of the University of Bonn (project identification 445/23). All data collected in this study has been pseudonymized to protect participant privacy. No reimbursement was provided to participants for their involvement in this study.

Results

From overall 80 study participants, 74 (27 experts) completed the NutriDiary evaluation study according to this study protocol and answered the evaluation questionnaire (Table 1). Most participants were female (51/74, 69%) and younger than 30 years of age (41/74, 55%).

The overall age ranged from 18 to 64 years and the median age was 29 years (IQR 25 - 45). Overall, 54% (40/74) of the participants owned a smartphone with an iOS operating system. Table 2 shows the SUS score for NutriDiary for the total study sample and stratified by sex, age groups, status, and operating system. In the overall study sample, the SUS score for NutriDiary ranged from 43 to 100 (data not shown). The median SUS score of 75 (IQR 63 - 88) indicates a good usability of NutriDiary. The mean SUS score was 74 (SD 15; 95% CI 70-77; data not shown). The median SUS score was higher in women than in men (80, IQR 65 - 88, vs 70, IQR 55 - 78) and higher in the group of experts than in the group of laypersons (80, IQR 65 - 88 vs 73, IQR 58 - 88), with female laypersons having a higher SUS score than female experts (83, IQR 66 - 88 vs 80, IQR 60 - 85). Looking at the group of laypersons after excluding nutrition students (labeled in Tables 1 and 2 as “others,” median age 55, IQR 29 - 58, years), the median SUS score was 63 (IQR 50 - 73).

Table . Characteristics of study participants of the NutriDiary evaluation study (N=74).

	Total	Experts	Laypersons		
			Total	Nutrition students	Others
Participants, n (%)	74 (100)	27 (36.5)	47 (63.5)	22 (47)	25 (53)
Sex (group), n (%)					
Women	51 (69)	23 (85)	28 (60)	19 (86)	9 (36)
Age, median (IQR)	29 (25 - 45)	35 (28 - 40)	27 (23 - 56)	23 (22 - 26)	55 (29 - 58)
Age (years), n (%)					
Age group 1: 18-≤30	41 (55.4)	12 (44.4)	29 (61.7)	22 (100)	7 (28)
Age group 2:>30-≤45	15 (20.3)	11 (40.7)	4 (8.5)	0 (0)	4 (16)
Age group 3:>45 - 65	18 (24.3)	4 (14.8)	14 (29.8)	0 (0)	14 (56)
Operating system, n (%)					
iOS	40 (54)	12 (44.4)	28 (59.6)	12 (54.5)	16 (64)
Android	34 (46)	15 (55.6)	19 (40.4)	10 (45.5)	9 (36)

Table . System usability scale (SUS) score for the NutriDiary app presented as median (IQR) values.

	Total		Women		Men	
	n	Median (IQR)	n	Median (IQR)	n	Median (IQR)
SUS score	74	75 (63 - 88)	51	80 (65 - 88)	23	70 (55 - 78)
Stratified by age group						
Age group 1: 18 -≤30 years	41	80 (70 - 88)	31	83 (70 - 88)	10	71 (63 - 85)
Age group 2: >30 -≤45 years	15	80 (68 - 90)	11	85 (65 - 93)	4	74 (70 - 78)
Age group 3: >45 - 65 years	18	58 (50 - 70)	9	58 (48 - 65)	9	65 (50 - 70)
Stratified by status						
Experts	27	80 (65 - 88)	23	80 (60 - 85)	4	83 (70 - 90)
Laypersons (total)	47	73 (58 - 88)	28	83 (66 - 88)	19	70 (55 - 73)
Nutrition students	22	85 (75 - 88)	19	88 (78 - 90)	3	73 (70 - 85)
Others	25	63 (50 - 73)	9	55 (48 - 65)	16	66 (53 - 73)
Stratified by operating system						
iOS	40	78 (65 - 88)	26	80 (68 - 90)	14	66 (55 - 73)
Android	34	74 (58 - 85)	25	75 (58 - 85)	9	73 (70 - 85)

Among the age groups 1 (18-≤30 y) and 2 (>30-≤45 y), the median SUS score was noticeably higher (80, IQR 70 - 88 and 80, IQR 68 - 90) than in age group 3 (58, IQR 50 - 70). The results of the backward selection procedure showed that age was the only characteristic identified as a potential predictor for the SUS score in the examined sample (P<.001).

Figure 3 shows the individual statements of the SUS questionnaire and a summary of the answers given by the 74 participants, presented as box plots. The figure shows that agreement tends to be high for the positive (odd-numbered) statements and tends to be low for the negative (even-numbered) statements, as is a prerequisite for a higher SUS score. Among the positive statements, the participants showed the lowest level of agreement with statement 1 “I think that I would like to use NutriDiary frequently.” For the negative statements, agreement was highest for statement 8 “I found NutriDiary very cumbersome to use.”

Figure 3. User rating (N=74) of the individual statements of the SUS evaluating the usability and acceptability of NutriDiary, shown as box plots. The dot represents the mean and the thick stripe the median. SUS: system usability scale.

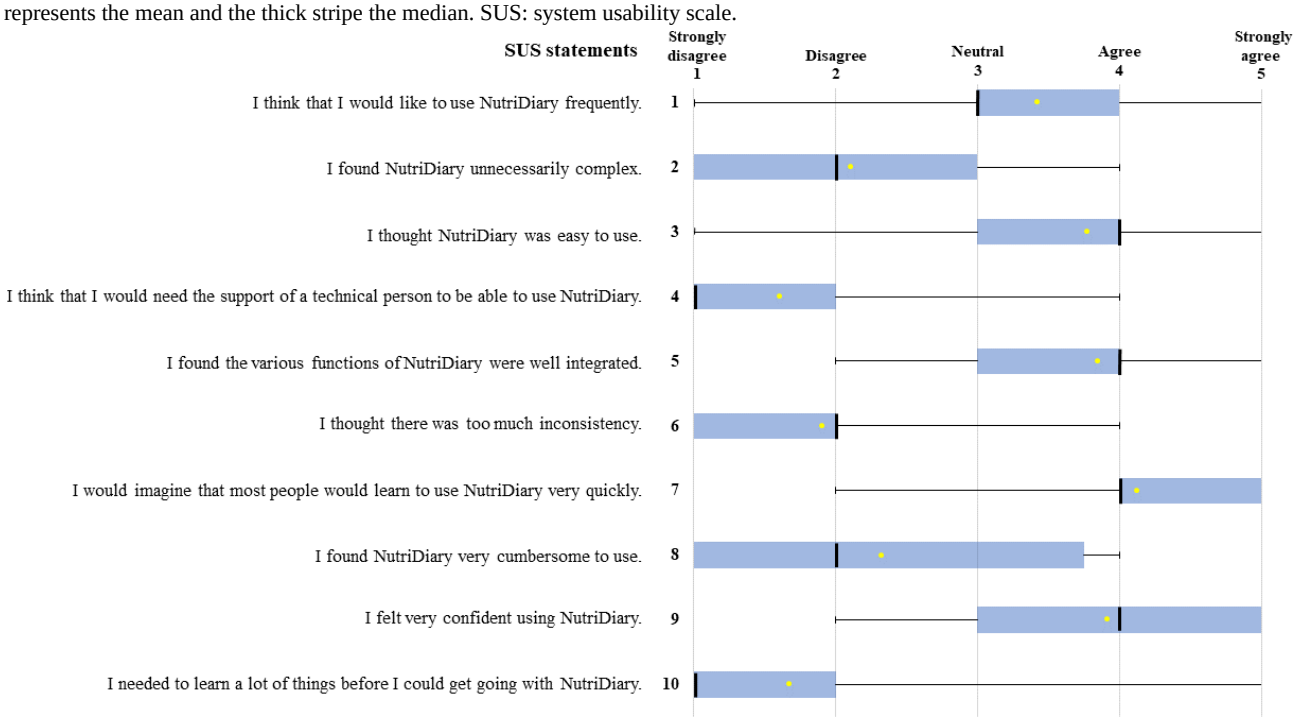


Table 3 shows the results of the evaluated in-app behavior logs and WDRs. The calculated median completion time for an individual WDR (day 1) with NutriDiary was 35 (IQR 19 - 52) minutes. Participants needed a median of 1.6 (IQR 1.2 - 2)

minutes to enter an item. This relative completion time was slightly higher in age group 3 (>45 - 63 y) compared to younger participants (1.8, IQR 1.3 - 2.3, min/item vs 1.5, IQR 1.1 - 2, min/item). The median time it took participants to enter the sample meal in NutriDiary on day 2 was 15 (IQR 12 - 18) minutes. The median relative completion time for entering the sample meal was 0.8 (IQR 0.7 - 0.9) min/item. Participants in age group 3 took slightly longer than younger participants. The median proportion of already coded items was 68% (IQR 55% - 82%) and the median proportion of estimated quantities (not weighed) was 8% (IQR 0% - 29%). Younger participants (age group 1) used more estimated household measurements instead of weighing than participants in age groups 2 and 3 (0% - 26%, 8% vs 0% - 31%, 7% and 0% - 23%, and 4%, respectively).

Table . Completion time and proportion of items already coded for the total sample (N=74) and stratified by age groups.

	Total	Age group 1: 18 - 30 y	Age group 2: 31 - 45 y	Age group 3: 46 - 65 y
Participants, n (%)	74 (100)	41 (55.4)	15 (20.3)	18 (24.3)
Number of entered items day 1[a]	21 (15 - 31)	22 (16 - 31)	21 (19 - 32)	21 (13 - 30)
Total completion time day 1 (min)[a]	35 (19 - 52)	35 (19 - 45)	44 (19 - 55)	36 (17 - 53)
Relative completion time day 1 (min/item)[a]	1.6 (1.2 - 2)	1.5 (1.1 - 2)	1.5 (1.1 - 2)	1.8 (1.3 - 2.3)
Total completion time sample meal (min)[a]	15 (12 - 18)	14 (11 - 17)	17 (11 - 19)	17 (13 - 23)
Relative completion time sample meal (min/item)[a]	0.8 (0.7 - 0.9)	0.8 (0.6 - 0.9)	0.9 (0.6 - 1.1)	0.9 (0.7 - 1.3)
Proportion of items already coded (%)[a]	68 (55 - 82)	63 (56 - 79)	77 (62 - 86)	71 (50 - 86)
Proportion of estimated household quantities (%)[a]	8 (0 - 29)	8 (0 - 26)	7 (0 - 31)	4 (0 - 23)

[a]Median (IQR).

In total, 24% (18/74) of the participants reported technical issues. In 2 cases, the app crashed, but could be reopened afterward and no data was lost. In 5 cases, participants stated that they had problems finding newly added products (this process is sometimes delayed in rare cases). Further, 4 participants reported that the selection from the drop-down menu did not work properly. In the remaining cases, participants described issues rather associated with this study design than with the technical functions of NutriDiary or gave general comments. For example, 4 participants reported that a barcode presented in the sample meal could not be scanned from the screen (probably due to varying screen-brightness and screen-resolution).

Overall, 85% (63/74) of the participants were able to enter the sample meal correctly. Of the 11 participants who made mistakes when entering the sample meal, 5 were in age group 1, 2 in age group 2, and 4 in age group 3, indicating that age did not affect the accuracy of data entry. In 2 cases, food items were missing. Further, 3 participants had difficulties in editing a WDR entry and entering hypothetical leftovers. Furthermore, 6 participants entered a different amount of food than that presented in the sample meal. When participants were asked whether they would prefer NutriDiary to the traditional paper method, a total of 77% (57/74) agreed. Only 9.5% (7/74) could imagine, that it would be easier to keep a WDR with pen-and-paper than to use NutriDiary (Multimedia Appendix 2).

Discussion

Principal Findings

To our knowledge, an app-based WDR system with barcode scanning function for scientific studies in Germany does not exist so far. The popularity and widespread use of smartphones make NutriDiary a promising alternative to the traditional pen-and-paper approach. Different ways for entering food items (text search, barcode scanning, and free text entry) and the NutriScan function enable users to record the products they consume in a very detailed manner. The digital data output has the potential to reduce the burden for researchers also. In this study, we evaluated NutriDiary in a convenience sample of experts and laypersons and found good usability and acceptability.

The median SUS score of 75 indicated good usability of NutriDiary. The SUS score has been developed as a means to measure the overall perceived usability of a system [26,27]. However, technology-based dietary assessment instruments for scientific purposes are very specific tools that are not designed for everyday use but to generate scientifically useful data. The collection of these data is often challenging for the participants. The first statement of the SUS questionnaire is “I think that I would like to use this system frequently.” This statement is unlikely to be agreed upon by many people in the case of a WDR due to the burden on participants by the method itself.

Nevertheless, the advantage of the SUS score is that it offers the possibility to compare systems used in the same context [27]. The median SUS score of 75 for NutriDiary (mean SUS score: 74, SD 15, for comparison) is comparable with SUS scores for other similar technology-based food records such as "METADIETA-web" (mean SUS score: 68, SD 15, n=26) [31], the "Eat and Track app" (mean SUS score: 69, n=15) [32] or the "Traqq app" (mean SUS score: 79, SD 15, n=22) [33].

Age has been discussed as a major limiting factor for the use of technology-based systems [29] or innovative dietary assessment instruments [31,34,35]. Consistently, the results of the backward selection procedure showed that age was identified as a potential predictor for a lower SUS score in the examined sample. Further, older participants took slightly longer to complete a WDR with NutriDiary than younger ones. Feasibility testing of the digital food record METADIETA-web by Vitale et al [31] also showed that the preference for using the digital tool instead of the traditional pen-and-paper method decreased with increasing age [31]. Older generations did not grow up with smartphones and computers and are therefore likely to be less intuitive with apps and web-based tools than younger generations. However, longer completion times could also be explained by higher accuracy in entering items and greater patience [36], which would be in line with the observation that older participants used fewer estimated household measurements instead of weighing than younger ones in our study (0% - 23%, 4% for age group 3 vs 0% - 31%, 7% and 0% - 26%, 8% for age group 2 and 1, respectively). Nevertheless, an understandable introduction to the use of the instrument might be particularly important in the group of older adults. For practical reasons, only an introductory video was sent out in this study. Our experience in training users to use the NutriDiary app shows that older people tend to ask more questions. This can only be addressed in a face-to-face conversation where it can be ensured that all relevant information is conveyed. Therefore, we recommend a personal introduction when using NutriDiary in epidemiological studies, if feasible.

The median SUS score was higher in women than in men and higher in the group of experts than in the group of laypersons. This may partly be explained by the fact that the proportion of older people was higher in men than in women and higher in the group of laypersons than in the group of experts. The group of laypersons also included students of nutritional science. Although this group certainly cannot be described as experts, the students may have some background knowledge that could have influenced the outcome. Whether this makes them more critical or less critical in their judgment remains questionable.

WDRs have the potential to provide the most accurate description of the types and amounts of the foods consumed over a specified period of time, but they are also considered to be one of the most burdensome and elaborate dietary assessment methods. When conducting a WDR, participants have to weigh and write down everything they eat and drink and always carry their kitchen scales, the record sheet, and a pen with them. This process is exhausting and time-consuming and requires a high level of cooperation from the participants [37]. The median completion time for conducting a WDR with NutriDiary was 35 minutes (1.6 min/item, Table 3) and can be rated as acceptable. When looking at the median relative completion time of the sample meal (here, the amount of the presented foods was predefined), it can be assumed that the single entering process (without weighing) takes around 0.8 minutes per item. This result suggests that weighing accounts for about half the completion time. Keeping this in mind, the single entering process is roughly comparable with the reported average completion time of other text-based DR apps, for example, with "My Meal Mate." Here, participants needed on average 22 minutes per day to complete a record with estimated (not weighed) portion sizes [38].

Whether the NutriDiary app significantly reduces the completion time compared to the traditional pen-and-paper method is questionable, because the digital version of a WDR does not change the fact that weighing is required for this dietary assessment method. However, NutriDiary offers some advantages that can make its use more attractive than the traditional method. First, most people always carry their smartphone with them and recording "on the go" is more practical than using pen-and-paper. Presumably, this makes it less likely that participants forget their records and need to add the meal at a later time. Second, features such as the recipe book and the barcode scanner can make recording easier, as frequently consumed food combinations and recipes can be stored and retrieved later, and consumed products can be added more easily. Furthermore, integrated standard household measurements make it easier to estimate the quantity if weighing is not possible, for example, when eating out of home. The photo function allows participants to add a photo of the meal, which can help the postprocessing. To figure out whether NutriDiary is more attractive to study participants than the traditional pen-and-paper method, we added 2 more questions to the SUS questionnaire (, Multimedia Appendix 2). The result clearly showed that the vast majority would prefer using the NutriDiary app instead of a paper-based food record. To avoid errors caused by application problems using technology-based instruments, an understandable introduction and information structure are necessary to prevent frustration and enable participants to help themselves quickly if they have difficulties. For this purpose, we designed a website where all information and support materials are centralized in 1 location [24].

When using traditional DRs in epidemiological studies, the postprocessing of the DRs is very time-consuming. The data needs to be digitized and manually coded by the study staff. In this study, 68% (IQR 55% - 82%) of the food entered in NutriDiary was already coded. Furthermore, the data was already available in digital form, suggesting less costs and time in data postprocessing, compared to the pen-and-paper method. NutriDiary was designed as an app for keeping WDRs, meaning that participants are asked to weigh all the food and drinks they consume. However, as experience showed that this is not always possible, the app also offers the choice of standard household measurements (eg, teaspoon, glass, or portion) to estimate the quantity in situations where weighing is not possible. Considering the burden of weighing all foods, this selection option might tempt participants to estimate rather than weigh. However, the proportion of estimated quantities was rather low and can be considered manageable in this study.

Within the development process of NutriDiary, building an appropriate food database structure and the collection, standardization, and integration of barcode and food packaging information to enable food entry via barcode scanning was one of the most challenging tasks. The underlying database determines the users' success in searching for food items and is essential for the functionality and accuracy of technology based, self-administered dietary assessment tools [3,39]. Therefore, we aimed to make the database as complete as possible. Due to a high number of available branded foods and the frequently changing food market, this is a major challenge [12,40-43]. According to the Food Federation Germany [44], there are more than 170,000 food products available on the German food market. Every year, about 40,000 new products are launched and just as many disappear [44]. It also happens that manufacturers change food recipes, which can also change the ingredient lists and nutritional values. These circumstances mean that the database needs to be constantly updated. To make this possible, the NutriScan function described above was developed and integrated. If the app is used regularly, the database is regularly updated with new products recorded by users.

Strengths and Limitations

The NutriDiary evaluation study had some strengths and limitations. As NutriDiary was developed for scientific use, practicing nutritionists were also recruited as experts. Although experts are not intended users of the app, their evaluation allows for a professional view of the usability of NutriDiary. Furthermore, experts decide on the use of the assessment instrument in scientific studies, which is why their opinion on usability is of particular importance in this context. To assess user-friendliness in older age groups as well, we specifically recruited older participants. However, this study population was not representative of the general German population. Most participants were female, young, and highly educated. This limited the generalizability of our results. Nevertheless, it is important to acknowledge that participants in epidemiological studies frequently possess a higher educational status compared to the general population. In addition, participants were aware of the purpose of this study, which was to evaluate the usability and acceptability of NutriDiary, making it difficult to assess the quality and transferability of the data on the completion time and proportion of items already coded. This study aimed to assess the usability and acceptability of NutriDiary and does not contain any data on the validity of the NutriDiary app. However, providing information on the app's validity and psychometric properties is a critical prerequisite for its effective application. Therefore, a validation study has already been initiated and will give insights into the validity and quality of the assessed nutritional data.

Conclusion

NutriDiary is the first smartphone based WDR app with integrated barcode scanning function for scientific purposes in Germany. The evaluation by experts and laypersons indicated an acceptable completion time, good usability and acceptability on the users' side, whereby younger experts and laypersons tended to rate the app better than older ones. Future research will give insights into the validity and feasibility of NutriDiary in different study populations.

Acknowledgments

The authors would like to thank all study participants for the provision of their data. Special thanks go to the students Sofie Frey, BSc, and Franziska Oidtmann, BSc, for their support with data collection. This work was supported by Diet-Body-Brain (DietBB) and the Competence Cluster in Nutrition Research funded by the Federal Ministry of Education and Research (FKZ: 01EA1410A).

Authors' Contributions

LK and UN did the conceptualization. IA, KB, JC, SAJK, LK, MEB, and UN developed the app. LK and MEB handled data curation and worked on the formal analyses. LK wrote the original draft. SAJK, MEB, UA, JC, IA, and UN reviewed and edited the writing. UN supervised the study.

Conflicts of Interest

The authors were involved in the development of the NutriDiary app.

Abstract

Background: Research supports the use of mobile phone apps to promote medication adherence, but the use of and satisfaction with these apps among medically underserved patients with chronic illnesses remain unclear.

Objective: This study reports on the overall use of and satisfaction with a medication adherence app (Medisafe) in a medically underserved population.

Methods: Medically underserved adults who received care for one or more chronic illnesses at a federally qualified health center (FQHC) were randomized to an intervention group in a larger randomized controlled trial and used the app for 1 month (n=30), after which they completed a web-based survey. Objective data on app usage were provided as secondary data by the app company.

Results: The participants were very satisfied with the app, with all participants (30/30, 100%) somewhat or strongly agreeing that they would recommend the app to family and friends. Participants strongly agreed (28/30, 93%) that the reminders helped them remember to take their medications at the correct time each day, and they (28/30, 93%) found the app easy to use. Additional features accessed by some included educational features and the adherence report. Participants noted the helpfulness of having a medication list on their phones, and some used it during medication reconciliation at doctor visits. Use of the Medfriend feature, which alerts a social support person if a medication is missed, was low (n=2), but those who used it were very positive about the feature.

Conclusions: A commercially available medication adherence app was found to be useful by participants, and they were satisfied with the app and the additional features provided. The use of medication adherence mobile phone apps has the potential to positively influence chronic disease management in a medically underserved population on a large scale.

Trial Registration: ClinicalTrials.gov NCT05098743; https://clinicaltrials.gov/study/NCT05098743

medication adherence; mHealth; mobile phone; app; medically underserved; chronic disease; satisfaction; usage; health disparities

Introduction

Background

Medication adherence is vital for those with chronic illnesses who require long-term medication therapies to maintain optimal health. For example, medication adherence and persistence with high blood pressure medications are known to significantly decrease the risk of both cardiac events and stroke [1,2]. In those with type 2 diabetes, medication adherence with hypoglycemics reduces microvascular complications [3]. Unfortunately, the burden of chronic diseases is increasing, with an estimated 60% of adults in the United States having 1 chronic disease and 40% having 2 or more chronic diseases [4]. The growth of chronic disease burden coupled with a lack of medication adherence is associated with increased health care expenditures due to increased demands on health care resources [5,6] and poor health outcomes such as worsening disease status and even death [5]. The economic impact of low medication adherence is estimated to cost the US health care system between US $100 billion and $290 billion annually [5-8].

Medication adherence is therefore particularly important in medically underserved populations who seek care at federally qualified health centers (FQHCs). These centers serve communities and populations with a demonstrable unmet need for health services [9]. These centers are reporting growth in more complex patient populations because their patients have higher rates of chronic conditions and social risk factors associated with poorer health outcomes [10]. Additionally, lower rates of medication adherence are seen in lower socioeconomic populations [11,12] and those with multiple chronic conditions [13]. The reasons for this are influenced by social determinants of health and the material and social conditions in which people live [14]. Adverse social determinants of health are associated with lower medication adherence [15].

Mobile health (mHealth) interventions, defined as the use of mobile wireless technologies for public health [16], have been cited as a potential way to reduce health disparities among chronically ill and medically underserved populations [17,18]. However, despite the promise of these technologies, researchers indicate that mHealth interventions remain understudied in medically underserved populations [17,18]. This is true of medication adherence apps, which can support patients in adhering to their medications through reminders, medication educational information, adherence data, and social support. Studies have shown mixed results for the interest in mobile phone interventions in vulnerable populations [18,19]. Furthermore, research testing commercially available apps to manage chronic disease in a racially and ethnically diverse sample found that the usability of the tested apps in this population was suboptimal [20]. Understanding and gathering detailed data from diverse perspectives regarding the user experience of medication adherence apps will provide important information that is needed to support wider implementation.

A recent meta-analysis of the effectiveness of mobile apps on medication adherence in adults with chronic illnesses found that medication adherence mobile apps, which are designed to be used across a range of multiple chronic health conditions, remain underexplored [21]. This meta-analysis reported that in general, patients have a high acceptance of medication apps, but none of the studies analyzed included medically underserved populations [21]. Eight studies have demonstrated increased medication adherence with the use of medication adherence apps [22-29], but only 3 of these were conducted in low-income medically underserved populations [27-29]. Two of those studies in underserved populations were focused on hypertension [27,28], and the other included hypertension and type 2 diabetes and was a post hoc analysis of a digital health offering using a cluster-randomized design [29]. Only 1 of these studies, conducted in an urban low-income population with hypertension, obtained satisfaction information on the intervention [28]. Satisfaction with the app was high, and most participants felt they would use the app or a similar program in the future. Participants agreed that the app made it easier to keep track of their medications and that having a medication list on their phone made it easier to take care of themselves. More detailed feedback from the participants or information on which features of the app were used was not gathered [28].

A high-quality, free, commercially available smartphone medication adherence app called Medisafe supports patients in adhering to their medication regimen across disease states [30]. It uses a variety of advanced features, such as daily reminders, which can be snoozed, rescheduled, and marked as taken or missed; medication educational information in the form of medication cards and videos; an interaction checker; customizable refill reminders; adherence reports; and the ability to designate a social support person to be notified if a medication is skipped [23]. A randomized controlled trial (RCT) mixed methods evaluation in patients with coronary artery disease examined the efficacy [23] and the utility, acceptability, and engagement [31] of the Medisafe app. This study was conducted in a large urban tertiary hospital in Sydney, Australia and did not focus on a medically underserved population. In addition to improving self-reported medication adherence, overall utility was rated positively, with participants indicating that having their medication list on their phone and receiving timed reminders were useful. Most participants engaged with the app and its features; found the app acceptable, convenient, and easy to use; planned to continue using the app; and would recommend it to a family member or friend [31].

A qualitative study explored the potential benefits and barriers of using a mobile medication app in a medically underserved population in the United States [18]. The researchers found that patients were willing to try smartphone apps but expressed concerns about affordability, the technology being too complicated, not keeping phones with them all the time, and not being able to use all the features [18]. That study exposed a knowledge gap regarding the perceptions and user experiences of medically underserved patients with chronic illnesses who use free commercially available medication adherence apps.

Purpose

To address the knowledge gaps, a larger RCT investigating the efficacy of the Medisafe app (reported elsewhere) [32] was performed for evaluating the overall use and satisfaction of patients with a variety of chronic illnesses in a medically

underserved population in an FQHC in the United States. The efficacy portion of the RCT found significant improvements in both medication adherence (Cohen *d*=0.52; *P*=.01) and medication self-efficacy (Cohen *d*=0.43; *P*=.04) for participants assigned to use the app compared to the usual care group [32]. As part of this RCT, participants assigned to the intervention arm provided feedback and usage data regarding their experience using the Medisafe app [32]. This manuscript presents the summaries of the perceptions of patients enrolled in the intervention arm of the RCT regarding the usefulness of and satisfaction with the app features after 1 month of use. Given the improvements observed in medication adherence and self-efficacy, understanding patients perceived usefulness and satisfaction with the app is important to address potential barriers for uptake and use in larger medically underserved patient populations who often receive care for chronic illnesses in FQHCs.

Methods

Setting and Recruitment

Participants were recruited from November 2021 through June 2022 from an outpatient adult medicine department in an FQHC in the northeastern United States. The inclusion criteria for the RCT study were as follows: (1) adults aged 18 years or older, (2) having the ability to speak and understand English, (3) personally owning and using an Android smartphone (version 5.0 or above and at least 88 MB of phone space) or iOS smartphone (version 13 or later and at least 165 MB of phone space), and (4) taking at least one medication for a chronic condition based on the computerized medical record at the health center. Patients were excluded if they: (1) were already using a medication reminder app or other electronic reminder system such as phone alarms, (2) owned a smartphone not capable of downloading the app, (3) had a diagnosis of severe dementia or serious mental illness, or (4) were otherwise unable to use a mobile phone or the medication reminder software either physically or cognitively. For this study, only those participants who were randomized to the intervention group and used the Medisafe app were invited to participate in the survey.

Recruitment involved an informational flyer, a referral form from clinicians at the health center, and in-person recruitment. The flyer and referral forms were available to clinicians, staff, and patients in the FQHC offices and at the reception desk. The form contained study information, the contact information of the principal investigator (PI), and a place for patients interested in participation to provide their contact information. The form also contained a section for health care providers (HCPs) to refer potential patients and a section for their signature to verify that the patient's medications listed in the electronic health record were correct and current. The PI (CH) conducted in-person recruitment at the FQHC on multiple days per week and worked with clinic staff to identify potentially eligible patients. Although a convenience sample was used (ie, patients visiting the clinic on any given day), the risk of selection bias was reduced by using the aforementioned 2-prong approach to identify eligible patients for recruitment, inviting all patients meeting the eligibility criteria to participate, and using random assignment to either the intervention or control group. The 2 groups were not statistically different [32]. The PI approached eligible patients at the end of the health center visit to inform them of the study. Once the PI confirmed participant eligibility and obtained informed consent, participants were randomized to either the intervention or control group. Additional details of study procedures for the RCT have been previously published [32].

Statistical Analysis

Based on a preliminary efficacy study for the RCT [33], a total sample of 60 participants was estimated to enable the detection of differences between the groups with Cohen *d* effect values of 0.6-0.7 (80% power; α=.05) for the quantitative study variables [32]. As 30 participants were randomized to the app intervention group, their usage and satisfaction data are presented in this manuscript. Descriptive statistics and frequency distributions were used to describe the sample and determine if the data were normally distributed. Qualitative participant responses were transcribed into an Excel spreadsheet, and the content was coded and summarized as themes by the researcher (CH) and PhD faculty advisor (DPS).

Ethical Considerations

This research was approved by the Vanderbilt University Institutional Review Board (IRB #211409) and is registered with ClinicalTrials.gov (NCT05098743). All participants received a copy of the consent form. Based on participant preference, informed consent was completed as either an IRB-approved e-consent form or a hard copy. The consent form contained a privacy and confidentiality protection description ensuring that all study data are deidentified. Participants received a US $25 gift card after completion of the baseline survey and a US $35 gift card after completion of the follow-up survey.

Medisafe App Intervention

The Medisafe app is a Health Insurance Portability and Accountability Act (HIPAA) compliant medication adherence app that is available at no cost in the iTunes and Google app stores. In previous studies, Medisafe was ranked highly among medication reminder apps [30,34]. The Medisafe app provides interactive and customizable daily timed reminders to reinforce medication taking at a set time every day through a push notification, equivalent to an alarm or text message. The reminders can be snoozed, rescheduled, or marked as taken or skipped, and they are repeated a total of 3 times in 10-minute intervals if the participant does not mark the medication dose. Additional features include educational information in the form of a medication database that includes written and video content [30]. The written content is in the form of a medication card, which Medisafe terms a leaflet, and it reviews what the medicine is used for, medication interactions, what to do if the user misses a dose, what the user should watch for, possible side effects, how it should be used, and where to store the medication. Some medications also have video content, consisting of a brief clip of an HCP reviewing the most important considerations when taking the medication, which can be viewed on tapping the information icon. There is also an interactions tab that lists possible interactions with the medications or food/alcohol.

Lastly, there is an interaction checker where participants can check for interactions between their medications. The app also has a Medfriend feature, which allows participants to designate a family member or friend as their support person. The Medfriend feature will alert the designated Medfriend who can provide peer support and additional reminders through text messages, emails, or a telephone call if the patient misses a dose. The language mode of the app can be switched, if desired, to multiple foreign languages, including Spanish.

The PI helped consented participants set up the app using a copy of the patient's medication list extracted from the electronic health record. The PI also reviewed how participants could access and edit their medications; access medication educational content; and indicate when a medication was taken, skipped, or rescheduled. The PI reviewed with participants additional app features such as Medfriend, medication interaction checking, adherence reports, and refill reminders. Participants were also shown how to access the help and support section in the app. Following the app set up, the PI provided previously developed educational materials as a take-home resource. These materials, specific to either an iPhone or Android smartphone, included a laminated "quick tips" card with short instructions on the reviewed features and how to access them. Additional detailed instructions on how to use the app were printed in a question-and-answer format and distributed to participants.

Data Collection and Study Procedures

All study data were collected using observation, a REDCap web-based survey, and secondary data provided by the app company and were obtained using a data-sharing agreement between institutions. REDCap is a secure web-based software platform designed to support data capture for research studies [35,36]. Following consent, all participants completed the baseline study survey. Those randomized to the intervention group also completed a survey at study end to obtain feedback on the app, including usability and satisfaction.

Observation

While setting up the app for the intervention group, the PI completed a study-specific observational behavioral checklist. The purpose of the checklist was to inform the researchers if participants had difficulty setting up the app and how long it took them to do so. The checklist included documenting whether the participant had difficulty visualizing the app and had difficulty with dexterity while setting up the app, and mentioning the number of times the participant's input of medications needed to be corrected. The length of time in minutes from starting the download of the app to completing app set up and reviewing the app was also documented.

Survey

After 1 month, based on preference, participants completed the follow-up survey online, by phone, or in-person at the health center. Participants who did not complete the follow-up survey within 10 days of the 1-month follow-up date received 2 reminders via phone, email, or text message.

Measures

The end-of-study survey included 11 questions that assessed satisfaction and usability using a 5-point Likert scale with responses ranging from "strongly disagree" to "strongly agree." The survey questions were developed and pilot tested before use [33]. Seven of the first 11 questions were developed by Santo et al [31] and were used with permission in this study, while the remaining 4 were developed by the researchers. Six additional questions asked about the use of additional features such as the educational information, Medfriend feature, interaction checker, adherence report, refill reminder, and additional morning reminder of the Medisafe app. These questions asked participants whether they used a given feature, and if they did, whether they found the feature useful. There were open-text response options available to elicit qualitative data from the app participants such as how a feature helped them manage their medications and what they found most useful about the feature. The remainder of the survey included 6 general use questions previously developed and pilot tested, 4 of which were "Yes/No" questions (eg, did you use the refill reminder and did you have technical issues with the smartphone app?). The remaining 2 questions assessed how often medication reminders were received each day and which language the participant used.

Secondary Data

Deidentified usage data were obtained from the Medisafe company at study completion. Medisafe provided the PI with objective user interactions with the Medisafe app, such as whether educational information in the form of a leaflet was accessed by participants and whether the Medfriend feature was used.

Analysis

Descriptive statistics and frequency distributions were used to describe the sample and determine if the data were normally distributed. Open-ended survey question responses were imported into an Excel (Microsoft Corp) spreadsheet, and the content was coded and summarized as themes by the researcher (CH) and the PhD faculty advisor (DPS). This approach was taken given the short, free-text, and limited responses received. Since the qualitative data came from the open-ended survey responses, data collection was based on sample size rather than data saturation.

Results

Participant Characteristics

Complete details are included in Table 1, and information can also be found in the app efficacy manuscript [32]. A flowchart of study participants in the main RCT can be found in Figure 1. The median age of the 30 participants using the app was 53.5 years (IQR 37-76 years). Most participants in the intervention group were non-White (23/29, 79%). Races/ethnicities were as follows: Asian (5/29, 17%), Black or African American (10/29, 35%), Hispanic/Latino (4/29, 14%), Native American or Alaska Native (1/29, 3%), and other (3/29, 10%). More than 75% of the participants had government insurance (25/30, 83%), and a small number of participants were uninsured (2/30, 7%). Brief

health literacy scores were generally high (median 12.0 of a possible score of 15, IQR 5-15). Slightly more than half of the participants (16/29, 55%) reported that it was either very or somewhat difficult to pay their monthly bills. The most common chronic illness was hypertension (22/30, 73%), followed by hyperlipidemia (19/30, 63%) and type 2 diabetes (14/30, 47%). Most participants (25/30, 83.3%) had 2 or more chronic illnesses.

Table 1. Sociodemographic characteristics of the participants using the app.

Characteristic	Value, n (%)
Race/ethnicity (N=29)	
Asian	5 (17)
Black or African American	10 (35)
Hispanic/Latino	4 (14)
Native American or Alaska Native	1 (3)
White	6 (21)
Other	3 (10)
Marital status (N=30)	
Married/partnered	15 (50)
Single/never married	15 (50)
Employment status (N=30)	
Employed	15 (50)
Unemployed	12 (40)
Retired	3 (10)
Education (N=30)	
Some high school or less	8 (27)
High school graduate	4 (13)
College credit, no degree	8 (27)
Trade/vocational training	4 (13)
Associate’s degree	2 (7)
Bachelor’s degree or higher	4 (13)
Difficulty paying bills (N=29)	
Very difficult	6 (21)
Somewhat difficult	10 (35)
Not very difficult	8 (28)
Not at all difficult	5 (17)
Type of health insurance (N=30)	
Uninsured (sliding scale)	2 (7)
Government insurance	25 (83)
Private insurance	3 (10)
Current chronic illness (N=30)	
Hypertension	22 (73)

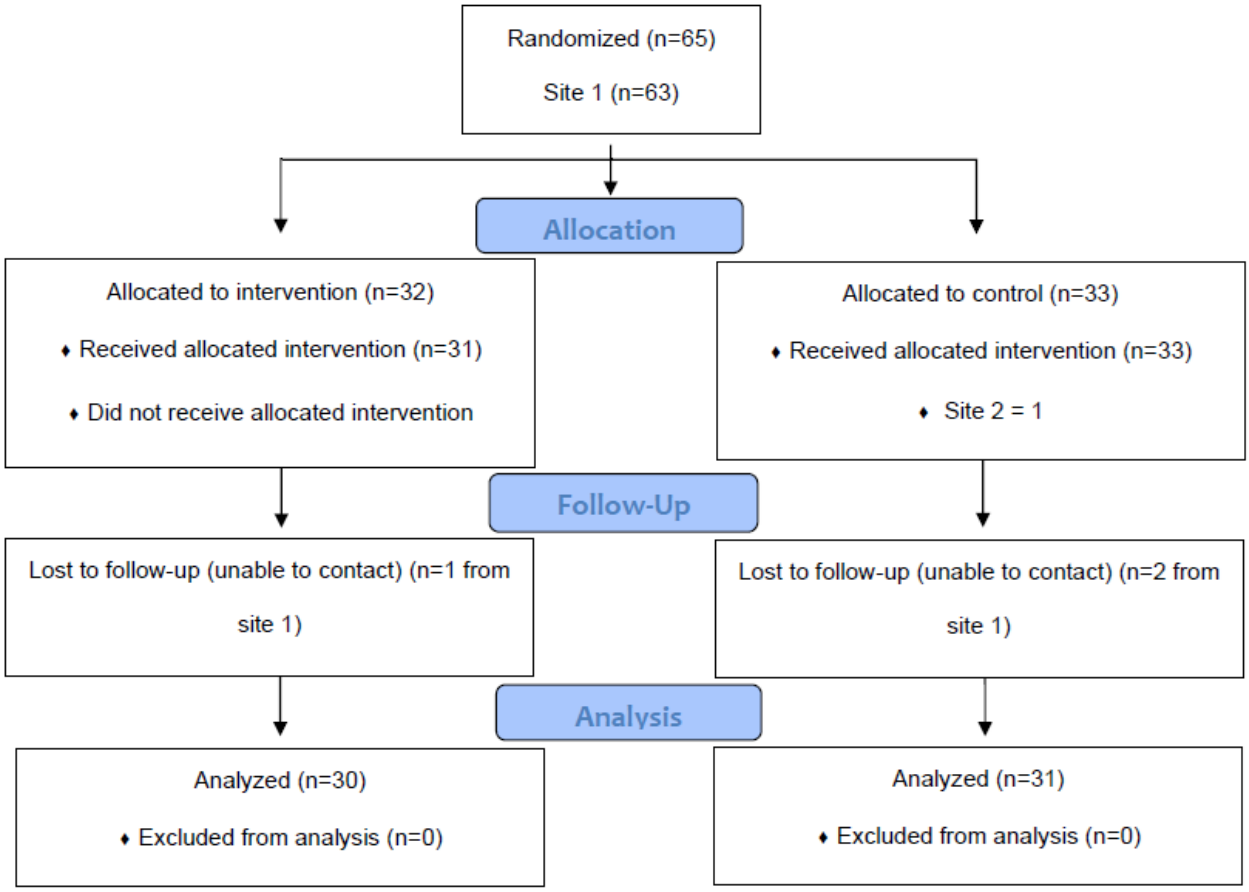
Hyperlipidemia	19 (63)
Asthma	5 (17)
Other[a]	11 (37)

[a]Includes depression (n=1), type 1 diabetes (n=1), chronic obstructive pulmonary disease (n=1), heart disease (n=1), cirrhosis (n=1), anxiety (n=1), gout (n=1), rheumatoid arthritis (n=1), thyroid disorder (n=1), hypothyroidism (n=2), gastroesophageal reflux disease (n=1), arthritis (chronic pain) (n=1), and fibromyalgia (n=1).

Figure 1. Flowchart of study participants in the larger randomized controlled trial of the efficacy of the app intervention.



Behavioral Observations While Setting Up the App

During app set up, some participants (4/30, 13%) expressed difficulty visualizing the app owing to the unavailability of their eyeglasses, which they stated were either in their car or left at home. No participants had difficulty with dexterity while setting up the app, and the median time it took from starting the app download to completing the set up and reviewing the app was 15 minutes (IQR 10.0-25.0; minimum 10, maximum 30 minutes). The majority of participants (21/30, 70%) did not need to be corrected when they entered the medications. However, 4 (13%) were corrected by the researcher once, 3 (10%) were corrected twice, and 2 (7%) were corrected thrice. Patients were corrected when they spelled the medication name incorrectly, chose the incorrect medication dose, or set an incorrect time for the reminder.

Satisfaction and Utility

Summaries of the participants' reports of satisfaction are presented in Table 2.

Most participants (27/30, 90%) strongly agreed that they liked the app design, while most (25/30, 83%) strongly agreed that it was useful to have their medication list on their smartphone. Some participants (2/30, 7%) mentioned the usefulness of the app when seeing other HCPs to indicate the medications they were taking during medication reconciliation. Furthermore, a large proportion of participants (28/30, 93%) strongly agreed that the reminders helped them to remember to take their medications at the correct time each day. The majority of participants strongly agreed that the app was easy to use (27/30, 90%) and convenient (28/30, 93%) and that they would continue using the app (26/30, 87%). A small number of participants (2/30, 7%) somewhat agreed that they would continue using the app. It is important to note that some participants (2/30, 7%) strongly disagreed that they would continue using the app, because they found the reminders annoying. All the participants (30/30, 100%) somewhat agreed or strongly agreed that they would recommend the app to family and friends.

Table 2. Satisfaction with the app (N=30).

Satisfaction information	Value (N=30), n (%)
Liked the app design	
Neutral	1 (3)
Somewhat agree	2 (7)
Strongly agree	27 (90)
It is easy to tap the correct icon with my finger	
Neutral	1 (3)
Somewhat agree	1 (3)
Strongly agree	28 (93)
I am able to see all the options in the app	
Neutral	3 (10)
Somewhat agree	1 (3)
Strongly agree	26 (87)
It is useful to have a medication list on the smartphone	
Somewhat disagree	1 (3)
Neutral	1 (3)
Somewhat agree	3 (10)
Strongly agree	25 (83)
Reminders helped me remember to take my medications at the correct time each day	
Neutral	1 (3)
Somewhat agree	1 (3)
Strongly agree	28 (93)
Found it easy to use the app	
Somewhat disagree	1 (3)
Neutral	1 (3)
Somewhat agree	1 (3)
Strongly agree	27 (90)
Found it easy to set up reminders in the app	
Neutral	3 (10)
Somewhat agree	2 (7)
Strongly agree	25 (83)
Found it convenient to have the app	
Strongly disagree	1 (3)
Somewhat disagree	1 (3)
Strongly agree	28 (93)
Found it useful to snooze the reminder	
Strongly disagree	1 (3)
Somewhat disagree	1 (3)
Neutral	10 (33)
Somewhat agree	3 (10)
Strongly agree	15 (50)
Will continue using the app	
Strongly disagree	2 (7)

Satisfaction information	Value (N=30), n (%)
Somewhat disagree	1 (3)
Neutral	1 (3)
Strongly agree	26 (87)
Will recommend the app to family and friends	
Somewhat agree	2 (7)
Strongly agree	28 (93)

The 2 participants (10%) who were dissatisfied with the app described the reasons why. One said:

> *It is annoying when you get a reminder and you are in the middle of doing your work. This is not for everybody. I work on the computer and on my cell phone and it is very distracting to receive the reminder in the middle of working on something. It might be better for someone who doesn't have as much going on. I find it very distracting.*

The other participant had technical difficulties but blamed it on the type of phone they had:

> *The bug thing with the notification alarms was a problem. I have an android - a cheap phone. My phones get destroyed because of the type of work I do.*

Use of Educational Information

Almost half of the participants (12/30, 40%), self-reported accessing educational information. To the contrary, objective usage data from Medisafe indicated that only 3 participants (10%) accessed the educational content, which was defined as cards termed “leaflets” or videos. According to Medisafe, this was done for a total of 14 medications. Additionally, Medisafe reported that only 1 participant accessed 4 different videos and 1 leaflet, 1 participant accessed 1 leaflet, and 1 participant accessed 6 different videos and 2 leaflets. Although not all participants actually accessed the information, those who reported accessing the educational information (12/12, 100%) found the information useful. When asked about how they used the educational information in the app, the participants reported learning about the side effects of the medications (6/12, 50%), reported that it was helpful for general knowledge (4/12, 33%), and mentioned using it to learn more about medication and food interactions (2/12, 17%).

Medfriend Feature

Based on usage data from Medisafe, only 1 participant (3%) used the Medfriend feature. That participant was very positive about the feature and reported that her husband would call her to say, “Are you taking your medicines?” She stated:

> *It gets him involved. It makes him recognize that I need support and I need to take the medicine. It makes me know he loves me.*

Another participant self-reported using the Medfriend feature, but there was no indication of use in the Medisafe data. The participant reported that when her husband was notified, he would send a text about her forgetting her medications and she would remember to take them. Those who did not use the Medfriend option were asked, “who might that person be for you?” Among those who responded (18/30, 60%), the top 3 most common responses were their sibling (4/18, 22%), their child (4/18, 22%), and their husband or wife (4/18, 22%).

Interaction Checker

All participants who used the interaction checker (5/30, 17%) agreed that it was useful. One participant reported that 2 of the medications she had been taking together should be taken separately and stated, “It was a lifesaver!” The other 4 participants expressed an appreciation for being able to have access to this type of information. The use of the interaction checker was distinct from the educational content and could not be verified in the Medisafe data as Medisafe does not register or track the use of the interaction checker.

Adherence Reports and Reminders

Participants (8/30, 27%) who checked their adherence report agreed it was useful. The adherence report provided them with a history of their daily missed and taken medications as well as a weekly adherence percentage based on what they reported when marking medication reminders in the app. Participants reported experiencing positive reinforcement for adhering to their medications through the adherence report, mentioned the affirmation they received when they saw a high percentage of adherence, and reported appreciating the positive reinforcement as useful. Some participants (2/30, 7%) mentioned that it incentivized them to reach higher levels of adherence.

Slightly less than half of the participants (13/30, 43%) received reminders to take their medications 2 times a day, while around one-third (9/30, 30%) received reminders 3 or more times a day. Reminders were generally well received:

> *I like the reminder. The shaking of the pill bottle helps me. Sometimes I will wake up at night and remember hearing the shaking pill bottle that day and I will get out of bed and check if I took my pills that day. I might be cooking with the grandkids and the first reminder goes off. I might ignore it but with the second reminder I might put the bottles on the counter so I can remember.*

Three participants (15%) mentioned the app’s helpfulness, particularly for those who have multiple chronic illnesses and take multiple medications.

> *This app was a lifesaver. I take a lot of different medication so sometimes I forget whether I took the*

> *medication or not. I can check the app to see if I took it or not.*

One of those 3 participants commented as follows:

> *It is perfect for people who have multiple illnesses and take a lot of different medications. I take eight different medications a day.*

Most of the participants (27/30, 90%) did not use the refill reminder. In their comments, a number of participants said they received automatic refill reminders from their pharmacy and therefore did not need this feature of the app. All participants (30/30, 100%) used the app in English, and the majority (24/30, 80%) did not make any changes, such as changing the time of a reminder, removing or adding a medication, or changing the medication dose in the app. Many participants (13/30, 43%) said they would use the app to manage someone else's medications.

Technical Difficulties Using the App

Some participants (4/30, 13%) mentioned they had technical difficulties. Of those who reported difficulties, 3 (75%) needed to allow notifications from the app to hear the reminders. Another user mentioned that they had to tap the "take all" icon a number of times before it registered and suggested that it should be made bigger or be more centrally placed. Participants gave additional feedback about the app when asked (20/30, 67%). In this section, participants (7/20, 35%) specifically mentioned liking the reminder.

> *It was really nice to hear that shaking sound. It was fun.*

Some participants (2/20, 10%) reported that the snooze function was particularly helpful when they were away from home.

> *The snooze option is helpful to use when I am out and don't have my medications. When I come back home it reminds me so I remember to take it.*

Social Support

The 2 participants (7%) who self-reported using the Medfriend feature were very enthusiastic.

> *It's a great app and I love it. My husband is on it for his meds and I am his Medfriend. I am also going to get my mother hooked up on it.*

The other participant shared her thoughts about the feature, highlighting her increased feelings of self-efficacy and social support.

> *This app is about being a team player. You are able to help me and I am able to help you. I can now say "I did it" "I can do this." This is a good app. I can't see anyone who is interested in their health not using this app. Since being introduced to this app I know that it is there for me.*

Discussion

Principal Findings

As part of an RCT using the Medisafe medication adherence app in a medically underserved population with a variety of chronic illnesses, behavioral observations on app use and satisfaction and usage data were gathered from participants in the intervention arm of the study and the Medisafe company. The quantitative RCT results (reported elsewhere) [32] found significant improvements in both medication adherence and medication self-efficacy for participants who used the app. The portion of the RCT presented in this manuscript, which collected behavioral observations and satisfaction and usage data from the intervention arm, identified that participants were satisfied with the app and found it useful. Even though the use of the additional features was generally low, those who used them found them useful. Most participants did not need help setting up the app. An important strength of this RCT is that it explored patients' perceptions of the usefulness of the app and their satisfaction with the app and therefore fills an important knowledge gap. This was done by collecting both quantitative and qualitative data through open-response questions, which gave voice to the perspectives of a low-income racially and ethnically diverse sample of adults with chronic illnesses receiving care in an FQHC [17,18]. As FQHCs are reporting a growth in the rates of treating complex chronic conditions [10] and there are lower rates of medication adherence among populations with lower socioeconomic status and those with multiple conditions [37], the implementation of tools to enhance medication adherence is imperative. Understanding the user experience with the Medisafe mobile app demonstrated that wider-scale use of the Medisafe app is feasible in a low-income population with multiple chronic illnesses. Systematic literature reviews have pointed out a gap in implementation studies of mobile app interventions in this population [38]. This study addressed an important knowledge gap by demonstrating that the use of a commercially available free medication adherence app is a viable option for medically underserved adult patients with chronic diseases.

Prior research found that medically underserved patients expressed reluctance about paying for a medication adherence app [18]. While not directly addressed in this study, some participants anecdotally asked before enrolling in the study if they would need to pay for the app, and when told it was free, they expressed interest in participating. This underscores the importance of not having patients incur additional costs for the technology and was a strength of this intervention.

Most participants were able to set up the app with minimal assistance, with a median duration time of 15 minutes during the behavioral observation. It is important to note that 30% of the participants needed to be corrected 1-3 times when setting up the app, thus pointing to the importance of helping some patients set up the app initially and checking that the medications are entered accurately. This highlights a difficulty with individuals setting up the app. Although not implemented in this study, another option is to import medications from other databases, such as Apple Health, or a pharmacy directly. This may shorten the time it takes to set up the app. Once the app is set up properly, in addition to HCPs assisting patients, the help and support page and the company contact could serve as a resource for patients.

Survey data indicated that satisfaction with the app was high, with most patients strongly agreeing it was easy to use. All

intervention group participants (30/30, 100%) strongly agreed that they would recommend the app to family or friends. This was higher than the proportion in the study by Santo et al [31], which used Medisafe and found that 78.6% of patients with coronary heart disease would recommend it [31], and the study by Anglada-Martinez et al [24], which used a similar app and found that 71.4% of patients receiving treatment for hypertension, dyslipidemia, heart failure, or HIV would recommend it [24]. Both these studies were, however, conducted outside of the United States. It may be that Americans are more familiar with app technologies and feel more comfortable recommending apps to others.

Qualitative research conducted in a medically underserved population with chronic illness regarding the use of medication adherence apps found that technical issues and complexity were concerns when setting up and using these apps [18]. One study involving a medication adherence app similar to Medisafe indicated that 50% of participants reported problems receiving reminders [24]. The Medisafe app used in this study is a commercially available app with high-quality assessment ratings [30,39], and in this study, technical issues were rare. The most common issue was not receiving the reminders until the participant allowed notifications from the app in their phone settings. No participants expressed that the app was technically complex, which was previously cited as a concern in this population but was not an issue in this study [18]. One participant had ongoing technical issues receiving reminders. These findings suggest that the Medisafe app can be implemented in this population from a technology standpoint, and participants did not find it difficult to use.

Similar to other studies involving the Medisafe app, feedback results point to receiving timed medication reminders as the most used aspect of the app [31]. Furthermore, feedback regarding the app aligns with the findings of other studies linking medication reminders with medication adherence [22,25,28,29]. Participants found the snooze function of the reminder helpful when they were not home to take their medications and used this function as a reminder to take their medications when they got home. The snooze function therefore was an important component of the app when participants experienced disruptions in their routines, such as being away from their medications. The findings also align with a previous study in a medically underserved population where participants indicated that disruptions in their daily routines negatively affected their medication adherence [18]. This study demonstrated that patients used the reminder feature when available, and the majority of patients found it helpful in improving medication adherence. The 1 participant who was bothered by the reminders used his phone for work and found the reminders distracting if he was using his phone for work purposes. The reminders predominantly targeted the phenomenon of forgetting, which has been found by a study to be the most likely cause of reported nonadherence in low-income uninsured patients with multiple chronic illnesses [13].

Research has shown that both patient knowledge of medications and their satisfaction with the information provided about their medications can improve medication adherence [40]. There was a discrepancy between the data reported by Medisafe and the number of participants who self-reported accessing educational information. Although the reason for this discrepancy is not clear, several possibilities exist. First, participants could have overstated the use of educational features. Another potential reason might be related to the specific data Medisafe defines as educational data. Medisafe does not collect data on the use of the interaction tracker or the “For You” tab at the bottom of the app and only collects data if a participant clicks on the educational leaflet and opens it up. In contrast, participants might have perceived content under the “For You” tab and drug interaction materials or videos as educational materials, resulting in a discrepancy between patient self-reported data and Medisafe data regarding accessing educational content. The feedback received demonstrated that participants who reported accessing the educational information (less than half) were very positive about doing so. The educational information was found to be useful for learning about side effects and food and medication interactions. Because individuals have different preferences for the amount of medication information they receive and the way that information is delivered [41], the modularity of the Medisafe app is useful to facilitate patient education in a practical and less burdensome way. The information is available at the patient’s fingertips and can be accessed as frequently as needed to learn what they want at their convenience. The educational app feature is also advantageous to HCPs as it alleviates some of the burden and time commitment associated with educating patients about their medications.

Social support has been found to have a positive effect on medication adherence [42-44]. Studies deploying digital technologies in the form of web-based online communities to provide social support have generally demonstrated that they can support people emotionally, socially, practically, and politically [45]. However, using technology to provide social support has not been studied in the context of a commercially available medication adherence mobile app. This study addressed this gap by studying social support via a commercially available app in the context of medication adherence. The Medisafe app offers social support in the form of Medfriend, and this is the first known study to incorporate this feature as part of the study intervention. Some studies have pointed out that online social support networks for those with specific chronic illnesses lessened the burden on relationships with family and friends, who are referred to as “offline” support persons [45,46]. However, despite asking and offering to demonstrate how to set up the Medfriend feature, usage of the Medfriend feature was very low. This study did not gather information on why participants chose not to set up the Medfriend feature, and this is a limitation of the study. It may have been because this feature was seen as too burdensome by the patients or their support people, most of whom were identified as family members. Patients might have avoided using Medfriend due to confidentiality concerns associated with this feature, which entails giving access to the user’s medication list, as many participants (13/30, 43%) were willing to use the app to manage someone else’s medications but chose not to share their own medication information. Another challenge regarding the Medfriend feature was that there was a discrepancy between Medisafe data and self-reported data on the use of the Medfriend feature. Despite the aforementioned concerns, the 2

participants who reported using the Medfriend feature were satisfied with it as they perceived that the app fostered social support. To further explore the social support feature of the app, research on dyads who use the app to manage the medications of family members might shed new light on the phenomenon of incorporating social support into mobile apps. By studying a subset of the population, including patients and their caregivers, the social support feature may be used more frequently. If the confidentiality of medication lists proves to be a barrier, a feature that dissociates specific medications from the reminder might address that concern. Support persons could receive a general text that their online Medfriend has not taken their medications without sharing details on the specific medications.

Participants reported that having a list of medications on their phone was beneficial, which was also noted in a population of patients with coronary heart disease who used the Medisafe app in Australia [31]. When managing chronic illnesses, patients are often referred outside of the FQHC setting or require hospitalization to receive care. Some participants mentioned using the phone medication list for medication reconciliation when seeing other HCPs. This finding is in contrast to that of another study of patients presenting to an emergency department setting, which found that emergency department patients rarely used their mobile phones to share their medication list during medication reconciliation [47]. Medication reconciliation can be facilitated through the adoption of these technologies. HCPs in both primary care and tertiary care settings should suggest and support patients with implementing researched medication adherence mobile apps. The sample of this study included many patients with multiple chronic conditions. These participants appreciated the ability of the app to work across multiple chronic illnesses and its helpfulness when taking multiple medications. This finding underscores the importance of advocating for the use of medication adherence apps like Medisafe, which can work across a range of illnesses and medications and can be easily adjusted when medications change over the disease trajectory. Additionally, participants who used the adherence report felt that it provided positive reinforcement and was an incentive to reach higher levels of adherence. Similar to what has been reported in other studies, a majority of participants reported not using the refill reminder because they already received text alerts from their pharmacy, which they found helpful [18]. When HCPs select apps for patients to enhance their medication adherence, careful attention to app features and evaluation of existing research findings, such as the findings of this study, are important.

Limitations

This study had several limitations. First, the study duration of 1 month does not provide insights regarding long-term patient satisfaction and continued use of app features, which are important aspects of chronic disease management. Though this study found high satisfaction and usability of the app during the first month of use, future studies should evaluate the role of time in app usage and satisfaction. Medisafe data and self-reported data showed that the uptake of educational information and the Medfriend social support feature was low. There was an unresolved discrepancy in the number of participants who reported accessing educational information and the actual usage identified from the Medisafe data. The discrepancy might be because Medisafe data only captured if the leaflet was accessed. Patients may have perceived accessing educational information as clicking the interaction button or clicking the “For You” tab at the bottom of the app, which Medisafe data did not capture. This can be clarified in the future by a more detailed definition of what constitutes the educational features of the app. Incorporating interviews to clarify subsequent survey results would strengthen future research studies. Another limitation of the study is that we did not gather participants’ inputs about why they chose not to use the Medfriend feature. Therefore, this study cannot speak about the potential benefits of this feature. Finally, although the app can be used in several languages and many patients who seek care at FQHCs speak a primary language other than English [48], the researchers were not able to incorporate multiple languages into the study protocol.

Future Research

FQHCs and primary care settings working with adults who are chronically ill should consider medication adherence mobile phone apps as acceptable and practical tools to support medication adherence. Future studies could include a larger sample, consider the use of the available provider portal, and consider the experiences of both providers and patients. Cost analysis could be performed, and hospitalization rates and long-term usage and health outcomes over time could be studied. This study was for a 30-day period, but a study with a longer duration is necessary to see if the use of the app is sustained over time. In this study, only 2 participants reported barriers to using the app, and a larger long-term study could further explore barriers to sustained use and strategies for maintaining engagement in this population. Future research should use mixed methods to provide insights into app modification, the nature of barriers to use, and how app features, such as the Medfriend feature, could more easily be implemented among patients who might benefit the most from such features. As uptake of the additional features of the app, such as educational information and the Medfriend option, was low in this study, future research using larger datasets could explore what types of patients chose to use specific features and why they did. We purposefully did not require certain features to be used because we wanted to organically discover which features were most often used, if any.

Studying the usability of the app and its associated effects in ethnic populations in various languages is an important area of future research as community health centers serve a large number of patients with limited English proficiency [48].

Conclusion

This study demonstrated that the medication adherence app is a useful, convenient, and feasible intervention in an FQHC setting. The various features of this app positively influenced the medication-taking behaviors of adults with one or more chronic illnesses. Participants were satisfied with the app and the features they chose to use. Reminders were viewed as helpful by the majority of participants. The medication list feature was particularly useful for patients who had multiple chronic

conditions and saw multiple providers, and some used it to facilitate medication reconciliation. The findings of this study have important clinical implications, as clinicians can recommend the use of medication adherence apps as tools to provide support in adhering to medication regimens and as additional tools to use during medication reconciliation.

Acknowledgments

We would like to extend our gratitude to the leadership and staff of the health center and the participants who made this work possible. Support for this study was provided by the Vanderbilt Institute for Clinical and Translational Research (VICTR) #VR56076, Student Achievement Research Award (SARA), and VICTR #VR60349. The research study was also supported by CTSA award UL1TR002243 from the National Center for Advancing Translational Sciences. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the National Center for Advancing Translational Sciences of the National Institutes of Health.

Abstract

Background: Digital health education can enhance the quality of life of patients with heart failure by providing accessible and tailored information, which is essential for effective self-care and self-management.

Objective: This work aims to develop a mobile health knowledge transfer concept for heart failure in a user-centered design process grounded in theoretical frameworks. This approach centers on enhancing the usability, patient engagement, and meaningfulness of mobile health education in the context of heart failure.

Methods: A user-centered design process was employed. First, semistructured stakeholder interviews were conducted with patients (n=9) and medical experts (n=5). The results were used to develop a health knowledge transfer concept for a mobile health app for heart failure. This concept was implemented as a digital prototype based on an existing German mobile health app for patients with heart failure. We used this prototype to evaluate our concept with patients with heart failure in a study composed of user testing and semistructured patient interviews (n=7).

Results: Stakeholder interviews identified five themes relevant to mobile health education: individualization, content relevance, media diversity, motivation strategies, and trust-building mechanisms. The evaluation of our prototype showed that patients value the adaptation of content to individual interests and prior knowledge. Digital rewards such as badges and push notifications can increase motivation and engagement but should be used with care to avoid overload, irrelevance, and repetition.

Conclusions: Our findings emphasize the importance of tailoring mobile health education to the specific needs and preferences of patients with heart failure. At the same time, they also highlight the careful implementation of motivation strategies to promote user engagement effectively. These implications offer guidance for developing more impactful interventions to improve health outcomes for this population.

Introduction

In 2019, heart failure affected more than 56 million people worldwide [1]. The diagnosis of heart failure entails severe health consequences for patients and significant financial resources for public health systems [2]. In light of an aging population, heart failure is becoming increasingly important in society and requires new approaches for prevention, management, and therapy to mitigate health impact [3,4].

Heart failure requires a high level of active patient involvement [5]. Self-monitoring of physiological parameters, medication intake, nutrition, and physical activity are crucial factors in preventing the hospitalizations of patients [6,7]. In this context, health literacy plays a major role since high levels of health literacy in patients with heart failure promote patient empowerment, self-care practices, and medication adherence [8-10]. Health literacy can be described as the capacity of a person to access and understand health-related information, place it in context, and use it responsibly to promote and

maintain good health [11]. With a focus on heart failure and other cardiovascular diseases, The American Heart Association concludes that health literacy is crucial for effective treatments for cardiovascular diseases and acknowledges information technology as a potential path to improving health literacy [12]. In the long-term, low health literacy is associated with an increased risk for hospitalizations and death in patients with heart failure [13].

To effectively deliver information to patients and achieve learning effects, mobile health technology offers great potential. This applies to populations with low health literacy in particular [14-16]. As smartphone access has become widespread across various demographic groups, including those with lower socioeconomic status, they provide an accessible platform for delivering tailored health interventions to underserved populations [17,18]. Enhancing health literacy requires attention not only to disease-specific content but also to digital health literacy, empowering users to navigate health-related inquiries online effectively [14,19,20]. However, several barriers have been identified, including the access to apps, the readability of content as well as the usability of digital health services [14,21]. In the context of heart failure, evidence about the effects of mobile health for promoting health literacy is still limited. Allida et al identified no increase in heart failure knowledge through digital educational content and unclear evidence on self-efficacy, self-care, and health-related quality of life [22]. In contrast, several recent studies demonstrated positive effects on quality of life, hospitalization rates, and self-management abilities [23-25]. However, despite the potential benefits, these approaches lack the incorporation of theoretical frameworks for engaging, appealing, and effective knowledge transfer. Furthermore, patients with heart failure are hardly involved in the development process of mobile health interventions.

Thus, the aim of this work was to develop a concept for a sustainable and engaging knowledge transfer with a specific focus on the needs and preferences of patients with heart failure. Theoretical frameworks for mobile health knowledge transfer and the involvement of end-users throughout the design process build a strong foundation for an engaging, user-friendly, and effective mobile health intervention. A digital prototype served as a tangible representation of our concept, which we evaluated with patients with heart failure.

Methods

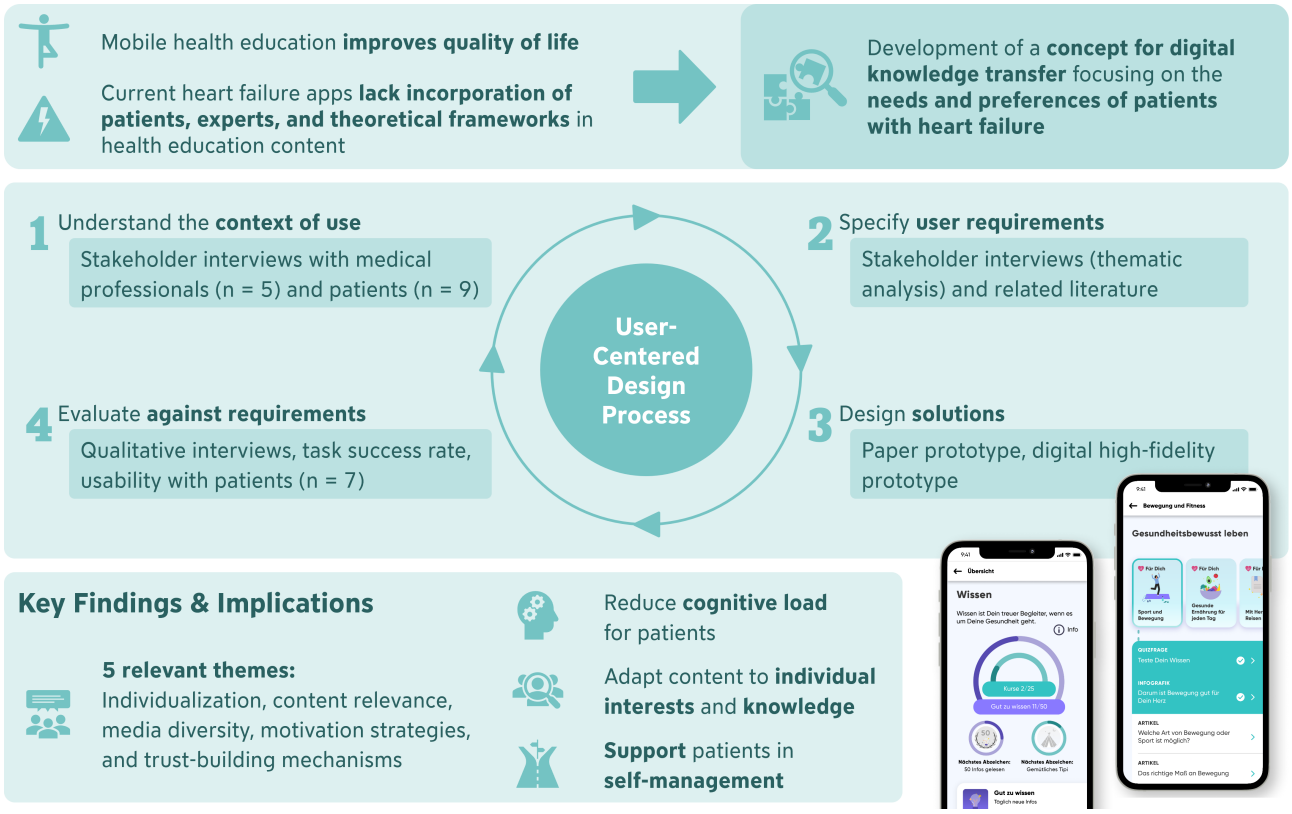
Study Design Overview

The foundation of this work was the user-centered design process, a common method in interaction design [26]. It emphasizes the involvement of the potential end-users throughout the developmental phases to ascertain that the resulting concepts align with their needs, preferences, and experiences of the target group. This iterative approach often incorporates techniques such as user interviews, focus groups, prototyping, and usability testing to refine the design based on continuous feedback. The graphical abstract (Figure 1) provides an overview of the methodology used.

First, we used current literature and semistructured qualitative interviews to understand the context of use and derive requirements. Based on the findings, possible design solutions were drafted as a paper prototype. Thereafter, a digital high-fidelity prototype was implemented. This digital prototype was then evaluated in a study focusing on the identified requirements of the target group.

The exemplary app we used for the prototype design is the ProHerz app (ProCarement Gmbh, Germany), a medical-grade mobile app for heart failure. This app is intended to support patients in managing their health by tracking vital signs and medication intake. Additionally, the company provides a ‘CareCenter,’ where, depending on the product used, medical experts regularly monitor the patients’ health parameters and stay in personal contact via messages and phone calls.

Figure 1. Graphical abstract illustrating the integration of the user-centered design process in the development of a health knowledge transfer concept for patients with heart failure.



Stakeholder Interviews

Recruitment

Qualitative semistructured interviews were conducted with patients (n=9) and medical experts (n=5). This approach is a flexible data collection method that combines predefined questions with the freedom to explore emerging topics to further enhance the understanding of participants' experiences and perspectives [27]. All patients were recruited from the ProHerz user base. Thus, all were patients with heart failure and previous experience with the ProHerz app. We chose this group because of their experience using a mobile health app for self-management. To allow for meaningful comparisons of feedback, our recruitment strategy aimed to include participants with varying levels of experience using the ProHerz app, aligning with best practices in end-user and usability testing. Medical experts were recruited through ProCarement, where they interact with the ProHerz users in their daily work. All experts were nurses with long-term experience in heart failure care. Their close exchange gives them a broad perspective on patients' characteristics, needs, and skills.

Procedure

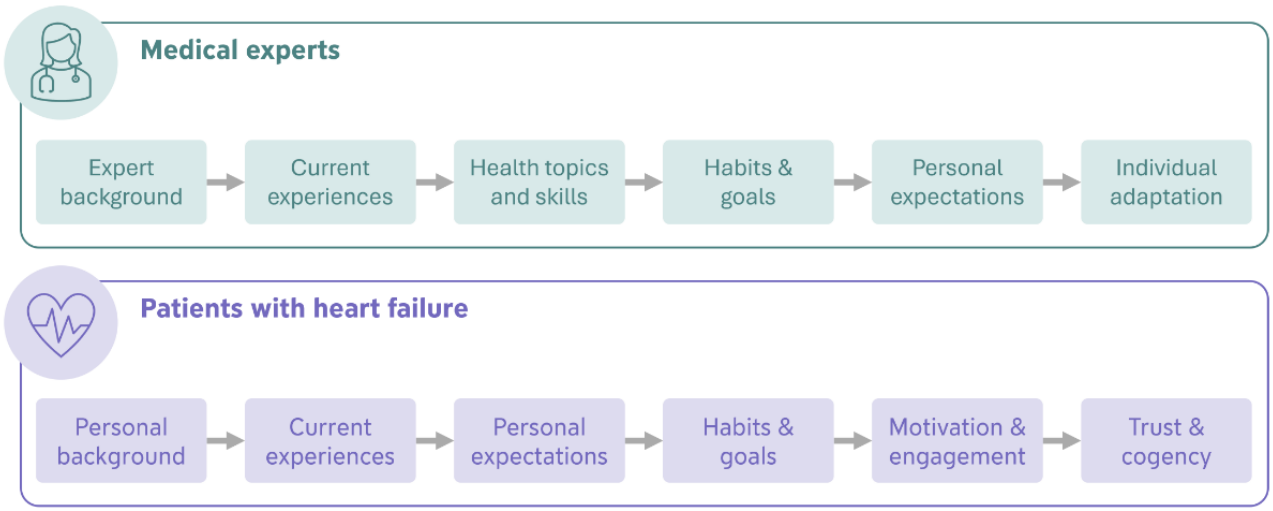
The interview guidelines were based on our research aims and current literature. Both stakeholder interviews covered similar aspects (Figure 2). The guidelines aimed to identify patients' specific needs and requirements regarding content and features within a mobile health knowledge transfer.

The interviews with the medical experts targeted explicitly at their perspective on essential knowledge and skill requirements that should be covered in a mobile health knowledge transfer concept. Besides, specific features, content presentation, and adaptation strategies for individual patient needs were discussed.

In the patient interviews, we inquired about experiences with specific features, their current interactions with the ProHerz app, and their expectations regarding knowledge transfer within a mobile health app designed for heart failure. Furthermore, the interviews included discussions on patients' health-related routines and goals and identifying requirements for trust-building and cogency. Additionally to the interview, patients were asked to complete the European Health Literacy Survey Questionnaire (EU-HLS-Q16) to assess their health literacy level [25,26]. Through this tool, participants rate general tasks related to health literacy based on their level of difficulty.

All interviews with medical experts were conducted via Microsoft Teams. Patient interviews were conducted in person.

Figure 2. The topics included in the interview with both stakeholder groups.



Prototype Development

The development of the knowledge transfer concept was based on the findings from the interviews and related literature.

We incorporated the framework of Riegel et al to structure the topics [28]. The content categories in the prototype are oriented toward the three self-care processes for heart failure: maintenance, symptom perception, and management. Information in the prototype was structured based on the principles for effective e-learning by Clark and Mayer and the recommendations for designing health-literate mobile apps by Broderick et al [29,30]. This included, for example, dividing information into manageable units, using different types of media, and writing in a conversational style.

Additionally, we considered possible cognitive limitations of users in the context of heart failure [22,31-34]. According to the Cognitive Load Theory, a reduction of cognitive load is able to improve learning outcomes. The theory describes three types of cognitive loads in the context of learning: intrinsic, extraneous, and germane cognitive load. We aimed at reducing the extraneous cognitive load by simplifying navigation, avoiding unnecessary elements, and ensuring a clear, uncluttered interface design. The intrinsic load was managed by sequencing information into smaller units aligned with the complexity of topics. The germane load was supported by including interactive elements such as quizzes or visual aids, encouraging active engagement.

Personalizing health education to address individual needs has been shown to improve health outcomes in areas such as physical activity, nutrition, and adherence to screening recommendations [35]. In the context of health education for heart failure, users face unique challenges through varying levels of health literacy and cognitive impairments [13]. As such, a personalized approach that takes relevant individual factors into account can meet diverse needs of patients, ensuring information is both accessible and relevant [22]. For this reason, we decided to incorporate the possibility of adapting the contents based on a short survey participants answered in the beginning.

The derived themes of the interviews were brought together with findings from the health literacy assessment that additionally revealed the needs of patients. We drafted a workflow for the mobile knowledge transfer and implemented this as a low-fidelity paper prototype.

For the first usability test, we embedded the paper prototype in Useberry (Useberry User Testing Technologies IKE, Greece). Useberry is a tool to test the usability of the paper-based prototype digitally. We aimed to find usability issues as early as possible in our design. For this initial testing, we invited healthy participants through personal contact. At this stage, the priority was gathering quick insights from users who were familiar with mobile apps to identify basic usability issues before moving on to the larger-scale user testing with patients with heart failure. This reduced the burden and required time and effort of the actual patients. Test users (n=5) were asked to perform different navigation-related tasks within the prototype. Outcome measures were the task completion rate and the recorded clicks.

After this initial usability testing, the paper prototype was then transferred into a digital high-fidelity prototype using Figma (Figma GmbH, Germany). This prototype included an example questionnaire for individualizing the information content based on the date of diagnosis, implanted devices (pacemaker and defibrillator), smoking habits, topics of interest, the preferred media formats and the New York Heart Association (NYHA) functional class (Figure 3). The NYHA classification is a commonly used system for categorizing the severity of heart failure based on physical activity limitations caused by cardiac symptoms. It ranges from Class I (no limitations) to Class IV (highest limitations) [36]. After the questionnaire, the basic landing page of the app was presented with an additional link to the health knowledge section. The main part of our prototype was the knowledge section with an overview and link to the available courses and the short information messages. Additionally, badges for learning-related achievements can be found there. Finally, an example course was implemented on the topic of sports and exercise (Figure 4).

Figure 3. Questionnaire for individual adaptation (left), home screen of the app with the link to the knowledge section (middle), and the main page of the knowledge section (right) of the digital prototype.

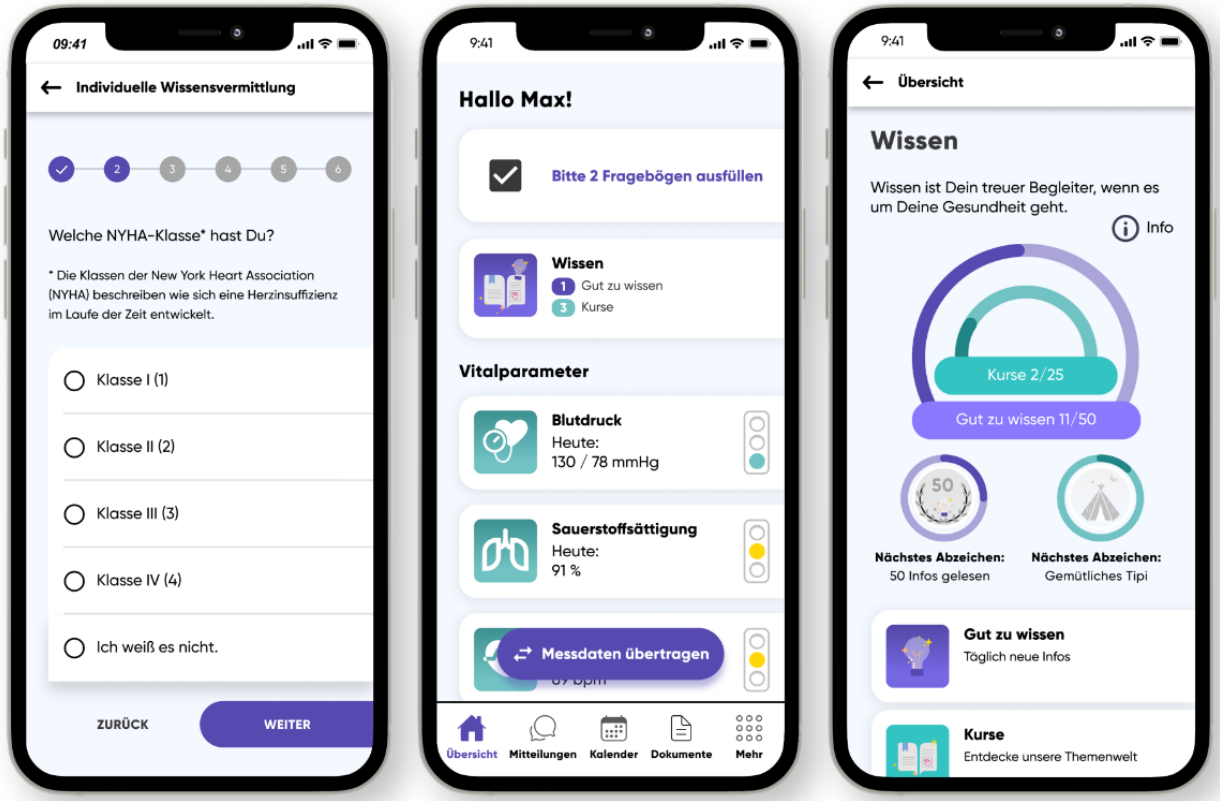


Figure 4. Structure of one exemplary course with (1) the overview of the content, (2) a quiz question, (3) an infographic presenting key facts, and (4) an article starting with information about the author of the text and a summary of the most important aspects of the article.

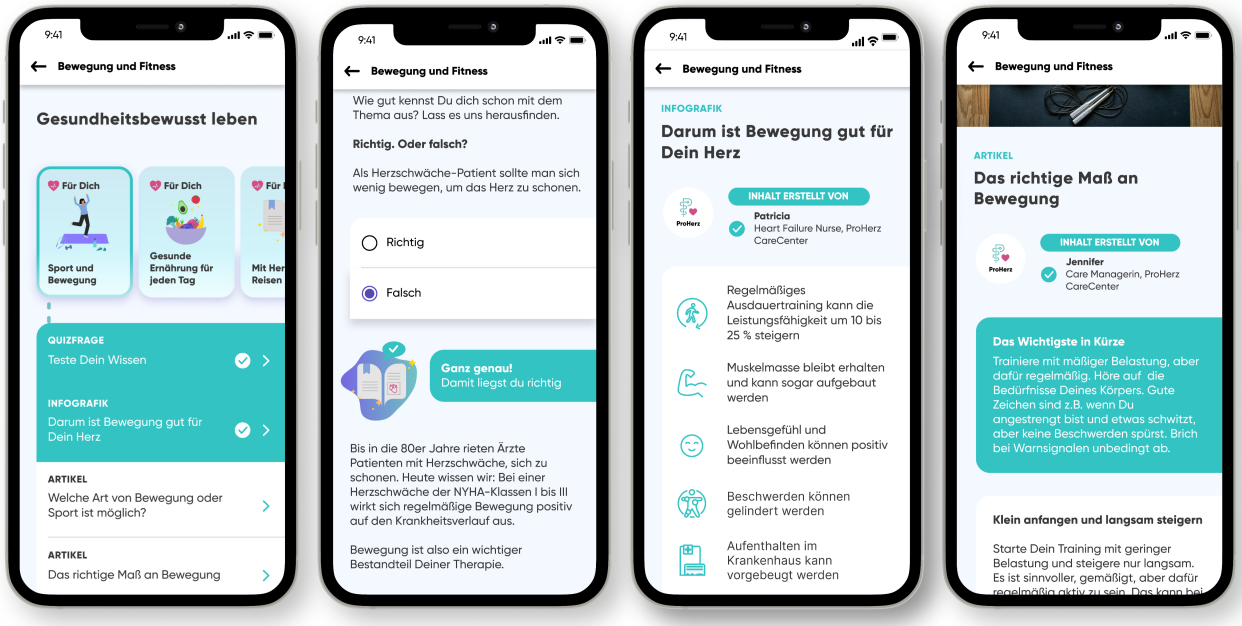


Concept Evaluation

Recruitment

For evaluating the knowledge transfer concept, we recruited patients with heart failure (n=7), who were already experienced in using a mobile health app. Therefore, all participants were recruited from the user base of ProCarement. Four participants already took part in the previous stakeholder interviews conducted as part of this study.

Procedure

After being instructed about the study procedure, participants were asked to complete 11 tasks with the digital prototype. Due to feasibility reasons, patients accessed the prototype on a computer interface. This approach allowed participants to interact with the app more comfortably during the evaluation, while also enabling researchers to observe user interactions in detail and collect qualitative feedback efficiently. Tasks included small, simple tasks and more complex, time-consuming tasks. An overview of all tasks is listed in Table 1. Afterwards, semistructured interviews were conducted to obtain the participants' overall impression and to identify features and characteristics that have the potential to improve engagement and increase health literacy.

Table . Tasks given to participants in the evaluation of the digital prototype of the health knowledge transfer concept.

No.	Description
1	Navigate to the questionnaire for individualization
2	Complete the questionnaire for individualization
3	Navigate to the knowledge section
4	Navigate to informative notifications, read the first unread notification
5	Navigate to the educational courses
6	Navigate to the course category 'symptoms'
7	Navigate to completed courses
8	Select a course within a course category
9	Navigate to recommended courses and select a recommended course
10	Complete one educational course
11	Navigate to the overview of badges

Analyses

All qualitative data obtained during interviews were analyzed using thematic analysis based on the approach of Braun and Clarke [37]. This method involves identifying, analyzing, and reporting patterns (themes) within the data, allowing for a rich and detailed interpretation of the participants' experiences and perspectives. The process includes familiarizing oneself with the data, generating initial codes, searching for themes, reviewing themes, and defining and naming them to ensure a comprehensive understanding of the qualitative insights.

Ethical Considerations

All presented substudies were approved by the institutional review board of the Friedrich-Alexander-Universität Erlangen-Nürnberg (approval no. 22 - 233-S), and we obtained written informed consent from all participants. The collected data were pseudonymized after collection to ensure participant confidentiality and data protection.

Results

Stakeholder Interviews

Demographics

The stakeholder interviews with patients and medical experts were conducted in August 2022. We recruited 9 patients with a mean (SD) age of 67 (7) years. Patients received their diagnosis between 15 and 3 years prior to this study. All patients were using the ProHerz app for at least 4 months (Table 2). Seven identified as women, and 2 identified as men. Additionally, 5 medical experts were recruited (Table 3) with work experience between 6 and 11 years.

Table . Characteristics of patients with heart failure included in the stakeholder interviews.

Interviewee ID	Age (y)	Identified as	Years since heart failure diagnosis	Months of app experience with ProHerz
P1	60	female	5	9
P2	58	female	3	5
P3	75	female	3	15
P4	78	female	5	15
P5	63	female	4	16
P6	75	female	9	4
P7	69	female	15	5
P8	60	male	3	4
P9	68	male	9	6

Table . Characteristics of medical experts included in the stakeholder interviews.

Interviewee ID	Identified as	Expert experience	Years of work experience with patients with heart failure
Expert 1	female	Heart failure nurse, licensed practical nurse	11
Expert 2	male	Licensed practical nurse	6
Expert 3	female	Licensed practical nurse	6
Expert 4	female	Bachelor of Science in Nursing, specialist in anesthesia and intensive care	9
Expert 5	male	State-qualified nurse	8

Thematic Analysis

We derived five themes relevant to a knowledge transfer concept from the stakeholder interviews with patients with heart failure and medical experts.

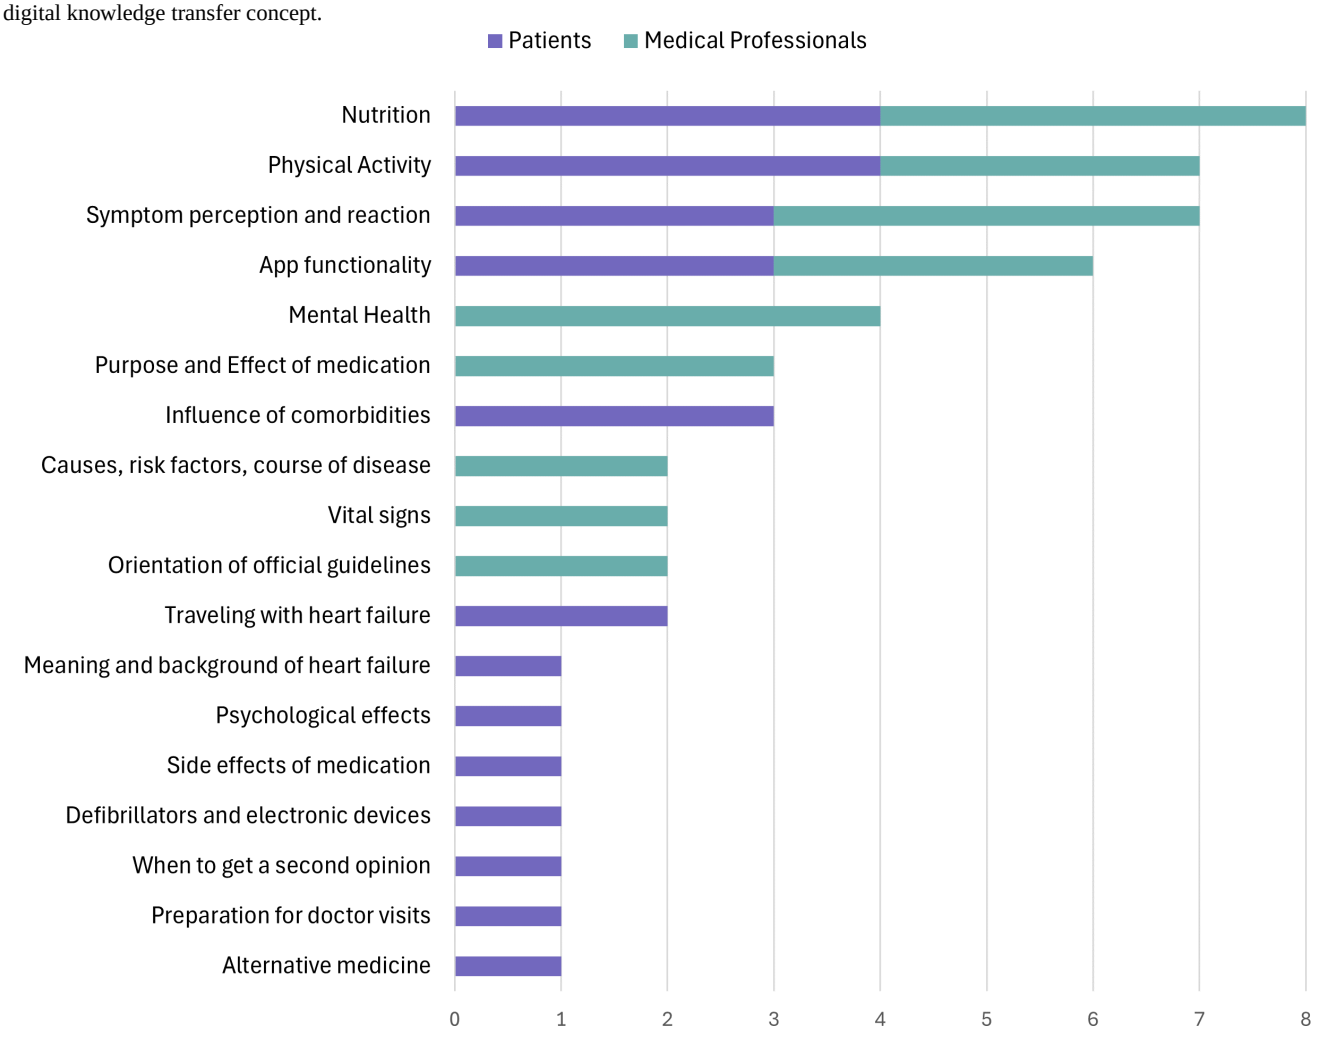
Individual Adaptation of Health Information

The interviews revealed a positive perspective towards the adaptation of content and push notifications to the different levels of knowledge of the users (4/5 experts, 2/9 patients). Our results suggest individualization based on different information such as the NYHA class, walking distance, app usage duration, physical condition age, prior knowledge, or personal preferences that could be determined for example through a quiz within the app.

Relevant Health Topics for Patients With Heart Failure

Several relevant health topics were identified within the stakeholder interviews (Figure 5). Health topics most requested by both patients and medical experts included nutrition (4/5 experts, 4/9 patients), physical activity (3/5 medical experts, 4/9 patients), symptom perception and reaction (4/5 medical experts, 3/9 patients), and app functionality (3/5 medical experts, 3/9 patients).

Figure 5. Health topics mentioned in the stakeholder interviews with patients and medical experts and that were considered relevant to be included in a digital knowledge transfer concept.



Diversity of Media Formats

Most of the interviewed patients (7/9 patients) preferred information in text format. For example, 1 participant stated, "you can read it two or three times if you say it's something that's difficult to absorb, maybe a text would be better" (P5, translated). Additionally, videos were perceived as useful by all medical experts but only desired by 2 patients. Related to the presentation of the information, patients mentioned using fewer technical terms and more simple language (2/9 patients) and shortly highlighting the most important aspects (2/9 patients). This can support easy comprehension of contents, which was also mentioned as a factor for the trustworthiness of health information (3/9 patients).

Promotion of Motivation, Engagement, and Joy

Medical experts (4/5 experts) suggested a reward system to increase engagement with the information contents. However, it should be ensured that this reward system is suitable for the specific target group of users (2/5). Three patients also mentioned the wish to receive positive feedback for progress within the app. Personal interest in the content was also mentioned (3/9) to have a positive influence on engagement.

Credibility and Trust

From the interviews with patients, we identified several factors related to the credibility of information. Positively perceived was the specification of authors (3/9 patients), especially if the authors are physicians (2/9 patients) or authors with an academic background (2/9 patients). In addition, the provider of the mHealth app should have a good reputation (3/9 patients). Factors restraining trust and credibility could be advertising (1/9 patients), authors without medical background (1/9 patients), or irrelevant information (1/9 patients).

Health Literacy

Health literacy levels based on the EU-HLS-Q16 were between 10 and 16 with an average (SD) score of 13.6 (2.1). Participants mostly had difficulties deciding on preventive actions based on media information (5/9 patients) and determining whether information about health risks in media is trustworthy (4/9 patients).

Evaluation of the Digital Prototype

Demographics

We evaluated the proposed digital prototype of the knowledge transfer concept with 7 patients with heart failure (Table 4). The mean (SD) age was 65 (6) years. Patients received their diagnosis between 2 and 24 years prior to this study. All patients were using the ProHerz app for at least 5 months. Four participants identified as women, and 3 as men. This group was less diverse in terms of ProHerz experience, which was a result of recruiting participants based on availability and willingness to participate.

Table . Characteristics of patients included in the evaluation study of the knowledge transfer concept.

Interviewee ID	Age (y)	Gender	Years since heart failure diagnosis	Months of app experience
P1	60	female	5	9
P2	58	female	3	5
P3	75	female	3	15
P5	63	female	4	16
P10	59	male	9	15
P11	71	male	2	15
P12	69	male	24	10

Usability

The mean task completion rate was 84%; 5 of the 11 tasks given during the study were completed by all participants. The lowest completion rate occurred with task 4, which was completed by 4 of 7 participants (Table 5).

Table . Task completion rate for all tasks performed by the participants within the usability testing.

No.	Description	Completion rate (%)
1	Navigate to the questionnaire for individualization	100
2	Complete the questionnaire for individualization	100
3	Navigate to the knowledge section	100
4	Navigate to informative notifications, read the first unread notification	57
5	Navigate to the educational courses	71
6	Navigate to the course category ‘symptoms’	71
7	Navigate to completed courses	71
8	Select a course within a course category	71
9	Navigate to recommended courses and select a recommended course	86
10	Complete one educational course	100
11	Navigate to the overview of badges	100

Interview Results

The thematic analysis of the semistructured interviews with patients within the evaluation of our proposed concept resulted in 3 main themes.

Knowledge Transfer

In the evaluation of the digital prototype, the majority of participants (4/7 patients) classified the prospective range of information as valuable. The organization and structure of contents received positive feedback from most participants (5/7 patients). Specifically, the clear arrangement of information (3/7 patients) and the definition of specific categories (2/7 patients) were highlighted. Patients also perceived the individual adaptation as positive, because personally irrelevant content would be hidden (4/7 patients).

To further improve the concept, participants indicated the necessity to update contents in response to potentially evolving needs over time due to lifestyle or health condition changes (2/7 patients).

Motivation and Engagement

A majority (5/7 patients) expressed an intention to utilize the course content in the future. Notably, reminders about feasible health-promoting measures were identified as a motivational factor by 3 out of 7 patients, with a specific emphasis from 2 participants on messages related to physical activity.

Concerns were raised about the potential negative impact of irrelevant, repetitive, or overly frequent notifications (4/7 patients). Conversely, aligning information with individual interests was identified as a key factor in promoting joy and sustaining engagement among users.

Patients expressed joy while answering the quiz questions, which may have contributed to a more engaging experience (2/7 patients). There was a suggestion to place quiz questions at the end of a course to assess the comprehension of the content effectively.

Participants generally responded positively to medical staff monitoring of progress, considering it a supportive element in their engagement with the course. However, 1 participant viewed social comparison negatively. Furthermore, intangible rewards, such as badges, were not universally well-received, with 1 out of 7 participants expressing a negative opinion, stating that it is solely virtual and not a real reward (P11).

Ease of Use

Out of 7 patients, 3 patients explicitly mentioned the app as easy to use. Other participants did not comment on this aspect, neither positively nor negatively. Concerns regarding the ease of use included potential initial overload when first using the app and potential individual difficulties with the technology and navigation.

Discussion

Principal Findings and Implications

In this study, we developed a concept for mobile health knowledge transfer for patients with heart failure. We grounded this concept on the requirements of patients with heart failure and current theoretical frameworks. From the patient and caregiver perspectives, we derived five central themes for a health knowledge transfer concept.

Our findings contribute to the understanding of user preferences and content organization in digital health interventions targeted at users with heart failure. The integration of diverse methodologies, including qualitative interviews, usability testing, and participant feedback, fortifies the study’s comprehensiveness, providing insights into user engagement, health literacy promotion, and the practical implications for digital health interventions. The results of this study represent an important step toward the development of a mobile health knowledge transfer tool for heart failure patients. By identifying relevant features and characteristics, this work provides a foundation for further refinement and testing, ultimately aiming to support health literacy and improve patient outcomes. It

becomes evident that a concept should focus on individualization, topic relevance, media diversity, motivation strategies, and trust-building mechanisms to optimize its impact on health literacy and engagement of patients with heart failure. Based on the findings, identified in the stakeholder interviews, we developed a concept for knowledge transfer in a digital health app for patients with heart failure.

We evaluated our concept with a digital prototype and identified features and characteristics that are perceived as supportive in increasing health literacy, that can promote motivation, engagement, and joy, and that are able to convince patients of a mobile health knowledge transfer. Most prominent was the wish for content that is individually adapted and balanced regarding the topics covered as well as media formats used to present those topics.

The results of the prototype evaluation presented both encouraging feedback and areas for refinement. Participants highlighted the app's structured design and ease of navigation, emphasizing that these features facilitated a straightforward user experience and enhanced the clarity of the presented information. The quiz elements, in particular, were frequently mentioned as engaging and motivating, showcasing the potential of interactive components to sustain user interest and reinforce learning. These positive responses suggest that the app effectively addressed some of its primary goals, including improving knowledge transfer and supporting patient engagement.

Conversely, the feedback also identified challenges that should be addressed in future iterations. Participants expressed concerns of getting overwhelmed, potentially hindering comprehension. This may reflect concerns about managing excessive information or complex interactions within the app, particularly in the context of their health condition. For users with chronic conditions like heart failure, the introduction of too much content or functionality in a single interface could exacerbate feelings of being overwhelmed and lead to disengagement or frustration [38]. Furthermore, badges and achievements were mentioned to be not motivating despite research showing the positive effects of such gamification elements [39,40]. Older users or those less familiar with gamification might find such features irrelevant or even patronizing if they do not see clear value in them. Other gamification elements such as progress bars, interactive storylines, or more useful rewards may be more effective in motivating users. Therefore, future iterations could explore the inclusion of a simple setup and customization menu to enable or disable features such as gamification and other user-preferred functionalities.

Accessibility is a critical consideration in designing digital health systems to ensure they meet the needs of diverse users. While none of the participants in our study raised concerns or reported difficulties with accessibility, indicating that the system was well-received by the target population, it is important to account for potential challenges in broader user groups. Features such as larger fonts, high-contrast visuals, simplified navigation, and optional audio support can further enhance usability, particularly for individuals with age-related changes in vision, hearing, or varying levels of digital literacy.

The high rates of completion for most tasks suggest that the interface and navigation design are intuitive, enabling users to locate and interact with the desired functions efficiently. This aligns with the positive feedback received during the interviews conducted within the evaluation. However, with a few tasks having a lower completion rate, some aspects of the design need further refinement in future iterations. Factors such as differences in technology familiarity, cognitive load, or previous experience with the ProHerz app could have contributed to these discrepancies. Interactive tutorials to onboard users and a further adaptation of content may be able to better account for different requirements, levels of experience, or cognitive abilities. In particular, task 4 with a completion rate of only 57% was the most problematic task for participants. The participants were not able to locate the button to navigate to the informative notifications. The reason for this is most likely the design of the progress bar on the same page (Figure 3, right) that users expected to be the button to the next page. Ensuring more consistent visual cues for interactive elements could further reduce the potential for misinterpretation and enhance the overall user experience.

Comparison With Prior Work

The need for individualization is in line with the findings of Giordan et al [41], calling for further customization especially related to the educational level and digital literacy of users. Our results additionally highlight the need for customization regarding personal interests and lifestyle and the importance of regular adaptation to changing circumstances in the life and knowledge of users. Future applications require new strategies to individually adapt educational content that can change over time. This can include regularly soliciting user feedback through surveys, using quizzes to assess understanding, or adaptive learning algorithms based on user behavior within the mobile app [42].

The topics covered in our knowledge transfer concept are in line with the recommendations of the European Society of Cardiology. They included information about heart failure, symptom monitoring, self-management, medication, fluid intake, implantable devices, physical activity, nutrition, smoking, sleep mental health, and traveling [43]. The information was presented using different media formats, which relates to current literature emphasizing the benefits of this approach. A variety of formats can support users with different health literacy levels and can deepen the learning effects [29,43,44].

Strengths and Weaknesses

Several limitations apply to this study. Firstly, the participant pool featured a restricted number of individuals, all German-speaking and residents in Germany. Moreover, participants were well-acquainted with the ProHerz app, potentially influencing their perspectives and feedback, especially regarding the ease of use. Given the advanced health literacy levels of the participants, our findings may not comprehensively represent the needs of individuals with lower health literacy. The initial usability testing was conducted with a convenience sample due to limited patient availability; therefore, results from this group need to be interpreted with caution. During the evaluation phase, 4 participants already

were part of the stakeholder interviews in the first phase of this study due to limited participant availability. Lastly, all participants accessed the app on a laptop rather than a mobile phone, introducing a potential discrepancy, as some users reported difficulties with computer usage and the overall interaction experience may be different. These limitations underscore the necessity for cautious interpretation and highlight avenues for future research refinement.

Our study combines several strengths: we were the first to conceptualize a mobile health knowledge transfer within a user-centered design approach. By prioritizing patient needs and requirements, and involving healthcare professionals to ensure relevance and meaningfulness, the study sets a precedent in fostering impactful and patient-centric digital health interventions. The incorporation of theoretical frameworks for mobile health education enriches the conceptual foundation, contributing to the overall robustness of the study and its potential impact on the enhancement of patient-centered care.

Conclusions

We were the first to develop a mobile health knowledge transfer for heart failure grounded on theoretical frameworks within a user-centered design process.

By addressing individual health literacy levels, cognitive challenges, and personal preferences, this knowledge transfer concept can help patients better understand and manage their condition. The active involvement of healthcare professionals ensures that the resulting intervention is meaningful and aligned with relevant healthcare aspects. The findings also emphasize a discrepancy between what healthcare professionals perceive as important for patients and what patients themselves prioritize, particularly when it comes to identifying relevant healthcare topics. Our results are paving the way to more personalized and effective mobile health education for individuals managing heart failure. The concept can be used as a foundation for other digital platforms and mobile health apps to provide tailored educational content and supporting clinicians in delivering consistent, patient-specific information in home settings.

Future research opportunities should focus on longitudinal studies to assess the sustained impact of this knowledge transfer concept on health literacy, self-care behavior, and patient outcomes. In this context, validated usability scales alongside user interviews should be incorporated during iterative development processes, while also addressing potential biases in design and testing to ensure more robust and generalizable findings. Additionally, possible strategies for better individualization of health information should be further explored. To better understand the impact of personalization, future studies could incorporate a comparison of user experiences before and after customizing the app, providing valuable insights into how individualization influences usability and user satisfaction. This presents an opportunity to investigate adaptive learning algorithms that dynamically tailor content based on user progress and preferences.

Acknowledgments

This project is supported by the Bavarian State Ministry of Health and Care, project grant number PBN-MGP-2010-0004-DigiOnko. The authors would like to acknowledge the financial support from Deutsche Forschungsgemeinschaft and Friedrich–Alexander Universität Erlangen-Nürnberg within the funding program Open Access Publication Funding.

Authors' Contributions

MF conceived the study, developed the study design, analyzed data, assisted in interviews, and wrote the manuscript draft. SB and JR assisted in developing the study design, interview conduction, and data analysis. KMJ, MN, and HL assisted in writing the manuscript. PT, SE, BME, and HL initiated and supervised the project. All authors reviewed the final manuscript.

Conflicts of Interest

JR, SE, and PT are employees of ProCarement GmbH. All other authors declare no conflicts of interest.

Abstract

Background: Long COVID is an often debilitating condition affecting millions of people. Its diverse clinical presentations make effective diagnosis and management at the primary care level difficult, while specialist services for long COVID face extensive wait times. An electronic consultation (eConsult) program in Ontario developed a long COVID specialist group to allow primary care providers (PCPs) prompt access to specialist advice for patients with long COVID.

Objective: This study aims to assess patterns of service use, response times, impact, and clinical content of eConsult cases submitted to an eConsult long COVID specialist group in Ontario.

Methods: This study is a mixed methods analysis of eConsults submitted by PCPs to the long COVID specialist group of 2 eConsult services (Champlain eConsult BASE and Ontario eConsult) between June 1, 2021, and July 31, 2022. Data sources included the use data collected automatically by the services, responses to a mandatory closeout survey, and the content of PCP questions and specialist responses (Champlain eConsult BASE service only). Clinical questions or responses were analyzed using 2 validated taxonomies. Descriptive statistics were used for survey responses and use data.

Results: A total of 40 PCPs submitted 47 eConsults through Champlain eConsult BASE and 197 PCPs submitted 228 cases through Ontario eConsult. The median specialist response time was 0.6 (IQR 0.19-2.36; mean 1.7, SD 2.29) days. The 5 most common symptoms of long COVID were fatigue (14/47, 30%), dyspnea (7/47, 15%), cough (6/47, 13%), altered sense of smell (ie, anosmia and parosmia; 6/47, 13%), and cognitive changes (6/47, 13%). The five main question categories asked by PCPs were: (1) management of chronic symptoms of COVID-19, (2) need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4) diagnostic clarification, and (5) guidance regarding COVID-19 vaccination.

Conclusions: The long COVID groups provided rapid access to a multispecialty service that facilitated the avoidance of unnecessary face-to-face referrals. An assessment of eConsults highlighted 5 common question types, providing insight into potential gaps in knowledge among PCPs that could help guide medical education and policy.

Introduction

The COVID-19 pandemic has had an unprecedented impact on health care systems and economies worldwide. As of November 2023, there have been over 700 million reported cases of COVID-19, resulting in over 6.5 million deaths [1]. As the pandemic began spreading, the potential for long-term morbidity from COVID-19 became apparent. The World Health Organization reports that 10% - 20% of those infected with COVID-19 report incomplete recovery months beyond the acute illness—a condition commonly referred to as long COVID or post-COVID-19 condition [2].

A recent Statistics Canada survey reported that 14.8% of respondents with a previous positive test or suspected infection for COVID-19 experienced ongoing symptoms at least 3 months after infection [3]. Potential symptoms of long COVID are varied, and people often experience symptoms across multiple organ systems.

Primary care is ideally positioned to diagnose and provide management for patients with long COVID. Unfortunately, given its diverse clinical presentations and limited empirical evidence guiding management, many primary care providers (PCPs) lack the specialized knowledge to effectively identify and manage long COVID. In certain jurisdictions, long COVID specialty clinics have been established to support primary care. However, demand and wait times for these clinics make timely access a challenge. There is a need for innovative tools to support PCPs in identifying and delivering care for those with long COVID.

One solution to these challenges is electronic consultation (eConsult), which allows PCPs to ask clinical questions regarding their patients to specialists using a secure web-based platform. In response to the pandemic, an eConsult service operating in Ontario, Canada, launched a long COVID specialist group, allowing PCPs to connect with specialists across multiple disciplines with expertise in long COVID to help with the diagnosis and management of their patients. Previous studies assessing this eConsult service in Ontario have demonstrated improved access to specialty care, reduced need for face-to-face specialist visits, cost savings, and high physician satisfaction [4-8].

In this study, we examined eConsult cases submitted to a long COVID specialist group in Ontario to assess patterns of service use, response times, the impact on the need for formal face-to-face referrals, and the content of clinical questions being asked.

Methods

Study Design

This study is a mixed methods analysis of eConsults submitted by PCPs to the long COVID specialist group between June 1, 2021, and July 31, 2022.

Ethical Considerations

This study received ethics approval from the Ottawa Health Science Network Research Ethics Board (REB protocol 2009848 - 01). The Ottawa Health Science Network Research Ethics Board waived informed consent for the study due to its retrospective, cross-sectional nature, so individualized patient consent was not obtained. All nonanonymized data were stored on secure servers that are accessible only by approved users who signed a privacy and confidentiality form.

Participants

Participants in the study were PCPs who were registered to 1 of the 2 eConsult services and who submitted at least 1 eConsult to the long COVID group within the study timeframe.

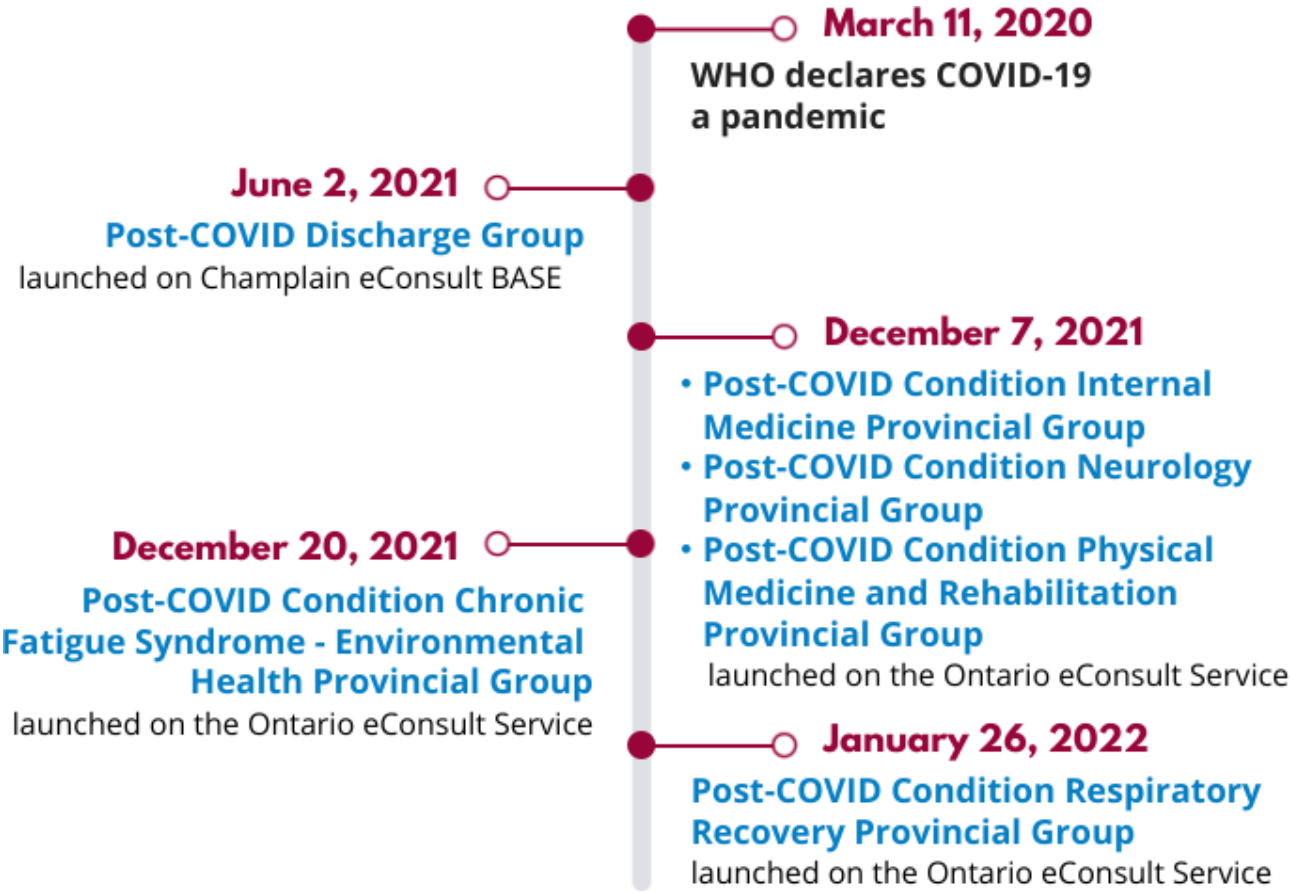
eConsult Services

Two multispecialty eConsult services currently operate in Ontario under the umbrella of Ontario eConsult. The first service, the Champlain eConsult BASE (Building Access to Specialists through eConsultation) service, was initially piloted in 2010 across the Champlain region of eastern Ontario, which includes Ottawa and its surrounding communities and has a population of around 1.3 million people. The second service, the Ontario eConsult Service, made eConsult available to all PCPs across Ontario in 2018. Both services are funded through the Ontario Ministry of Health. On June 2, 2021, a long COVID specialty group was established on the Champlain eConsult BASE service. Later in the year, a similar service was made available on the Ontario eConsult Service, providing PCPs with access to five different long COVID specialty subgroups that were rolled out between December 2021 to January 2022: (1) Post-COVID Condition Internal Medicine Provincial Group, (2) Post-COVID Condition Neurology Provincial Group, (3) Post-COVID Condition Phys Med/Rehab Provincial Group, (4) Post-COVID Condition Chronic Fatigue Syndrome—Environ Health Provincial Group, and (5) Post-COVID Condition Respiratory Recovery Provincial Group.

Measures considered when recruiting specialists to eConsult BASE-managed groups include the specialist's experience, level of interest, and ability to maintain an adequate case volume, as well as maintaining equity across and within regions or organizations. The services leveraged existing eConsult specialists and recommendations from peers to identify eligible specialists.

In total, 19 specialists were available to respond to long COVID questions during the study period (5 on the Champlain BASE and 14 on the Ontario eConsult service) from various specialty backgrounds, including internal medicine, infectious disease, neurology, physiatry and respirology (Figure 1).

Figure 1. Timeline of the establishment of a long COVID specialty group for eConsult services. WHO: World Health Organization.



PCPs initiate an eConsult by logging onto a secure web portal and selecting the specific specialty service from a dropdown menu. The PCP fills out a structured electronic form and submits the case along with any pertinent attachments (eg, laboratory or imaging data). The case is assigned to a specialist from the chosen group, who responds within 7 days (the median specialist response time is typically 1 day [5]). When a case is closed, the PCP completes a mandatory close-out questionnaire that gathers information about the case's outcome, whether a referral was originally contemplated and whether it was ultimately avoided as a result of the specialist's advice, and the case's educational value and capacity to serve as material for continuing medical education by using a 5-point Likert scale (Multimedia Appendix 1).

Data Collection and Analysis

We computed descriptive statistics to examine the overall use of the long COVID specialist group from June 1, 2021, to July 31, 2022. Data from both the Ontario eConsult and Champlain eConsult BASE services were analyzed to determine the total number of cases submitted to the long COVID specialty group. Time stamps for each eConsult were assessed to examine the response interval for specialist responses, and the total self-reported time billed was used to determine the amount of time each specialist spent responding to the eConsult.

Following the established methodology, case transcripts of PCP questions from eConsults submitted through the Champlain eConsult BASE between June 1, 2021, and July 31, 2022, were retrospectively reviewed. Case-level data were accessible for Champlain eConsult BASE but not for Ontario eConsult. Two investigators (MQ and JS) reviewed cases retrospectively using 2 validated taxonomies: the International Classification for Primary Care, version 2 and Ely et al's taxonomy of generic clinical questions. The International Classification for Primary Care, version 2 was used to classify clinical topics and patient-presenting symptoms. The taxonomy of generic clinical question was used for question classification. In many cases, a single eConsult case had multiple questions, and patients often presented with multiple symptoms; therefore, each case was not restricted to a single clinical question or presenting complaint or symptom.

We performed a descriptive analysis of all eConsult close-out questionnaires completed by the PCPs. Specifically, we sought to determine the PCP's course of action after the eConsult (eg, face-to-face referral avoided and face-to-face referral still needed) and to gain insight into the nature of the advice given to the PCP (eg, new advice given and advice confirmed course of action initially contemplated).

Results

Overview

A total of 40 PCPs submitted 47 eConsults through Champlain eConsult BASE between June 1, 2021, and July 31, 2022, and 197 PCPs submitted 228 cases through Ontario eConsult between December 1, 2021, and July 31, 2022. These cases comprised 0.2% (n=23,067) of the total number of closed cases submitted to Champlain eConsult BASE and 0.5% (n=45,494)

of all Ontario eConsult closed cases during their respective time frames.

The median time for a specialist to respond to the eConsult was 0.6 (IQR 0.19 - 2.36; mean 1.7, SD 2.29) and the average time the specialist billed in responding to each eConsult was 27.5 (SD 18.53; median 20, IQR 15-45) minutes.

Clinical Content of eConsults

The retrospective taxonomy analysis assessed the clinical questions PCPs asked in the 47 cases submitted through Champlain eConsult BASE. Patients had a median age of 43 (IQR 6-65) and presented 24 unique symptoms across cases (Table 1).

Table . Percentage of patients with reported symptom or finding.

Symptom or finding	Patients (n=47), n (%)
Fatigue	14 (30)
Dyspnea	7 (15)
Altered smell (anosmia, parasomnia)	6 (13)
Cough	6 (13)
Cognitive changes	6 (13)
Chest pain	5 (11)
Palpitations	3 (6)
Altered taste (dysgeusia, ageusia)	3 (6)
Congestion	3 (6)
Alopecia	2 (4)
Myalgia	2 (4)
Rash	2 (4)
Paresthesia	2 (4)
Headache	2 (4)
Tremor	2 (4)
Insomnia	2 (4)
Fever	1 (2)
Eye pain	1 (2)
Tinnitus	1 (2)
Arthralgia	1 (2)
Back pain	1 (2)
Abdominal pain	1 (2)
Edema	1 (2)
Asthenia	1 (2)

The 5 most common symptoms were fatigue (14/47, 30%), dyspnea (7/47, 15%), cough (6/47, 13%), altered sense of smell (ie, anosmia and parosmia; 6/47, 13%), and cognitive changes (6/47, 13%). The five main question categories asked by PCPs were: (1) management of chronic symptoms of COVID-19, (2) need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4) diagnostic clarification, and (5) guidance regarding COVID-19 vaccination (Table 2; sample questions in Multimedia Appendix 2). The most common topics pertained to guidance on the management of chronic symptoms of COVID-19 (22/47 cases, 47%), the need for additional work-up or follow-up testing (20/47 cases, 43%), suggestions for community resources to help support or manage patients with chronic COVID-19 (9/47 cases, 19%), and diagnostic clarification (7/47 cases, 15%).

Table . Content of clinical questions asked of post-COVlD-19 condition specialists by electronic consultation (eConsult).

Content topic	eConsult cases (n=47), n (%)
Management of chronic symptoms of COVID-19	22 (47)
Need for additional work-up or follow-up testing	20 (43)
Community resources to support or manage patients	9 (19)
Diagnostic clarification	7 (15)
Guidance related to COVID-19 vaccination	7 (15)
Necessary to refer to specialist	6 (13)
Interpretation of testing	4 (9)
Other	3 (6)

Outcome of eConsults

PCPs completed the post-eConsult questionnaire for 268 of the 275 cases submitted on both the Champlain eConsult BASE and Ontario eConsult services during the study timeframe. Through eConsult, PCPs were able to confirm a course of action that they had initially contemplated in 35% (95/268) of cases and received advice on a new or additional course of action in 59% (157/268) of cases (Table 3). In 38% (102/268) of cases, PCPs had initially contemplated a face-to-face referral but found it unnecessary after the eConsult, while an actual face-to-face referral was needed in only 24% (64/268) of cases (Table 4).

Table . Impact of electronic consultation (eConsult) on PCP[a] course of action.

PCP survey answer	Responses (n=268), n (%)
I got good advice for a new or additional course of action	157 (59)
I was able to confirm a course of action that I originally had in mind	95 (35)
I got good advice for a new or additional course of action that I am not able to implement[b]	5 (2)
I did not find the advice very useful[c]	5 (2)
Other	6 (2)

[a]PCP: primary care provider.

[b]Response option available only for the Champlain eConsult BASE Service.

[c]Response option available only for the Ontario eConsult Service.

Table . Impact of electronic consultation (eConsult) on need for face-to-face referral.

PCP[a] survey answer	Responses (n=268), n (%)
Referral was originally contemplated but now avoided at this stage	102 (38)
Referral was not originally contemplated and is still not needed	88 (33)
Referral was originally contemplated and is still needed	57 (21)
Referral was not originally contemplated, but eConsult process resulted in a referral being initiated	7 (3)
There was no particular benefit to using eConsult in this case[b]	2 (1)
Other	12 (4)

[a]PCP: primary care provider.

[b]Response option available only for the Ontario eConsult Service.

Discussion

Principal Results

This study demonstrates the considerable potential of an eConsult service to support PCPs navigating the complexity and diversity of long COVID symptoms. By facilitating quick, low-barrier access to specialist advice, eConsult empowered PCPs to provide the best possible care for patients with long COVID while avoiding long wait times for specialist referrals. PCPs were able to get prompt specialist advice from a specialist with a median response time of just over 12 hours. The main question types identified in the study related to (1) the management of chronic symptoms of COVID-19, (2) the need for additional work-up or follow-up testing, (3) community resources to support or manage patients with long COVID, (4)

diagnostic clarification, and (5) guidance regarding COVID-19 vaccination. A face-to-face referral was not needed after the majority of eConsult cases, so patients could be given an expert-guided treatment plan without waiting to see a specialist. To our knowledge, this is the first study to examine an innovative electronic solution to help support PCPs in managing long COVID.

Limitations

This study has several limitations. First, the taxonomy analysis used data from a single health region in Ontario, which may impact the generalizability of our findings. As mentioned above, we only had access to case-level data from the Champlain eConsult BASE service and not the Ontario eConsult service. The Champlain region is a culturally and linguistically diverse region and our findings were externally validated by specialist team members who answered eConsults from across Ontario and confirm the nature of the questions identified in this study are representative of common questions asked across the province. Furthermore, this study only examined eConsults submitted to the long COVID group and it is possible that relevant COVID-19 cases were submitted to other specialty groups such as infectious disease. Finally, neither service collects detailed demographic information about the PCPs using the service, so we were unable to report any of this information in our results section.

Comparison With Prior Work

With studies and data continuing to emerge about long COVID, there remain significant challenges in diagnosing and managing patients with this condition (O'Hare et al [9]). A systematic review conducted by Macpherson et al [10] found patients commonly expressed concerns about the lack of knowledge about long COVID, and often found they received conflicting or inconsistent advice from providers. There is currently no effective validated treatment for long COVID [11]. This challenge with management was evident in our findings, as approximately half of the questions PCPs posed were related to advice on management, and one-fifth inquired about community resources to support with management. Furthermore, 59% of PCPs surveyed reported receiving new advice that changed their management plans.

Recognizing the burden of long COVID, many jurisdictions worldwide have implemented multispecialty long COVID clinics and rehabilitation centers. Previous studies have shown that these rehabilitation programs can have a positive impact on various patient outcomes [12,13], such as increased quality of life, reduced fatigue, improved functional status, and better mental health [13]. Unfortunately, the demand for such clinics is high, with many reporting long wait times. Digital strategies such as eConsult provide a means for quicker access to support patients and initiate management. They also have the potential to reduce demand by allowing the PCP to provide guided care; approximately 40% of PCPs surveyed highlighted that a face-to-face referral was not needed as a result of the advice they received through eConsult. This may lessen the backlog of seeing long COVID specialists by decreasing the number of unnecessary in-person referrals. Additionally, we were able to quickly adapt the eConsult service to implement long COVID groups, whereas setting up specific specialty clinics requires greater coordination, time, and cost.

One of the other challenges in identifying and managing long COVID relates to its diversity of presentation; the Public Health Agency of Canada has reported over 100 different symptoms associated with long COVID. In the 47 eConsults examined in this study, 24 unique symptoms were reported, with the 5 most common being fatigue, dyspnea, cough, altered sense of smell (ie, anosmia and parosmia), and cognitive changes. These findings are in line with other international studies. For example, a UK-based study conducted by Carfi et al [14] also noted fatigue as the most common long COVID symptom (51%), followed by dyspnea (35%), arthralgia (25%), and concentration difficulties (25%). This diversity in presentations can lead to challenges with diagnosis, which is particularly important as the symptoms of long COVID overlap with other serious and possibly life-threatening complications associated with COVID-19, such as pulmonary embolism, myocarditis, and organizing pneumonia. Several publications have reported delays in the diagnosis of life-threatening conditions such as pulmonary embolism as they were mistaken for symptoms of COVID-19 (Yousefazai and Bhimaraj [15]; Melazzini et al [16]). In total, 15% (7/47) of PCP questions related to diagnostic clarification, while 43% (20/47) of eConsults asked about the need for additional testing to rule out other conditions. This highlights the importance of getting timely advice to confirm the diagnosis and avoid delays in the diagnosis of possibly life-threatening conditions. The diversity of presentations also demonstrates the need for a multidisciplinary approach to providing support for patients with long COVID. To address this need, Ontario eConsult established 5 unique subgroups that PCPs can select (ie, internal medicine, neurology, physical medicine or rehabilitation, chronic fatigue syndrome, and respirology) involving providers from various specialties to better support PCPs and their patients in getting helpful and appropriate advice in a timely manner.

Conclusions

The long COVID groups available through the Champlain eConsult BASE and Ontario eConsult services provided rapid access to a multispecialty service that facilitated the avoidance of unnecessary face-to-face referrals. Long COVID is a multisystemic condition that is often debilitating, with a significant impact on one's quality of life and mental health. Given the lack of knowledge around long COVID, limited timely access to specialized long COVID clinics, and the possibility of delayed diagnosis of life-threatening conditions associated with COVID-19 (eg, pulmonary embolism), there is an urgent need for innovative digital solutions such as eConsult to better support PCPs to provide patients with timely access to specialty advice. An assessment of eConsults highlighted 5 common question types, providing insight into potential gaps in knowledge among PCPs that could help guide medical education and policy.

Acknowledgments

This research received funding from Ontario Health.

Conflicts of Interest

CL and EK are the cofounders of the eConsultBASE service but have no commercial interest in the service. EK is the executive director of the Ontario eConsult Centre of Excellence and receives salary support from Ontario Health. EK completes occasional electronic consultations (eConsults) as a specialist through the service for which she is reimbursed. CL is the director of evaluation for the Ontario eConsult Centre and receives salary support from Ontario Health.

Abstract

Background: Digital self-monitoring tools, such as the experience sampling method (ESM), enable individuals to collect detailed information about their mental health and daily life context and may help guide and support person-centered mental health care. However, similar to many digital interventions, the ESM struggles to move from research to clinical integration. To guide the implementation of self-monitoring tools in mental health care, it is important to understand why and how clinicians and clients adopted, adapted, and incorporated these tools in practice.

Objective: Therefore, this study examined how clinicians and clients within a psychiatric center appropriated an ESM-based self-monitoring tool within their therapy.

Methods: Twelve clinicians and 24 clients participated in the piloting of the ESM tool, IMPROVE. After utilizing the tool, 7 clinicians and 11 clients took part in semistructured interviews. A thematic framework analysis was performed focusing on participants' prior knowledge and expectations, actual use in practice, and potential future use of ESM tools.

Results: Many participants experienced that the ESM tool provided useful information about clients' mental health, especially when clinicians and clients engaged in collaborative data interpretation. However, clinicians experienced several mismatches between system usability and their technical competencies, and many clients found it difficult to comply with the self-assessments. Importantly, most participants wanted to use digital self-monitoring tools in the future.

Conclusions: Clinicians' and clients' choice to adopt and integrate self-monitoring tools in their practice seems to depend upon the perceived balance between the added benefits and the effort required to achieve them. Enhancing user support or redesigning ESM tools to reduce workload and data burden could help overcome implementation barriers. Future research should involve end users in the development of ESM self-monitoring tools for mental health care and further investigate the perspectives of nonadopters.

Introduction

To improve access to and facilitate person-centered mental health care, digital technologies are increasingly being deployed to collect and share health-related data, deliver care, and support individuals in managing their health [1,2]. The experience sampling method (ESM; also termed ecological momentary assessment) is a structured diary technique that enables individuals to collect detailed information about their mental health in their daily lives [3]. Using smartphone apps, the ESM prompts individuals to complete brief self-assessments multiple times daily, assessing their emotional states, behaviors, and psychological symptoms. By allowing individuals to collect this information and share it with their clinicians, the ESM can ensure that therapeutic decisions are aligned with clients' everyday experiences and needs. For example, by providing insights into which activities an individual commonly engages in, and how they respond to different daily life situations and stressors, clients and clinicians can make shared decisions about the focus of treatment [4].

Despite its potential, the ESM, similar to many other digital mental health interventions [5,6], struggles to move from

piloting and trialing to actual clinical implementation. To address this research-to-practice gap, scholars have made calls to adopt user-centered design strategies for developing digital mental health tools [7]. User-centered design emphasizes the importance of conducting in-depth analyses of users' goals, needs, and context of use to inform technology design [8]. Nonetheless, most evaluations of digital health technologies focus primarily on quantifiable, technical aspects such as system performance, usability scores, and cost benefits [9,10]. However, an often overlooked but crucial step in implementing the ESM and self-monitoring tools is understanding how and why people integrate these technologies into their daily practices [11]. For example, what are the goals people hope technologies will help them achieve, what difficulties do individuals encounter when using new technologies, and what strategies do they apply to overcome technology use obstacles?

Studying the situated use of the ESM can provide essential knowledge into how users appropriate and make sense of these tools [12,13]. Technology appropriation can be examined in three main stages [13]. The first stage involves users' prior knowledge and expectations, which determine their initial willingness to adopt the technology. Expectations about potential benefits (eg, simplifying tasks) and the effort required (eg, time spent on training) are particularly crucial in shaping the initial interest [14,15]. In the second phase, users explore and evaluate the technology's capabilities, while becoming familiar with its functions. They adapt their practices to integrate the technology (eg, maintaining an internet connection), and adapt the technology to suit their needs (eg, disabling certain features or altering settings) [13]. They will test the technology's applicability in different situations and determine what features are most useful to them. Finally, if users find that the technology has added value and helps them achieve their goals and tasks, they might develop new routines and workflows that allow them to integrate and use the technology in their daily practice, thus moving into the third stage of persistent use [13].

To date, the appropriation of ESM tools in health care has largely been overlooked. While one study has examined how individuals with back pain appropriated ESM tools for pain management [16], there is a lack of research in the field of mental health care. As a consequence, we have a limited understanding of how individuals with mental illnesses and their clinicians interact with and make sense of digital ESM tools, and what might lead them to adopt or abandon these technologies. However, understanding this is vital for facilitating successful implementation [15,17]. To address this knowledge gap, we undertook a pilot implementation study, using the ESM tool "IMPROVE," a clinical prototype tool informed by research examining clinicians' and clients' design preferences [18,19]. IMPROVE was used as a part of therapy following a 3-step intervention, in which clinicians and their clients could (1) personalize the tool to clients' specific problems and situations, (2) self-monitor clients' mental health and daily activities via an app, and (3) review the collected data in summarized graphs in an online dashboard. To inform the further development and implementation of clinical ESM tools, this paper aimed to evaluate participants' (1) prior knowledge and expectations, (2) actual use in practice, and (3) potential future integration of ESM-based self-monitoring tools. Addressing these gaps in the literature will provide valuable insights into why and how clients and clinicians in mental health care choose to adopt or abandon digital self-monitoring tools in therapy.

Methods

Ethical Considerations

All participants provided written informed consent, and all procedures were approved by the medical ethics committee of KU Leuven (S64244). Participants were given a study ID to ensure anonymity, and interviews were pseudonymized during the transcription by removing personally identifiable information and replacing them with pseudo codes. Finally, participants were allowed to freely use the IMPROVE tool after completion of the study but were not given additional compensation.

Study Design and Recruitment

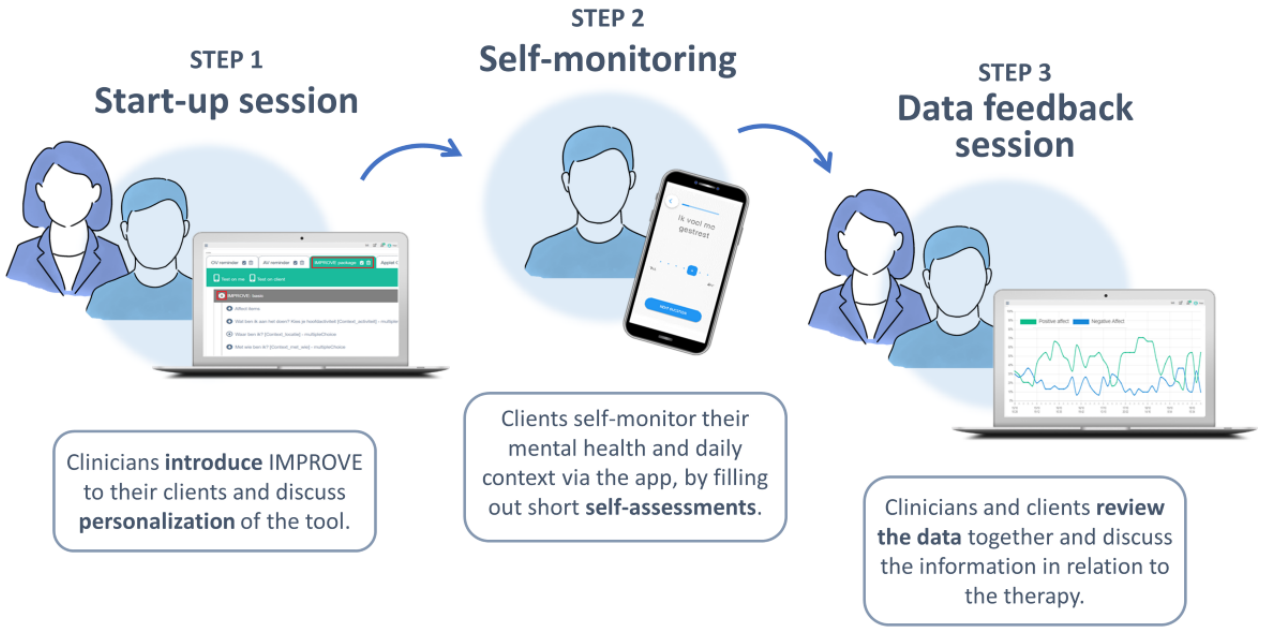
We conducted a pilot study within the University Psychiatric Center KU Leuven in Belgium in which we involved clients and clinicians in testing and evaluating IMPROVE. The research team was unable to access the clinic directly, due to COVID-19 restrictions. Therefore, invitations to participate were emailed to all psychiatrists and psychologists affiliated with the psychiatric center (N=142). The study aimed to enroll 12 clinicians, and initial invitations were followed by up to 2 reminder emails. For those interested, online informational sessions with the research team were organized. Participating clinicians were asked to recruit at least 1 client from their practice. By allowing clinicians to select clients, the referred sample provided a practical representation of the clients with whom clinicians were likely to use the tool within a real-life context.

The inclusion criteria were kept broad to reflect the diverse reality of clinical practice. To be eligible, clinicians needed to be certified mental health professionals and proficient in Dutch, which was the language the intervention was designed in. Clients had to be 18 years or older and also proficient in Dutch. To replicate real-world implementation, clients were asked to use their own smartphones. As a result, only clients owning a smartphone with at least 3G coverage were eligible to participate.

IMPROVE was run on the digital platform m-Path [20]. To enable clinicians to use IMPROVE, they received a manual with instructions on using the tool in their practice (Multimedia Appendix 1: IMPROVE training manual) and were invited to join an online training session. Clinicians and their clients were then requested to complete the 3-step intervention (Figure 1). In the first step, clinicians introduced IMPROVE to their clients and assisted them in downloading the app on their smartphones. They also discussed personalization of the tool, such as adding symptom-specific questions or adjusting the notification schedule. In the second step, clients self-monitored their mental health for 6 consecutive days. They received 10 semirandom notifications daily, prompting them to complete brief self-assessments on mood and context. Additionally, they received a morning notification to assess their sleep and an evening notification to evaluate the day. In the third step,

clinicians and clients reviewed the collected data together, exploring factors such as clients' activities, mood variability, and mood-context interactions.

Figure 1. Overview of the steps included in the IMPROVE intervention.



Data Collection and Analysis

Due to COVID-19 measures, data were collected remotely via online surveys in RedCap (Research Electronic Data Capture, Vanderbilt University) [21] and through Skype interviews (Version MSO; Skype Technologies). In some cases, poor connections affected the quality of the interview recordings; however, the overall data collection was not hindered by remote methods. Demographic information was collected at study enrollment and participants who completed the intervention were invited to participate in a semistructured interview (Multimedia Appendix 2: Interview guides). Interviews were audio recorded and transcribed verbatim. We performed a thematic analysis [22] in which we first conducted top-down content-coding of the transcripts using a thematic framework that identified interview material related to clinicians' and clients': (1) previous knowledge and expectations, (2) actual use in practice, and (3) potential future integration of the IMPROVE tool (Table 1). Hereafter, we performed additional inductive in vivo coding and used pattern and focused coding to create labels for the in vivo codes and compiled them into additional subthemes [23]. LdT undertook all primary and secondary coding, which was then revised by the coauthors and discussed in multiple peer debriefing sessions [24]. After each session, the coding categorizations and labels were modified and refined based on feedback from coauthors. To explore the potential impact of the different themes on the discontinued use of IMPROVE, additional information was extracted from informal participant contact records kept by the research team.

Table . Thematic framework for top-down coding of interviews.

Theme	Description
Prior knowledge and expectations	Participants talk about any prior experiences or knowledge they have regarding the ESM[a] or self-monitoring tools (analog or digital). Participants talk about their motivations and expectations related to using the ESM or self-monitoring tools and participating in the study.
Actual use in practice	Participants talk about how they used the IMPROVE tool and how they judged these experiences. Mentioning eg, what purpose they used it for, when, and how often they used it.
Potential future integration	Participants talk about their interest in using the IMPROVE tool (or similar tools) in the future. Participants talk about potential changes that they find would be relevant for future use and integration of the IMPROVE tool.

[a]ESM: experience sampling method.

Results

Participant Characteristics

Nineteen clinicians expressed interest in participating in the study, of whom 12 were enrolled. While a systematic record of the number of clients approached by clinicians was not maintained, at least 29 clients were invited, with 24 agreeing to participate. Of the enrolled participants, 8/12 clinicians (67%) and 17/24 clients (71%) completed the intervention; among these, 7/8 clinicians (88%) and 11/17 clients (65%) subsequently participated in an interview. A demographic summary of interview participants can be consulted in Multimedia Appendix 3: Demographic summary.

Thematic Analysis

A complete overview of the themes and subthemes of the analysis and how frequently they were mentioned by participants can be found in Multimedia Appendix 4: Overview of themes. Tabulated in vivo code summaries of participants' individual experiences can be found in Multimedia Appendix 5: Individually summarized experiences. Additionally, illustrative summaries are displayed in text boxes.

Previous Experience and Expectations

Individuals' experiences and expectations are important indicators of their initial willingness to adopt technologies. While only 1 clinician had experience using digital self-monitoring tools, most clinicians and some clients had experience using analog self-monitoring or diary techniques. Some clinicians also had experience with different forms of digital tools within their practice (eg, online training platforms, video consultations, and virtual reality). Similarly, several clients had experience using mental health apps, eg for practicing breathing techniques and cognitive-behavioral therapy exercises. Despite their limited experience, clinicians generally expected that IMPROVE would offer benefits over analog registration methods, allowing them to more easily collect and summarize information about their clients. However, several clinicians also anticipated that there would be challenges and limitations for using the tool. The most commonly mentioned was that low digital literacy could be a barrier for both clients and clinicians (Clinician 0100 Textbox 1). Clinicians' motivation for testing the tool was primarily driven by curiosity and the conviction that they need to master digital tools, as these are becoming increasingly dominant in the health care sector. Interestingly, most clients were primarily motivated by a wish to help and contribute to research but also expressed a curiosity toward what digital mental health tools might offer (Client 0501 Textbox 2). Some clients hoped that IMPROVE would allow them and their clinicians to get a better understanding of their mental health problems.

Textbox 1. "Might use digital self-monitoring tools in the future"– selected participants' experiences.

CLINICIAN 0100:

Prior knowledge and expectations

- I had no experience with digital self-monitoring, but I am currently testing VR technology in therapy. I have previously worked with analog self-registration in therapy.
- I expected it would be technically challenging to work with the tool.
- I want to try using new methods in therapy and I was eager to try the tool.

Actual use in practice

- It was difficult to find things in the dashboard and I needed help from the research team to use the tool. After a while using the platform got easier, but it required a lot of time to get started.
- It was difficult to draw conclusions about my clients' data, but I asked my client for clarifications when I was not able to interpret their data.

Potential future integration

- The tool gave me more information about what happens in clients' lives.
- I might use the tool again if it is made easier to use.

CLIENT 0503:

Prior knowledge and expectations

- I had no experience with self-monitoring apps.
- I hoped to gain more insight into my mental health.

Actual use in practice

- Assessment frequency was high, but okay for 1 week.
- I think I responded to almost all notifications, but I sometimes missed notifications because I forgot my phone. Also, when I was not feeling well I didn't respond to the notifications.
- Identifying, labeling, and scoring emotions on a scale are difficult.
- My therapist had difficulties operating the dashboard, so we didn't go into detail with the data.

Potential future integration

- I might use the tool again, but it is tiring to do for a long time.
- I prefer using the tool as a part of therapy, but I would like to have access to the data myself.

CLIENT 0802:

Prior knowledge and expectations

- I have no experience with health apps, but I use analog methods to keep track of my mental health.
- Digital tools allow you to do more than analog tools, so I thought it would be interesting to try.

Actual use in practice

- The number of notifications was okay, but I sometimes missed notifications because I was working or sleeping.
- Using the tool during the therapy session made it easier to recollect things that had happened.

Potential future integration

- I might consider using the tool again.

Textbox 2. "Not likely to use digital self-monitoring tools in the future"– selected participants' experiences.

CLIENT 0501:

Prior knowledge and expectations

- I had no experience with self-monitoring apps.
- I was hesitant to participate because I do not like self-assessments.
- I thought it was worth trying and I wanted to contribute to improving mental health care.

Actual use in practice

- It was difficult always to remember to have my phone with me.
- Notifications were sometimes disturbing and the assessment frequency was too high.
- It was important to me that I did not miss notifications; therefore, fear of missing notifications would sometimes stress me.
- Self-reflection was sometimes difficult and confronting.
- It was interesting to look at my data.

Potential future integration

- I don't find it likely that I will use the tool again.

Actual Use in Practice

Participants' willingness to test the IMPROVE tool was influenced by their initial expectations that digital self-monitoring would provide them with benefits and advantages. Below we describe how clinicians and clients used the tool in practice and how they evaluated its capabilities and contextual fit.

Step 1: Start-Up Session

Clinicians generally found that the time investment required to learn to use IMPROVE was too much considering the time they had available. Experiencing time constraints was also one of the most common reasons reported by clinicians who did not complete the intervention. Personalizing clients' questionnaires in particular asked for extra time and effort from clinicians. Despite emphasizing that the personalization of the IMPROVE questionnaires made the tool more relevant, clinicians made limited use of the available personalization options. Most clients also expressed that personalization of the tool is desirable but that clinicians did not discuss this with them.

Furthermore, while most clinicians were convinced that using the IMPROVE tool would become easier with practice, many clinicians indicated that the complexity of the tool was too high. In particular, clinicians found that navigating the dashboard was not intuitive and that it was difficult to find things and set up the clients' questionnaires. Thus, many experienced that they did not have adequate competencies to make full use of the tool; "I constantly felt I was doing something wrong," 1 clinician explained. However, at the same time, clinicians made limited use of the training manual and expressed a wish for more in-person support. This was also reflected by several clinicians contacting the research team for additional support after the initial training (Clinician 0100,Textbox 1). Interestingly, some clinicians resolved their need for support by organizing training sessions with colleagues.

Step 2: Self-Monitoring

The majority of clients reported that they made an effort to comply with the notifications, but many found that the frequency of the self-assessments (10 notifications per day) was too high. A few clients indicated that they would consciously skip assessments because they did not consider it important to respond to all notifications. Conversely, some clients also mentioned that missing notifications would make them feel guilty and annoyed, or that the thought of missing assessments made them nervous and stressed (Client 0501, Textbox 2). Although clients reported that completing the assessments did not take them long, many experienced difficulties responding to the notifications within the fixed 15-minute response window. Several reasons for this were voiced, of which being occupied with work and other daily activities was the most frequent (Client 0802, Textbox 1; Client 0601, Textbox 3). Having an irregular day rhythm or sleep schedule that did not match the notification schedule, needing to carry one's phone and ensure an internet connection, and feeling unwell or tired were also factors that made complying difficult. Importantly, clients who dropped out of the study also reported a lack of time, difficulties complying with the assessments, notifications stress, and feeling unwell as reasons for not completing the intervention.

Textbox 3. "Likely to use digital self-monitoring tools in the future"– selected participants' experiences.

CLINICIAN 0600:

Prior knowledge and expectations

- I have no experience with digital self-monitoring, but I have used analog self-monitoring techniques in therapy.
- I think digital tools are easier to use than analog self-monitoring methods. Digital tools are used more and more, and we need to offer clients tools that can help them achieve their goals.

Actual use in practice

- It takes time and effort to learn to use the tool.
- I didn't personalize my client questionnaire, because I wanted to start with the basics.
- I monitored my clients' responses and contacted them if I could see they weren't responding.
- There was a lot of data; I started with simpler visualizations and gradually added things. If I didn't know the client beforehand, I would not be able to make sense of the data.

Potential future integration

- The tool provided more details and an overview and allowed us to go more in-depth with problems that we already knew were there. We used the tool to identify what was important for the client.
- I will certainly consider using this tool again with my clients.

CLIENT 0601:

Prior knowledge and expectations

- I had no experience with health apps.
- I had no specific expectations and I'm generally skeptical about health apps, but I wanted to help research.

Actual use in practice

- I responded to as many notifications as I could, but I missed a lot because I was busy. I didn't consider it a problem that I missed some notifications. I also had to remember to bring my phone and connect it to 4G.
- It is sometimes difficult to assess whether your mood changed and how much.
- I was amazed to see what came out of the data. My therapist was able to do a lot with the data, despite my low compliance.

Potential future integration

- The tool provided useful information and allowed me to get to know myself better.
- I would be interested in using the tool again, but I would like to have access to the data myself.

CLINICIAN 1200:

Prior knowledge and expectations

- I used digital self-monitoring tools before in therapy.
- Digital self-monitoring tools are easier to use and give better insight into clients' lives than other methods. However, self-monitoring can be difficult for some clients.

Actual use in practice

- Setting up the tool took a lot of time.
- It was interesting to look at the data, but the many visualizations were somewhat overwhelming.

Potential future integration

- The tool quickly provides you with an overview of how your client is doing.
- I would like to use the tool again, but it should be made less burdensome for clients. It would be interesting to monitor clients for a longer period to evaluate their progress and the effect of treatments.

CLIENT 1201:

Prior knowledge and expectations

- I had no experience with mental health apps.

- I expected the tool would make it easier for my therapist to understand my problems.
- I think there is a need for more mHealth in mental health care and that this tool might help me and others.

Actual use in practice

- There are too many notifications and they are sometimes disturbing. People should be allowed to snooze notifications if they are busy.
- I did my best to respond to the notifications. On good days, it is okay to complete the assessments, but on bad days, it is difficult.
- My therapist identified moments when I was feeling bad and tried to understand these.

Potential future integration

- The tool can make you aware of what you need to work on, and it makes it easier to monitor the effects of your treatment.
- I would like to keep using the tool to check how I am doing.

Several clients found the practice of labeling and rating their emotions difficult. Some indicated that they were unsure whether they completed the self-assessments correctly and expressed a need for more guidance from their clinicians on how to respond to the assessments. Several clients also expressed a wish for more open questions that would allow them to describe their experiences in more detail, as they did not find that the default questions were sufficiently able to capture their experiences. Interestingly, while clinicians were not instructed to do so, some monitored their clients' responses during the self-monitoring week as a form of remote monitoring of clients (Clinician 0600, Textbox 3).

Step 3: Data Feedback Session

To get the most out of the data feedback session, most clinicians reviewed their clients' data in preparation for the session. Many felt that preparation was necessary for them to understand the data and be able to discuss it with clients. Many clinicians found it challenging to interpret and navigate the graphs, which they often perceived as overwhelming. This generally led clinicians to be selective in the data they would review and discuss with clients. All clinicians reviewed the data with their clients and some also encouraged their clients to give their interpretation of the data or to provide further clarification (Clinician 0100, Textbox 1*)*. Similarly, clients indicated that the support of a clinician was crucial for them to make sense of their data. While most clients reported that they could understand the graphs, they also indicated relying on their clinician to help them interpret the data. These findings indicate that, despite challenges, most clinicians could provide useful feedback to their clients based on the self-monitoring data.

Potential Future Integration

Despite encountering challenges, both clinicians and clients described that the IMPROVE tool provided them with useful insights. Next, we will explore how these experiences influenced participants' willingness to integrate and use digital self-monitoring tools in their future practice. Clinicians and clients were generally open to using digital self-monitoring tools again. Participants who expressed the greatest interest in continued use more often experienced an added value of using IMPROVE (see Textbox 3). This included having access to more detailed information about clients' mental health, which helped create an overview and clarity, and identify focus points to discuss in therapy. Clinicians who had initial positive expectations and believed digital tools were important in supporting mental health care were also more willing to use digital self-monitoring again. The clinicians who were more hesitant reported more difficulties using IMPROVE and expressed a greater need for support (see Textbox 1).

Clients who expressed a low interest in using digital self-monitoring tools in the future also reported negative reactivity in the form of stress and increased negative emotions during self-monitoring (see Textbox 2). Interestingly, all these clients had high compliance during the self-monitoring. However, clients overall reported that the assessment frequency should be lowered to make future self-monitoring less burdensome. Moreover, some clients and clinicians expressed an interest in using the tool for extended periods to monitor progress and the effects of therapy. Finally, clients and clinicians also expressed a desire to adapt the self-assessment further and monitor factors more specific to the individual client.

Discussion

Principal Findings and Implications

To guide the successful implementation of digital self-monitoring tools in mental health care, it is pivotal to understand how people react, respond, and adapt to these technologies. We examined how clinicians and clients in a psychiatric center appropriated the ESM-based self-monitoring tool IMPROVE within their therapeutic practices. In line with existing theories, our results indicate that clinicians' and clients' willingness to adopt and integrate digital self-monitoring tools into their practice depend on the perceived balance between added benefits and the effort necessary to accomplish these [17]. The main benefits identified in our study included better information about clients' mental health, while system usability and assessment burden demanded extra effort from participants. Below we discuss the potential implications of this for the implementation of the ESM tools in clinical practice.

While some struggled more than others, all interviewed participants managed to reach a basic level of use of the IMPROVE tool within the intervention period. Furthermore, we observed a great interest and curiosity towards digital mental health tools, especially among clinicians. Many clinicians experienced that using IMPROVE added value and generated more clarity and focus in the therapy, by providing more detailed

information about the clients' mental health. Several clients also experienced these benefits. Our findings suggest that a collaborative effort between clients and clinicians is key to maximizing the experienced benefits of the ESM tools. While many clinicians struggled to construct a frame for the interpretation of clients' data, several turned to their clients to help make sense of the data. Clients also stressed the importance of having a clinician support them in interpreting their data and doubted whether they would be able to do this themselves. Other studies similarly highlighted the value of patients providing clinicians with additional information about patient-generated health data to unveil the subjective meanings of the data [25]. This indicates that collaborative data interpretation is an essential component in the clinical application of the ESM tools, which boosts the perceived usefulness of the tool. Therefore this component should be emphasized and strengthened in future implementation initiatives.

Most participants in our study expressed willingness to use the ESM or similar tools in the future, although many emphasized the necessity of making changes and improvements to the tool. This aligns with previous findings that clinicians and clients are generally interested in the ESM-based self-monitoring [18,19,26]. However, the need for further adaption was reflected by participants encountering several challenges in using and integrating IMPROVE into their practice. Many clinicians experienced difficulties navigating the tool's functionalities, which made it difficult for them to start using the tool and apply more advanced features, such as personalizing clients' questionnaires. Clinicians, therefore, expressed a need for more in-person support. Unfortunately, these types of usability issues are common in digital health tools [27]. A study examining usability problems of eHealth applications found that system navigation, interface design, and lack of built-in guidance and support accounted for 69% of users' usability issues [27]. Furthermore, consistent with other research [28,29], our study indicated that technology literacy and attitude can influence willingness to use digital tools. More anthropological field research on mental health care workers' existing technology habits and literacy might help inform the system design of the ESM tools and understand users' context and capabilities. Similarly, engaging end-users in co-design processes could help tackle usability issues that could lead users to abandon the tools. Finally, our results show that adequate support for clinicians and clients is needed to facilitate the implementation of the ESM tools in mental health care. Especially in the early adoption phases, users should be supported in familiarizing themselves with the tools and integrating them into their work routines. Potential solutions could include more built-in guidance functions in the tool or establishing additional structures (eg, service centers) that can provide direct user support.

Furthermore, our findings emphasize that self-monitoring demands a lot of clients, and can be difficult and burdensome for people with mental health problems. While clients expressed a wish to comply with the self-assessments, they often found it practically challenging. In line with other self-monitoring studies [30], we found that competing activities (eg, working) and technical issues (eg, device or internet access) were the most common reasons for missing assessments. To comply with the assessments, several clients had to change their phone habits, eg, ensuring that they always had their phone with them, and had notifications and internet connection on. As it is known that existing habits are important predictors of technology acceptance [17], this need to change habits can become a threat for sustained clinical implementation of ESM tools. Furthermore, some clients reported negative reactivity to self-monitoring, which was associated with less interest in using the tool again. Other studies also found that while self-monitoring can be motivating and helpful, it can also become a stressful activity that clients feel obliged to comply with [31]. This highlights the need to investigate how self-monitoring tools can be made less burdensome for users while still producing valuable information. Potential solutions could include the integration of passive monitoring [32,33] or adaptive assessment schemes that allow for periods with lower and higher assessment intensity [34,35].

Limitations

The findings of the study should be interpreted considering the following limitations. One limitation is that the study relied on referral sampling, which might have influenced the representativeness and diversity of the sample. Furthermore, the study was conducted in a large psychiatric center of a university in Belgium. Clients and clinicians within different health care settings or with different demographic backgrounds might have different experiences of using digital self-monitoring tools. Another limitation is the potential overrepresentation of people with a positive attitude towards digital mental health tools. Several clinicians for example recruited clients who they expected were interested in using digital tools and had the necessary technical literacy. Furthermore, none of the participants who dropped out of the intervention participated in the interviews. However, using contact records data, we established that some of the challenges experienced by participants who were interviewed were also reported as reasons for dropout by participants who did not complete the intervention. Future research should aim to better understand the views of nonadoptors, identify the main reasons for nonadoption, and work towards tackling these barriers in the design and implementation of ESM self-monitoring tools.

Conclusion

ESM-based self-monitoring can provide clinicians and clients with useful information about how clients' daily life activities correspond to fluctuations in their mental health. These benefits seem to increase when clinicians and clients engage in collaborative interpretation and sense-making of the clients' data. Therefore, ESM tools have a clear potential to support a person-centered approach to mental health care rooted in clients' daily life experiences. However, our study highlights that the effort required by clinicians and clients to integrate ESM tools into daily practice remains substantial due to system usability challenges and the burden of repeated assessments. Addressing these issues in future ESM tool developments will be crucial for successful implementation. One potential solution to tackle these barriers is enhancing user support. Another is modifying key features of ESM tools to better suit users and their contexts, such as reducing the frequency of assessment and data information load. Engaging end-users directly in this process

through user-centered design approaches may ensure a better fit between the tools, their context of use, and user goals and ultimately facilitate better adoption.

Acknowledgments

The authors would like to thank all clinicians and clients for participating in the study and contributing to this work. We also thank Merijn Mestdagh and Stijn Verdonck for programming the necessary software functionalities on the m-Path software platform. In addition, the authors would like to thank Silke Apers, Daphne Tuyaerts, and Tessa Biesemans for their contribution to data collection and Ana Teixeira and Daphne Tuyaerts for their help in designing the study. Finally, the authors would like to thank the Leuven IMMERSE patient advisory board members for providing feedback on the interpretation of the study results. This project received funding from the European Union's Horizon 2020 research and innovation program (777084; DynaMORE project and 945263; IMMERSE). GK is supported by the Research Foundation–Flanders (12ZZM21N and 1204924N).

Data Availability

To avoid potential identification of study participants, the complete interview transcripts will not be made publicly available.

Authors' Contributions

LT, GK, JW, MW, and IMG were involved in designing the study and setting up the data collection. Data analysis was undertaken in a collaboration between LT and LU. The first manuscript draft was written by LT with the support of GK. All authors contributed to the critical review of the manuscript and approved the final version.

Abstract

Background: First Nations children and youths may have unique ways to convey their health needs that have not been recognized by health providers. This may contribute to the disparity between high rates of mental health and physical pain and low rates of treatment for the conditions they experience. Evidence suggests that a colonial history has resulted in poor experiences with the health care system, lack of trust with health providers, and miscommunication between clinicians and patients. Contemporary ways, using both Indigenous and Western knowledge, are needed to bridge the gap in communicating pain.

Objective: The aim of this qualitative study was to test the usability and clinical feasibility of the Kids Hurt App with First Nations youths and clinicians working with youths.

Methods: Using a Two-Eyed Seeing approach, the Kids Hurt App was developed using concepts from validated mood and pain assessment apps combined with community-based research that gathered First Nations youths and clinicians perspectives on quality, intensity, and location of pain and hurt. The Kids Hurt App contains 16 screens accessible on any web-based device.

Results: In total, 3 rounds of low-fidelity testing (n=19), 2 rounds of high-fidelity testing (n=20), and 2 rounds of clinical feasibility testing (n=10) were conducted with First Nations youths (10 - 19 years) to determine the relevance, validity, and usability of the Kids Hurt App. High-fidelity testing was also conducted with 15 clinicians after completing the high-fidelity youth sessions. Youths had constructive suggestions that were used to improve the app in subsequent rounds of version testing. There was one main discrepancy between youths and clinicians related to preference for how best to visually convey pain. The youth's preference was maintained in the app.

Conclusions: All youths in all rounds of testing indicated that they would use the Kids Hurt App if it was available to them in a health care setting, with most clinicians noting that the app would be useful in practice.

Introduction

Overview

Indigenous peoples in Canada are comprised of 3 distinct groups: First Nations, Inuit, and Métis. They reside across Canada, from large cities to small isolated communities [1]. In comparison to non-Indigenous peoples, Indigenous peoples are the fastest-growing cohort in Canada with a significantly younger population [1]. Indigenous children younger than 14 years of age represent 25.4% of the total Indigenous population, while the same age group in the non-Indigenous population only compromises 16% [1]. Repeated reports of racism in health care, such as those in the In Plain Sight report describing Joyce

Echaquan's fatal health care experience in Quebec [2], combined with research findings [3,4] suggest that health care providers need to understand the structural and historical factors that contribute to the current racial disparities faced by Indigenous peoples [5]. A legacy of colonialism and present-day racism is a determinant of health that is unique to Indigenous peoples so efforts need to be made to create better understanding, appropriate assessment, and improved care for health conditions such as pain [6].

While 1 in every 5 Canadian people experiences chronic pain, this number is significantly higher in Indigenous communities, and most types of pain are more prevalent in Indigenous peoples [7]. Indigenous children are particularly vulnerable to experiencing pain. In one study examining pain diagnoses, a large sample of First Nations children (n=2631) who were compared to an age-, sex-, and location-matched sample of non–First Nations children, demonstrated that the First Nations cohort experienced significantly more physical pain–related diagnoses for 10 of the 13 pain indicators studied [7]. Further to this, while ear- and throat-related diagnoses were the 2 most diagnosed pain conditions for both groups, the First Nations cohort was significantly less likely than the non–First Nations cohort to visit a specialist for these same conditions, demonstrating inequities in diagnosis and treatment [7]. Additionally, these data showed that children (0 - 9 years) who had a physical pain diagnosis were more likely to have a mental health diagnosis in adolescence, a finding only evident in the non–First Nation cohort who were seemingly able to access mental health care [7].

Cultural variances in pain expression have also been found between Indigenous and non-Indigenous children and youths [8,9]. Latimer et al [8] concluded that Mi'kmaq children were stoic and hid their pain. Children reported that they would not cry when enduring pain and preferred instead to be "brave" or "tough it out" [8]. These findings led researchers to conclude that health clinicians may not have ways to accurately assess or document the level of pain a child or youth is experiencing. Similar findings of stoicism were reported in Indigenous peoples in Australia, with participants often being described as quiet about their pain and not reporting pain due to higher pain tolerance, fear of Western medicine, or intercultural communication difficulties [10]. Clinicians are trained to use numerical or face pain scales to assess pain; however, only minimal research has been done to determine if these self-report pain scales are culturally appropriate for use with Indigenous children, and indeed to our knowledge, none in First Nations children [11,12]. Community members reported that numerical pain rating assessment scales are confusing, and it is difficult to attach hurt or pain to one measure such as a face or number [9]. The evidence suggests that there is a clinical practice gap in assisting Indigenous youths to convey their pain to health providers. This study endeavored to find a culturally appropriate mechanism to support youths in sharing their pain and to address reports of a lack of clinician's ability to recognize pain, which creates a barrier to appropriate health care [13]. In response to these needs, the Kids Hurt App [14] was cocreated with Indigenous and clinical partners. It was created with the notion that Indigenous peoples have many effective ways of communicating knowledge that include visual images and storytelling. This led the developers to explore how both Indigenous and Western ways could be used to develop a better assessment tool that puts the technology in the hands of the youths. The aim of this qualitative study was to test the usability and feasibility of the Kids Hurt App with First Nations youths and clinicians working with youths.

Background

Two-Eyed Seeing

The project used a Two-Eyed Seeing (TES) approach, a term coined by Elders Murdena and Albert Marshall, which recognizes the benefit of seeing Indigenous knowledge and experience from one eye while also seeing strengths from another eye's perspective that is different from one's own [15]. The Western perspective is most typically how health care is currently delivered. When both eyes are used, the ultimate benefit is achieved by effectively enhancing the health of Indigenous peoples through the practical sharing of knowledge [16].

Digital Health Interventions for Indigenous Children and Youths

Although there is a growing body of literature on digital health and app-based interventions to manage pain in children and youths, research on the development and usability of app-based interventions for Indigenous peoples is limited. In a review of digital health solutions for Indigenous mental well-being across Canada, the United States, Australia, and New Zealand, Hensel et al [17] indicated that co-designed app-based interventions had been shown to reduce anxiety and depression symptoms and contribute to well-being. The Aboriginal and Islander Mental Health Initiative for Youth App, or AIMhi-Y, was developed in consultation with Indigenous youths from Australia and the Torres Strait Islands [18]. The youths identified apps as a potential way to mitigate barriers to accessing help and highlighted the need for a strength-based approach [18,19]. A randomized controlled trial found that iBobbly, a suicide prevention app developed in consultation with Indigenous youths living in Australia, had only a minimal, nonsignificant impact on psychological well-being outcomes, although qualitative data indicated the app was helpful and that construct validity issues may have been the reason why there was not a significant impact [20]. To date, there is no research on the development or usability of apps for Indigenous children and youths in Canada [21].

Development of the Kids Hurt App

The Kids Hurt App was developed by the Aboriginal Children's Hurt and Healing Initiative for children aged 10 - 19 years. Funding for the app development and testing was received from the Canadian Institutes of Health Research (FRN# 162455 & SCA-145102), Indigenous Health Nursing Research Chair, Dalhousie University (FRN# 167603), and IWK Health Foundation. The Aboriginal Children's Hurt and Healing Initiative is a broad partnership, consisting of Indigenous community leaders, clinicians, elders, youths, researchers from universities, and health delivery systems. In keeping with Ownership, Control, Access and Possession (OCAP) principles

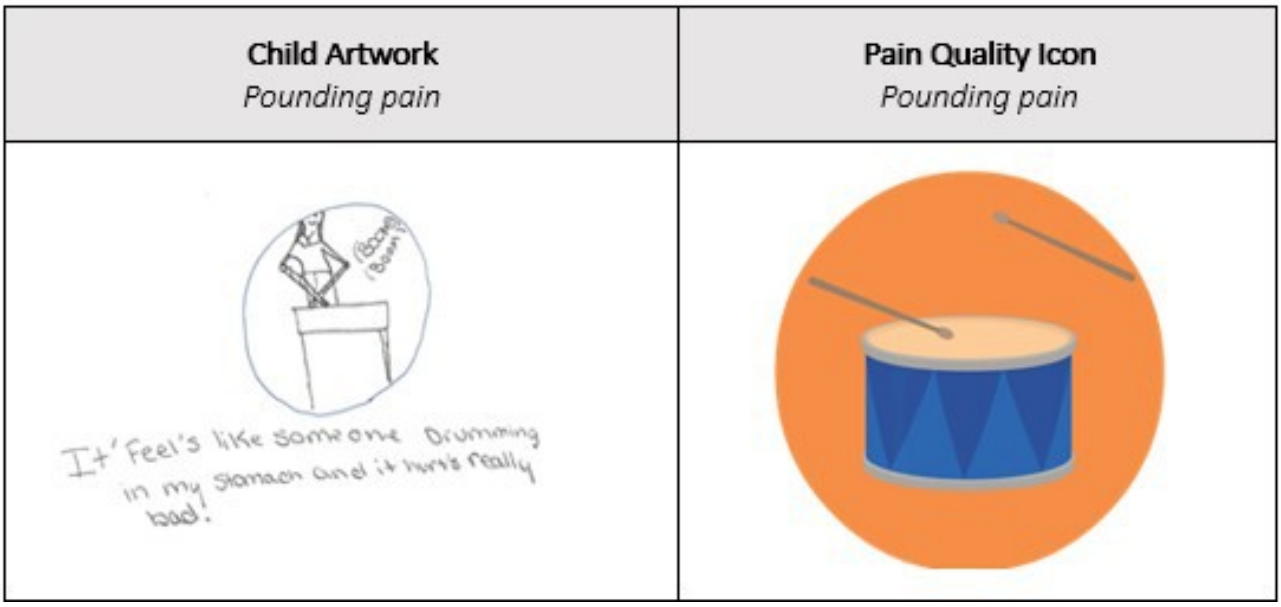
[22], the app is owned by communities involved in this research study. OCAP is a registered trademark of the First Nations Information Governance Centre and describes the principles of ownership, control, access, and possession to ensure that First Nations have control over data processes including ownership and how their information is used. The app was developed to facilitate pain communication between clinicians and Indigenous youths in a culturally safe manner. It is not meant to replace the history-taking step of a health care interaction but rather serves to augment the quality of communication exchange by giving youths an opportunity to share their pain story in a comfortable, culturally safe way.

The app was developed using TES to ensure both Indigenous and Western concepts and content were included. In total, 16 "screens" or interfaces were developed. Multimedia Appendix 1 provides an example of the final 16 screens developed. Previous versions of these screens were used throughout various stages of testing.

The first app screen asks users their gender and age (see Screen 1 in Multimedia Appendix 1), with the subsequent screen providing them with the option to create an avatar or choose a predesigned one (see Screen 2-3 in Multimedia Appendix 1). First Nations youths were involved in the development of the avatar designs through initial content validity testing to ensure that visual representation was present. Once an avatar is chosen, it is prompted to answer a series of responses to physical and emotional pain prompts. The inclusion of both physical and emotional pain prompts provides an example of how TES [15] was used throughout the development of the app. Earlier design ideas for the app had only physical pain prompts; however, community feedback suggested that incorporating both physical and emotional pain prompts would better represent the Indigenous holistic view of health, which involves "a healthy balance of 4 elements or aspects of wellness: physical, emotional, mental, and spiritual" [23]. While this version of the Kids Hurt App does not incorporate all 4 wellness aspects, emotional and physical pain were chosen because they were the most reported types of pain in previous research [7]. Future app iterations are expected to include spiritual and mental dimensions. There is also evidence that physical and emotional pain are interconnected, and the app presents an opportunity to highlight this for both youths and clinicians.

Additional incorporation of TES [15] involved the use of the International Association for the Study of Pain assessment tool guidelines [24] in the development, ensuring three key assessment features were embedded into the app: (1) pain location (see Screen 4-6 in Multimedia Appendix 1), (2) pain quality (see Screen 7 in Multimedia Appendix 1, and (3) pain intensity (see Screen 8 in Multimedia Appendix 1). Pain quality icons were conceptualized based on previous art-based research with Indigenous youths [8,9] as well as the Iconic Pain Assessment Tool [25] and the Pain Quality Icon (QuILT) [26] as illustrated in Figure 1.

Figure 1. Pain quality icon development.



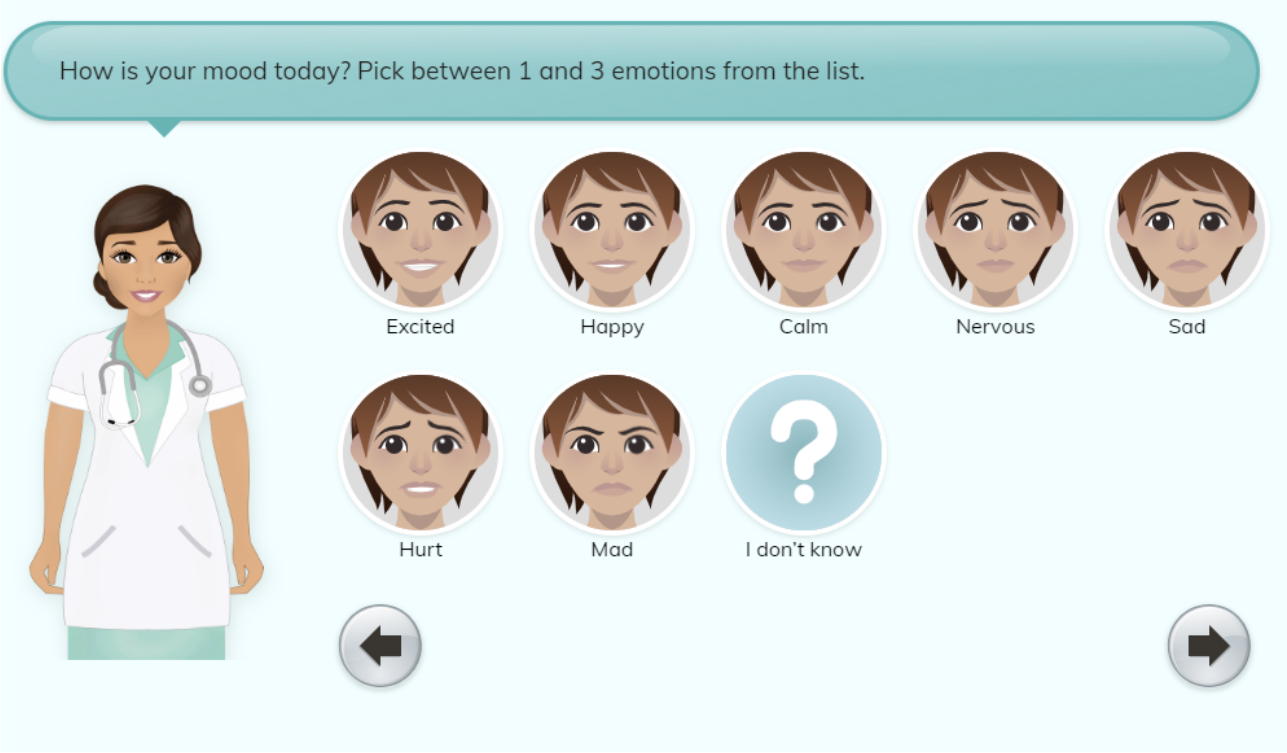
Pain intensity was initially captured using 2 scales: a 10-point "face scale," mimicking the Faces Pain Scale—Revised (FPS-R) [27], and a newly developed "Jar of Hurt," building on the concept of the "Pieces of Hurt" tool [28] and respecting the nation's language and word for "pain" which is "hurt" [8]. A jar was used as a common, everyday item that would provide the imagery of filling something up with pain or hurt. In addition, details of *where* users were when they got hurt (ie, school) and *what* they were doing (ie, playing) were also included with options based on common places of injury noted in the First Nations Regional Health Survey [29].The inclusion of the *where* and *what* aspects of the app allowed the incorporation of storytelling (see Screen 9-10 in Multimedia Appendix 1), an approach with significant cultural ties for Indigenous populations [30].

After completing questions regarding the user's physical pain, users are then prompted to provide information on their emotional pain through a series of similar screens (see Screen 11-14 in Multimedia Appendix 1). Emotional pain icons were initially chosen based on 22 common emotions identified from

20 validated mood apps (Multimedia Appendix 2). Through the initial content validity testing with First Nations youths, these 22 emotions were narrowed down to 8, which were identified as most likely to be used to describe their emotional mood. The resulting 8 emotions, both "negative" and "positive," provided a range of options and avoided bias in responses (Figure 2). Emotional pain questions focused on users' current emotional state (happy, sad, and anxious), intensity of those emotions (using the 10-point Jar of Hurt), and any physical symptoms that may be associated with their emotional pain (ie, chest tightness).

Upon answering both the physical and emotional pain questions, information is presented on a final storyboard screen (see Screen 15 in Multimedia Appendix 1).

Figure 2. Emotional pain icons.



Methods

Study Design

Once an initial version of the app was finalized three types of testing took place: (1) low-fidelity testing, (2) high-fidelity testing, and (3) clinical feasibility testing. This testing or development strategy mirrored the process published by Stinson et al [31].

Ethical Considerations

Prior to project initiation, the study was approved by both an Indigenous and tertiary pediatric hospital research ethics board (Mi'kmaw Ethics Watch & IWK Health Research Ethics Board; #1017831). Informed consent was obtained from all participants or their parents or guardians prior to taking part in study procedures. Youth participants received a CAD $10 (US $6.98) gift card after completing the testing. Clinician participants were not compensated. Data were deidentified immediately following data collection sessions.

Participants

First Nation youth participants were recruited through social media platforms and community organizations or contacts to complete low-fidelity, high-fidelity, and clinical feasibility testing. Clinicians recruited from a First Nation Health Centre and a pediatric health center unit specializing in emotional or physical pain–related services (rheumatology, pain clinic, etc) also completed high-fidelity testing. Eligibility criteria for youth participants included (1) self-identifying as Indigenous, (2) residing in a First Nation community, and (3) being between 10 and 19 years of age.

Data Collection

Overview

The study took place over a 5-year period between April 2017 and March 2022. Significant delays were experienced due to the COVID-19 pandemic. All youth data collection sessions were completed within the youth's Indigenous community to ensure that local support resources were available if a youth felt distressed. A trained mental health clinician was available as a resource for each session, and smudging was offered for youths who took part in the clinical feasibility sessions.

Low-Fidelity Testing

Low-fidelity testing is a qualitative usability approach where youths were able to view a paper-based version of the app. Youths completed a demographic survey prior to reviewing the app screens. In total, 3 rounds of low-fidelity testing took place. During each round, youths were shown paper-based screenshots of the Kids Hurt App and asked what they liked and disliked about the design through a series of semistructured questions.

Sessions were audio-recorded and transcribed for clarity and accuracy. After each round of testing, feedback was reviewed and integrated into the app. Screenshots of the updated version of the app were then shown to the next round of participating youths until no further changes were suggested based on the methods of Stinson et al [31].

High-Fidelity Testing

High-fidelity testing is similar to low-fidelity testing; however, participants were able to review a fully functioning version of the app rather than paper-based screenshots. Youths completed a demographic survey prior to using the app, and all sessions were audio-recorded and transcribed. Two rounds of high-fidelity testing were completed with participating youths to determine functionality and acceptability and to allow for any suggested revisions to be shared. The app was viewed on an iPad, and the youths worked through the app in the presence of the research assistant. At the start of each session, youths were asked to complete the app by themselves and to talk out loud about any likes, dislikes, or difficulties. The length of time it took for youths to complete the app from start to finish was recorded. Then, they were asked to go through the app for the second time with the research assistant who asked them semistructured questions. Once finished, they were asked open-ended questions on their overall thoughts regarding likes, dislikes, ease of use, and whether they would use the app in a health care setting if it was available. Feedback from each round was incorporated until no further changes were suggested (2 rounds). Interviews with the youths were audio-recorded in each of the 2 rounds to maintain the integrity and accuracy of the findings.

After the youths completed the high-fidelity testing, clinicians were then invited to take part in high-fidelity testing. Clinicians were invited to use the app and then answer a series of questions either through a digital survey or during a focus group. Focus group sessions were transcribed to ensure data accuracy. Questions assessed the clarity and importance of the various app components and also allowed space for participants to provide suggestions on what they would like to change or add for each screen. Demographic questions were also asked to determine participant's profession and types of experience.

Clinical Feasibility Testing

Clinical feasibility testing was completed with youths to help determine if the app works well, if it is easy to use, and if youths found it relevant for use in their care. Youths were asked to work through the app with the research assistant present and then answer a series of questions in a digital survey format. Questions ranged from demographic questions to those regarding the app's usefulness as well as functionality. Once an initial 5 youths had completed their review of the app, changes were incorporated, and an additional 5 youths were invited to take part. After 2 rounds of clinical feasibility testing with very positive results and minimal changes, it was determined that a third round was not needed.

Data Analysis

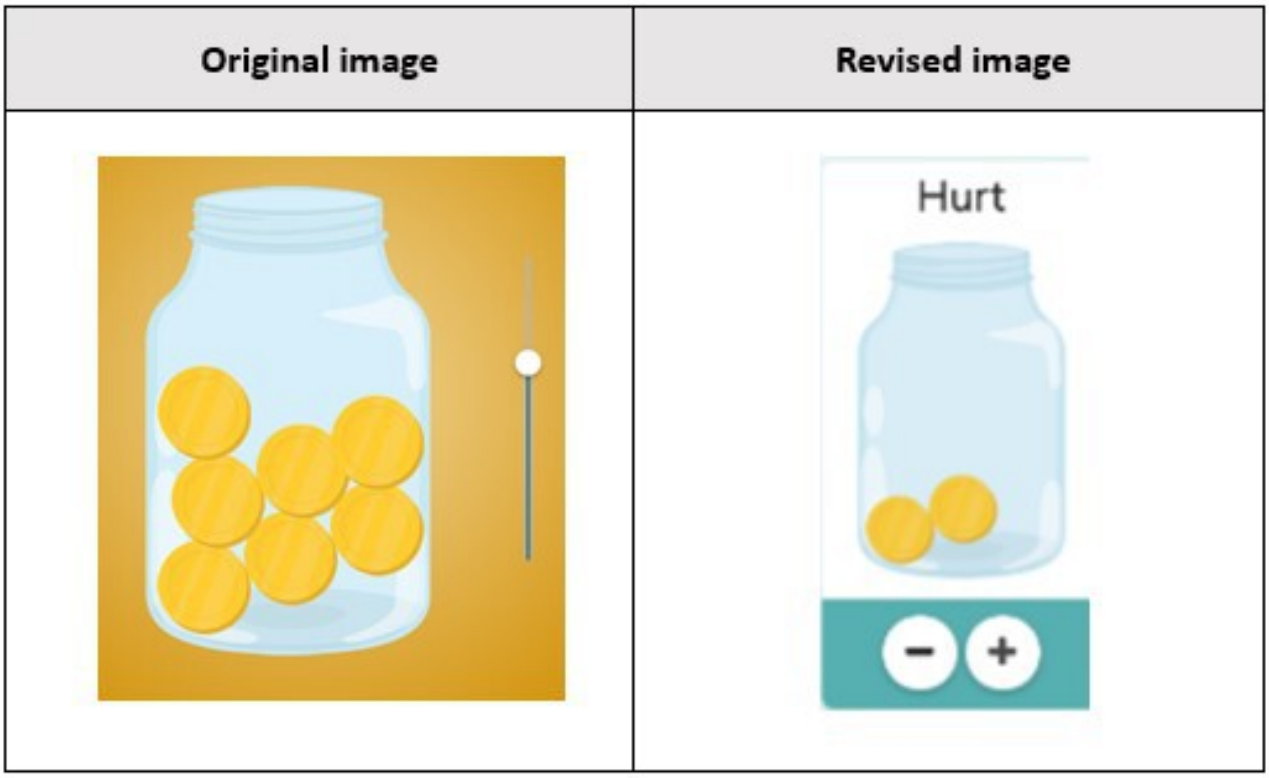
Demographic survey responses from all rounds of testing were analyzed using the SPSS Statistics (version 24; IBM Corp) database system to provide an overall breakdown of age and gender. Field notes and transcribed interviews were reviewed to determine any changes needed for subsequent rounds of testing. Revisions associated with more large-scale app functionality that were unable to be incorporated between testing rounds, such as incorporating a feature to track pain over time, were added to a database for future recommendations.

Results

Low-Fidelity Testing

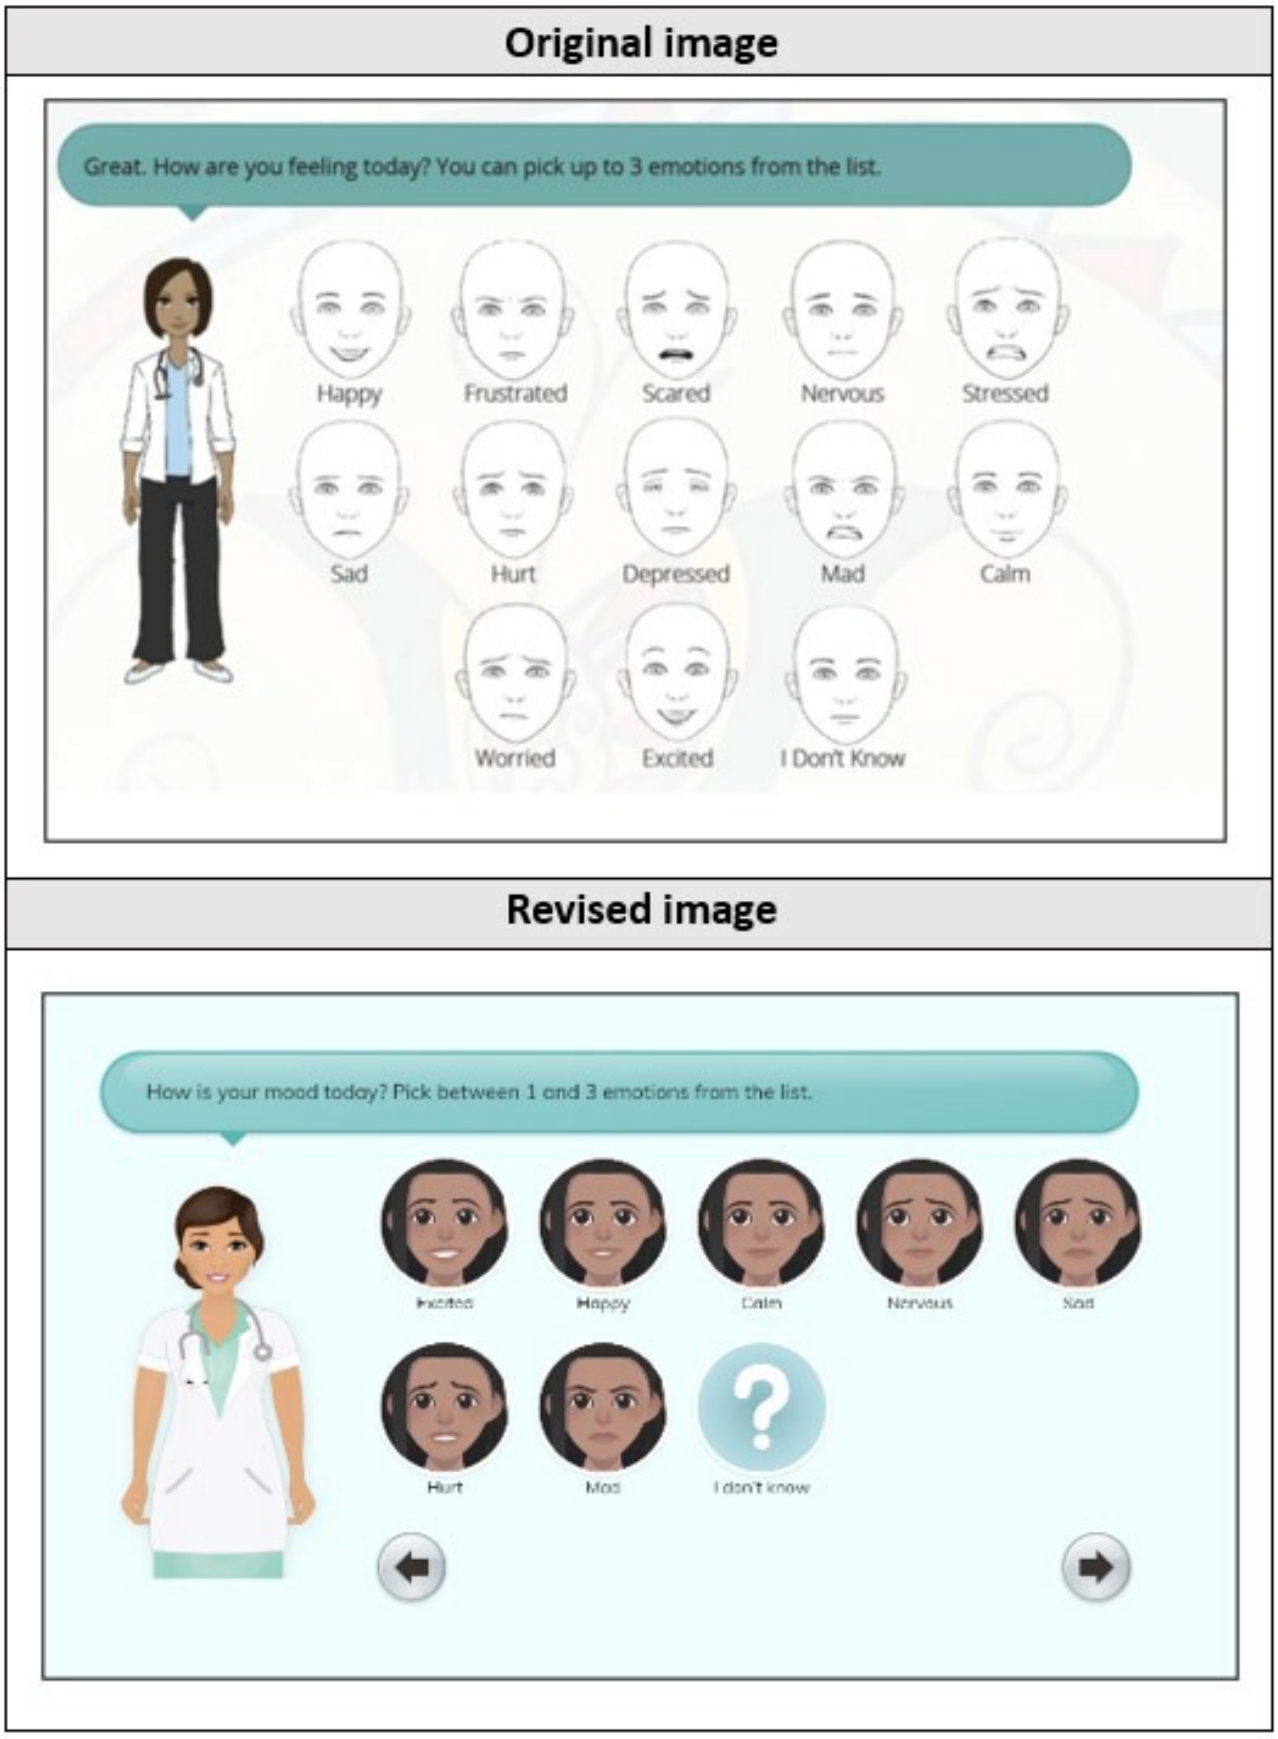
A total of 19 youths participated in 3 rounds of low-fidelity testing (round 1: 7 youths, round 2: 6 youths, and round 3: 6 youths). In total, 63% (n=12) of the participants were identified as female. The average age for all participants was 13 (SD 2.46) years. In the first round of low-fidelity testing, 1 participant suggested that the Jar of Hurt scale should use a plus or minus button to increase or decrease the amount of hurt rather than the original "slider" option (Figure 3). In subsequent rounds, youths were shown both the slider and the plus or minus option and asked their preference. The majority of youths (n=11) preferred the plus or minus option. The directions for describing how to use the Jar of Hurt were also identified during low-fidelity testing as needing clarification. A total of 6 of the 19 youths identified this issue. "I don't know, it's a little confusing. It sounds complicated" (Female, 14 years). The language was simplified, and it was agreed that it would be further reviewed in the high-fidelity rounds.

Figure 3. Jar of Hurt—plus or minus button addition.



The final noted change from low-fidelity testing was an overall dislike of the way the emotion face icons looked. One youth described the faces as “creepy.” To address this, the facial icons were redesigned to look like the user’s avatar rather than a generic face as illustrated in Figure 4.

Figure 4. Emotion faces—revised. Original image depicts 10 emotions rather than the finalized 8 emotions, as this was an initial mock-up screenshot for testing purposes only.



High-Fidelity Testing

A total of 20 youths participated in the 2 rounds of high-fidelity testing (round 1: 10 youths and round 2: 10 youths). In total, 70% (n=14) of participants were female, and the average age for youth participants was 16 (SD 2.46) years. The average time it took youths to complete the app was 3.61 minutes (216.6 seconds; SD 48). All youth participants identified enjoying the app and agreed it would be helpful to them.

> *It was pretty helpful. I know when you go to your doctor, you don't really want to open up. Sometimes you're nervous. At least the app helps explain how you feel.* [Female, 17 years]

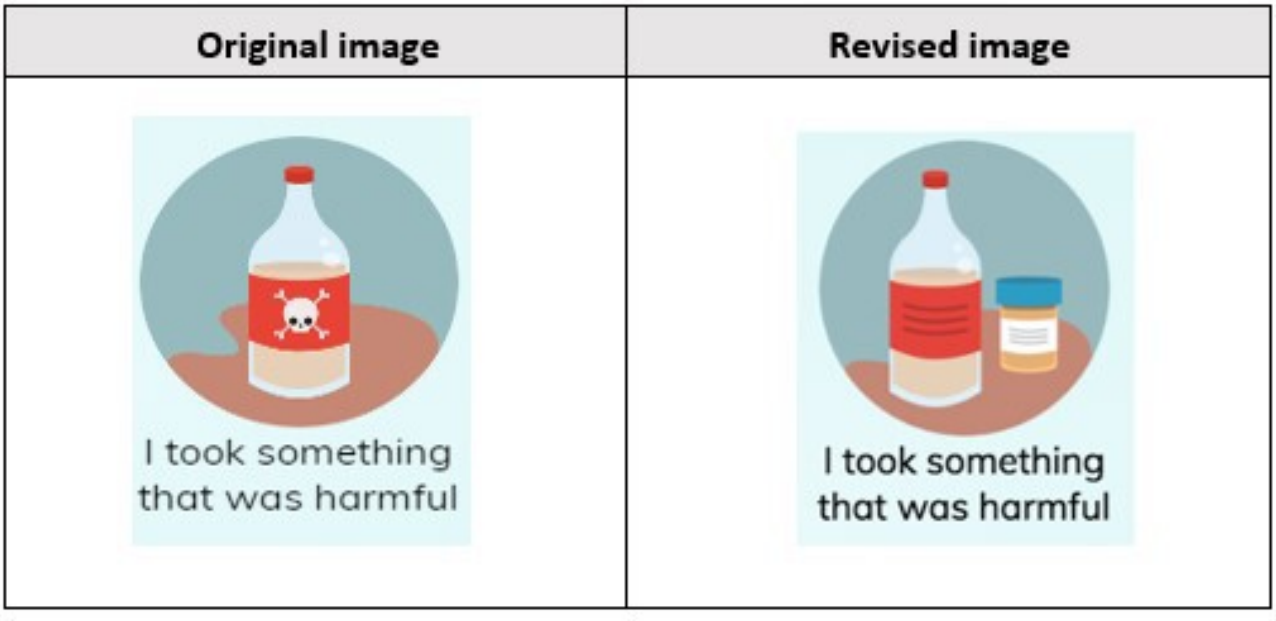
Confusion remained regarding the use of the Jar of Hurt with 2 of 10 youths in the first round of testing describing it as confusing. As a result, examples of an empty jar and a full jar were added beside the plus or minus buttons to provide a visual of how to increase or decrease the amount of pain or hurt (see Screen 7 and 8 in Multimedia Appendix 1). After this change was implemented, no confusion was noted in the remaining high-fidelity testing round.

Participants also suggested revisions to the "I took something harmful" icon in the "how you were hurt" section. Initially, this icon included a skull and crossbones to symbolize poison; however, youths suggested that something more representative of drugs or alcohol should be included.

> *I think this would be something chemical, based on the picture and skull thing. But I think something that can be added is maybe drugs or alcohol. Because the person may not always feel comfortable saying it but hitting it on the button without thinking and if it's right in front of you, they may be honest.* [Female, 18 years]

This icon was revised to better reflect youth participant's perception of which icons are most relevant to them (Figure 5).

Figure 5. "Harmful" icon changes.



A final revision resulting from the youth high-fidelity sessions was determining a preference for which scale to use to represent the quantity of pain. Youths were shown a scale with facial images similar to those in the FPS-R and superimposed in the avatar [27] (Figure 6) and the Jar of Hurt scale (Figure 7) and asked which they felt would best allow them to quantify their pain. The majority (n=12, 60%) preferred the Jar of Hurt scale. One youth shared their reason why:

> *If you had to choose one option, I would say the jar scale would be a lot better. Because maybe some people, they know how to hide it. Their pain. So, I'd say the jar scale is a lot better.* [Male, 16 years]

Figure 6. Faces Pain Scale—Revised expressions avatar adapted faces scale.

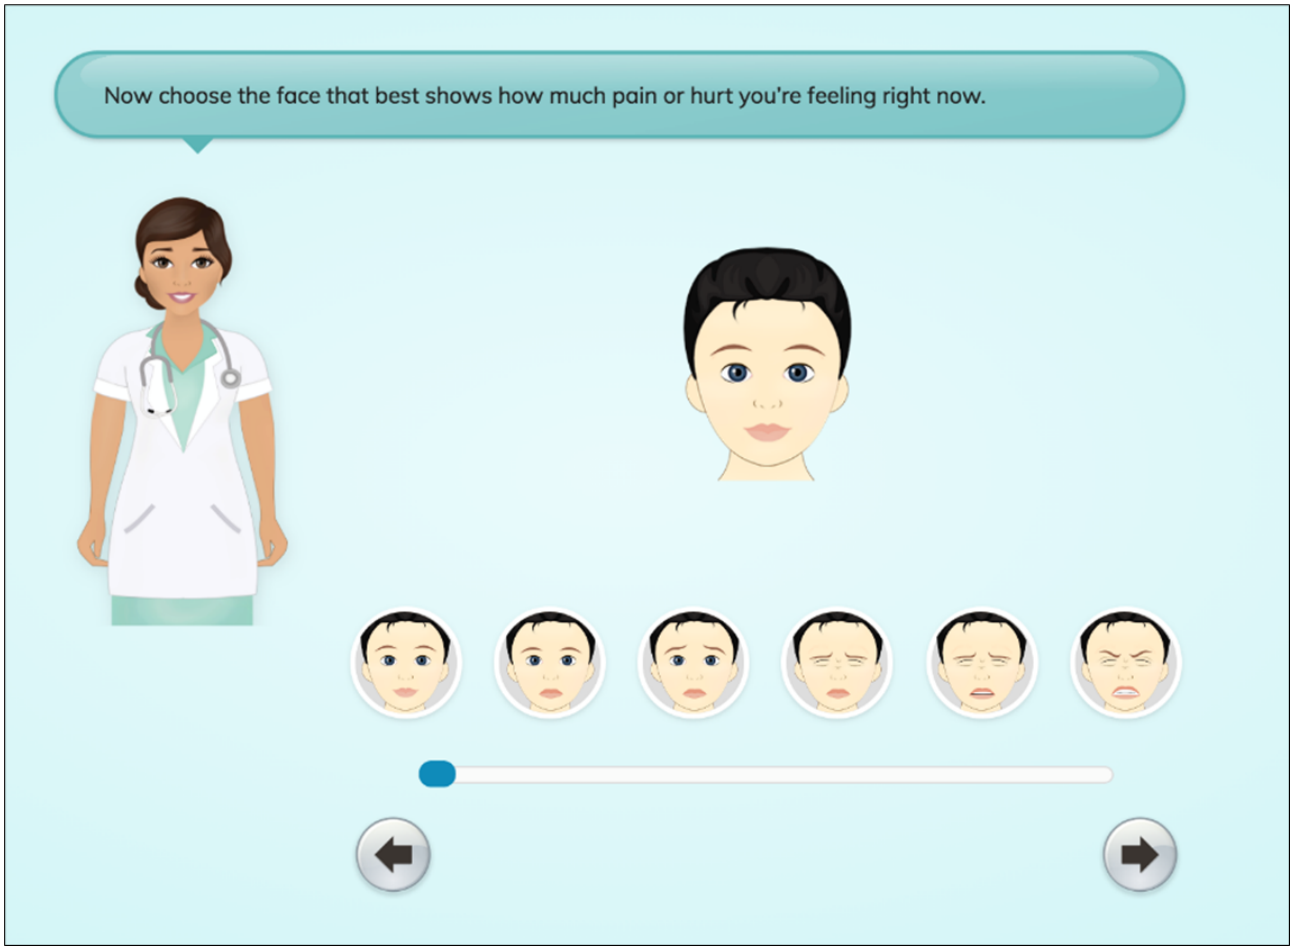


Figure 7. Jar of Hurt scale.

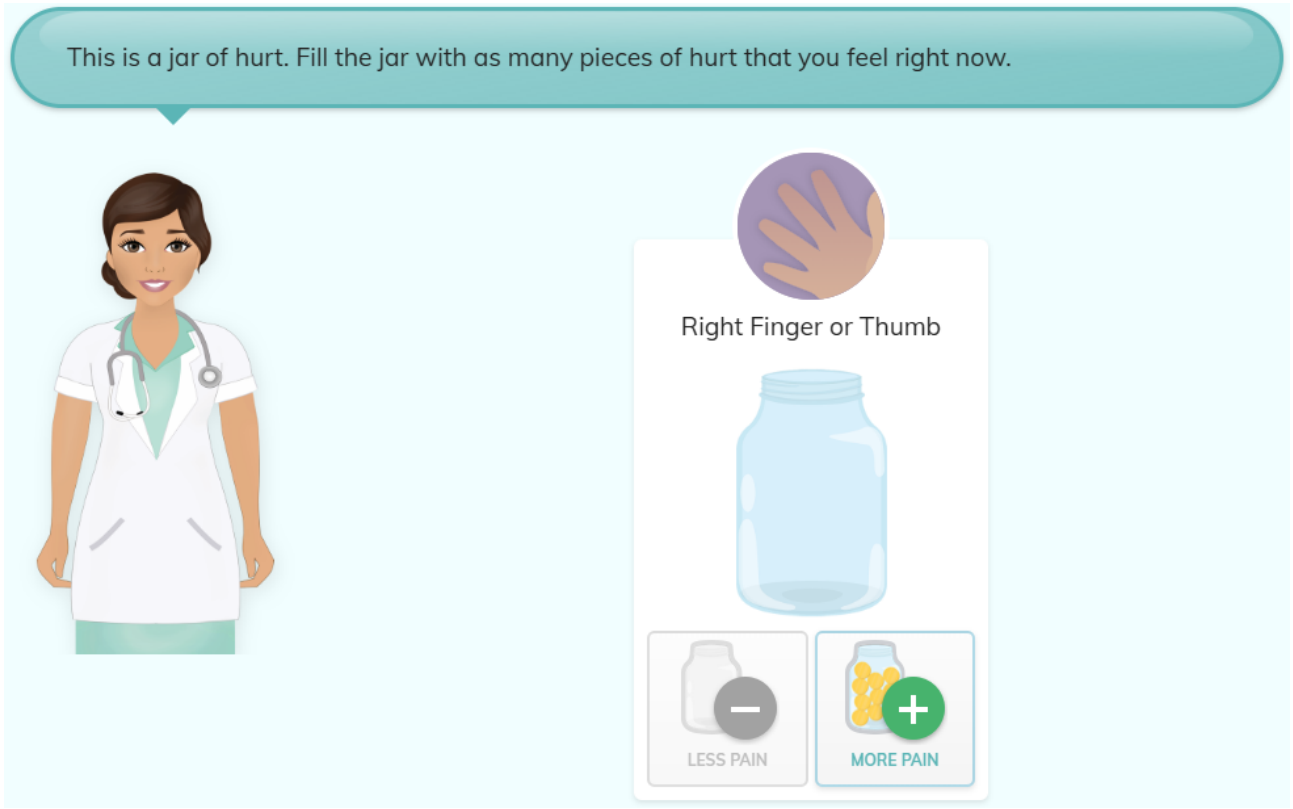

In addition to youths, a total of 15 clinicians participated in high-fidelity testing. In total, 10 clinicians completed this through a digital survey, and 5 participants took part in a focus group session. Most survey respondents were nurses (n=7, 70%), and focus group participants included physicians, physiotherapists, nurses, and psychologists.

In total, 14 of 15 clinicians found the app to be moderately or extremely useful. Like youths, clinicians were asked to identify their preference between the Jar of Hurt or the FPS-R adapted scale (Figures 6 and 7) through the survey questions. A total of 7 of the 9 clinician respondents identified a preference for the FPS-R adapted scale.

On 2 different screens, clinicians suggested adding an "other" option. For the quality of pain screen, 4 of 5 clinicians from the focus group felt that an "other" option should be included to allow users to add their own quality of pain descriptors. Similarly, for the emotional pain screen, all clinician participants suggested adding an "other" option to allow users the flexibility of adding any emotion they felt, even if not in the presented list. These additions were made in subsequent versions of the app.

Clinical Feasibility Testing

A total of 10 youths completed clinical feasibility testing (round 1: 5 and round 2: 5). Results from the clinical feasibility testing were very positive, with 80% (n=8) of respondents identifying that they found the app easy to use and 90% (n=9) saying they would use the app in a hospital or health care setting. No technical errors were found. Participants suggested that the Jar of Hurt method was more geared toward younger youths but also noted that they were happy to use the scale either way. Suggestions for change were mainly larger design changes identified as "future changes" including having a text or email function to send results to themselves or their care providers, having the ability to track changes in their pain or hurt over time, and including translation in their Indigenous language.

Discussion

Principal Findings

In this study of clinicians and First Nations youths, 3 types of testing occurred in the development of the Kids Hurt App: low-fidelity, high-fidelity, and clinical feasibility. For the 2 groups of participants, each subsequent round of testing reduced the app modifications. Overall changes were minor, but important observations were thought to increase the usefulness of the app for users.

Recent literature has identified that app-based interventions may remove barriers to accessing care for youths [18,32,33]. Apps are accessible and may mitigate confidential concerns and concerns about stigma. Smartphone-based apps may be particularly useful, as authors from one study found that smartphones are a mainstream technology and are an advantage within the health care system [34]. While existing research suggests that Western pain assessment tools are not appropriate for Indigenous peoples [10], this study demonstrates how an app can be developed collaboratively and engage youths to share their pain respecting both Indigenous and Western knowledge systems. All youths stated that they would use the Kids Hurt App if it was available in the health care setting. Youths reaffirmed that they often found it difficult to articulate their feelings and felt that the app could help them communicate their needs. This app allows them to share their pain and help facilitate enhanced communication.

One notable finding in this study was the process of determining which pain scale to use, the "Jar of Hurt" scale or the "face scale." In the initial development stages of the app, the "Jar of Hurt" concept was chosen based on previous research regarding the "Pieces of Hurt" tool [28]. While this research was completed with younger children than our target population, the concept of using objects rather than faces was appealing based on previous research indicating that Indigenous children are often stoic in their expression of pain and may hide their pain rather than displaying it outwardly through facial expressions [8]. Through high-fidelity testing, 60% (n=12) of youths preferred the "Jar of Hurt" scale over the "face scale," and while it was noted in clinical feasibility testing that the scale was more geared toward younger youths, participants identified being happy to use the tool, regardless of that. Clinician preference was strongly noted for the face scale likely because of its similarity to the FPS-R scale, a well-known pain measurement tool [27]. However, given that the app was developed to provide youths with a valid way to convey their pain and hurt and to develop an alternative to Western pain assessment tools, the "Jar of Hurt" was maintained as the preference for conveying pain intensity. This finding highlights the importance of taking the time to validate patient indicators of pain consistent with different age groups and populations.

Improved Health Care Experience

During a typical patient visit, a clinician obtains the patient's history, current pain experience, and future needs in a short amount of time [35]. This can be challenging if a patient finds it difficult to articulate their pain and hurt for a range of reasons, such as stoicism or power dynamic, further causing delay in timely and appropriate care [34,36]. In this study, participants identified the app as "easy to use" and were able to complete the app screens in an average of 3.61 minutes (216.6 seconds; SD 48). The youths' suggestions for app improvement, such as the Jar of Hurt being a better way to capture pain instead of a face that may hide pain, provide some indication that the Kids Hurt App may facilitate better communication, and consequently health care experience, by allowing Indigenous youths to convey their pain through an app. Other comments such as the youths who indicated pushing a button might be easier than talking could imply that the app offers a nonthreatening and safe way for youths to share their stories. Research has shown that youths have high technological literacy and are comfortable using eHealth apps [37,38]. In a generation where technology is fluent, the Kids Hurt App can give youths a voice in the health care system, in a medium they are comfortable with, to personally advocate for their physical and emotional pain care.

Limitations

At the time of testing, the app was not yet available in the youth participant nation's language. The current version of the app [14] is fully translated into Mi'kmaw. Communication between

the provider and patient should always be clear and effective, and having health information accessible in one's primary language is important [39]. Thus, we recommend that the app be available in the nation's primary language in any further testing. An additional limitation is that testing was only completed with 2 First Nation communities so results cannot be assumed to be accurate for all Indigenous nations.

Conclusions

Culturally safe care acknowledges the attitudes, knowledge, and behaviors of another's culture in a respectful manner. If a provider encounters an Indigenous patient, it would be important to understand the patient's unique historical legacies, ways of communicating, and any potential intergenerational trauma that may influence pain report [40]. Implications of creating and using an app that has been codeveloped by the end users (First Nations youths) increase the usefulness of the app and provide a space for the provider and patient relationship to be optimized for best care outcomes. The short app completion time is an indication of the minimal effort it takes to offer a culturally appropriate alternative to pain self-report and may reduce miscommunication and repeat visits for the same condition. Future research will include testing the app with non-Indigenous youths as well as in various health settings such as mental health, tertiary, primary care, and emergency departments. Further development of the app related to youth's self-report of effective strategies that reduce pain and hurt is planned. The Kids Hurt App is a culturally safe and evidence-based communication tool that may allow First Nations youths to comfortably share their pain and hurt stories. Each nation may be different in its communication and will need to review the app for usability and feasibility in its own communities.

Acknowledgments

The authors would like to thank the First Nations youths and the clinicians for taking the time to support the development and testing of the Kids Hurt App.

Abstract

Background: It is widely accepted that the COVID-19 pandemic has accelerated the era of online health care delivery, including within community palliative care. This study was part of a larger project involving a collaboration between universities, health care services, government agencies, and software developers that sought to enhance an existing telehealth (video call) platform with additional features to improve both patient and health care professional (HCP) experience in a palliative care context.

Objective: The aim of this study was to understand palliative care patients' and HCPs' experiences of telehealth delivery in a palliative care context in Victoria, Australia. For the purposes of this study, telehealth included consultations by both video and telephone calls. By better understanding users' experiences and perceptions of telehealth, we hoped to determine users' preferences for new telehealth enhancement features.

Methods: A total of 6 health care professionals and 6 patients were recruited from a major tertiary hospital network's palliative care unit in Victoria, Australia. Participants were asked to generate 3 - 5 photographs depicting their telehealth experiences. These photographs were used as visual aids to prompt discussion during subsequent one-on-one interviews. Intertextual analysis was conducted to identify key themes.

Results: A total of 3 overarching themes emerged: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. Patients (n=6) described telehealth as supporting their physical and psychological comfort and maintaining connection with HCPs, yet there were specific situations where it failed to meet their needs or impacted care quality and delayed treatment. HCPs (n=6) recognized the benefit of telehealth for patients but reported several limitations of telehealth, in particular due to lack of physical examination opportunities. Participants indicated that 2 types of connection were imperative for effective telehealth delivery: technical connection (eg, good internet connectivity or clear phone line) and interpersonal connection (ie, good rapport and therapeutic alliance between the HCPs and patients). Often technical connection issues impeded the development of interpersonal connection between the HCPs and patients in telehealth.

Conclusions: The findings presented in this study combined with other co-design activities, which are outside the scope of this paper, indicated the potential value of a telehealth enhancement feature that generates patient-facing clinical consultation summaries. Our team has developed a video telehealth enhancement feature (or "add-on"), which will enable clinicians to distill key actionable advice and self-management guidance discussed during teleconsultations for a take-home summary document for patients. The add-on's prototype has also been subjected to an initial simulation study, which will be reported in a future publication.

Introduction

In Australia, chronic illness continues to be a major challenge in health care [1] with more than three-quarters (78.6%) of Australians impacted by at least one chronic condition [2]. Many of these chronic conditions are life-limiting [3], and thus patients may benefit from palliative care [4]. The 2018 National Palliative Care Strategy recommends the approach of using palliative care as a "means to improve the quality of life of patients and their families affected with life-threatening illnesses through the prevention and relief of suffering by means of early identification, assessment, and treatment of pain and other problems" [5]. Studies have shown that palliative care improves quality of life by improving independence, providing symptom relief and pain control, and supporting the physical, emotional, and spiritual needs of patients, their carers, and loved ones [6-9]. Furthermore, palliative care is linked with a significant decrease in health care use and prolongment of survival [10].

Specialist palliative care in Australia is delivered using different models of care depending on the geographic location and available resources [11]. Many of these models of care were transformed during the COVID-19 pandemic to promote physical distancing [12,13]. One such approach for the delivery of specialist palliative care in Australia was a move to telehealth to limit hospital attendance and in-home visits [12]. The implementation of telehealth in palliative care in Australia demonstrated promise beyond the pandemic, with the potential to improve communication, facilitating more equitable access to palliative care (especially for those in rural and regional areas), avoiding lengthy travel to hospitals or clinics (particularly when patients are very unwell), and potentially assisting with timely symptom relief [14]. However, for continued sustainability and success of telehealth models, telehealth needs to adapt and evolve based on feedback from patients and health care professionals (HCPs) [15].

The importance of user involvement in the implementation of palliative care services has been recognized and prioritized by researchers to improve productivity, quality, and relevance of care [16]. The aim of this study was to understand palliative care patients' and HCPs' experiences of telehealth delivery in a palliative care context in Victoria, Australia. For the purposes of this study, telehealth included consultations by both video and telephone calls. This study was part of a larger project involving a collaboration between universities, health care services, government agencies, and software developers, which sought to enhance an existing telehealth (video call) platform with additional features to improve both patient and HCP experience. By better understanding users' experiences and perceptions of telehealth, we hoped to determine users' preferences for other telehealth enhancement features.

Methods

Participants

Palliative care professionals and patients were recruited from the Monash Health Supportive and Palliative Care Unit at a tertiary hospital network in Victoria, Australia. HCPs, including palliative care medical and nursing staff, and interpreters involved in the Unit's use of telehealth were invited to participate by email. The Unit has video telehealth palliative care clinics for oncology patients. In addition, during COVID-19 outbreak, the Unit provided a telehealth outreach service when in-person home visits were not possible.

Patients aged 18 years and older, with conversational English proficiency, currently using telehealth to access palliative care were invited through email invitations and postcards. A total of 6 patients and 6 HCPs participated in the study. All participants lived in Victoria and spoke English as their primary language. The patients' ages ranged between 54 and 61 years old. In addition, 4 of the 6 patient participants identified as female and 2 identified as male. The HCPs' ages ranged between 33 and 62 years old, with 5 identifying as female and 1 as male. The duration in their health care roles ranged from 6 months to 8 years. Their roles were 'doctor' (n=3), 'interpreter' (n=2), and 'nursing clinical coordinator' (n=1). Our 6 patient participants have been deidentified as P009, P012, P013, P014, P015, and P016, and HCP participants as HCP001, HCP003, HCP 004, HCP005, HCP010, and HCP011.

Data Collection

The study used a qualitative photo interviewing technique [17,18]. Participants were requested to generate 3‐5 photographs based on certain prompts and share them with the research team. HCPs were asked to click photographs to depict their everyday work life in the context of telehealth models of care, what telehealth represents in their work, general experiences, and opportunities for improving current telehealth models. Similarly, patients were asked to generate photographs to illustrate their experience of receiving health care through telehealth, what telehealth represents for them as patients and their everyday lives, and opportunities for improving telehealth models of care. Multimedia Appendix 1 and Multimedia Appendix 2 shows the specific instructions provided to both HCPs and patients.

Participants emailed their photographs to a member of the research team. Subsequently, telephone interviews, lasting between 30 and 45 minutes, were conducted with each HCP and patient participant. During the interviews, participants were asked to elaborate on what each of the photos meant for them and how the photographs related to their experiences of telehealth. During the interviews, use of participant-generated photographs helped trigger participants' memories and invoke their deeper consciousness, values, attitudes, and personal

meanings of telehealth [19-21]. The visual aids also helped the researcher and participant reach a shared understanding of the topic [22]. All the interviews were audio-recorded and transcribed verbatim by a professional transcribing company. The interview transcripts were deidentified, and photos blurred to protect participants' identities. The anonymized transcripts were imported into Microsoft Word and the photos inserted at the point where they were discussed during the interviews, allowing for an intertextual analysis in which the participants' photos and words could be viewed together [23].

Data Analysis

A multistep data analysis process was conducted, involving intertextual analysis wherein participants' words and photos were viewed together and analyzed using a 3-step process involving (1) preview, (2) review, and (3) cross-photo comparison [23]. In the first "preview" stage, the first author reviewed all the photos and identified recurring motifs. These motifs were recorded in a PowerPoint slide deck and shared with the research team at a meeting for feedback and further interpretation. Subsequently, a more in-depth "review" was conducted wherein one researcher coded all the interview transcripts with relevant themes and subthemes in more granular detail. The emergent codebook was shared and workshopped with the research team to further distill the emerging patterns.

The final stage in the data analysis process was "cross-photo comparison." During this phase, the research team discussed the similarities and differences within and across participant groups (eg, within patient participants' or within HCPs' accounts, or across patients' and HCPs' accounts). Often the patients' and HCPs' accounts provided contrasting experiences of the same facet of telehealth use (referred as "counter-examples"). For example, where patients valued the convenience of telehealth and being able to liaise with their doctors from anywhere, HCPs found patients' use of telehealth in certain places (eg, public spaces) disruptive and uncongenial to the therapeutic process. To organize the emergent themes, a storyboard was developed by the first author containing illustrative quotes and photographs from both patients and HCPs. This story board has been provided in Multimedia Appendix 3 . The storyboard was presented to the research team and subsequently, manuscript development commenced.

Ethical Considerations

Ethics approval for the study was obtained from the Monash Health Human Research Ethics Committee (project identification number 79681). All participants were provided plain language summaries of the research project, and what their participation would entail. All participants provided informed written consent. They also had the option to stop the interview at any point. Only approved members of the research team had access to the identifiable participant information. All interview transcripts were deidentified before the commencement of the data analysis process. Photos generated by participants showing any humans were also blurred to preserve participants' privacy.

Results

Overview

A total of 3 themes were identified: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. It should be noted that while these themes are presented as distinct categories, they are not necessarily mutually exclusive. In addition, in some cases the themes included counter-examples, as mentioned above.

Comfort (Or Lack Thereof) Afforded by Telehealth

For some participants, telehealth afforded them greater physical and psychological comfort. However, for some others, telehealth hampered their physical and psychological comfort. Therefore, this theme elucidates how telehealth use impacted patients' and HCPs' physical and psychological comfort.

Physical Comfort

Palliative care patients often experience physical discomfort, including pain and fatigue, which in turn impacts their ability to visit clinics for in-person consultations. Patient participants advised that they had arranged their homes in ways that minimized their discomfort. Telehealth enabled them to remain in this environment, unlike in-person appointments, which lead to physical exertion due to travel and wait times, with this issue compounded for rural patients.

Patient participant P015 captured this theme when discussing a photo (Figure 1) of the room where they spent most of their time. They reported being "in pain 24/7" and explained how telehealth helped minimize their discomfort:

> *...You can actually see how close my bed; my chair is to my office desk. And so, I just use the walking frame, I get to the chair very easily. I sit in my chair, I'm listening to a bit of music, or I'm just watching TV…I'll sit in the wait in the chair, waiting for the doctor to come in.* [P015]

Figure 1. Patient home office for telehealth consultations (P015).

By contrast, some HCPs associated telehealth with physical discomfort. HCPs working in the palliative care outreach service during the pandemic, as opposed to the Unit's dedicated telehealth clinics, reported that private rooms were not always available. Therefore, telehealth appointments were often conducted in shared workspaces, which could be noisy and distracting, impacting their ability to effectively conduct quality consultations with patients. For example, HCP001 included a photo of the shared office space (Figure 2) where they often conducted telehealth consultations and stated:

> *It gets very loud because we're [all] talking… So then anybody else talking on the phone, someone else has to talk up to talk over the top of that, and then anybody having a conversation with each other in the office has to talk up.* [HCP001]

Figure 2. Palliative care service shared office space (HCP001).

Psychological Comfort

Alongside physical comfort, telehealth provided patients with psychological comfort by reducing the stress associated with in-person appointments. Participants reported a variety of psychological stressors associated with in-person appointments, which were mitigated by using telehealth, for example, travel and wait times, risk of exposure to COVID-19 in hospitals, forgetting key questions for their doctors, and financial stress, particularly for rural patients who may need to make overnight accommodation arrangements for brief appointments. P013 provided a photo of a piggybank (Figure 3) and stated:

> *…going to appointments, car wear and tear, fuel for my daughter, parking fees, petrol... [With] telehealth, [I] don't have to spend that money… [the money saved could be spent on] all the bits and bobs that they keep chucking at me to take.* [P013]

Figure 3. Piggy bank (P013).

The psychological comfort associated with the freedom to stay in one's chosen location and receive health care from the comfort of their own homes is also illustrated in P014's photo (Figure 4) and quote as follows:

My bush family are my reason for living out here … This is my family. Because of telehealth, I get to stay home and enjoy them. You know, I don't lose a day or two being on the road away from them. I know it's only animals but for some people, you know, animals are our family. [P014]

Figure 4. Life in 'the bush' (P014).

For some outreach service HCPs, however, the sudden large-scale transition to telehealth in the aftermath of the COVID-19 outbreak, led to some psychological discomfort at their perceived inability to provide their usual standard of care. Given their professional training had primarily been in face-to-face care, they felt ill-equipped to efficaciously transition to online care. HCP005 provided a photo of themselves holding their stethoscope up to the camera (Figure 5), demonstrating the limitation of physical examination in telehealth consultations. HCP005 said that the return to more in-person consultations was "almost a relief" post–COVID-19 pandemic. They further elaborated:

> *…often to be thorough in your assessment, as a doctor, you've been trained [to] do your history, examination and do investigations. I guess telehealth takes away … what we're trained to do.* [HCP005]

Figure 5. Health care professional (HCP) uncomfortable about limitations of telehealth (HCP005).

Connection Considerations in Telehealth

Participants indicated that 2 types of connection were imperative for effective telehealth delivery: technical connection (eg, good internet connectivity or clear phone line) and interpersonal connection (ie, good rapport and therapeutic alliance between HCPs and patients). Often technical connection issues impeded the development of interpersonal connection between the HCPs

and patients in telehealth. This theme illustrates how technical connection and interpersonal connection impacted the participants' telehealth experiences.

Technical Connection

The technical aspects of connection included the skills required to use the technology, internet and mobile phone connectivity, and specific hardware and software concerns. HCP participants noted that their patients had first been introduced to the telehealth model of care during the pandemic with varying levels of technological proficiency. Patients with limited technological proficiency needed to build their confidence and skills over time, with support from HCPs, support staff, and family members. HCPs described situations where no one had checked whether or not a patient's computer had required microphone and video capabilities. Internet connectivity and bandwidth issues were also reported by both patients and HCPs. HCPs, in particular, due to their volume of telehealth calls, reported a lot of time lost to troubleshooting connectivity issues, which impacted the time available for clinical conversations. Often participants had to transition to telephone calls. For example, P012 shared an image of their landline home phone (Figure 6), describing it as follows:

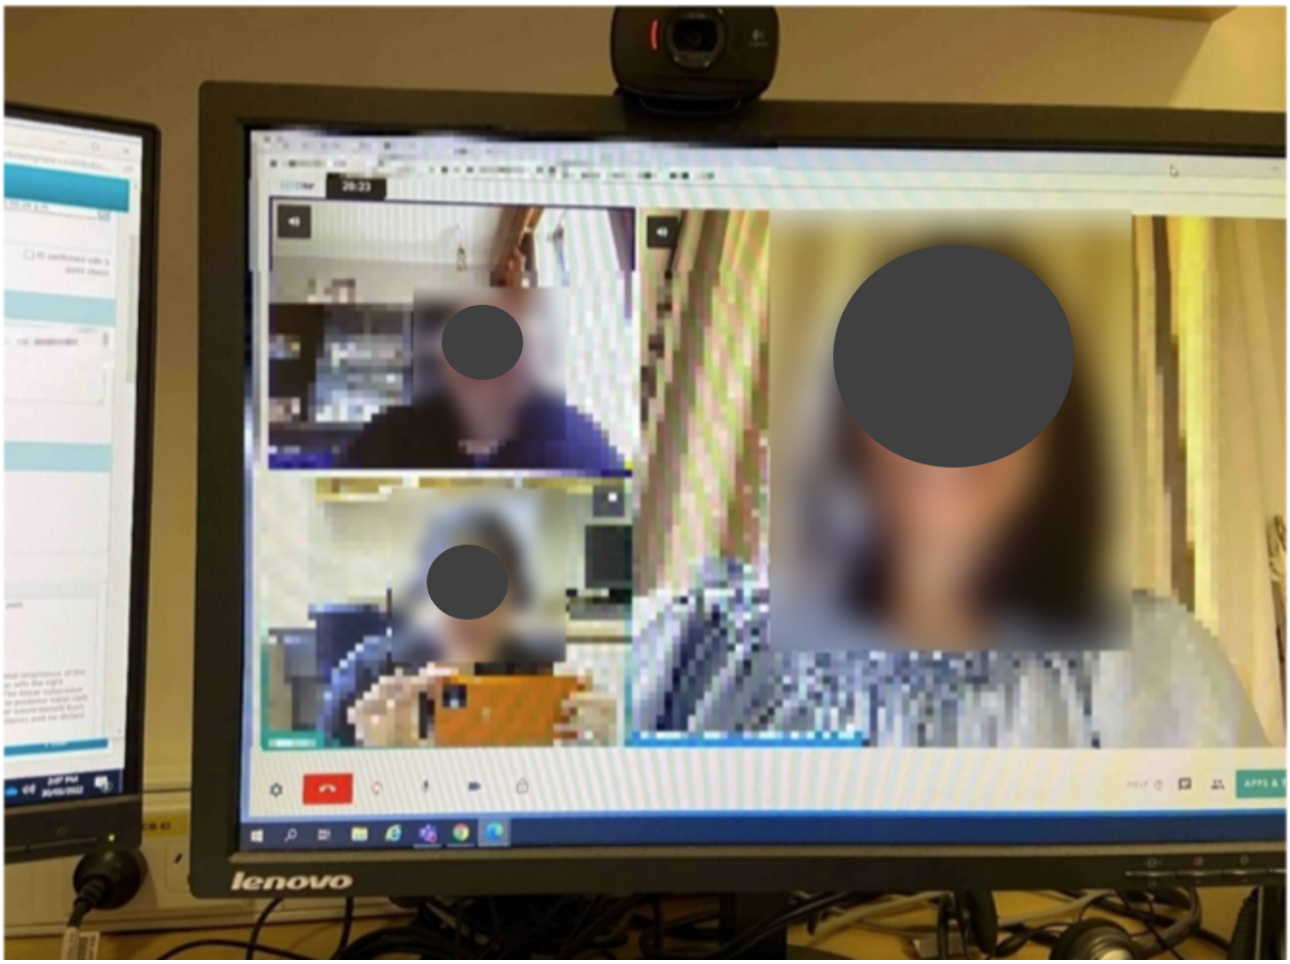
> *It is the most reliable tool in my house. It never drops out. Whereas the Internet … the internet on my computer can be slow or drop out or whatever at a telehealth appointment. And my mobile phone drops out, it's unreliable as well. But this phone is not unreliable. So if I lose a connection with any of the doctors, I know I can ring them on that phone … and it's not going to drop out. That's really important … So the landline is a good back up source for me for telehealth. I always have it sitting there in case something happens.* [P012]

Figure 6. Landline home phone as back-up (P012).

Nevertheless, participants also reported that in the absence of connectivity issues, and with the appropriate skill level to use, and availability of the right technology, telehealth can be very useful and seamless. For example, HCP003 illustrated a good experience of using telehealth involving both a patient and their carer in Figure 7, and recounted:

> *… essentially showing how we can make it work when everyone is capable of using telehealth. On the right … that's actually the patient's son … But it just shows how it can work. So … having patient caregiver in telehealth, it is all very possible. The video worked well the audio worked well ... there was no barrier there.* [HCP003]

Figure 7. Positive experience of telehealth (HCP003).

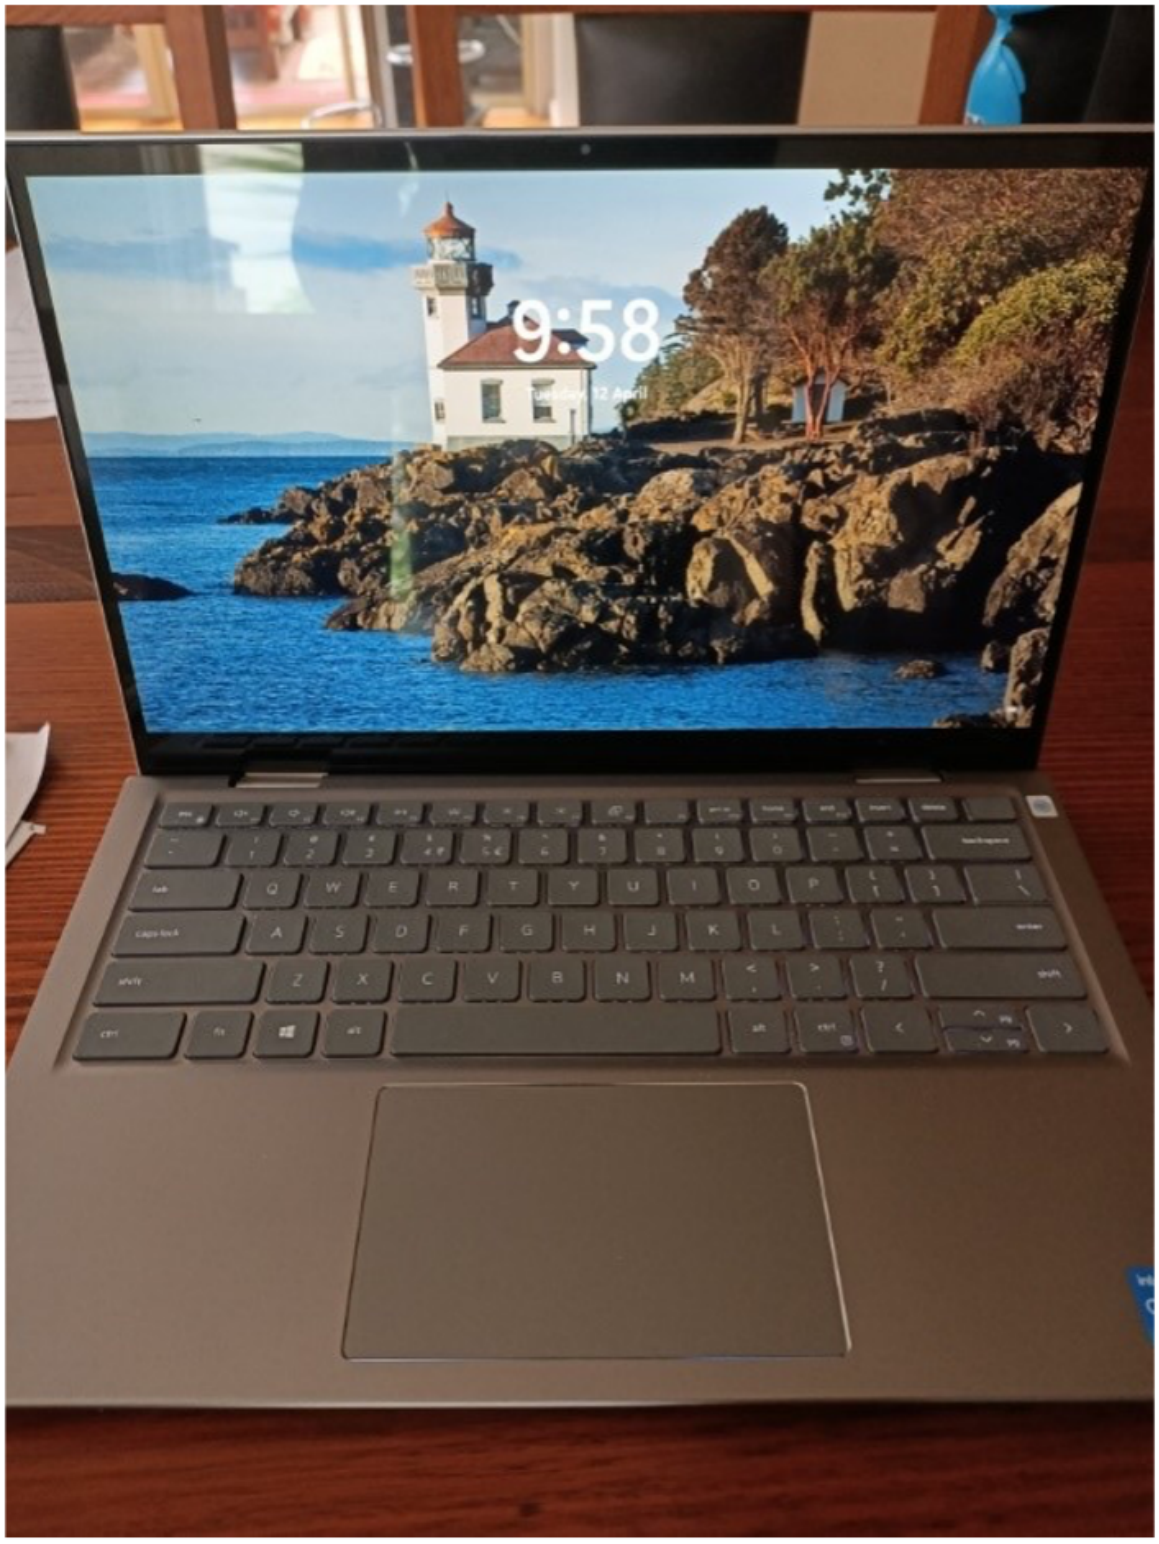


Interpersonal Connection

Participants expressed a general preference for video consultations over telephone consultations because of more opportunities for eye contact, and reading of facial expressions or other nonverbal cues. The notion of power dynamics between HCPs and patients also emerged, with some participants stating that conducting the consultations over telehealth made patients feel more relaxed and open, as opposed to feeling nervous in front of their HCP in person. P012 provided an image of their laptop (Figure 8), which they used for video consultations and stated:

> *I've noticed for me that I open up and talk more ... But when I'm in his rooms, I'm intimidated when I'm in person with him, face to face. I'm more conscious of myself and self-conscious. Whereas over the computer I'm not. I'm really confident and I just pour everything out.* [P012]

Figure 8. Patient's laptop used for video consultations makes them feel more relaxed (P012).



The type of technology used for video consultations also played a role in the quality of the clinical conversations. As previously mentioned, participants sometimes had to rely on backup options such as mobile phones or landlines for consultations due to technological failures, which also impacted the quality of their telehealth consultations. HCP011 shared a photo of an outreach service consultation that they had joined using their mobile phone, because the laptop and desktop were being used by other HCPs (Figure 9), and reflected:

> *The pictures are very small. So it just does not give you a realistic feeling of seeing a patient.* [HCP011]

Figure 9. Video consultation conducted on a mobile phone (HCP011).

In addition, participants generally agreed that periodic in-person consultations interspersed between their regular telehealth appointments were necessary to generate rapport between patients and HCPs. P015 had video telehealth oncology appointments every 6 - 8 weeks for over a year, despite which they said, "I've never met my oncologist," by which they meant that they had never met their oncologist in person. Even P012, who felt they were able to be more open through telehealth said:

> *the doctors should touch base with you specifically in person after a period of at least six months…. seeing them person to person sort of reconnects the relationship.* [P012]

In considering the benefits of in-person care, HCP010 said:

> *…we still want that relationship with the patient, we want to look them in the face and an important aspect of interpreting is body language. So even if you see them on the screen, [it] is not the same.* [HCP010]

HCP005 explained that some patients, "feel a bit suspicious or not completely trusting when you are not there [in person]."

Separately, HCP004 and HCP005 both also said that breaking bad news was more difficult through telehealth because of their inability to offer comfort through nonverbal communication like touch.

Care Quality Impacts of Telehealth

This final theme elucidates participants' perceptions about how telehealth impacts the quality of health care for patients.

Patient participants expressed mixed feelings regarding their satisfaction with the telehealth model of health care. While some participants perceived that the care they received through telehealth was satisfactory, others expressed concerns around issues such as lack of physical examination, impact on treatment timeliness, and communication.

Patients who described telehealth care positively viewed the crucial elements of care as unaffected. P014 explained that being able to share documents and show the HCP medications meant that:

> *[telehealth] doesn't stop the communication process in anyway…as [a] patient I'm not missing anything.* [P014]

Participant P014 was also able to monitor their blood pressure and oxygen saturation at home and share this information with their HCP. HCP004 saw telehealth as working well when there was another complementary team, for example, "hospital-in-the-home," which offered in-person care and provided clinical information to the palliative care patients. They also described the benefits of using telehealth to determine when an in-person visit was necessary:

> *it works best where there's opportunity for, or being able to identify that you can't rely on telehealth alone.* [HCP004]

Participants who believed that the lack of an in-person examination had compromised their care were more negative about telehealth. For example, P013 shared a photo of their arm in their lymphoedema sleeve (Figure 10) to describe the way telehealth had limited their care:

> *I was seeing her [my HCP] pretty much monthly on telehealth. As my arm would flare up, there was still not much she could do because we weren't allowed in … she finally got face to face with me, measured me up for the sleeve, so that was six months without proper diagnosis.* [P013]

Figure 10. Lymphoedema sleeve (P013).

This participant perceived that their symptoms had not been taken as seriously or treated as effectively because the HCPs involved had not been able to examine them.

P016 used a photo of their skin (Figure 11) to discuss the implications of limited physical examination opportunities in telehealth:

> *I was trying to explain to the doctor what the problem was … he actually couldn't see me, what I was trying to explain he couldn't see … And we didn't really get to the bottom of what it was.* [P016]

Figure 11. Patient finding it difficult to show the health care professional (HCP) her skin redness concern (P016).

For this participant, in-person care was important not only in this specific instance, but also because:

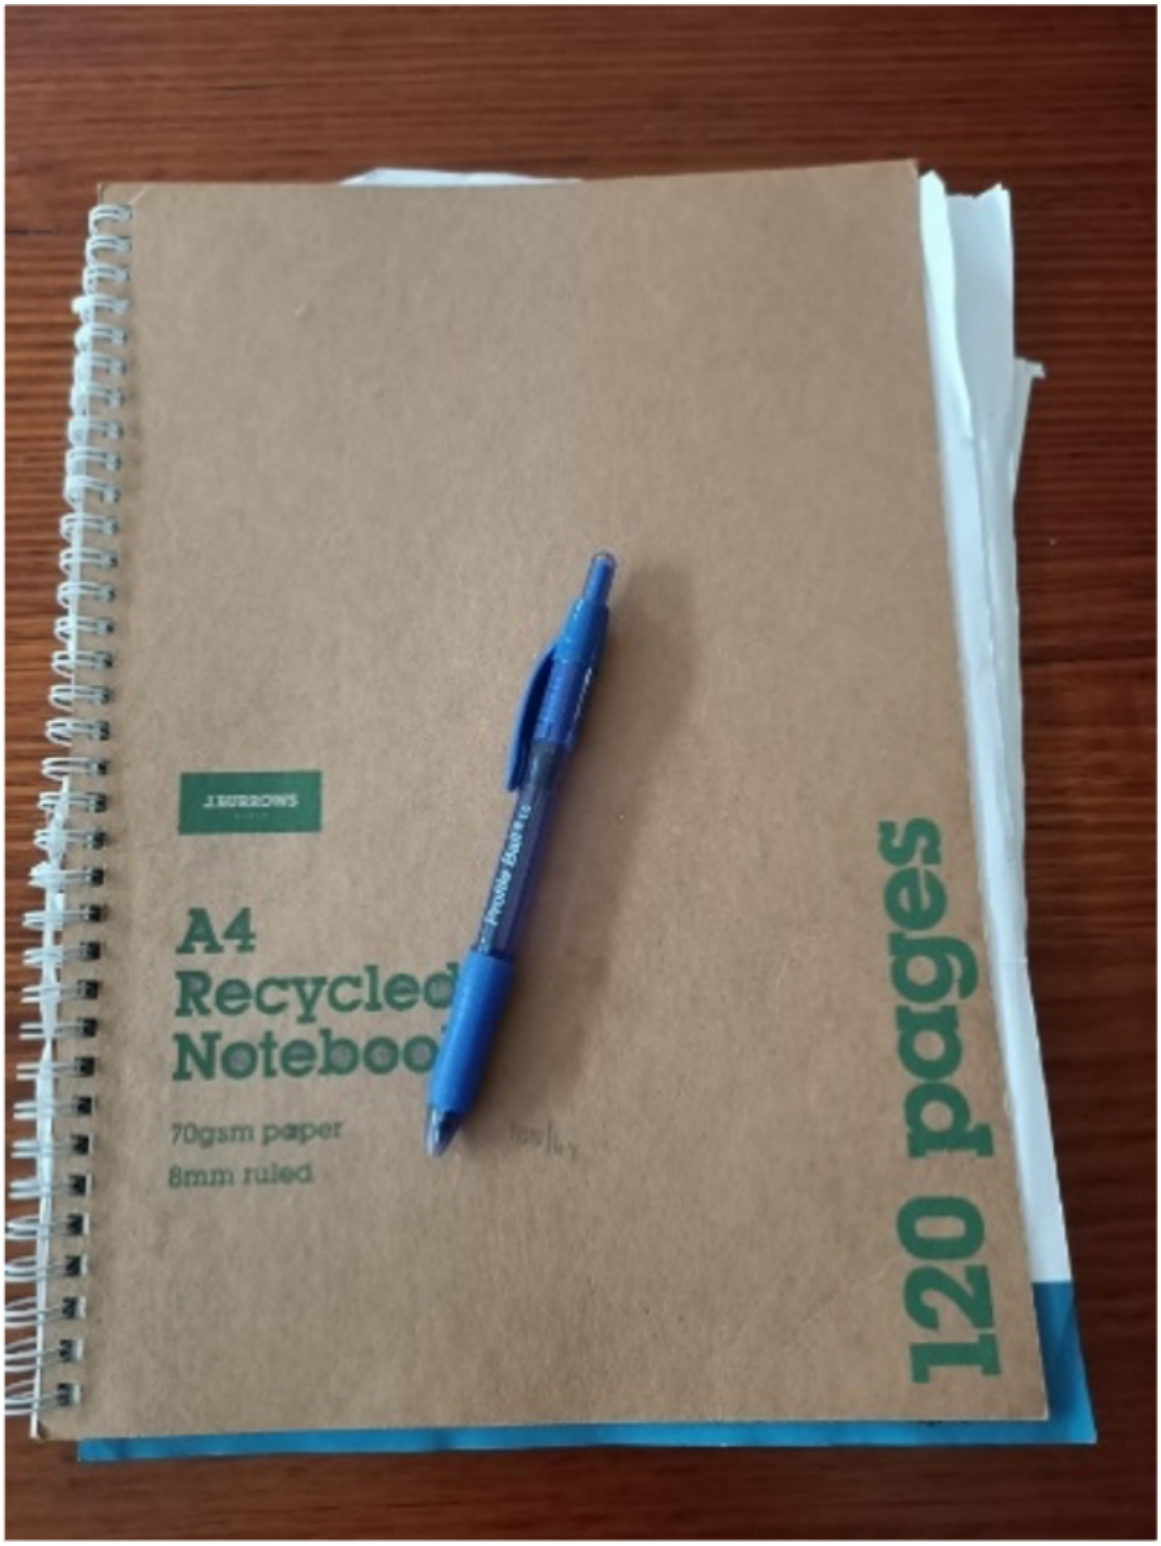
> *the doctor would pick up from the last time he saw you or your oncologist who last saw you [on] sort of things that you don't notice in yourself … I just feel as I'm getting more unwell, that I need to have more face-to-face appointments than telehealth appointments, but they tend to push you towards telehealth.* [P016]

HCPs also stated that telehealth sometimes resulted in less thorough assessments. HCP001 explained that this may be the result of poor technical connection, whereas HCP005 described it as a problem when the assessment required a third party to facilitate the telehealth consultation, such as staff in an aged care facility, whose other duties meant they did not have the requisite time to devote to the consultation.

On the other hand, a positive aspect of the telehealth model of care for patients was their ability to feel more in control of their self-care and self-management during telehealth consultations. For example, patient P012 took a photo of their notebook (Figure 12) to illustrate that they felt more comfortable bringing prewritten notes for discussion and scribing notes during a telehealth consultation than they would in person:

> *Notebook [is] very important ... Leading up to all my appointments I have, I make notes. And then when my appointment comes up, I cross stuff off … that's really important. For me, it's my notes. That way, I know I'm not going to forget anything. And whatever they say to me that's relevant or important, something I had to do or whatever, I'll write it down … I probably wouldn't do that at the doctor's … But online I can just do it on the side while I'm talking to them.* [P012]

Figure 12. Patient feels more in control of their ability to take notes before and during telehealth consultations (P012).



Similarly, another patient P009 recounted a similar experience of feeling more comfortable about their ability to capture important information before and during a telehealth consultation by having family members present with them from the comfort of their homes:

> *Part of the brain tumors is that I can't remember stuff afterwards. So I have to have someone there who's like my virtual notepad … they can answer things that I may have forgotten especially to do with medication because it seems to be the main one or [one of the] side effects … So it works well as in, they've [husband and/or daughter] got an area where they can be comfortable … I have a pad and pen here. But of course I have sometimes husband and/or daughter not only remembering stuff like that's said but going back and reminding me of stuff I need to tell the oncologist that I may have forgotten about.* [P009]

Discussion

Principal Findings

Our intertextual analysis yielded 3 key themes: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. Participants' relationship to telehealth was nuanced. Generally, participants acknowledged the myriad of benefits that telehealth brings, such as greater psychological and physical comfort for patients, especially those based in rural areas. However, there was also a general sense that telehealth should be combined with in-person care for optimal patient-HCP therapeutic alliance and better patient outcomes. It should be noted that this study's data collection commenced during the pandemic, amid nation-wide efforts to rapidly scale telehealth models of care across Australia. Eastman et al [15] sought to understand patients' and HCPs' experiences of telehealth in community palliative care. Their findings were congruent with ours, suggesting that telehealth is being increasingly used in palliative care and generally patients and HCPs are supportive of using this model of health care, combined with regular in-person touchpoints.

A salient finding from our study was the notion of greater power symmetry between patients and HCPs in telehealth compared with in-person consultations. Patients alluded to feeling more empowered, in control, and psychologically comfortable during teleconsultations. This translated into them feeling more confident about "pouring out" information in front of their HCPs, than they would face-to-face. Furthermore, the safety of a device's screen afforded patients the space to take notes during consultations. Having teleconsultations from the comfort of their homes where family members could also be present where needed, meant that patients felt more at ease. In some cases, family members also served the important function of remembering what had been discussed during consultations, which enhanced patients' quality of care.

Our team conducted additional co-design activities with consumers which are outside the scope of this article. In those activities too, participants had reported the importance of taking notes before, during, and after their telehealth appointments. Participants described forgetting important details from their appointments and relying on their family to attend consultations to remember what had happened during the appointment.

Literature suggests that 40% - 80% of medical information and recommendations provided by HCPs during clinical consultations is forgotten by patients almost immediately. The poor information recall may have downstream impacts for treatment adherence [24]. Issues of memory recall may be exacerbated in palliative care patients who experience complex illness symptomatology. There is some evidence to suggest that patient-facing clinical consultation recordings can be helpful for patients in general. A scoping review conducted by Tsulukidze et al [25] in 2014 suggested that patients place a high value on audio recordings of clinical consultations and benefit from subsequently listening to the consultation recordings.

The participants of our study reported in this paper and subsequent co-design activities indicated that having a summary of the consultation at the end of telehealth session would mean that this information is kept secure and in one place for patients. Memory and cognitive deficits are often experienced by palliative care patients. Therefore, a mechanism to record salient information discussed during consultations would be particularly useful for this patient population.

The literature on patient-facing consultation summaries generated during telehealth is currently limited. A non-systematic literature scan in Google Scholar on this subject yielded no relevant papers. The closest relevant literature appears to be about artificial intelligence (AI) enabled digital scribes or documentation systems, which can help automate clinical documentation tasks ordinarily conducted by humans [26-28]. However, the literature on patient-facing clinical summaries in telehealth (whether generated manually by HCPs or through AI-enabled algorithms) is not yet developed.

The paucity of literature on this subject combined with the participants' unanimous views emergent in our investigations, emphasized the need for innovating in the area of patient-facing clinical consultation summaries. Since the conduct of the study presented in this paper, our team of software developers has created a telehealth-enhancement add-on feature which seeks to generate patient-facing summaries of clinical consultations during video telehealth sessions. The prototype was developed in an agile manner, involving think-aloud testing activities with end users. Subsequently, the minimum viable product (MVP) was subjected to a simulation study to generate early-stage evidence about end-users' perceptions of the add-on's potential clinical usefulness. The findings of our think-aloud and simulation studies will be reported in future papers. However, based on participants' accounts presented in this paper, we expect that the provision of a patient-facing document that summarizes the telehealth consultation and distills key actionable clinical advice for patient self-management, might enhance patient experience and self-management.

Limitations

The limitations of this project include the small number of participants interviewed. The small sample size was partly due to challenges in recruiting palliative care patients. Patients' complex symptomatology and in some cases, limited life expectancy, impacts their ability to participate in research studies. In addition, as the data collection was conducted during the pandemic, this posed additional challenges for HCP recruitment. Nevertheless, our multimodal data collection approach involving the use of photographs and interviews combined with dual perspectives of patients and HCPs meant that we had a rich dataset to generate an in-depth understanding of users' experiences of telehealth.

In this instance, we did not collect information about, or pose eligibility restrictions regarding participants' ethnic and racial background, socioeconomic status, and level of experience with telehealth. This decision was driven by the small number of palliative care participant population available to participate in the study. Future telehealth research may include

contextualisation of emergent findings through the lens of one or more of these socio-demographic characteristics.

Conclusion

This study explored patients' and HCPs' experiences of telehealth in a palliative care context. A total of 3 themes emerged: comfort (or lack thereof) afforded by telehealth, connection considerations in telehealth, and care quality impacts of telehealth. The findings presented in this article combined with other co-design activities, which are outside the scope of this paper, indicated the potential value of a telehealth enhancement add-on feature that generates patient-facing clinical consultation summaries. Our team has developed a video telehealth enhancement feature, which will enable clinicians to distill key actionable advice and self-management guidance discussed during teleconsultations in a take-home summary document for patients. The add-on prototype has been subjected to a preliminary simulation study which will be reported in a future publication.

Acknowledgments

We thank Ms Roxanne Kritharidis who conducted all of the interviews, cleaned transcripts, and prepared the data for analysis. We thank Dr Jennifer Bibb who obtained ethics approvals, supported data collection, and participated in data analysis and writing of the final co-design report on which this work is based. We thank Dr Elton Lobo who contributed to analysis discussions and started early paper drafts. Thank you to Dr Kate Robins-Browne who led data analysis and drafted first versions of this paper. We also thank Prof Victoria Palmer who designed the photo interviewing study as part of the co-design stage for the early parts of this project, oversaw data collection and analysis, and contributed to the early draft of the paper. This research is supported by the Digital Health Cooperative Research Centre Limited (DHCRC), Monash University, Healthdirect Australia, Monash Health, University of Melbourne, and Victorian Department of Health. DHCRC is funded under the Commonwealth Government Cooperative Research Centres (CRC) Program. Finally, we thank all the participants of this study who generously contributed their time towards this research.

Data Availability

The datasets generated during and analyzed during this study are not publicly available due to the sensitive nature of the data and vulnerable nature of the population.

Generative artificial intelligence was not used for any part of the study reported in this paper nor for manuscript development.

Abstract

Background: Irritable bowel syndrome (IBS) has a high worldwide prevalence and there are few effective treatment options. Patient education can influence patient behavior that subsequently may lead to changes in attitudes and skills necessary for maintenance or improvement in management of symptom severity and quality of life. However, as postdiagnostic patient education can be resource demanding, assessment of digital approaches and verification of their effectiveness is warranted.

Objective: This cohort study aimed to investigate the effects of a digital web-based multidisciplinary eHealth program on the domains of symptom severity (Irritable Bowel Syndrome Symptom Severity Scale [IBS-SSS]), quality of life (irritable bowel syndrome quality of life [IBS-QOL]), anxiety and depression (Hospital Anxiety and Depression Scale), and a measure of general client satisfaction (client satisfaction questionnaire), compared with an onsite multidisciplinary 2-day group-based education program ("IBS-school"), in 2 cohorts of 255 patients with IBS.

Methods: Patients diagnosed with IBS, aged 15-70 years, were enrolled after referral to the Section of Gastroenterology at Haukeland University Hospital, Norway. In total, 132 patients were recruited to the eHealth program and 123 to the IBS-school group for comparison. Data were self-reported and collected digitally at enrollment and after 3 months, between 2017 and 2019. Furthermore, 71 attending the eHealth program and 49 attending the IBS-school completed the questionnaires at 3 months. Intervention response was defined as a reduction of ≥50 points on the IBS-SSS.

Results: Patients attending the eHealth program reported a significant reduction in IBS symptom severity 3 months after treatment (n=71), compared with patients attending the IBS-school (n=50). Overall, patients categorized as intervention responders in both programs showed a significant reduction in symptom severity at 3 months. Here, 41% (29/71) of patients attending the eHealth program reported a mean IBS-SSS reduction of 103 (SD 72.0) points (P<.001). In addition, these patients reported reduced anxiety (P>.001) and depression (P=.002) and enhanced quality of life (P=.03), especially the degrees of dysphoria, body image, food avoidance, health worry, interference with activity, relations, and social relations. Patients responding to the IBS-school intervention (18/50, 36%) reported a mean IBS-SSS reduction of 119 (SD 86.2) points (P<.001), and reduced depression scores (P=.046), but no difference in overall quality of life. Both groups reported the respective interventions as "good" quality health care programs, scoring them 23.5 (SD 4)—the eHealth program 23.5 (SD 4), and the IBS-school 24.2 (SD 4)—on the client satisfaction questionnaire.

Conclusions: We conclude that the digital multidisciplinary eHealth program has a significant effect on IBS symptom severity in a portion of patients; it is useful as a tool in disease self-management and does not result in worse symptom scores than an onsite multidisciplinary 2-day group-based education program after 3 months. We believe these results indicate that a digital eHealth approach is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

Introduction

Irritable bowel syndrome (IBS) is a chronic disorder manifested by recurrent abdominal pain and alterations in stool form or frequency [1,2]. The condition affects between 4% and 9.2% of the global population [3-5] and it is highly heterogenous. IBS' unclear etiology involves multifactorial disturbances of the bidirectional communication between the gut and the brain, including visceral hypersensitivity, low-grade inflammatory responses, intestinal motility disturbances, alterations of central nervous system processing, and alterations in gut microbiota composition [6]. However, no clear biomarker or therapeutic target for IBS has been identified. The condition lacks both a cure and medication that gives sufficient symptom relief, a fact that highlights the necessity of integrating nonpharmacological approaches including patient education in patient care [7]. Patients with IBS require personalized treatment for successful symptom relief. Approaches may include physical therapy, cognitive behavioral therapy (CBT), hypnotherapy, mindfulness and exposure therapy, and comprehensive dietary guidance by registered dietitians such as the low FODMAP (fermentable oligosaccharides, disaccharides, monosaccharides, and polyols) diet. However, access to these treatment options is often limited due to lack of trained professionals, travel distances, and cost. Thus, more accessible treatment options are warranted. Web-based interventions, patient education, and self-management has been demonstrated to be effective in patients suffering from chronic diseases, including IBS [8-10]. A systematic review from 2017 concluded with mixed results regarding the effectiveness of web-based mindfulness-based interventions compared with active control treatment conditions such as CBT. However, the study showed that treatment targeting symptoms of IBS had the largest effect size improvements [11]. A longitudinal qualitative study from 2020 showed that both telephone-based CBT and web-based CBT for IBS were positively received and had lasting positive impacts on participants' understanding of IBS symptoms, quality of life, and IBS-related behaviors [12]. A recent Japanese randomized controlled trial has shown that a multidisciplinary eHealth self-management program can reduce the severity of IBS-symptoms and improved the quality of life [13].

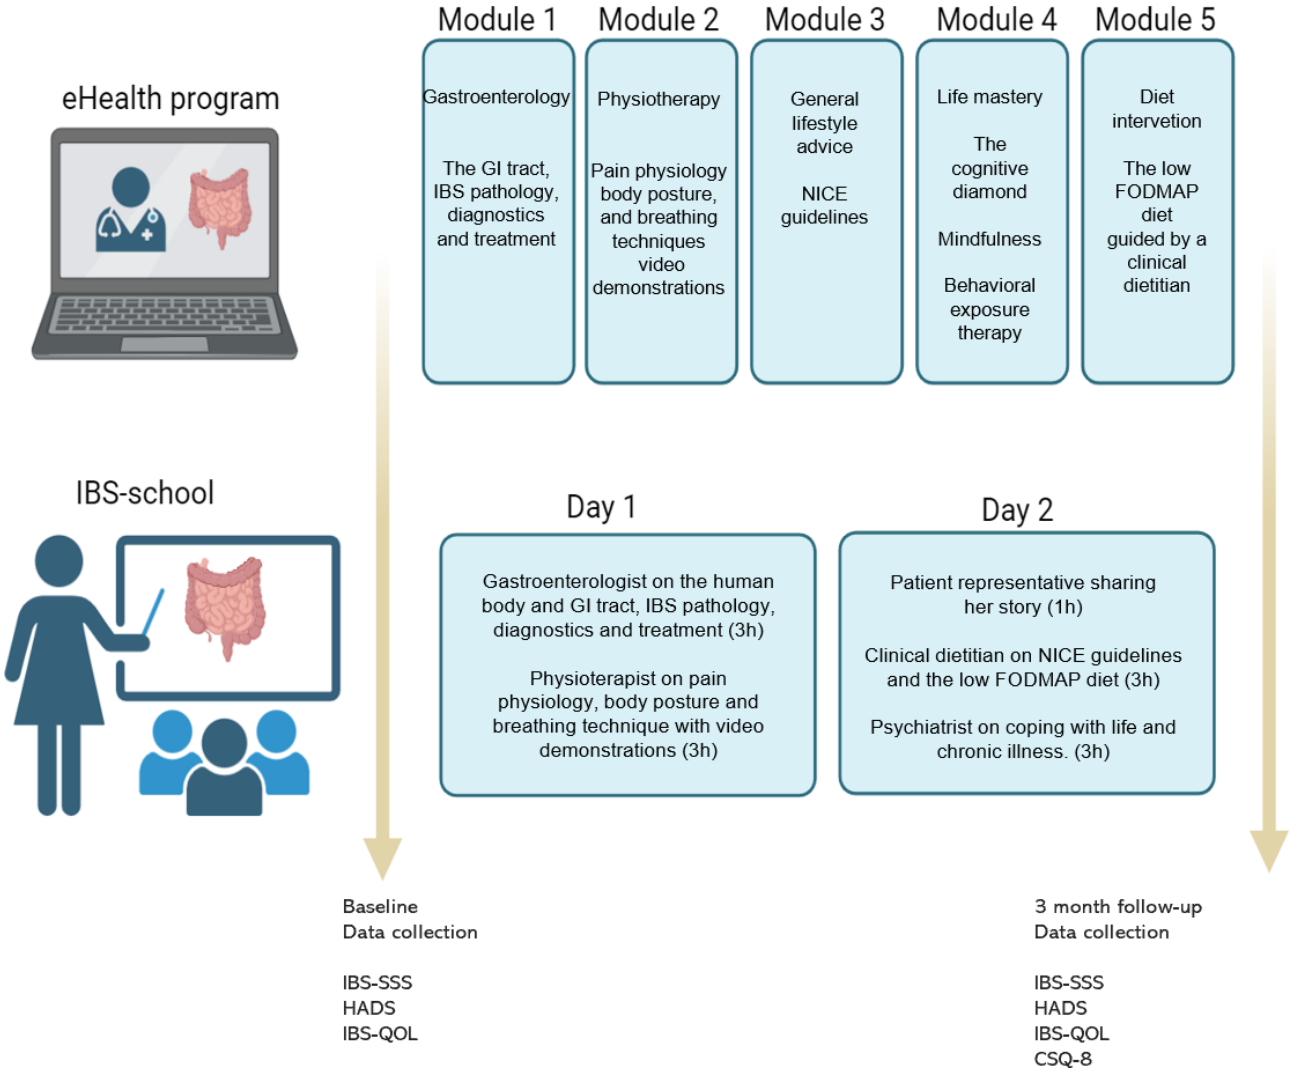
Indeed, limited health care resources, national priority guidelines, and sparse treatment options may restrict any long-term follow-up that patients with IBS may request from a secondary or tertiary care institution. Since 2012, Haukeland University Hospital has offered patients with IBS an onsite multidisciplinary 2-day group-based education program, a so-called "IBS-school." The multidisciplinary approach is designed to provide patients with evidence-based information and practical skills that may lead to improved IBS management, reduced IBS symptoms, and enhanced quality of life. Based on our clinical experience with group education, we have developed a novel internet-guided multidisciplinary self-care management program for patients with IBS, from now on referred to as the "eHealth program." The content in the eHealth program is based on topics covered in the IBS-school, but the patients also have access to digital clinical support during the program. Herein, we hypothesized that the eHealth program would have an equally good effect on symptom severity, quality of life, and patient satisfaction, compared with a cohort of patients attending IBS-school. Data from neither program have been published before. In this study, we aimed to investigate the effects of a digital web-based multidisciplinary eHealth program on the domains of symptom severity (Irritable Bowel Syndrome Symptom Severity Scale [IBS-SSS]), quality of life (irritable bowel syndrome quality of life [IBS-QOL]), anxiety and depression (Hospital Anxiety and Depression Scale [HADS]), and a measure of general client satisfaction (client satisfaction questionnaire [CSQ-8]), compared with an onsite multidisciplinary 2-day group-based education program, IBS-school, in 2 cohorts of 255 patients with IBS.

Methods

Patient Sample, Randomization, and Treatments

In this study**,** 255 patients between 15 and 70 years were recruited after being accepted for patient education at Haukeland University Hospital in Norway between 2017 and 2019. Random patients on the waiting list to the onsite multidisciplinary 2-day group-based education program, IBS-school, were contacted by phone by a study nurse and offered to attend the novel multidisciplinary digital 5-module eHealth program, from here on referred to as the "eHealth program." Patients attending the IBS-school were recruited on site when attending the 2-day group-based education program. Patients received oral and written information before giving written consent and sent it to the hospital by post. Furthermore, 123 patients that attended the IBS-school were used for comparison (N=255, 1:1). Here, patients were recruited by a study nurse on site. They received an oral and written information about the study before signing consent (Figure 1). Inclusion criteria included (1) being referred to receiving patient education on IBS by a gastroenterologist or general practitioner after the diagnosis of IBS had been determined (*International Classification of Primary Care, Second Editon* [*ICPC-2*] code D93; *International Statistical Classification of Diseases, Tenth Revision* [*ICD-10*] code K58), (2) being between 18 and 70 years, and (3) understanding written and oral Norwegian. There were no specific exclusion criteria.

Figure 1. Intervention overview. CSQ-8: client satisfaction questionnaire; FODMAP: fermentable oligosaccharides, disaccharides, monosaccharides, and polyols; GI: gastrointestinal; HADS: Hospital Anxiety and Depression Scale; IBS: irritable bowel syndrome; IBS-QOL: irritable bowel syndrome quality of life; IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale; NICE: National Institute for Health and Care Excellence.



Ethical Considerations

Eligible patients gave informed written consent and participants were given the option to withdraw from the study at any time point without a specific reason. The data were deidentified and stored on a secure hospital server, and analysis was performed on anonymous data. None of the participants were compensated. The study was approved by the Regional Ethical Committee of Western Norway (REC-2016/1098).

Interventions

The Irritable Bowel Syndrome–School

Patients attended an onsite multidisciplinary 2-day group-based education program, IBS-school, at Haukeland University Hospital. The number of participants varied between 15 and 40 each month. The program involved lectures and question and answer sessions by 4 health care professionals. Refer to Figure 1 for the intervention outline. On day 1, a gastroenterologist talked about the human body and the gastrointestinal system, what IBS is, what causes it, diagnostics, and treatment options (3 hours). Second, a physiotherapist was giving a lecture on body posture and breathing techniques including demonstrations, introducing pain physiology, and the function of the human nervous system (3 hours). On day 2, a patient representative shared her personal experience with IBS (1 hour), and a clinical dietitian gave a lecture on National Institute for Health and Care Excellence (NICE) guidelines [14] that summarizes the most recent recommendations on IBS in adults in primary care, and the low FODMAP diet [15] (3 hours). Finally, a psychiatrist gave a lecture on coping with life including health worry, social relations, tiring thoughts and feelings, adaptations, and symptoms. A nurse with specialization in gastroenterology hosted the group education program to create a comfortable environment for exchange of personal experiences and participate in group assignments.

The eHealth Program

Patients who were enrolled in the digital eHealth program had access to a comprehensive, multidisciplinary web-based program that consisted of 5 modules (refer to Figure 1 for the outline). The modules consisted of instructive texts, videos, animations, and images over 150 web-pages on a digital treatment platform by CheckWare AS [16]. In addition, patients carried out “home assignments” based on principles of CBT, a protocol by Ljótsson et al [17] at the Swedish Karolinska Institute, followed by an

optional low FODMAP diet intervention guided by a clinical dietitian. The eHealth program allowed a secure login (eg, bank-ID) and digital communication between patient and a clinical dietitian throughout the process, at the patient's own request and need. The patients were expected to finish the program over a period of 3 - 12 weeks, at his or her own pace, all dependent on their motivation and work capacity. Module contents have been described further in this study. Module 1 describes the body and the gastrointestinal system. In this first module, the patient gets an introduction to what IBS is, how it is diagnosed, and what causes it. The patient learns about the function of our digestive system and how it is regulated, and how it can be disturbed in people with IBS. Module 2 describes the posture and breathing techniques. This module focuses on the connection between IBS and musculoskeletal disorders. Many people with IBS may have a "hyperactive" nervous system that can cause pain and physical maladjustments. In this module, a physiotherapist introduces the patient to pain physiology and how the nervous system works. There is a practical section with useful exercises for people with IBS. The module will give the patient an understanding of how long-term pain occurs, why it often persists, and how to influence it. Module 3 consists of diet and lifestyle advices. There is no miracle cure for IBS, but many people experience improvement by following some general advice. In this module, we look at lifestyle advice that has been shown by research to improve symptoms in people with IBS. It is recommended to try this before eliminating other foods or following strict diets. Module 4 focuses on coping with life. In this module, the patient learns techniques from cognitive therapy including "the cognitive diamond," mindfulness, and practice systematic exposure exercises has previously shown beneficial effects for patients with IBS. The protocol has been described in a study by Ljótsson et al [17]. Module 5 describes the dietary intervention with a low FODMAP diet. This is a dietary treatment that provides symptom relief in approximately 70% of patients with IBS [18]. In this module, the patient will be introduced to the low FODMAP diet in both theory and practice. The patient had access to digital guidance by a clinical dietitian during the entire course of the study.

Questionnaires

Overview

Patients completed questionnaires related to IBS symptom severity (IBS-SSS) [2], quality of life, (IBS-QOL) [19], and anxiety and depression (HADS) [20] upon enrollment at baseline and after 3 months.

The IBS-SSS is considered the gold standard measure of IBS symptoms and contains 5 questions that measure the frequency of abdominal pain, the severity of abdominal distention, dissatisfaction with bowel habits, and interference with quality of life, scored in the range of 0 - 500. A higher score indicating worse condition, scores <175 represent mild IBS symptoms, 175 - 300 represents moderate severity, scores >300 represent severe IBS [2].

The IBS-QOL is a condition-specific measure for assessing health-related quality of life in IBS. It consists of 34 items, each with a 5-point response scale in a range of 0 - 100, where the higher score indicates a better IBS specific quality of life. There are 8 subscale scores for the IBS-QOL: dysphoria, interference with activity, body image, health worry, food avoidance, social reaction, sexual, and relationships [21].

HADS is a scale of 14 items designed to measure anxiety and depression, 7 items for each subscale (ie, anxiety and depression). The total score is the sum of the 14 items, and for each subscale the score is the sum of the respective 7 items that range from 0 to 21 [20].

CSQ-8 [22] was completed at 3 months. The questionnaire is an 8-item measure with a total score ranging from 8 to 32, with the higher number indicating greater satisfaction with treatment.

Primary Outcome Measure and Definition of Intervention Responders

In the field of IBS research, a change of 50 points in IBS-SSS score has shown to reliably indicate improvement in IBS symptom severity [2]. Our primary outcome measure was a >50-point reduction in IBS-SSS at 3 months, compared with baseline. Patients reporting a ≥50-point reduction in IBS-SSS at 3 months were categorized as "responders" to the intervention. Patients reporting <50-points on IBS-SSS were categorized as "nonresponders" to the intervention.

Statistical Analysis

Statistical analyses were performed using SPSS Statistics (version 26, IBM) for Microsoft Windows. Baseline patient characteristics and questionnaires were first presented according to intervention—eHealth group and IBS-school. At 3 months after intervention, patients were categorized as responders or nonresponders. For comparison between groups, unpaired *t* test were performed for parametric data and Mann-Whitney *U* for nonparametric data. For comparisons before and after interventions, paired *t* tests were performed for parametric data and Wilcoxon signed rank test for nonparametric data. A *P* value <.05 was considered statistically significant. The intervention responder or nonresponder analysis to the eHealth program or IBS-school was carried out performing a paired *t* test on data from patients who filled out the 3-month questionnaires (n=71 and n=50, respectively). A χ^2 test of independence was used to assess differences between intervention response.

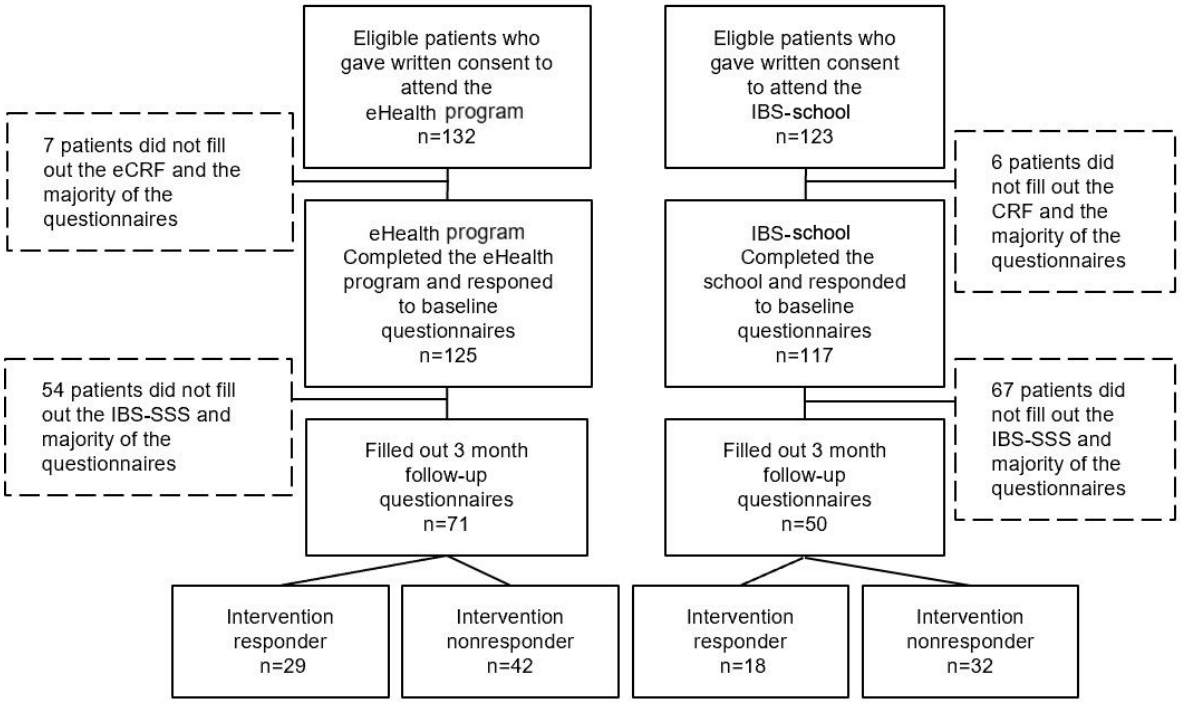
Results

Patients and Characteristics

A flowchart of participating patients is illustrated in Figure 2. Of the 132 eligible patients who gave written consent to participate in the eHealth program group of the study, 7 did not fill out the minimum requirement including the electronic case report form and the IBS-SSS questionnaire. Of the 125 patients who completed the program, 54 patients did not respond to the IBS-SSS questionnaire at 3 months. Hence, the follow-up data from patients attending the eHealth program reduced to n=71 at 3 months. Of the 123 eligible patients who gave written consent to participate in the IBS-school group of the study, 5 did not fill out the minimum requirement including the electronic case report form and the IBS-SSS questionnaire. Thus, of the 118 patients who completed the program, 69 patients did not

respond to the IBS-SSS questionnaire at 3 months. Hence, the follow-up data from patients attending the eHealth program reduced to n=49 at 3 months.

Figure 2. Flow chart of participating patients with IBS. Patients reporting a ≥50-point reduction in the IBS-SSS at 3 months were categorized as "responders to the intervention". Patients reporting <50-points on the IBS-SSS were categorized as "nonresponders to the intervention". CRF: case report form; eCRF: electronic case report form; IBS: irritable bowel syndrome; IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.



Participants were predominantly female (190/235, 81%) with a mean age of 38.3 (SD 12.4) years (Characteristics are summarized in Table 1). An unpaired *t* test showed that there was no difference in age between groups. A Mann-Whitney *U* test was performed to evaluate whether sex differed between groups, reveling no significant difference between patients attending the eHealth program and patients attending the IBS-school (Table S1 in Multimedia Appendix 1, U=6407.0, z=−1.394, P=.16). Furthermore, participants at the IBS-school and eHealth program displayed similar baseline characteristics upon enrollment, including moderate to severe IBS symptom severity.

There was no significant difference between most relevant features at baseline, except for anxiety and depression, as shown in Table 1. Here, patients attending the eHealth program scored an average of 11 (SD 5.2) which corresponds to mild to moderate anxiety, while patients attending the IBS-school scored 9.4 (SD 5.1), corresponding to a mild level of anxiety (2-tailed t_{232}=2.37, P=.02). Thus, both patient groups displayed an anxiety score typical of a clinical case of anxiety (HADS-anxiety ≥8 is considered a clinical case [20]), and patients attending the eHealth program presented a significantly higher baseline score than patients attending the IBS-school. Furthermore, patients attending the eHealth program reported significantly higher depression scores than patients attending the IBS-school (mean 7, SD 4.1 vs mean 5.9, SD 4, respectively; t_{232}=2.01, P=.045). However, both groups displayed an average depression score corresponding to nonclinical severity of depression (HADS-depression ≤8 is considered noncase [20]) which gives the difference little relevance on group level.

Table . Baseline patient characteristics and questionnaire data of 242 patients with irritable bowel syndrome (IBS) at enrollment to the eHealth program or IBS-school interventions. Unpaired *t* test unless otherwise stated; the reduced number from total number of participants indicate missing data.

	eHealth program		IBS-school		Significance

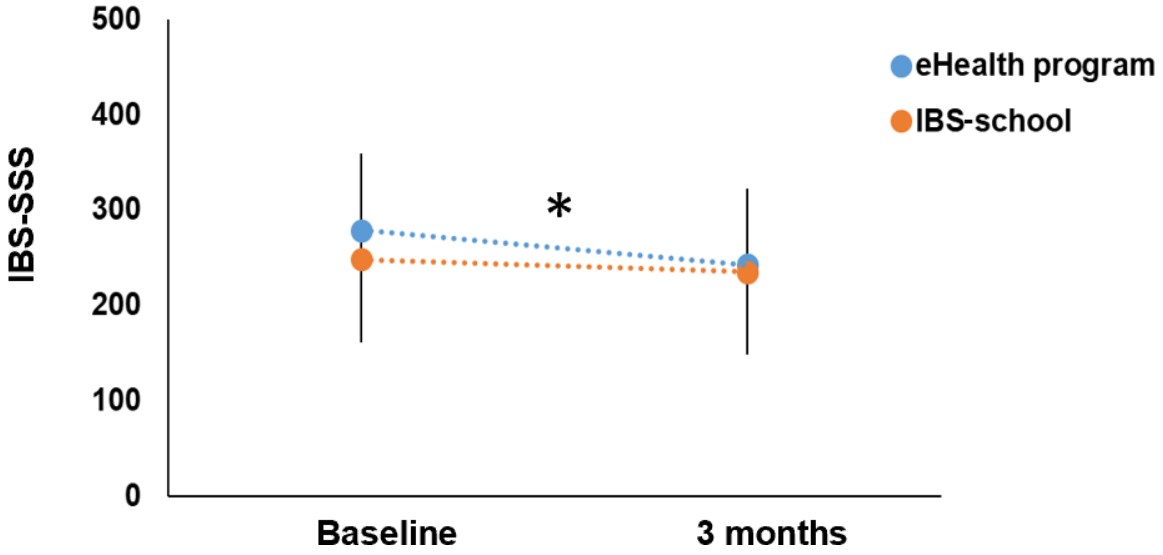
Symptom Relief and Enhanced Quality of Life

Overview

A paired *t* test revealed that patients attending the eHealth program reported a significant reduction in IBS symptom severity at 3 months, shown in Figure 3 (mean 279.3, SD 80 vs mean 242.7, SD 79.3; t_{70}=4.91, *P*<.001). Comparably, patients attending the IBS-school did not report a significant reduction in symptom severity (mean 248.6, SD 86.6 vs mean 235.4, SD 98.9; t_{49}=0.85, *P*=.40). Refer to Table S2 of Multimedia Appendix 1 for data. However, none of the groups achieved a clinically meaningful improvement of ≥50 points on IBS-SSS at 3 months. Patients in the eHealth program-group reported a 37-point reduction, whereas patients attending IBS-school reported a 13-point reduction in IBS-SSS total score (Table S2 of Multimedia Appendix 1). Thus, for further analysis we categorized participants as a “responder” or “non-responder” to the intervention, where the sample response threshold for responders was set as ≥50-point decrease in total IBS-SSS score, a threshold that has been demonstrated to correlate with improvements in clinical symptoms [2].

Figure 3. Overall change in IBS-SSS over time. On average, patients who completed the 3-month questionnaires at the IBS-school reported a 13 point reduction in IBS-SSS (n= 50), whereas eHealth program participants reported a 37-point reduction (n=71). A decrease of 50 points is defined as a clinical response to the intervention, categorizing the patient as a "responder to the intervention." The IBS-SSS eHealth program score at baseline was 279 (SD 80) and 243 (SD 79) at 3 months, *P*<.001; the IBS-SSS IBS-school score at baseline was 248 (SD 87) and 235 (SD 99) at 3 months (*P*=.40). Paired *t* test results are summarized in Table S2 in Multimedia Appendix 1. **P*<.001, indicating a significant difference in IBS-SSS scores before and after eHealth program intervention. Blue dot represents the eHealth program; orange dot represents the IBS-school. Paired *t* test was performed. Error bars present SD. Lower n indicate missing data. The reduced number from the total number of participants indicate missing data. IBS: irritable bowel syndrome. IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.



Responders

Of the 71 patients, 29 (41%) attending the eHealth program responded to the intervention with a reduction in IBS-SSS score of ≥50 points, compared with 36% (18/50) who attended the IBS-school after 3 months (Figure 3). The results in this section are summarized in Tables 2 and 3. Patients categorized as responders to the eHealth program reported a significant mean reduction in IBS-SSS score of 103 (SD 72.0) points with a moderate effect size of 0.56 (t_{28}=7.62, Cohen *d*=1.33, *P*<.001). In addition, eHealth program–responding patients reported a significant reduction in anxiety, changing from a clinical case to a noncase classification (mean −4.7, SD 6.2; t_{28}=6.89, Cohen *d*=0.85, *P*<.001). Here, the effect size of 0.39 indicated a moderate effect. On average, these patients also reported an increase in overall quality of life, summarized in Tables 2 and 3 (mean 5.80, SD 19.1; t_{28}=−2.28, Cohen *d*=−0.30, *P*=.03). Here, features such as dysphoria (mean 18, SD 23.3; t_{28}=−2.1, Cohen *d*=−0.85, *P*<.001) and body image (mean 14.8, SD 18.6; t_{28}=−3.9, Cohen *d*=−0.72, *P*<.001) increased significantly with a moderate effect size. Features such as food avoidance (mean 6.3, SD 22.5; t_{28}=−2.10, Cohen *d*=−0.13, *P*=.045), health worry (mean 10.8, SD 23.5; t_{28}=−3.44, Cohen *d*=−0.43, *P*=.002), interference with activity (mean 13.4, SD 18.8; t_{28}=−4.03, Cohen *d*=−0.63, *P*<.001), relations (mean 9.5, SD 22.9; t_{28}=−2.72, Cohen *d*=−0.37, *P*=.01), and social relations (mean 10.7, SD 19.4; t_{28}=−3.62, Cohen *d*=−0.56, *P*=.001), all improved significantly, compared with baseline. The changes in sexual activity were not significantly different after 3 months (mean 5.4, SD 29.8; t_{28}=−1.52, Cohen *d*=−0.19, *P*=.14).

Table . Changes in symptom severity, anxiety and depression, and quality of life 3 months after the eHealth program in patients with irritable bowel syndrome (IBS) who attended the eHealth program. [a]IBS-SSS: Irritable Bowel Syndrome Symptom Severity Scale.

[b]Significant at the $P<.05$ level.

[c]HADS-A: Hospital Anxiety and Depression Scale – Anxiety.

[d]HADS-D: Hospital Anxiety and Depression Scale – Depression.

[e]IBS-QOL: irritable bowel syndrome quality of life.

Patients who responded to the IBS-school intervention reported an average reduction in IBS symptom severity score of 119 (SD 86.2) points (n=18; t_{17}=5.54), Cohen d=1.33, P<.001). In addition, patients reported a reduction in depression scores (mean −2.3, SD 4.4; t_{15}=2.17, Cohen d, P=.046). However, these patients did not report significant improvements in anxiety or overall quality of life (mean 2.5, SD 6.8; t_{15}=1.97, Cohen d=0.43, P=.07 and mean 2.4, SD 27.9; t_7=−0.57, Cohen d=−0.08, P=.64, respectively). Furthermore, the number of responding patients were too low for further in-depth statistical analysis of quality of life (n=8). Data for these analyses are presented in Table S3 of Multimedia Appendix 1.

Nonresponders

Patients who were nonresponders to the eHealth program reported no improvement in symptom severity or quality of life (mean 9.2, SD 70.4; t_{41}=−1.73, Cohen d=−0.13, P=.09) and a significant decrease in anxiety scores (mean −2.4, SD 4.8, t_{38}=3.65, Cohen d=0.52, P=.001), compared with baseline. However, both changes were of small effect (r=−0.27 and 0.25, respectively). Results are summarized in Tables 2 and 3. There were no significant changes in depression scores or overall quality of life or the respective sub-categories (P>.05). Nonresponding patients attending IBS-school reported significantly enhanced symptom scores (mean 46.5, SD 77.8; t_{31}=−4.08, Cohen d=−0.57, P<.001). However, it is worth noting that these enhanced symptoms scores were not above the 50-point threshold for clinical relevance. Furthermore, these

patients reported a significantly reduced overall quality of life (mean −11.4, SD 23.8; t_{23}=3.16, Cohen *d*=5.52, *P*=.004) and a significant increase in the domain of relationships (mean 18.7, SD 17; t_{23}=−2.11, Cohen *d*=−0.86, *P*=.046). Baseline characteristics for these analyses are presented in Table S3 of Multimedia Appendix 1.

Association Between Type of Intervention and Outcome

A χ^2 test of independence analysis was used to test whether the type of intervention was independent from the intervention outcome. Results showed that the proportion of patients who responded to the intervention in both groups (29/71 vs 18/50) were the same. Hence, there was no significant association between the type of intervention and response to the intervention (Pearson χ^2_1=0.2, Φ=0.041, *P*=.65). Thus, we conclude that there is no difference in treatment response between the eHealth program and IBS-school in affecting symptom severity scores. Data from this analysis is reported in Table S4 of Multimedia Appendix 1.

Patient Satisfaction

Patient satisfaction was investigated in both groups 3 months after enrollment (CSQ-8). Patients who attended the IBS-school reported a mean score of 24.2 (SD 3.7), compared with patients attending the eHealth program with a mean score of 23.5 (SD 4.0), which are both equivalent to "good" health care offers [22]. An unpaired *t* test revealed no significant difference between group scores (t_{115}=−1.032, *P*=.31; Table 4).

Table . Difference in client satisfaction scores (CSQ-8) between patients attending the eHealth program and irritable bowel syndrome (IBS)–school. A χ^2 test of independence was conducted. The reduced number from the total number of participants indicate missing data.

		n	mean (SD)	*t* test (*df*)	Cohen *d*	Effect size r	*P* value
Overall				−1.032 (115)	−0.193	−0.01	.31
	eHealth program	68	23.46 (4.0)				
	IBS-school	49	24.20 (3.67)				

Discussion

Principal Findings

In this study, we have shown that the novel digital multidisciplinary eHealth program has a significant reducing effect on IBS symptom severity and is useful as a tool in disease self-management. In total, 41% (29/71) of participants reported significant and clinically relevant symptom relief. Furthermore, we show that the eHealth program is safe, as patients not responding to the intervention reported unchanged symptoms and quality of life at 3 months. In addition, eHealth intervention–responding patients reported significant benefits on multiple domains of IBS-related quality of life such as body image, food avoidance, health worry, interference with activity, relations, and social relations. Levels of anxiety were significantly reduced, and levels of dysphoria were improved.

Comparably, 36% (18/50) of participants reported a clinically significant effect to the onsite multidisciplinary 2-day group-based education program, the so-called "IBS-school." Thus, our results indicate that the digital multidisciplinary eHealth program may be equally effective to the IBS-school, which is often a standard treatment offer to newly diagnosed patients. Furthermore, patients responding to the IBS-school intervention did not report any significant improvements in quality of life or in anxiety, but a small not clinically meaningful decrease in depression scores. The number of IBS-school responders were too low for more in-depth statistical analysis on the domains of quality of life.

A χ^2 test of independence showed no difference between intervention outcome in the 2 groups; hence the eHealth program did not have a better intervention response than the IBS-school on the measures of symptom severity. However, the eHealth program had a significant effect on other aspects of IBS symptomatology, including anxiety and quality of life, whereas IBS-school did not.

Patients rated both the eHealth program and the IBS-school as good health care offers on measures of patient satisfaction of health care quality, scoring them 23.5 and 24.2 out of a maximum of 32 points, respectively.

We believe these results indicate that a digital eHealth approach, designed to provide patients with evidence-based information and practical skills, is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

Comparison With Previous Work

Initially at baseline in both groups, the greatest impairment in quality of life was observed for the subscale of food avoidance followed by body image, inactivity, and dysphoria. This order of impairment is similar to findings by Drossmann et al [21] in an international study from 2009 (n=1966). However, our findings show lower scores on all subscales except dysphoria and health worries, which are in the same magnitude. In comparison with a newer study on quality of life by Kopczyńska et al [23] (n=87), our baseline results show much lower scores on both overall and all subscales of quality of life. A recent Vietnamese study showed that patient education, lifestyle, and dietary intervention, administered by clinical pharmacists, improved IBS related quality of life compared with standard medical therapy over 8 weeks [10]. These study patients also showed a much higher baseline and postintervention quality of life-scores compared with our study. We speculate that our study participants represent a group with more severe IBS because they are referred to a tertiary health care institution that due to capacity issues has to prioritize those patients who need it the most. However, the low baseline scores on food avoidance in our study indicate that both our interventions with a key focus on diet was the right call. This core problem was targeted

because food is a known important trigger of IBS-symptoms [24]. On the domain of food avoidance, we observed an improvement in eHealth program-responders, compared with baseline (Tables 2 and 3). No such improvement was observed in patients attending the IBS-school. We speculate that this is due to the differences in comprehensiveness and durability. The eHealth program is designed to engage the patient interactively to learn how to make appropriate changes in diet. It offers a thorough guidance with videos and instructions on how to follow the low FODMAP diet, including the exclusion and reintroduction of foods. In addition, the patient has the option of digital question and answer sessions with a clinical dietitian throughout the program. The IBS-school is also designed for patients to learn how to self-help, but the program is much shorter with its 2 days of physical attendance. In the light of these results, we deduce that the eHealth program is not inferior to the established IBS-school as a health care offer. In fact, we show that an eHealth intervention program can provide the patient with self-help tools that can lead to reduced gastrointestinal symptoms and enhance quality of life for patients with IBS. This aligns with a recent randomized controlled study by Tayama et al [13] (n=40) showing that a multidisciplinary eHealth self-management program leads to an increased intake of FODMAP-groups and subsequently a more extensive diet. Severe food avoidance and dietary restriction is previously reported in 13% (829/955) of IBS-patients and this subgroup of IBS-patients reported more severe IBS-symptoms, reduced quality of life, and reduced intake of nutrients [24]. Thus, providing patients with evidence-based information, practical tools, and support by a clinical dietitian is important in clinical care of patients with IBS.

eHealth programs in the form of apps, internet-guided programs, or telehealth has recently accelerated as useful tools in clinical medicine. In an American study on satisfaction during COVID-19, most patients with IBS reported high satisfaction rates and ease of use with telehealth [25]. Here the authors reported on multiple benefits including the patient having to take less time off from work and improved access to the care team. Their most commonly reported challenges with telehealth included feeling impersonal and being unable to address all of their issues or concerns. A majority felt that telehealth was as good as or better than face-to-face visits and would use telehealth for future care. Only approximately 10% (130/1311) of the patients remained dissatisfied. In 2020, a Polish study showed that an educational program combined with elements of behavioral therapy, individualized for patients with IBS, is an important part of therapy [26]. In addition, as a part of a dietetic-led gastroenterology service in primary care, feasibility, acceptability, and cost-efficiency of using webinars to deliver first-line patient education for patients with IBS, has been shown to be successful [27]. A meta-analysis of chronic gastrointestinal illness interventions (19 studies conducted in 8 countries, n=3193) showed that eHealth gastrointestinal interventions improved patients' quality of life, psychological distress, medication adherence, and illness-related knowledge [28]. The meta-analysis also showed that eHealth gastrointestinal interventions significantly reduced the number of patient visits to the hospital. Taken together with our results, these findings support eHealth interventions holding decent promise in improving outcomes for patients with IBS.

Comparably on patient satisfaction, a randomized controlled trial by Lackner et al [29] showed that patients who received 4 gastroenterologist-led patient education sessions over 2 weeks reported 26.6 in patient satisfaction. Here, 43.5% (63/145) of patients reported improvement in addition to a higher satisfaction score than in our study. However, both these and our results reflect that subjective symptom relief may not be required for the patient to experience the treatment as useful. This is also highlighted by our patients attending the IBS-school who did not experience significant enhancement in quality of life nor reduction in symptom severity, but still reported a higher satisfaction than patients who objectively benefited more from the eHealth program.

Limitations

All 255 recruited patients completed the programs. However, there was a very high percentage that did not submit the 3-month questionnaires. In total, 41% (54/132) percent of patients attending the eHealth program, and 54% (67/123) of the patients who attended the IBS-school did not submit the 3-month follow-up questionnaires on IBS symptoms severity (Figure 1). Unfortunately, this occurred despite multiple efforts and reminders (phone calls, emails, and SMS text messages) from the research team encouraging the participants to respond. First, this high percentage of missing data are significant and may have affected the results of the study even though the rates appear similar across the groups. However, high dropout rates are a common issue in eHealth studies and known as "the law of attrition" [30]. This warrants the need for a larger study where an intention-to-treat analysis can be carried out without diminishing the power of the study. Second, eHealth literacy is defined by Norman and Skinner [31] as "the ability to seek, find, understand, and appraise health information from electronic sources and apply the knowledge gained to addressing or solving a health problem". The individual patient's level of health literacy was not mapped during the study and variations in these abilities may have affected our results. Third, the patient population represents all subtypes of IBS and there are no analyses focusing on the differences in response between patients with predominant diarrhea, constipation, or a mix of the 2. Comorbidities or other additional diagnoses are common in IBS [32] but have not been excluded in this study and may have affected the results. Fourth, the use of drugs during the study period have not been reported. Hence, many drugs have side effects such as nausea, vomiting, diarrhea, constipation, flatulence, which are symptoms that the patient may confused with IBS symptoms. Fifth, a high placebo effect, which can be up to 40%, is a known challenge in clinical studies on IBS [20]. Although this study has not been designed with a control group, the placebo effect may have affected our results in either group and have not been adjusted for. However, we may speculate that the phenomenon has affected patients in both groups equally and importantly, the placebo effect may recede after 12 weeks, which was our end point [33]. Sixth, as both programs are broad and cover a variety of information, advice, and treatment including the low FODMAP diet and principles of CBT, another limitation of this study is the unknown specifics patients were

responding to in either program. Indeed, there are no measures on cognition verifying the direct effects of the principles of CBT or exposure therapy. This needs to be further investigated in a prospective study, and we acknowledge that an in-depth explanation for our observed benefits after attending the eHealth program remain to be clarified. Thus, these aspects are objectives in our currently ongoing randomized controlled trial [34]. In the light of limited primary and secondary health care resources, it will be useful to develop prediction tools to identify which patients may achieve improvement in both symptom severity and domains of quality of life. For these stratification analyses to be clinically meaningful, the number of participants need to be higher than reported in this study and performed in and randomized controlled trial.

Conclusions

We conclude that the digital multidisciplinary eHealth program has a significant effect on IBS symptom severity in a portion of patients, and is useful as a tool in disease self-management. In addition, it does not result in worse symptom scores than an onsite multidisciplinary 2-day group-based education program after 3 months. We believe these results indicate that a digital eHealth approach, that include benefits such as 3 months unlimited access to quality assured information and treatment with documented effect, is preferable to an onsite multidisciplinary 2-day group-based education program covering the same topics.

Acknowledgments

The authors wish to thank all patients who participated at the irritable bowel syndrom (IBS)–school and the eHealth program. In addition, we wish to thank Haukeland University Hospital's “Learning and Mastering Center” and their wonderful employees, the patient educators psychiatrist Tor Jacob Moe, physiotherapist Eirik Østhammer, psychosomatic psychiatrist Jørn Bødtker, patient representative Cecilie Ågotnes, IBS-school host nurse Per Førde Refsnes, clinical dietitians Cecilie Larsen and CT, CheckWare AS, and eHealth program developer Jan Gunnar Hesthammer, Section for eHealth, Haukeland University Hospital. We also wish to thank the Department of Medicine and Section for Gastroenterology at Haukeland University Hospital, Tine Nordgreen and Research Centre for Digital Mental Health Services, Centre for Research-Based Innovation, Haukeland University Hospital, and Bjrann Ljottson, Karolinska Institutet, and Pelle Lindfors, Sahlgrenska, Sweden. This work was supported by Helse Vest under grants HV1148 and R-10923.

Abstract

Background: Bangladesh and West Bengal, India, are 2 densely populated South Asian neighboring regions with many socioeconomic and cultural similarities. In dealing with breast cancer (BC)–related issues, statistics show that people from these regions are having similar problems and fates. According to the Global Cancer Statistics 2020 and 2012 reports, for BC (particularly female BC), the age-standardized incidence rate is approximately 22 to 25 per 100,000 people, and the age-standardized mortality rate is approximately 11 to 13 per 100,000 for these areas. In Bangladesh, approximately 90% of patients are at stages III or IV, compared with 60% in India. For the broader South Asian population, this figure is 16%, while it is 11% in the United States and the United Kingdom. These statistics highlight the need for an urgent investigation into the reasons behind these regions' late diagnoses and treatment.

Objective: Early detection is essential for managing BC and reducing its impact on individuals. However, raising awareness in diverse societies is challenging due to differing cultural norms and socioeconomic conditions. We aimed to interview residents to identify barriers to BC awareness in specific regions.

Methods: We conducted semistructured interviews with 17 participants from West Bengal and Bangladesh through Zoom (Zoom Video Communications). These were later transcribed and translated into English for qualitative data analysis. All our participants were older than 18 years, primarily identified as female, and most were married.

Results: We have identified 20 significant barriers to effective BC care across 5 levels—individual, family, local society, health care system, and country or region. Key obstacles include neglect of early symptoms, reluctance to communicate, societal stigma, financial fears, uncertainty about treatment costs, inadequate mental health support, and lack of comprehensive health insurance. To address these issues, we recommend context-specific solutions such as integrating BC education into middle and high-school curricula, providing updates through media channels like talk shows and podcasts, promoting family health budgeting, enhancing communication at cultural events and religious gatherings, offering installment payment plans from health care providers, encouraging regular self-examination, and organizing statewide awareness campaigns. In addition, social media can be a powerful tool for raising mass awareness while respecting cultural and socioeconomic norms.

Conclusions: Fighting BC or any fatal disease is challenging and requires support from various dimensions. However, studies show that raising mass awareness is crucial for the early detection of BC. By adopting a sensitive and well-informed approach, we aim to improve the early detection of BC and help reduce its impact on South Asian communities.

Introduction

According to the GLOBOCAN (Global Cancer Observatory) 2020 report on the estimates of cancer incidence and mortality among the people of 185 countries (produced by the International Agency for Research on Cancer), female breast cancer (BC) has been identified as the most commonly diagnosed cancer (11.7%) and is the fifth leading cause of cancer mortality worldwide [1]. The same report suggests that among women, BC accounts for 1 in 4 cancer cases and for 1 in 6 cancer deaths, ranking first for incidence in most of the countries (159 of 185 countries). Through numerous studies, researchers found that early detection can significantly reduce fatal outcomes, and awareness is one of the keys to early detection [2]. Spreading awareness is a challenge for different societies for various reasons, and researchers have been working on identifying those for a long time. In this work, we assess the barriers to mass awareness (and thus far early detection) of BC among people in 2 very densely populated but culturally similar and geographically neighboring areas—Bangladesh and West Bengal, India.

Bangladesh (area: 57,321 square miles) and West Bengal, India (area: 34,267 square miles) are 2 territories in South Asia. Bangladesh's official language is Bengali, and the mass people primarily use the Bengali language for daily conversation. In total, 8% (91,276,115/1,210,569,573) of the Indian population speaks Bengali and mainly resides east of the country, with a concentration in West Bengal [3]. The population density of Bangladesh is 1328.68 people per sq km (collected from the web), and in West Bengal, India is 1028 people per sq km (according to their 2021 census). The deep sociocultural linkages between the Bengali linguistic community in eastern India and Bangladesh remain stable even after India's partition and independence in 1947. The unemployment rate in Bangladesh is 5.23%, and in West Bengal, it is 5.2% (as of June 2022). A total of 70.54% (64,385,546/91,276,115) of people from West Bengal follow Hinduism, and 27.01% (24,654,825/91,276,115) follow Islam. In Bangladesh, 91.04% (150,360,405/169,828,921) are Muslims, and 7.95% (13,130,109/169,828,921) are Hindus. The life expectancy in West Bengal, India, is 71.2 years [4], and in Bangladesh, it is 73.57 years [5]. The approximate sex ratio (as of 2022) in Bangladesh is 102.12 males per 100 females, whereas in West Bengal, it is 105 males for every 100 females. The average literacy in Bangladesh is 74.91% [6], and in West Bengal is 76.26% [6]. The commonality in the history and sociocultural environment of eastern India and Bangladesh has created a pseudo-homogeneous society where language is one of the fundamental elements in this connectivity. Hence, our work focuses on understanding attitudes, perceptions, and behaviors around BC-related issues in these 2 densely populated areas.

Unfortunately, there are no available sources of comprehensive epidemiological, pathological, and outcomes data for patients with BC [7,8] for the chosen regions; so, we are using the closest information from the GLOBOCAN 2020 report [1] to estimate the incidence and mortality rate of BC in this part of the world (Table 1). The factors contributing to the rising incidence and mortality of BC in low-income countries such as Bangladesh and West Bengal, India, are multifaceted. It is important to acknowledge that the solutions required for addressing these challenges differ significantly from those implemented in high-income countries [9]. Therefore, adopting models or policies directly from high- or middle-income countries, which have demonstrated success in tackling BC, may not be applicable in this context.

Table 1. Age-standardized incidence rate and age-standardized mortality rate of breast cancer in India and Bangladesh (GLOBOCAN 2020 report) and some relevant sources like the World Health Organization.

Scope	Age-standardized incidence rate in 100,000	Age-standardized mortality rate in 100,000
World	47.8 [1]	13.6 [1]
South Central Asia (Bangladesh and India are geographically part of the area)	26.2 [1]	13.1 [1]
West Bengal, India	25.2 [8]	13.62 [10]
Bangladesh	21.4 [8]	10.69 [11]

Despite being classified as least developed countries, Bangladesh and West Bengal, India, are home to several highly equipped and specialized cancer hospitals, some for BC only; for example, the National Institute of Cancer Research and Hospital (Dhaka, Bangladesh) or Tata Medical Center (Kolkata, West Bengal, India). These institutions, staffed with highly skilled and experienced surgeons, oncologists, and gynecologists, offer mammograms, CT (computed tomography) scans, and other modern screening and medical facilities. However, advanced medical facilities are scarce in rural and suburban areas, and the capacity of existing institutions often falls short of meeting the demand. In addition, there are also significant uncertainties regarding the overall cost of treatment, the duration of care, mental health support, and gaps in preventative measures. Given this context, our goal is to identify key gaps in existing approaches to raising awareness about BC and addressing the barriers that prevent people from seeking preventative care and timely treatment. By targeting these blind spots, we aim to make meaningful changes that promote early detection and improve access to necessary medical services.

In this work, to understand the barriers to BC awareness, we conducted an open-ended interview with the residents from both regions about BC awareness (to assess their current state of knowledge, attitude and readiness, awareness, and so on) After carefully analyzing our interview data, we highlighted some common obstacles in both regions or societies, by grouping

them into different societal levels such as individual, family, local society, health care system, and state or country. In the upcoming sections, we discuss the study design (Methods), the highlighted barriers with some root causes, and suggested solutions (Results); then, we suggest how technology and social media can play a crucial role in resolving some of those effectively (Discussion).

Methods

Study Design

The main objective was to evaluate the general knowledge and awareness of the participants regarding BC, identify sociocultural factors that could hinder mass awareness campaigns, and examine health care disparities and systemic issues. We conducted individual interviews with the participants using a semi structured questionnaire that included a variety of specific questions as well as 1 open-ended question (Table 2). The participants' responses included personal experiences and anecdotal stories.

Table 2. Our questionnaire.

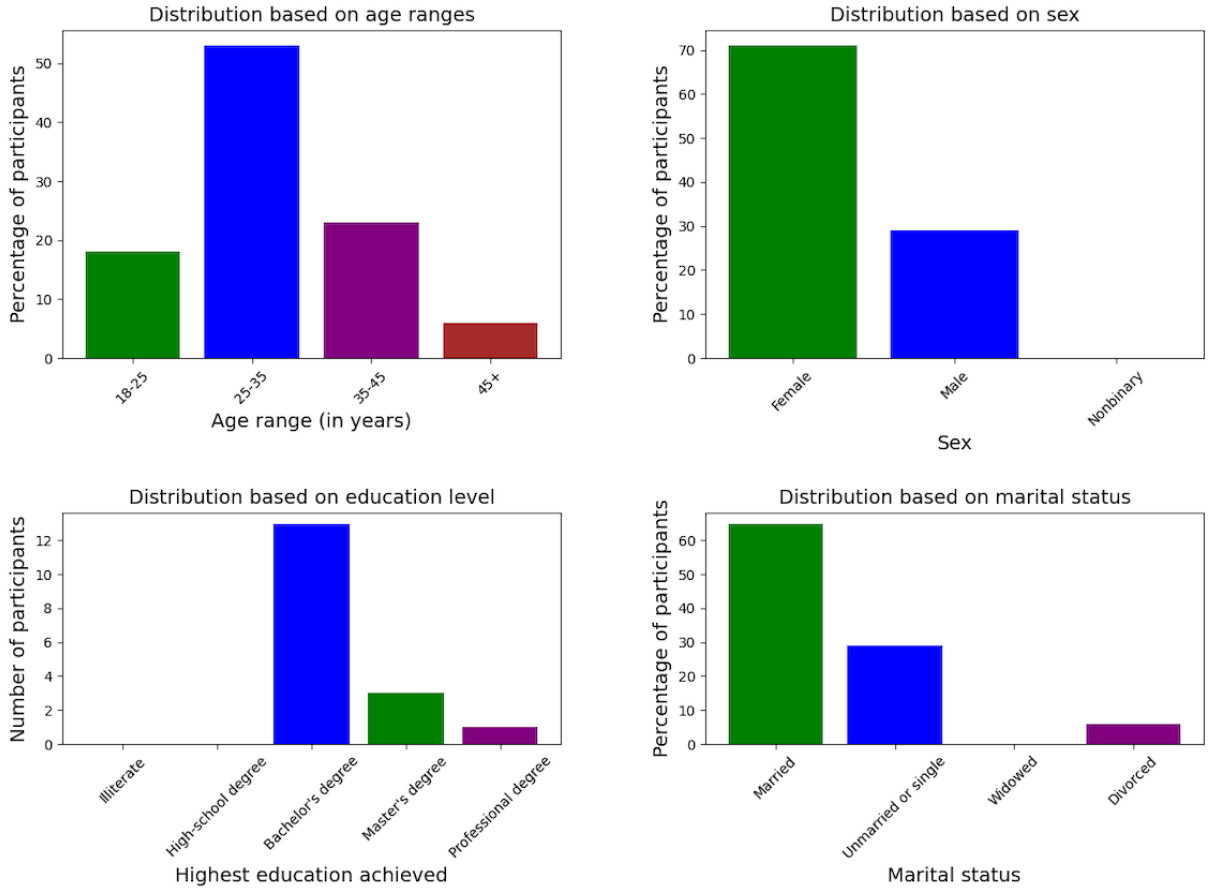
Category	Questions
Awareness	• People of which age range do you think are at high risk of getting breast cancer? • What are the most common symptoms of Breast Cancer? • What are the common misconceptions about Breast Cancer? • Are there any media-related programs that have provided information regarding Breast Cancer or Breast Cancer diagnosis or progression of the disease? Example: Television talk shows, YouTube, WhatsApp, Facebook groups, or movie or television shows • Are you aware that breast cancer can affect anybody regardless of their sex and gender classification? If not, what gender and sex demographic do you think have the possibility of getting Breast Cancer?
Self-diagnosis	• Do you know and voluntarily do the Breast test yourself at home?
Post-diagnosis support	• What were the support mechanisms (nonpharma) provided to you? For example, mental health or NGO support, nutrition, or self-care. • Was the financial impact of the proposed treatment plan discussed with the doctor?
Open-ended	• Is there anything you would like to share about your journey or experience with Breast Cancer?

[a]NGO: nongovernmental organization.

Participant Selection and Recruitment

We recruited participants through snowball sampling [12], using mutual connections and social media platforms such as Facebook (Meta). Semistructured interviews were conducted with 17 participants from West Bengal and Bangladesh. All our participants were above the age of 18 years, and recruitment was focused on participants who resided (at the time of study) in the 2 regions mentioned above. Our participants primarily identified as female, with an average age of 25-35 years, and most were married (Figure 1). The participants selected the language during the interview; most spoke Bengali. The researchers conducted the study through Zoom (Zoom Video Communications), and the audio recordings were transcribed and translated into English for data analysis.

Figure 1. Distribution of participants.



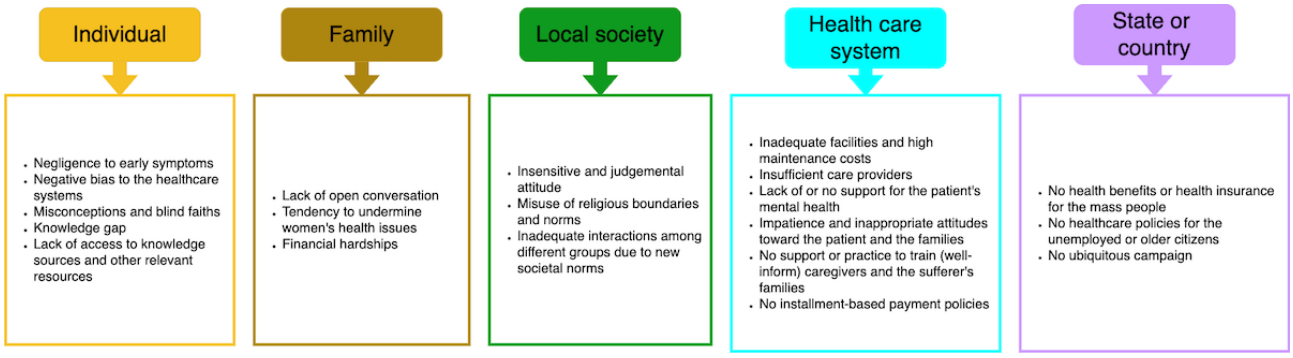
Demographics

We aimed to recruit a representative sample of participants from diverse educational and financial backgrounds from the region, as socioeconomic status and education play a huge role in the participants' access to health care in the region. Also, a cultural stereotype related to educational qualifications is widely propagated, relating educational accomplishments to open-mindedness, access to health care, and overall "success" in life [13]. Our participants self-declared their financial status as middle- and high-economic classes and were all in professions such as business, architecture, social development work, or education. Most of our participants had completed their undergraduate degrees (n=13), few had graduate degrees (n=3), and some were currently working toward a professional degree (n=1). The socioeconomic status of our participants is important in the larger context of interpreting the results and will be discussed further in the upcoming section.

Data Collection and Analysis

We transcribed the interview audio recordings, which were between 15 and 45 minutes long, and translated into English. Our qualitative data analysis follows a tiered approach and an inductive methodology [14,15] to generate themes. In tier 1, the initial coder examined the transcript identifying recurring themes, clustering them based on similarity, and using the descriptive coding methodology to label them. This clustering formed the foundation for subsequent analysis. Moving to tier 2, a second coder independently reviewed the clustered themes and descriptive terms associated with them, providing validation by either corroborating existing clusters or proposing new ones as necessary. Finally, tier 3 involved collaborative discussions between both coders to assess the relevance and significance of the clustered themes and descriptive terms associated with them. Through iterative deliberations and consensus-building, the final classification of themes was determined (Figure 2). As our interviews were semistructured (where the participants had the freedom to take the narrative and provide more information beyond a fixed set of questions), this method of generating themes bottom up and assigning descriptive terms to it allowed us the flexibility to show nuance and highlight subthemes. Both coders were familiar with the language spoken by the participants (Bengali) to parse through the linguistic, cultural, and social significance of the data generated during the interview sessions.

Figure 2. Outcome of our qualitative data analysis: major barriers to breast cancer awareness in the region.



The hierarchical representation of our themes and subsequent categories (Figure 2) is inspired by the presentation of the barrier tree [16] developed for a mobile-based BC monitoring study for the people in rural Bangladesh around 2012. Notably, several factors (such as feeling shy, fear, lack of familiarity, undermining women problems, religious belief, shared beliefs and practices, communication problems, scarcity of doctors, inconsistent patient data, long-term monitoring, and poverty) identified then are still highly relevant and came up during our analysis. The distinctions between both works are listed below.

First, most of our participants are city dwellers, but they shared stories and experiences from different parts (city, suburb, or rural) of the country or state during their interviews. Haque et al [16] studied in rural setups about 1.2 decades ago.

Second, we present the barriers by clustering them into 5 socioeconomic themes (individual, family, local society, health care system, and country or state). Haque et al [16] presented their findings into categories like identification and disclosure, achieving treatment, continuation of treatment, environmental issues, and user issues.

Third, while many research articles in the domain of BC primarily adopt a medical science perspective, such as the study by Haque et al [16], where the team visited a clinic or hospital to gather data and generate a barrier tree, our approach diverges by examining BC through a societal framework. By doing so, we aim to offer a comprehensive analysis that encompasses both the medical and societal impacts of BC. This approach allows us to explore the same problem from different lenses, shedding light on the multifaceted challenges and implications of BC beyond the purely medical aspect.

Finally, as a novel addition to the field, we delve into the mental health relevancy of patients with cancer and their caregivers, a crucial aspect that was not addressed in the other work.

We discuss the outcome of the qualitative analysis in the next section.

Ethical Considerations

The institutional review board of New College of Florida approved the study (Protocol #22-037), and we strictly followed all protocols to ensure data privacy and integrity, demonstrating our commitment to ethical standards. For the study, participation was voluntary; participants did not have to participate and could stop at any time. There were no penalties or loss of benefits or opportunities if the participant did not participate or decided to stop once started. Their decision to participate or not to participate did not affect their job status, employment record, employee evaluations, or advancement opportunities. The participants did not receive any benefit from the research team. There was no cost to participate. This research was considered minimal risk. Minimal risk means that the study risks are the same as those in daily life.

Results

The results of the data analysis are discussed in 2 phases; first, barrier identification and second, awareness raising.

Barrier Identification

The majority of our participants were aware of BC's symptoms, possible treatment mechanisms, costs, survival rate, and so on. During the interviews, they were able to list most of the significant symptoms of BC, like deformed breasts or nipples, lumps in the breast and armpit, discharge of pus or liquids, irritation, flaky breast skin, irregular breast pains, overall fatigue and weight loss, and so on. All but 3 participants knew of at least 1 person who has or had BC—either in their own or extended family, in the neighborhood, or in a friend's family—indicating how predominant this disease has become (Tables 3 and 4). A total of 14 participants "had heard of" self–breast-examinations, 13 participants "knew how to" perform self–breast-examinations, and 7 participants "had performed" self–breast-examinations (Figure 3). A greater than 50% decrease in the number of participants who had conducted self–breast examination is noteworthy.

Table 3. Number of responses to the question: "How many patients with breast cancer do you know of?"

Percentage of participants	Number of patients or survivors with BC[a]
18	0
35	1
35	2
6	3
6	4

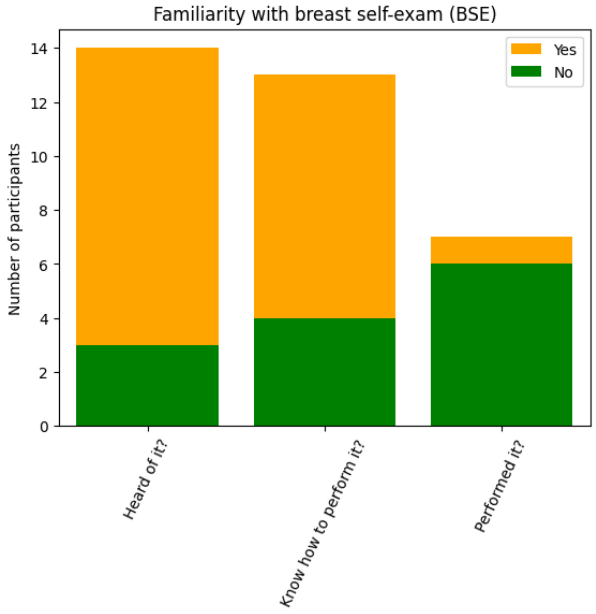
[a]BC: breast cancer.

Table 4. Patients with breast cancer in immediate family.

Percentage of participants	Number of patients or survivors with BC[a] in immediate family
59	0
24	1
17	2

[a]BC: breast cancer.

Figure 3. Familiarity test for "breast self-examination.".



The following sections share the barriers we highlighted from our data. Since the barriers often have cause-and-effect relationships and circular causality, we will not present them according to the identified societal levels like in Figure 2; instead, we would discuss them under the same section or title if they mostly appeared together during the interviews.

Tendency to Neglect Early Symptoms and Knowledge Gap

Our survey participants agreed that although BC is well-known, many people are unaware of the symptoms and often miss early signs. Specifically, when trying to identify symptoms in themselves, they either don't know what to look for or tend to disregard early signs of discomfort. For example, 1 participant stated:

> *One day, my mom had severe stomach pain. We took her to the doctor, who asked us to complete a USG of her abdomen as the doctor suspected that my mom had a tumor in her stomach. While doing the USG for the tumor, the doctor detected that she had gotten breast cancer, not a tumor…… it was already a late detection. It's at a deadly stage already. The treatment would have been much less painful if she had been diagnosed earlier.* [b007]

A similar story also stated the reluctance to pay heed to early symptoms or disclose them:

> *Though she (a neighbor) suspected it, she did not disclose it initially. When the pain became unbearable, then only she went to the doctor. She went to the doctors in the middle stage (not the early stage).* [b011]

> *One of my aunts (a family friend) had been diagnosed with breast cancer. However, it had already spread to the throat and jaw when she was diagnosed. So, the doctors could not remove/cure it, and she passed away.* [b008]

These responses reflect the results Amin et al [17] found in a survey that the research team conducted in Bangladesh in 2020; out of the 9 symptoms of BC, approximately 50% (N=500) of participants were unaware of 5 or more symptoms.

Misconceptions

Although none of our participants were medical professionals, our participant pool consisted of individuals who had all completed at least an undergraduate degree, were socioeconomically affluent, and were self-professed, open-minded individuals. Due to their educational backgrounds, we assumed that the number of misconceptions about BC would be lower than other groups. However, our participants had several deep-rooted misconceptions about BC, which are listed below.

First, it can only afflict females. Surprisingly, 10 out of 17 participants (59%) believed BC could only afflict females. The rest of the participants agreed BC occurred, irrespective of sex.

Second, it is more likely to afflict married women and those who have recently become mothers. Several participants stated that in married women, especially after giving birth to a child or during the breastfeeding period, it is highly likely to get inflicted with BC.

Third, it is more likely to afflict older women. Several participants responded that BC only affects older women; when probed further, they believed that the age range between 25 and 45 was not particularly susceptible to BC. Reports have suggested that Indian women in their early thirties till fifties are at considerable risk of developing BC, and the incidence risk increases till its peak when they reach 50-64 years of age. Furthermore, 1 in 28 Indian women are likely to develop BC during their lifetime [18-21]. It is more (1 in 22) for urban women than for the rural group (1 in 60). Amin et al [17] report similar statistics for Bangladesh (22.5 per 100,000 women and mean age being 41.8 years and 56% of the diagnoses were for reproductive-age women).

At the end of our interviews, we informed our participants that (1) BC is statistically more dominant among females but can afflict anyone, irrespective of gender and (2) there are various types (metastatic, inflammatory, and so on) of BCs that afflict people from various age ranges, so directly linking it to a particular age, marital status, or maternity may not be the best idea.

These factual misconceptions and knowledge gaps about BC are major factors related to the diagnosis of BC at an early stage. Our participant responses reinforced the need to disseminate accurate information to raise awareness.

Social Stigma and Lack of Open Conversation

First, beauty and breasts—judgmental attitudes. In addition to being an organ, breasts play a significant role in defining femininity and women's role in South Asian cultures. The fear of the disease attacks the fundamentals of female identity as a woman's breast conjures her sexuality and her capacity to nurture [22]. In patriarchal societies, such as Bengalis in West Bengal and Bangladesh, irrespective of educational or financial gains and social liberties through the years, women are perceived to have the roles of mothers, wives, or homemakers, whereas men are mostly seen as primary breadwinners of the family [23].

According to a report by a Pakistani Non-Governmental Organization, Aurat Foundation and USAID (United States Agency for International Development; 2016), in South Asian cultures, feminine traits include emotional, nurturing, passive, good homemakers, fair-skinned, without body or facial hair, long-haired, with a narrow waist, and sexually submissive. In contrast, masculine traits include being assertive, primary breadwinners, risk-taking, rational, and brave [24]. The ultimate danger of this notion to a Bengali (or maybe many people from other parts of the world) is that they feel one becomes "lesser feminine" if one has any breast health-related issue. On top of that, many people assume that BC's ultimate aftereffect is mastectomy, if not death, which adds a new level of stigma [25,26].

> *When I was very young, I learned that one of my friend's mom had breast cancer. At that time, my parents were very conservative; they would not open up in front of other family members/us. I learned later that doctors had to remove her breast. But the good thing is, she recovered totally, and it's been 20 years. She has an everyday life. I believe she received good treatment. Every treatment doesn't go wrong!* [b009]

> *Of the few breast-cancer and other cancer survivors I know of, I say it is common for breast cancer patients to feel humiliated or more mentally upset than other cancer patients. …… I don't notice any initiative in our society in this matter; neither is it commonly seen to provide some counseling for the patients for overcoming/fighting cancer.* [b005]

For several reasons, anyone with BC is reluctant to share their experiences. In many cases, patients with BC suffer from depression [17] due to a lack of a support system to debunk the body image and societal myths. The image of an ideal woman propagated in the media (television or social media) reinforces the narrative that is sometimes unhealthy to a person's body image [27]. Particularly the lack of influential media personalities sharing their stories of struggle and recovery or the absence of characters that represent the struggles of patients or survivors of cancer in television shows or media portrayals impacts the perception of the journey and struggles.

Our participants echoed these sentiments in their statements:

> *There is a taboo around breast cancer, regardless of class and status. People do not talk about it. We learn about it later, like once someone has recovered or died of breast cancer. Mostly, no one shares their journey with breast cancer.* [b014]

> *She (a breast cancer survivor) used to talk to me and hang out with our family. However, she and I never*

> *talked about it. Neither I asked, nor she opened up. If it is not very necessary, we will not share. That is the mindset.* [b012]

The term cancer comes with a connotation of impending doom and death; however, the significantly higher chances of patients surviving cancer because of early detection strategies and awareness are not emphasized at all [28]. When it comes to the 5-year overall survival, a study reported it to be 95% for stage I patients, 92% for stage II, 70% for stage III, and only 21% for stage IV patients [29]. It is important to highlight these statistics widely to encourage early detection and awareness. Survival rates of patients with BC are lower compared with Western countries, primarily attributed to early age onset, late-stage detection and delayed initiation of definitive management, and inadequate or fragmented treatment [28].

Second, cultural sensitivities. In addition to not expressing discomfort, awareness campaigns in India and Bangladesh must be wary of the strict cultural, religious, and moral censorship, which does not allow the posting of revealing images of breasts. People, in general, are brought up in an environment where they do not feel comfortable discussing sexual health or women's health concerns, including BC. The term "breast" is perceived through the lens of hypersexualization and hence comes under deep scrutiny from moral and religious sensitivities. As researchers embark on developing awareness campaigns, it becomes crucial to exercise cultural sensitivity, especially considering the conservative nature of the audience in these regions. Being mindful of cultural nuances is essential to ensure that the true essence of the campaign is not overshadowed by moral policing or societal restrictions. It is important to point out that women's health or sexual health and the term breast are not taboo; we cannot undo decades of cultural teaching and biases in a day. Hence respecting the norms and designing awareness campaigns around them would be a more sensitive approach.

> *She (my paternal aunt, who was a teacher) had lung infections and troubled breathing due to breast cancer, but the doctor tracked it back to breast cancer after doing several medical tests; she was never open about the symptoms (or discomforts with her breasts) upfront to the doctor.* [b001]

> *People are not comfortable talking about it. Since I am the son, my mom also never shared about her symptoms or sufferings.* [b007]

Third, women's health care is a necessity, not a luxury. Irrespective of South Asian patriarchal societies or more progressive Western societies, a woman's role in society, economy, and family cannot be ignored. The roles of caregiver, parent, and wife for a rural woman with added burdens of maintaining appearance and body image in the case of an urban woman all contribute to the issues that the contributions women make to the world are "nonproductive" or "nonessential." This perception sometimes from women themselves (in some cases, the family members) leads to the health concerns of women being ignored or underprioritized [23]. This includes a lack of attention to proper nutrition, timely intervention, care after diagnosis, and adequate mental health support. This practice or habit stood out as one of the major reasons why female patients often get a late detection of health-related problems.

> *We wait and hope that the discomforts will disappear automatically after a while – so we tend to linger. I have noticed this among my friends and family (especially females), including myself; we tend not to go to doctors so easily. I am not sure if it's a cultural thing! But it is less about financial conditions and more about awareness.* [b014]

Certainly, that mindset is changing gradually. Nonetheless, there is a need for increased awareness in this particular area:

> *A woman in the family will likely delay her treatment as she thinks it's the least important issue and is probably putting financial pressure on the family. But sometimes, they forget that delayed treatments may invite worse consequences.* [b003]

The Disconnect Between Health Care Models and People

Although none of the existing health care models worldwide are perfect, in the context of a deadly disease like BC and health-related supports, we noted the flaws, inconsistencies, and lack of patient-centered policies in the regions.

First, lack of a yearly health examination policy. Unlike in the United States or other parts of the world, Bengalis usually do not go for yearly health examinations, or it is not a common practice among doctors to prescribe yearly health checkups. The lack of adequate resources, such as available medical professionals, provider-centric consultations, and a symptom-based health care model, is partially responsible for this issue [30]. The region requires immediate advocacy for a robust primary health care system and the use of existing community care efforts to enhance awareness.

Second, out-of-pocket medical expenses. Health examinations are expensive, and it is unusual for the region to support health insurance employers [31]. There is no system of national health insurance in Bangladesh [31]. People whose employers cover health benefits also must pay to the facilities out of pocket first and then later ask for a reimbursement. This cost barrier leads to patients not seeking treatment early on.

Third, lack of integrated service and long-term plans. Those on tight budgets usually have to prioritize the price over reliability and integrated service available to few modern (and more expensive) health care facilities. Patients and their family members are often not fully aware of the overall costs (long-term plans alongside short-term plans) and risk factors so that they can make informed decisions.

> *Talking to the patient and their family about the situation and possibilities is crucial. Only then can we make an informed decision. But if the doctor dictates the options, the patient's family has to follow the order, no matter how expensive or if they have to lose their property in arranging the financial support.* [b009]

Fourth, open conversation between patients and the doctors. Due to various reasons, including high volume of patients,

doctors seem to spend much less time with the patients, which has been a consistent story we heard from our participants.

> *The more renowned the doctors are, the less interactive they are, or the less compassionate they are. There is much less scope and the chance of openly conversing with them.* [b014]

Fifth, insensitive and judgmental commenting. Medical professionals lack adequate training when addressing patients and their concerns. A dearth of empathy compounded by the enormous patient loads leads to negative interactions with the health care providers, and patients or family members do not feel comfortable asking essential questions. An insensitive comment may cause severe damage to the patient's (or their caregiver's) confidence and motivation. Effective doctor-patient communication is determined by the doctor's bedside manner, which patients judge as a major indicator of their doctor's general competence [32,33]. Doctor-patient communication skills are based on verbal and nonverbal communication, where 22% is transferred through voice tone, 55% through visual cues, and 7% verbally [34]. Lack of training to demonstrate effective behavior leads to scarring patient outcomes, one such is listed below:

> *I remember an oncologist's comment to his patient (lung cancer survivor, 65+ years of age) regarding the side effects of Chemo/radiotherapy: you don't have your natural hair anymore! So why worry about that?* [b003]

Sixth, the doctor's gender. BC disproportionately afflicts the female population, and since it concerns an intimate body part, it is common among the patients and their family members to withhold the treatment until they find a female specialist; in short, they prioritize the doctors' gender over professional expertise [32]. In a cross-sectional study conducted with 1257 female patients in Udaipur, India (August 2014), by Nagarajappa et al [32] found an overwhelming 85% (1069/1257) of the respondents said yes to the question: "I would always prefer being treated by a doctor of my gender." In some other similar studies conducted in 2019, researchers found that the most important attributes of maternal health care facility choice for Bangladeshi women were consistent access to a female doctor, the availability of branded drugs, respectful provider attitudes, and a continuum of maternal health care [35,36].

> *My aunt and uncle delayed the treatment as they were hesitant about choosing a doctor; they were looking for a female doctor, but there were not many female breast cancer specialists in Bangladesh during that period. My uncle (my mother's cousin) had hesitation. Had she been diagnosed earlier, she would have had a better chance of survival. She was a survivor, but her entire family suffered greatly due to the delay. My uncle later regretted his decision. I remember him expressing that to my mother (his sister).* [b003]

Although 61.1% (198/324) of medical students in India identify as female, a study by Bajpai et al [37] in 2020 found that men led 67.3% (218/324) of oncology teams in India. These numbers are similar to the numbers in the United States, where out of 667 female respondents, 442 identified as academic oncologists versus nonacademic ones [38]. This gender disbalance among physicians leads to patients not seeking timely medical care.

Seventh, lack of trust. Many people in the region believe that:

> *…an institute (hospital and caregiving center) that is capitalist in nature cannot have people's best interest at heart.* [b016]

This may play a significant role in people's hesitancy to seek health advice unless necessary.

Mental Health Support Infrastructure

All participants expressed concerns about lacking mental health support systems. Most reported that:

- family members and caregivers are never made aware of the patient's mental health, its relevance, and how to handle them [26].
- "I didn't know and never thought mental health could be impacted directly by these (or any) diseases." [b007]
- there is no infrastructure to support the mental health of patients suffering from terminal or deadly diseases.
- "Mental health is considered taboo, more significant of a taboo than breast cancer. People don't usually talk about it. Doctors also don't do a good job in this regard. Providing professional mental health support is not common in India/West Bengal to battle cancer." [b016]
- "Since cancer is associated with a lot of uncertainty, fear, and stress, the moment patients get diagnosed with cancer, they must get counseling. Mental support from proper channels can help patients gather the strength and courage to defeat it." [b010]

Role of Media

Media has always played a significant role in spreading awareness among the general population on various issues. We wanted to learn how our participants felt about the role of media around them in spreading BC awareness. A survey conducted by YouGov Global Media in India identified that in 2022, 59% of Indians under the age of 24 years depended on websites or web apps as their primary media source, whereas people above the age of 45 years depended on television (live or nonlive broadcast) as a primary media source [39]. In Bangladesh, USAID conducted a similar survey and found that 46.6% of respondents mentioned television, and then 33.1% said the internet was a primary source of information media [40]. Similarly, in India, 60% of the population in the age group of 45 years and above depend on television for news, whereas younger audiences tend to lean toward updates from social media instead of watching traditional television news (which broadcasts news at specific hours).

Social media and traditional media (television and newspapers) can substantially spread awareness among people. We wanted to understand whether the media's contribution to raising awareness was limited to a date or time (eg, Breast Cancer Awareness Month) or whether there is any consistent campaigning.

Our participants have reported seeing numerous posts, symbols (such as the pink ribbon or black screen), and talk shows on specific days, weeks, or months of the year (such as during

Breast Cancer Awareness Day). However, these efforts are transitory. They come and go; many posts are left unattended, unread, and unfollowed, and many programs and talk shows are left unwatched. The lack of consistent programming on any platform that regularly sends out relevant messages throughout the year leads to reduced engagement and interest.

> *I have seen many programs aired on the national television of Bangladesh, but I believe that is not sufficient…. I haven't noticed any program regularly on this topic. If we talk about social media, I don't see enough posts relevant to this topic.* [b004]

> *People share (even if that's at a minimal level, especially on special occasions like Breast Cancer Month). But others may not have time to read it carefully due to their busy schedules. I sometimes see such posts but don't have time to read them thoroughly. I feel until it hits someone, they are likely to ignore (or blindside) it.* [b003]

Most BC-related posts (eg, Figure 4) on media platforms include either a pink bow [41,42] or wearing the color pink at campaign events [43,44]. To urban audiences' mammograms are widely promoted by health care professionals or organizations [41,45].

Figure 4. Media coverage, rallies, and campaigns.

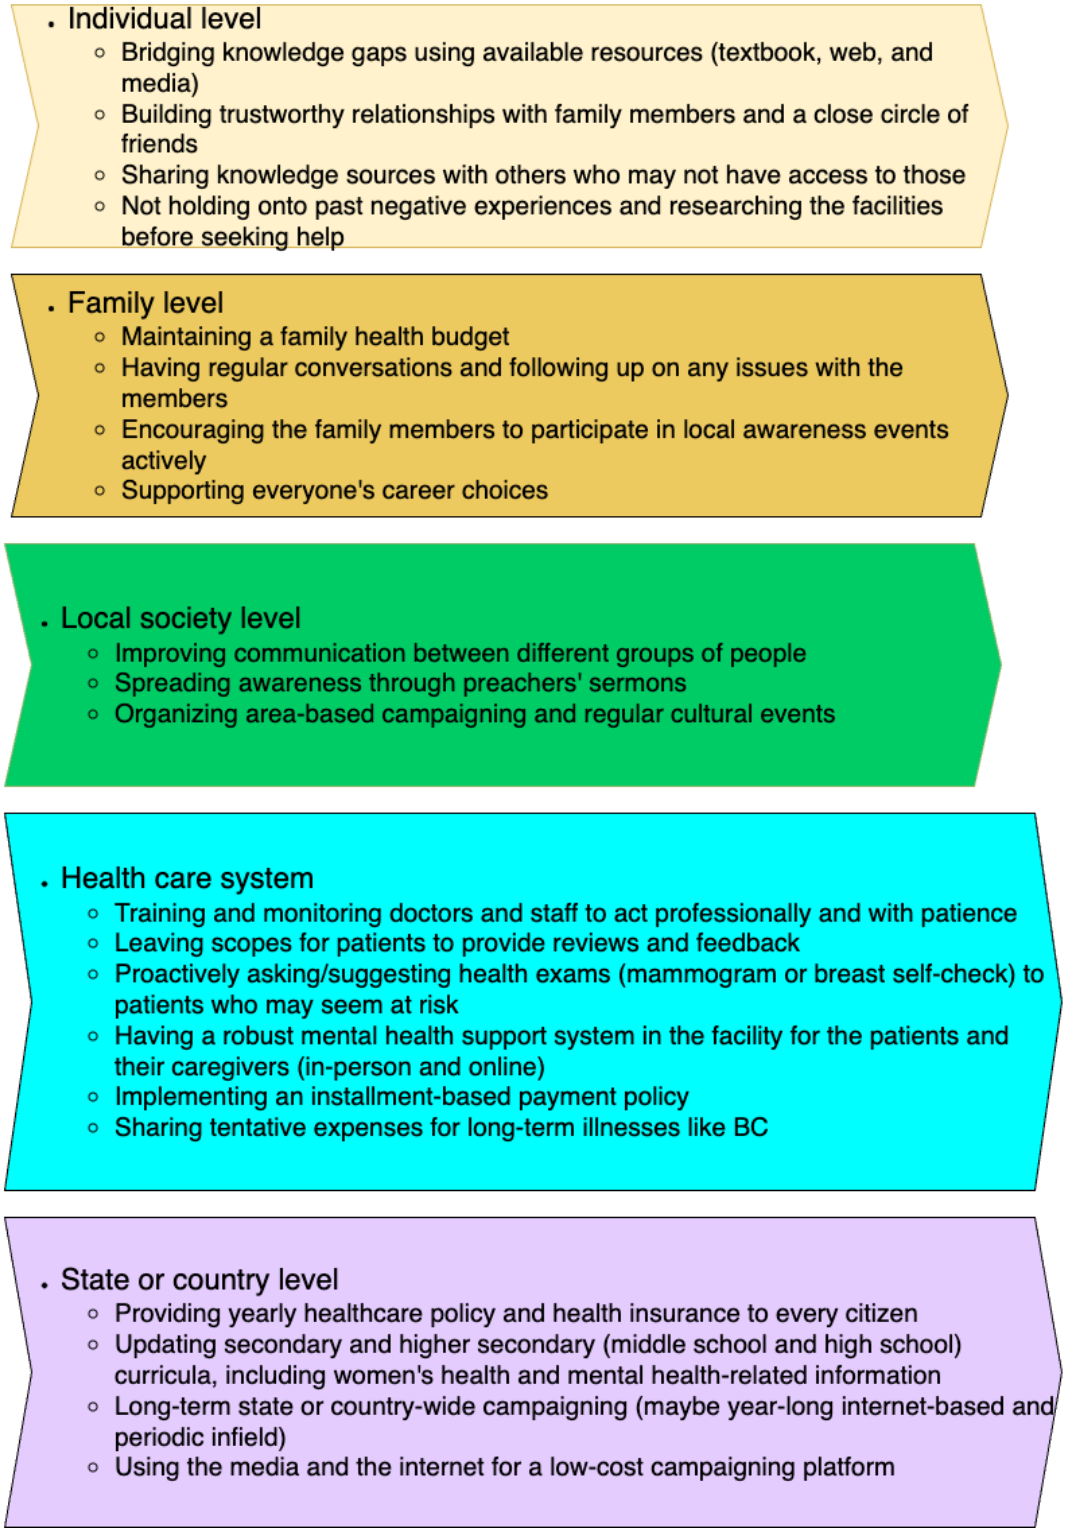
The absence of relevant information about the disease, prognosis, and symptoms is stark and leaves the audience wondering how to perceive this awareness campaign. Often, momentum is lost, and true engagement is not achieved, leading to lackluster awareness numbers.

> *We see advertisements relating to breast cancer, sometimes on the television or elsewhere, or billboards, but then it is very short and crisp. And it just says that we should be aware of breast cancer, but then what to be aware of it is never mentioned anywhere.* [b017]

Awareness Raising

Many of the findings are codependent and mutually recursive. For example, lack of trust in health care systems in the area and financial hardships implicitly push people to neglect early symptoms of deadly diseases; lack of open conversation and social stigma block them from reaching out for mental health support, to name a few. Our discussions with the participants highlighted several means to help spread mass awareness in the regions. In this section, we present the summary of our suggestions to achieve mass awareness through Figure 5 and briefly discuss them right after.

Figure 5. Our recommendation to help raise awareness. BC: breast cancer.



Designing a Yearly Health Care Routine for Everyone

> *Society must believe that early diagnosis can help increase survival and reduce suffering. We need to build the practice of going through a yearly checkup.* [b008]

Given the population, unemployment, and other issues, achieving mass success in building this practice will require support and cooperation from international organizations (such as the World Health Organization) and local governments.

Spreading the Voice of Survivors

We often hear words from specialists (doctors and scientists) on mass media (eg, Shastho Kotha [46]). Aside from their knowledgeable notes, the programs will draw attention to the mass scale if BC survivors' interviews are included regularly. This will also reduce fear, hesitancy, and social stigma. When

people see interviews of BC survivors belonging to the same community (age, gender, social status, and so on), it will help everyone to open up about similar issues.

> *I believe cancer changes our views and ways of life. We must break the practice of neglecting minor symptoms and not seeking medical advice. We need to improve trust and healthy communication between doctors and patients. Roughly 50% of the population is female. So, whichever cancer is more probabilistic to which population, they need to take it seriously. Financial hurdles should not be the first concern. It will be beneficial if there is a platform where people can talk about it and not treat it as something that cannot be discussed.* [b016]

Sharing the experiences of BC survivors as they navigate treatment plans, manage financial burdens, and embark on their journey toward recovery can play a crucial role in dispelling fear, reducing anxiety, and challenging the taboos surrounding BC. Narratives that illuminate the resilience of these survivors, highlight the support of their families, and shed light on the obstacles they overcome contribute to humanizing this daunting illness.

Using the Grassroots Health Workers

> *NGOs like Surjer Hashi Clinic, Shobuj Chata Community Clinic, etc., wildly succeeded in child immunization and birth control in Bangladesh. So, if cancer awareness (like breast and cervical cancer) is taken as an agenda by such organizations, I am hopeful it will succeed.* [b003]

If the health workers spread a simple flyer about BC with some visuals and depictions in Bangla during their weekly visits, it will help raise awareness in rural areas quickly.

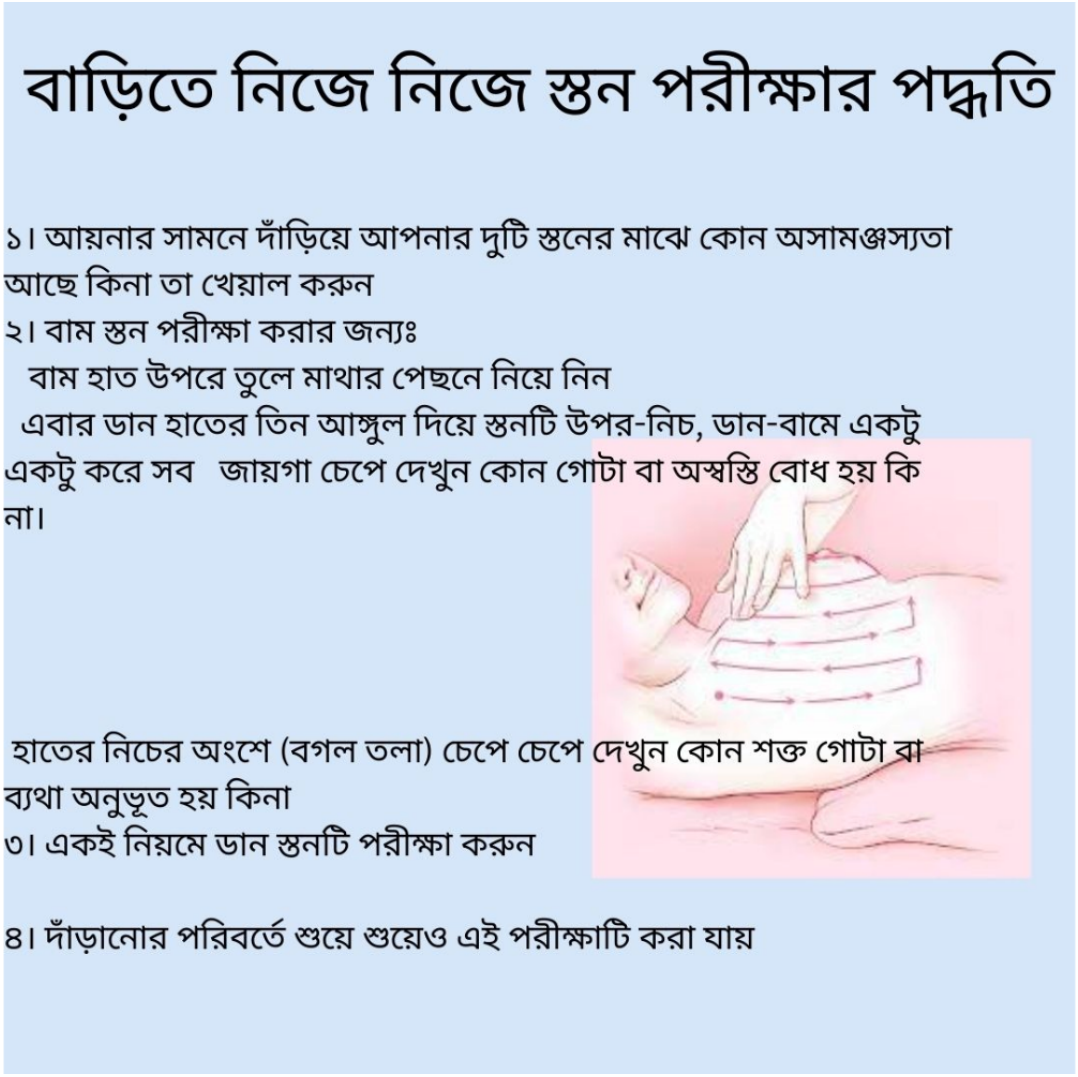
> *Bangladesh has successfully rolled out the idea of condoms and contraception, though we are considered a very conservative society. Major religions of our land directly oppose the idea of birth control. Yet the success came not because of the paid advertisements or programs in media but because of sending medical advice to the grassroots level. So, I believe we can succeed in growing awareness about breast cancer if the Government takes such programs into the hand.* [b005]

Establishing a Collaborative Effort on Social Media

Bangladesh's internet penetration rate stood at 31.5% (52.58 million/167.1 million) of the total population at the start of 2022 [47], and India's 47% (658 million/1.40 billion) of the population has internet access [48]. India and Bangladesh have both shown steady growth in mobile cell phone service, too. Instant messaging apps such as WhatsApp (Meta; 487 million users in India and 40 million users in Bangladesh) [49,50]. We strongly believe these platforms can be used to spread accurate awareness messages to users, particularly if government health organizations partner.

We suggest regularly preparing WhatsApp message broadcasts or mass forwards to groups, patients, or individuals from credible organizations such as local government branches (eg, zilla panchayat or district offices), medical associations (eg, Bangladesh Medical Association or Medical Council of India), or nonprofit organizations (eg, Sabuj Sathi). Sending these messages individually to users also avoids making anyone uncomfortable with the content, keeping in mind the social and religious sentiments or barriers in these regions. WhatsApp's ubiquitous presence in the digital communication ecosystem of both countries removes additional app downloads or installations. We propose using WhatsApp forwards (illustrated in Figure 6) as a cost-effective, easy-to-understand, and time-efficient method for dissemination. However, it is essential that these messages are reviewed by an expert before distribution to ensure accuracy and reliability.

Figure 6. Proposed self-breast examination instruction flyer.



Inclusive Texts in Secondary and Higher Secondary (Middle and High School) Curricula

Many people in both regions finish their education till middle- or high-school level. Some inclusive articles (written with appropriate languages and cultural values in mind) regarding women's health and the terminal and most predominant diseases in society will help spread awareness. The students and their families will gradually become aware; thus, many of the causes blocking the attention can be addressed thus far. Because textbooks can reach families where social media or entertainment media cannot.

> *I grew up in a village. I can talk to you from that context.… It isn't easy to spread awareness in the villages. For example, I grew up in a Muslim family where watching TV was not allowed, as it is anticipated that kids will be misguided by watching cartoons or inappropriate programs. So, getting this knowledge through TV was/is challenging for many kids like me.* [b006]

Per our research, no story, article, or novel about BC is included in the secondary and higher-secondary curricula of Bangladesh and West Bengal, India.

Educating the Caregivers and the Family Members

Besides building infrastructure for mental health support, doctors and other associates must educate the family members and caregivers about the patient's mental health and how to deal with it. We heard stories suggesting how a family can motivate a survivor to fight BC:

> *Someone very close to me has breast cancer. Initially, when it was diagnosed, the doctor prescribed her some medicine but barely communicated with her about her mental health. So, she melted down. After battling breast cancer for two years, she started self-motivating and regained her mental strength. She is a mother of two young kids, so that pushed her to keep going and not give up. She involved herself in activities like Yoga. Due to regaining mental strength, she started handling the treatment better (I am not suggesting that the cancer has disappeared, but she started driving it better).* [b002]

> *She (a relative) went into depression after the mastectomy. But since she has kids, she motivated herself. Her family also supported her very strongly. This support has helped her come out of the trauma. She is still following up with her breast cancer-related*

treatment. It is four years that she has been receiving treatments. [b011]

Discussion

In this research study, we aimed to understand the attitudes and perceptions of South Asian people, specifically people from Bangladesh and West Bengal, India, regarding BC. Our goal was to identify common barriers to raising mass awareness about BC in this population. In the results section, we discussed the significant barriers to BC awareness, which included a lack of knowledge and open conversation, negligence of early symptoms, negative bias toward health care systems, judgmental attitudes, and insensitive comments toward patients and their families, and financial hardship with limited options for financial support. We also provided suggestions to effectively raise mass awareness, including encouraging open conversations among family members and different groups, discussing relevant topics in social events and places of religious practices, integrating the topic into school curriculums, and disseminating accurate information through social and traditional media.

We present, in this work, the summaries of our findings in Figure 2 and Figure 5, where we clustered the critical points into 5 themes based on different societal levels—individual, family, local society, health care system, and state or country. Our findings highlighted the need for long-term planning and cooperation between people and the government, collaboration between national and international organizations, the use of media and education systems, and the importance of modern technologies and mass media in raising BC awareness.

Considering our dataset size (N=17) and the demographics of the participants, particularly their socioeconomic status and educational background, it is important to acknowledge that our findings are not fully representative of the entire population. Specifically, our dataset may not adequately capture the experiences of individuals living in rural areas, those below the poverty line, or those in the wealthiest brackets. These socioeconomic statuses certainly have disparate health care experiences and struggles. Our participant pool does offer valuable insights into the perspectives of the upper-middle-class segment of society and gives a general overview of barriers that should be further investigated.

For future work, it will be essential to extend this study to include participants from a wider range of economic and educational backgrounds. This broader approach will enable us to evaluate the generalizability of our findings and recommendations across diverse demographic groups and to uncover any critical issues that may have been overlooked in the current analysis. Such an expansion will contribute to a more comprehensive understanding of the nuances of this important issue and increase the applicability of our conclusions to a broader audience.

Abstract

Background: Patients with cerebrovascular accident (CVA) should be involved in setting their rehabilitation goals. A personalized prediction of CVA outcomes would allow care professionals to better inform patients and informal caregivers. Several accurate prediction models have been created, but acceptance and proper implementation of the models are prerequisites for model adoption.

Objective: This study aimed to assess the added value of a prediction model for long-term outcomes of rehabilitation after CVA and evaluate how it can best be displayed, implemented, and integrated into the care process.

Methods: We designed a mock-up version, including visualizations, based on our recently developed prediction model. We conducted focus groups with CVA patients and informal caregivers, and separate focus groups with health care professionals (HCPs). Their opinions on the current information management and the model were analyzed using a thematic analysis approach. Lastly, a Measurement Instrument for Determinants of Innovations (MIDI) questionnaire was used to collect insights into the prediction model and visualizations with HCPs.

Results: The analysis of 6 focus groups, with 9 patients, 4 informal caregivers, and 8 HCPs, resulted in 10 themes in 3 categories: evaluation of the current care process (information absorption, expectations of rehabilitation, prediction of outcomes, and decision aid), content of the prediction model (reliability, relevance, and influence on the care process), and accessibility of the model (ease of understanding, model type preference, and moment of use). We extracted recommendations for the prediction model and visualizations. The results of the questionnaire survey (9 responses, 56% response rate) underscored the themes of the focus groups.

Conclusions: There is a need for the use of a prediction model to assess CVA outcomes, as indicated by the general approval of participants in both the focus groups and the questionnaire survey. We recommend that the prediction model be geared toward HCPs, as they can provide the context necessary for patients and informal caregivers. Good reliability and relevance of the prediction model will be essential for its wide adoption.

KEYWORDS

cerebrovascular accident; machine learning; artificial intelligence; visualization; focus groups; questionnaire; informal caregivers; health care professionals

Introduction

Cerebrovascular accident (CVA), the collective name for ischemic stroke and intracerebral hemorrhagic stroke, affects 15 million people each year globally [1]. A CVA can have a range of symptoms that vary from patient to patient. Unilateral paralysis or weakness, numbness or loss of vision, speech difficulties and other cognitive dysfunctions, ataxia, diplopia, and nonorthostatic dizziness are some of these symptoms [2]. After the acute phase of treatment, patients often undergo a long rehabilitation process, although the length, intensity, and outcome can vary greatly between patients. In the Netherlands, 65% of CVA patients undergo rehabilitation at home after their hospitalization. The remaining 35% of CVA patients visit a rehabilitation center or geriatric rehabilitation center. Among patients in this group, 25% will not return to their homes and will go to nursing homes [3].

To provide the best care, health care professionals (HCPs) and patients should decide together which path to take in the care process [4]: shared decision-making. Efficient and practical goals can be determined when patients are involved in decision-making, leading to a more appropriate and suitable discharge location. Thus, CVA patients should be involved in decision-making regarding where rehabilitation will take place and setting rehabilitation goals [5]. A considerable number of CVA patients prefer active involvement in decision-making and consider themselves capable of doing so [6]. An important part of supporting active involvement in the decision-making process is to offer patients insights into expected outcomes.

Recovery is very heterogeneous for CVA patients in terms of speed, process, and outcomes, and is often considered too complex for HCPs to predict. As such, little information about expected medium- and long-term outcomes (3 months to >1 year) is provided to patients. Over the last few years, using artificial intelligence (AI) methods, several outcome prediction models have been developed. Some models on certain aspects of functional status have been developed, such as rehabilitation of motoric upper limb skills [7] or independent walking [8]. Others have reported testing at rehabilitation admission [9] or the use of wearable sensors [10] to provide useful data to predict postrehabilitation CVA outcomes. Most of these models use machine learning algorithms on structured clinical data, with varying accuracy [11,12]. Deep learning has offered the opportunity to combine more data and more different data types, such as imaging or free text, into a prediction model [13] and as such increase the accuracy of predictions. Several studies have investigated how deep learning can lead to better CVA outcome predictions [13,14] to reach clinically acceptable reliability. One of our previous studies [15] showed that combining structured clinical data and perfusion computed tomography (CT) scans can lead to an increase in performance.

While having accurate and reliable predictions is important, the explainability and clinical relevance of AI methods are essential for their adoption in medical practice [16,17], and many prediction model implementations currently fall short in these aspects [18]. Using a functional tool based on AI in a real-world setting would require both HCPs and patients to understand and trust the outcome prediction and see its relevance. Understanding a predicted outcome can be challenging for healthy people, but even more for CVA patients. These patients can have impaired cognition and often have a higher age [2]. Thus, information should be provided in an easy and clear manner for low cognitive effort. For example, when numerical data are presented, it is recommended to use simple visual forms such as flow or bar charts and circle diagrams [19].

The discharge interview usually addresses the duration and location of the rehabilitation. There are typically multiple possibilities after discharge, such as going home without or with home therapy, outpatient rehabilitation, geriatric rehabilitation, and clinical rehabilitation treatment [3]. A personalized prediction of CVA outcomes and the length of the rehabilitation process would allow HCPs to better inform patients and informal caregivers. This could form a basis for shared decision-making, as a more informed conversation about the preferences of the patient can be held. This research aims to assess the added value of a prediction model for long-term outcomes of rehabilitation after CVA, to investigate how its results can be best displayed, and to determine the best way to implement and integrate it into the care process.

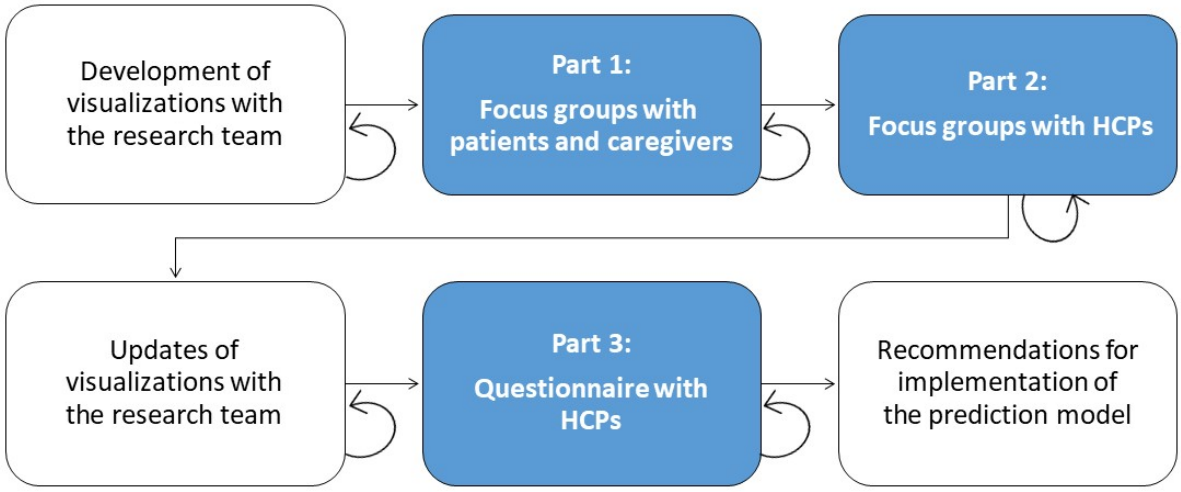
Methods

Design

A qualitative study was designed with the goal of evaluating the added value of a prediction model for stroke outcomes in CVA care. More specifically, this study aims to investigate how to best display the outcomes of the model, and integrate and implement them in the care process in an appropriate manner. We based our study on a prediction model previously designed in our hospital [15]. Before the qualitative evaluation, the research team developed a mock-up of a display of the prediction model, together with several different visualizations of the model outcome and interpretability. The research team included a neurologist and an expert on medical AI. The mock-up design was iterative, allowing for an update after each part of the study.

The study consisted of 3 parts: focus group discussions with CVA patients and their informal caregivers, focus group discussions with HCPs, and a follow-up questionnaire to HCPs, as shown in Figure 1. In both sets of focus groups, the opinions of patients and HCPs on the current information management and their needs with regard to the prediction model were explored and analyzed using a thematic analysis approach. The questionnaire was used to evaluate the finalized prediction model and visualizations with the HCPs.

Figure 1. Schematic overview of the different parts of the study. The circular arrow refers to the iterative aspect of each step. HCP: health care professional.



Focus Groups

Study Population

Patients who were admitted to St. Antonius Hospital between January 2020 and December 2021 for a CVA were selected using convenience sampling. Patients who had a CVA in the previous 3 months or who did not speak Dutch were excluded. We selected participants with a wide variation in age, gender, rehabilitation type (medical specialist, geriatric, home, or outpatient), and education level. An overview of the characteristics of the selected participants can be found in Table 1. Patients were approached by phone, and information letters were sent by email or postal address. Patients could bring their informal caregivers to the focus groups if this was of added value due to impaired cognition or higher age. The research team thought that an informal caregiver could assist in interpreting the model and could discuss patient preferences. Another advantage of including informal caregivers is that they are often involved in the entire hospitalization process of patients, and their opinions can therefore be valuable. Participants signed up by contacting the researcher and were asked to sign an informed consent form before the focus group started.

Table 1. Cerebrovascular accident participants in focus groups.

Participant	Age range (years)	Gender	Level of education	Rehabilitation
P1	71-75	Female	Vocational education	Geriatric rehabilitation center
P2	41-45	Male	Vocational education	Rehabilitation at home
P3	41-45	Female	Vocational education	Rehabilitation center
P4	71-75	Male	Applied university	Rehabilitation at home
P5	81-85	Female	High school	Rehabilitation at home
P6	66-70	Female	Applied university	Rehabilitation at home
P7	41-45	Male	High school	Rehabilitation at home
P8	76-80	Female	Vocational education	Geriatric rehabilitation center
P9	61-65	Female	Vocational education	Rehabilitation center

For HCPs, participants were recruited from a pool of HCPs involved in the discharge or rehabilitation process in the hospital. This included neurologists, rehabilitation doctors, junior doctors, nurses, and nurse specialists. All participants were approached via email or in person. The research team aimed to have 3 participants in each focus group, specifically a medical specialist, a general doctor, and a nurse.

Data Collection

The focus groups were led by 2 researchers (CGA and SvH). SvH moderated the focus groups with patients, and CGA moderated the focus groups with HCPs. We opted for the separation of patients and HCPs in different focus groups, such that the participants in both groups would be able to speak more freely about their experiences. We started with 3 focus groups for patients and their informal caregivers and 3 focus groups for HCPs, and we assessed whether saturation of data was reached or more focus groups were necessary. Each focus group had different participants.

The focus groups consisted of 2 phases. The first phase of the focus group was intended to explore the needs and expectations of the use of a prediction model during the discharge interview. This started with a reflection on the discharge interview and rehabilitation process, what expectations were created, what shared decisions were made, how the process went, and other

questions about topics and components that were addressed in the prediction model. The goal was also to determine how a prediction model could contribute to better expectations and improve the discharge interview.

In the second phase of the focus groups, different options for visualizations of the prediction model were discussed. We have elaborated on their design in the section on visualizations. Before the second phase of the focus group started, there was a short explanation of the visualizations. After this, the participants were asked to discuss several topics. First, whether the visualizations were clearly explained. Second, they were asked about relevance and what they think about the visualizations being used. During the focus groups with HCPs, this also included the predictors included in the model. Finally, they were asked to discuss which of the visualizations they preferred and why.

Focus Group Guide

Focus group guides were used, consisting of open and follow-up questions for the 2 phases of the focus groups (Multimedia Appendix 1 for patients and Multimedia Appendix 2 for HCPs). The focus group guides consisted of a few open questions, aimed at starting a discussion on information provision to patients in the current care process and the suitability of the prediction model and its visualizations. The focus groups followed an iterative design, which meant that after each focus group, the questions in the interview guide were adjusted if certain topics needed to be added or changed.

Data Analysis

Analysis of the focus groups was performed by researchers CGA and SvH in a thematic analysis approach using Atlas.ti [20]. CGA and SvH are early stage researchers with educational training and some research experience in focus group research. The thematic analysis was performed as follows. First, the researchers transcribed and anonymized the interviews. Then, both researchers separately open coded the transcripts. The data were coded axially by clustering codes by meaning, and the clusters were assigned themes. When all 6 transcripts were axially coded, the data were selectively coded to determine the relevance and consistency of the themes [21]. Finally, the themes were defined by noting the characteristics of the themes for consistent use. After analysis, the researchers held discussions about the data until a consensus was reached. We aimed for research triangulation by having 2 researchers independently analyze the data and iterate until agreement.

Questionnaire Survey

Study Population

The study population of the questionnaire consisted of HCPs. Similar to the focus groups, the participants were recruited from the pool of HCPs involved in the discharge or rehabilitation process in the hospital. However, only HCPs who directly worked with the prediction mode, such as junior doctors and neurologists, were asked to fill out the questionnaire. They were contacted by email or phone, or in person.

Data Collection

The last part of this study consisted of a questionnaire for a final analysis of the visualizations by HCPs. A simulated visualization (updated after the focus groups; see section visualizations) was shown to the HCPs for different scenarios for possible situations of patients in a discharge interview. They were asked to answer a modified Measurement Instrument for Determinants of Innovations (MIDI) questionnaire [22], which is a tool for describing the helpfulness and possibilities of medical technological devices. We selected 2 relevant sections out of 4 in the questionnaire regarding the innovation itself and the end users. The other 2 sections regarding work environment and sociopolitical environment were out of scope and more suitable for a later implementation phase. The questionnaire was adapted to fit the setting of the prediction model and was distributed via RedCap [23]. The questions were divided into 5 sections: general opinions, advantages and disadvantages, effects on patients, effects on colleagues, and opinions on implementation. The questionnaire consisted of 21 questions on a Likert scale and 1 open question.

Data Analysis

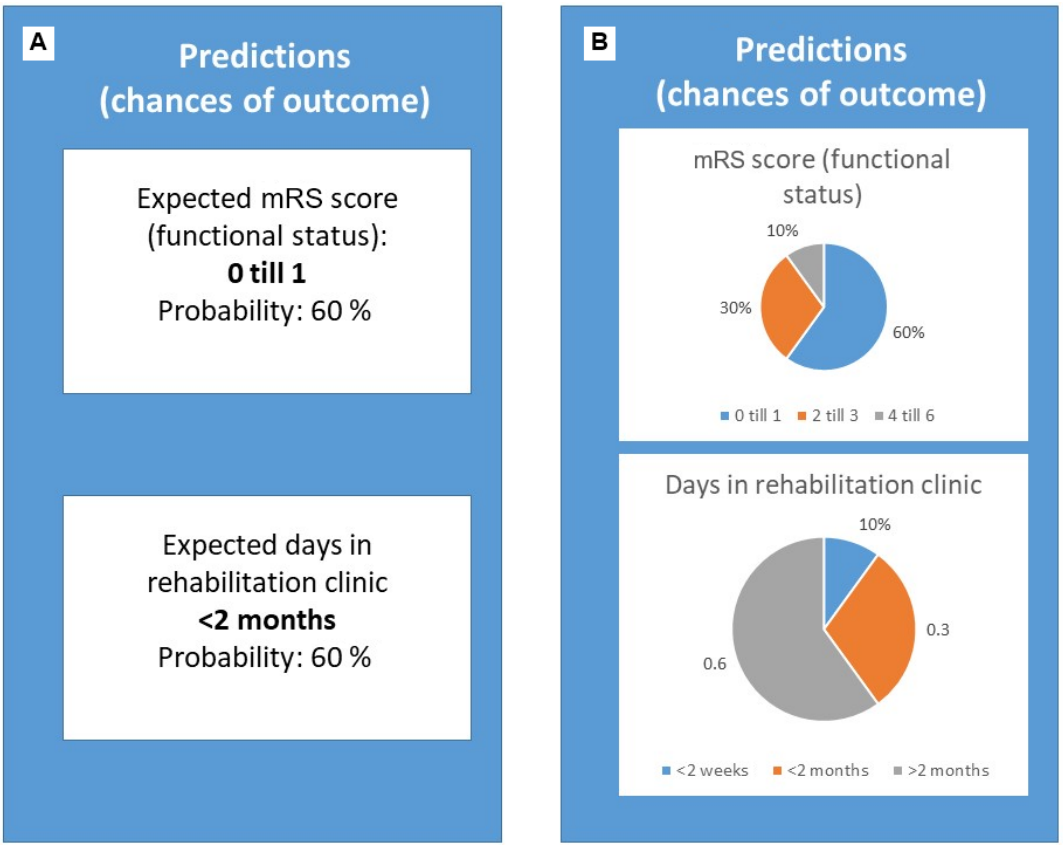
No statistical analyses were performed on the questionnaire, as the MIDI questionnaire is not a validated questionnaire and the sample size is small. Instead, the questions were meant to provide a formalized evaluation of the prediction model and its visualizations. Both the general score of the prediction model and the agreement have been reported.

Prediction Model and Visualizations

The model visualizations were based on the model described in a previous article [24]. This model aims to predict a 2-fold outcome: functional outcome (modified Rankin scale [mRS] score) after 3 months and length of stay in a rehabilitation center. Two feature sets were used as predictors: hospital data and data from geriatric rehabilitation clinics. The hospital data were based on registry data from the Dutch Acute Stroke Audit [25], such as medical history, treatment data, and admission data, and the other data included intake data, admission data, and discharge data.

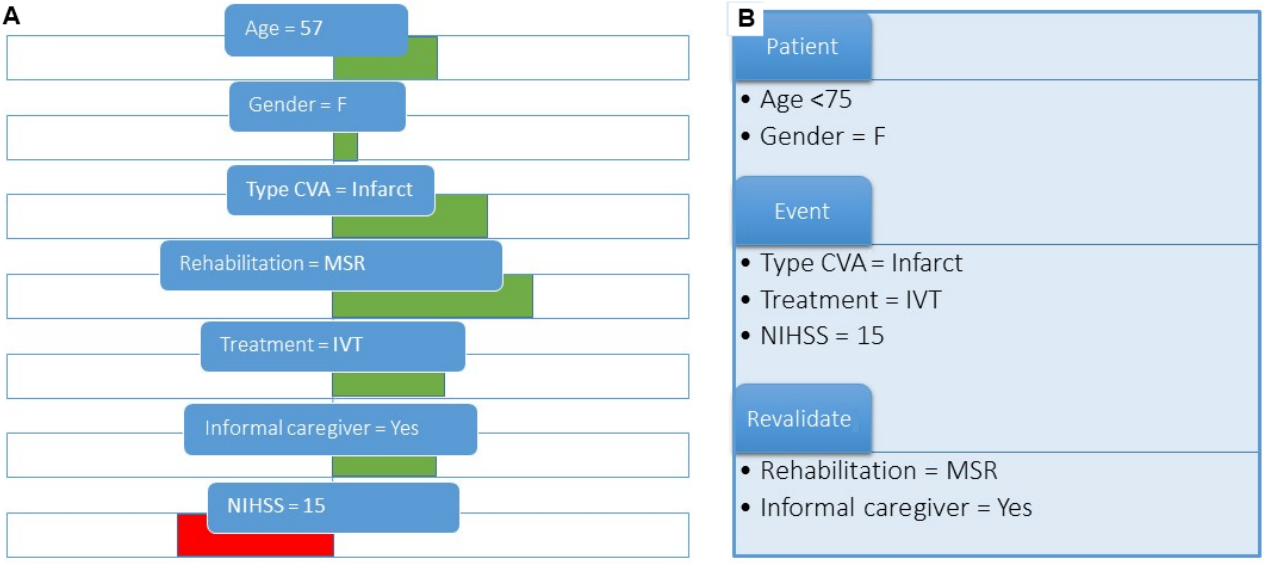
The design of the visualizations followed an iterative setup with the research team. Before the focus groups, the research team created a mock-up, with outcomes and visualizations for 2 fictional patients, as a functional model with real patient data was not yet available. Based on examples and previous literature about explainable AI in health care [26,27], a choice of 2 different visualization styles was made. One with a more simplified textual approach having clear and limited information, and one with a more detailed visualized approach having more information in the form of diagrams. We chose circle and bar charts for this style, as they are considered the most “approachable style” of visualization of numbers [19]. The visualizations of the outcomes in both styles are shown in Figure 2.

Figure 2. Different visualizations of outcomes (translated from Dutch). (A) Textual limited information; (B) Visual detailed information. mRS: modified Rankin scale.



Next to outcome visualizations, we also included explanations of the predicted outcomes by the models, which have been shown to be important for the adoption of AI in medicine [14]. We opted to show the model explainability through feature importance, where for the predicted outcome of the model for each patient, the contribution of each feature is shown. This can also be described as local interpretability, which has been further explained previously [19,23]. For example, it can show that the age of that specific patient contributed 20% to the decision of their personal outcome. This can be both positive or negative feature importance, indicating whether it made the predicted outcome more or less likely. The detailed visualization (Figure 3A) shows this in red and green bars. For the simplified version (Figure 3B), only the most important features for the outcome were mentioned (not the extent of their contribution).

Figure 3. Different visualizations of influencing factors (translated from Dutch). (A) Visual detailed information. The color and length of the bars indicate the size of the effect on the outcome. (B) Textual limited information. CVA: cerebrovascular accident; IVT: intravenous thrombolysis; MSR: medical specialistic rehabilitation; NIHSS: National Institutes of Health Stroke Scale.



Visualizations were developed for 2 fictional patients in 2 different visualization styles, resulting in 4 examples. The complete translated visualizations can be found in Multimedia Appendix 3. Based on the feedback from the focus groups, 1 visualization style was selected, and the visualizations were modified in accordance with the focus group feedback. These final visualizations were used for the questionnaire.

Ethical Considerations

The Medical Ethics committee of Utrecht (MEC-U) declared that this study is not subject to the Dutch Medical Research Involving Human Subjects Act (WMO) and issued a non-WMO statement under number W22.007, and subsequently, the board of directors of St. Antonius Hospital issued a statement of no objection (permission to perform) under number Z22.009. All participants provided informed consent.

Results

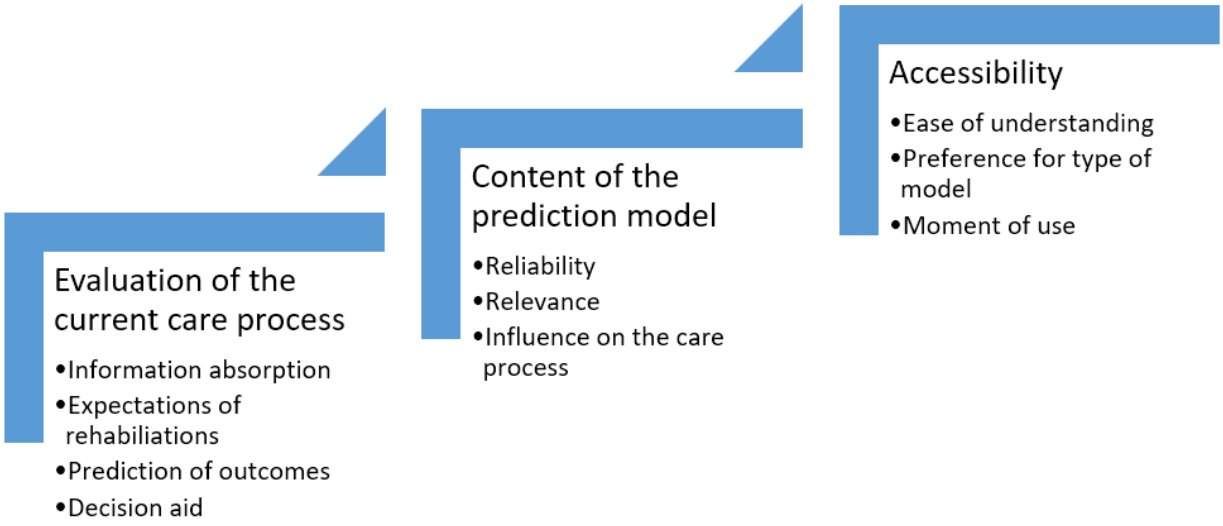
Focus Groups

The focus groups took place in April and May 2022 and lasted for 60-90 minutes with patients and caregivers and for about an hour with HCPs. We conducted 3 focus groups of each type (total 9 patients, 4 informal caregivers, and 8 HCPs). After these sessions, further focus groups were not deemed necessary, as saturation was reached.

A few minor changes were made to the interview guide after the first focus group with patients. We put less focus on the discharge interview and more on the questions about the care process in general for patients and the family interview for HCPs. For the focus groups with patients and informal caregivers, the transcripts were sent to these participants for a member check. None of the participants had any remarks on the transcripts.

The results of the focus groups have been organized by theme in prediction model development in 3 sections: evaluation of the current care process, content of the prediction model, and accessibility of the model (Figure 4).

Figure 4. The 10 themes in the focus groups divided into 3 categories.



Evaluation of the Current Care Process

Information Absorption

Some of the patients said that they either could not remember or did not understand the information given at the discharge interview. This could be due to the symptoms of their CVA. For example, a patient developed aphasia because of the CVA. As a result, she did not know what questions to ask during the discharge interview and did not manage to do so. However, most patients said this was due to information overload caused by discharge taking place shortly after the CVA, and the impressions and emotions during admission. On the other hand, most of the informal caregivers said that they received the information provided during the discharge interview and helped the patients with the information when necessary.

The patients and informal caregivers who could remember said that they were positive about the information provision, calling it clear, open, and informative, with a lot of room for questions. HCPs mentioned that they often found it hard to estimate whether patients and caregivers truly understood the given information, saying that patients always say they understand, even if they do not. They also mentioned language barriers as a common issue. Moreover, they were not sure whether the extra resources given, such as websites or information flyers, were read and understood by patients, as they did not discuss these with them.

Expectations of Rehabilitation

Most patients and informal caregivers had little idea of what to expect from rehabilitation and expressed that they felt thrown in at the deep end. One patient described her lack of expectations as follows:

> *I just let everything wash over me. That was all I could do.*

Only 1 patient said he knew what he could expect in his personal situation, even if daily tasks proved more difficult. Informal

caregivers expressed wishes for more information from the hospital about rehabilitation, with 1 informal caregiver expressing that he would have wanted a rehabilitation plan from the hospital:

> *[...] my mom is not the first one with a CVA, so there is a certain expectation and based on that […] protocols are made. It's my first time, and then there's nothing […] that's hard. Something has to be done about that. That's what I missed.*

Eventually, most patients were happy with the rehabilitation, except for a few bad experiences with HCPs. HCPs' experiences matched with the views of the patients and caregivers, and they stated that they do not have a good overview of rehabilitation and therefore cannot give patients an expectation of what will happen during rehabilitation. Some HCPs believed that this information should be given in rehabilitation clinics. They also mentioned that there could be a disparity in the expectations between patients and informal caregivers. In those situations, patients often felt like they were ready to be discharged home, while caregivers would still be very worried and push for inpatient rehabilitation.

Predictions of Outcomes

Almost all HCPs mentioned the difficulty of making individual predictions. They explained that this was due to patients, even similar patients, having varying recovery paths and because they did not have oversight over recovery during rehabilitation. Only the 2 most experienced neurologists felt more comfortable giving general predictions using age and the severity of the event. One of the junior doctors mentioned that they did not feel like they had enough knowledge and data to make such predictions.

> *I also don't know the exact scientific evidence from the top of my head […] for someone with a hemiparesis after 3 months.*

These statements were in agreement with the experiences of the patients. In the perception of the patients, if the physician did predict outcomes, it was not very precise. For example, they mentioned that the physician predicted that they would recover gradually in the first 3 months. Moreover, they said that no data in the form of numbers or percentages were used.

We asked all participants what they considered the most important outcomes to have a prediction on. Three outcomes were mainly mentioned: functional status in the medium or long term (multiple months or years), time of rehabilitation, and the chance of a new CVA. A new event was something that many patients were very scared about. They wanted to know how high the chance of recurrence was and wanted reassurance that it was as low as possible. HCPs mentioned it was not necessary to have a prediction of recurrence, as medications will always be given to minimize those chances.

Decision Aid

Many patients and informal caregivers felt like the physician took their opinions into account. According to the participants, it varied for each patient whether they had a choice in discharge location. Most participants said they did not have a choice in this decision. However, most participants felt that they could not make a better decision than a physician could, and they accepted the physician's opinion and professionalism. According to the participants, physicians have more knowledge about a CVA than patients and therefore know what is better for them.

> *You have to imagine; it was all new to us. So […] how can your opinion be different from what they recommend to you? It's almost impossible because you're in a situation like that so you can't judge it.*

Physicians mentioned shared decision-making. There is often not really any discussion on where the patient should be discharged.

Content of the Prediction Model

Reliability

Many patients were initially skeptical about a model that would predict outcomes. This was based on the physician's statement that it is not possible to make personal predictions. Several patients and informal caregivers said they did not believe that a physician could make accurate predictions and that consequences could only be seen after rehabilitation. Furthermore, some caregivers also found the prediction too absolute and programmed.

> *If it's such a well-founded prediction but we asked the neurologist about the whole thing, and he couldn't really give us any answers about predictions […]. Won't we get the wrong expectations from an overview like this?*

HCPs were also skeptical of the reliability of the model. They similarly argued that they see a lot of variation between patients and wondered if it is possible to make accurate predictions. In general, they believed that all included predictors would be usable. However, the HCPs questioned the reliability of the model due to the absence of certain important predictors, such as pre-existent functioning (Barthel score), detailed comorbidity, and the character of the patient. They acknowledged that the last aspect would be hard to measure. Moreover, if it is just a tool for information, the doctors argued that it is not that bad if the prediction is not 100% accurate**.**

> *[perfect performance] would be preferable, but you can never predict that […] maybe the important part is how to translate model performance to the patient*

One of the informal caregivers felt that there should be a disclaimer with the model because the outcome could never be 100% right.

Relevance

While most HCPs were generally enthusiastic about the proposed model, another point of skepticism was regarding relevance, as they were hesitant about how to explain the predicted outcomes to patients, especially regarding percentages. Patients confirmed these concerns. One of the patients said he did not like percentages because one can never say what 90%, for example, truly quantifies. Patients agreed that it is better to have a conversation and explain the information instead of simply showing the model. HCPs mentioned that while a general model for outcome prediction would be good, a more useful option would be if there were more different outcomes. For

example, where it would be more useful if we could split it into several types of complaints or symptoms (like aphasia or paralysis).

There was disagreement among patients regarding whether they wanted predictions at all. Some stated that they would be curious to know their predictions. Another participant stated that the information he received from his physician was sufficient and that he did not need a more specific prediction. Some of the caregivers said they would find it convenient to use a prediction model during a discharge conversation and that a prediction could supplement the information given by HCPs. Most HCPs were slightly worried about the risk of giving too much information, as it is currently already too much. However, some physicians also thought that a prediction could help clarify the situation, making the other information more digestible.

Influence on the Care Process

There were several points discussed concerning the possible influence of a prediction model on the care process. There was agreement among HCPs that it would be good for the patient as guidance if it is understandable for the patient. Junior doctors especially thought it would be good for HCPs as well for guidance in conversations with patients, reaching a better ground to make prognoses and overcoming unconscious biases about patients.

While most patients and informal caregivers expressed the positive aspects of guidance similar to HCPs, some patients worried that if the prediction is negative, it could be scary or it could demotivate the rehabilitation process. The patients stated that a lot of motivation is necessary for the best recovery.

> *And if I were [example patient] and 82 [years old] I don't know if I would be up for knowing […] that bad outcome*

However, most patients and informal caregivers did not want HCPs to hold back negative results from them. Moreover, doctors mentioned they would not be worried about this, as they are used to delivering bad news.

The main importance for HCPs was a way to inform patients and to offer clearer information for expectation management in the further rehabilitation process. As such, using this prediction tool would not have a direct result on the treatment or outcome of patients. There was the question of why this would be useful, and it was expressed that the goal of the tool should be clear; otherwise, it might not be used.

Accessibility

Ease of Understanding

The HCPs in general found the prediction model and the visualizations quite clear, and most thought that with explanation the model should be understandable for patients. However, several patients and informal caregivers found it hard to understand. Even after another explanation, they struggled to fully comprehend the meaning. One patient mentioned this might be due to one of the complications of his CVA being a lack of concentration and thus not having enough concentration to read. They struggled with the medical terminology, even after explanation. One patient said that it might be convenient for a physician but it is too hard for a patient. Most patients and caregivers understood the visualizations if they looked at them for a little longer but concurred that an explanation is needed from someone with a medical background or a more detailed but simple explanation is needed in additional text.

Preference for a Model Style

There were differences among patients regarding the preferences for the style of visualizations. Most of the participants preferred the prediction model with more graphics and less text because it was more visual and easier to understand. One participant stated that when a patient has symptoms like trouble with reading or concentration, it is easier to see the graphs.

> *I also think that for people who have […] more symptoms, who understand it a […] less easily […] the pictures are a little bit more informative.*

A few patients said the bar charts for feature importance did not have their preferences, as they contained too much information and the features could not be changed.

All HCPs preferred the more detailed visualization, and they argued that they contained more information and made the prediction more "alive." Interestingly, they thought patients would not have the same preferences. The HCPs also argued for integration into the electronic health record (EHR), as this would help with ease of use and adoption in the care process. Some HCPs were afraid that due to the high workload and the model not having a direct impact on the care process, the model might not be used if it is not easily accessible.

Moment of Use

Whether to use the model during the discharge interview or during the family interview, which happens a few days into admission with informal caregivers, was a point of discussion among HCPs. It could be beneficial for both. The discharge interview can be very rushed, and during the family interview, there might be more time to go over the predictions. However, this would be earlier in the process, which means that less information might be included in the predictions. Moreover, they agreed that having some form of access afterward would be good. Different options were mentioned: at the rehabilitation center, with the general practitioner, or at the 3-month follow-up.

The patients generally agreed with this view. One patient stated that it would be good to see the prediction when you feel like it, but it would have been too much during the discharge interview.

> *It is useful but […] too extensive [for] a normal person […] does not understand a thing. [...] Then it is explained by someone with a medical background […] who can perhaps explain it better. […] Maybe after a few months go back and look at it again […]. What are the expectations now, what are the expectations later.*

Questionnaire Survey

Based on the results of the focus groups, we extracted a set of recommendations. These recommendations were either immediately included in the visualizations of the prediction

model or served as general recommendations for further development or for the context of the implementation in current care. The recommendations are summarized in Table 2.

Table 2. Recommendations from the focus groups.

Category	Theme	Recommendation	Incorporation
Evaluation of current care	Information absorption	Recognize that the information might not be understood at the discharge interview	Implementation
Evaluation of current care	Expectations of rehabilitation	Create a better overview of rehabilitation for patients, informal caregivers, and health care professionals	Context of care
Evaluation of current care	Prediction of outcomes	Highlight that the model meets the needs of patients, informal caregivers, and health care professionals regarding providing a prediction of the outcome	Immediately
Evaluation of current care	Decision aid	Make sure the patient's opinion is heard in the decision process, for example, through shared decision-making	Context of care
Accessibility	Ease of understanding	The target audience of visualizations should be health care professionals and not patients	Immediately
Accessibility	Moment of use	Do not limit the use of prediction to the discharge interview	Implementation
Accessibility	Model preference	Visualize outcome and feature importance (visualization version b)	Immediately
Content of the model	Reliability	Include the general predictive performance of the model, for example, according to the margin of error	Future research
Content of the model	Relevance	mRS[a] score in 3 categories, including the possible functional score, measured during hospital stay	Future research
Content of the model	Influence on the care process	Clarify the goal of the model (informing patients) to improve adherence	Immediately

[a]mRS: modified Rankin scale.

The visualizations were adapted according to the recommendations. We selected the more "visualized" versions (see Figures 2B and 3A). Moreover, we focused on HCPs as our target audience and therefore removed explanations of well-known abbreviations and concepts, such as the National Institutes of Health Stroke Scale (NIHSS) score. We also specified that the moment of use could be the discharge or family interview and that the goal of the prediction model was to inform patients. Moreover, we included more detailed information on feature importance, based on our underlying model. The adapted visualizations can be found in Multimedia Appendix 3.

The questionnaire was sent to 16 relevant HCPs in St. Antonius Hospital, and we received 9 responses. The answers to the closed questions are summarized in Table 3. For each question, we have reported scores. Moreover, we have presented the average score and SD for each section. Negatively phrased questions (questions 4, 8, and 9) were scored in reverse.

Table 3. Questionnaire results reported on a Likert scale (0-5).

Question[a]	Score, mean (SD)
General statements	
1. The prediction model matches well with my usual way of working.	4.0 (0.5)
2. The prediction model is based on factually correct information.	3.7 (0.5)
3. The prediction model offers all the information and materials necessary to work with it properly.	3.6 (0.5)
4. The prediction model is too complicated for me to use.	4.1 (0.8)
5. I expect that the effects of the use of the prediction model will be clearly visible.	2.9 (0.4)
6. I think the prediction model is suitable for my patients.	3.8 (1.0)
Advantages and disadvantages	
7. The use of the prediction model gives me the opportunity to inform my patients better.	3.8 (1.0)
8. The use of the prediction model during discharge or family interviews will cost me more time than usual.	3.2 (0.5)
9. I find it too complicated to use the prediction model during discharge or family interviews.	3.9 (0.8)
Prediction model and patients	
11. I expect that with the prediction model, my patients will be better informed about the expected functional status after 3 months and the duration of rehabilitation.	3.4 (0.5)
12. I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation.	4.0 (0.5)
13. I consider it part of my job to use the prediction model.	3.6 (0.7)
14. Patients will generally be satisfied if I use this prediction model.	3.8 (0.4)
15. Patients will generally be cooperative if I use this prediction model.	3.7 (0.5)
Prediction model and colleagues	
16. I can count on sufficient help from my colleagues when necessary while using the prediction model.	3.5 (0.5)
17. How many doctors who conduct discharge interviews will actually use this prediction model?	3.8 (0.7)
18. To what extent will (your fellow) neurologists expect you to use the prediction model?	3.2 (0.4)
19. When it comes to working with the prediction model, how much do you care about the opinion of (your fellow) neurologists?	3.7 (0.5)
Application of the prediction model	
20. If you wanted to, do you think you would be able to apply the prediction model during the discharge or family discussions?	3.9 (0.3)
21. I have sufficient knowledge to be able to use the prediction model.	3.8 (0.8)
22. To what extent are you aware of the content of the prediction model?	3.1 (1.1)

[a]Question 10 was an open question (What are the other advantages or disadvantages of this prediction model?) and is not included in the table.

We considered statements with a score of ≥3.5 and an SD of <1.0 to be sufficient to positive, with agreement among HCPs. Most statements were received as such, and we considered the general feedback to be moderately positive. Moreover, in all categories of statements, we noted that most statements were at least moderately positive with agreement, highlighting that there is no topic where the prediction model consistently underperforms. The high scores for "*The prediction model matches well with my usual way of working*" (score 4.0), "*I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation*" (score 4.0), and "*If you wanted to, do you think you would be able to apply the prediction model during the discharge or family discussions?*" (score 3.9) indicate a high willingness to implement the prediction model.

For some questions/statements, the HCPs were not positive on average (score of <3.5) or were not in agreement (SD ≥1.0). The statement "*I expect that with the prediction model, my patients will be better informed about the expected functional status after 3 months and the duration of rehabilitation*" had a score of 3.4. This was just under our set threshold. Interestingly, the statement "*I think it is important to use the prediction model to better inform my patients about the expected outcomes: the functional status after 3 months, and the duration of rehabilitation*" had a score of 4.0. It shows that the HCPs, even when not sure about the positive outcome of use, still found it important to use the prediction model. The same concern was highlighted in 2 statements that had high disagreement among the HCPs: "*I think the prediction model is suitable for my patients*" (score 3.8, SD 1.0) and "*The use of the prediction model gives me the opportunity to inform my patients better*" (score 3.8, SD 1.0). This shows consistency with the focus

groups indicating that there seems to be variety in the extent to which HCPs are positive about the effects of the prediction model.

In the other statements that were not positive on average or had high disagreement, we also noted similar findings that came up in the focus groups as well. The statement "*Iexpect that the effects of the use of the prediction model will be clearly visible*" had the lowest score of 2.9. This is not completely unexpected as the model's primary function is to inform and not provide decision support. Moreover, the issue of high workload was reflected in the statement "*The use of the prediction model during discharge or family interviews will cost me more time than usual*" (score 3.2). Lastly, the statement "*To what extent are you aware of the content of the prediction model?*" had both a low score and high disagreement (score 3.1, SD 1.1), indicating that more detailed explanation and training are necessary to understand the model.

The statement "*To what extent will (your fellow) neurologists expect you to use the prediction model?*" had a low score of 3.2. This shows that many HCPs would consider the use of such a prediction model to be more elective. Next to the scaled questions, we also asked 1 open question "*what are the other advantages or disadvantages of this prediction model?*" A big point of contention was whether the prediction model would be accurate enough, as certain factors like recovery during the time in the hospital and mental resilience were not included. A positive aspect mentioned a few times was that it could also be used to preinform the rehabilitation clinics for helping with planning.

Discussion

Principal Findings

This study shows the added value of a prediction model for long-term outcomes of rehabilitation after stroke in CVA care under certain conditions. The need for a prediction model was consistently shown in focus groups and a questionnaire survey, as evidenced by the general approval of participants. Several recommendations can be made, most importantly on the following 5 conditions: primary target, timing of discussing the predictions, different focuses of HCPs and patients, goal of the prediction model, and visualization of the model.

First, the primary target audience of the prediction model should be HCPs. While the information provided is of interest to both patients and informal caregivers, not all patients can fully understand the outcomes of the prediction model. This resembles the findings of other studies that investigated different digital health tools for stroke patients, which reported complaints of difficulty [28] or disinterest among some patients [29]. Our study specifically found that patients prefer HCPs to provide information and guide them through the visualizations of the model.

Second, the timing for using predictions should also be considered. As patients mentioned, it could be more useful when targeted toward patients at different points in the care process. Here, it is interesting to see if the model can be simplified, as was requested by interested patients, and how that should be offered. Another study on digital health tools for patients with brain injuries [30] highlighted the importance of user testing among these patients. This would be a good way to ensure that the simplified model fits the patient's needs and understanding.

Third, for HCPs, the reliability and relevance of the model are key. HCPs focus largely on the reliability and relevance of the model. It is essential to not only provide good reliability and relevance but also clearly communicate the aspects to HCPs. Reliability is essential to validate the performance of the model. Therefore, changes in outcome reporting were considered to be more in line with the current care [31]: divide the mRS score into 3 categories and include predictive factors. By including the general predictive performance of the model (eg, according to the margin of error), the reliability can be better communicated to HCPs. These 2 points of reliability and relevance are very much in agreement with the guidelines for the implementation of AI in health care [32,33]. While the performance and generalizability of the model were not the focus of this study, they should be properly validated before model implementation. We found that patients focused more on the impact on rehabilitation, the emotional aspects, and understandability.

Fourth, HCPs and patients should understand the goal of the prediction model. This understanding can improve adherence and the willingness of HCPs to cooperate, which are essential for the adoption of the model in practice [32]. This matched our results, as this was one of the main points of the HCPs in both focus groups and the questionnaire survey. We aimed to clarify the goal of the prediction model after the focus groups. However, the questionnaires showed that the goal of the prediction model was still unclear to some HCPs, even after a more detailed explanation in the introduction of the questionnaire. This could be mitigated by properly informing HCPs, for example, by providing in-person training or a detailed demonstration of the model. It is also essential to highlight the goal of the explainability aspect of the model. The visualizations showed to what extent certain factors contributed to the model's decision, but that did not mean changing those factors would necessarily lead to a different outcome for the patient. For example, while the model might assign high importance to a certain treatment in the prediction of negative outcomes, it does not mean that not performing this treatment would lead to a better outcome.

Finally, all participant groups showed a preference for a more visual model. This matches the general consensus in visualization science, which argues for presenting numerical data in simple visualizations, such as bar or pie charts [15]. Our results showed that this is even more relevant for patients who have experienced a stroke. However, the visualizations that we used relied on red and green bars to highlight the importance of features, which can be an issue for colorblind people [34]. While none of our participants reported issues related to colorblindness, it should be adapted to a more inclusive visualization.

Strengths and Limitations

One of the main strengths of this study was the involvement of different stakeholder groups, including patients, informal

caregivers, and HCPs, with different roles. Moreover, the double setup with separate focus groups and questionnaires allowed for a check of agreement between the results of the different methods. One limitation to consider is our use of convenience sampling, which could have skewed the results. People with very severe stroke or with trouble reading or understanding were not represented. For HCPs, we mainly included people who were already open to research and new developments. The interviews with patients and informal caregivers were performed several months after the CVA, so their actual responses at the time of discharge might have been different. Moreover, we used mock-ups for the visualizations and not "real" predictions based on actual patient data. Although the visualizations were based on our existing models and data as much as possible, this was not a personal prediction. This made the visualizations more difficult to understand than expected, and the focus groups might have been more efficient with a functional model based on the actual patient data.

For the questionnaires, we had a relatively small sample size, and therefore, we did not perform any statistical analyses. As there was high agreement among the HCPs and the majority (9/16) of invited HCPs responded, it is likely they are a representative sample of the HCP group in the hospital, but we cannot know this for sure. Moreover, this group did not include all HCPs involved in stroke care. It is possible that physical therapists or general practitioners would have a different outlook on the prediction models, as they might be more involved in the rehabilitation of patients or involved at a different point in rehabilitation care. Lastly, this study was limited to a single hospital in the Netherlands. Differences between hospitals and especially between medical practices among countries can impact the generalizability of our results. Combining these limitations, we would recommend a quantitative follow-up study based on our questionnaire. Preferably, this should be a multicenter and international study to confirm the generalizability of our results outside the confines of our hospital.

Implications and Future Directions

From this study, we can extract lessons to be considered when implementing AI in medicine in general. An important aspect is that the need for information provision is highly variable between groups as well as individuals. The results of the prediction model can be highly personal, and similarly, the needs of a patient and the setting and specific illness of the patient can be personal. It is essential to clearly define the purpose of the tool, as there are not only different levels of understanding but also different priorities. For example, patients do not always appreciate detailed information, especially if the information is not actionable but only informative. It is also essential to consider a model that can have multiple purposes. A model, such as ours, could also be used for advanced resource planning in rehabilitation clinics by estimating the future demand on the clinics and evaluating the effectiveness of the rehabilitation.

An important point is to investigate how to include patients who struggle with technology due to language, socioeconomic, or medical issues. For example, this study excluded non-Dutch speakers, but HCPs mentioned that language issues could further complicate explaining the expectations of recovery. This difficulty in communication should not be increased by a new technological tool or prediction model. Relying more on technology can lead to more inequality in care [35], especially for vulnerable patients, such as stroke patients [32]. One effort that can prevent such issues is the development of a comprehensive framework for AI implementation in health care and the creation of a roadmap for AI implementation. Such frameworks are being developed [31,33], but none of them are exhaustive, and having resources that detail considerations for AI application and evaluation are still necessary to develop AI with meaningful medical applications [33].

Conclusions

The findings of this study show that participants are generally positive toward a prediction model for long-term outcomes of rehabilitation after stroke in CVA care under certain conditions, with a general preference for a more visualized prediction model. The prediction model should be geared toward HCPs, as they can provide the context necessary for patients and their informal caregivers. For HCPs, good reliability and relevance of the prediction model are essential for its proper integration. We recommend a quantitative follow-up study to confirm these results in multicenter and international settings.

Abstract

Background: Problem gambling and gambling disorder cause severe social, psychiatric, and financial consequences, and voluntary self-exclusion is a common harm reduction tool used by individuals with gambling problems.

Objective: The aim of this study was to explore users' experience of a novel nationwide, multioperator gambling self-exclusion service, "Spelpaus," in Sweden and to inform stakeholders and policy makers in order to improve harm reduction tools against gambling problems.

Methods: Semistructured interviews were conducted with 15 individuals who reported self-perceived gambling problems and who had experience of having used the self-exclusion service Spelpaus in Sweden. Interviews were transcribed and analyzed through qualitative content analysis.

Results: We identified 3 categories and 8 subcategories. The categories were (1) reasons for the decision to self-exclude, (2) positive experiences, and (3) suggestions for improvement. The subcategories identified a number of reasons for self-exclusion, such as financial reasons and family reasons, and positive experiences described as a relief from gambling; in addition, important suggestions for improvement were cited, such as a more gradual return to gambling post–self-exclusion, better ways to address loopholes in the system, and transfer from self-exclusion to treatment.

Conclusions: Voluntary self-exclusion from gambling, using a nationwide multioperator service, remains an appreciated harm-reducing tool. However, transfer from self-exclusion to treatment should be facilitated by policy making, and loopholes allowing for breaching of the self-exclusion need to be counteracted.

Introduction

Background

Gambling disorder is a behavioral addictive disorder known to cause severe financial, social, and mental health consequences to affected individuals [1-3]. Among the harm-reducing or harm-preventive strategies used against gambling-related harm, voluntary self-exclusion is a well-established responsible gambling measure aiming to prevent and reduce the damage that can be caused by gambling [4].

Through self-exclusion, gamblers can voluntarily suspend themselves from gambling. However, 1 well-known limitation of self-exclusion services may be the possibility to gamble with another operator than the one the gambler has been self-excluded

from [5]. Gamblers are therefore usually required to self-exclude from multiple different operators. Consequently, in recent years, to further prevent gamblers from breaching their self-exclusion, it has become more common to offer gamblers the possibility to self-exclude from multiple operators at the same time.

In January 2019, the legislation for the Swedish gambling market changed, and monopoly was replaced by a license-regulated market [6]. This regulation meant that gambling operators, including overseas operators, needed to apply for a Swedish gambling license to operate on the Swedish market. In connection to the new regulations, the nationwide self-exclusion service "Spelpaus" was launched. Gambling operators with a Swedish license must adhere to this self-exclusion service, along with a series of other measures for responsible gambling. Spelpaus offers the possibility to self-exclude from all gambling operators with a Swedish license for 1, 3, 6, or 12 months. Self-exclusion cannot be canceled prematurely, and if the 12-month option is chosen, the self-exclusion continues beyond the 12 months, unless the individual actively chooses to cancel it after that period. Self-exclusion via Spelpaus also prohibits gambling operators from sending direct advertisements to self-excluded customers.

Spelpaus is in many ways a unique harm-reducing tool since it is nationwide, covers all licensed gambling operators (both online and land based), and can be accessed separately from the gambling operators. Thus, it theoretically represents a novel harm reduction strategy over and above other responsible gambling measures. Indeed, theoretically, this system may have a larger coverage and fewer loopholes (ie, fewer practical possibilities to turn into other gambling modalities and gamble despite self-exclusion) compared to a self-exclusion system involving 1 or few gambling operators. Around 100 gambling companies have a Swedish gambling license, with most of them operating exclusively online.

The prevalence of gambling problems in the Swedish population is estimated to be approximately 0.5% on a diagnostic level and a total of 1%-2% with at least moderate-risk gambling according to the Problem Gambling Severity Index [7,8]. Formal treatment seeking, or treatment provision, is low; less than 1000 people annually receive a gambling disorder diagnosis in the whole of Sweden, and even when taking other care providers into considerations, it can be assumed that only a small minority of people with a gambling problem on a diagnostic level receive formal treatment [9]. In contrast, low formal treatment seeking is often described in gambling disorder; however, a more informal but still active help-seeking behavior appears to be common, and voluntary self-exclusion from gambling can be part of this [10].

In Sweden, around 110,000 inhabitants are enrolled in Spelpaus [11], a number that has steadily increased since the launch in 2019 [12]. Thus, we believe that an increasing number of people with problematic gambling are attempting to intervene against their problem through self-exclusion, although we must consider that people without gambling problems also choose to self-exclude.

The steady increase in registrations in Spelpaus indicates that it is perceived as a helpful tool for many people. However, there are also limitations in the self-exclusion service, making it possible to breach the self-exclusion. Such a limitation is that Spelpaus only covers operators with a Swedish license, therefore making it possible for gamblers to gamble with overseas operators outside the Swedish license gambling market. In a 2020 web survey among gamblers, 38% of gamblers stated that they had gambled with unlicensed operators, while being self-excluded through Spelpaus [13], and in a later survey in 2022, the corresponding figure was 49% [14]. In another survey, conducted by the Swedish Gambling Authority, 25% gamblers stated that they had gambled with unlicensed operators during their self-exclusion [15]. In addition, continued gambling despite self-exclusion remains part of the clinical picture in clinical gambling disorder treatment in this setting [16].

Previous international experience of responsible gambling tools has demonstrated not only the feasibility of self-exclusion services and their use by individuals with gambling problems [4,17,18] but also that users experience limitations of these services [10,18]. Altogether, previous research calls for more in-depth examinations of user experience with self-exclusion services and suggestions for improvement of their effectiveness. In particular, this is relevant for the present type of self-exclusion service, which theoretically has been designed to overcome well-known limitations of older self-excluson systems; this novel Swedish service (1) is government based and independent of gambling operators, such that an individual does not need to enter a gambling site in order to self-exclude; (2) covers all licensed operators in the country and therefore prevents the possibility to change between licensed operators during an ongoing self-exclusion period; and (3) involves both land-based and online-based operators.

Thus, altogether, the relatively recent introduction of a unique, large-scale, multioperator self-exclusion service in Sweden has attracted a large number of users, but it is hindered by the risk of breaching one's self-exclusion to an extent that is clearly of relevance in the treatment setting. Therefore, it is of great value to study which effects of the Spelpaus service are perceived as favorable and challenging by its users and to also study this in more detail than in previous quantitative survey studies.

Aim

Based on the aforementioned research gap, the aim of this study was to enhance comprehension of the user experience of the Spelpaus service within the gambling community and to acquire a more profound insight into the reasons for use of this harm reduction tool and its advantages and challenges. Thereby, the overarching goal of the study was to inform policy makers about potential drawbacks and the potential for improvement of the harm reduction tool.

Methods

Study Design

This research was exploratory in nature. A semistructured interview guide was developed to ensure the exploration of diverse perspectives and experiences related to Spelpaus. Notably, this study represents the first attempt to comprehensively examine user experiences of Spelpaus, thus

justifying the use of qualitative content analysis for its methodological flexibility. The protocol of this study has been published previously [19].

An initial interview guide was developed based on the study's aim and research questions. A test interview with a peer support worker who had experience with self-exclusion services was conducted, leading to refinements of some questions to be more open ended. Further details of the interview questions are provided in the study protocol [19].

Context

The study was conducted in Sweden, a country with approximately 10.4 million inhabitants, where gambling is prevalent, with around 56% of individuals aged from 16 to 84 years having engaged in gambling activities in the past year. Moreover, 18% gamble at least once per month. The prevalence of gambling is higher among men aged 45-84 years, and online gambling has increased markedly in popularity in Sweden over the past decade [20]. Problem gambling in the present setting is predominated by online casino gambling and sports betting, with online casino gambling representing a large majority of patients seeking treatment at a gambling disorder facility in Sweden [16].

Sweden has a license gambling market since 2019, where online and land-based gambling operators are allowed to operate, provided they adhere to a number of responsible gambling regulations, one of which is adherence to the nationwide Spelpaus service. The legal gambling age in Sweden is 18 years [6]. After being a more traditional, land-based gambling market, but with a large predominance of a government-owned gambling monopoly for many years [21], the Swedish gambling market was gradually increasingly affected by overseas online operators, which represented a large proportion of visible gambling advertising despite their unregulated status [22]. This led to the decision to liberalize the gambling market into a licensed, but controlled, market from 2019. Given the new license-based gambling market since 2019, and thereby the relative recency of a unique self-exclusion service, the present setting is of interest to assess the qualities and challenges of such a new harm reduction instrument.

Potential stakeholders and users of the study's findings may include policy makers, public health officials, mental health professionals, gambling addiction counselors, researchers in the field of addiction studies, advocacy groups, and individuals and families affected by problem gambling. The insights garnered from this research could inform the development of targeted interventions, public health campaigns, regulatory measures, and support services aimed at addressing and mitigating the adverse effects of gambling behavior within the Swedish population.

Recruitment Process

Criterion sampling was used in the recruitment process. Participants were selected based on 2 critera: (1) being 18 years old or older during the time of the interview and (2) having previous or ongoing experience of using Spelpaus (any experience was enough, and it was not a requirement that the self-exclusion be in close temporal association with the interview). Recruitment was conducted online through social media advertisements managed by Trialy, a company specializing in research recruitment. Potential participants received information about the study and registered their interest via the Trialy website, completing a short online survey regarding their age and experience with Spelpaus. Eligible individuals were contacted by the first author (JT) and provided with additional study information. They were then sent written information about the study and about participants' rights and asked to sign and return (by mail) an informed consent form. When written consent was obtained, an interview was scheduled. Individuals were recruited during spring-summer 2023.

Sample

In total, 13 men and 2 women, aged between 31 and 62 years, participated in the study, representing various regions of Sweden. All participants reported either a gambling problem or identified themselves as being at risk, with prior or current experience using the Spelpaus self-exclusion service. This gender distribution aligned with existing research findings on gambling demographics in Sweden, which indicate a higher prevalence of gambling-related issues among men [16]. The gambling types involved in each person's gambling pattern were reported. Although the study did not systematically record whether gambling occurred (and had occurred) in online-based or land-based settings, the distribution of gambling types reported by the participants was comparable with the gambling types typically seen in Swedish problem gambling treatment settings, where online casino and sports betting is predominant [16].

Interviews

All interviews were digital (both video and audio) and were carried out by the first author (JT) of the paper, who has experience in qualitative interviewing and psychiatric research, especially in psychiatric research, ensuring a sensitive and nuanced data collection approach. The interviews were audiorecorded but not videorecorded and lasted between 23 and 67 minutes. During the interview process, the authors continuously reviewed and assessed the interviews to discern recurring patterns. Following the completion of 12 interviews, the emergence of new categories began to decline. In the final 2 interviews, only categories closely aligned with those identified previously surfaced. Consequently, the authors made the decision to conclude recruitment for the study. All interviews were then transcribed verbatim by the first and second authors (JT and SH).

As compensation for their time and efforts in the study, all participants received 2 cinema tickets.

Researcher Characteristics and Reflexivity

Our research team included professionals in psychiatry and social work, with substantial experience in qualitative research and interviewing. Throughout the study, we reflected on our backgrounds and preconceptions, particularly regarding gambling disorders and harm reduction strategies, and their potential influence on data interpretation. This reflexivity was integrated into our coding and analysis discussions to include

multiple perspectives and thereby to expand our own perspectives.

To ensure trustworthiness, triangulation was used throughout the analysis process. Multiple researchers independently coded the data, followed by discussions to reach consensus, minimizing the influence of individual biases and ensuring comprehensive data representation.

Data Analysis

This study used qualitative content analysis as the primary method for data analysis, chosen for its flexibility in systematically describing textual data, aligning well with the exploratory nature of this research. The analysis focused on manifest content, which involves identifying clear, descriptive categories that summarize data without deeper interpretive meanings. As noted by Graneheim and Lundman [23], categories represent the descriptive level of content and express the manifest content of the text, consistent with this study's goals. We deliberately chose not to identify themes, aiming instead to capture the descriptive aspects of participants' experiences, a recommended approach when focusing on manifest content rather than latent content [24,25]. Although themes can provide interpretative layers, we chose not to use them in this analysis, maintaining a descriptive focus to capture clear, observable patterns in participants' experiences with Spelpaus. This approach reflects the strength of qualitative content analysis in emphasizing the descriptive aspect without requiring thematic depth when the aim is to focus on manifest content [23].

The qualitative content analysis followed Graneheim and Lundman's [23] approach, focusing on identifying categories that represented the manifest content of participants' responses. Key analysis steps included repeated readings of the transcripts by 3 authors (JT, SH, and HH), identifying meaning units, condensing those units, and labeling them with codes, which were then grouped into categories based on similarities. The transcribed interviews were read through repeatedly and independently, and then the material was discussed by all authors. The content of the interviews related to the aim of the study was divided into meaning units, which were then condensed and labeled with codes. Similarities and differences in the codes were identified before they were divided into different categories and subcategories (Table 1). All steps of the analysis process were carried out separately and then discussed within the group to reach consensus. Various meetings within the group were held during the analysis process to discuss the different findings before a consensus about the results was reached.

Table 1. Examples of the data analysis process.

Meaning unit	Condensed meaning units	Code	Category	Subcategory
"If you should have a gambling stop like this, it should really apply to everything, because the brain will always find a way otherwise. This is the good thing—that it is a stop. You can't make a phone call, you can't just change your mind, because now it is a stop. I think that is very important." [Male participant, 31 years old]	The gambling stop should really apply to everything. Because the brain will always find a way otherwise. The good thing is that it is a stop, you cannot just change your mind. I think that is important.	Satisfaction with Spelpaus	Positive experiences	Prevention of future gambling problems
"Well, the downside is that it gives a little bit of a false sense of security. At least when it comes to certain people...as if you gamble on other gambling sites...it doesn't help anything." [Female participant, 35 years old]	The downside is that it gives a little bit of a false sense of security. When it comes to certain people who gamble on other sites, it does not help anything.	Suggestion for improvement: to also stop overseas gambling sites	Suggestions for improvement	Addressing loopholes

Ethical Considerations

The study was conducted according to the principles of the Declaration of Helsinki and was approved by the Swedish Ethical Review Authority (approval number 2022/06933-01, amendment 2023/01684-02). All participants received oral and written information about the study and about participants' rights, prior to signing a consent form. Written informed consent was obtained from all participants.

Results

Participant Details

A detailed description of the 15 participants is presented in Table 2.

Table 2. Background information about the participants (N=15).

Characteristics	Participants, n (%)
Social relationships	
In a relationship	8 (53)
Have children	9 (60)
Gambling form	
Casino	3 (20)
Sports betting	1 (7)
Horse race betting	0
Lottery	1 (7)
Casino + sports betting	2 (13)
Casino + poker	3 (20)
Casino + horse race betting	1 (7)
>2 different gambling forms	4 (27)
Enrolled in Spelpaus at the time of the interview	
Yes	10 (67)
No	3 (20)
N/A[a]	2 (13)
In active gambling at the time of the interview	
Yes	3 (20)
No	11 (73)
N/A	1 (7)
Number of times using Spelpaus	
1	4 (27)
≥2	11 (73)
Chosen time interval of self-exclusion	
12 months	7 (47)
1, 3, or 6 months	3 (20)
Both of the above	5 (33)
Overseas gambling during Spelpaus	
Yes	6 (40)
No	9 (60)

Categories and Subcategories

As shown in Table 3, we identified 3 categories: motivations and reasons for self-exclusion (including triggers, such as financial strain and concern for close relationships), perceived positive experiences (eg, reduced gambling urges and improved quality of life), and challenges and suggestions for improvement (notably, breaches through unlicensed gambling sites and lack of integrated support).

Table 3. Categories and subcategories.

Category	Subcategories
Reasons for the decision to self-exclude	• Precipitating factors • Self-awareness of gambling habits • Concern for close ones
Positive experiences	• Prevention of future gambling problems • Improved quality of life
Suggestions for improvement	• Integrated support systems • Addressing loopholes • Practical enhancements

Reasons for the Decision to Self-Exclude

The motivations underlying the choice to use the self-exclusion service were multifaceted, often encompassing a combination of factors.

Precipitating Factors

Numerous participants reported specific events that precipitated heightened gambling activity, ultimately leading to the decision to self-exclude. Common triggers included winning a large amount of money and quickly gambling it away, traumatic family incidents, interpersonal conflicts, financial struggles, and the onset of the COVID-19 pandemic. For instance, 1 (7%) participant articulated:

> *I was facing unemployment without insurance, which exacerbated my gambling tendencies. Although I secured employment thereafter, the meager income did not deter my gambling. The resurgence of COVID-19 in September restarted my gambling habits, leading to a downward spiral.* [Male participant, 44 years old]

Additionally, some participants opted for self-exclusion to prevent the risk of others accessing their gambling accounts as part of gambling-related criminal behavior. An example of this was the following interviewee who had a gambling problem but who also had a family member with a severe gambling problem:

> *...At the same time, this has helped us a lot every time she has wished to gamble on our accounts.* [Female participant, 35 years old]

Another reason to self-exclude was because the individual wished to facilitate debt settlement, as self-exclusion was a prerequisite for debt relief applications.

> *I applied for a debt settlement, but since I did not take it [self-exclusion] for a year, I did not get it…I would like to make another attempt for a debt settlement application, but then I probably have to take a 12-month period [of self-exclusion] as well.*

Self-Awareness of Gambling Habits

A prevalent reason for self-exclusion was an enhanced awareness of one's gambling behavior. Participants acknowledged excessive gambling tendencies, albeit with varying perspectives on whether they had developed a full-fledged gambling problem or were teetering on the brink of one. Fueled by these insights, individuals opted for Spelpaus to forestall further progression into problem gambling or to address existing issues. As 1 (7%) participant reflected:

> *I have had a realization, particularly in recent months...I recognize that I need to address this behavior before it escalates.* [Female participant, 56 years old]

This introspective process often unfolded gradually, sometimes facilitated by professional guidance or peer support.

Concern for Close Ones

Many participants described the adverse impact of their gambling habits on loved ones, with 10 (67%) individuals mentioning that their loved ones had been negatively impacted to a great extent. Financial strain, deceit, and compromised relationships were common themes. Some participants lamented fractured relationships resulting from their gambling, while others acknowledged the toll gambling took on family bonds and quality time spent together. One participant expressed:

> *It is not just about the money lost—it is the betrayal, the lies...and the time squandered gambling instead of being with my family that truly stings.* [Male participant, 39 years old]

Although self-exclusion was often an independent decision, familial influence or shared deliberation with loved ones also played a role. The following 2 (13%) citations are examples of this:

> *The relationship with my parents is starting to get a little bit better; for many years, it was pretty bad. They have helped me out with money a lot of times. Every time I call them, they think I am going to ask them for money again, so it [gambling] has hurt our relationship a lot.* [Male participant, 44 years old]

> *If you fail in a game or something, you get kind of aggressive, depressed, and angry. You also get very affected emotionally. If you bet on 7 games and 1 of them fails, you get upset, angry, or sad. It has affected my close ones the most.* [Male participant, 40 years old]

Positive Experiences

Participants identified several benefits associated with using the Spelpaus self-exclusion service.

Prevention of Future Gambling Problems

Self-exclusion was perceived as a preemptive measure to safeguard against relapse into gambling behaviors. Even individuals who had not experienced gambling urges for an extended period recognized the potential for future vulnerability. By enacting self-exclusion, participants closed the door to impulsive gambling, thus mitigating the risk of relapse. Several participants credited the Spelpaus service for preventing immediate urges to gamble. A couple of the participants who began gambling again described how they after the end of the self-exclusion period managed to gamble in a more controlled way than before.

> *After the self-exclusion, it was much more under control. I gambled a lot less, bet smaller amounts…if I felt I need to limit it now or I have to stop now. When you feel it is starting to be too much or take too much time, you feel a little self-control. Then I take a free weekend or several days free from betting, and after that, I bet a little, and then it feels like everything is under control.* [Male participant, 40 years old]

Another participant described the partial effect on gambling, primarily on impulse-driven uncontrolled gambling:

> *A part of me does not really want to say goodbye and never gamble again, but I want it to be at a reasonable level. It is at ATG [Swedish horse-betting company]. I am staying there. I think I gamble for 96 (Swedish) kronor a week now, but it was still that break (self-exclusion) that forced me to deal with it somehow.* [Male participant, 55 years old]

Improved Quality of Life

Many participants reported enhanced well-being during the self-exclusion period. Freed from the grip of gambling, individuals experienced a newfound sense of calm, happiness, and control over their lives. Moreover, self-exclusion provided an opportunity for personal growth and self-improvement, allowing participants to redirect their focus toward constructive pursuits, such as physical exercise and social interactions. One individual reflected:

> *You can relax because you have given away the control to something else…once I have chosen to self-exclude, I cannot do anything about it…and I get so mentally relaxed, I do not have to think about it at all anymore.* [Male participant, 32 years old]

Financial stability and restored trust within familial relationships were also cited as positive outcomes, as 1 (7%) respondent expressed:

> *My family can tell that I feel better when I do not gamble. I am happier, more positive, and I do not call them and ask for help. Of course, they notice a big difference when I do not gamble.* [Male participant, 31 years old]

In addition, the self-exclusion period provided an opportunity for reflection within the motivational process:

> *When I had my Spelpaus, I became quite aware of the problem, so I had a lot of thoughts about the need to do something about this problem.* [Male participant, 40 years old]

Suggestions for Improvement

Participants identified several areas for enhancement within the Spelpaus self-exclusion service.

Integrated Support Systems

Acknowledging self-exclusion as 1 component of the multifaceted approach to gambling cessation, participants emphasized the need for additional support mechanisms. One participant expressed:
